InstallShield 2013

You can use InstallShield to rapidly build, test, and deploy installations that target Windows-based systems.

The InstallShield Help Library contains information about the functionality and features of InstallShield. The Help Library contains the following sections:

Table 1-1 • Help Library Sections

Section	Description
What's New in InstallShield 2013	Informs you about the changes in InstallShield 2013.
What Was New in Earlier Versions of InstallShield	Informs you about changes that were made in earlier versions of InstallShield.
Target System Requirements	Lists the requirements for target systems.
Launching InstallShield with vs. Without Administrative Privileges	Alerts you to functionality that is not available if you are running InstallShield without administrative privileges; also describes a potential problem that may occur if you switch between full Administrator and non-Administrator contexts and you use mapped-drive locations in your projects.
Developing and Building Installations on 32-Bit vs. 64-Bit Systems	Alerts you to differences that you may notice if you use InstallShield on some 32-bit systems compared to some 64-bit systems.
Using Help	Provides information about the InstallShield documentation.
Getting Started	Contains information to help you become familiar with InstallShield, begin creating an installation project, and customize the InstallShield user interface.

Table 1-1 • Help Library Sections (cont.)

Section	Description
Tutorials	Leads you step-by-step through the process of creating InstallScript and Basic MSI installation projects, and creating global installations.
Creating Installations	Explains how to create user-friendly, reliable installations and guides you through every step of the process—from specifying information for Add or Remove Programs to building, testing, and deploying an installation.
Creating Advanced UI and Suite/Advanced UI Installations	Contains an overview, plus some detailed how-to information, about Suite/Advanced UI and Advanced UI projects. The Suite/Advanced UI project type that is available in the Premier edition of InstallShield lets you package multiple .msi packages, .msp packages, InstallScript packages, .exe packages, sideloading app packages (.appx), and Windows Installer transactions as a single installation while providing a contemporary, customizable user interface. The Advanced UI project type that is available in the Professional edition of InstallShield lets you provide a contemporary, customizable user interface for a single .msi package, .msp package, or InstallScript package.
Designing InstallShield Prerequisites and Other Redistributables	Introduces some basic concepts to help you get started designing your own InstallShield prerequisites, merge modules, and InstallScript objects that can be used in any of your installation projects or distributed for use by other installation developers.
Modularizing Installation Projects to Distribute Development Work and Enable Reuse	Introduces developer installation manifests (DIMs), a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete portion of a product installation.
Updating Applications	Leads you through steps for planning and implementing the various types of upgrades and patches for updating a product. Also explains how you can use FlexNet Connect to notify end users about upgrades and patches that are available.
Creating Customized Virtual Applications	Explains how to use InstallShield to create customized virtual applications.
Additional Installation Options	Discusses a broad range of options available in InstallShield: creating multilingual installations, installing multiple instances of a product, building conditional statements, searching for installed data, editing installation tables, and more.

Table 1-1 • Help Library Sections (cont.)

Section	Description
Integrating InstallShield with External Applications	Contains details about integrating InstallShield with third-party tools such as source code control software, Microsoft Visual Studio, and Microsoft Visual Studio Team Foundation Server (TFS).
Automating Build Processes	Provides information about the InstallShield automation interface, which enables you to automate processes for creating installation projects without having to directly open the InstallShield user interface.
Reference	Contains comprehensive reference information for the InstallShield user interface; the InstallScript language; errors and warnings that might occur when you create, compile, build, or run your installation; tools that you can use from the command line to perform tasks such as building a release and running an installation; the InstallShield custom actions that are added to projects; and objects, methods, properties, and collections used to modify an installation project through the automation interface.
Frequently Asked Questions	Directs you to help topics that answer many commonly asked questions about InstallShield and project creation.
Glossary	Contains a collection of terms and their meanings.

Note • *Because the InstallShield Help Library is designed to interact with InstallShield, it is recommended that you open the help from within InstallShield. Copying the help files to another folder or system causes many of its features to work incorrectly.*

For answers to many commonly asked questions and new information about InstallShield that do not appear in the documentation, visit the Knowledge Base.

What's New in InstallShield 2013

New Features

InstallShield includes the following new features.

Ability to Create Run-Time Actions That Extend the Behavior of a Suite/Advanced UI Installation

You may require your Suite/Advanced UI installation to perform various run-time tasks that are outside the scope of the packages that you are including in the installation. For example, you may need the Suite/Advanced UI installation to do one or more of the following:

- Install an application before the user interface of the Suite/Advanced UI installation is displayed.

One sample scenario in which this may be necessary is when one of the packages in your Suite/Advanced UI installation runs SQL scripts to install an Oracle database. Before this package is run, you may want the Suite/Advanced UI interface to display a wizard page that lets end users select the appropriate server from a list of servers that are available on the network. This type of UI support requires that ODBC drivers be installed on the target system.

- Search the target system for the presence or absence of a particular product, technology, folder, file, registry entry, or other item.
- Configure the target system before or after running a package in the Suite/Advanced UI installation.

To extend the capabilities of a Suite/Advanced UI installation and make it possible to perform those sorts of tasks and more, you can use the new Events view in your Suite/Advanced UI project to create actions that run executable files, call DLL functions, run PowerShell scripts, or set Suite/Advanced UI properties at run time.

When you add an action to your project, you can schedule when at run time you want it be launched:

- Use the Events explorer in the Events view to schedule the action to run during one or more of the built-in events that the Suite/Advanced UI manages. This area of the view lists the events and the actions that occur during each event in chronological order from top to bottom.
- Use the settings in the Events area of the Packages view to schedule an action to run before or after the Suite/Advanced UI engine installs, removes, modifies, or repairs a package.

When you schedule an action, you can build conditional statements that control whether the action should be run. You can use the same types of condition checks that are available in other areas of a Suite/Advanced UI project, as well as two additional new types of condition checks:

- **Package Operation**—Check the state (for example, install or remove) in which a particular package in the Suite/Advanced UI installation is running.
- **Feature Operation**—Check the state (for example, install or remove) in which a particular feature in the Suite/Advanced UI installation is running.

These types of conditions are available only for actions that are associated with an event in the Events view, or with a package in the Packages view.

Note that the PowerShell action support requires PowerShell 2.0 or later on target systems.

This new feature is available in the Premier edition of InstallShield.

For more information, see:

- Using Actions to Extend the Behavior of a Suite/Advanced UI Installation
- Working with an .exe File for an Action in a Suite/Advanced UI Installation
- Working with a DLL File for an Action in a Suite/Advanced UI Installation
- Working with a PowerShell Script for an Action in a Suite/Advanced UI Installation
- Adding an Action to a Suite/Advanced UI Project
- Configuring a Suite/Advanced UI Action's Settings
- Scheduling a Suite/Advanced UI Action

- Types of Events in a Suite/Advanced UI Installation
- Events View
- Packages View
- Package Operation Condition Settings
- Feature Operation Condition Settings

Support for Enabling Windows Roles and Features During a Suite/Advanced UI Installation

If a particular package in your Suite/Advanced UI installation requires that one or more Windows roles and features be enabled on target systems, you can specify this requirement through the new Windows Features setting in the Packages view when you are configuring the package in your Suite/Advanced UI project. At run time, if an eligible package that is being installed requires one or more Windows roles or features that are disabled, the Suite/Advanced UI installation enables those roles and features before launching the package.

For example, your Suite/Advanced UI project may have a package that installs an IIS Web site that requires that the Internet Information Services feature in Windows be turned on. Another package in the same project may require that the PowerShell feature be turned on. When you are configuring the settings of those packages in your project, you can specify the Windows features that are required; at run time, if a package is eligible to be installed on a target system but any of its required Windows features are disabled, the Suite/Advanced UI installation enables those disabled Windows features before launching it. If the package is not eligible, its required Windows features are not enabled.

InstallShield has built-in support for enabling several Windows features:

- Internet Information Services
- PowerShell
- .NET Framework 3.x

InstallShield also lets you specify additional Windows roles and features that a package requires.

This new feature is available in the Premier edition of InstallShield.

To learn more, see:

- Enabling Windows Roles and Features During a Suite/Advanced UI Installation
- Packages View

Ability to Create Advanced UI and Suite/Advanced UI Project Templates

InstallShield has support for using Advanced UI and Suite/Advanced UI projects as templates. A project template contains default settings and design elements that you want to use as a starting point when you create a new Advanced UI or Suite/Advanced UI project.

You can designate any Advanced UI or Suite Advanced UI project to be a template. Project files and template files have the same file extension: .issuite.

To designate that an .issuite project file is a template file and make the template available for selection in the New Project dialog box, right-click in the All Types tab on the New Project dialog box and then click Add New Template. InstallShield lets you browse to the .issuite file that you want to use as a template, and it adds a new icon for it to the All Types tab.

To create a new Advanced UI or Suite/Advanced UI project using your .issuite file as a template, select the template's icon on the All Types tab of the New Project dialog box when you are creating the new project.

For instructions, see:

- Creating Project Templates
- Basing New Projects on Templates

New Built-in Template Available for Creating Installations that Install Multi-tier Applications

InstallShield includes a new Multi-tier Application template that helps you get started with creating a Suite/Advanced UI installation for cloud-based multi-tier applications. You can create this sort of installation to enable end users to easily manage the installation of tiers that install Web sites, databases, and applications. They can use the wizard pages in the Suite/Advanced UI installation to select which tiers they want to install, or they can use the command-line support to select the appropriate features.

The new Multi-tier Application template contains three tiers that are exposed as features. You can customize these features to include the tiers of your product, adding or removing features as needed. The template also contains four releases in the Releases view: one flagged for each of the three predefined features, and one that includes all of the features. This enables you to build separate installations—one for each tier, and one that lets end users install all available tiers.

This feature is available in the Premier edition of InstallShield.

New Application Virtualization Suitability Tests

Several new validation suites are available in InstallShield for helping you to determine how ready your products are for virtualization. The InstallShield virtualization internal consistency evaluators (ISVICEs) that are included in these suites let you check suitability for Microsoft App-V, Microsoft Server App-V, VMware ThinApp, and Citrix XenApp. The validation suites can enable you to make more informed decisions about how you build your product if you are considering offering your customers a virtualized version.

If you want to configure InstallShield to perform validation with these validation suites each time that a Basic MSI release is successfully built: On the Tools menu, click Options. On the Validation tab, select the appropriate check boxes.

If you want to perform validation separately from the build process: On the Build menu, point to Validation, and then click the appropriate new suite.

The virtualization suites are available in the Virtualization Pack.

This feature is available in the following project types: Basic MSI and InstallScript MSI.

For more information, see:

- ISVICEs
- Validating Projects

Support for Creating Microsoft App-V 5.x Packages

The Microsoft App-V Assistant in InstallShield includes support for creating virtual applications in the Microsoft App-V 5.x format. The Package Information page in this assistant lets you specify which version of App-V—5.x or 4.x—you want to target.

If you are targeting App-V 5.x, a new version of the App-V Launcher tool is available for testing App-V 5.x packages before moving them to the deployment server. The new version of this tool is capable of launching a Command Prompt window within the virtual environment of the App-V package. Thus, it is no longer necessary to inject diagnostic tool shortcuts for `Cmd.exe` or `Regedit.exe` directly into an App-V package beginning with App-V 5.x.

The name of the directory in which InstallShield saves an App-V package at build time varies, depending on which version of App-V you are targeting. For App-V 5.x packages, the directory is ProductName, and it is placed in a folder called App-VPackage. For App-V 4.x packages, InstallShield includes the product version number to the ProductName folder; that is, ProductName_v*N*, (where *N* is the product version number).

Note that although you can configure settings for an App-V 5.x package on any version of Windows that InstallShield supports, building an App-V 5.x package from within InstallShield requires Windows 8 or Windows Server 2012. Attempting to build an App-V 5.x package on an earlier version of Windows causes build error -9424.

The Microsoft App-V Assistant is available in the Virtualization Pack.

For information, see:

- Components of an App-V Package
- Build Output for App-V Packages

New Property Comparison Type of Condition Check; New Property for Determining the Install Mode for Suite/Advanced UI and Advanced UI Projects

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in a Suite/Advanced UI or Advanced UI project, or for an action in a Suite/Advanced UI project, you can select from a number of different types of checks that you want to be evaluated on target systems. Use the new Property Comparison type of condition check to check the value of a particular built-in Advanced UI or Suite/Advanced UI property, or a property that is defined in the Property Manager view.

In addition, a new read-only property called **ISInstallMode** is now available. This property stores a value that indicates the mode (first-time installation, maintenance/UI maintenance selection, modify, remove, repair, or stage only) in which the Suite/Advanced UI or Advanced UI installation is running. You can use this property in conditional statements that you configure in your project.

For more information, see:

- Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects
- Property Comparison Condition Settings
- Advanced UI and Suite/Advanced UI Property Reference

Ability to Build Pure 64-Bit .msi and .msm Packages; New Build-Time Architecture Validation

Windows Server Core supports disabling 32-bit Windows-on-Windows (WOW64) support. As this configuration becomes more popular, you may want to ensure that your 64-bit applications can install without any reliance on 32-bit functionality. To make this possible, InstallShield now enables you to build pure 64-bit .msi packages; these can

be run on 64-bit Windows-based systems that do not have WOW64 functionality. You can also build pure 64-bit merge modules and include them in InstallShield projects that have 64-bit support. If your installation or merge module project targets a pure 64-bit environment and includes support that requires any built-in InstallShield custom action DLLs, InstallShield includes new 64-bit versions of these DLLs in your releases at build time.

InstallShield now has architecture validation that you can use when building a release in InstallShield. Architecture validation enables you to detect potentially problematic cases in which your installation may try to install product files or use run-time binaries that may not match the architecture of a target system.

For example, if end users may run your installation on 64-bit target systems that do not have WOW64 support, architecture validation can help you identify any 32-bit product files or 32-bit custom action files in your installation. In addition, if you are mixing 64-bit and 32-bit product files (or 64-bit and 32-bit custom actions) in a single project and generating separate 32-bit and 64-bit .msi packages, you can use architecture validation to identify any 64-bit product or custom action files in your 32-bit releases, since these files cannot be loaded on 32-bit target systems.

To specify what type of architecture validation you want to use and identify whether you want to build a pure 32-bit or 64-bit package, use the new Architecture Validation setting, which is available on the General tab when you select a product configuration in the Releases view. Two types of validation are available: strict and lenient.

Strict validation may trigger build errors if the architecture that the Template Summary property specifies does not match the architecture for one or more of the custom action files that are being included in the release. This type of validation may also trigger build warnings if the architecture that the Template Summary property specifies does not match the architecture for one or more of the product files that are being included in the release.

Lenient architecture validation, which is the default type of validation, does not trigger build errors or warnings if the architecture that the Template Summary property specifies does not match the architecture for one or more of the product files or the custom action files that are being included in the release.

The automation interface includes support for the new architecture validation support. The ISWiProductConfig object includes a new read-write ArchitectureValidation property that lets you specify the type of architecture validation that you want to use for a product configuration.

This feature is available in the following project types: Basic MSI and Merge Module.

To learn more, see:

- Selecting the Appropriate Type of Architecture Validation for Builds
- Targeting 64-Bit Operating Systems
- Using the Template Summary Property
- ISWiProductConfig Object

Validation for the Windows 8 Logo Program

InstallShield includes two new validation suites: InstallShield Validation Suite for Windows 8 and InstallShield Merge Module Validation Suite for Windows 8. These validation suites contain several new InstallShield internal consistency evaluators (ISICEs): ISICE21 through ISICE26. The suites can help you verify whether your Windows Installer–based installation or merge module meets the installation requirements of the Windows 8 Desktop App Certification Program. If you want to be able to use the Windows 8 logo artwork, your product's installation must meet the program's requirements. These suites can also help you verify that your installation or merge module will work on Windows Server 2012 systems.

If you want to configure InstallShield to perform validation with these validation suites each time that a release is successfully built: On the Tools menu, click Options. On the Validation tab, select the appropriate check boxes.

If you want to perform validation separately from the build process: On the Build menu, point to Validation, and then click the appropriate new suite.

For more information, see the following:

- Validating Projects
- ISICEs
- Requirements for the Windows Logo Program

Improvements for Configuring Shortcuts on the Latest Platforms; InstallScript Language Improvements for Shortcut Creation

InstallShield offers enhancements for configuring shortcuts in your projects.

Support for Preventing a Shortcut from Being Pinned to the Windows 8 Start Screen

InstallShield lets you specify whether you want each shortcut in your installation to be pinned by default to the Start screen on Windows 8 target systems. You may want to disable pinning for shortcuts that are for tools and secondary products that are part of your installation. If you disable pinning for a shortcut, the shortcut is still available in the Apps list that contains shortcuts to all of the applications on the system.

To prevent Start Screen pinning for a shortcut, use the new Pin to Windows 8 Start Screen setting for a shortcut in the Shortcuts view.

This feature is available for the following project types: Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

The automation interface includes support for specifying whether you want a shortcut to be pinned to the Windows 8 Start screen. The ISWiShortcut object includes a new read-write Boolean EnableWin8StartPin property that indicates whether the shortcut is configured to be pinned by default to the Start screen on Windows 8 target systems.

To learn more, see:

- Specifying Whether a Shortcut Should Be Pinned to the Windows 8 Start Screen
- Shortcuts View
- ISWiShortcut Object

Support for Preventing End Users from Pinning a Shortcut to the Taskbar or Start Menu

For each shortcut in your installation, InstallShield lets you specify whether you want to let end users pin the shortcut to the taskbar or to the Start menu. If you want to prevent this type of pinning, the installation sets a property that hides the context menu commands for pinning the shortcut to the taskbar and the Start menu. You may want to prevent pinning for shortcuts that are for tools and secondary products that are part of your installation.

Support for preventing end users from pinning a shortcut to the taskbar or Start menu varies, depending on the project type that you are using.

In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects: To prevent taskbar and Start menu pinning for a shortcut, use the Shell Properties setting for a shortcut in the Shortcuts view. This setting has a new Prevent Pinning option that lets you disable pinning for the selected shortcut. Windows Installer 5 includes support for this shortcut setting. Previously, it was necessary to manually enter the appropriate property name and value to configure this behavior.

In InstallScript projects: To prevent taskbar and Start menu pinning for a shortcut, use the new Prevent Pinning setting in the Shortcuts view. Windows 7 and later include support for this shortcut setting. Previously, InstallShield did not have support for configuring this functionality in InstallScript projects.

The automation interface includes support for specifying whether you want the context menu commands for pinning a shortcut to the taskbar and to the Start menu to be displayed after end users install your product. The ISWiShortcut object includes a new read-write Boolean PreventPinning property that indicates whether the shortcut is configured to hide the context menu commands for pinning.

For more information, see:

- Specifying Whether End Users Should Be Able to Pin a Shortcut to the Taskbar or Start Menu
- Shortcuts View
- ISWiShortcut Object

Support for Preventing a Shortcut on the Start Menu from Being Highlighted as Newly Installed

InstallShield lets you optionally prevent a shortcut on the Start Menu from being highlighted as newly installed after end users install your product. This has the same effect as clearing the **Highlight newly installed programs** check box in the Customize Start Menu dialog box for an individual item on a target system. You may want to set this property for shortcuts that are for tools and secondary products that are part of your installation.

Support for the highlighting behavior varies, depending on the project type that you are using.

In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects: To prevent the highlighting behavior for a shortcut, use the Shell Properties setting for a shortcut in the Shortcuts view. This setting has a new Do Not Highlight as New option that lets you disable highlighting for the selected shortcut. Windows Installer 5 includes support for this shortcut setting. Previously, it was necessary to manually enter the appropriate property name and value to configure this behavior.

In InstallScript projects: To prevent the highlighting behavior for a shortcut, use the new Do Not Highlight as New setting in the Shortcuts view. Windows 7 and later include support for this shortcut setting. Previously, InstallShield did not have support for configuring this functionality in InstallScript projects.

The automation interface includes support for specifying whether you want a shortcut to be highlighted on the Start menu as new after end users install the product. The ISWiShortcut object includes a new read-write Boolean DoNotHighlightAsNew property that indicates whether you want to prevent the highlighting.

To learn more, see:

- Preventing a Shortcut on the Start Menu from Being Highlighted as Newly Installed
- Shortcuts View
- ISWiShortcut Object

Built-in Support for Configuring Additional Windows Shell Properties for a Shortcut

InstallShield lets you specify one or more additional shortcut properties that need to be set by the Windows Shell at run time. The properties that the Shell can set are defined in `propkey.h`, which is part of the Windows SDK.

To configure additional properties for a shortcut, use the Shell Properties setting for a shortcut in the Shortcuts view. This setting has a new Custom Property option that lets you specify additional properties and their corresponding values for the selected shortcut.

Windows Installer 5 includes support for configuring Shell properties.

The automation interface includes a new ISWiShellProperty object for custom Windows Shell properties for a shortcut. In addition, the ISWiShortcut object includes two new methods and a collection that let you add a Shell property (AddShellProperty), delete a Shell property (DeleteShellProperty), and retrieve the collection of Shell properties (ISWiShellProperties) for a shortcut.

This support is available in the following project types: Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

To learn more, see:

- Setting Custom Shell Properties
- Shortcuts View
- ISWiShellProperty Object
- AddShellProperty Method
- DeleteShellProperty Method
- ISWiShellProperties Collection
- ISWiShortcut Object

InstallScript Language Improvements for Setting a Shortcut Property, and for Other Shortcut Functionality

A new InstallScript function called **SetShortcutProperty** is available. You can use this function in your InstallScript code to set Windows Shell properties for a shortcut. The function lets you prevent end users from pinning a shortcut to the Windows 8 Start screen, prevent end users from pinning a shortcut to the taskbar or Start menu on Windows 7 or later systems, or prevent a shortcut on the Start menu from being highlighted as newly installed on Windows 7 or later systems. You can also use this function to specify additional Shell properties that are defined in `propkey.h`, which is part of the Windows SDK.

The InstallShield Cabinet and Log File Viewer has been updated to reflect the state of the aforementioned Shell properties.

To reflect the current operating system terminology, some of the existing shortcut functions have been renamed. Note that the old function names will continue to compile and run as they did with earlier versions of InstallShield. The new InstallScript functions are:

- **CreateShortcut**—This function supersedes AddFolderIcon. **CreateShortcut** accepts the same parameters as **AddFolderIcon** but adds or replaces the following options for the nFlag parameter:
  - CS_OPTION_FLAG_REPLACE_EXISTING

    - CS_OPTION_FLAG_RUN_MAXIMIZED
    - CS_OPTION_FLAG_RUN_MINIMIZED
    - CS_OPTION_FLAG_PREVENT_PINNING
    - CS_OPTION_FLAG_NO_NEW_INSTALL_HIGHLIGHT
    - CS_OPTION_FLAG_NO_STARTSCREEN_PIN
- **CreateShortcutFolder**—This function supersedes **CreateProgramFolder**. Both functions use the same parameters.
- **DeleteShortcut**—This function supersedes **DeleteFolderIcon**. Both functions use the same parameters.
- **DeleteShortcutFolder**—This function supersedes **DeleteProgramFolder**. Both functions use the same parameters.
- **GetShortcutInfo**—This function supersedes **QueryProgItem**. Both functions use the same parameters.
- **ReplaceShortcut**—This function supersedes **ReplaceFolderIcon**. **ReplaceShortcut** accepts the same parameters as **ReplaceFolderIcon** but adds or replaces the same options for the nFlag parameter as **CreateShortcut**.

For more details, see:

- CreateShortcut
- CreateShortcut Examples
- CreateShortcutFolder
- CreateShortcutFolder Example
- DeleteShortcut
- DeleteShortcut Example
- DeleteShortcutFolder
- DeleteShortcutFolder Example
- GetShortcutInfo
- GetShortcutInfo Example
- ReplaceShortcut
- ReplaceShortcut Example
- SetShortcutProperty
- SetShortcutProperty Example

Usability Improvements for Customizing the Wizard Interface in Advanced UI and Suite/Advanced UI Projects

No More Confusing Syntax Requirements

Various UI settings in the Wizard Interface view in Advanced UI and Suite/Advanced UI projects have been improved to make it much easier to customize the wizard interface of Advanced UI and Suite/Advanced UI installations. For example, the following settings, which are displayed when a wizard page or wizard control is selected in the Wizard Interface view, have been improved:

- **Visible**—This setting lets you specify one or more conditions that the Advanced UI or Suite/Advanced UI installation should use to evaluate whether the selected page or control should be displayed.
- **Enabled**—This setting lets you specify one or more conditions that the Advanced UI or Suite/Advanced UI installation should use to evaluate whether the selected control should be enabled.
- **Validate**—This setting lets you specify one or more validation statements that the Advanced UI or Suite/Advanced UI installation should use to validate an end user's response to a control. For example, you can use this setting to specify the format that end users should use for entering a serial number in a text box control.
- **Action**—Each instance of this setting has been renamed to better reflect the specific type of trigger that is applicable to the selected control. For example, the Action setting for a list box control has been renamed Selection Changed. The Action setting for a button has been renamed Click. The renamed settings let you select one or more actions that you want to be triggered when an end user uses the selected control.

Now those settings contain drop-down lists and buttons that are similar to the ones that are available in other areas of Advanced UI and Suite/Advanced UI projects for quickly building conditional statements. These settings now make it easy to quickly configure visible/hidden status, enabled/disabled status, validation, and action responses for various parts of the UI, and to build conditional statements for that behavior if appropriate. Previously, these settings were edit fields that required manually entry of statements using a difficult-to-remember syntax.

For more information, see:

- Configuring Validation for a Control on a Wizard Page or Window
- Configuring an Action for a Control on a Wizard Page or Window
- Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

Built-In Support for Using Only One Background for the Header, Body, and Navigation Areas of the Wizard Interface

The Wizard Pages node in the Wizard Interface view has a new Full Wizard Background setting. This setting lets you specify a single background that you want to use across the header, body, and navigation areas of your wizard pages. Previously, the only built-in way to specify backgrounds in InstallShield was to use separate background styles in the Default Body Background, Header Background, and Navigation Background settings. If you wanted to use a single background across all three areas of the wizard interface, you had to use the process that was documented in an InstallTalk blog article; the process involved modifying the InstallShield project file (.issuite) in a text editor.

Note that if you select a background in this new Full Wizard Background setting, you should delete any values from the other background settings: Default Body Background, Header Background, and Navigation Background.

To learn more, see Specifying the Background for the Header, Body, and Navigation Areas of the Wizard Interface.

Ability to Specify a Global Text Style for All Navigation Buttons

The Wizard Pages node in the Wizard Interface view has a new Navigation Text Style setting. This setting lets you select a single text style that you want to use for the text on all of the navigation buttons. You can override the global text style for individual navigation buttons as needed.

Logically Organized Setting Grids

In the Wizard Interface view, the setting grids for wizard pages, secondary windows, and wizard controls have been reorganized to make it easier to find the settings that are needed for customizing the wizard interface.

Support for Defining Font Sets with Optional Language-Specific Choices for Advanced UI and Suite/Advanced UI Projects

Advanced UI and Suite/Advanced UI projects have support for a new kind of wizard interface style: a font set. A font set is a collection of fonts (including attributes such as font name, size, and weight). For each font in a font set, you can specify to which language the font is applicable. This enables you to select a different font for each language that your project supports.

Font sets work in conjunction with text styles. Text styles, which are styles that define text attributes such as text color and alignment, now reference a font set but can optionally override various font attributes that are defined at the font set level.

Thus, for example, when you are specifying font information for the body text of your wizard interface, you can use a font set called BodyFonts, and specify a different font for each of the languages that your project supports. You can then select the BodyFonts font set for various text styles—Body, Header, and BodyBold—but with special overrides for smaller sizes and bold where necessary. This enables you to specify a large set of possible fonts once, and change attributes such as text size or color for specific wizard interface uses.

To learn more, see:

- Using Styles to Customize the Wizard Interface
- Defining a Custom Style for the Wizard Interface

Enhancements

InstallShield includes the following enhancements.

New Services View

InstallShield has a new Services view—under the System Configuration node of the View List—that lets you specify the required information about a Windows service that you are installing, starting, configuring, stopping, or deleting at run time.

This new Services view has been added to make it easier for new users to configure services. The view provides the same functionality as the following existing areas:

- The Services area under the Advanced Settings node for a component in the Setup Design view (of installation projects)
- The Services area under the Advanced Settings node for a component in the Components view

If you configure service information in any of the three views (the Services view, the Setup Design view, or the Components view), the other views are updated automatically.

The Services view is available in the following project types: Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

For more information, see:

- Installing, Controlling, and Configuring Windows Services
- Services View

New Wizard Format for the Suite/Advanced UI and Advanced UI Wizard Interface

A new Glass wizard format is available for the wizard interface of Suite/Advanced UI and Advanced UI installations. This new format is similar to the existing Aero format. For both formats, the installation uses user-chosen system colors (instead of brush styles that you defined in your project) to display the caption bar, header, and navigation areas of the wizard interface. It also may use the glass effect (translucency) for these same areas of the wizard interface on target systems that have the translucency support that was introduced in Windows Vista.

In some scenarios, an installation uses the Wizard 97 format instead of the Glass or Aero formats:

- Windows 8 and Windows Server 2012 systems do not have translucency support. On these systems, a Glass-formatted wizard interface uses the Wizard 97 format. However, an Aero-formatted wizard interface uses Aero (which includes user-chosen system colors), but without the glass effect.
- Windows 7, Windows Vista, Windows Server 2008 R2, and Windows Server 2008 have translucency support that end users can enable or disable. On these systems, Glass-formatted wizard interfaces and Aero-formatted wizard interfaces use the Wizard 97 format if translucency is disabled. These wizard interfaces also use the Wizard 97 format if the desktop composition feature on the target system is disabled.
- On Windows XP and Windows Server 2003, Glass-formatted wizard interfaces and Aero-formatted wizard interfaces use the Wizard 97 format.

To configure the format, use the Wizard Format setting that is displayed in the Wizard Interface view when the Wizard Pages node is selected. The Glass format is the default option for all new Suite/Advanced UI and Advanced UI projects.

For more information, see Selecting the Format for the Wizard Interface.

Automation Interface Enhancement: New OnUpgrade Property for Minor Upgrades and Small Updates

A new read-write OnUpgrade property has been added to the ISWiProject object in the automation interface. You can set this property to one of the supported values to specify whether you want the installation to display a prompt before installing a minor upgrade or a small update.

This property corresponds with the Small/Minor Upgrade Settings options on the Common tab in the Upgrades view.

For more information, see ISWiProject Object.

What Was New in Earlier Versions of InstallShield

This section describes features and enhancements that were released in earlier versions of InstallShield:

What's New in InstallShield 2012 Spring SP1

InstallShield 2012 Spring Service Pack 1 (SP1) includes changes that offer support for the final released versions of Windows 8, Windows Server 2012, and Visual Studio 2012. It also includes additional changes.

Important • *If you want to open an InstallShield 2012 Spring Advanced UI or Suite/Advanced UI project (.issuite) in InstallShield 2012 Spring SP1, you must allow InstallShield to upgrade your project to InstallShield 2012 Spring SP1. InstallShield 2012 Spring SP1 Advanced UI and Suite/Advanced UI projects include support for functionality that was not available in these project types in InstallShield 2012 Spring, and this support needs to be added during the upgrade. Note that it is not possible to open InstallShield 2012 Spring SP1 Advanced UI or Suite/Advanced UI projects in earlier versions of InstallShield (including InstallShield 2012 Spring without SP1). Therefore, if multiple users need to open and modify your InstallShield projects, ensure that all of you apply the SP1 patch at the same time.*

If you open an InstallShield 2012 Spring Advanced UI or Suite/Advanced UI project in InstallShield 2012 Spring SP1, InstallShield 2012 Spring SP1 displays a message box that asks you if you want to convert the project to the new

version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project before converting it.

Support for Adding Sideloading App Packages (.appx) to Suite/Advanced UI Projects

InstallShield now lets you add sideloading app packages (.appx) to a Suite/Advanced UI project. You can add this package type through the Packages view of the Suite/Advanced UI project just as you would add other types of packages to the project.

Sideloading an app is the process of installing an app without obtaining it through the Windows Store. This type of app is sometimes distributed to enterprise environments. Windows 8 and Windows Server 2012 include support for sideloading apps.

This support is available in the Premier edition of InstallShield.

Note that support for creating and building Suite/Advanced UI installations that include sideloading app packages (.appx) requires Windows Vista or later or Windows Server 2008 or later on the machine that has InstallShield or the Standalone Build.

For more information, see:

- Adding a Sideloading App Package (.appx) to a Suite/Advanced UI Project
- Packages View

New AppX Package Type of Condition Check in Suite/Advanced UI and Advanced UI Projects

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in a Suite/Advanced UI or Advanced UI project, you can select from a number of different types of checks that you want to be evaluated on target systems. Use the new AppX Package type of condition check to check target systems for the presence of a particular .appx package. The condition checks for a particular app name, and it can also check other information, such as the version.

For more information, see:

- Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects
- AppX Package Condition Settings
- Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

Support for Visual Studio 2012, .NET Framework 4.5, and Visual C++ 2012

InstallShield includes changes that offer support for the final released version of Visual Studio 2012, enabling development of installations and products within this version of the Visual Studio interface.

In addition, InstallShield includes two updated InstallShield prerequisites for the .NET Framework and two new InstallShield prerequisites for Visual C++:

- Microsoft .NET Framework 4.5 Full
- Microsoft .NET Framework 4.5 Web

- Microsoft Visual C++ 2012 Redistributable Package (x86)
- Microsoft Visual C++ 2012 Redistributable Package (x64)

You can add any of these prerequisites to Advanced UI, Basic MSI, InstallScript, InstallScript MSI, and Suite/Advanced UI projects.

The Web prerequisite for the .NET Framework requires an Internet connection. This prerequisite downloads the required redistributable files if appropriate. The full prerequisite is a stand-alone installation that does not require an Internet connection.

Additional Changes

For a list of issues that are resolved in InstallShield 2012 Spring SP1, see the release notes. The release notes are available from the Help menu in InstallShield.

What's New in InstallShield 2012 Spring

New Features

InstallShield includes the following new features.

Ability to Target Windows 8 and Windows Server 2012 Systems

InstallShield enables you to specify that your installation requires Windows 8 or Windows Server 2012. It also lets you build feature and component conditions for these operating systems.

The InstallShield prerequisites that should be installable on Windows 8 and Windows Server 2012 have been updated so that they are installed on those systems if needed. Previously, the prerequisites were not run by default on those systems. This applies to the following InstallShield prerequisites:

- FSharp Redistributable Package 2.0
- Microsoft ReportViewer 2010
- Microsoft SQL CE 3.5 SP2
- Microsoft SQL Server 2005 Express SP3
- Microsoft SQL Server 2008 Express SP1
- Microsoft SQL Server 2008 Management Objects 10.00.2531
- Microsoft SQL Server 2008 Native Client 10.00.2531
- Microsoft SQL Server 2008 R2 Express RTM
- Microsoft SQL Server 2008 R2 Native Client 10.50.1600.1
- Microsoft SQL Server Native Client 9.00.4035
- Microsoft SQL Server System CLR Types 10.00.2531
- Microsoft Visual C++ 2005 SP1 Redistributable MFC Security Update KB2538242

- Microsoft Visual C++ 2005 SP1 Redistributable Package
- Microsoft Visual C++ 2008 SP1 Redistributable MFC Security Update KB2538243
- Microsoft Visual C++ 2008 SP1 Redistributable Package
- Microsoft Visual C++ 2010 Redistributable Package
- Microsoft Visual C++ 2010 RTM Redistributable MFC Security Update KB2467173
- Microsoft Visual C++ 2010 SP1 Redistributable Package
- Microsoft VSTO 2010 Runtime

Support for a New Contemporary, Customizable End-User Interface in InstallShield Professional Edition

The new Advanced UI project type lets you create a new end-user interface, with redesigned, contemporary wizard pages, for a Windows Installer package or an InstallScript package. This new project type is available in the Professional edition of InstallShield, and it is based on the technology that was previously introduced as the Suite project type (now known as the Suite/Advanced UI project type) in the Premier edition of InstallShield.

The new Advanced UI project type includes built-in wizard pages that you can include and customize in your Advanced UI installations. The wizard page editor in this project type lets you add, sequence, and remove pages as needed; it also lets you modify the layout of any page—adding, moving, and removing a variety of different kinds of controls. All of the new UI functionality that was previously available only through the Premier edition is now available through Advanced UI projects.

Like Suite/Advanced UI projects, an Advanced UI project uses the next-generation setup launcher (`Setup.exe`) for launching a package on target systems. Also like Suite/Advanced UI projects, an Advanced UI project includes flexible options for specifying the run-time source location of the package that you are including in the Advanced UI installation. The available location options are:

- On the Web, available for download by `Setup.exe` if needed
- Embedded in `Setup.exe` and extracted to the target system if needed
- Uncompressed and stored on the Advanced UI source media

Your end users can quickly download a small Advanced UI `Setup.exe` file, and the `Setup.exe` file can download and launch the Windows Installer–based or InstallScript package if needed.

Note that the Advanced UI project type includes support for including only one primary .msi package, one primary .msp package, or one primary InstallScript package. The Suite/Advanced UI project type that is available in the Premier edition of InstallShield includes support for packaging multiple primary installations (including .exe packages) as a single installation.

To learn more, see the following:

- Creating Advanced UI and Suite/Advanced UI Installations
- Advanced UI Projects vs. Suite/Advanced UI Projects
- Adding an .msi Package, an .msp Patch, or a Transaction to an Advanced UI or Suite/Advanced UI Project
- Working with the Wizard Interface

Microsoft Windows Azure SQL Database Support

InstallShield now includes support for running SQL scripts on Microsoft Windows Azure SQL database servers. In addition, InstallShield includes Microsoft Windows Azure in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports.

If your installation targets Windows Azure, the SQLBrowse run-time dialog that is displayed when end users choose to browse for a database catalog can now list catalogs on the specified SQL database server.

This support is available in the following project types: Basic MSI, DIM, InstallScript, and InstallScript MSI.

To learn more, see:

- Connecting to a Microsoft Windows Azure Database Server and Running SQL Scripts
- Configuring SQL Support
- SQL Scripts View

This support is available in the following project types: Basic MSI, DIM, InstallScript, and InstallScript MSI.

Beta Support for Microsoft Visual Studio 2012

InstallShield includes support for the beta of Visual Studio 2012. You can create InstallShield projects from within this version of Visual Studio.

Microsoft .NET Framework 4.5 Prerequisites

InstallShield includes two new .NET-related InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Microsoft .NET Framework 4.5 Full
- Microsoft .NET Framework 4.5 Web

These InstallShield prerequisites install the beta versions of the .NET Framework 4.5 on supported target systems.

The Web prerequisite requires an Internet connection. This prerequisite downloads the required redistributable files if appropriate. The full prerequisite is a stand-alone installation that does not require an Internet connection.

Microsoft SQL Server 2012 Support

InstallShield now includes support for running SQL scripts on SQL Server 2012 database servers. In addition, InstallShield includes SQL Server 2012 in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports.

If your installation targets SQL Server 2012, the SQLBrowse run-time dialog that is displayed when end users choose to browse for a database server can now list instances of SQL Server 2012, SQL Server 2012 Express, and SQL Server 2012 Express LocalDB. In addition, the SQLBrowse run-time dialog that is displayed when end users choose to browse for a database catalog can now list catalogs on the specified SQL Server 2012 database server.

To learn more, see:

- Requirements for Connecting to Instances of SQL Server Express LocalDB
- Configuring SQL Support

- SQL Scripts View

This support is available in the following project types: Basic MSI, DIM, InstallScript, and InstallScript MSI.

Microsoft SQL Server 2012 Prerequisites

InstallShield includes several new SQL Server 2012–related InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Microsoft SQL Server 2012 Express
- Microsoft SQL Server 2012 Express LocalDB
- Microsoft SQL Server 2012 Native Client

InstallShield also includes InstallShield prerequisites that install Microsoft .NET Framework 3.5 SP1 Update KB956250, which is a dependency of Microsoft SQL Server 2012 Express.

These InstallShield prerequisites install the technology on supported target systems.

New InstallShield Prerequisites for App-V 4.6 SP1, SQL Server Compact 4.0, and JRE SE 1.7

InstallShield includes new InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Java Runtime Environment Second Edition (JRE SE) 1.7
- Microsoft App-V 4.6 SP1 Desktop Client (The redistributable files for these InstallShield prerequisites—available in 32-bit and 64-bit versions—are not available for download from within InstallShield, since you must obtain them from Microsoft. Once you obtain them from Microsoft, place them in the location that is displayed when you are editing these prerequisites in the InstallShield Prerequisite Editor.)
- SQL Server Compact 4.0

These InstallShield prerequisites install the technology on supported target systems.

Support for the Configuring System Center 2012 Configuration Manager Application Model Data

Accurate identification of deployment metadata is necessary for migrating applications into the System Center 2012 Configuration Manager application model. InstallShield includes several new settings in the General Information view that let you specify some of the application model metadata for an application through a software identification tag. When AdminStudio users import a package into the AdminStudio Application Catalog, AdminStudio Application Manager mines package elements for deployment data such as detection methods, dependencies, requirements, as well as information in the software identification tag. AdminStudio makes this information available to users for review and tests before publishing to Microsoft System Center 2012 Configuration Manager.

This feature is available in Basic MSI projects.

To learn more, see Including Microsoft System Center Configuration Manager Application Model Data About Your Product.

Support for PowerShell Custom Actions

Windows PowerShell is a .NET Framework–based command-line shell and script language that enables system administrators to automate system configuration tasks. InstallShield now has support for custom actions that run PowerShell scripts. You may want to add this type of custom action to a project to perform system configuration tasks at installation run time.

Note that in order for an installation to run a PowerShell custom action, Windows PowerShell must be installed on target systems. InstallShield includes a new predefined PowerShell system search that checks for the presence of PowerShell on target systems. You can include this system search in your project and configure your PowerShell custom action to run only if the system search determines that PowerShell is installed.

The PowerShell execution policy, which determines whether PowerShell scripts can be run on a target system, is set to restricted by default, which does not permit PowerShell scripts to be run. If you want your installation to override the target system's execution policy with an appropriate one for your installation's PowerShell custom actions, you can use the new Windows Installer property **IS_PS_EXECUTIONPOLICY** to indicate the appropriate execution policy.

This feature is available in the following project types: Basic MSI and InstallScript MSI.

To learn more, see Calling a PowerShell Custom Action.

Automatic Update Check and Download Support for Suite/Advanced UI and Advanced UI Installations

Suite/Advanced UI and Advanced UI installations now have the ability to automatically check for an updated Suite/Advanced UI or Advanced UI `Setup.exe` file that you host on your Web site, and download and launch it if it is available. The updated Suite/Advanced UI or Advanced UI `Setup.exe` file can be used to deploy upgrades and patches for your latest Suite/Advanced UI and Advanced UI packages.

The Setup.exe tab in the Releases view of Suite/Advanced UI and Advanced UI projects has a new Update URL setting that lets you specify the absolute path (including the file name) for an updated Suite/Advanced UI or Advanced UI setup launcher. If the base Suite/Advanced UI or Advanced UI setup launcher is running a non-maintenance operation, the Suite/Advanced UI or Advanced UI setup launcher checks the update URL for a download. If a download is available, the base Suite/Advanced UI or Advanced UI setup launcher downloads it and then verifies its digital signature. If the digital signature in the update setup launcher matches that in the base setup launcher, the update setup launcher runs automatically. If the digital signature does not match, or if the base setup launcher is not digitally signed, a security warning is displayed, allowing the end user to choose whether to proceed with the update setup launcher.

To learn more, see Adding Support for Automatic Updates to an Advanced UI or Suite/Advanced UI Installation.

Ability to Detect Whether a Specific Version of a Suite/Advanced UI or Advanced UI Installation Is Already Installed

Suite/Advanced UI and Advanced UI projects now include support for determining whether a particular version of a Suite/Advanced UI or Advanced UI installation is already installed on target systems. This type of condition check is called a Suite Installed condition.

InstallShield now includes two Suite Installed conditions in each Suite/Advanced UI and Advanced UI project by default:

- A new Suite Installed exit condition prevents end users from being able to install the current version of the Suite/Advanced UI or Advanced UI installation over a future newer version of the same Suite/Advanced UI or Advanced UI installation.
- A new Suite Installed mode condition may prevent the installation from running in first-time installation mode if the same version of the Suite/Advanced UI or Advanced UI installation is already installed.

These new default conditions are available in all new Suite/Advanced UI and Advanced UI projects. If you upgrade an InstallShield 2012 Suite project to InstallShield 2013, InstallShield automatically adds these default conditions to the project.

You can edit the default Suite Installed conditions if necessary. You can also add your own Suite Installed conditions to a project as needed.

For more information, see:

- Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed
- Triggering Install Mode or Maintenance Mode of an Advanced UI or Suite/Advanced UI Installation
- Suite Installed Condition Settings
- Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

Ability to Configure Network Sharing of Folders in an Installation

InstallShield now lets you create, modify, and delete network shares to enable file sharing over networks. When you are configuring a folder in your project, you can indicate that you want to enable network sharing, which is disabled by default. You can also configure other options such as the name of the share, as well as the maximum number of simultaneous users who can access the share.

To enable sharing, use the new Sharing tab on the Properties dialog box, which is displayed when you right-click a folder in the Files and Folders view and then click Properties.

This feature is available in the following project types: Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, and MSM Database.

For more information, see Folder Properties Dialog Box.

New Built-In Custom Action that Terminates Specific Processes

InstallShield includes support for a new kill-process type of custom action. If you add this type of custom action to your project, you can specify the name or process identifier (PID) of one or more processes that you want to be terminated at run time, and you can schedule the custom action for immediate or deferred mode.

The procedure for creating this type of custom action involves adding and configuring the custom action in the Custom Actions and Sequences view of your project, and using the Property Manager view to define a property with the names or PIDs of the appropriate processes.

This feature is available in the following project types: Basic MSI and InstallScript MSI.

For detailed instructions, see Calling a Kill-Process Custom Action.

Ability to Create Predetermined User Accounts and Groups at Run Time

InstallShield now has built-in support for creating multiple user accounts and corresponding groups at run time without using logon dialogs. To configure the accounts and groups, define values for the properties **ISNetApiLogonUsername**, **ISNetApiLogonGroup**, and **ISNetApiLogonPassword** in your project with the user names, groups, and passwords, respectively. Separate multiple names, groups, or passwords with a tilde enclosed by square brackets: [~].

This feature is available in the following project types: Basic MSI and InstallScript MSI.

To learn more, see Creating Predetermined User Accounts and Groups at Run Time.

Ability to Include InstallShield Prerequisites as Packages in Suite/Advanced UI and Advanced UI Projects

InstallShield now lets you import InstallShield prerequisites as .msi and .exe packages into Suite/Advanced UI and Advanced UI projects. You can import the InstallShield prerequisites that are included with InstallShield, as well as any custom InstallShield prerequisites that you have created. When you right-click the Packages explorer in the Packages view and then click the new Import Prerequisite (.prq) command, InstallShield adds to your project an .msi package or an .exe package, depending on the type of file that is configured to run for the prerequisite. InstallShield also automatically configures default values for each of the prerequisite package's settings, based on the settings that are configured in the .prq file. You can change these settings as needed, just as you can change the settings for packages in your Suite/Advanced UI or Advanced UI project.

If an InstallShield prerequisite has dependencies (that is, if one or more other .prq files are specified as dependencies in the InstallShield prerequisite that you are adding to the Suite/Advanced UI or Advanced UI project), InstallShield automatically adds the dependency prerequisites as separate packages in the Packages explorer.

Previously it was necessary to add the .msi and .exe installations as packages in a Suite project and then manually configure all of the conditions and settings for each of those packages.

For more information, see Including InstallShield Prerequisites (.prq) in an Advanced UI or Suite/Advanced UI Project.

Ability to Include InstallScript Installations as Packages in Suite/Advanced UI and Advanced UI Projects; New Suite/Advanced UI– and Advanced UI–Specific InstallScript Events and Functions

InstallShield now lets you add InstallScript installations as packages in Suite/Advanced UI and Advanced UI projects. When a Suite/Advanced UI or Advanced UI installation launches an InstallScript package, the Suite/Advanced UI or Advanced UI installation displays its own user interface (UI) while automatically suppressing the UI of the InstallScript package. This enables you to provide a contemporary UI experience for the installation. The Suite/Advanced UI or Advanced UI installation also displays progress information for the InstallScript package.

To make these changes possible, Suite/Advanced UI and Advanced UI installations use several new Suite/Advanced UI– and Advanced UI–specific InstallScript events and functions by default, and ignores some of the standard InstallScript events and functions.

New InstallScript Package Support in Suite/Advanced UI and Advanced UI Projects

InstallShield lets you add an InstallScript package to a Suite/Advanced UI or Advanced UI project if the InstallScript package meets the following requirements:

- The InstallScript package is uncompressed.
- InstallShield 2012 Spring or later is used to build the InstallScript package and the Suite/Advanced UI or Advanced UI installation.
- The InstallScript package uses an event-based script; it should not use the program...endprogram style script.

For more information, see Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project.

New Suite/Advanced UI– and Advanced UI–Specific InstallScript Events and Functions

In a standard InstallScript installation that is launched via the InstallScript `Setup.exe` file (that is, not launched from a Suite/Advanced UI or Advanced UI installation), most events are called directly from the OnShowUI event. In a Suite/Advanced UI or Advanced UI installation that launches an InstallScript package, OnShowUI is replaced with OnSuiteShowUI. Depending on the installation state (first-time installation, maintenance, or update), OnSuiteShowUI ignores the UI events such as OnFirstUIBefore and OnFirstUIAfter and instead calls the following events:

- **First-time installation**—OnSuiteInstallBefore, OnSuiteInstallAfter
- **Maintenance**—OnSuiteMaintBefore, OnSuiteMaintAfter
- **Update**—OnSuiteUpdateBefore, OnSuiteUpdateAfter

The InstallScript language includes some new Suite/Advanced UI– and Advanced UI–specific functions that enable interaction between an InstallScript package and the Suite/Advanced UI installation or the Advanced UI installation that is running it. For example, InstallScript includes new functions that let you log InstallScript package information to Suite/Advanced UI and Advanced UI debug logs, set and retrieve Suite/Advanced UI and Advanced UI properties, and pass data from Suite/Advanced UI and Advanced UI installations to the InstallScript package.

To determine whether the InstallScript installation is running as an InstallScript package in a Suite/Advanced UI or Advanced UI installation, use the new SUITE_HOSTED variable in your InstallScript code.

New InstallScript Package Type of Condition Check in Suite/Advanced UI and Advanced UI Projects

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in a Suite/Advanced UI or Advanced UI project, you can select from a number of different types of checks that you want to be evaluated on target systems. Use the new InstallScript package type of condition check to check target systems for the presence of a product that was installed by a particular InstallScript installation. The condition checks for a particular product code, and it can also check other information, such as the product version.

To learn more, see the following:

- Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects
- InstallScript Package Condition Settings
- Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

Dynamic File Link Support for Package Files in Suite/Advanced UI and Advanced UI Projects

When you are adding or configuring an .msi, .msp, or .exe package in an Advanced UI or Suite/Advanced UI project, you can indicate whether the package requires additional files that are located near the package file. For example, if a package that you are adding is an uncompressed .msi package, you may need to include other files—such as .cab files and uncompressed data files in nearby subfolders—along with the package file.

InstallShield now lets you use dynamic links for the additional package files. Dynamic links are useful if the list of additional files that the package requires is likely to change between builds. InstallShield scans the source folder before every build and automatically incorporates any new or changed package files in your release.

InstallShield also lets you define filters that control which additional files InstallShield should include in the dynamic link at build time, and which ones InstallShield should exclude. You can change the order in which InstallShield evaluates any filter criteria that you have defined for a dynamic link. Each time that you build your Advanced UI or Suite/Advanced UI installation, InstallShield includes the appropriate additional files based on the dynamic link's filters.

Previously, only static links could be used for additional files. If the list of additional files changed between builds, it was necessary to manually update the list of package files.

For more information, see:

- Static vs. Dynamic Files for Packages in an Advanced UI or Suite/Advanced UI Project
- Creating a Dynamic Link in an Advanced UI or Suite/Advanced UI Project
- Defining Filters for a Dynamically Linked Folder in an Advanced UI or Suite/Advanced UI Project

Ability to Give Enhanced Feedback When Validating End-User Input During a Suite/Advanced UI or Advanced UI Installation

Suite/Advanced UI and Advanced UI installations now have support for providing enhanced feedback when validating end-user input at run time. Various interface controls in the Wizard Interface view of a Suite/Advanced UI project and an Advanced UI project have three new subsettings under the existing Text Style setting: Default, Valid, and Invalid. You can configure these subsettings to select different text styles that you want the Suite/Advanced UI or Advanced UI installation to use under different circumstances.

Support for Creating Package Log Files When Launching a Suite/Advanced UI or Advanced UI Installation from the Command Line

When you are configuring the settings for a package in a Suite/Advanced UI or Advanced UI project, you can use the new Enable Logging Support setting to specify whether you want the package to generate a log file if the Suite/Advanced UI or Advanced UI installation is launched from the command line with the new `/log` command-line parameter. Depending on the type of package (.msi package, .msp package, or some other type of package), you can also configure one or two other settings to specify information such as which log options you want the Suite/Advanced UI or Advanced UI installation to pass to the package when the log file is being created.

The new `/log` command-line parameter for the Suite/Advanced UI or Advanced UI `Setup.exe` file lets you specify the path to the directory that contains the package log files. If a path is not specified with the `/log` parameter, the Suite/Advanced UI or Advanced UI installation creates the package log files in the %TEMP% directory.

The new property **ISLogDir** in Suite/Advanced UI and Advanced UI installations stores the path to that directory that contains the package log files.

Previously, the only way to enable logging for a Windows Installer–based package in a Suite installation was to use the logging system policy or the **MsiLogging** property.

For more information, see:

- Supporting the Creation of Package Log Files for Command-Line Launching of an Advanced UI or Suite/Advanced UI Installation
- Advanced UI and Suite/Advanced UI Setup.exe Command-Line Parameters
- Advanced UI and Suite/Advanced UI Property Reference

Support for 64-Bit Components in InstallScript Installations

InstallScript projects now have support for installing files to WINSYSDIR64 (the InstallScript variable that maps to the 64-bit System32 folder), and for installing registry data to the 64-bit registry locations, without requiring you to modify your InstallScript code. If you have files or registry data that need to be installed to these 64-bit locations, you can add the files and registry data to a component, and select Yes for that component's new 64-Bit Component setting. At run time, the installation automatically disables file system redirection for the component's System32 files, and it prevents redirection for the component's 64-bit registry data.

Previously, to install files to WINSYSDIR64, it was necessary to override the Installing and Installed events for features that contained components that installed to that location. In the Installing event, it was necessary to use the WOW64FSREDIRECTION constant with the **Disable** function to disable file system redirection; in the Installed event, it was necessary to use WOW64FSREDIRECTION with the **Enable** function to re-enable file system redirection for other parts of the installation. The same sort of disabling and enabling was necessary for the UnInstalling and UnInstalled events to ensure that those files were removed correctly during uninstallation.

If file system redirection is not disabled when an InstallScript installation installs to WINSYSDIR64, 64-bit Windows automatically redirects the file transfers to the 32-bit System32 folder (SysWOW64).

Also previously, to install registry data to a 64-bit area of the registry, it was necessary to use the InstallScript registry functions to create registry data with REGDB_OPTION_WOW64_64KEY set in REGDB_OPTIONS. Then it was necessary to use REGDB_OPTION_USE_DEFAULT_OPTIONS with REGDB_OPTIONS to re-enable registry redirection for other parts of the installation.

If registry redirection is not disabled when an InstallScript installation installs to a 64-bit registry location (HKEY_LOCAL_MACHINE\Software), 64-bit Windows automatically redirects the registry changes to the equivalent 32-bit registry location (HKEY_LOCAL_MACHINE\Software\Wow6432Node).

The InstallScript log files (.ilg) that InstallScript installations create at run time when installing a product now use a new OPTYPE_FILE64 type to identify files that are installed when file system redirection is disabled. The InstallScript log files use the existing OPTYPE_REGISTRY64 type to identify registry data that are installed when registry redirection is disabled. You can see these OPTYPE_FILE64 and OPTYPE_REGISTRY64 types when viewing an .ilg file in the InstallShield Cabinet and Log File Viewer.

For more information, see the following:

- Targeting 64-Bit Operating Systems with InstallScript Installations
- Component Settings
- WINSYSDIR64

- REGDB_OPTIONS
- InstallShield Cabinet and Log File Viewer

New Locale Type of Condition Check in Suite/Advanced UI and Advanced UI Projects

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in a Suite/Advanced UI or Advanced UI project, you can select from a number of different types of checks that you want to be evaluated on target systems. Use the new locale type of condition check to check for matching one or more locale-related settings on target systems.

To learn more, see:

- Using Locale Conditions in Advanced UI and Suite/Advanced UI Projects
- Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects
- Locale Condition Settings
- Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

New Wizard Interface Toolbar for Editing the Layout in Suite/Advanced UI and Advanced UI Projects, with Support for Switching Languages in Suite/Advanced UI Projects

If you select a wizard page or secondary window in the Wizard Interface view of a Suite/Advanced UI project, the toolbar that InstallShield shows directly above the wizard interface preview pane includes several different buttons and other controls that let you modify the layout of the selected page or window. InstallShield also displays this toolbar in the Wizard Interface view if you select one or more controls on a wizard page or a secondary window.

The new toolbar has buttons that let you add labels, text boxes, check boxes, and other controls to the installation's user interface. The toolbar also has buttons that let you easily align selected controls, resize them, and position them in relation to each other. In Suite/Advanced UI projects, the Default Languages list in the new toolbar enables you to switch the strings that InstallShield displays on the wizard pages and secondary windows in this view to those in a different language in your project.

For more information, see:

- Adding a Control to a Wizard Page or Secondary Window
- Wizard Interface View Toolbar

Support for Adding Languages to Suite/Advanced UI Projects

The InstallShield Premier edition includes default run-time strings in 35 supported languages. When you add a supported language to a Suite/Advanced UI project, that language is made available in various language-related settings throughout InstallShield. In addition, InstallShield adds translated string entries for that language to your project. The string entries are for the default wizard pages, messages, and other end-user interface elements.

InstallShield now lets you add unsupported languages, beyond the built-in 35 languages, to Suite/Advanced UI projects through the New Language Wizard. An unsupported language is one in which none of the default run-time strings are translated. When you add an unsupported language to a Suite/Advanced UI project, that language is made available in various language-related settings throughout the project. In addition, InstallShield uses the strings from your project's default language as placeholders for the strings in that newly added unsupported language; you can use the String Editor view to provide translated strings for the unsupported languages.

To launch the New Language Wizard in a Suite/Advanced UI project, on the Tools menu, click Add New Language.

To learn more, see the following:

- New Language Wizard
- Run-Time Language Support in InstallShield

Ability to Create and Configure Scheduled Tasks on Target Systems at Run Time

InstallShield has a new Scheduled Tasks view that lets you configure one or more tasks that you want to be created through the Windows task scheduler at run time on target systems. The view lets you specify information such as the file that you want to be launched for a task, as well as the start date and time. The file that you want to be launched can be part of your installation, or it can be a file that is already present on target systems.

This feature is available in the following project types: Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, Transform.

For more information, see:

- Scheduling Tasks
- Scheduled Tasks View

New FlexNet Connect 13.03 Redistributables Available

InstallShield includes support for FlexNet Connect 13.03 in Basic MSI and InstallScript MSI projects. Use the Update Notifications view in InstallShield to include one of the two FlexNet Connect 13.03 merge modules—one has the Common Software Manager, and the other does not.

Enhancements

InstallShield includes the following enhancements.

Enhancements to the InstallScript Language for Operating Systems

The following structure members and predefined constants were added to the InstallScript language:

- **SYSINFO.WINNT.bWin8**—This is a new SYSINFO structure member. If the operating system is Windows 8 or Windows Server 2012, this value is TRUE.
- **ISOSL_WIN8**—This is a new predefined constant that is available for use with the **FeatureFilterOS** function and the SYSINFO structure variable. It indicates that the target system is running Windows 8 or Windows Server 2012.

For more information, see FeatureFilterOS function and the SYSINFO structure variable.

Automation Interface Enhancement: OSFilter Property Value for Windows 8 and Windows Server 2012

The following constants are now available for use with the OSFilter member of the ISWiComponent and ISWiRelease objects in the automation interface:

eosWin8 = &H4000000 (67108864)—These are for Windows 8 and Windows Server 2012.

In addition, the value for the eosAll constant is now &7D100D0 (131137744); previously, it was &3D100D0 (64028880).

The OSFilter member applies to the ISWiComponent object in InstallScript, InstallScript MSI, and InstallScript Object projects. The OSFilter member applies to the ISWiRelease object in InstallScript and InstallScript Object projects.

For more information, see the following:

- ISWiComponent Object
- ISWiRelease Object

Ability to Easily Move Conditions in Suite/Advanced UI and Advanced UI Projects

When you have more than one conditional statement for an exit, detection, eligibility, or feature condition in a Suite/Advanced UI or Advanced UI project, you now can move the conditional statements to reorder conditions or change the hierarchy of a condition tree. For example, if you have a platform conditional statement in a None condition group, and the None condition group is in an All condition group, you can move the platform conditional statement left, so that it is only part of the All condition group.

To move a conditional statement or group, click the new Move Condition button in the setting of the item that you want to move, and then click the appropriate option (Move Up, Move Down, Move Left, or Move Right).

Previously, it was necessary to manually create the new conditional statement in the new location and delete the one in the old location. Or, as an alternative, you could edit the .issuite file in a text editor and change the order of the conditional statements.

For more information, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.

New Extension Condition Support and Enhanced Condition Settings in Suite/Advanced UI and Advanced UI Projects

In Suite/Advanced UI and Advanced UI projects, new extension condition functionality is available. This type of condition lets you browse to a C/C++ DLL that you have created to check for your own custom conditions on target systems.

In addition, many of the condition-related settings that are available in Suite/Advanced UI and Advanced UI projects have been enhanced to make it easier to build conditional statements. For example, instead of manually trying to enter a product code, upgrade code, patch code, or other various types of data in any one of several of the condition settings, you can now click a new ellipsis button (...) in the setting; when you do this, InstallShield displays a browse dialog box that lets you browse to and select the appropriate package. Once you have selected a package, InstallShield enters the appropriate information from that package in the setting of the Suite/Advanced UI or Advanced UI project.

When you are configuring an eligible package condition, you can now select from a list of packages in your Suite/Advanced UI or Advanced UI project instead of having to manually enter the package GUID of the appropriate package.

For more information, see:

- Creating a Custom Condition for an Advanced UI or Suite/Advanced UI Installation
- Creating an Extension Condition DLL for an Advanced UI or Suite/Advanced UI Project

- Adding an Extension Condition DLL to an Advanced UI or Suite/Advanced UI Project
- Extension Condition Settings

Enhancements for Configuring Validation and Actions for a Control on a Wizard Page or Window in Suite/Advanced UI and Advanced UI Projects

In Suite/Advanced UI and Advanced UI projects, the Validation and Action settings for various controls on the wizard interface have been enhanced to make it easier to define validation and trigger various actions. These settings now contain drop-down lists of sample statements that you can enter in these settings; these settings are also still text boxes that let you enter statements manually. For example, the Validation setting lets you specify a format that end users must match when they enter a serial number in a control. As an alternative to manually entering the entire validation statement, you can now select the mask type of validation in the Validation setting and then override the default format in the setting.

Similarly, the Action setting lets you define—for example—a print action for a button control; when an end user clicks the Print button, the Print dialog box opens, enabling the end user to print the license agreement. As an alternative to manually entering the action statement, you can now select the print action in the Action setting and then override the file name with the name of the file that you want to be printed.

The drop-down lists in the Validation and Action settings also now include C/C++ DLL files that you have created and added to your project through the Support Files view. This functionality lets you trigger your own validation or your own action for various controls on the wizard interface.

To learn more, see:

- Configuring Validation for a Control on a Wizard Page or Window
- Configuring an Action for a Control on a Wizard Page or Window

Ability to Use Custom Folder Names for Packages in Suite/Advanced UI and Advanced UI Releases

When you build an Suite/Advanced UI or Advanced UI installation, InstallShield creates a folder for each package that is included in the installation; these folders are created in the same folder that contains the Suite/Advanced UI or Advanced UI setup launcher. By default, the name of each folder is a GUID that InstallShield generates.

The Packages view in InstallShield now lets you override the GUID name with a user-friendly name for each package folder. To enter a custom folder name in this view, find a Package Files folder under the package whose folder name you want to customize. Right-click that folder, click Rename, and enter a new name. If you customize more than one folder name, ensure that each folder name is different.

Previously, InstallShield used a GUID for the name of each folder and did not have support for customizing the names.

For instructions, see Using Custom Folder Names for Packages in Advanced UI and Suite/Advanced UI Installations.

New Formatted Support for Properties Whose Values Reference Other Properties in Suite/Advanced UI and Advanced UI Projects

Each property that is defined in the Property Manager view in a Suite/Advanced UI or Advanced UI project has a new Formatted check box. This new check box lets you indicate whether you want the properties that are referenced in a property's value to be resolved and replaced by their property values at run time.

To replace properties that are enclosed within square brackets (such as **[PropertyName]**) at run time, select this check box. To leave square brackets and the content within them as is, clear this check box.

For more information, see Property Manager View.

Improved Timing for UAC Prompts of Downloaded Packages that Require Elevation for Suite/Advanced UI and Advanced UI Installations that Have an Invoker Manifest

If you build an Advanced UI or Suite/Advanced UI release with an Invoker manifest, and if Yes is selected in the Require Elevated Privileges setting for any of the installation's packages that need to be downloaded and launched on the target system, the installation triggers the UAC prompt soon after end users click the Install button—before the download occurs.

Previously, the installation triggered the UAC prompt after the download occurred. Thus, if package staging was slow (for example, if the package download took a long time), there could be a big gap between the moment that an end user clicked the Install button and the moment that Windows displayed the UAC prompt for elevation for the package. If an end user did not provide consent or credentials quickly enough, the UAC prompt timed out, and the installation failed.

In some previous cases, using an Administrator manifest was a possible workaround, since the UAC prompt was displayed soon after end users clicked the Install button. However, with this workaround, the entire installation had elevated privileges.

Support for Specifying the Alignment for Text in the Wizard Interface of Suite/Advanced UI and Advanced UI Installations

InstallShield has a number of built-in text styles that define text attributes such as color, size, and font name for the text on the wizard interface of Suite/Advanced UI and Advanced UI projects. You can edit any of the settings for these built-in styles or define your own styles, through the Wizard Interface view in your Advanced UI or Suite/Advanced UI project.

Each built-in or custom text style includes a new Text Alignment setting that lets you select the type of alignment that you want to use for the text in controls that use that particular style.

To learn more, see Using Styles to Customize the Wizard Interface.

Enhanced Combo Box Controls for the Wizard Interface of Suite/Advanced UI and Advanced UI Installations

InstallShield lets you add a combo box control to a wizard page or a secondary window in Suite/Advanced UI and Advanced UI projects. This type of control is a combination of two controls by default:

- A box that contains a drop-down list of predefined values
- A text box that lets end users enter a custom value

Previously, if you added a new combo box control, the control contained a drop-down list, but it was not also a text box; that is, end users could not enter a custom value.

To change this control to a drop-down list without the text box (that is, if end users should be able to select a predefined value but not enter a custom value), set the CBS_DROPDOWNLIST style for this control to True.

Enhancements and Changes to the Aero Format for the Suite/Advanced UI and Advanced UI Wizard Interface

Some enhancements and changes have been made to Aero-formatted wizard pages in Suite/Advanced UI and Advanced UI installations:

- The header and navigation areas of wizard pages are now displayed with the Aero glass effect, or translucency. Previously, only the caption bar of wizard pages were displayed with the Aero glass effect.
- The Aero-formatted wizard pages now use the same layout as Wizard 97–formatted wizard pages. That is, the caption bar on Aero-formatted wizard pages is no longer extra tall; it is the same height as the caption bar on Wizard 97–formatted wizard pages. In addition, the Back button on Aero-formatted wizard pages is now displayed in the navigation area, which is consistent with the placement on Wizard 97–formatted wizard pages. Previously, the top-left corner of the caption bar in Aero-formatted wizard pages contained the Back button.

Ability to Remove a String Value and Its Identifier from a Setting

When you are entering the value of a setting in one of the views in InstallShield and that value is a text string that can be presented to end users, InstallShield automatically uses a string identifier for that setting. InstallShield places the string identifier in curly brackets before the string value. These types of settings now contain a new **Delete this string reference** button.

If you want to remove the string identifier and its value from a setting, you can now click this new button. The button lets you clear the entry in the setting. Note that if you want to delete the string identifier and its value from your project, you must use the String Editor view.

What's New in InstallShield 2012 SP1

Enhancements

InstallShield includes the following enhancement.

Support for Digitally Signing Software Identification Tags

If you configure your project to include a software identification tag and you also configure the release in the Releases view to use a .pfx file to digitally sign your release, InstallShield digitally signs the tag at build time. Note that the .NET Framework 2.0 or later must be installed on your build machine in order to sign a tag file.

For more information, see Including a Software Identification Tag for Your Product.

What's New in InstallShield 2012

New Features

InstallShield includes the following new features.

Ability to Create Suite Installations that Run Multiple Packages; New Contemporary, Customizable End-User Interface; Ability to Build Hybrid 32-Bit/64-Bit Installations

The Premier edition of InstallShield now lets you build a Suite installation that uses the next-generation setup launcher (`Setup.exe`) to conditionally run multiple installations and apply Windows Installer patches (.msp) as needed on target systems. This support is available through a new Suite project type. Suite installations can be run on systems with Windows XP and later and with Windows Server 2003 and later.

Following are some highlights of this functionality.

Ability to Package Multiple Installations as a Single Installation

The new Suite project type contains a Packages view that lets you specify one or more of the following types of packages:

- Executable files (.exe), including Windows Installer–based and non-Windows Installer–based installations that you want to be run on target systems
- Windows Installer packages (.msi) that you want to be run on target systems
- Windows Installer patches (.msp) that you want to be applied on target systems

The Packages view also lets you include multiple .msi and .msp packages that you want to be run using transaction processing, a feature of Windows Installer 4.5 and later. The packages are chained together and processed as a single transaction. Each Suite installation can have multiple separate transactions. If one or more of the packages in a transaction cannot be installed successfully or if the end user cancels the installation, Windows Installer initiates rollback for all of the chained packages within the current transaction to restore the system to its earlier state.

The Suite installation launches the appropriate packages at run time based on conditions that you have defined and the order in which you listed the packages in the Packages view.

Contemporary, Customizable User Interface for the Installation; New Editor for Customizing Suite Setup.exe Wizard Pages

The Suite project type in InstallShield includes an entirely new end-user interface, with redesigned, contemporary built-in wizard pages that you can include and customize in your Suite installations. The new wizard page editor in this project type lets you add, sequence, and remove pages as needed; it also lets you modify the layout of any page—adding, moving, and removing a variety of different kinds of controls.

Support for Combining 64-Bit and 32-Bit Windows Installer Packages Into a Single Installation

As more and more users move to 64-bit versions of Windows, you may need to now, or in the near future, deliver to customers a single installation that installs to 32-bit locations on 32-bit systems and to 64-bit locations on 64-bit systems. The Suite project type lets you include both 32-bit packages and 64-bit packages in one Suite installation,

and run only the appropriate packages on each target system. Previously, other alternatives required delivering two separate installations (one for 32-bit systems and one for 64-bit systems) or creating a custom launcher, a bootstrap application, or an InstallScript installation.

Support for Displaying a Single Progress Bar that Shows the Overall Status of the Entire Suite of Packages

The progress bar on the progress wizard page in a Suite installation shows the status of the entire suite of packages. This integrated progress bar presents end users with a clear visual indication of how far along the Suite installation is overall. To ensure that end users see only the integrated progress bar, you must include only .exe installations for which you have specified command-line parameters that hide the user interface (that is, run silently), .msi packages, and .msp patches.

Optional Add or Remove Programs Entry for the Suite Installation

Suite projects let you specify whether you want to have an entry in Add or Remove Programs for your Suite installation. This entry lets end users perform maintenance for your Suite, modifying or removing if needed. The General Information view in a Suite project has a Show Add or Remove Programs Entry setting that lets you indicate the appropriate behavior.

If you want to show only a single entry for the entire Suite, ensure that you hide the entries from the packages that you include in the Suite project.

Support for Running Suite Installations Without a User Interface

End users can run your Suite installations with a user interface or silently, without a user interface. Silent installations run without user intervention; end users can avoid monitoring the installation and providing input through run-time wizard pages.

Default Setup.exe User Interface Strings Included for All 35 Supported Languages; Ability to Edit the Suite Run-Time Strings

Translations of all of the default strings that are displayed in the built-in wizard pages of Suite projects are available in all 35 of the run-time languages that InstallShield supports. All of these Suite strings are displayed in the String Editor view of a Suite project. This String Editor view offers the same robust support that other types of projects offer, giving you complete and centralized control over the text strings that are displayed at run time during the Suite installation process.

Small Base Setup.exe File with the Ability to Download Only the Required Packages As Needed

Suite projects include flexible options for specifying the run-time source location of each package in the Suite installation. When you define the packages that you are including in a Suite project, you can specify the location of each individual package. The available options are:

- On the Web, available for download by `Setup.exe` if needed
- Embedded in `Setup.exe` and extracted to the target system if needed
- Uncompressed and stored on the Suite source media

The base `Setup.exe` file that is used for Suite installations is much smaller than the base `Setup.exe` files that are used for Basic MSI, InstallScript MSI, and InstallScript installations. Thus, your end users can quickly download a small Suite `Setup.exe` file, and the `Setup.exe` file can download and launch one or more required packages as needed.

For more information, see:

- Creating Advanced UI and Suite/Advanced UI Installations
- Adding an .msi Package, an .msp Patch, or a Transaction to an Advanced UI or Suite/Advanced UI Project
- Adding an Executable Package (.exe) to a Suite/Advanced UI Project
- Working with the Wizard Interface
- Advanced UI and Suite/Advanced UI Setup.exe Command-Line Parameters
- Advanced UI and Suite/Advanced UI Property Reference
- Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

Redesigned, Expanded Support for Modularizing Installation Projects to Enable Reuse and Distribute Development Work

InstallShield includes a new project type called DIM, which is known as a *developer installation manifest*. A DIM project is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete portion of a product installation. Some benefits of using DIMs are as follows:

- DIMs include support for virtually the same functionality that is available in Basic MSI projects. This gives authors of DIMs all of the flexibility that they need to develop their portions of an installation.
- Release engineers can reuse DIMs in multiple Basic MSI projects, enabling efficiency.
- Working with DIMs enables multiple team members to contribute to the development of the installation simultaneously. Each software developer or other team member can work on a separate DIM that the release engineer can reference in one or more Basic MSI projects.

Once you have created a DIM, you can add it to a Basic MSI project in one of two ways:

- **By reference**—You can add a reference for a DIM project to your Basic MSI project through the Setup Design view or the DIM References view. With this method, the DIM elements are merged into the Basic MSI project at build time. Each time that you build the Basic MSI installation, InstallShield references the latest version of the DIM project and includes it in the installation that it generates. This method is the more commonly performed method.
- **By import**—You can import a DIM project into your Basic MSI project by using the new Import DIM Wizard. This method is a one-time, irreversible import that merges the DIM data into the Basic MSI project at design time.

This redesigned, expanded DIM support replaces the previous support that required users to create DIMs in a separate tool called InstallShield Collaboration, and then import the DIM files into InstallShield Basic MSI projects. The new DIM support is more robust than the previous support. The new DIM project type lets you have virtually the same complete level of authoring flexibility that is available for Basic MSI projects. For example, the new DIM project type lets you have full control over component creation: you can add components to a new DIM project, set the key file of a component, and configure the component's settings. The new DIM project type also lets you configure IIS Web sites. InstallShield Collaboration did not have that sort of flexibility over component design, and it did not have any built-in support for configuring IIS Web sites.

The ability to create DIM projects is available in the Premier edition of InstallShield. This support is also available in the InstallShield Developer Installation Manifest Editor, a new collaboration add-on. The ability to add DIM files to Basic MSI projects is available in the Premier edition of InstallShield.

For more information, see the following:

- Modularizing Installation Projects to Distribute Development Work and Enable Reuse
- Including DIMs in a Project
- Determining the Appropriate Method for Incorporating DIMs in Installation Projects
- Using Path Variables in a DIM
- DIM References View
- Import DIM Wizard

New InstallShield Prerequisites for Internet Explorer 9, SQL Server 2008 R2 Native Client, Windows Identity Foundation, and Other Redistributables

InstallShield includes several new InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Internet Explorer 9.0
- Microsoft SQL Server 2008 R2 Native Client 10.50.1600.1
- Windows Identity Foundation
- Microsoft VSTO 2010 Runtime (x64)
- Microsoft Office 2010 PIA (This prerequisite installs the Microsoft Office 2010 Primary Interop Assemblies. To use this prerequisite, download the `PrimaryInteropAssembly.exe` file from Microsoft's Web site and run it to extract the .msi file.)

Support for 64-Bit Dependency Scanning

The Static Scanning Wizard and the Dynamic Scanning Wizard—dependency scanners in InstallShield—now include support for identifying 64-bit dependencies of the 64-bit files in your project. If you are using InstallShield on a 64-bit version of Windows Vista or later or a 64-bit version of Windows Server 2008 or later, the scanners can detect the 64-bit dependencies. The wizards let you specify whether you want to include each detected potential dependency in your project.

In addition, if you use InstallShield on a 64-bit version of Windows Vista or later or a 64-bit version of Windows Server 2008 or later, and you use either of the following built-in methods for detecting dependencies, InstallShield can scan for 64-bit dependencies of the 64-bit .NET assemblies in your project:

- The Static Scanning Wizard helps you identify a 64-bit .NET assembly's possible dependencies on demand. This wizard displays a list of the dependencies that it finds, and it lets you specify whether you want to include each one in your project.
- A component's .NET Scan at Build setting lets you specify whether you want InstallShield to identify a 64-bit .NET assembly's dependencies each time that you build your project. For InstallScript projects, the

component's .NET Assembly setting must also be set to Local Assembly. If InstallShield detects any possible missing dependencies at build time, InstallShield incorporates them into the release that it generates.

InstallShield must be installed on a 64-bit operating system in order to scan 64-bit files for 64-bit dependencies. Note that if you use InstallShield on a 32-bit version of Windows, these built-in scans can check for only 32-bit dependencies of the 32-bit files in your project. If your project includes 64-bit files, you can manually add any dependencies to the project as needed.

To learn more, see:

- Developing and Building Installations on 32-Bit vs. 64-Bit Systems
- Scanning for 64-Bit Dependencies
- Identifying Application Dependencies
- Scanning 64-Bit .NET Assemblies for Dependencies
- Identifying Properties and Dependencies of .NET Assemblies

Support for Setting Permissions for Files, Folders, and Registry Keys in 64-Bit Locations

InstallShield has support for setting permissions for files, folders, and registry keys in 64-bit locations. The support varies, depending on which project type you are using.

Using the Custom InstallShield Handling Method in Windows Installer–Based Projects

If you are using the custom InstallShield handling method to set permissions for files, folders, and registry keys, you can now set permissions for these items when they are in 64-bit locations; this includes 64-bit locations in the registry, as well as the 64-bit System32 folder on 64-bit systems. The file, folder, or registry key must be included in a component that is marked as 64 bit (that is, Yes is selected for its 64-Bit Component setting). Previously, if the component was marked as 64 bit, permissions could not be set, and a run-time error was displayed.

This custom InstallShield handling support is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform. The Locked-Down Permission setting in the General Information view lets you specify which method you want to use for setting permissions: either the custom InstallShield handling method or the traditional Windows Installer handling method.

Using the InstallScript Function SetObjectPermissions in InstallScript-Based Projects and Windows Installer–Based Projects

If the REGDB_OPTION_WOW64_64KEY option is enabled and you use the InstallScript function **SetObjectPermissions** to set permissions for a 64-bit registry key, the function can set its permissions correctly. To force **SetObjectPermissions** to set permissions for a 64-bit registry key regardless of whether the REGDB_OPTION_WOW64_64KEY option is enabled, you can use the new IS_PERMISSIONS_OPTION_64BIT_OBJECT constant; pass this constant in the nOptions parameter of **SetObjectPermissions**. Note that the IS_PERMISSIONS_OPTION_64BIT_OBJECT constant should not be passed on 32-bit target systems.

If file system redirection is disabled using the WOW64FSREDIRECTION constant when **SetObjectPermissions** is called to set permissions for a file or folder in the 64-bit System32 folder, the function can set the permissions correctly. If file system redirection is not disabled, the permissions cannot be set.

You can use the **SetObjectPermissions** function in InstallScript events in InstallScript and InstallScript MSI projects. You can also use this function in InstallScript custom actions in the following project types: InstallScript, Basic MSI, InstallScript MSI, and Merge Module.

For more information, see SetObjectPermissions.

Improvements for COM Extraction

InstallShield supports a new monitoring method for COM extraction. If you are using InstallShield on a Windows Vista or later system or a Windows Server 2008 or later system, this new method is used by default. The method uses a kernel driver to monitor the areas of the registry that are modified during dynamic COM extraction at build time and static COM extraction at design time. It combines the advantages that the earlier methods provided, allowing the DLL to read existing registries entries and preventing changes to the build machine.

If necessary, you can switch between the three different COM extraction methods by setting the value data of the UseAPIRegistryHooks registry value, which is in the registry key HKEY_LOCAL_MACHINE\SOFTWARE\InstallShield\RegSpy (on 32-bit machines) or HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\InstallShield\RegSpy (on 64-bit machines). Possible REG_DWORD value data are:

- **0**—Use API hooking to read existing registry entries for the DLL.
- **1**—Use registry redirection to prevent making changes to the registered DLLs on the build machine. If the value is not set, this is the default behavior on Windows XP and Windows Server 2003 systems.
- **2**—Use the new kernel mode monitoring, which combines the advantages of both of the other methods. If the value is not set, this is the default behavior on Windows Vista and later systems and on Windows Server 2008 and later systems.

This feature applies to the following project types: Basic MSI, DIM, InstallScript MSI, and Merge Module.

Predefined System Searches for Adobe Reader 10, Internet Explorer 9, and Microsoft Office

InstallShield has new predefined system searches:

- Adobe Reader 10
- Internet Explorer 9
- Microsoft Office 2010
- Microsoft Office 2007
- Microsoft Office 2003

If your installation requires one or more of these, you can use the System Search view or the Installation Requirements page in the Project Assistant to add these system searches to your project. When end users launch your installation, Windows Installer checks the target system to see if the requirements are met; if they are not met, the installation displays the error message that is defined for the system search.

This feature applies to Basic MSI and InstallScript MSI projects.

Support for Software Identification Tagging

ISO/IEC 19770-2 is an international standard for the creation of software identification tags. A software identification tag is an XML-based file that contains descriptive information about the software, such as the product name, product edition, product version, and publisher. Software asset management tools collect the data in the tags to provide accurate application identification for software that is installed in an enterprise.

Software identification tagging is evolving as an industry standard, enabling independent software vendors to create smarter applications that give their customers better information for software asset management and license optimization initiatives. Including the identification tag in your product's installation makes it possible for your customers to use tools that can monitor their internal usage of your product, allowing them to manage and optimize the number of licenses of your product that they obtain from you, and stay in compliance with your licensing policies.

InstallShield includes several new settings in the General Information view that let you specify information that is required to create an identification tag for your product. This view also contains a new Use Software Identification Tag setting that lets you specify whether you want InstallShield to create the tag at build time and include it in your installation; the default value of this setting is Yes.

Note that if Yes is selected for the Use Software Identification Tag setting but you have not entered values in one or more of the required identification settings (the Unique ID, Tag Creator, and Tag Creator ID settings in the General Information view), build warning -7235 occurs, once for each of the settings that are blank. This build warning explains that the software identification tag could not be created and included in the installation because a specific required setting was left blank. To resolve this warning, enter appropriate value in each specific setting, or select No for the Use Software Identification Tag setting.

The automation interface includes support for the new tag settings. The ISWiProject object includes a new EnableSwidtag property that lets you enable or disable the creation of a software identification tag in a project. It also includes a new SwidtagProperty property that you can use to configure various tag-related settings that are also configurable in the General Information view.

This feature applies to Basic MSI projects.

For more information, see:

- Including a Software Identification Tag for Your Product
- General Information View Settings
- ISWiProject Object

Enhancements

InstallShield includes the following enhancements.

Merge Module Projects Now Include Built-In Support for IIS, Text File Changes, and XML File Changes

Several existing views are now available in Merge Module projects in InstallShield:

- **Internet Information Services**—This view enables you to create and manage new IIS Web sites, applications, virtual directories, application pools, and Web service extensions.

- **Text File Changes**—This view lets you configure search-and-replace behavior for content in text files—for example, .txt, .htm, .xml, .config, .ini, and .sql files—that you want to modify at run time on the target system.
- **XML File Changes**—This view lets you add references for nodes and node sets of XML files that you want to change at run time.

Use these views in Merge Module projects to configure IIS, specify text file changes, and specify XML file changes. The same procedures that were used for configuring these changes in installation projects are now supported in Merge Module projects. When you build a merge module that contains project information in these views, add the merge module to an installation project, and then build a release in the installation project, InstallShield includes the applicable run-time support in the installation.

Previously, these views were available only in installation projects.

To learn more, see:

- Managing Internet Information Services
- Modifying Text Files
- Modifying XML Files

New Application Pool Identity Option for IIS 7.x

A new ApplicationPoolIdentity option is available in the Identity setting for an application pool that is configured in the Internet Information Services view. If you want a virtual identity account that is unique to the selected application pool to be used for running the application pool's worker process, select this option. Support for this option is available on target systems that have IIS 7 and later. If this new option is selected in an installation that is run on a system that has IIS 6, the NetworkService account is used instead for the application pool's identity.

This feature applies to the following project types: Basic MSI, InstallScript, InstallScript MSI, and Merge Module.

For more information, see Application Pool Settings.

Automation Interface Enhancement: New RequiredExecutionLevel Property for Specifying the Required Execution Level for Setup.exe

The read-write RequiredExecutionLevel property has been added to the ISWiRelease object. This property corresponds with the Required Execution Level setting on the Setup.exe tab for a release in the Releases view. This property is available for Basic MSI, InstallScript, and InstallScript MSI projects.

What's New in InstallShield 2011

New Features

InstallShield includes the following new features.

Unicode Support in InstallScript

InstallShield now lets you create InstallScript installations and InstallScript custom actions that support the use of Unicode in run-time strings, files, paths, registry entries, and other installation data. In addition, the InstallScript compiler and the InstallScript engine now let you pass pointers to Unicode strings to functions that are

implemented outside script code; they also let you store Unicode strings in structures that are passed outside script code. Other changes in InstallScript offer additional benefits for fully supporting modern multilanguage installations.

As a result of these changes, any language displays correctly on a system that has support for it installed. End users no longer need to match the language that is used on their systems for non-Unicode programs with the language that is used in the installation. Note that the font must be installed on the target system. On some versions of Windows, the fonts for some languages are not installed by default. For example, Japanese fonts are not installed on a Windows XP English system by default; in order for an installation to use Japanese characters on such a system, the fonts would need to be installed.

Unicode Setup Launchers for InstallScript and InstallScript MSI Projects

Now all `Setup.exe` and `Update.exe` files that are built in InstallShield are Unicode. Previously, all `Setup.exe` and `Update.exe` files that were built in InstallScript and InstallScript MSI projects were ANSI.

A Unicode setup launcher can correctly display characters in the user interface of the setup launcher, regardless of whether the target system is running the appropriate code page for the language. ANSI setup launchers correctly displayed characters in the setup launcher dialogs if the target system was running the appropriate code page. However, it may have displayed garbled characters in those dialogs if the target system was not running the appropriate code page.

End users can launch `Setup.exe` and `Update.exe` files from within Unicode paths, regardless of the language on the target system. For example, end users can now launch the installation in the following path on an English system: `C:\Users\`*`Japanese characters`*`\Desktop\Setup.exe`. Previously, the installation would fail.

Unicode Support for Files, Folders, Registry Entries, and Support Files

Unicode support has been added to key parts of the installation run time, enabling you to use characters from any languages simultaneously in file names, folder names, registry entries, and support file names. This enables you to install, for example, a file that has Japanese characters in its name or target path on an English system. Mixing languages works correctly regardless of the current language of the target system.

Pointer Support

The InstallScript engine and compiler now support a new pointer type called WPOINTER; wpointer and LPWSTR are equivalent names that are also available. Thus, for example, if you have a DLL function that accepts pointers to Unicode strings in its parameters, you can use this new pointer type; when the DLL function is called in the script at run time, the InstallScript engine passes a pointer to a Unicode copy of the strings instead of an ANSI version. Previously, it was possible to pass a pointer to only an ANSI copy of the strings.

Note that passing Unicode strings with the WSTRING data type that was introduced in an earlier version of InstallShield is still supported.

For more information, see:

- Pointers
- Data Types and Predefined Structures

Structure Support

Structures in InstallScript can contain any basic data type, including strings and pointers, or other structures. Now if a structure needs to contain a Unicode string and the structure is passed to an external DLL, the InstallScript engine can distinguish between string member types in that structure, and then size the structure and calculate member offsets correctly. String members that need to be stored and passed as Unicode can be declared with the WSTRING type.

Previously, if a structure needed to contain a Unicode string and the structure was passed to an external DLL, the InstallScript engine assumed that any strings in the structure were ANSI. As a result, the size of the structure and member offsets in the structure could have been wrong, causing the DLL to incorrectly read or write data related to the structure. Attempting to use WSTRING for string members of a structure did not have any effect.

You can leave existing strings as STRING types; the InstallScript engine will continue to treat these as ANSI strings when passing them outside of script code.

Pointer members in structures can also now be declared as WPOINTER. This enables you to store pointers to Unicode strings in a structure.

For more information, see:

- Data Structures
- Data Types and Predefined Structures

String Table Support

InstallShield now uses Unicode encoding to build the string tables for InstallScript projects. Because of this support, string tables for InstallScript projects can now contain multiple languages, and they are not affected by a target system's code page settings. In addition, string tables can now include strings for languages—such as Hindi—that have no code page.

It is recommended that any strings that will be displayed in the user interface of an installation be stored in the string table. Although strings can be written directly in InstallScript code, they are not stored as Unicode; thus, they are displayed correctly only when the installation is run on systems that have the correct code page. Storing strings in the string table and referencing them from InstallScript code eliminates this issue.

For more information, see:

- Using String Entries in InstallShield
- String Constant Operator (@)

Unicode InstallScript Dialogs

InstallScript dialogs now include support for Unicode. This enables you to mix, for example, Japanese and German, or Russian and Polish, on InstallScript dialogs. These mixed languages work correctly regardless of the current language of the target system.

This feature is available in the following project types: InstallScript and InstallScript MSI.

Unicode Support in the InstallScript Debugger

The InstallScript Debugger now has support for Unicode. Thus, for example, if you are debugging a line of InstallScript code such as szMsg = @ID_MSG, you can now see the value in szMsg, regardless of what language operating system you are using and what language is used for the strings. If the value of ID_MSG contains Chinese characters or characters from mixed languages, you can now see the appropriate characters instead of question marks in various areas of the InstallScript Debugger: in the variable window, in the watch window, and in the tooltip that appears for the variable in the script window.

For information on the InstallScript Debugger, see Debugging InstallScript-Based Installations.

Unicode Support in InstallShield Cabinet and Log File Viewer

The InstallShield Cabinet File Viewer and the InstallShield Log File Viewer have been combined into one new tool—the InstallShield Cabinet and Log File Viewer—which lets you open and review InstallScript cabinet files (.cab), InstallScript header files (.hdr), and InstallScript log files (.ilg). This tool now includes Unicode support. Thus, the tool can correctly display the characters in each file name, registry key, shortcut, and other data in the .cab, .hdr, or .ilg file, regardless of what language operating system you are using and what language is used for the strings. Previously, in some cases, some of the characters were displayed as question marks.

The cabinet and header file support applies to the following project types: InstallScript and InstallScript Object.

The log file support applies to the following project types: InstallScript and InstallScript MSI.

To learn about this tool, see:

- InstallShield Cabinet and Log File Viewer
- Viewing InstallScript Cabinet Files (.cab) and Header Files (.hdr)
- Viewing InstallScript Log Files (.ilg)

Integration with Team Foundation Server (TFS)

InstallShield has enhanced support for integrating with Team Foundation Server (TFS) 2010.

Now when you are using InstallShield from within Visual Studio 2010, you can access the Source Control Explorer to integrate your InstallShield project with Team Foundation version control and manage changes to your InstallShield projects and your Visual Studio solutions.

You can also use Team Foundation Build to compile, test, and deploy your InstallShield projects and your Visual Studio solutions on a regular basis, or on demand. Your installation is automatically updated with your latest source files every time that your solution is built.

In addition, if you install Team Explorer on the same machine that has InstallShield and Visual Studio, you can use Team Explorer from within your InstallShield projects that are open in Visual Studio. This enables you to perform tasks such as the following:

- Use Source Control Explorer when you are working on your InstallShield projects.
- Configure builds for your InstallShield projects and Visual Studio solutions.
- Queue new builds.
- Track work items such as bugs and tasks for your InstallShield projects and your Visual Studio solutions.

For more information, see:

- Integrating with Microsoft Visual Studio Team Foundation Server
- Adding InstallShield Projects to Team Explorer

Microsoft SQL Server 2008 R2 Support

InstallShield now includes support for running SQL script on SQL Server 2008 R2. In addition, InstallShield includes SQL Server 2008 R2 in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports.

This feature is available in the following project types: Basic MSI, InstallScript, and InstallScript MSI.

New InstallShield Prerequisites for SQL Server 2008 R2 Express, SQL Server Native Client, Visual C++ 2010, and Other Redistributables

InstallShield includes a number of new InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Microsoft SQL Server 2008 R2 Express
- Microsoft SQL Server 2008 Native Client 10.00.2531
- Microsoft SQL Server Native Client 9.00.4035
- Microsoft SQL Server System CLR Types 10.00.2531
- Microsoft SQL Server 2008 Management Objects 10.00.2531
- Microsoft Visual C++ 2010 Redistributable Package
- Microsoft Visual C++ 2008 SP1 Redistributable Package
- Microsoft Visual C++ 2005 SP1 Redistributable Package (x64)
- Windows Installer 3.1 - Japanese
- MSXML 6.0 SP1 - Japanese
- Microsoft .NET Framework 4.0 Client Japanese Language Pack
- Microsoft .NET Framework 4.0 Full Japanese Language Pack

Improved Script Editors for Creating and Modifying InstallScript Code, SQL Scripts, VBScript Custom Actions, and JScript Custom Actions

Several views in InstallShield have an improved script editor that you can use to write code for your projects. The script editors include the following improvements:

- **Expanded auto completion**—When you are typing in a script editor, InstallShield displays a pop-up list of alphabetically ordered functions, keywords, and constants that begin with the letters that you are typing. Instead of manually typing the entire word, you can select it in the pop-up list, and InstallShield adds it to your script.

If you are using the script editor in the InstallScript view, you can enter the string constant operator (@) to see a pop-up list of the available string identifiers. You can select the appropriate one in the list, and InstallShield adds it to your script.

If auto completion for local variables is also enabled, the pop-up list in the script editor of the InstallScript view also contains local variables.

Auto completion can increase your efficiency because it can reduce the time that you spend typing code. It can also help you avoid typographical errors in your code.

The script editor in the InstallScript view of earlier versions of InstallShield is the only script editor that provided some auto completion support; thus, auto completion functionality was not available for SQL scripts, VBScript code, or JScript code. In addition, the available pop-up list was limited to InstallScript functions; none of the keywords, constants, local variables, or string identifiers were available for auto completion.

- **Detailed InstallScript Function Call Tips**—If function call tips are enabled, InstallShield shows InstallScript function call tips—a type of tooltip—when you are entering function calls in your script in the InstallScript view. A function call tip shows a built-in function's parameter information. It also shows a description of the built-in function, as well as a description of the parameter that you are entering. The detailed call tips enable you to see help information about a function without switching from the script editor to the help library, and then back to the script editor.

  The InstallScript view in earlier versions of InstallShield included support for call tips, but the call tips did not display as much information. The call tips showed a function call with all of the function's parameters; however, the call tips did not include a description of the function, or of the parameter that you are entering.

- **Syntax folding**—InstallShield now lets you specify whether you want the script editors in various views in InstallShield to include support for syntax folding. When syntax folding is enabled, InstallShield adds a plus sign (+) or a minus sign (–) in the margin next to each line of code that starts an expandable or collapsible block of script. You can click a plus sign to expand hidden code, or a minus sign to hide visible code.

  Syntax folding can help you minimize the clutter of large scripts and focus on the code that is relevant to the work that you are currently doing. It can also help you see the overall structure of a script.

The views that contain the improved script editor are the InstallScript view, the SQL Scripts view, and the Custom Actions and Sequences view (when you are viewing a VBScript or JScript file in this view).

By default, syntax folding is disabled in the script editors; auto completion, local variable auto completion, and function call tips are enabled. To enable or disable any of the aforementioned functionality, use the Script Editor Properties dialog box. This dialog box also lets you modify other settings in the script editors, such as font, syntax colors, and line numbering. To access this dialog box, right-click in a script editor and then click Properties.

For more information, see the following:

- Working with the Script Editor Pane in Various Views
- Using Auto Completion when Writing Code in the Script Editors
- Viewing Function Call Tips for an InstallScript Function in the Script Editor
- Changing Colors for Syntax Highlighting in the Script Editors
- Enabling or Disabling Syntax Folding in the Script Editors
- Keyboard Shortcuts for the Script Editors

- Script Editor Properties Dialog Box

Ability to Create 64-Bit Microsoft App-V Packages

The Microsoft App-V Assistant in InstallShield includes support for converting a 64-bit Windows Installer package into a 64-bit Microsoft App-V package, which can be deployed on 64-bit Windows systems with the 64-bit Microsoft App-V 4.6 client. This, in combination with the new 64-bit repackaging support that is available with the Repackager, enables you to convert any 64-bit installation into a 64-bit App-V package.

It is recommended that you perform the conversion of 64-bit Windows Installer packages to App-V packages on a 64-bit Windows system. If you attempt the conversion on a 32-bit system, it could result in a failure to extract COM information for 64-bit binaries. Also, in some cases, Windows Installer packages contain shortcuts that target executable files that are not found in the package itself. If these shortcuts target executable files are found in 64-bit locations, these shortcuts are not handled correctly on 32-bit systems.

The Microsoft App-V Assistant is available if you purchase InstallShield with the Virtualization Pack.

Ability to Specify a Search Path for InstallShield Prerequisites; Path Variable and Relative Path Support for Source Locations of Prerequisite Files

InstallShield now lets you specify the folders where InstallShield should search for InstallShield prerequisite files (.prq files). This functionality makes it easier for teams of users to share InstallShield prerequisites with each other, and for storing prerequisites in source code control. Previously, InstallShield searched for .prq files in the following location only: *InstallShield Program Files Folder*\SetupPrerequisites.

InstallShield offers several ways for specifying the folders:

- If you are editing or building from within InstallShield, use the new Prerequisites tab on the Options dialog box—which is displayed when you click Options on the Tools menu—to specify a comma-delimited list of machine-wide folders and current-user folders. This tab is similar to the Merge Modules tab on the Options dialog box, which lets you specify search paths for merge modules.
- If you are building from the command line with `ISCmdBld.exe`, use the new `-prqpath` parameter to specify a comma-delimited list of folders.

  If you use an .ini file to specify `ISCmdBld.exe` parameters, you can use the new PrerequisitePath parameter in the [Mode] section of your .ini file to specify a comma-delimited list of folders.
- If you are building through MSBuild or Team Foundation Server (TFS), use the new PrerequisitePath parameter on the InstallShield task. This parameter is exposed as the ItemGroup InstallShieldPrerequisitePath when the default targets file is used. To specify multiple paths, use an ordered array of paths.

When you are using the Files to Include tab in the InstallShield Prerequisite Editor to add files to an InstallShield prerequisite, the editor now uses predefined path variables such as <WindowsFolder> and <ISProductFolder> if appropriate. In addition, if the files that you are adding are stored in the same folder as the InstallShield prerequisite's .prq file—or a subfolder of the folder that contains the .prq file—the InstallShield Prerequisite Editor uses a relative path for the file in the .prq file. Note that if you view the file's path on the Files to Include tab, the InstallShield Prerequisite Editor lists the full path, not the relative path.

Note that if you use the Save As command in the InstallShield Prerequisite Editor to change the location of a .prq file, the InstallShield Prerequisite Editor updates the paths of the prerequisite's files if appropriate.

To learn more, see:

- Specifying the Directories that Contain InstallShield Prerequisites
- Prerequisites Tab
- ISCmdBld.exe
- Passing Command-Line Build Parameters in an .ini File
- Microsoft Build Engine (MSBuild)

New Hyperlink Control for Windows Installer–Based Dialogs

The Controls toolbar includes a new hyperlink control that you can use in the Dialogs view for Windows Installer–based dialogs. The hyperlink control displays an HTML link; clicking the link at run time opens a page in the default browser on the target system.

Windows Installer 5 includes support for this new hyperlink control. If this control is used on a dialog that is displayed on a system that has an earlier version of Windows Installer, run-time error 2885 occurs, and the installation aborts. Therefore, if you want to use the hyperlink control on a dialog but your installation targets systems that have Windows Installer 4.5 or earlier, it is recommended that you include two versions of the dialog in your project: one with the hyperlink control, and one without it. Add conditions to the dialogs to show or hide them, depending on the version of Windows Installer that is present.

This feature is available in the following project types: Basic MSI and Merge Module.

To learn more, see Hyperlink Control.

Ability to Specify a Custom Icon and Custom Version Resource Properties for Setup.exe and Update.exe

InstallShield now lets you use a custom icon and custom version resource properties for `Setup.exe` files that you create at build time. The icon and the version resource properties are displayed on the Properties dialog box for `Setup.exe`; this Properties dialog box opens when end users right-click the `Setup.exe` file and then click Properties. End users can also see the icon when they view your `Setup.exe` file in Windows Explorer. This support is available in Basic MSI, InstallScript, and InstallScript MSI projects.

The same functionality (the ability to specify a custom icon and custom version resource properties) is also now available for `Update.exe` files that you create in Basic MSI, InstallScript MSI, and QuickPatch projects.

Custom Icon for Setup.exe and Update.exe

The Setup.exe tab in the Releases view has a Setup.exe Icon File setting that lets you specify the icon that should be used for your `Setup.exe` setup launcher. The icon can be in an .exe, .dll, or .ico file. If you do not specify an icon, InstallShield uses a default icon for your `Setup.exe` file.

Previously, support for specifying a custom `Setup.exe` icon was available for InstallScript projects if the `Setup.exe` file that you were building was a self-extracting, single-file setup launcher. The support was not available in Basic MSI or InstallScript MSI projects. In addition, it was not available for uncompressed InstallScript installations.

A new Icon setting lets you specify the icon that should be used for your `Update.exe` launcher. This setting is available on the Advanced tab for a patch configuration in the Patch Design view of Basic MSI and InstallScript MSI projects. It is also available on the Advanced tab of the Build Settings area in the General Information view of QuickPatch projects. If you do not specify an icon, InstallShield uses a default icon for your `Update.exe` file.

Previously, InstallShield did not include any support for specifying a custom icon for `Update.exe` files.

Custom Version Resource Properties for Setup.exe and Update.exe

When InstallShield is configuring the following version resources of your `Setup.exe` setup launcher at build time, it now uses the custom information that you entered in the General Information view and the Releases view:

- Company name
- Product name
- Product version
- Copyright
- File version
- File description

To use a custom copyright notice and a custom file description, ensure that you select Yes in the Use Custom Version Properties setting for the release in the Releases view.

Previously, InstallShield did not use any custom information in many cases. For example, the InstallScript `Setup.exe` files that InstallShield previously created contained details that pertained to the version of InstallShield that was used to build the `Setup.exe` file. Thus, the product name that was displayed in the `Setup.exe` Properties dialog box was InstallShield, rather than the name of your product.

Several new settings—Company Name, Product Name, Product Version, Description, and Copyright—let you specify the custom information that you want InstallShield to use when you build an `Update.exe` file. These settings are available on the Advanced tab for a patch configuration in the Patch Design view of Basic MSI and InstallScript MSI projects.They are also available on the Advanced tab of the Build Settings area in the General Information view of QuickPatch projects.

Previously, InstallShield did not use any custom version resource information for `Update.exe` files.

To learn more, see:

- Specifying the Icon for the Setup Launcher
- Customizing File Properties for the Setup Launcher
- Setup.exe Tab for a Release
- Specifying the Icon for the Update Launcher
- Customizing File Properties for the Update Launcher
- Advanced Tab (in the Patch Design view)
- Advanced Tab (for a QuickPatch project)

Ability to Specify Commands that Run Before, During, and After Builds

The Premier edition of InstallShield includes new release settings that you can use to specify commands that you want to be run at various stages of the build process. These new settings are available on a new Events tab when you select a release in the Releases view:

- **Prebuild Event**—Use this setting to specify the command that you want to be run before InstallShield starts building the release. This event runs after InstallShield creates the release folder and log file, but before InstallShield starts building the release.

  This setting is available in the following project types: Basic MSI, InstallScript, InstallScript MSI, and Merge Module.

- **Precompression Event**—Use this setting to specify the command that you want to be run after InstallShield has built the .msi package and the .cab files (if your product's data files are to be stored in .cab files). Note that this event occurs after .cab files are streamed into the .msi package, but before the .msi package has been digitally signed and streamed into the `Setup.exe` file.

  This setting is available in the following project types: Basic MSI and InstallScript MSI.

- **Postbuild Event**—Use this setting to specify the command that you want to be run after InstallShield has built and signed the release.

  This setting is available in the following project types: Basic MSI, InstallScript, InstallScript MSI, and Merge Module.

The new Events tab replaces the previously available Postbuild tab. Note that the settings that were previously available on the Postbuild tab are now displayed on the new Events tab. In addition, the publish-related settings that were previously available on the Build tab in Merge Module projects have been moved to the Events tab.

The automation interface now includes support for the new build event settings. The ISWiRelease object includes three new properties that let you specify commands for various stages of the build process:

- PrebuildEvent
- PrecompressionEvent
- PostbuildEvent

To learn more, see:

- Specifying Commands that Run Before, During, and After Builds
- Events Tab for a Release
- ISWiRelease Object

Ability to Set an Expiration Date for Setup.exe

InstallShield now lets you set an expiration date, as well as an expiration message, for `Setup.exe`. If end users try to run `Setup.exe` on or after the date that you have specified in your project, the expiration message is displayed, and the installation exits.

To set an expiration date and a message for your `Setup.exe` file, use the new Expiration Date and Expiration Message settings on the Setup.exe tab for a selected release in the Releases view. By default, no expiration date is configured for `Setup.exe`. If you specify an expiration date, you can use the default expiration message, or specify your own custom message.

The automation interface now includes support for these new settings. The ISWiRelease object includes two new properties that let you set the expiration date and message: ExpirationDate and ExpirationMessage.

This feature is available in the following project types: Basic MSI and InstallScript MSI.

For more information, see:

- Setup.exe Tab for a Release
- ISWiRelease Object

Ability to Import Visual Studio Setup and Merge Module Projects into Existing InstallShield Projects; Improvements for the Project Converter

InstallShield now lets you import a Visual Studio setup project (.vdproj) into an InstallShield Basic MSI or Merge Module project (.ism), or import a Visual Studio merge module project (.vdproj) into an InstallShield Basic MSI or Merge Module project (.ism). These tasks enable you to develop InstallShield installation and merge module projects that contain the same data and settings that were in your Visual Studio project. The wizard imports the project outputs, files, registry keys, file extensions, custom actions, target system searches, and launch conditions from your Visual Studio project into your existing InstallShield project.

To import a Visual Studio project into an existing InstallShield project, use the new Visual Studio Deployment Project Import Wizard in InstallShield. The wizard lets you choose whether to import or ignore certain settings in the Visual Studio project.

The existing support for converting a Visual Studio project into a new InstallShield project has been expanded. If your Visual Studio project contains predefined prerequisites, InstallShield now converts them to equivalent InstallShield prerequisites during the conversion process. This same prerequisite conversion functionality is available if you use the new wizard to import a Visual Studio project into an InstallShield project.

If your Visual Studio project contains one or more project outputs, use the import wizard instead of the conversion process. The InstallShield project must be in the same Visual Studio solution that contains the Visual Studio setup or merge module project and all of its project dependencies. Note that you must be using InstallShield from within Visual Studio when you use the import wizard in order for the wizard to import the project outputs into your InstallShield project.

To learn more, see the following:

- Converting or Importing Visual Studio Projects into InstallShield Projects
- Visual Studio Deployment Project Import Wizard

Unicode and UTF-8 Support for SQL Scripts

InstallShield now has design-time and run-time support for SQL scripts that have either Unicode BOM encoding or UTF-8 BOM encoding. You can use the SQL Scripts view to add SQL scripts with either of these encoding types to your project. You can also edit those SQL scripts from within that view as necessary. At run time, the SQL scripts are executed during installation and uninstallation when needed.

Previously, InstallShield had run-time support but not design-time support for SQL scripts with Unicode BOM encoding. Thus, when you added a script with this encoding to the SQL Scripts view of your project, InstallShield prompted you to specify whether you wanted to convert the script to ANSI format. If you allowed InstallShield to convert it to ANSI, you could edit it from within the SQL Scripts view. However, in some cases, it might have displayed and used garbled characters at design time and at run time. If you did not allow InstallShield to convert it to ANSI, the file remained with Unicode BOM encoding. Although this encoding allowed your installation to properly use strings in languages that did not match the code page of the target system at run time, you could not view or edit the script from within InstallShield.

In addition, InstallShield previously did not have adequate support for SQL scripts with UTF-8 BOM encoding. If you added a SQL script with this encoding type to your project and the script contained strings in a language that did not match the code page of the development system, the SQL Scripts view treated the file as an ANSI file, and it may have displayed garbled characters. In addition, garbled characters were used when your SQL script was executed at run time. Also, the byte order mark was represented as garbled characters.

If you create a new SQL script from within the SQL Scripts view, InstallShield uses Unicode BOM encoding for the file. If you prefer to use ANSI or UTF-8 BOM encoding for the SQL scripts view, it is recommended that you create an .sql file with the proper encoding in a different tool, and then import or insert the script in the SQL Scripts view of your project.

This feature is available in the following project types: Basic MSI, InstallScript, and InstallScript MSI.

Predefined System Searches for SQL Server 2008 Express SP1 and Adobe Reader 9

InstallShield has new predefined system searches:

- SQL Server 2008 Express SP1
- Adobe Reader 9

If your installation requires one or both of these, you can use the System Search view or the Installation Requirements page in the Project Assistant to add these system searches to your project. When end users launch your installation, Windows Installer checks the target system to see if the requirements are met; if they are not met, the installation displays the error message that is defined for the system search.

This feature applies to Basic MSI and InstallScript MSI projects.

Support for 64-Bit Managed-Code Custom Actions

InstallShield now has support for 64-bit managed-code custom actions. When you build a release that includes a managed-code custom action in your project, InstallShield attempts to determine the target architecture (32 bit or 64 bit) of the main .NET assembly that is associated with the custom action. InstallShield configures the release so that the appropriate version of the .NET Framework—32 bit or 64 bit—is used to run your managed code at run time.

If you want to override the new default behavior, use the Direct Editor view to add a new record with the following fields to the **ISCIrWrap** table.

- **Action_**—Indicate the name of the managed-code custom action that you want to modify.
- **Name**—Enter the following: `TargetPlatform`
- **Value**—Specify the appropriate architecture. To use a 32-bit version of the .NET Framework, enter the following: `x86`

  To use a 64-bit version of the .NET Framework, enter the following: `x64`

This feature is available in the following project types: Basic MSI, InstallScript MSI, and Merge Module.

To learn more, see Using 32-Bit vs. 64-Bit Managed-Code Custom Actions.

Support for 64-Bit .NET Installer Classes and COM Interop

InstallShield now has support for 64-bit .NET installer classes and COM interop. If you are using InstallShield on a 64-bit system, the .NET tab on the Options dialog box—which is displayed when you click Options on the Tools menu in InstallShield—now lets you specify different paths for the 32-bit and 64-bit locations of the `Regasm.exe` and `InstallUtilLib.dll` files that are included with the .NET Framework. InstallShield uses the paths that you specify at build time for releases that include .NET installer classes and COM interop.

If you are building from the command line with `ISCmdBld.exe` and you use the existing `-t` parameter to specify the path of the 32-bit version of the .NET Framework, `ISCmdBld.exe` now uses the 64-bit location of `Regasm.exe` and `InstallUtilLib.dll` when appropriate.

If you are building through MSBuild or Team Foundation Server (TFS) and you use the existing DotNetUtilPath parameter on the InstallShield task to specify the path of the 32-bit version of the .NET Framework, the build now uses the 64-bit location of `Regasm.exe` and `InstallUtilLib.dll` when appropriate.

To learn more, see:

- .NET Tab (on the Options dialog box)
- ISCmdBld.exe
- Microsoft Build Engine (MSBuild)

Support for Using the InstallScript Function DotNetCoCreateObject or Managed-Code Custom Actions with DLLs that Target .NET Framework 4

If you create a DLL in Visual Studio 2010 and the DLL uses .NET Framework 4, you can now use the InstallScript function **DotNetCoCreateObject** to call functions in this DLL. Previously, the installation crashed if the DLL used version 4 of the .NET Framework, but not with earlier versions. This feature is available in the following project types: InstallScript and InstallScript MSI; it is also available in Basic MSI and Merge Module projects with InstallScript custom actions.

In addition, you can now use the same sort of DLL file in a managed-code custom action. Previously, the installation crashed if it contained a managed-code custom action for a DLL that used version 4 of the .NET Framework. This feature is available in the following project types: Basic MSI, InstallScript MSI, Merge Module.

For more information, see:

- DotNetCoCreateObject
- Using 32-Bit vs. 64-Bit Managed-Code Custom Actions

Ability to Override Path Variables for a Release

InstallShield now lets you override the values of your project's user-defined path variables, environment variables, and registry variables for each release in your project. This functionality enables you to essentially replace certain files and folders in your project with others at build time, depending on the particular release that you are building.

For example, you might use this feature to swap out the binaries for custom actions. If you have set up separate releases for 32-bit and 64-bit target systems, you can override the path variable that is used to refer to the DLL that is selected for a custom action. Then InstallShield could include a 32-bit DLL for your 32-bit release and a 64-bit DLL for your 64-bit release. Note that overriding path variables to swap out files that your installation is installing is not recommended. This is because you should use separate components for 32-bit and 64-bit versions of a file.

To override one or more path variables in your project, use the new Path Variables Overrides setting, which is on the Build tab for a release in the Releases view. Note that if you override a path variable both in the new Path Variables Overrides setting, and with the `-l` parameter to `IsCmdBld.exe` or through MSBuild, the command line or MSBuild value takes precedence over the value that is set in the release setting.

The automation interface now includes support for this new setting. The ISWiRelease object includes a new PathVariableOverrides property that lets you override the values of your project's user-defined path variables, environment variables, and registry variables for a release.

This feature is available in the following project types: Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, and Merge Module.

To learn more, see the following:

- Path Variable Overrides setting
- Path Variable Overrides Dialog Box
- ISWiRelease Object

Ability to Configure MIME Types for IIS Web Sites, Applications, and Virtual Directories

The Internet Information Services view has a new MIME Types setting that you can configure for a Web site, application, or virtual directory in your project. This setting lets you identify the types of content that can be served from the Web server on the target system to a browser or mail client.

This feature applies to the following project types: Basic MSI, InstallScript, and InstallScript MSI.

For more information, see:

- MIME Types setting for a Web site
- MIME Types setting for an application or virtual directory

Ability to Overwrite Existing IIS Application Pool or Only Create It If It Does Not Exist

The Internet Information Services view has a new Overwrite Existing Application Pool setting. This setting is displayed in the right pane when you select an application pool in the Internet Information Services view. This setting lets you specify the behavior that you want to occur if the selected application pool already exists on the target system at run time: the installation can either overwrite the application pool's settings on the target system, or leave the application pool as is. The default value for this setting is Yes, indicating the an existing application pool is overwritten at run time.

This feature applies to the following project types: Basic MSI, InstallScript, and InstallScript MSI.

For more information, see the description of the Overwrite Existing Application Pool setting for an application pool.

New Billboard Style in InstallScript and InstallScript MSI Projects

InstallScript and InstallScript MSI projects include support for a new style of billboard that is displayed above the progress bar on the progress dialog. This style of billboard supports Adobe Flash application files (.swf), as well as image files (.bmp, .gif, .jpg, and .jpeg).

If a project contains both Flash files and image files but a target system does not have the Adobe Flash Player, the installation can detect that and display image billboards in place of the Flash billboard.

Previously, the only available billboard support in InstallScript and InstallScript MSI projects required the use of a background window. The new billboard style does not require a background window.

To add the new style of billboard to a project, use the Support Files/Billboards view to add billboard files to your project. To display this new style of billboard at run time, use the new STATUSBBRD constant with the **Enable** function.

Note that the new style of billboard is not available in projects that use skinned dialogs.

To learn more, see:

- Displaying Billboards in InstallScript and InstallScript MSI Installations
- Billboard Styles and File Types for InstallScript and InstallScript MSI Projects
- Adding or Modifying the Code in an InstallScript or InstallScript MSI Project to Display Billboards
- Adding an Adobe Flash Application File Billboard to an InstallScript or InstallScript MSI Project
- Adding an Image Billboard to an InstallScript or InstallScript MSI Project
- Naming Billboard Files in an InstallScript or InstallScript MSI Project

Support for Looping Through Image Billboards in Basic MSI Projects

The Billboards view in Basic MSI projects has a new Loop Billboards setting that lets you specify whether you want your installation to continuously loop the image billboards until the file transfer completes and the installation displays the appropriate SetupComplete dialog.

If you select Yes for this setting and the file transfer takes more time than you have allocated for the billboards, the installation restarts the display of billboards from the beginning. The loop continues, if necessary, until the file transfer ends. The default value for this setting is No, which matches the behavior in earlier versions of InstallShield.

Previously, if the file transfer took more time than what you had allocated for the billboards, the installation continued to display the last billboard until the file transfer finished; it did not loop the billboards.

For more information, see:

- Run-Time Behavior of a Basic MSI Installation that Includes Billboards
- Billboard Settings

Windows Installer 5 Support for Configuring Windows Service Permissions

InstallShield now includes support for configuring permissions for Windows services; this support uses the **MsiLockPermissionsEx** table that was introduced with Windows Installer 5. Windows Installer 5 supports the new service permission settings; earlier versions of Windows Installer ignore them.

To configure the new permission settings for a service, use the Services node in the Advanced Settings area for a component in the Setup Design view (in installation projects) or the Components view. The Services node is where you add new services to your project. When you select a subnode under the Services node, you can configure the settings—including the new permission-related settings—of that service in the right pane.

This functionality is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

For more information, see:

- Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment
- Services Settings

Automation Interface Support for Configuring Dynamic File Links in InstallScript Projects

The ISWiDynamicFileLinking object and the ISWiDynamicFileLinkings collection of the automation interface now include support for dynamic file links in InstallScript projects. In addition, two methods and a property of the ISWiComponent object are now applicable to InstallScript projects: the AddDynamicFileLinking method lets you add a new dynamic file link to a component, the RemoveDynamicFileLinking method lets you remove a component's dynamic file links, and the ISWiDynamicFileLinkings property lets you get a component's collection of dynamic file links. The read-only DynamicFile property for the ISWiFile object is also now applicable to InstallScript projects: use this property to determine whether the file's source is linked to the component dynamically or statically.

For more details, see:

- ISWiDynamicFileLinking Object
- ISWiDynamicFileLinkings Collection
- ISWiComponent Object
- AddDynamicFileLinking Method
- RemoveDynamicFileLinking Method
- ISWiFile Object

New FlexNet Connect 12.01 Redistributables Available

InstallShield includes support for FlexNet Connect 12.01 in Basic MSI and InstallScript MSI projects. Use the Update Notifications view in InstallShield to include one of the two FlexNet Connect 12.01 merge modules—one has the Common Software Manager, and the other does not.

Enhancements

InstallShield includes the following enhancements.

Unicode Views in InstallShield

Several views and areas in InstallShield have been enhanced to display and allow you to enter characters from all languages. For example, now you can use Chinese characters in file names, paths, and registry entries if you are configuring system searches in the System Search view on an English machine. Previously, the characters were displayed in these areas of InstallShield as question marks.

The areas in InstallShield that have been enhanced to include the Unicode support are the System Search view, the tabs for a release in the Releases view, and the Multiple Instances tab for a release in the Releases view. Note that Unicode support was previously introduced in many other views in InstallShield 2010.

The improvements for the System Search view are applicable to the following projects: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

The improvements for the tabs for a release in the Releases view are applicable to the following projects: Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, and Merge Module.

The improvements for the Multiple Instances tab in the Releases view are applicable to Basic MSI projects.

Command-Line Support for Generating a Log File While Using InstallShield MSI Diff

InstallShield MSI Diff includes a new `/out` command-line parameter. You can use this new parameter while running InstallShield MSI Diff from the command line to generate a log file that identifies the differences between two .msi, .msm, or .pcp files, or that shows the differences that are applied to a Windows Installer database by a transform (.mst) or patch file (.msp). You can also use this tool from the command line to generate a log file that identifies the differences between two InstallShield project files (.ism or .ise) that are saved in binary format.

To learn more, see Running InstallShield MSI Diff from the Command Line to Generate a Log File of Differences.

Support for Listing Local Microsoft SQL Server Instances on 64-Bit Systems

If you add SQL support to a project through the SQL Scripts view in InstallShield and the installation is run on a 64-bit target system, the built-in SQL-related run-time dialogs now list 64-bit local SQL Server instances, as well as 32-bit local SQL Server instances, 32-bit network SQL Server instances, and 64-bit network SQL Server instances. Previously when the installation was run on a 64-bit target system, the built-in SQL-related run-time dialogs did not list any 64-bit local SQL Server instances; they listed only 32-bit local instances, 32-bit network instances, and 64-bit network instances.

This functionality is available in the following project types: Basic MSI, InstallScript, and InstallScript MSI.

InstallScript Logging and Uninstallation of 64-Bit Registry Changes

By default, the InstallScript engine now logs the changes that it makes to the 64-bit part of the registry during an InstallScript or InstallScript MSI installation on 64-bit target systems. Furthermore, the 64-bit registry changes that are logged by the InstallScript engine are now uninstalled during uninstallation.

Previously, if the InstallScript engine made changes to the 64-bit part of the registry during an installation, those changes were not logged as 64 bit specific, so they were not removed during uninstallation.

Support for Microsoft SQL Server Management Studio

The SQL Scripts view now includes support for Microsoft SQL Server Management Studio. To open a SQL script file of your project in SQL Server Management Studio, right-click the SQL script file in the SQL Scripts view and then click Open Script in Microsoft SQL Server Management Studio. This new command replaces the Open Script in Microsoft Query Analyzer command on the same context menu.

This functionality is available in the following project types: Basic MSI, InstallScript, and InstallScript MSI.

Support for Adding Project Outputs from Visual Studio Web Setup Projects

If you create a Visual Studio solution that includes a Web setup project and an InstallShield installation project and you are using InstallShield from within Visual Studio, you can now add project outputs from the Web setup project to your InstallShield project.

Ability to Select a Windows Installer Property when Configuring a Text File Change

Two settings in the Text File Changes view have been enhanced to make it easier to configure search-and-replace behavior for content in text files. The Find What and Replace What settings, which are displayed in the right pane when you select a replacement node in the Text File Changes view, now let you select a Windows Installer property from a list, or type a string. The list consists of all of the properties that are available in the Property Manager view of your project. Previously, you could manually enter a string or a property in these settings, but the list of properties was not available.

This enhancement is available in the following project types: Basic MSI and InstallScript MSI.

InstallScript Text Substitution Improvements for Resolving Environment Variable Paths in IISROOTFOLDER

InstallScript installations now have support for installing IIS data to IISROOTFOLDER if the IIS PathWWWRoot registry value contains an environment variable. Previously, when text substitution was performed for the IISROOTFOLDER variable in an InstallScript installation that included IIS support, the environment variable part of the path of IISROOTFOLDER was not resolved on Windows Server 2008 and later systems. If any components were configured to be installed to IISROOTFOLDER, they failed to install because the unresolved path was an invalid path.

Ability to Specify the Required Execution Level for Update.exe Manifests

The Required Execution Level setting is now available on the Advanced tab for a patch configuration in the Patch Design view of Basic MSI and InstallScript MSI projects. It is also available on the Advanced tab of the Build Settings area in the General Information view of QuickPatch projects.

Use these new settings to specify the minimum execution level that is required by your installation's `Update.exe` file for running the upgrade on Windows Vista and later platforms. InstallShield adds a manifest that specifies the required level. By default, InstallShield uses the level that was configured in the previous setup launcher's manifest.

Previously, the Required Execution Level setting was available only for the `Setup.exe` setup launchers. If you created an `Update.exe` patch, InstallShield used the same required execution level that was configured in the previous setup launcher's manifest.

To learn more, see:

- Advanced Tab (in the Patch Design view)
- Advanced Tab (for a QuickPatch project)

Ability to Create .cab Files Without Compression

A new Cab Optimization Type setting is available on the Build tab for a release that is selected in the Releases view. If Compressed or one of the custom options is selected for the Compression setting, use the Cab Optimization Type setting to specify the type of compression that InstallShield should use when building the release's .cab files. The available options are LZX compression, MSZIP compression, or no compression.

The Cab Optimization Type setting replaces the Optimize Size setting, which had support for only LZX compression and MSZIP compression; it did not let you skip compression.

The automation interface now includes support for this new setting. The ISWiRelease object includes a new CabCompressionType property that lets you specify which of the three compression options you want to use when you build a release through the automation interface.

This enhancement is available in the following project types: Basic MSI and InstallScript MSI.

For more information, see Build Tab for a Release.

Expanded List of Predefined Operating System Conditions in the InstallShield Prerequisite Editor

The Prerequisite Condition dialog box, which is displayed when you are adding or modifying a condition for an InstallShield prerequisite in the InstallShield Prerequisite Editor, now has predefined operating system conditions for Windows Server 2008 R2. Some of the Windows 7 options have been renamed to make it more clear which versions of Windows are checked, since some of the options check for the workstation version, the server version, or either version. The Prerequisite Condition dialog box also has new options that check only for Windows 7, not Windows Server 2008 R2. These changes let you quickly define more-targeted operating system conditions for any InstallShield prerequisites.

You can add InstallShield prerequisites to the following project types: Basic MSI, InstallScript, and InstallScript MSI.

New Refresh Button in the Redistributables and Prerequisites Views

The Redistributables view (in Basic MSI, InstallScript MSI, and Transform projects) and the Prerequisites view (in InstallScript projects) contains a new Refresh button that you can use to refresh the list of redistributables that are displayed in the view. Previously, if you added redistributables to your machine when either view was open in InstallShield, it was necessary to close and then reopen the project in order to see an updated list in the view.

This enhancement is available in the following project types: Basic MSI, InstallScript, InstallScript MSI, and Transform.

Support for Setting Permissions for the IUSR User Account

InstallShield now has support for securing files, folders, and registry keys for the well-known user account IUSR.

If you are using the custom InstallShield handling method of configuring permissions in your project, the User list on the Permissions dialog box has a new IUSR option. To use the custom InstallShield handling method, select this option in the Locked-Down Permissions setting in the General Information view. This functionality is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, and Transform.

If you are using the InstallScript function **SetObjectPermissions** to set permissions, you can now pass IUSR for the szUser parameter. This functionality is available in InstallScript events in the following project types: InstallScript and InstallScript MSI. This functionality is also available through InstallScript custom actions in Basic MSI, InstallScript MSI, and Merge Module projects.

New IS_PERMISSIONS_OPTION_ALLOW_ACCESS Constant for the SetObjectPermissions Function

A new IS_PERMISSIONS_OPTION_ALLOW_ACCESS constant is available for use with the InstallScript function **SetObjectPermissions**. You can pass this constant instead of the number 0 in the nOptions parameter of **SetObjectPermissions** to indicate that the permissions that are being set should allow access to the specified file, folder, or registry key.

This functionality is available in InstallScript events in the following project types: InstallScript and InstallScript MSI. This functionality is also available through InstallScript custom actions in Basic MSI, InstallScript MSI, and Merge Module projects.

For more information, see SetObjectPermissions

New Constants for the DialogSetInfo Function

Two new constants are available for the nParameter parameter of the InstallScript function **DialogSetInfo** when you are using DLG_INFO_ALTIMAGE for the nInfoType parameter:

- **DLG_INFO_ALTIMAGE_VERIFY_BMP**—This constant specifies that the bitmap that is indicated by szInfoString should be used in subsequent dialogs. Before this bitmap is used, the installation checks for the existence of the bitmap. If the bitmap does not exist, the function returns an error that indicates that the bitmap was not found.
- **DLG_INFO_ALTIMAGE_REVERT_IMAGE**—This constant specifies that dialogs should display the default bitmap. This constant is an alternative equivalent to the value of -1. The installation does not check for the existence of the bitmap when you use this constant.

If you pass TRUE in the nParameter parameter, the installation does not check for the existence of the bitmap; if the bitmap does not exist in this scenario, the function does not return an error.

This functionality is available in InstallScript events in the following project types: InstallScript and InstallScript MSI.

For more information, see DialogSetInfo.

Enhancements for .NET Framework 4.0 Support

A new FOLDER_DOTNET_40 InstallScript variable is available. This variable stores the path of the .NET Framework 4.0 files.

Two new constants are available for use with the function Is:

- REGDB_KEYPATH_DOTNET_40_CLIENT
- REGDB_KEYPATH_DOTNET_40_FULL

Path Variable Support for Each Patch Configuration's Output Location and Cache

The Common tab for a patch configuration that is selected in the Patch Design view contains two settings that let you browse to the appropriate folder: Patch Output Location and Patch Creation Cache. InstallShield now lets you use path variables for the folders instead of absolute paths. This support makes it easier to build releases on different build and development machines that use different directory structures.

This support is available if InstallShield is configured to use path variables on your system. (That is, the Path Variables tab on the Options dialog box must be configured to allow path variable support.) If you configure InstallShield to use absolute paths, the Patch Design view shows the absolute path to folders.

This enhancement is available in the following project types: Basic MSI and InstallScript MSI.

InstallScript Functions ServiceExistsService and ServiceGetServiceState No Longer Require Elevated Privileges

The InstallScript functions **ServiceExistsService** and **ServiceGetServiceState** no longer require elevated privileges. Therefore, installations can now call these functions when end users have limited privileges, such as in the Install UI sequence of a Basic MSI installation.

Important Information

Installing More than One Edition of InstallShield

Only one edition of InstallShield 2013—Premier, Professional, or Express—can be installed on a system at a time.

Installing More than One Version of InstallShield

InstallShield 2013 can coexist on the same machine with other versions of InstallShield.

The InstallShield 2013 Standalone Build can coexist on the same machine with other versions of the Standalone Build. In most cases, the Standalone Build is not installed on the same machine where InstallShield is installed. If you do install both on the same machine and you want to use the automation interface, review the Installing the Standalone Build and InstallShield on the Same Machine to learn about special registration and uninstallation considerations.

Integrating InstallShield with Visual Studio

Microsoft Visual Studio can be integrated with only one version of InstallShield at a time. The last version of InstallShield that is installed or repaired on a system is the one that is used for Visual Studio integration.

What's New in InstallShield 2010 Expansion Pack for Visual Studio 2010

InstallShield 2010 Expansion Pack for Visual Studio 2010 includes changes that offer support for the final released version of Visual Studio 2010 and .NET Framework 4. It also includes additional changes.

Microsoft .NET Framework 4 Prerequisites

InstallShield includes four new .NET-related InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Microsoft .NET Framework 4.0 Full
- Microsoft .NET Framework 4.0 Full (Web Download)
- Microsoft .NET Framework 4.0 Client
- Microsoft .NET Framework 4.0 Client (Web Download)

Note the following details about these prerequisites:

- The full prerequisites install the .NET Framework runtime and associated files that are required to run and develop applications that target the .NET Framework 4.

- The client prerequisites install the .NET Framework runtime and associated files that are required to run most client applications.
- The two Web download prerequisites require an Internet connection. These prerequisites download the required redistributable files if appropriate. The other two prerequisites are stand-alone installations that do not require an Internet connection.

The .NET Framework 4.0 requires Windows Installer 3.1 or later, as well as the Windows Imaging Component. Therefore, the .NET Framework 4.0 Full prerequisites are configured to have dependencies for the following InstallShield prerequisites:

- Windows Installer 3.1 (x86)
- Windows Imaging Component (x86)
- Windows Installer 3.1 for Windows Server 2003 SP1 (x86)
- Windows Imaging Component (x64)
- Windows Installer 3.1 for Windows Server 2003 SP1 (IA64)
- Windows Installer 3.1 for Windows Server 2003 SP1 (x64)
- Windows Installer 3.1 for Windows XP (x64)

In addition, the .NET Framework 4.0 Client prerequisites are configured to have dependencies for the following InstallShield prerequisites:

- Windows Installer 3.1 (x86)
- Windows Imaging Component (x86)
- Windows Installer 3.1 for Windows Server 2003 SP1 (x86)
- Windows Imaging Component (x64)
- Windows Installer 3.1 for Windows Server 2003 SP1 (x64)
- Windows Installer 3.1 for Windows XP (x64)

Thus, if you add any of the .NET Framework 4.0 prerequisites to your project, InstallShield also adds prerequisites for Windows Installer and Windows Imaging Component to your installation automatically by default. This could increase the size of your installation. In some cases, you may want to edit the .NET Framework 4 prerequisites in the InstallShield Prerequisite Editor (which is available in the Premier and Professional editions of InstallShield) to remove some of the dependencies. For example, if your product requires Windows Vista or later or Windows Server 2008 and later, you may want to remove the Windows Installer 3.1 dependencies that target earlier versions of Windows.

Additional Prerequisites for Visual Studio 2010 Support

InstallShield includes the following new InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Microsoft SQL CE 3.5 SP2
- Microsoft ReportViewer 2010

- Microsoft VSTO 2010 Runtime
- FSharp Redistributable Package 2.0
- Microsoft Office 2007 PIA (This prerequisite installs the Microsoft Office 2007 Primary Interop Assemblies. To use this prerequisite, download the `PrimaryInteropAssembly.exe` file from Microsoft's Web site and run it to extract the `o2007pia.msi` file. Note that you may need to change the path of the `o2007pia.msi` installation in the .prq file, depending on where the .msi package is located on your system.)

Predefined System Searches for .NET Framework 4

InstallShield includes two new predefined system searches:

- Microsoft .NET Framework 4.0 Full package
- Microsoft .NET Framework 4.0 Client package

If your installation requires either of these, you can use the Installation Requirements page in the Project Assistant or the System Search view to add these system searches to your project. When end users launch your installation, Windows Installer checks the target system to see if the requirements are met; if they are not met, the installation displays the error message that is defined for the system search.

This functionality applies to Basic MSI and InstallScript MSI projects.

What's New in InstallShield 2010 SP1

InstallShield 2010 Service Pack 1 (SP1) includes changes that offer support for the final released versions of Windows 7, Windows Server 2008 R2, and Windows Installer 4.5. It also includes additional changes.

Important • *If you want to open an InstallShield 2010 project in InstallShield 2010 SP1, you must allow InstallShield to upgrade your project to InstallShield 2010 SP1. InstallShield 2010 SP1 includes support for tables that were not available in InstallShield 2010 projects, and these tables need to be added during the upgrade. Note that it is not possible to open InstallShield 2010 SP1 projects in earlier versions of InstallShield (including InstallShield 2010 without SP1). Therefore, if multiple users need to open and modify your InstallShield projects, ensure that all of you apply the SP1 patch at the same time.*

If you open an InstallShield 2010 project in InstallShield 2010 SP1, InstallShield 2010 SP1 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project before converting it.

Setup.exe Manifests Now Have Compatibility Section to Avoid Triggering Program Compatibility Assistant on Windows 7 and Windows Server 2008 R2 Systems

If you configure your InstallShield project to create a setup launcher for your installation, the manifest that InstallShield creates for the setup launcher now includes a compatibility section. Previously, without this compatibility section, a Program Compatibility Assistant (PCA) dialog box may have appeared at the end of an installation on Windows 7 and Windows Server 2008 R2 systems. The PCA dialog box indicated that the program

might not have installed correctly. This dialog box was displayed if the installation did not create the application uninstallation key. This may happen if the end user cancels the installation or the installation fails to complete successfully.

Support for Creating App-V Package Upgrades and for Compressing App-V Packages

InstallShield now has support for creating App-V package upgrades. The Package Information page in the Microsoft App-V Assistant has a new Upgrade Settings link. Click this link to specify whether you want to create an upgrade. If you specify that you do want to create an upgrade, you can specify additional information about the upgrade, such as whether to append the version number to the App-V package file name. By default, App-V package upgrades are not created.

The Build Options page in the Microsoft App-V Assistant has a new setting that lets you specify whether you want to use compression for the data files in the App-V package. If you select Yes for this setting, InstallShield uses zlib compression for your App-V package.

The App-V upgrade and compression functionality is available in the following project types: Basic MSI and MSI Database.

The Microsoft App-V Assistant is available if you purchase InstallShield with the Virtualization Pack.

For more information, see:

- Specifying Upgrade Package Information
- Specifying Whether to Compress the Data Files in an App-V Package

Windows Installer 5 Support for Configuring New Customization Options for Windows Services, Plus Other Service-Related Improvements

InstallShield now includes support for configuring extended customization options for Windows services. The customization options include a new delayed auto-start capability to help system startup performance, improved failure detection and recovery options to improve system reliability, and more. Windows Installer 5 supports these new options; earlier versions of Windows Installer ignore them.

To configure the new service-related settings, use the new Services node in the Advanced Settings area for a component in the Setup Design view (in installation projects) or the Components view. All of the services for a component are now grouped and listed by service name under the Services node. In addition, the previously available service-related settings are now consolidated in the same grid with the new settings. In earlier versions of InstallShield, these previously available service-related settings were split among separate subviews for the Install NT Services and Control NT Services nodes. The consolidated grid of settings makes it easier to create a component that installs, configures, starts, stops, or deletes a new or existing service during installation or uninstallation.

This functionality is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

For more information, see:

- Installing, Controlling, and Configuring Windows Services
- Services Settings

Validation for the Windows 7 Logo Program

InstallShield includes two new validation suites: InstallShield Validation Suite for Windows 7 and InstallShield Merge Module Validation Suite for Windows 7. These validation suites can help you verify that your Windows Installer–based installation or merge module meets the installation requirements of the Compatible with Windows 7 logo program. If you want to be able to use the Windows 7 logo artwork, your product's installation must meet the program's requirements.

If you want to configure InstallShield to perform validation with these validation suites each time that a release is successfully built: On the Tools menu, click Options. On the Validation tab, select the appropriate check boxes.

If you want to perform validation separately from the build process: On the Build menu, point to Validation, and then click the appropriate new suite.

Windows Installer 5 Support for Setting Windows Shell Properties for a Shortcut

The Shortcuts view in InstallShield now lets you specify one or more shortcut properties that need to be set by the Windows Shell at run time. For example, if you do not want the Start menu entry for one of your shortcuts to be highlighted as newly installed after end users install your product, you can set a property for that shortcut. You might want to use this property with shortcuts that are for tools and secondary products that are part of your installation.

Windows Installer 5 includes support for setting Shell shortcut properties. Earlier versions of Windows Installer ignore those properties.

For more information, see Setting Shell Properties for a Shortcut.

Windows Installer 5 Support for the MsiPrint and MsiLaunchApp Control Events

When you are adding a control to a dialog in your project, you can select one of the new events that is now available for Windows Installer 5:

- **MsiPrint**—You can add this event to a push button control that is on a dialog that has a scrollable text control. When an end user clicks the push button control, the contents of the scrollable text control are printed.
- **MsiLaunchApp**—You can add this event to a check box control on a dialog, and select the file that you want to be launched in the event's Argument setting. The check box enables end users to choose whether to run the file at the end of the installation. This event is typically used with a check box control that is on the SetupCompleteSuccess dialog. The check box control should include a condition that prevents the control from being displayed during uninstallation.

Windows Installer 5 includes support for these control events. Earlier versions of Windows Installer ignore these events. Therefore, if your installation is run on a system that has Windows Installer 4.5 or earlier and you want to use one or both of these new events, add a condition to the dialog controls so that they are not displayed on systems that have Windows Installer 4.5 or earlier.

This functionality is available in Basic MSI projects.

Note that if you want to add the print or launch support to your project but your installation targets systems that have Windows Installer 4.5 or earlier, consider using the support that InstallShield provides. For information on adding the print support, see Specifying Dialogs for Your Installation in the Project Assistant. For information on adding the print support, see Adding a Print Button to a Dialog. The support that is available with InstallShield does not require Windows Installer 5.

Additional Changes

For a list of issues that are resolved in InstallShield 2010 SP1, see the release notes. The release notes are available from the Help menu in InstallShield.

What's New in InstallShield 2010

New Features

InstallShield includes the following new features.

Support for Creating Customized Virtual Applications

Now you can use InstallShield to create customized virtual applications in the Microsoft App-V format. Virtualization enables you to isolate an application in its own environment so that it does not conflict with existing applications or modify the underlying operating system.

Virtual applications run in virtual environments that keep the application layer and the operating system layer separate. Each application includes its own configuration information in its virtual environment. As a result, many applications can run side-by-side with other applications on the same computer without any conflicts.

To create a virtual application, use the new Microsoft App-V tab that is available in the following project types: Basic MSI and MSI Database.

The virtualization support is available if you purchase InstallShield with the Virtualization Pack.

InstallShield also includes InstallShield prerequisites for the Microsoft App-V 4.5 Desktop Client installation and the Microsoft Application Error Reporting installation. The Application Error Reporting prerequisite is a dependency of the App-V prerequisite. The redistributable files for these InstallShield prerequisites are not available for download from within InstallShield, since you must obtain them from Microsoft. Once you obtain them from Microsoft, place them in the location that is displayed when you are editing these prerequisites in the InstallShield Prerequisite Editor.

For more information, see:

- Creating Customized Virtual Applications
- About Virtualization
- Creating Microsoft App-V Applications

Ability to Target Windows 7 and Windows Server 2008 R2 Systems

InstallShield enables you to specify that your installation requires Windows 7 or Windows Server 2008 R2. It also lets you build feature and component conditions for these operating systems.

Windows 7 and Windows Server 2008 R2 Support for Displaying Installation Progress on the Taskbar

Installations that are run on Windows 7 and Windows Server 2008 R2 now show a progress bar on the Windows taskbar during file transfer. This applies to InstallScript and InstallScript MSI installations. In addition, it applies to Basic MSI installations that display billboards that were configured in the Billboards view. Note that a progress bar is not displayed on the taskbar on earlier versions of Windows. It is also not displayed during setup initialization or while InstallShield prerequisites are being installed.

Beta Windows Installer 5 Support for Per-User Installations

The General Information view has a new Show Per-User Option setting. This setting lets you specify whether you want the ReadyToInstall dialog—in certain scenarios—to include buttons that let end users indicate how they want to install the product: for the current user or for all users. The per-user button sets the new Windows Installer property **MSIINSTALLPERUSER** equal to 1 to indicate that the package should be installed for the current user. The **MSIINSTALLPERUSER** property is available with the beta of Windows Installer 5.

This feature is available in Basic MSI projects.

To learn more, see Per-User vs. Per-Machine Installations.

Beta Windows Installer 5 Support for Reducing the Time for Installing Large Packages

Use the new Fast Install setting in the General Information view to select one or more options that may help reduce the time that is required to install a large Windows Installer package. For example, you can specify that you do not want a system restore point to be saved for your installation. You can also specify that you want the installation to perform file costing, but not any other costing.

This setting configures the new Windows Installer property **MSIFASTINSTALL**, which can be set at the command line. Windows Installer 5 includes support for this property. Earlier versions of Windows Installer ignore it.

This setting is available in the following project types: Basic MSI, InstallScript MSI, MSI Database, and Transform.

To learn more, see the description of the Fast Install setting.

Beta Support for Additional Windows Installer 5 Features

The Director Editor in InstallShield includes beta support for the new Windows Installer 5 tables (**MsiLockPermissionEx**, **MsiServiceConfig**, **MsiServiceConfigFailureActions**, and **MsiShortcutProperty**).

This feature is available in the following project types: Basic MSI and InstallScript MSI.

Ability to Detect the Presence of a Virtual Machine

InstallShield lets you determine whether an installation is running on any of the following types of virtual machines:

- Microsoft Hyper-V
- A VMware product such as VMware Player, VMware Workstation, or VMware Server
- Microsoft Virtual PC

Two new Windows Installer properties are available when you add an MSI DLL custom action to your project to detect virtual machines: **IS_VM_DETECTED** and **IS_VM_TYPE**. The custom action should be configured to call the ISDetectVM function in the SetAllUsers.dll file, which is installed with InstallShield.

In addition, the InstallScript language has been expanded to support the detection. The structure SYSINFO contains a new bIsVirtualMachine member, and a new VIRTUAL_MACHINE_TYPE constant is available for use with the InstallScript function **GetSystemInfo**.

This feature is available in the following project types: Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, and Merge Module.

For more information, see Detecting Whether the Installation Is Being Run on a Virtual Machine.

Support for 64-Bit COM Extraction

InstallShield now supports 64-bit COM extraction. If you are using InstallShield on a 64-bit operating system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit.

InstallShield must be installed on a 64-bit operating system in order to perform 64-bit COM extraction.

This feature is available in the following project types: Basic MSI, InstallScript MSI, and Merge Module.

To learn more, see:

- Targeting 64-Bit Operating Systems
- Extracting COM Information from a COM Server

New Support for Setting Permissions for Files, Folders, and Registry Keys

InstallShield offers two new ways to secure files, folders, and registry keys for end users who run your product in a locked-down environment:

- **Custom InstallShield handling**—In Windows Installer–based projects, you can choose to use custom support for setting permissions at run time. With this option, InstallShield stores permission information for your product in the custom **ISLockPermissions** table of the .msi database. InstallShield also adds custom actions to your project to set the permissions. This support is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.
- **SetObjectPermissions, an InstallScript Function**—You can use the new **SetObjectPermissions** function in InstallScript events and InstallScript custom actions to set permissions at run time. You can use this function in the following project types: InstallScript, Basic MSI, InstallScript MSI, and Merge Module.

With the custom InstallShield handling option, the file, folder, or registry key for which you are setting permissions must be installed as part of your installation. With the **SetObjectPermissions** function, the file, folder, or registry key can be installed as part of your installation, or it can be already present on the target system.

Previously, the only option that InstallShield offered for setting permissions was to use the traditional Windows Installer handling. With this option, the permission information is stored in the **LockPermissions** table of the .msi database. The new custom InstallShield handling option and the **SetObjectPermissions** function offer several advantages over the traditional Windows Installer handling:

- The custom option and the **SetObjectPermissions** function include support for many well-known security identifiers (SIDs) that are not supported by the traditional Windows Installer handling option.

- The custom option and the **SetObjectPermissions** function support the use of localized user names for the supported SIDs, unlike the traditional option. With the traditional option, if you try to use a localized name to set permissions on a non-English system, the installation may fail.
- The custom option and the **SetObjectPermissions** function let you specify that you want to deny a user or group from having the permissions that you are specifying. The traditional handling does not allow you to do this.
- The custom option and the **SetObjectPermissions** function let you add permissions to a file, folder, or registry key that already exists on the target system, without deleting any existing permissions for that object. With the traditional handling, the existing permissions are deleted.
- The custom option and the **SetObjectPermissions** function let you configure permissions for a folder (or a registry key), and indicate whether you want the permissions to be applied to all of the folder's subfolders and files (or the registry key's subkeys). With the traditional handling, if you want to configure permissions for a subfolder or a file in a folder (or a subkey under a registry key), the parent that is created on the target system automatically inherits the permissions of its child.
- The custom option and the **SetObjectPermissions** function let you configure permissions for a new user that is being created during the installation. The traditional handling does not allow you to do this; the user must already exist on the target system at run time.

The General Information view has a new Locked-Down Permissions setting that lets you specify whether you want to use the new custom InstallShield handling or the traditional Windows Installer handling for all new permissions that you set for files, folders, and registry keys in your project. If you have already configured some permissions in your project and then you change the value of this setting, InstallShield lets you specify whether you want to use the alternate handling method for those already-existing permissions. In all new projects, the default value for this setting is the custom InstallShield handling option. If you upgrade a project from InstallShield 2009 or earlier to InstallShield 2010, the traditional Windows Installer handling option is the default value of this setting. This new setting is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

For more information, see the following:

- Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment
- Selecting the Locked-Down Permissions Type for a Project
- SetObjectPermissions
- SetObjectPermissions Example

Support for InstallShield Prerequisites in InstallScript Projects

InstallShield now enables you to add InstallShield prerequisites to InstallScript projects. Previously, only Basic MSI and InstallScript MSI projects included support for this type of redistributable.

InstallShield prerequisites are redistributables that usually install a product or technology framework that is required by your product. Now you can add any of the InstallShield prerequisites that are provided with InstallShield—or any of your own custom-designed InstallShield prerequisites—to InstallScript projects. If you work on a mix of different project types, InstallShield lets you simplify your testing matrix by enabling you to reuse this type of redistributable in all of your Basic MSI, InstallScript, and InstallScript MSI projects.

To add an InstallShield prerequisite to an InstallScript project, use the new Prerequisites view. InstallScript projects include support for the setup prerequisite type of InstallShield prerequisite, which is run before the main installation's user interface is run. InstallScript projects do not have support for feature prerequisites, which are InstallShield prerequisites that are associated with features.

For more information, see:

- Adding InstallShield Prerequisites, Merge Modules, and Objects to InstallScript Projects
- Run-Time Behavior for an Installation that Includes InstallShield Prerequisites
- Specifying the Installation Order of InstallShield Prerequisites
- Specifying a Run-Time Location for a Specific InstallShield Prerequisite
- Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level
- Designing InstallShield Prerequisites and Other Redistributables
- Prerequisites View

New InstallShield Prerequisites for Windows Installer, .NET Framework, Crystal Reports, and Other Redistributables

InstallShield includes a number of new InstallShield prerequisites that you can add to Basic MSI, InstallScript, and InstallScript MSI projects:

- Windows Installer 4.5 (The InstallShield prerequisites for Windows Installer 4.5 include the fix that is described in Microsoft KB958655.)
- Windows Installer 4.5 Update (The InstallShield prerequisites for the Windows Installer 4.5 Update include the fix that is described in Microsoft KB958655. Windows Installer 4.5 must already be installed on the target system for this update.)
- Windows Installer 3.1, Windows Installer 3.0, and Windows Installer 2.0 (These versions of Windows Installer redistributables were previously available if you added Windows Installer to your project in the Releases view. These versions were not previously available as InstallShield prerequisites.)
- .NET Framework 3.0 SP1
- .NET Framework 2.0 SP2
- Internet Explorer 8
- Microsoft SQL Server 2008 Express SP1
- Microsoft SQL Server 2005 Express SP3
- Microsoft Visual C++ 2005 SP1 Redistributable Package
- Oracle 11g Instant Client 11.1.0.7 (Oracle does not provide an installer for the Oracle Instant Client files, so you need to create an .msi package before you can use this InstallShield prerequisite in your projects. You can do so easily by using the Oracle Instant Client installation project that is installed with InstallShield (*InstallShield Program Files Folder*\Support\Oracle Instant Client.)

- Crystal Reports Basic for Visual Studio 2008 (Use this prerequisite with the Crystal Reports Basic installation that is installed with Visual Studio 2008. Note that you may need to change the path of the Crystal Reports Basic installation in the .prq file, depending on where the .msi package is located on your system.)

Microsoft SQL Server 2008 SP1 Support

InstallShield now includes support for running SQL script on SQL Server 2008 SP1. In addition, InstallShield includes SQL Server 2008 SP1 in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports.

Oracle 11g Support

InstallShield now includes support for running SQL script on Oracle 11g. In addition, InstallShield includes Oracle 11g in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports.

New Tool for Scanning an IIS Web Site, Recording Its Settings, and Importing Those Settings into an InstallShield Project

InstallShield includes an IIS scanner (`IISscan.exe`), a new command-line tool for scanning an existing IIS Web site and recording IIS data about the Web site. The IIS scanner creates an XML file that contains all of the settings for the Web site, its virtual directories, its applications, and its application pools. You can use the XML file to import the IIS data into the Internet Information Services view in InstallShield. Once you have imported the IIS data into a project, you can use the Internet Information Services view to make changes to the IIS settings as needed.

The ability to import the IIS data into an InstallShield project is available only in the Premier edition of InstallShield.

For more information, see:

- Scanning an IIS Web Site and Importing Its Settings into an InstallShield Project
- Filtering IIS Data When Importing a Web Site and Its Settings into an InstallShield Project
- IISscan.exe

Ability to Add IIS Web Applications to Web Sites, Plus Other IIS-Related Improvements

InstallShield now lets you add IIS Web applications to Web sites. You can do so by right-clicking a Web site in the Internet Information Services view and clicking New Application. Once you have added a new application, you can configure its settings in the right pane.

InstallShield also lets you create a virtual directory without an application. Previously whenever you created a virtual directory, an application was also created automatically.

In addition, InstallShield has new IIS settings:

- **Managed Pipeline Mode**—This setting enables you to specify the appropriate request-processing pipeline mode—either integrated or classic—for an application pool.
- **Enable 32-Bit Applications**—This setting lets you specify whether you want to allow 32-bit applications in the selected application pool to be run on 64-bit systems.
- **.NET Framework Version**—This setting is where you specify the version of the .NET Framework that an application pool should load.

- **ASP.NET Platform**—If your installation may be run on a 64-bit version of Windows with the .NET Framework, use this setting to specify which ASP.NET platform should be used to map a Web site, application, or virtual directory to the ASP.NET version.

This feature is available in the following project types: Basic MSI, InstallScript, and InstallScript MSI.

To learn more, see:

- Creating a Web Site and Adding an Application or a Virtual Directory
- Internet Information Services View

New View for Configuring Run-Time Text File Changes

InstallShield has a new Text File Changes view, which enables you to configure search-and-replace behavior for content in text files—for example, .txt, .htm, .xml, .config, .ini, and .sql files—that you want to modify at run time on the target system. The text files can be part of your installation, or they can be files that are already present on target systems.

You can use Windows Installer properties to specify the names of the text files that you want to include in or exclude from your search. You can also use properties to specify the search strings and the replacement strings. This enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's text files are modified on the target system. For example, if your project includes a dialog in which end users must specify an IP address, your installation can search a set of files for a token, and replace it with the IP address that end users enter.

Note that the Text File Changes view offers an alternative for configuring XML file changes in the XML File Changes view. Using the Text File Changes view offers some advantages. For example, this new view does not have any run-time requirements; however, changes that are configured through the XML File Changes view require MSXML to be present on the target system. In addition, configuring changes in the Text File Changes view does not require you to enter XPath queries, as is required in the XML File Changes view.

The Text File Changes view is available in the following project types: Basic MSI and InstallScript MSI.

For more information, see:

- Modifying Text Files
- Creating a Text File Reference
- Specifying Search-and-Replace Criteria for a Text File Change
- Changing the Order in Which Text File Changes Are Made
- Using Windows Installer Properties to Dynamically Modify Text Files
- Specifying the Code Page that Should Be Used for Opening ANSI Text Files

New String Editor View

InstallShield has a new String Editor view. This view contains a spreadsheetlike table that shows the collection of language-independent identifiers and corresponding language-specific values for your project. In the String Editor view, you have complete and centralized control over the localizable text strings that are displayed at run time during the installation process. The view replaces the string tables that were previously available as nodes within the General Information view. Following is a list of some of the highlights of the new view:

- The view has a toolbar with buttons that let you add, edit, delete, find, replace, export, and import string entries. It also has a button that lets you search the project to identify all of the instances in which a specific string identifier is used.
- The top of the view has a new group box area; you can drag and drop column headings onto this area to organize the rows in the view in a hierarchical format. This functionality makes it easy to sort string entries by categories such as language and by modified date.
- This view has support for dynamic searches—as you are typing a string in the search box, InstallShield hides all of the string entries that do not contain it.

This feature is available in the following project types: Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module.

For more information, see:

- String Editor View
- Localizing the End-User Interface

Support for Unicode

InstallShield takes a three-pronged approach to fully supporting modern multilanguage installations: Windows Installer databases can now be built in a Unicode format, InstallShield projects are now stored in a Unicode format, and the InstallShield interface now supports entering and viewing Unicode characters from multiple character sets at the same time.

Unicode (UTF-8) Databases

The Build tab in the Releases view has a new Build UTF-8 Database setting that lets you specify that a Windows Installer database, along with any instance or language transforms, be built using the UTF-8 encoding. The UTF-8 encoding supports characters from all languages simultaneously, enabling you to mix and match, for example, Japanese and German, or Russian and Polish, both in text shown to end users and in file names and registry keys. These mixed languages work correctly regardless of the current language of the target system. Unicode support has also been added to key parts of the installation run times, including IIS support and changes to text and XML files.

The default value for the new Build UTF-8 Database setting is No.

The automation interface now includes support for this new setting. The ISWiRelease object includes a new BuildUTF8Database property that lets you specify whether you want to use the UTF-8 encoding.

This feature is available in the following project types: Basic MSI, InstallScript MSI, and Merge Module projects.

To learn more, see the description of the Build UTF-8 Database setting.

Unicode Project Files (.ism)*

InstallShield now uses the UTF-8 encoding when saving both binary and XML project files. Because of this change, the files, registry data, and other strings that are used in the project can include characters from all languages simultaneously. With this encoding, InstallShield no longer needs to use an unreadable Base64 encoding for strings that are stored in the **ISString** table. Instead, as you add or modify strings in a project, InstallShield now saves them as human-readable Unicode strings that you can easily examine for changes across revisions of your

project. Therefore, InstallShield uses only Unicode strings for all new projects that are created in InstallShield 2010; for upgraded projects, InstallShield uses Unicode for new and modified strings, as well as for strings that have been exported and reimported.

If you use Unicode values that cannot be represented in the target build (for example, an InstallScript installation, or a Basic MSI installation in which No is selected for the Build UTF-8 Database setting), a new build error points to the item that needs to be changed. In some instances, this reveals invalid string entries that were silently allowed in earlier versions of InstallShield.

This feature applies to all project types.

Unicode Views in InstallShield

Many views in InstallShield have been enhanced to display and allow you to enter characters from all languages. For example, in the Files and Folders view, Chinese file names from your local English system are no longer displayed with question marks for their names, and now you can add these files to your project. Similarly, the Registry view no longer converts Thai registry keys or values to question marks, and you can install them with your Windows Installer–based projects. In addition, you can view and edit strings from all languages in the String Editor view, a new separate view; previously, string entries were available from separate language nodes in the General Information view. Examples of other enhanced views include the Property Manager, Path Variables, Direct Editor, General Information, and Setup Design views.

Note that whenever No is selected for the Build UTF-8 Database setting, all file names, registry keys, and other strings must still consist of characters from the code page of all target languages that will use it. In this scenario, if an item uses a character that is not available on the code page of a target language, InstallShield reports a new build error that points to this item; the Chinese file name cannot be used in an English installation unless Yes is selected for the Build UTF-8 Database setting.

This feature applies to all project types.

New Billboard Support in Basic MSI Projects

Basic MSI projects now include support for billboards. You can add billboards to your projects to display information to end users during the installation process. The billboards can be used to communicate, advertise, educate, and entertain end users. For example, billboards can present overviews on new features of the product being installed or other products from your company. Each billboard is a file that you or your company's graphics department creates for complete control over the look and feel of the file transfer.

Following are some of the highlights regarding billboard support in Basic MSI projects:

- You can add an Adobe Flash application file (.swf) as a billboard in your project. Flash application files can consist of videos, movies, sounds, interactive interfaces, games, text, and more—anything that is supported by the .swf type of file.
- InstallShield lets you use .bmp, .gif, .jpg, and .jpeg files as billboards.
- InstallShield includes a Billboard Type setting that lets you specify which style of billboard you want to use in your installation. For example, with one style, the installation displays a full-screen background, with billboards in the foreground, and a small progress box in the lower-right corner of the screen. With another style, the installation displays a standard-size dialog that shows the billboards. The bottom of this dialog shows the progress bar.

- InstallShield lets you preview a billboard to see how it would be displayed at run time, without requiring you to build and run a release. Previewing a billboard lets you see how your billboard will look with the background color, position, and related settings that are currently configured for your billboard.

The Billboards view in InstallShield is where you add billboard files, configure billboard-related settings, and preview billboards.

To learn more, see:

- Displaying Billboards in Basic MSI Installations
- Billboard File Types for Basic MSI Projects
- Types of Billboards for Basic MSI Projects
- Adding an Adobe Flash Application File Billboard to a Basic MSI Project
- Adding Image Billboards to a Basic MSI Project
- Configuring Billboard Settings in a Basic MSI Project
- Previewing Billboards Without Building and Launching a Release
- Setting the Billboard Order in a Basic MSI Project
- Run-Time Behavior of a Basic MSI Installation that Includes Billboards

Previously, only InstallScript and InstallScript MSI projects included support for billboards. Note that billboard support in these project types is different than support in Basic MSI projects. For more information, see Displaying Billboards.

Expanded Billboard Support in InstallScript and InstallScript MSI Projects

InstallScript and InstallScript MSI projects now let you use .gif, .jpg, and .jpeg files as billboards. Previously, only .bmp files were supported. Use the Support Files/Billboards view to add billboards to your project.

Billboard files in InstallScript and InstallScript MSI projects must follow a designated naming convention. Each file name must begin with **bbrd**, followed by the number of the billboard (from 1 through 99); each must end with a supported file extension (.bmp, .gif, .jpg, or .jpeg). Note that it is no longer necessary for the file name numbers to be contiguous; that is, you can add `bbrd1.jpg`, `bbrd3.jpg`, and `bbrd5.jpg` to your project, and each image is displayed at run time in order. Previously, there could not be any numbers missing from the file name sequence for your billboards. For example, if you added `bbrd1.bmp`, `bbrd2.bmp`, and `bbrd4.bmp` to your installation project, then `bbrd1.bmp` and `bbrd2.bmp` were displayed at run time; however, `bbrd4.bmp` was not displayed, since `bbrd3.bmp` was missing from the sequence.

For more information, see:

- Displaying Billboards in InstallScript and InstallScript MSI Installations
- Naming Billboard Files in an InstallScript or InstallScript MSI Project
- Adding an Image Billboard to an InstallScript or InstallScript MSI Project

Ability to Play an Adobe Flash Application File (.swf) with the InstallScript Function PlayMMedia

The InstallScript function **PlayMMedia** now includes support for playing an Adobe Flash application file (.swf) on a background window during InstallScript and InstallScript MSI installations. Flash application files can consist of videos, movies, sounds, interactive interfaces, games, text, and more—anything that is supported by the .swf type of file.

If you are using a Flash file, you can use **SizeWindow** and **PlaceWindow** to control the size and placement of the background window that displays the Flash file.

For more information, see:

- PlayMMedia
- SizeWindow
- PlaceWindow
- Displaying a Background Window in InstallScript and InstallScript MSI Installations

Support for HTML Controls on Dialogs During InstallScript and InstallScript MSI Installations

InstallShield includes support for HTML controls on dialogs in InstallScript and InstallScript MSI projects. HTML controls enable you to use HTML markup for dialog controls. You can include on dialogs links to Web pages, installed HTML files, and HTML support files. If an end user clicks the hyperlink on the run-time dialog, you can have the HTML page open in an Internet browser, or you can trigger other behavior that you have defined through your InstallScript code. The HTML control lets you use any valid HTML markup, including styles to control their appearance.

The HTML control also lets you display the HTML content directly on a dialog if the content is an installed HTML file or HTML support file.

A new InstallScript function called **CtrlGetUrlForLinkClicked** is available. This function retrieves the URL for a link that an end user clicked.

For more information, see:

- Using an HTML Control on a Dialog
- CtrlGetUrlForLinkClicked
- CtrlGetUrlForLinkClicked Example

Ability to Add Unsupported Languages to InstallScript Projects

The InstallShield Premier edition includes default run-time strings for InstallScript projects in 33 different languages. The InstallShield Premier edition also lets you use the New Language Wizard to add unsupported languages, beyond the built-in 33 languages, to InstallScript projects. Once you have added unsupported languages to an InstallScript project, you can use the String Editor view to provide translated strings for the unsupported languages. As an alternative, you can export a language's string entries to a file, translate the string values in the file, and then import the translated file into your project. Previously, the New Language Wizard enabled you to add unsupported languages to only Basic MSI and InstallScript MSI projects.

For more information, see:

- Run-Time Language Support in InstallShield
- New Language Wizard
- String Editor View

Ability to Specify Paths for Libraries to Which the InstallScript Compiler Should Link

The Compile/Link tab on the Settings dialog box has a new Additional Library Paths box that lets you specify the locations where the InstallScript compiler should search for InstallScript libraries (.obl files) that should be linked to your script. In addition, when you specify your custom libraries on this tab, you can now specify just the file name, without the full path. These changes enable you to move your libraries to different directories but still successfully compile your script without manually changing the path for libraries on the Compile/Link tab.

For more information, see Compile/Link Tab.

New FlexNet Connect 11.6 Redistributables Available

InstallShield includes support for FlexNet Connect 11.6 in Basic MSI and InstallScript MSI projects. Use the Update Notifications view in InstallShield to include one of the two FlexNet Connect 11.6 merge modules—one has the Common Software Manager, and the other does not. These merge modules replace the FlexNet Connect 11 merge modules.

DIFx 2.1.1 Support

InstallShield includes support for the latest version of Driver Install Frameworks for Applications (DIFx 2.1.1). This new version, which includes the latest binary files from Microsoft, is available for the following project types: Basic MSI, InstallScript, and InstallScript MSI.

Enhancements

InstallShield includes the following enhancements.

Usability Enhancements

Many of the views in InstallShield have been enhanced to improve productivity and usability. For example, several views contain new toolbars that make options easier to find. Some of the views that contain grids let you customize how the rows in a grid are organized. Searches are performed more quickly in the views that offer search capabilities. Following are examples of some of the highlights:

- Direct Editor view—When you select a table in this view, a new toolbar is displayed. The toolbar has buttons that let you add, cut, copy, paste, find, and replace data in the table. This view also has support for dynamic searches—as you are typing a string in the search box, InstallShield hides all of the table records that do not contain it. When you are adding or editing a record, InstallShield displays help text for each field.
- Property Manager view—This view contains a new toolbar that has buttons for performing tasks such as adding and deleting properties. This view also has support for dynamic searches—as you are typing a string in the search box, InstallShield hides all of the table records that do not contain it. The top of the view has a new group box area; you can drag and drop column headings onto this area to organize the rows in the view in a hierarchical format. You can now select multiple properties in this view (by using the mouse and the SHIFT or CTRL button) and then delete them all at once.

- Redistributables view—The new toolbar and the new group box area in this view provide robust search and organizational functionality. You can drag and drop column headings onto the group box area to organize the list of redistributables in a hierarchical format. In addition, you can type a string in the toolbar's search box, and InstallShield hides all of the redistributables that do not contain it.
- Internet Information Services view—This view has been redesigned to look similar to IIS 7: the settings are now displayed in grids, instead of on tabs. The grids have buttons that let you sort the grid settings by category or alphabetically. When you select a setting in one of the grids in this view, InstallShield displays help information for that setting in the lower-right pane.
- General Information view—All of the settings in this view are displayed in one grid, instead of as separate grids that are associated with nodes within this view. The settings are grouped into several categories to make it easy to find a particular setting. In addition, the grid has a button that lets you sort the grid settings by category or alphabetically. The string tables that were previously in this view have been moved to a new String Editor view.
- Path Variables view—This view contains a new toolbar that has buttons for performing tasks such as adding and deleting path variables. This view also has support for dynamic searches—as you are typing a string in the search box, InstallShield hides all of the rows that do not contain it. The top of the view has a new group box area; you can drag and drop column headings onto this area to organize the rows in the view in a hierarchical format. You can now select multiple path variables in this view (by using the mouse and the SHIFT or CTRL button) and then delete them all at once.

In addition, the Output window, which is displayed when you are building a release, performing validation, or compiling script, has been enhanced. The Output window or its individual tabs can be docked to any side of the workspace in InstallShield, or they can be dragged to free-floating positions. If you drag the Output window or one of its tabs to the edge of the InstallShield interface, it becomes a docked window. If you drag the Output window or one of its tabs away from any of the edges of the InstallShield interface, it becomes undocked.

For more information, see the following:

- Working with the Group Box Area in Various Views
- Docking or Undocking the Output Window

Support for Specifying Action Progress Messages

To keep end users informed, installations commonly display text on the progress dialog to describe the installation's current activity. This usually accompanies the progress bar as a means of installation status. As each standard action and custom action is encountered, a message about the action is displayed on the progress dialog. This may be especially useful for actions that take a long time to execute. The same action text is also written to the installation's log file if one is created.

The Custom Actions and Sequences view has a new Action Text area that lets you specify action descriptions and details. This is available in the following project types: Basic MSI, InstallScript MSI, MSI Database, and Transform.

For more information, see:

- Using Action Text
- Specifying an Action Description and a Template for Action Data
- Displaying Action Descriptions on the Progress Dialog

- Displaying Action Data on the Progress Dialog

Ability to Detect Whether a 64-Bit System Allows 32-Bit IIS Applications to Be Run

At run time, you may need to have your installation check the Enable32bitAppOnWin64 property on systems that have IIS 6. Depending on the requirements for your product and the results of that check, you may want the installation to skip a particular component that contains a 32-bit IIS 6 application, or a 64-bit IIS application, for example, and proceed with the rest of the file transfer.

InstallShield includes a sample Windows Installer DLL file that detects how the Enable32bitAppOnWin64 property is set on a target system. You can add a custom action for this DLL to your project. If 32-bit applications are allowed, the Windows Installer property **ISIIS6APPPOOLSUPPORTS32BIT** is set to a value of 1; if they are not allowed, this property is not set. You can use this property in conditions to prevent or trigger certain behavior. For example, you can create a launch condition if you want the installation to exit if the **ISIIS6APPPOOLSUPPORTS32BIT** is set or not set.

This feature is available in the following project types: Basic MSI and InstallScript MSI.

For instructions on how to add the custom action to your project, see Considerations for Supporting IIS 6 on 64-Bit Platforms.

Ability to Detect Whether the IIS 6 Metabase Compatibility Feature Is Installed

At run time, you can have your installation detect if the IIS Metabase and IIS 6 Configuration Compatibility feature is installed on a target system, or if IIS 6 or earlier is installed. Depending on the requirements for your product and the results of that detection, you may want the installation to exit and display an error message.

For example, Web service extensions can be installed on systems that have IIS 6. On systems that have IIS 7, Web service extensions can be installed only if the IIS Metabase and IIS 6 Configuration Compatibility feature is installed. Thus, you might want to configure your installation to verify that IIS 6 is present or the IIS 6 compatibility feature is installed; if either of those conditions are false, the installation would exit and display an error message.

InstallShield includes a sample Windows Installer DLL file that detects whether the IIS Metabase and IIS 6 Configuration Compatibility feature is installed. You can add a custom action for this DLL to your project. If the IIS Metabase and IIS 6 Configuration Compatibility feature is installed, the Windows Installer property **ISIISMETABASECOMPATPRESENT** is set to a value of 1; if it is not installed, this property is not set. You can use this property in conditions to prevent or trigger certain behavior. For example, you can create a launch condition if you want the installation to exit if the **ISIISMETABASECOMPATPRESENT** is set or not set.

This feature is available in the following project types: Basic MSI and InstallScript MSI.

For instructions on how to add the custom action to your project, see Determining If a Target System Has IIS 6 or Earlier or the IIS 6 Metabase Compatibility Feature.

Ability to Associate a Namespace Prefix with an Attribute of an XML File's Element

InstallShield now lets you add a namespace prefix to an attribute in the XML File Changes view. To do so, you can type the prefix, followed by a colon (:), in front of the attribute name. Previously, if an attribute contained a namespace prefix, the installation failed.

This enhancement applies to the following project types: Basic MSI, InstallScript, and InstallScript MSI.

For more information, see Adding a Namespace Prefix to an Attribute.

Ability to Specify Whether an XML File Should Be Formatted After Run-Time Changes

The Advanced tab for an XML file in the XML File Changes view has a new **Format XML after changes** check box that lets you specify whether you want the XML file to be formatted after the run-time changes are made to the file. When formatting the file, the installation adds indentations to the file and replaces empty-element tags with start tags and end tags. This may cause problems for `web.config` files, so you may want to clear this check box for your project.

This enhancement applies to the following project types: Basic MSI, InstallScript, and InstallScript MSI.

For more information, see Advanced Tab for an XML File.

Predefined System Searches for the .NET Framework and Internet Explorer 8

InstallShield has two new predefined system searches:

- Microsoft .NET Framework 3.5 SP1
- Internet Explorer 8

If your installation requires any of these, you can use the System Search view or the Installation Requirements page in the Project Assistant to add these system searches to your project. When end users launch your installation, Windows Installer checks the target system to see if the requirements are met; if they are not met, the installation displays the error message that is defined for the system search.

This enhancement applies to Basic MSI and InstallScript MSI projects.

Custom Properties Are Now Listed in Condition Builder

The Properties list on the Condition Builder dialog box now includes properties that are added in the Property Manager view. It also includes properties from searches that are created through the System Search Wizard. Therefore, when you are creating or editing a condition in InstallShield, you can now select your own custom properties without having to manually type them.

This enhancement applies to the following project types: Basic MSI, InstallScript MSI, Merge Module, and Transform.

Ability to Specify a Maximum Service Pack Number and 64-Bit Locations for InstallShield Prerequisite Conditions

The Prerequisite Condition dialog box, which is displayed when you are adding or modifying a condition for an InstallShield prerequisite in the InstallShield Prerequisite Editor, has a new field that lets you specify the maximum service pack number. Previously, it was possible to specify a minimum service pack number, but not a maximum service pack number.

In addition, the Prerequisite Condition dialog box now includes the following 64-bit locations in the box that is displayed when you are specifying file-related conditions: [CommonFiles64Folder], [ProgramFiles64Folder], and [System64Folder]. You can select any of these properties if you want to use 64-bit locations in the file path. At run time, the installation checks these 64-bit locations if the target system is 64 bit. For 32-bit systems, the installation checks the 32-bit location equivalents.

For more information, see Prerequisite Condition Dialog Box.

Enhancements to MSBuild Support

The InstallShield task for MSBuild includes several new parameters:

- **RunMsiValidator**—Use this parameter to specify the .cub file that you want to use for validation. This parameter is exposed as the ItemGroup InstallShieldMsiValidators when the default targets file is used.
- **PatchConfiguration**—Use this parameter to specify the patch configuration that you want to build through MSBuild. This parameter is exposed as the property InstallShieldPatchConfiguration when the default targets file is used.
- **PathVariables**—Use this parameter to override the value of a path variable. This parameter is exposed as the ItemGroup InstallShieldPathVariableOverrides when the default targets file is used.
- **PreprocessorDefines**—Use this parameter to specify preprocessor definitions for compiling InstallScript. This parameter is exposed as the ItemGroup InstallShieldPreprocessorDefines when the default targets file is used.

For more information, see Microsoft Build Engine (MSBuild).

Automation Interface Enhancements

OSFilter Property Values for Windows 7, Windows Server 2008 R2, Windows Vista, Windows Server 2008, and Windows Server 2003

The following constants are now available for use with the OSFilter member of the ISWiComponent and ISWiRelease objects in the automation interface:

- eosWin7 (33554432)—This is for Windows 7 and Windows Server 2008 R2.
- eosWinVista (16777216)—This is for Windows Vista and Windows Server 2008.
- eosWinServer2003 (8388608)

In addition, the value for the eosAll constant is now 64028880; previously, it was 5308624.

The OSFilter member applies to the ISWiComponent object in InstallScript, InstallScript MSI, and InstallScript Object projects. The OSFilter member applies to the ISWiRelease object in InstallScript and InstallScript Object projects.

For more information, see the following:

- ISWiComponent Object
- ISWiRelease Object

New IsPlatformSelected Property Values

The list of available property values for the IsPlatformSelected property of the ISWiComponent object has been expanded. This property now has values for 32-bit, 64-bit Itanium, AMD64, and Windows Server 2003 R2. This applies to the following project types: InstallScript and InstallScript Object.

Note that some of the values for the existing constants have changed. To learn the new values, see ISWiComponent Object.

New AddSQLScriptEx Method for Adding a SQL Script to a Connection

The AddSQLScriptEx method has been added to the ISWiSQLConnection object. Use this method to add an ISSQLScriptFile entry and generate a valid name from the passed string. The method ensures that the names of the entries in the ISSQLScriptFile table are unique and less than 47 characters in length.

New RunOnLogon and Condition Properties for the ISWiSQLScript Object

The read-write RunOnLogon property has been added to the ISWiSQLScript object. This property corresponds with the Run Script During Login check box on the Runtime tab for a SQL script in the SQL Scripts view.

The read-write Condition property has also been added to the ISWiSQLScript object. This property specifies the condition that is evaluated at run time to determine whether the SQL script should be run during installation or uninstallation. If the condition evaluates to true, the script is run. This property is available for the following project types: Basic MSI and InstallScript MSI.

New DisplayName Property for the ISWiUpgradeTableEntry Object

The read-write DisplayName property has been added to the ISWiUpgradeTableEntry object. This property gets or sets the name of an upgrade entry. This is the internal name that is displayed for an upgrade item in the Upgrades view. This property is available for the following project types: Basic MSI and InstallScript MSI.

Enhancements to the InstallScript Language for Operating Systems

The following structure members and predefined constants were added to the InstallScript language:

- **SYSINFO.WINNT.bWin7_Server2008R2**—This is a new SYSINFO structure member. If the operating system is Windows 7 or Windows Server 2008 R2, this value is TRUE.
- **SYSINFO.bWinServer2003R2**—This is a new SYSINFO structure member. If the operating system is Windows Server 2003 R2, this value is TRUE. (Note that the value of SYSINFO.WINNT.bWinServer2003 is also TRUE on this operating system.)
- **ISOSL_WIN7_SERVER2008R2**—This is a new predefined constant that is available for use with the **FeatureFilterOS** function and the SYSINFO structure variable. It indicates that the target system is running Windows 7 or Windows Server 2008 R2.
- **ISOS_ST_SERVER2003_R2**—This is a new operating system suite that is available for use with the **FeatureFilterOS** function and the SYSINFO structure variable. It indicates that the target system is running Windows Server 2003 R2.

In addition, some items were renamed:

- The SYSINFO.WINNT.bWinVista structure member does not distinguish between Windows Vista or Windows Server 2008. Therefore, the new member SYSINFO.WINNT.bWinVista_Server2008 is now available. The old alias is still available, but the new one may be preferred for clarity in code.
- The ISOSL_WINVISTA predefined constant does not distinguish between Windows Vista or Windows Server 2008. Therefore, the new constant ISOSL_WINVISTA_SERVER2008 is now available. The old alias is still available, but the new one may be preferred for clarity in code.

For more information, see FeatureFilterOS function and the SYSINFO structure variable.

Ability to Easily Override InstallScript Dialog Source Code in the InstallScript View

The event category drop-down list in the InstallScript view has a new Dialog Source option. If you select this option, the event handler drop-down list shows all of the built-in InstallScript dialogs. You can select any dialog in this list to modify its code.

This functionality applies to the following project types: InstallScript, InstallScript MSI, and InstallScript Object.

For information about built-in InstallScript dialog functions that are available when you select the Dialog Source option, see Dialog Functions.

Changes to the Major and Minor Version Registry Entries for the Uninstall Key of InstallScript Installations

InstallScript installations now create VersionMajor and VersionMinor registry values in the Uninstall key; the names of these values now match the entries that are created during Basic MSI and InstallScript MSI installations. This applies to new installations that are created in InstallShield 2010, as well as installations that are upgraded from InstallShield 2009 or earlier. Previously, in InstallShield 2009 and earlier, the names of the values that InstallScript installations created were MajorVersion and MinorVersion; these are no longer created.

In order to use the new registry values, the values of the following InstallScript constants have been changed:

- REGDB_VALUENAME_UNINSTALL_MAJORVERSION is now VersionMajor instead of MajorVersion.
- REGDB_VALUENAME_UNINSTALL_MINORVERSION is now VersionMinor instead of MinorVersion.

When the **MaintenanceStart** function is called, it creates the updated value names in the registry. By default, it also deletes the old value names if they exist. If you do not want the old value names to be deleted from target systems, you can use the new REGDB_OPTIONS option called REGDB_OPTION_NO_DELETE_OLD_MAJMIN_VERSION.

If REGDB_UNINSTALL_MAJOR_VERSION or REGDB_UNINSTALL_MINOR_VERSION is used with the **RegDBGetItem** function, **RegDBGetItem** first checks for the new value; if the new value is found, the function returns the value data from the new value. If the new value is not found, the function automatically checks for the old value; if the old value is found, the function returns the value data from the old value.

To provide backwards compatibility, the following new constants are available:

- REGDB_UNINSTALL_MAJOR_VERSION_OLD
- REGDB_UNINSTALL_MINOR_VERSION_OLD

You can specify these constants with the **RegDBGetItem**, **RegDBSetItem**, and **RegDBDeleteItem** functions to get, set, and delete the old values.

The following new string constants are also available:

- REGDB_VALUENAME_UNINSTALL_MAJORVERSION_OLD is defined as MajorVersion.
- REGDB_VALUENAME_UNINSTALL_MINORVERSION_OLD is defined as MinorVersion.

For more information, see the following:

- REGDB_VALUENAME_UNINSTALL_MAJORVERSION
- REGDB_VALUENAME_UNINSTALL_MAJORVERSION_OLD

- REGDB_VALUENAME_UNINSTALL_MINORVERSION
- REGDB_VALUENAME_UNINSTALL_MINORVERSION_OLD
- REGDB_UNINSTALL_MAJOR_VERSION_OLD
- REGDB_UNINSTALL_MINOR_VERSION_OLD
- REGDB_OPTIONS
- RegDBSetItem
- RegDBGetItem
- RegDBDeleteItem

New CtrlGetDlgItem Function for Retrieving the Window Handle of a Control in a Custom InstallScript Dialog

A new InstallScript function called **CtrlGetDlgItem** is now available. The **CtrlGetDlgItem** function retrieves the window handle of a control in a custom dialog. **CtrlGetDlgItem** is similar to the Windows API **GetDlgItem**, except that with **CtrlGetDlgItem**, you can specify the InstallScript dialog name instead of the dialog's window handle. For more information, see CtrlGetDlgItem.

New InstallScript Constant for Passing a Null Pointer for an InstallScript String to an External DLL Function

You can use the IS_NULLSTR_PTR variable to pass a null pointer to an external DLL function or Windows API through a parameter that has been prototyped as an InstallScript string. This functionality works for byval string, byref string, wstring, and binary data types. For more information, see IS_NULLSTR_PTR.

New StrConvertSizeUnit Function for Converting an InstallScript Size Unit Constant to a Display String

A new InstallScript function called **StrConvertSizeUnit** is now available. The **StrConvertSizeUnit** function returns the appropriate display string for the InstallScript size unit constant that is specified.For more information, see StrConvertSizeUnit.

New StrTrim Function for Removing Leading and Trailing Spaces and Tabs from a String

A new InstallScript function called **StrTrim** is now available. The **StrTrim** function removes the leading and trailing spaces and tabs from a string. For more information, see StrTrim.

New SdLicense* Dialog Functions to Supersede Existing SdLicense* Dialog Functions

Two new InstallScript dialog functions—**SdLicenseEx** and **SdLicense2Ex**—are now available. They both display a dialog that contains a license agreement in a multi-line edit field. The license agreement can be stored in a text file (.txt) or a rich text file (.rtf).

- SdLicenseEx displays a dialog that shows a question in a static text field. The end user responds by clicking the Yes or No button.

  SdLicenseEx supersedes **SdLicense** and **SdLicenseRtf**.

- SdLicense2Ex displays a dialog that has two radio buttons (one for accepting the terms of the license agreement, and one for not accepting them). The Next button becomes enabled when the end user clicks the appropriate button to accept the terms of the license agreement.

  SdLicense2Ex supersedes **SdLicense2** and **SdLicense2Rtf**.

New ListFindKeyValueString Function for Searching Lists of Key-Value Pairs

A new InstallScript function called **ListFindKeyValueString** is now available. The **ListFindKeyValueString** function searches a string or number list for a specified value. It returns a value from an additional list that corresponds with the position of the found string in the first list. This enables you to search lists of key-value pairs for a particular key and retrieve the corresponding value.

For more information, see ListFindKeyValueString.

New InstallScript Code Examples

The InstallShield documentation now has sample code for the following InstallScript functions:

- AdminAskPath
- CharReplace
- FormatMessage
- LogReadCustomNumber
- LogReadCustomString
- LogWriteCustomNumber
- LogWriteCustomString

You can copy this code from the InstallShield documentation, paste it into your InstallScript code, and customize it as necessary.

Expanded InstallScript Cabinet File Viewer

The Cabinet File Viewer now provides additional information about .cab files for InstallScript projects.

- For features that were built by InstallShield, the viewer has the following new fields: Password Protected, Split Before, Split After, Split Not Allowed, and Split Before Not Allowed, and Image Index.
- For InstallScript Objects that are included in the InstallScript installation, the viewer has a new Object version field.
- For components, the viewer has the following new fields: Encrypted, Data as Files, and .NET Assembly.
- For media, the viewer has the following new field: Executable File.

What's New in InstallShield 2009 SP2

InstallShield 2009 Service Pack 2 (SP2) includes the following changes:

Microsoft Visual Studio 2008 SP1 Support

InstallShield now supports Microsoft .NET Framework 3.5 SP1 and Microsoft SQL Server 2008, as described below.

In addition, InstallShield integration with Visual Studio supports Visual Studio 2008 SP1, enabling development of installations and products within the Visual Studio interface.

Microsoft .NET Framework 3.5 SP1 Prerequisite Available

InstallShield includes two new .NET-related InstallShield prerequisites that you can add to Basic MSI and InstallScript MSI projects:

- Microsoft .NET Framework 3.5 SP1 (Web Download)
- Microsoft .NET Framework 3.5 SP1 (Full Package)

To learn more, see Adding .NET Framework Redistributables to Projects.

Microsoft SQL Server 2008 Support

InstallShield now includes support for running SQL script on SQL Server 2008. In addition, InstallShield includes SQL Server 2008 in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports.

Microsoft SQL Server 2008 Express Prerequisites Available

InstallShield now includes InstallShield prerequisites for Microsoft SQL Server 2008 Express Edition. You can add these InstallShield prerequisites to Basic MSI, and InstallScript MSI projects.

In order to support these new prerequisites, the InstallShield Prerequisite Editor has a new registry condition type.

New Registry Condition Type in the InstallShield Prerequisite Editor

The InstallShield Prerequisite Editor has a new type of condition option called **A registry entry has a specified version value**. Use this condition type when you want the installation to check the target system to see if a version number that is stored as the value data of a particular registry entry is greater than, less than, or equal to a version number that you specify in the InstallShield Prerequisite Editor. For more information about this new condition, see Prerequisite Condition Dialog Box.

Microsoft SQL Server 2005 Express SP2 (x86 and x64 WOW) Prerequisite Available

InstallShield now includes a new InstallShield prerequisite for Microsoft SQL Server 2005 Express Edition SP2. This prerequisite installs Microsoft SQL Server 2005 Express Edition SP2 on 32-bit and 64-bit (WOW) systems. You can add this InstallShield prerequisite to Basic MSI and InstallScript MSI projects.

New FlexNet Connect 11.0.1 Redistributables Available

InstallShield includes support for FlexNet Connect 11.0.1 in Basic MSI and InstallScript MSI projects. Use the Update Notifications view in InstallShield to include one of the two FlexNet Connect 11.0.1 merge modules—one has the Common Software Manager, and the other does not. These merge modules replace the FlexNet Connect 11 merge modules. For details about the changes in the updated merge modules, see the FlexNet Connect release notes.

Additional Changes

For a list of issues that are resolved in InstallShield 2009 SP2, see the release notes. The release notes are available from the Help menu in InstallShield.

What's New in InstallShield 2009 SP1

InstallShield 2009 supports a beta version of Windows Installer 4.5. InstallShield 2009 Service Pack 1 (SP1) includes changes that offer support for the final released version of Windows Installer 4.5:

InstallShield Prerequisites for Windows Installer 4.5

InstallShield now includes the following InstallShield prerequisites for the final released version of the Windows Installer 4.5 redistributables:

- Windows Installer 4.5 for Windows Vista and Server 2008 (x86)
- Windows Installer 4.5 for Windows Vista and Server 2008 (x64)
- Windows Installer 4.5 for Windows Vista and Server 2008 (IA64)
- Windows Installer 4.5 for Windows Server 2003 SP1 and later (x86)
- Windows Installer 4.5 for Windows Server 2003 and XP (x64)
- Windows Installer 4.5 for Windows Server 2003 (IA64)
- Windows Installer 4.5 for Windows XP SP2 and later (x86)

You can add these InstallShield prerequisites to Basic MSI and InstallScript MSI projects if you want Windows Installer 4.5 to be installed at run time.

For more information, see Adding Windows Installer Redistributables to Projects.

Additional Changes

For a list of issues that are resolved in InstallShield 2009 SP1, see the release notes. The release notes are available from the Help menu in InstallShield.

What's New in InstallShield 2009

New Features

InstallShield includes the following new features.

Ability to Associate InstallShield Prerequisites with Features for Chaining Installations

InstallShield now enables you to associate InstallShield prerequisites with one or more features. This new type of InstallShield prerequisite is called a *feature prerequisite*. It is installed if a feature that contains the prerequisite is installed and if the prerequisite is not already installed on the system.

Including InstallShield prerequisites in your project enables you to chain multiple installations together, bypassing the Windows Installer limitation that permits only one Execute sequence to be run at a time. The `Setup.exe` setup launcher serves as a bootstrap application that manages the chaining.

The Redistributables view is where you add InstallShield prerequisites to a project and specify whether you want them to run before your main installation or be associated with one or more features in your main installation.

Previously, all InstallShield prerequisite installations were run before the main installation ran, and the InstallShield prerequisites could not be associated with any features. This type of prerequisite, which is still available, is called a *setup prerequisite*.

Basic MSI projects include support for this feature.

To learn more, see:

- Setup Prerequisites vs. Feature Prerequisites
- Associating an InstallShield Prerequisite with a Feature in a Basic MSI Project
- Run-Time Behavior for an Installation that Includes InstallShield Prerequisites
- Working with InstallShield Prerequisites that Are Included in Installation Projects

Beta Windows Installer 4.5 Support for Installation of Multiple Packages Using Transaction Processing

InstallShield lets you add Windows Installer packages to Basic MSI and InstallScript MSI projects as chained .msi packages. If your Basic MSI or InstallScript MSI installation includes chained .msi packages and Windows Installer 4.5 is present on the target system, the Windows Installer installs the multiple packages using transaction processing. The packages are chained together and processed as a single transaction. If one or more of the packages in the transaction cannot be installed successfully or if the end user cancels the installation, the Windows Installer initiates rollback for all of the packages to restore the system to its earlier state.

The Chained .msi Packages area of the Releases view is where you add to your project one or more .msi packages that you want to be chained to your main installation. This area is also where you can assign release flags to the chained .msi packages, configure settings such as the properties that should be passed to the chained packages, and specify conditions.

For more information, see:

- Configuring Multiple Packages for Installation Using Transaction Processing
- Overview of Multiple-Package Installations that Use Transaction Processing
- Adding a New Chained .msi Package to Your Project
- Chained .msi Package Settings

Beta Windows Installer 4.5 Support for Using the InstallScript Engine as an Embedded User Interface for InstallScript MSI Installations

For InstallScript MSI projects, you now have the option to use the InstallScript engine as an embedded custom user interface (UI) handler, rather than as an external custom UI handler, as it has traditionally been used. Windows Installer 4.5 includes support for this new capability. Use this new embedded option if you want end users to be able to launch your installation directly from an .msi package, but you also want your installation to include a highly customized user interface that you have defined through InstallScript.

To specify whether you want to use the new embedded InstallScript UI functionality or the traditional external InstallScript UI functionality, use the new InstallScript User Interface Type setting; this is a project-wide setting in the General Information view. By default, InstallShield uses the traditional style for all InstallScript MSI projects; a `Setup.exe` setup launcher is required for this traditional option.

A new INSTALLSCRIPTMSIEEUI variable is available. This variable is set to True at run time if the new style is used; otherwise, it is set to False.

Note that the new style does have some limitations that the traditional style does not. For example, some of the InstallScript functions and command-line parameters are not supported or behave differently with the new style. For detailed information about the two styles, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

For additional information, see:

- Specifying the InstallScript User Interface Type for InstallScript MSI Installations
- InstallScript MSI Installation Projects
- INSTALLSCRIPTMSIEEUI

Beta Windows Installer 4.5 Support for Shared Component Patching

InstallShield includes support for the new shared component patching feature that is available with Windows Installer 4.5. The new Multiple Package Shared Component setting in the Components view lets you specify whether you want to enable shared component patching for the selected component. Selecting Yes sets a new component attribute that is designed to prevent Windows Installer from downgrading files when patches that contain components shared across multiple packages are uninstalled. The intent is to keep the highest version of a component present on the target system, even if the patch that contains that highest version is being uninstalled. The default value for this option is No.

Windows Installer 4.5 supports this new functionality; earlier versions of Windows Installer ignore this new setting. In addition, if the DisableSharedComponent policy is set to 1 on a target system, Windows Installer ignores this setting for all packages.

This feature applies to Basic MSI, InstallScript MSI, Merge Module, and Transform projects.

To learn more, see Specifying Whether Shared Component Patching Should Be Enabled for a Component.

Beta Windows Installer 4.5 Support for Superseding Components

Use the new Uninstall Superseded Component setting in the Components view to specify how you want Windows Installer 4.5 to handle the selected component during installation of a superseding patch under certain conditions. To specify that this component in the current patch should be flagged for uninstallation in order to avoid leaving this component orphaned on the target system after a superseding patch is applied, select Yes. If a subsequent

patch is installed and it is flagged to supersede the first patch, Windows Installer can unregister and uninstall this component if appropriate. If you select No, the superseding patch can leave an orphaned component on the target system, and none of the feature's remaining components can be maintained. The default value for this setting is No.

Windows Installer 4.5 supports this new functionality; earlier versions of Windows Installer ignore this new setting.

This feature applies to Basic MSI, InstallScript MSI, Merge Module, and Transform projects.

For more information, see the description of the Uninstall Superseded Component setting.

To learn more about patch sequences, see Patch Sequencing.

Beta Windows Installer 4.5 Support for Running a Custom Action Only During Patch Uninstallation

Use the new Run During Patch Uninstall setting for a custom action to indicate whether Windows Installer should run the selected custom action only when a patch is being uninstalled. This setting is available in the Custom Actions and Sequences view of Basic MSI, InstallScript MSI, MSI Database, and Transform projects. It is also available in the Custom Actions view of Merge Module and MSM Database projects.

You can also use the Run During Patch Uninstall check box on the Additional Options panel in the Custom Action Wizard to configure the behavior of a custom action.

For details about this new functionality, see Run During Patch Uninstall.

Beta Support for Windows Installer 4.5 Redistributables

InstallShield includes several InstallShield prerequisite files (.prq) for Windows Installer 4.5.

This feature applies to Basic MSI and InstallScript MSI projects.

For more information, see Adding Windows Installer Redistributables to Projects.

Ability to Create Unicode Versions of the Setup.exe and Update.exe Bootstrappers

InstallShield now enables you to specify whether you want to create a Unicode version or an ANSI version of the `Setup.exe` setup launcher for a Basic MSI project. Previously, if your Basic MSI project included a setup launcher, InstallShield always built an ANSI version; it did not include support for building a Unicode version.

A Unicode setup launcher can correctly display double-byte characters in the user interface of the setup launcher, regardless of whether the target system is running the appropriate code page for the double-byte-character language. An ANSI setup launcher displays double-byte characters in the setup launcher dialogs if the target system is running the appropriate code page. However, it displays garbled characters instead of double-byte characters in those dialogs if the target system is not running the appropriate code page.

Use the new Setup Launcher Type setting on the Setup.exe tab for a release in the Releases view to specify whether you want to use Unicode or ANSI. Unicode is the default type for all new Basic MSI projects.

InstallShield also now enables you to specify whether you want to create a Unicode version or an ANSI version of the `Update.exe` update launcher for a patch or a QuickPatch package.

Use the new Update Launcher Type setting on the Advanced tab for a patch configuration in the Patch Design view to specify whether you want to use Unicode or ANSI. For a QuickPatch project, the Update Launcher Type setting is on the Advanced tab in the Build Settings area of the General Information view. Unicode is the default type for all new patch configurations and QuickPatch packages.

Ability to Create a Log File for the Setup.exe Bootstrapper

A new `/debuglog` command-line parameter is available for the `Setup.exe` setup launcher for Basic MSI and InstallScript MSI projects. Use this command-line parameter to generate a log file for debugging. For more information, see /debuglog.

Support for Managed-Code Custom Actions

InstallShield lets you add managed-code custom actions to Basic MSI, InstallScript MSI, and Merge Module projects. This type of custom action calls a public method in a .NET assembly that is written in managed code such as Visual Basic .NET or C#.

For detailed information, see:

- Calling a Public Method in a Managed Assembly
- Run-Time Requirements for Managed-Code Custom Actions
- Specifying the Signature for a Managed Method in an Assembly Custom Action
- Configuring Custom Action Settings

Support for Installing Multiple Instances of a Product

InstallShield now includes support for creating an installation that allows an .msi package to be used to install multiple instances of a product in the same context on the same machine. Use the new Multiple Instances tab for a product configuration in the Releases view to define different instances of your product and configure the properties that are associated with each instance.

At build time, InstallShield creates a product code–changing instance transform for each instance and streams the instance transforms into the .msi package. At run time, the setup launcher displays a new instance selection dialog that lets end users specify whether they want to install a new instance, or update or maintain an already installed instance.

In addition, if you build a patch in the Patch Design view for a product whose installation includes multiple-instance support, InstallShield now creates a patch that enables end users to update a specific instance or all instances. At run time, the `Update.exe` file displays a patch version of the instance selection dialog.

A new `/instance` command-line option is available for `Setup.exe` and `Update.exe`. This option lets you specify which instance you want to install, update, or uninstall; it also lets you suppress the instance selection dialog.

Multiple-instance support is available for Basic MSI projects.

For more information, see:

- Installing Multiple Instances of Products
- Run-Time Requirements for Multiple-Instance Support
- Configuring Multiple Instances in InstallShield

- Special Considerations for Multiple-Instance Support
- Configuring and Building a Release that Includes Multiple-Instance Support
- Creating Patches for Multiple Instances of a Product
- Run-Time Behavior for Installing Multiple Instances of a Product
- Creating a Setup Launcher
- Multiple Instances Tab for a Product Configuration
- Setup.exe and Update.exe Command-Line Parameters

New Microsoft .NET Redistributables Available

InstallShield now includes many new .NET-related InstallShield prerequisites that you can add to Basic MSI and InstallScript MSI projects:

- Microsoft .NET Framework 3.5 (Web Download)
- Microsoft .NET Framework 3.5 (Full Package)
- Microsoft .NET Framework 3.5 Language Packs (x86, x64, IA64)
- Microsoft .NET Framework 3.0 SP1 (Web Download)
- Microsoft .NET Framework 3.0 Language Packs
- Microsoft .NET Framework 2.0 SP1 (x86, x64, IA64)

In addition, an updated Microsoft .NET Framework object is available in InstallShield for InstallScript projects. This object includes support for versions 3.5, 3.0 SP1, 3.0, 2.0 SP1, 2.0, 1.1 SP1, and 1.0 SP3 of the .NET Framework, including 32-bit, 64-bit x64, and 64-bit Itanium versions. The object also includes all supported language packs, as well as the Web downloader redistributables where available.

For more information, see:

- Adding .NET Framework Redistributables to Projects
- Including the Microsoft .NET Framework and Microsoft .NET Framework Language Pack Prerequisites
- Microsoft .NET Framework Object Wizard

New .msi Package Tools

InstallShield includes several new tools:

- InstallShield MSI Diff enables you to quickly compare two .msi, .msm, or .pcp files. It lets you apply one or more .msp and .mst files to an .msi file and see the changes in the resulting .msi database. You can also use this tool to compare two InstallShield project files (.ism or .ise) that are saved in binary format. This tool uses color coding to show additions, modifications, deletions, and schema differences. You can easily integrate it with most source code control systems.
- InstallShield MSI Query lets you test SQL statements using the Windows Installer version of SQL before you run them in your build script. You can quickly see if a SQL statement is formatted correctly and view the results that it generates.

- InstallShield MSI Sleuth is a diagnostic tool that lets you view the current installed state of a target system. InstallShield MSI Sleuth displays a list of all of the .msi packages that are installed. You can click any .msi package in the list to see the status of its features and components, its known source locations, as well as tables and binary streams within the database. This tool also helps you identify the installed product or products whose packages contain a specific component code.
- InstallShield MSI Grep searches a collection of .msi and .msm packages for specific text. You can narrow the search to show results for only certain tables or columns.

You can launch any of these tools from the InstallShield Tools subfolder on the Windows Start menu.

These InstallShield MSI tools are included with the Premier and Professional editions of InstallShield. The Premier edition also includes a separate installation and extra licenses that let you install just the tools, without InstallShield, on separate machines. For specific terms, see the InstallShield End-User License Agreement.

For more information, see InstallShield MSI Tools.

Ability to Compress Files that Are Streamed into Setup.exe and ISSetup.dll and to Specify the Compression Level

If you build a release that uses a `Setup.exe` setup launcher or a `ISSetup.dll` file (which contains the InstallScript engine), InstallShield now compresses files that it streams into the `Setup.exe` file or the `ISSetup.dll` file. The default compression level that InstallShield uses offers a balance between file size and time that is required to extract the compressed files at run time. If you want to change the compression level or you do not want to use any compression, you can override the default level through a machine-wide setting.

By default, InstallShield does not compress any files that have a .cab file extension when it is streaming them into the `Setup.exe` file at build time, since .cab files are already a compressed type of file. You can modify this default compression exclusion list to include other file types or specific files as needed. The exclusion list is a machine-wide setting.

This feature applies to Basic MSI and InstallScript MSI projects.

For more information, see Configuring the Compression Level for Files that Are Streamed into Setup.exe and ISSetup.dll.

Support for Multi-Part .cab Files

The .cab file type has some limitations. For example, the maximum size of a single .cab file is 2 GB. In addition, some users have had trouble signing large .cab files and verifying the digital signature of large signed .cab files. To work around these limitations, InstallShield now has a new default limit of 600 MB for a .cab file. When InstallShield is creating the .cab files for your release and it reaches the limit, it splits the data into two or more .cab files, creating multi-part .cab files.

You can modify the maximum size limit if necessary. In addition, if you do not want InstallShield to create multi-part .cab files, you can configure it to create single .cab files.

This functionality applies to Basic MSI and InstallScript MSI projects. In addition, it is applicable only if you are building a compressed network image release in which all of the files are embedded in the single-file .msi package or the `Setup.exe` setup launcher. This functionality does not apply to custom compression, where only the files that are associated with one or more features are compressed into .cab files.

For more information, see Configuring the Maximum Size for .cab Files.

Support for Adding an Open Dialog to a Basic MSI Installation to Let End Users Browse to a File

InstallShield includes support for launching the Open dialog from one of the dialogs in your Basic MSI installation. End users click a browse button in one of your dialogs, and this launches the Open dialog. The Open dialog lets the end user browse for a file. When the end user selects the file and clicks the Open button, the Open dialog closes, and the installation writes the full path and file name in an edit field on the dialog. The installation also sets the value of the **IS_BROWSE_FILEBROWSED** property to the path and file name of the file that the end user selected.

To use this functionality, you must add to your project the new Windows Installer DLL custom action called FileBrowse. This custom action calls the `FileBrowse.dll` file. In addition, you must add an edit field control and the browse button that launches the Open dialog, and set a related dialog event. For complete instructions, see Launching a File Open Dialog.

Support for Installing IIS 7 Web Sites on Windows Server 2008

InstallShield now lets you create and manage IIS 7 Web sites, virtual directories, Web service extensions, and application pools on Windows Server 2008 systems. This functionality is available in Basic MSI, InstallScript, and InstallScript MSI projects.

Microsoft SQL Server 2005 Express SP2 Prerequisite Available

InstallShield now includes an InstallShield prerequisite for Microsoft SQL Server 2005 Express Edition SP2. You can add this InstallShield prerequisite to Basic MSI and InstallScript MSI projects.

MySQL 5.0 Support

InstallShield now lists the 5.0.x versions of MySQL in the predefined list of database servers that you can select when you are specifying in the SQL Scripts view the target database servers that your product supports. Previously, it was necessary to create a custom version requirement.

Microsoft Visual Studio 2008 Support

InstallShield is now integrated with Visual Studio 2008, enabling development of installations and products within the same Visual Studio interface.

Ability to Convert Visual Studio Setup and Merge Module Projects to InstallShield Projects

InstallShield now lets you convert a Visual Studio 2008, Visual Studio 2005, Visual Studio .NET 2003, or Visual Studio .NET setup project (.vdproj) to a Basic MSI project (.ism). In addition, InstallShield enables you to convert a Visual Studio 2008, Visual Studio 2005, Visual Studio .NET 2003, or Visual Studio .NET merge module project (.vdproj) to an InstallShield Merge Module project (.ism).

Converting these Visual Studio projects to InstallShield projects enables you to modify the layout of dialogs through a visual Dialog Editor, manage features and components, and use other functionality that is available in InstallShield.

To learn more, see Converting or Importing Visual Studio Projects into InstallShield Projects.

Arabic (Saudi Arabia) and Hebrew Language Support, and Dialog Editor Support for Right-to-Left Languages

InstallShield now includes support for Arabic (Saudi Arabia) and Hebrew languages, which are written and read from right to left. All of the default end-user dialog strings are available in these languages.

Since these languages are read from right to left, InstallShield also includes support for mirroring Arabic and Hebrew dialogs; that is, InstallShield uses a right-to-left layout for Arabic and Hebrew dialogs. Thus, for example, buttons that are on the right side of dialogs in English and other left-to-right languages are moved to the left side of right-to-left-language dialogs. In addition, InstallShield uses mirror-image versions of the dialog images that are displayed for the built-in dialog themes.

The right-to-left layouts and reversed images are used in the Dialog Editor pane in the Dialogs view of InstallShield, and also at run time.

The Arabic and Hebrew support is available in the InstallShield Premier Edition. The Premier edition now includes support for 35 different languages.

The following project types include support for this feature: Basic MSI and Merge Module.

For more information, see Dialog Support for Right-to-Left Languages.

String Entry Validation in InstallScript Files (.rul)

When you build a project that includes an InstallScript file (.rul) and the InstallScript code contains one or more references to string entries that use the string constant operator (@), InstallShield now validates the string entries at build time.

If a string identifier in the project's InstallScript file is not defined for one of the project's string entries, InstallShield displays build warning -7174.

This applies to the following project types: Basic MSI with InstallScript custom actions, InstallScript, InstallScript MSI, InstallScript Object, and Merge Module with InstallScript custom actions.

To learn more, see:

- Description of build warning -7174
- String Constant Operator (@)

New FlexNet Connect 11 Redistributables Available

InstallShield includes support for FlexNet Connect 11 in Basic MSI and InstallScript MSI projects. Use the Update Notifications view in InstallShield to include one of the two FlexNet Connect 11 merge modules—one has the Common Software Manager, and the other does not.

Enhancements

InstallShield includes the following enhancements.

Best Practice Dynamic File Linking

When you add or modify a dynamic file link in your project, you can now specify which component creation method you want InstallShield to use: a new best practice method, or the previously available one-component-per-directory method.

When best practices for component creation are followed, InstallShield creates a separate component for each portable executable (PE) file in the dynamically linked folder and sets each PE file as the key file of its component. If you later want to create a patch that updates one of the dynamically linked PE files, it is easier to do so than it would be if you had used the one-component-per-directory method.

Previously, any time that you added dynamic file links to a project, InstallShield automatically created one component for all of the dynamically linked files at build time. However, if your dynamic file link included PE files, Windows Installer best practices for component creation were not followed.

By default, InstallShield considers the following file types to be PE files: .exe, .dll, .ocx, .vxd, .chm, .hlp, .tlb, and .ax. You can modify this list through the new File Extensions tab on the Options dialog box.

The automation interface includes support for this new best practice method. The ISWiDynamicFileLinking object includes a new CreateBestPracticeComponents property that lets you specify whether you want to use the best practice method, or the previously available one-component-per-directory method for a dynamic file link. When you create a new dynamic file link using the AddDynamicFileLinking method, the best practice method is used by default.

The best practice dynamic file linking applies to Basic MSI, InstallScript MSI, and Merge Module projects.

To learn more, see:

- Determining the Appropriate Component Creation Method for Dynamically Linked Files
- Dynamic File Link Settings Dialog Box
- File Extensions Tab
- ISWiDynamicFileLinking Object
- AddDynamicFileLinking Method

Ability to Hide Setup Prerequisites from the List of Prerequisites to Be Installed

If a target system needs one or more setup prerequisites to be installed, the setup prerequisite dialog is displayed at run time before the main installation runs. The Behavior tab in the InstallShield Prerequisite Editor has a new check box that lets you specify whether you want a setup prerequisite to be hidden from the list of prerequisites in the prerequisite dialog. If a prerequisite is hidden, it is installed when the conditions require it, even though it is not listed as one of the prerequisites that needs to be installed.

New prerequisites and existing prerequisites that were created before this functionality was available are not hidden by default. You can change this behavior by selecting the new check box on the Behavior tab.

For more information, see Specifying Whether to Include the Name of a Prerequisite in the List of Setup Prerequisites to Be Installed on the Target System.

Ability to Show the Progress of an InstallShield Prerequisite Installation at Run Time

The Behavior tab in the InstallShield Prerequisite Editor has a new check box that lets you specify whether you want the prerequisite installation to show installation progress messages from Windows Installer at run time. This augments the progress bar to reflect the current progress status of the .msi installation. This functionality is available only if the prerequisite launches an .msi file; it is not possible if the prerequisite launches a `Setup.exe` file. For more information, see Specifying Whether to Show the Progress of an InstallShield Prerequisite Installation at Run Time.

For new prerequisites and existing prerequisites that were created before this functionality was available, the progress is not shown by default. You can change this behavior by selecting the new check box on the Behavior tab.

Note that if you specify that you want to show the progress, only some of the available command-line parameters are supported. To learn more, see Specifying Command-Line Parameters for an InstallShield Prerequisite.

Ability to Use Windows Installer Properties in Command-Line Statements for InstallShield Prerequisites

Basic MSI and InstallScript MSI installations now can substitute and pass the following properties on setup prerequisite command lines: **ProductLanguage**, **ISPREREQDIR**, **SETUPEXEDIR**, and **SETUPEXENAME**. You can use these properties to identify the launching installation (`"[SETUPEXEDIR]\[SETUPEXENAME]"`), to identify full paths to files that are included in the prerequisite (`"[ISPREREQDIR]myconfig.ini"`), or to pass the selected language to multilingual prerequisites such as an InstallShield setup launcher (`/l[ProductLanguage]`). The new feature prerequisites include command-line support for any Windows Installer property, including the aforementioned properties.

You can specify the command lines on the Application to Run tab of the InstallShield Prerequisite Editor.

For more information, see Specifying Command-Line Parameters for an InstallShield Prerequisite.

New Option for Reboot Behavior of InstallShield Prerequisites

The Behavior tab of the InstallShield Prerequisite Editor is where you specify how an InstallShield prerequisite installation should proceed if it appears that the target machine needs to be restarted. The **If the prerequisite appears to need a reboot** list is where you specify the behavior. This list has a new option, called **Note it, fail to resume if the machine is rebooted, and reboot after the installation**. If it appears that a restart is required at run time but you want to postpone it until the end of the main installation (or until a subsequent prerequisite triggers a restart), select this new option.

For more information, see Behavior Tab.

Support for Single-File, Compressed InstallScript Installations of up to 4 GB

A single-file, compressed InstallScript installation can now be up to 4 GB in size. Previously, when end users ran large single-file, compressed InstallScript installations, the installations crashed during setup initialization.

Note that `Setup.exe` files cannot exceed 4 GB because Windows will not load an executable file that is larger than 4 GB.

Ability to Install IIS Web Sites Without Virtual Directories and to Associate Web Sites with Components

InstallShield now includes support for installing IIS Web sites without any virtual directories. In addition, the General tab that InstallShield displays when you select a Web site in the Internet Information Services view now has a Component setting; use this setting to associate the selected Web site with a component. As a result of these enhancements, a Web site is created on a target machine if a virtual directory or a component that is associated with it is installed.

If a Web site is associated with a component, the Web site's **Delete Web Site on Uninstall** check box corresponds with the Permanent setting for that component in a Basic MSI or InstallScript MSI project, or with the Uninstall setting for that component in an InstallScript project. That is, if you select or clear the **Delete Web Site on Uninstall** check box for a Web site, InstallShield automatically updates the value of the component's Permanent setting or Uninstall setting, as appropriate.

Previously, InstallShield did not include support for associating Web sites with components. Therefore, if a Web site in an installation did not have any virtual directories, the Web site would not be created at run time.

If you add a new Web site through the Internet Information Services view in InstallShield 2009, InstallShield automatically associates that Web site with a component. If you upgrade an InstallShield 2008 or earlier project that already has an IIS Web site, InstallShield does not automatically associate that Web site with a component.

The following project types support these IIS enhancements: Basic MSI, InstallScript, and InstallScript MSI.

Note that if a Web site is associated with a component in an InstallScript project, any virtual directories that are added to that Web site must be associated with the same component. Therefore, if you try to change the component for a Web site that contains one or more virtual directories, InstallShield displays a message box to inform you that it will also make the same component change for all of that Web site's virtual directories; InstallShield also displays this message box if you try to change the component for any virtual directories in a Web site. In either case, the message box enables you to proceed or cancel the component change. For Basic MSI and InstallScript MSI projects, keeping a Web site in the same component as all of the Web site's virtual directories is not required, but it is recommended.

To learn more, see:

- Creating a Web Site and Adding an Application or a Virtual Directory
- Feature and Component Associations for IIS Support
- Uninstalling Web Sites, Applications, and Virtual Directories

Simplification of QuickPatch Packages

InstallShield now offers the ability to build streamlined QuickPatch packages, which typically have fewer new subfeatures and built-in InstallShield custom actions than those built in earlier releases of InstallShield. A new Streamline QuickPatch setting on the Advanced tab in QuickPatch projects lets you specify whether InstallShield should create this new simpler type of QuickPatch package.

For more information, see:

- Specifying Whether to Streamline the QuickPatch Package
- Advanced Tab

Ability to Build a Patch from the Command Line and from MSBuild

The `-patch_config` command-line parameter is available for command-line builds (including the Standalone Build command-line builds) with `ISCmdBld.exe`. Use this parameter to build a patch from the command line.

If you use an .ini file to pass parameters to the command line, you can use the new `PatchConfigName` parameter in the [Project] section of your .ini file to indicate the patch configuration that you want to build.

In addition, the InstallShield task for MSBuild now includes a PatchConfiguration parameter, which you can use to specify the patch configuration that you want to build through MSBuild.

To learn more, see:

- ISCmdBld.exe
- Passing Command-Line Build Parameters in an .ini File
- Microsoft Build Engine (MSBuild)

Ability to Password-Protect Patches and QuickPatch Packages

InstallShield now has new password settings that let you password-protect patches and QuickPatch packages. These settings are on the Advanced tab in the Patch Design view of Basic MSI and InstallScript MSI projects, and on the Advanced tab of QuickPatch projects.

If you password-protect a patch or QuickPatch package, any end user who wants to install the package must enter a case-sensitive password to launch your update.

To learn more, see the following:

- Password-Protecting a Patch Package
- Password-Protecting a QuickPatch Package
- Advanced Tab (for a patch configuration in the Patch Design view)
- Advanced Tab (for a QuickPatch project)

Patch and Upgrade Validation Support in QuickPatch Projects

When you build QuickPatch projects, InstallShield now runs patch and upgrade validation. This validation helps identify some common problems that may be encountered when attempting to upgrade a product with a QuickPatch package.

Previously, the patch and upgrade validation was available only for Basic MSI projects and InstallScript MSI projects, and patches that were created in the Patch Design view.

To learn more, see Validating Upgrades, Patches, and QuickPatch Packages.

Ability to Select Multiple .cub Files for Performing Validation at Build Time

The Validation tab on the Options dialog box in InstallShield now lets you specify more than one .cub file that should be used to validate your installation package or merge module when it is built from within InstallShield.

In addition, you can now pass more than one .cub file through the `-m` command-line parameter for command-line builds (including the Standalone Build command-line builds) with `ISCmdBld.exe`. If you use an .ini file to pass parameters to the command line, you can now specify more than one .cub file for the CubFile parameter in your .ini file.

The RunMsiValidator parameter of the InstallShield task for MSBuild has been enhanced to accept more than one .cub file.

For more information, see:

- Requirements for the Windows Logo Program
- Validating an Installation Package or Merge Module
- Specifying Whether Validation Should Be Performed at Build Time
- Validating an Installation Package or Merge Module
- Validation Tab (on the Options dialog box)
- Build Menu
- ISCmdBld.exe
- Passing Command-Line Build Parameters in an .ini File
- Microsoft Build Engine (MSBuild)

New Validator for the InstallShield Best Practice Suite

ISBP20 is a new validator that is available with the InstallShield Best Practice Suite. ISBP20 verifies that no registry entries contained in the **Registry** table attempt to remove root-level registry keys or other keys that would cause adverse issues on target machines during uninstallation.

The InstallShield Best Practice Suite is available in the Premier edition of InstallShield for Basic MSI, InstallScript MSI, and MSI Database projects.

Ability to Use the /v Command-Line Parameter More than Once to Pass More than One Parameter from Setup.exe to the .msi File

If you want to pass more than one argument from `Setup.exe` to `Msiexec.exe`, you can use the `/v` option multiple times at the command line, once for each argument. Previously, the `/v` option could be used only once, and all parameters were passed through this instance.

The following project types include support for this enhancement: Basic MSI and InstallScript MSI.

For more information, see Setup.exe and Update.exe Command-Line Parameters.

Improved Compatibility Between the Standalone Build and InstallShield

The Standalone Build that is available with InstallShield Premier Edition now uses the same directory structure that InstallShield uses for its program files. Therefore, if you need to copy a redistributable or some other file from a machine that has InstallShield to a machine that has the Standalone Build, use the same relative path. Previously, the directory structures were different and inconsistent.

In addition, the `ISCmdBld.exe` file that is used for command-line builds with InstallShield is now installed with the Standalone Build. Previously, the Standalone Build used `IsSaBld.exe`, a different file, for command-line builds. `ISCmdBld.exe` now supports parameters that previously only `IsSaBld.exe` supported:

- -o <merge module search path>—Specifies one or more comma-delimited folders that contain the merge module (.msm) files referenced by your project.
- -t <Microsoft .NET Framework path>—Specifies the path to the Microsoft .NET Framework. The path is the location of the .NET Framework that is installed on the build machine.
- `-h`—Indicates that you want to skip the upgrade validators at the end of the build.
- `-g <minimum target MSI version>`—Specifies the minimum version of Windows Installer that the installation requires on the target machine.
- `-j <minimum target Microsoft .NET Framework version>`—Specifies the minimum version of the .NET Framework that the installation requires on the target machine.

Also as part of this enhancement, the Standalone Automation Interface uses the same `ISWiAutomation15.dll` file that InstallShield uses, but it is installed to a different location. If you have existing automation scripts that work with the InstallShield Automation Interface, you no longer need to change the library name from IswiAuto*N* to SAAuto*N* throughout the scripts in order to use them with the Standalone Automation Interface. Note that with this change, the ISWiProject object includes support for several properties that were previously available for only the Standalone Automation Interface:

- DotNetFrameworkPath
- MergeModuleSearchPath
- MinimumTargetDotNetVersion
- MinimumTargetMSIVersion
- SelfRegistrationMethod
- SkipUpgradeValidators

An advantage of these compatibility improvements is that only one set of binaries, rather than two separate sets, is built for the Standalone Build and InstallShield; if an InstallShield hotfix or service pack is released, it can be used to update the Standalone Build and InstallShield. Previously, separate hotfixes and service packs were required.

To learn more, see:

- Installing the Standalone Build on a Build Machine
- Adding Redistributables to the Build Machine for the Standalone Build
- Standalone Command-Line Build
- Standalone Automation Interface
- Installing the Standalone Build and InstallShield on the Same Machine
- ISCmdBld.exe
- ISWiProject Object

Support for Browsing to Local, Remote, and Alias SQL Servers in the SQLBrowse Run-Time Dialog

The filter functionality of the SQLBrowse dialogs has been enhanced.

To show only remote servers in the SQL Server browse combo box and list box controls in Basic MSI and InstallScript MSI installations, you can set the new Windows Installer property **IS_SQLSERVER_REMOTE_ONLY**. To show only server aliases in the SQL Server browse combo box and list box controls in Basic MSI and InstallScript MSI installations, you can set the new Windows Installer property **IS_SQLSERVER_ALIAS_ONLY**. Previously, the only filtering that was available was showing only local servers; this is available if you set the **IS_SQLSERVER_LOCAL_ONLY** property. You can now set any combinations of these properties to display multiple types of servers in the SQL Server browse combo box and list box controls.

To learn more, see Overriding the Default SQL Run-Time Behavior.

Two new InstallScript functions are available for InstallScript projects:

- SQLRTSetBrowseOption—This function lets you specify whether the SQL Server browse combo box and list box controls show local servers, remote servers, server aliases, or a combination of these types.
- SQLRTGetBrowseOption—This function returns the current value of the browse option for the SQL Server browse combo box and list box controls, which can display local servers, remote servers, server aliases, or a combination of these types.

Ability to Continue an Installation If the Minimum SQL Database Server Requirements Are Not Met

The Requirements tab that is displayed when you select a SQL connection in the SQL Scripts view has a new **Allow installation to continue when minimum requirements are not met** check box.

If you select this check box and the minimum database server requirements are not met on a target system, the run time skips the SQL connection and all of its SQL scripts, and continues with the installation.

If you clear this check box and the minimum requirements are not met, the installation does not allow the end user to continue with the rest of the installation. This is the default behavior.

This enhancement applies to Basic MSI, InstallScript, and InstallScript MSI projects.

For more information, see Requirements Tab.

SQL Server Alias Support

The SQL run-time support has been enhanced: installations can now list SQL Server alias names in the SQLBrowse dialog. In addition, the SQLLogin dialogs let end users use an alias name to connect to a SQL Server.

This enhancement applies to Basic MSI, InstallScript, and InstallScript MSI projects.

To learn more, see Adding a New SQL Connection.

Predefined System Searches for the .NET Framework

InstallShield has several new predefined system searches:

- Microsoft .NET Framework 3.5
- Microsoft .NET Framework 3.0 SP1

- Microsoft .NET Framework 3.0
- Microsoft .NET Framework 2.0 SP1
- Microsoft .NET Framework 2.0
- Microsoft .NET Framework 1.1
- Microsoft .NET Framework 1.0

If your installation requires any of these, you can use the System Search view or the Installation Requirements page in the Project Assistant to add these system searches to your project. When end users launch your installation, Windows Installer checks the target system to see if the requirements are met; if they are not met, the installation displays the error message that is defined for the system search.

This enhancement applies to Basic MSI and InstallScript MSI projects.

Expanded Support for the Error Type of Custom Action

The Custom Action Wizard now includes support for a type 19 custom action, which displays a specified error message, returns failure, and ends the installation. Previously, the only way to create this type of custom action was to right-click the Custom Actions explorer in the Custom Actions and Sequences view and then click Error, or to use the Direct Editor to manually enter the custom action's table entry.

The following project types now support the error custom action: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform. Previously, only Basic MSI and InstallScript MSI projects included support.

Ability to Specify Whether to Digitally Sign Source Files

The Signing tab in the Releases view has a new **Sign files in their original location** check box. This check box lets you specify whether you want InstallShield to sign your original source files or just the files that are built into the release. This check box is also available on the Digital Signature Options panel in the Release Wizard. The check box is cleared by default.

The benefit of selecting this check box for a Basic MSI or InstallScript MSI project is that it helps create one patch that updates both compressed and uncompressed versions of a release that contains originally unsigned files.

Previously, the check box was not available, and InstallShield never enabled you to sign the files in their original location.

The automation interface now includes support for this new digital signing functionality. The ISWiRelease object includes a new **SignFilesInPlace** property that lets you specify whether you want InstallShield to sign your original source files or just the files that are built into the release.

To learn more, see:

- Signing Tab for a Release
- Digital Signature Options Panel
- Digital Signing and Security
- ISWiRelease Object

Improved Static COM Extraction

If you use static COM extraction, InstallShield now uses an MD5 algorithm when generating primary keys for the **Registry** table. Therefore, if the COM data does not change, the primary keys do not change between different versions of a package and when the extracted COM data is refreshed.

Previously, InstallShield used random values for the primary keys that it created during static COM extraction. As a result, if the COM data were refreshed or a patch were built, it was possible for new primary keys to be created, even if the COM data had not changed. In the patch scenario, the COM data would be included in the patch if the primary keys changed. If a patch updated a component with unchanged COM data, the COM data could be removed during patch uninstallation, and this could cause issues in the earlier version of the product.

This enhancement applies to Basic MSI and InstallScript MSI projects.

InstallScript Language Enhancements and New Functionality

Some enhancements have been made to the InstallScript language.

Enhancements for .NET Framework 3.5 and .NET Framework 3.0 SP1 Support

A new FOLDER_DOTNET_35 InstallScript variable is available. This variable stores the path of the .NET Framework 3.0 files.

Two new constants are available for use with the function Is:

- REGDB_KEYPATH_DOTNET_35
- REGDB_KEYPATH_DOTNET_30_SP

You can use the REGDB_KEYPATH_DOTNET_30_SP variable when querying whether SP1—or a later service pack—of the .NET Framework 3.0 is installed. To detect whether the RTM version of the .NET Framework 3.0 is installed, use REGDB_KEYPATH_DOTNET_30.

New GetTempFileNameIS Function that Calls the Windows API GetTempFileName to Create a Temporary File

A new InstallScript function called **GetTempFileNameIS** is available. This function calls the Windows API **GetTempFileName** to create a temporary file and perform related actions.

To learn more, see GetTempFileName.

What's New in InstallShield 2008

New Features

InstallShield includes the following new features.

New End-User Dialog Themes for Basic MSI Projects

Dialog themes are predefined sets of images that give your end-user dialogs a unified and distinctive look. With the click of a button, you can now select one of the available themes for your project, and InstallShield applies that theme to all of the interior and exterior dialogs, as well as the `Setup.exe` initialization dialog, in your project. You can easily preview each dialog from within the Dialogs view to see how it looks with the selected theme.

Some of the themes are available in both the Premier and Professional editions of InstallShield, and some are available in only the Premier edition. For more information, see Available Themes and Corresponding Dialog Sizes.

For more information about this feature, see the Dialog Themes section of this documentation.

Digital Signing Improvements

InstallShield now lets you digitally sign any files—including your product's executable files—in your project at build time. In addition, you can now use a personal information exchange file (.pfx) for digital signatures. All of the following project types support this functionality: Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, and Merge Module.

The new Signing tab in the Releases view is where you specify the digital signature information—including the digital signature files granted to you by a certification authority—that InstallShield should use to sign your files. The Signing tab is also where you specify which files in your installation should be digitally signed. You can also use the Release Wizard to specify all of the digital signature information.

If you specify a .pfx file for signing, InstallShield uses `SignTool.exe` to sign your files. If you specify an .spc file and a .pvk file, InstallShield uses `Signcode.exe` to sign your files. Using a .pfx file is often the preferred method, since it is more likely to work in many different environments (such as locked build machines). If you specify the digital signature password in InstallShield, you will never see a password prompt if you are using a .pfx file. However, if you are using .spc and .pvk files, a password prompt may be displayed.

Note that InstallShield does not support not support using .pfx files to sign media header files (.hdr files), which are used for the One-Click Install type of installation for InstallScript projects. For this type of installation, consider one of the following alternatives:

- Use .spc and .pvk files instead of a .pfx file for your digital signature.
- Build a compressed installation, which would enable you to sign with a .pfx file.

Previously, InstallShield included support for signing only the .msi, .hdr, and `Setup.exe` files. In addition, InstallShield allowed you to specify .spc and .pvk files for the digital signature, but not .pfx files.

To learn more, see the following:

- Digital Signing and Security
- Digitally Signing a Release and Its Files at Build Time
- Signing Tab for a Release

InstallShield Best Practice Suite Available in Premier Edition

InstallShield includes a set of validators called the InstallShield Best Practice Suite. The InstallShield Best Practice (ISBP) validators in this suite alert you if your installation violates best-practice guidelines.

This feature is available for Basic MSI, InstallScript MSI, and MSI Database projects.

For more information, see:

- InstallShield Best Practice Suite
- Specifying Which ICEs, ISICEs, ISVICEs and ISBPs Should Be Run During Validation

Support for Internet Information Services (IIS) 7.0 and SSL

InstallShield now includes support for IIS 7.

In addition, InstallShield lets you include an SSL certificate for a Web site in your installation. Including an SSL server certificate enables users to authenticate the Web server, check the validity of the Web content, and establish a secure connection.

For more information, see:

- Internet Information Services View
- Specifying the SSL Certificate for a Web Site
- Determining If a Target System Has IIS 6 or Earlier or the IIS 6 Metabase Compatibility Feature
- Version-Specific Information for IIS Support in InstallShield

New Microsoft .NET Prerequisites Available

InstallShield now includes many new .NET-related setup prerequisites that you can add to Basic MSI and InstallScript MSI projects:

- .NET Framework 2.0 (x64)
- .NET Framework 2.0 (x64) Language Packs
- .NET Framework 2.0 (IA64)
- .NET Framework 2.0 (IA64) Language Packs
- .NET Framework 3.0 (x64)

For more information, see Adding .NET Framework Redistributables to Projects.

Updated Microsoft .NET Object for InstallScript Projects

An updated Microsoft .NET object is available in InstallShield. This object includes support for versions 1.0 (SP3), 1.1 (SP1), 2.0, and 3.0 of the .NET Framework, including 32-bit, 64-bit x64, and 64-bit Itanium versions. The object also includes all supported language packs, and the latest service packs of 1.0 and 1.1.

In addition, the object launches and completes the .NET Framework installation as the feature containing the .NET object installs. This allows the .NET Framework to be available as early as possible, in case it is needed to install or configure files that are subsequently installed during the installation.

For more information, see Microsoft .NET Framework Object Wizard.

Visual C++ 8.0 SP1 Merge Modules Available

InstallShield now includes Visual C++ 8.0 SP1 merge modules (version 8.0.50727.762).

Support for the UAC Shield Icon on Dialog Buttons (Basic MSI Projects)

In the Dialog Editor of Basic MSI projects, a new Show UAC Shield Icon property is available for all button controls. If you select True for this property, the User Account Control (UAC) icon is displayed on the button when end users run the installation on Windows Vista systems. If you are using InstallShield on a Windows Vista system, you can see the shield icon on the button in the Dialog Editor as it will be displayed at run time. The shield icon signals to end users that elevated privileges may be required.

For any new Basic MSI projects that you create, the Show UAC Shield Icon property is set to True for the Install button on the ReadyToInstall dialog. If you upgrade a Basic MSI project that was created with InstallShield 12 or earlier to InstallShield 2008, the default value for the Install button's Show UAC Shield Icon property is False. You can override the value for this button, or for any other buttons, as required.

Ability to Require End Users to Scroll Through the EULA in the LicenseAgreement Dialog

InstallShield includes support for disabling the Next button on the LicenseAgreement dialog until the end user reaches the end of the End-User License Agreement (EULA) text in the scrollable EULA control through mouse or keyboard scrolling.

The end user must also select the **I accept the terms in the license agreement** option before the Next button is enabled; this behavior is the same as with earlier releases of InstallShield.

The scroll requirement is not available in the LicenseAgreement dialog by default. To use this functionality, you must add to your project the new Windows Installer DLL custom action called WatchScroll. This custom action calls the `EulaScrollWatcher.dll` file. In addition, you must modify the Next button's Control conditions and add an event to the Memo control.

This is available for Basic MSI projects.

For detailed instructions, see Requiring End Users to Scroll Through the EULA in the LicenseAgreement Dialog.

Microsoft SQL Server 2005 Express SP1 Setup Prerequisite Available

InstallShield now includes a setup prerequisite for Microsoft SQL Server 2005 Express Edition SP1. You can add this setup prerequisite to Basic MSI and InstallScript MSI projects.

Updated DirectX 9.0c Objects

Two DirectX 9.0c objects are available with InstallShield: a Windows Installer–based object that is available for Basic MSI and InstallScript MSI projects, and an InstallScript-based object that is available for InstallScript projects. Both of these objects install all of the latest DirectX 9.0c core and optional components, including 32-bit-specific and 64-bit-specific components.

In addition, some changes have been made to the DirectX 9 Object Wizard for Basic MSI and InstallScript MSI projects. The wizard now lets you specify whether the redistributable files should be included in the Disk1 folder or streamed into the .msi file. This change enables you to use the DirectX 9 object in compressed installations. Also, you can now use the DirectX 9 object in silent installations.

For Basic MSI and InstallScript MSI projects, the custom action that launches the DirectX installation is now sequenced in the Execute sequence and run in deferred system context so that it can be run with elevated privileges on Windows Vista systems.

To learn more, see:

- Including the DirectX 9.0 Object
- DirectX Object Wizard

DIFx 2.1 Support

InstallShield includes support for the latest version of Driver Install Frameworks for Applications (DIFx). This new version, which includes the latest binary files from Microsoft, is available for any Basic MSI, InstallScript, or InstallScript MSI projects that you create in InstallShield. This new version can be installed on Windows Vista systems. Earlier versions of InstallShield included an earlier version of DIFx that failed to install on Windows Vista in some cases.

Support for 64-Bit Self-Registration of COM Servers (Basic MSI Projects)

InstallShield now includes support for 64-bit self-registration of COM servers in Basic MSI projects. If you mark a component as 64 bit and then add a file to that component, you can select the file's Self Register check box to enable 64-bit self-registration of that file during installation. In addition, InstallShield also supports 64-bit self-registration of dynamically linked COM servers. For more information, see:

- Targeting 64-Bit Operating Systems with Basic MSI and InstallScript MSI Installations
- File Properties Dialog Box
- Adding Dynamic File Links to Components

Expanded Operating System Condition Settings in the Setup Prerequisite Editor

The Setup Prerequisite Editor now enables you to specify more details about operating system requirements when you are creating conditions for a prerequisite. The Prerequisite Condition dialog box, which is displayed when you are adding or modifying a condition for a prerequisite through the Setup Prerequisite Editor, lets you select a predefined operating system or select the custom option. With the new custom option, you can configure settings for operating system requirements such as platform, major and minor versions, processor architecture (64-bit or 32-bit), and service pack. If a target system does not meet the operating system requirements, the prerequisite is not installed.

For more information, see the following:

- Adding an Operating System Condition for an InstallShield Prerequisite
- Prerequisite Condition Dialog Box
- Conditions Tab

Ability to Target Windows Server 2008 Systems

InstallShield enables you to specify that your installation requires Windows Server 2008. It also lets you build Windows Server 2008–related conditions for features and components.

Note that Windows Vista and Windows Server 2008 use the same major and minor version numbers. Therefore, if you want to use InstallScript to distinguish between Windows Server 2008 and Windows Vista, check whether SYSINFO.nOSProductType = VER_NT_WORKSTATION; for Windows Vista, this is TRUE; for Windows Server 2008, it is FALSE. For more information, see SYSINFO.

New MSXML 6 SP1 Setup Prerequisites Available

InstallShield now includes some new MSXML setup prerequisites that you can add to Basic MSI and InstallScript MSI projects:

- MSXML 6.0 SP1
- MSXML 6.0 SP1 (IA64)
- MSXML 6.0 SP1 (x64)

To learn more about MSXML, see Run-Time Requirements for XML File Changes.

FlexNet Connect Support

You can add a redistributable for FlexNet Connect 6.1 to Basic MSI and InstallScript MSI projects.

The Update Notifications view in Basic MSI and InstallScript MSI projects lets you select which version of FlexNet Connect you want to include in your project. You can include version 6.1 or any version that is installed in any of the locations that are specified in the Merge Module Location area on the Merge Module tab of the Options dialog box.

The Update Notifications view includes a new Vendor Database setting, which FlexNet Connect 6.1 supports.

Enhancements

Usability Enhancements for Releases

The release settings are now organized by category on several different tabs in the Releases view.

In addition, you can now select Compressed or Uncompressed for the Compression setting from within the Releases view. Previously, the only way to modify this setting was to use the Release Wizard. Note that if you want to specify a custom compression setting (one .cab file per feature or one .cab file per component), you must still use the Release Wizard. The Compression setting is available in Basic MSI, InstallScript MSI, and Merge Module.

The settings in the Distribution view have been moved to the new Postbuild tab in the Releases view for Basic MSI, InstallScript MSI, and Merge Module projects. The Postbuild tab lets you configure settings for distributing releases to a folder or FTP site automatically at build time.

A new Distribute command is available when you right-click a release in the Releases view for Basic MSI, InstallScript MSI, and Merge Module projects. When you select this command, InstallShield copies all of the relevant files for your release to the locations that are specified on the Postbuild tab. Note that for InstallScript and InstallScript Object projects, InstallShield automatically copies the release to the locations that you specify on the Postbuild tab every time that you build the release.

To learn more, see:

- Build Tab for a Release
- Setup.exe Tab for a Release
- Signing Tab for a Release
- .NET/J# Tab for a Release
- Internet Tab for a Release

- Events Tab for a Release
- Distributing Releases to a Folder or FTP Site Automatically

Usability Enhancements for Custom Actions and Sequences

The Custom Actions view and the Sequences view have been combined into a more robust view called the Custom Actions and Sequences view. The combined view supports drag-and-drop editing and copying:

- To sequence a new custom action, drag it from the Custom Actions explorer to the appropriate location in a sequence under the Sequences explorer.
- To move a dialog, standard action, or custom action to a different point in a sequence (or from one sequence to another), drag it from the old location to the new location.
- To copy a custom action from one sequence to another, press and hold CTRL while dragging the custom action from one sequence to another sequence.

The Custom Actions and Sequences view is available in Basic MSI, InstallScript MSI, MSI Database, and Transform projects.

For more information, see:

- Custom Actions and Sequences View (or Custom Actions View)
- Creating Custom Actions in the Custom Actions and Sequences View (or the Custom Actions View)
- Inserting Actions into Sequences
- Copying a Custom Action from One Sequence to Another
- Reordering a Sequence

Usability Enhancements for the Files and Folders view, the Registry View, and the Redistributables View

Several enhancements are available for the Files and Folders view:

- You can right-click a file in the **Destination computer's files** pane and then click the new Open Containing Folder command. Doing so opens a Windows Explorer window and displays the folder that contains the file that you right-clicked.
- A new Add command is available when you right-click the **Destination computer's files** pane. Use this command to display an Open dialog box that lets you browse to the file that you want to add to your project.
- The upper-right corner of this view has a new link (either Show Source Panes or Hide Source Panes). Use this new link to show or hide the two top panes—the **Source computer's folders** pane and the **Source computer's files** pane—in this view. You can hide the two panes, open a Windows Explorer window, and drag and drop files from the Windows Explorer window to the two remaining panes in InstallShield.

The Registry view also has a new link (either Show Source Panes or Hide Source Panes) in the upper-right corner. Use this new link to show or hide the two top panes—the **Source computer's folders** pane and the **Source computer's files** pane—in this view.

Two enhancements have also been made to the Redistributables view for Basic MSI and InstallScript MSI projects:

- The right pane in this view shows details about the merge module, object, or setup prerequisite that is selected in the upper-left pane. You can now hide or show the details pane by clicking the Show Details or Hide Details link in the upper-right corner of this view.
- The Details pane that is displayed for setup prerequisites now shows complete information about the selected setup prerequisite. This includes conditions, command-line parameters, and other information that is configured for the prerequisite.

Automation Interface Enhancements

Many enhancements have been made to the automation interface.

CreateProject Method Now Enables Creation of Merge Module Projects

The CreateProject method for the ISWiProject object now enables you to create merge module projects. Previously, this method supported only Basic MSI, InstallScript, InstallScript MSI, and InstallScript Object projects.

To learn more, see CreateProject Method.

Support for Configuring Dynamic File Links

The automation interface includes a new object and a new collection for dynamic file links. In addition, the ISWiComponent object includes two new methods and a property that let you add (AddDynamicFileLinking) and remove (RemoveDynamicFileLinking) a component's dynamic file link, as well as get the collection of dynamic file links (ISWiDynamicFileLinkings).

For more details, see:

- ISWiDynamicFileLinking Object
- ISWiDynamicFileLinkings Collection
- ISWiComponent Object
- AddDynamicFileLinking Method
- RemoveDynamicFileLinking Method

Support for Configuring Path Variables

The automation interface includes a new object and a new collection for configuring path variables in a project. In addition, the ISWiProject object includes two new methods and a property that let you add (AddPathVariable) and remove (DeletePathVariable) a path variable from a project, as well as get the collection of path variables (ISWiPathVariables).

To learn more, see:

- ISWiPathVariable Object
- ISWiPathVariables Collection
- ISWiProject Object
- AddPathVariable Method
- DeletePathVariable Method

Support for Modifying String-Table Entries

The automation interface includes new objects and collections for configuring languages and string entries in a project. The ISWiLanguage object includes two methods and a property that let you add (AddStringEntry) and remove (DeleteStringEntry) a string entry from a project, as well as get the collection of string entries (ISWiStringEntries). In addition, the ISWiProject object includes a new property (ISWiLanguages) that gets the collection of languages included in the current project.

For more information, see:

- ISWiLanguage Object
- ISWiLanguages Collection
- ISWiStringEntry Object
- ISWiStringEntries Collection
- AddStringEntry Method
- DeleteStringEntry Method
- ISWiProject Object

Support for Configuring Environment Variables

The automation interface includes a new object and a new collection for environment variables. In addition, the ISWiComponent object includes two new methods and a property that let you add (AddEnvironmentVar) and remove (RemoveEnvironmentVar) a component's environment variables, as well as get the collection of environment variables (ISWiEnvironmentVars).

- ISWiEnvironmentVar Object
- ISWiEnvironmentVars Collection
- ISWiComponent Object
- AddEnvironmentVar Method
- RemoveEnvironmentVar Method

ISWiProject Object Properties for Setting the Company Name, Company URL, and Company Phone Number

The ISWiProject object includes several new properties that let you specify values for General Information view settings:

- CompanyName
- CompanyURL
- CompanyPhone

ISWiRelease Object Properties for Digitally Signing Files

The ISWiRelease object includes several new properties that enable you to configure settings for digitally signing files for releases at build time. The new properties are:

- CertificatePassword

- SignFiles
- SignFilesExclude
- SignFilesInclude
- SignSignedFiles

ISWiRelease Object Properties for Specifying Whether to Keep Unused Directories in the Directory Table

The ISWiRelease object includes a new KeepUnusedDirectories property that lets you specify whether you want to want InstallShield to remove unused directories from the **Directory** table of the .msi file when you build this release.

ISWiRelease Object Property for Configuring Whether to Postpone Any Reboot for Installing or Updating the .NET Framework

The ISWiRelease object includes a new DotNetDelayReboot property that lets you specify whether you want to postpone any reboot associated with installing or updating the .NET Framework on the target system until after your installation has completed.

ISWiRelease Object Property for Specifying Whether to Display a Message Box Asking the End User if They Want to Install the .NET Framework

The ISWiRelease object includes a new DisplayDotNetOptionDialog property. Use this property to specify if a message box should be displayed at run time to let end users indicate whether the .NET Framework should be installed.

ISWiRelease Object Properties for Configuring Build-Time Distribution Options

The ISWiRelease object now includes several new properties that enable you to configure settings for distributing releases to a folder or FTP site automatically at build time. The new properties are:

- DistributeLoc
- DistributeToURLLoc
- DistributeToURLUserName
- DistributeToURLPassword
- DistributeAfterBuild

New RemoveSequenceRecord Method for the ISWiSequence Collection

The ISWiSequence collection has a new RemoveSequenceRecord method that enables you to delete an item from a sequence. To learn more, see RemoveSequenceRecord Method.

Basic MSI Projects Now Support Adding and Removing Support Files

The automation interface now includes support for the ISWiSetupFile and ISWiAdvancedFile objects in Basic MSI projects. These objects include methods (AddSetupFile, DeleteSetupFile, AddAdvancedFile, and DeleteAdvancedFile) that are now available in Basic MSI projects. Previously, these objects and methods were available in only InstallScript, InstallScript MSI, and InstallScript Object projects.

To learn more, see:

- ISWiAdvancedFile Object
- ISWiAdvancedFiles Collection
- AddAdvancedFile Method
- DeleteAdvancedFile Method
- ISWiSetupFile Object
- ISWiSetupFiles Collection
- AddSetupFile Method
- DeleteSetupFile Method
- ISWiProject Object

XML File Change Enhancements

Support for XML file changes has been expanded in InstallShield:

- Now you can test just the XML file changes that are configured for your project through the XML File Changes view without having to build and run your entire installation.
- The XML File Changes view now supports namespaces in XML files.
- InstallShield lets you specify the XML encoding of an XML file.

To learn more, see the following areas:

- Testing Installation Changes to an XML File
- Testing Uninstallation Changes to an XML File
- Using Namespaces in XML Files
- Declaring Namespace Mappings for an XML File
- Adding a Namespace Prefix to an Element
- XML File Changes View
- Namespace Tab for an XML File

To learn more about XML file changes, see the Modifying XML Files section of the InstallShield Help Library.

Faster Direct Editor, String Table Editor, and Files Subview

Loading records in the Direct Editor and the String Table editor in InstallShield takes less time now. In addition, for projects that contain a large number of files, InstallShield now displays the files in the Files subview within the Components view more quickly than in earlier releases.

Enhanced User Account Control Support for InstallScript Projects

The Required Execution Level setting is now available on the `Setup.exe` tab in the Releases view for InstallScript projects. Use this setting to specify the minimum level required by your installation's `Setup.exe` file for running the installation (the setup launcher) on Windows Vista platforms. InstallShield adds a manifest that specifies the required level.

Previously, InstallShield always included a Highest Available manifest for InstallScript projects, and the Required Execution Level setting was available in only Basic MSI and InstallScript MSI projects.

For more information, see Specifying the Required Execution Level for Your Setup Launcher on Windows Vista and Later Platforms.

Shortcuts View Enhancements

Some enhancements have been made to the Shortcuts view for Basic MSI, InstallScript MSI, and merge module projects.

- To change the icon that is used for a shortcut, you can right-click the shortcut and then click the new **Change Shortcut icon** command. InstallShield opens the Change Icon dialog box, which enables you to select the icon file and associated icon index that should be used when the shortcut is created on target systems at run time.
- Shortcuts that are listed in the Shortcuts explorer now show the icon image that will be used on the target system. Previously, the Shortcuts explorer used a different image for all types of shortcuts, even if an icon was specified for the shortcut.

For more details about these enhancements, see:

- Specifying the Icon for a Shortcut
- Shortcuts View

Windows Vista and Internet Explorer 7 Support for One-Click Install Installations

One-Click Install installations in InstallScript projects can now be used on Windows Vista systems and with Internet Explorer 7. The One-Click Install setup player is now an external .ocx file, instead of being embedded in the `Setup.exe` file. The setup player downloads and then launches the `Setup.exe` file with the appropriate command line. This enables end users who are using Windows Vista with limited privileges to run the installation; if elevated privileges are required because of the required execution level specified in the installation's manifest, the appropriate User Account Control (UAC) prompt is displayed when the `Setup.exe` file is launched.

To support this new behavior, a new Generate One-Click Install setting is available on the Internet tab in the Releases view and on the Internet Options panel in the Release Wizard. If you select Yes for this setting, InstallShield includes an .ocx file for the installation.

To learn more about One-Click Install installations, see the Typical Web Installation vs. One-Click Install section of the documentation. In addition, see the following:

- Internet Tab for a Release
- Internet Options Panel

Enhanced Support for the SecureCustomProperties Property

If you set a public property in the user interface sequence of an installation that requests elevated privileges for the execute sequence, and you want to pass the property's value to the execute sequence, the property must be listed as a value for the **SecureCustomProperties** property, or it must be a restricted public property.

InstallShield now automatically adds to the **SecureCustomProperties** property properties that may need to be passed from the user interface sequence to the execute sequence. To learn more, see Specifying that a Public Property Should Be a Restricted Public Property.

This support applies to Basic MSI, InstallScript MSI, and Merge Module projects.

Automatic Downgrade Prevention Entries in Basic MSI and InstallScript MSI Projects

To prevent end users from being able to install the current version of your product over a future major version of the same product, the following conditions should be met: The Upgrades view should contain a major upgrade item, the major upgrade item should be properly configured to prevent the current version of your product from being installed over a future version, and your project should include a properly configured and scheduled type 19 custom action.

When you create a new Basic MSI or InstallScript MSI project, InstallShield automatically adds support for preventing the current installation from overwriting a future major version. To learn more, see the following:

- Preventing the Current Installation from Overwriting a Future Major Version of the Same Product
- ISICE19

Changes for ALLUSERS and for the CustomerInformation Dialog

Beginning with InstallShield 2008, the **ALLUSERS** property is set to 1 by default in all new Basic MSI projects. This is the recommended implementation, since most installations must be run in a per-machine context with administrative privileges.

If you upgrade a project that was created with InstallShield 12 or earlier to InstallShield 2013, InstallShield does not automatically change the value of the **ALLUSERS** property or add this property if it was not defined in the earlier project.

Also new with InstallShield 2008, by default, the CustomerInformation dialog in all new Basic MSI projects does not display the radio button group that enables end users to specify whether they want to install the product for all users or for only the current user. This is the recommended implementation for this dialog.

If you upgrade a project that was created with InstallShield 12 or earlier to InstallShield 2013, InstallShield does not automatically change the CustomerInformation dialog.

To learn more, see:

- Per-User vs. Per-Machine Installations
- ALLUSERS

Ability to Change the Product Version from the Command Line or Through an MSBuild Task Parameter

The `-y` command-line parameter is available for command-line builds with `ISCmdBld.exe` and `IsSaBld.exe`. Use this parameter to specify a product version from the command line.

In addition, the InstallShield task for MSBuild now includes a ProductVersion parameter, which you can use to specify the product version through MSBuild. This parameter is exposed as the property InstallShieldProductVersion when the default targets file is used.

Using the -y command-line parameter or the InstallShield task ProductVersion parameter is especially helpful if you want to increment the build version (the third field) of the product version.

To learn more, see:

- ISCmdBld.exe
- Standalone Command-Line Build
- Microsoft Build Engine (MSBuild)

Ability to Override Windows Installer Property Values from the Command Line or Through an MSBuild Task Parameter

The -z command-line parameter is available for command-line builds with `ISCmdBld.exe` and `IsSaBld.exe`. Use this parameter to override the value of a Windows Installer property or create the property if it does not exist.

In addition, the InstallShield task for MSBuild now includes a PropertyOverrides parameter, which you can use to override the value of a Windows Installer property or create the property if it does not exist. This property is exposed as the InstallShieldPropertyOverrides ItemGroup passthrough to the PropertyOverrides property on the InstallShield task.

To learn more, see:

- ISCmdBld.exe
- Standalone Command-Line Build
- Microsoft Build Engine (MSBuild)

Windows Installer Properties Used for IIS Data Are Stored in the Registry by Default

Installations that install IIS Web sites and use Windows Installer properties to dynamically set IIS data at run time now write the property and its value to the following registry key:
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\InstallShield Uninstall Information\{ProductCode}

This change was made to make the value available during uninstallation and repair. Therefore, if your Web site is installed to an end user–specified site number, the Web site and its virtual directories can be successfully uninstalled from that site number. If you do not want the IIS data to be stored in the registry, set the **IS_IIS_DO_NOT_USE_REG** property in your project.

This change applies to Basic MSI and InstallScript MSI projects.

New Setting for Specifying Whether an IIS Web Server Should Allow the CMD Command to Be Used for SSI #exec Directives

You can configure an IIS Web server to prevent the CMD command for the #exec directive from being used to execute shell commands, or you can configure it to allow the CMD command to be used to execute this type of command. The SSIEnableCmdDirective registry value for the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters registry key is what determines whether the CMD command is permitted.

The Internet Information Services view in InstallShield includes a new SSIEnableCmdDirective registry value setting. This setting lets you specify how your installation should configure the SSIEnableCmdDirective registry value on target systems. This setting also lets you specify that the SSIEnableCmdDirective registry value should not be changed at installation run time; this is the default behavior.

For more information, see Specifying Whether a Web Server Should Allow the CMD Command to Be Used for SSI #exec Directives.

New Host Header Name Setting for IIS Web Sites

You can now use the new Host Header Name setting on the Web Site tab for a Web site in the Internet Information Services view to specify the host header name that identifies the IIS Web site that is installed during your installation. Previously, it was necessary to configure the ServerBindings property on the Advanced tab in this view in order to specify the host header name.

For more information, see Specifying the IIS Host Header Name for a Web Site.

Ability to Install an IIS Web Site and Its Virtual Directories to the Next Available New Site Number

InstallShield provides support for installing an IIS Web site and its virtual directories to the next available new site number. The implementation is slightly different, depending on which project type you are using. For more information, see Configuring the TCP Port and Site Numbers.

Ability to Specify Whether New SQL Connections Should Share the Same Windows Installer Properties

A new SQL Scripts tab on the Options dialog box lets you specify how InstallShield should create new database connections by default—either by using the same Windows Installer properties that were used by default for the first connection in your project, or by using a unique set of new Windows Installer properties.

This applies to the following project types: Basic MSI and InstallScript MSI.

For more information, see the following:

- Specifying Whether New SQL Connections Should Share the Same Windows Installer Properties
- SQL Scripts Tab

SQLLogin Dialog Enhancements

The SQLLogin dialog now includes a new control that enables end users to specify the name of the target database catalog. This dialog also has a Browse button next to the new control; the Browse button lets end users select from the list of database catalogs that are available on the target database server.

If you upgrade a Basic MSI project that includes SQL support from InstallShield 12 or earlier to InstallShield 2013, you need to manually import the `SQLLogin.isd` and `SQLBrowse.isd` dialogs into your project to use the new version of the SQLLogin dialog. The .isd files are installed in the following location: *`InstallShield Program Files Folder`*`\Support`. To use this updated SQLLogin dialog in InstallScript and InstallScript MSI projects, replace the **SQLServerSelectLogin** function call in your InstallScript code with a call to the new **SQLServerSelectLogin2** function.

Database Import Wizard Enhancements

The Database Import Wizard has a new Advanced Scripting Options panel that lets you specify security script options such as script database, script database users and database roles, script SQL Server logins, and script object-level permissions.

For more information, see Advanced Scripting Options Panel.

New Windows Installer Property for Specifying SQL Connections That Should Not Be Installed or Uninstalled

InstallShield includes support for a new Windows Installer property called **IS_SQLSERVER_CXNS_ABSENT_FROM_INSTALL**. Use this property to specify one or more SQL connections that should be skipped during installation or uninstallation. To specify more than one SQL connection, separate each with a semicolon (;). To skip all of the SQL connections, set the value of this property to `ALL`. Using this property is helpful if you cannot uninstall a product because of a SQL scripting error.

For details about SQL-related properties, see Overriding the Default SQL Run-Time Behavior.

Ability to Remove Unreferenced Directories from the .msi File

The Build tab in the Releases view includes a new Keep Unused Directories setting. Use this setting to specify whether you want InstallShield to remove unused directories from the **Directory** table of the .msi file when you build the selected release. The default value is No.

This setting is available for Basic MSI, InstallScript MSI, and Merge Module projects.

For more information, see Build Tab for a Release.

Ability to Specify COM+ Component File Destinations from Within the Component Services View

The Component Services view has two new Destination fields on the Installation tab: one for a server type of installation, and one for a proxy type of installation. Use these fields to specify the target destination of the selected COM+ component files. Previously, the only way to specify the destination of the components associated with a COM+ application was in the Components view or the Setup Design view.

New Windows Installer Property for Specifying COM+ Applications to Be Installed After the InstallFinalize Action

InstallShield includes support for a new Windows Installer property called **IS_COMPLUS_INSTALL_AT_FINALIZE**. Use this property to specify one or more COM+ applications that should be installed by the ISComponentServiceFinalize action, which is called after the InstallFinalize action. To specify more than one COM+ application, separate each with a semicolon (;). To specify that all COM+ applications should be installed by the ISComponentServiceFinalize action, set the value of this property to `ALL`.

Using this property is helpful if you want to install a COM+ application that contains .NET assemblies to be installed to the GAC because Windows Installer does not commit the changes made in the in-script session to the GAC until the InstallFinalize action.

Additional Predefined System Searches for Basic MSI and InstallScript MSI Projects

InstallShield has several new predefined system searches:

- Adobe Reader 7
- Adobe Reader 6
- Internet Explorer 7.0

If your installation requires any of these products, you can use the System Search view or the Installation Requirements page in the Project Assistant to add these system searches to your project. When end users launch your installation, Windows Installer checks the target system to see if the requirements are met; if they are not met, the installation displays the error message that is defined for the system search.

New and Enhanced Setup.exe and Update.exe Command-Line Parameters (InstallScript Projects)

Two new command-line parameters are available for `Setup.exe` and `Update.exe`:

- `/installfromweb`
- `/media_path`

In addition, the `/L` parameter now supports both hex and decimal language values.

To learn more, see Setup.exe and Update.exe Command-Line Parameters.

Downloader Web Release Type Supports More Location Options for .cab Files

The Downloader type of Web release now lets you specify whether InstallShield should create external .cab files that are downloaded at installation time as needed. Previously, .cab files were always streamed into the .msi package for the Downloader Web release type.

The new external .cab file options are available on the Downloader Options panel of the Release Wizard. This panel is displayed in the Release Wizard if the media type is Web and the Web type is Downloader. The Downloader Options panel has a new Create external .cab files check box. If you clear this check box, the behavior is the same as it was previously: the .cab files are streamed into the .msi package. If you select this check box, you can specify how .cab files should be created: one .cab file per feature, one .cab file per component, or multiple .cab files based on a particular size that you specify.

Downloader and Install from the Web Types of Web Releases Embed All Transforms

The Downloader type of Web release and the Install from the Web type of Web release now always embed all .mst and .ini files in the `Setup.exe` file.

Enhancements for Patch Display Information

The Identification tab, which was previously called the Uninstall tab, is where you specify information that should be displayed for a patch in Add or Remove Programs on systems running Windows Installer 3.0 or later. This tab in the Patch Design view of Basic MSI and InstallScript MSI projects and in the General Information view in

QuickPatch projects has settings for items such as the display name, the manufacturer name, and the support URL. Now every time that you change the latest setup for a patch configuration in the Patch Design view or in a QuickPatch project, InstallShield uses the Add or Remove Programs information from the latest setup as the values for the Identification tab settings. You can override the values on the Identification tab as needed.

In addition, the **Allow Patch to Be Uninstalled (Requires Windows Installer 3.0)** check box is now available on the Common tab. This setting was previously available on the Uninstall tab.

For more information, see:

- Common Tab (in the Patch Design view)
- Identification Tab (in the Patch Design view)
- Common Tab (in a QuickPatch project)
- Identification Tab (in a QuickPatch project)

Ability to Specify the Minimum Initialization Time

InstallShield includes a new Minimum Initialization Time setting on the `Setup.exe` tab for a release in the Releases view. Use this setting to specify the minimum number of seconds that the installation should display the initialization dialog—as well as the splash screen, if one is included—when end users run this release.

InstallScript Language Enhancements and New Functionality

Several enhancements have been made to the InstallScript language.

New LaunchApplication and WaitForApplication Functions to Supersede LaunchAppAndWait for Launching Applications with Elevated Privileges

The **LaunchApplication** function uses either the Windows API function **CreateProcess** or the Windows API function **ShellExecuteEx** to launch the specified application. After the application is launched, the installation can optionally call the new **WaitForApplication** function to wait for the application to terminate.

The **WaitForApplication** function waits for a running application, and optionally all child applications that are launched by the running application, to terminate before returning.

Note that calling **LaunchAppAndWait** now calls the following:

```
LaunchApplication( szProgram, szCmdLine, "", LAAW_STARTUPINFO.wShowWindow, LAAW_PARAMETERS.nTimeOut,
nOptions | LAAW_OPTION_CHANGEDIRECTORY | LAAW_OPTION_FIXUP_PROGRAM );
```

The new **LaunchApplicationInit** function is available. This function, which was added to match the naming convention of the **LaunchApplication** function, has the same behavior as the **LaunchAppAndWaitInitStartupInfo** function.

For more information, see:

- LaunchApplication
- WaitForApplication
- LaunchAppAndWait
- LaunchApplicationInit

Several new predefined constants are available:

- LAAW_OPTION_CHANGEDIRECTORY
- LAAW_OPTION_FIXUP_PROGRAM
- LAAW_OPTION_USE_SHELLEXECUTE
- LAAW_OPTION_WAIT_INCL_CHILD

In addition, the LAAW_OPTION_NO_CHANGEDIRECTORY is now obsolete. Passing this parameter has no effect.

The following script variables are also now available:

- LAAW_SHELLEXECUTEINFO
- LAAW_SHELLEXECUTEVERB

New SdRMFilesInUse Dialog and OnRMFilesInUse Event Handler for Minimizing Reboots Through the Restart Manager Infrastructure in InstallScript MSI Projects

A new **SdRMFilesInUse** function is available. This function displays a dialog that includes a list box containing a list of the applications that are open and are locking files. The dialog also includes two radio buttons that allow end users to specify whether the installation should attempt to use the Restart Manager to shut down the applications that are locking files or overwrite the locked files (which most likely results in the need for a reboot to complete the installation).

For InstallScript MSI projects, the new OnRMFilesInUse event handler displays the new **SdRMFilesInUse** dialog. This event handler is called when the Restart Manager is enabled and Windows Installer 4.0 sends an INSTALLMESSAGE_RMFILESINUSE message to the installation.

For more details, see:

- SdRMFilesInUse
- OnRMFilesInUse

Ability to Specify Additional Compiler Include Paths on a Per-Project Basis

The Compile/Link tab on the Settings dialog box, which is available from the Build menu in InstallShield, now has an Include Paths box. Use this Include Paths box to specify which directories InstallShield should search for source files that have been included in the main installation's InstallScript code through #include statements. It corresponds with the `-i` option for `Compile.exe`, the command-line compiler.

To learn more, see Compile/Link Tab.

Enhancements for .NET Framework 3.0 Support

A new FOLDER_DOTNET_30 InstallScript variable is available. This variable stores the path of the .NET Framework 3.0. The corresponding text substitution for this variable is <FOLDER_DOTNET_30>.

The .NET Framework 3.0 writes the value *InstallSuccess* with value data of 1 to the registry to indicate that it is installed. To check for this InstallSuccess value, you can now use the **Is** function and pass the DOTNETFRAMEWORKINSTALLED constant. You can still pass this constant through the **Is** function to check for the value of *Install*, which is used by earlier versions of the .NET Framework. For more information, see Is.

Two new constants are available for use with the **Is** function:

- REGDB_KEYPATH_DOTNET_30
- REGDB_VALUENAME_INSTALLSUCCESS

New Is Constant for Checking for the Presence of a Minimum Service Pack Number of the .NET Framework

Use the new DOTNETSERVICEPACKINSTALLED constant with the **Is** function to determine whether a particular service pack—or a later version of the service pack—of the .NET Framework is installed. For more information, see Is.

New and Updated Functions for SQL Support

Several InstallScript functions for SQL support have been added or updated.

The following InstallScript functions are now available for InstallScript and InstallScript MSI projects:

- SQLRTInitialize2—Loads the `SQLRT.dll` file for InstallScript projects and the `ISSQLSRV.dll` file for InstallScript MSI projects, and it uses the settings file to initialize the .dll file. This function supersedes the SQLRTInitialize function.
- SQLServerSelectLogin2—Creates a login dialog that lets the targeted end user specify which SQL Server should be used for the current connection, as well as which login credential should be used. This dialog also optionally shows the connection name that is associated with the connection information. In addition, it optionally allows the end user to specify which database catalog should be used for the current connection. This function supersedes the SQLServerSelectLogin function.
- SQLDatabaseBrowse—Creates a dialog that lets the end user display a list of all database catalogs available on the specified database server.
- SQLBrowse2—Creates a dialog that lets an end user display a list of all database servers that are available on the network for the database technologies specified for a connection. This function supersedes the SQLBrowse function.
- SQLRTPutConnectionInfo2—Sets the connection information (the default server, default database catalog, default user name, and default password). This function supersedes the SQLRTPutConnectionInfo function.

The following InstallScript functions are now available for InstallScript projects:

- SQLRTGetLastError2—Returns detailed information about the last error encountered by the SQL run time and loads the proper SQL error message.This function supersedes the SQLRTGetLastError function.
- SQLRTGetErrorMessage—Returns the descriptive message of the last error encountered by the SQL run time when a connection is being opened.
- SQLRTGetScriptErrorMessage—Returns the descriptive message of the last error encountered by the SQL run time when a SQL script is executing.

The following InstallScript function is now available for InstallScript MSI projects:

- SQLRTTestConnection2—Establishes a connection.This function supersedes the SQLRTTestConnection function.

The following InstallScript functions, which were previously available only for InstallScript projects, are now also available for InstallScript MSI projects:

- SQLRTGetConnections
- SQLRTGetConnectionInfo
- SQLRTPutConnectionInfo
- SQLRTGetConnectionAuthentication
- SQLRTPutConnectionAuthentication

InstallShield still supports the functions that are superseded by new versions of the functions. However, if you upgrade a project that was created in InstallShield 12 or earlier to InstallShield 2013, InstallShield does not automatically update the existing InstallScript code to use the new functions.

For more information, see:

- Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects
- SQL Functions

New Is Constant for Checking If a User Is in the Administrators Group

Use the new USER_INADMINGROUP constant with the **Is** function to determine whether a user is in the Administrators group, regardless of whether that user is running the installation with a standard access token. For more information, see Is.

Note that passing the USER_ADMINISTRATOR constant through the **Is** function now returns FALSE if the user is in the Administrators group but the group has the SE_GROUP_USE_FOR_DENY_ONLY security identifier (SID) attribute set (that is, the user is running with a standard access token).

New Functions that Enable a .NET Library Loaded Through InstallScript to Be Unloaded Before the Installation Completes

Two new InstallScript functions are available: DotNetCoCreateObject and DotNetUnloadAppDomain.

- The **DotNetCoCreateObject** function calls functions in .NET assemblies without the assembly being registered for COM interoperability. This function lets you specify the .NET application domain in which the .NET assemblies should be loaded and run.

  The **DotNetCoCreateObject** function is similar to the CoCreateObjectDotNet function. The only difference is that with **DotNetCoCreateObject**, you can specify the .NET application domain that should be loaded; the assembly is then run in this domain.

  For **CoCreateObjectDotNet**, the .NET assembly is loaded into the default application domain after the installation completes; thus, the .NET assembly file is locked until the installation has finished.

- The **DotNetUnloadAppDomain** function unloads the specified .NET application domain and releases any assemblies that are currently loaded into the specified application domain.

New RegDBDeleteItem Function

A new InstallScript function called RegDBDeleteItem is now available. The **RegDBDeleteItem** function deletes values under the per application paths key or the application uninstallation key, depending on the value of nItem. For more information, see RegDBDeleteItem.

New GetStatus Function for Objects

A new InstallScript function called **GetStatus** is now available for InstallScript Object projects. The **GetStatus** function retrieves the current status of the object; that is, the current value of Status.Number. For more information, see GetStatus.

Changes to the ListWriteToFileEx Function and Related Constants

The LWTF_OPTION_APPEND_TO_FILE constant has been added to the InstallScript language. You can pass this constant as the nOptions parameter for the **ListWriteToFileEx** function to append a list to an existing file.

In addition, two existing nOptions constants have been renamed:

- LWFT_OPTION_WRITE_AS_ANSI is now LWTF_OPTION_WRITE_AS_ANSI.
- LWFT_OPTION_WRITE_AS_UNICODE is now LWTF_OPTION_WRITE_AS_UNICODE.

To maintain backwards compatibility, the aforementioned two LWFT_* constants are still available, and they are defined the same way as the corresponding new LWTF_* constants.

For more information, see the following:

- ListWriteToFileEx
- LWTF_OPTION_APPEND_TO_FILE
- LWTF_OPTION_WRITE_AS_ANSI
- LWTF_OPTION_WRITE_AS_UNICODE

Expanded InstallScript Text Substitution Functionality

An InstallScript text-substitution association can now be embedded in another text-substitution association; for example, "<MYTEXTSUB1>" can be associated with "My Text Sub 1 Value" and "<MYTEXTSUB2>" with "Text Sub <MYTEXTSUB1> Embedded". Previously, if a local text-substitution association was embedded in a global text-substitution association, the local text substitution was not performed.

What's New in InstallShield 12 SP1

InstallShield 12 supports a beta version of Microsoft Windows Vista. InstallShield 12 SP1 includes changes that offer support for the RTM version of Microsoft Windows Vista.

New Microsoft .NET 3.0 Prerequisite Available

InstallShield now includes a .NET Framework 3.0 setup prerequisite that you can add to Basic MSI and InstallScript MSI projects.

To learn more about setup prerequisites, see Adding InstallShield Prerequisites, Merge Modules, and Objects to Basic MSI and InstallScript MSI Projects.

Ability to Minimize the Number of UAC Prompts by Advertising as Part of Prerequisite Installation

Use the new Advertise If Prerequisites Are Elevated setting in the Releases view to specify whether your .msi file should be advertised and run after the setup prerequisites in the installation have been successfully installed with elevated privileges on Windows Vista machines. The advertisement may allow end users to avoid the User Account Control (UAC) prompt that would otherwise be displayed for an .msi package that requires elevated privileges. For more information, see Specifying Whether a Product Should Be Advertised If Its InstallShield Prerequisites Are Run with Elevated Privileges.

The Advertise If Prerequisites Are Elevated setting is one of several settings in InstallShield that affect whether an installation triggers UAC consent or credential prompts for elevated privileges. Understanding these different settings will help you create the appropriate UAC experience for your installation when end users run it on Windows Vista systems. It will also enable you to try to minimize the number of UAC prompts that are displayed during your installation. To learn about all of these settings, see Minimizing the Number of User Account Control Prompts During Installation.

Enhanced Validation for the Certified for Windows Vista Program

InstallShield includes several new InstallShield internal consistency evaluators (ISICEs) that help you ensure that your installation follows the best practices outlined in the Certified for Windows Vista program. The new evaluators—ISICE11 through ISICE20—check that all .exe files have embedded manifests, that none of the protected registry keys have been modified, that the .dll and .exe files do not use any obsolete API calls, and more. In addition, ISICE02 now verifies that .ocx, .sys, .cpl, .drv, and .scr files are signed. Previously, ISICE02 verified only that .exe files are signed. ISICE06 now checks the destination path of files that are in your installation and that have the same name as a Windows Protected File. If the destination path for the file in your installation does not match the location of the Windows Protected File, ISICE06 now displays a validation warning instead of a validation error.

When you validate your package, InstallShield lists any validation messages on the Tasks tab of the Output window. Now you can double-click a validation message on the Tasks tab to jump to the area of the Direct Editor that corresponds to the validation message. This functionality is available for ISICEs, as well as for standard ICEs. Previously, it was available only for standard ICEs.

For more information, see:

- ISICEs
- Viewing Validation Results

Additional Changes

For a list of issues that are resolved in InstallShield 12 SP1, see the release notes. The release notes are available from the Help menu in InstallShield.

What's New in InstallShield 12

New Features

InstallShield includes the following new features.

Ability to Target Windows Vista Systems

InstallShield enables you to specify that your installation requires Windows Vista. It also lets you build Windows Vista–related conditions for features and components.

Validation for the Certified for Windows Vista Program

To provide the best possible installation experience for end users, ensure that your installation follows the best practices outlined in the Certified for Windows Vista program. InstallShield now includes a validation suite that helps you verify that your installation meets the installation requirements of the Certified for Windows Vista program for Basic MSI and InstallScript MSI projects. If you want to be able to use the Windows Vista Logo artwork, your application's installation must meet the program's requirements.

In addition, InstallShield now lets you customize the list of internal consistency evaluators (ICEs) that should be used for installation package validation and merge module validation. This is helpful if you do not want to pursue logo certification but you still want to ensure that your installation or merge module meets specific best practices that are verified during validation. To configure validation settings: on the Tools menu, click Options and select the Validation tab.

To learn more, see the following:

- Specifying Whether Validation Should Be Performed at Build Time
- Specifying Which ICEs, ISICEs, ISVICEs and ISBPs Should Be Run During Validation
- ISICEs

User Account Control Support

InstallShield includes support for the User Account Control functionality that Microsoft added for Windows Vista. Use the new Require Administrative Privileges setting in the General Information view to specify at a project-wide basis whether administrative privileges are required for an installation. Also, use the Required Execution Level setting in the Releases view to specify the minimum level required by your installation's `Setup.exe` file for running the installation (the setup launcher, any setup prerequisites, and the .msi file) on Windows Vista platforms.

For details, see:

- Entering Summary Information Stream Data
- Specifying the Required Execution Level for Your Setup Launcher on Windows Vista and Later Platforms

Support for Minimizing Reboots Through the Restart Manager Infrastructure

Restarting the system after an installation is inconvenient for end users. One of the Certified for Windows Vista program requirements is that all installations must contain an option that enables end users to automatically close applications and attempt to restart them after the installation is complete.

To support this quality guideline, an MsiRMFilesInUse dialog is available in all Basic MSI projects. The installation displays this dialog if one or more files that needs to be updated are currently in use during the installation. To learn more, see Minimizing Reboots on Windows Vista and Later Systems.

Digital Signature Enhancements

If you specify digital signature information for your installation, InstallShield automatically adds the necessary information to the **MsiDigitalCertificate** and **MsiPatchCertificate** tables. The **MsiPatchCertificate** table contains the information that is needed to enable User Account Control (UAC) patching. This enables you to create patches that can be installed by non-administrators.

In addition, the Build Installation page in the Project Assistant now offers the ability to specify digital signature information for your installation.

For more information, see:

- Preparing Installations for Non-Administrator Patches
- Digital Signing and Security

Support for Documentation about Custom Action Behavior

The intended behavior of each custom action must be documented for the Certified for Windows Vista program. This is especially helpful if system administrators deploy your product to enterprise environments; they sometimes need to know what the custom actions do. InstallShield now has a new Help File Path setting in the Custom Actions view to help you meet this requirement. Use this setting to specify the path of a document that describes the behavior of a custom action that you create for your project. For details, see:

- Documenting the Behavior of Custom Actions
- Guidelines for Creating Custom Actions that Meet Requirements of the Windows Logo Program

This documentation now describes each of the built-in InstallShield custom actions that are added automatically to InstallShield projects to support different functionality. See InstallShield Custom Action Reference.

Setup Prerequisite Enhancements

Many enhancements have been made to the Setup Prerequisite Editor:

- The user interface has been improved; it now has menus that list easy-to-access commands.
- The new Behavior tab lets you specify whether end users may skip the prerequisite installation. You can also specify how the prerequisite installation should proceed if it appears that the target machine does or does not need to be restarted.
- Now you can create prerequisite installation conditions for DWORD registry comparisons. You can also create conditions for 64-bit machines.

For more details, see:

- Behavior Tab
- Allowing End Users to Choose Whether to Install an InstallShield Prerequisite
- Planning for Issues that Could Occur with an InstallShield Prerequisite Installation

- Specifying the Behavior for an InstallShield Prerequisite that Requires a Restart

Redistributing setup prerequisites is now more flexible than ever. You can specify different methods for supplying each individual setup prerequisite in your installation. This enables you to store some of the setup prerequisite files on the source media; compress some of the setup prerequisite files into `Setup.exe`, to be extracted at run time; and download some of the setup prerequisite files. In addition, you can now assign release flags to setup prerequisites. Then you can include and exclude any combinations of setup prerequisites when you build different releases.

To learn more, see:

- Specifying a Run-Time Location for a Specific InstallShield Prerequisite
- Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level
- Assigning Release Flags to InstallShield Prerequisites

Windows Installer 4.0 Log File Support on a Project-Wide Basis

InstallShield provides support for the option to easily log installations run with Windows Installer 4.0 on a project-wide basis without having to use the command line or configure log parameters through the registry. To enable logging, specify Yes in the new Create MSI Logs setting in the General Information view. To override the default logging parameters, edit the **MsiLogging** property in the Property Manager view. If the installation is run on a target system that has Windows Installer 4.0, the installer creates a log file and populates the **MsiLogFileLocation** property with its path. In addition, a **Show the Windows Installer log** check box is added to the SetupCompleteSuccess, SetupCompleteError, and SetupInterrupted dialogs.

For more information, see Specifying Whether Windows Installer Installations Should Be Logged.

Registry Reflection Support for 64-Bit Systems

InstallShield includes support for the new Windows Installer 4.0 attribute called msidbComponentAttributesDisableRegistryReflection in the **Component** table. To easily configure this attribute, set the Disable Registry Reflection setting for a selected component in the Components view. Registry reflection keeps the 32-bit registry view and the 64-bit registry view in sync on a target machine. Only 64-bit systems with Windows Installer 4.0 support this setting. Other systems ignore it. For more specific information, see Enabling and Disabling Registry Reflection.

Multilingual User Interface (MUI) Support

If you are preparing an installation for a multilingual application and Windows Installer 4.0 will be running the installation, you can now use InstallShield to create shortcuts that include support for the Windows multilingual user interface (MUI). Four new settings are available in the Shortcuts view for a selected shortcut:

- Display Resource DLL
- Display Resource ID
- Description Resource DLL
- Description Resource ID

These new settings correspond with the four new columns in the **Shortcut** table for Windows Installer 4.0. To learn more, see Shortcuts View.

Additional InstallShield Collaboration Licenses for Premier Edition

InstallShield Premier Edition now includes a five-pack of licenses for InstallShield Collaboration for Visual Studio. You can use these licenses to install InstallShield Collaboration on development systems that do not have InstallShield but do have Visual Studio .NET 2002, Visual Studio .NET 2003, or Visual Studio 2005.

InstallScript Rearchitecture Enhancements for InstallScript MSI Projects and Basic MSI Projects with InstallScript Custom Actions

The InstallScript MSI architecture has had a number of issues with security (COM/DCOM) and other areas that can cause some installations to fail for various reasons. The architecture has been improved dramatically for InstallShield 12 to resolve these issues and to make InstallScript MSI a more reliable project type. The improvements also help increase the reliability of Basic MSI projects that include InstallScript custom actions.

To learn more, see the following:

- Run-Time Behavior for Basic MSI Installations with InstallScript Custom Actions
- Run-Time Behavior for InstallScript MSI Installations
- Upgrading Projects from InstallShield 11.5 or Earlier

DIFx 2.01 Support

InstallShield includes support for the latest version of Driver Install Frameworks for Applications (DIFx). This new version, which includes the latest binary files from Microsoft, is available for any Basic MSI, InstallScript, or InstallScript MSI projects that you create in InstallShield.

Enhancements for Setup.exe and Update.exe Command-Line Parameters

Some of the command-line parameters for `Setup.exe` and `Update.exe` were added or modified:

- `/clone_wait` (InstallScript only)
- `/runfromtemp` (Basic MSI, InstallScript, and InstallScript MSI)
- `/v"ISSCRIPTCMDLINE=\"<Option1> <Option2>\""` (Basic MSI only)
- /hide_progress (Basic MSI, InstallScript, and InstallScript MSI projects)
- /hide_splash (InstallScript and InstallScript MSI projects)

For more information, see Setup.exe and Update.exe Command-Line Parameters.

Registry and File Filtering Enhancements for COM Extraction and Dependency Scanners

To prevent InstallShield from extracting undesired COM data from a COM server, you can edit a new `Filters.xml` file that is installed with InstallShield. Editing this `Filters.xml` file enables you to customize the list of registry keys that will be excluded from COM extraction.

The `Filters.xml` file also now lists files that the Static, Dynamic, and Visual Basic dependency scanners will exclude or include. Previously, two different files—`Userscan.ini` and `Iswiscan.ini`—were used to list excluded and included files.

For more information, see:

- Filtering Registry Changes for COM Extraction
- Filtering Files in Dependency Scanners

Internet Explorer 7.0 Compatibility

Several areas of InstallShield have been revised so that it is now compatible with Internet Explorer 7.0. The Transform Wizard, Custom Action Wizard, the String Table Editor, the Distribute view, and the General Information view are all examples of areas that have been updated.

Enhanced Start Page

The list of recently opened projects that are displayed on the Start Page now includes a column that shows the project type. In addition, the maximum number of projects that are listed has been increased from four to eight.

InstallScript Enhancements and New Functionality

Several enhancements have been made to the InstallScript language. New and revised variables, functions, and constants are now available.

System Variable Changes and Text Substitution Additions

A system variable called DISK1SETUPEXENAME has been added.

Two system variables have new default values:

- UNINST
- UNINSTALL_STRING

Two new InstallScript text substitutions are available:

- DISK1SETUPEXENAME
- SELECTED_LANGUAGE

For more information, see System Variables.

Script Variable Additions

Two new script variables are available:

- INSTALLSCRIPTMSI
- BASICMSI

Function and Predefined Constant Changes

A new LANGUAGE_SUPPORTED predefined constant is available for use with the **Is** function. To learn more, see Is.

A new ISOSL_WINVISTA predefined constant is available for use with the **FeatureFilterOS** function and the SYSINFO structure variable. For more information, see FeatureFilterOS function and the SYSINFO.

The **DoInstall** function is now similar to the **LaunchAppAndWait** function. For more details, see DoInstall.

Upgrade Details

For InstallShield 12, a number of improvements were made to the InstallScript MSI architecture to resolve issues with security (COM/DCOM) and other areas that can cause some installations to fail for various reasons. The architecture was improved for InstallShield 12 to resolve these issues and to make InstallScript MSI a more reliable project type. The improvements also help increase the reliability of InstallScript projects, as well as Basic MSI projects that include InstallScript custom actions.

In addition, the merge module project type has been enhanced: it now has the same InstallScript view that is available in Basic MSI projects. This enhanced version of the merge module project type replaces the InstallScript MSI object project type, which is no longer available in InstallShield.

To learn more, see Upgrading Projects from InstallShield 11.5 or Earlier.

Target System Requirements

You can use InstallShield to rapidly build, test, and deploy installations that target Windows-based systems.

Requirements For Desktop Computers

Operating System

Target systems must meet the following minimum operating system requirement:

- Windows XP (Windows XP SP3 for Advanced UI and Suite/Advanced UI installations)
- Windows Server 2003 (Windows Server 2003 for Advanced UI and Suite/Advanced UI installations)
- Windows Vista
- Windows Server 2008
- Windows 7
- Windows Server 2008 R2
- Windows 8
- Windows Server 2012

Installer Engine Requirements

The minimum target system requirements for the various installer engines are as follows.

Table 1-2 • Target System Requirements for Desktop Computers

Installer Engine	Operating System and Other Requirements
Windows Installer 5.0 **(This is not available as a redistributable.)**	Windows 7 or later, Windows Server 2008 R2 or later

Table 1-2 • Target System Requirements for Desktop Computers

Installer Engine	Operating System and Other Requirements
Windows Installer 4.5	Windows XP SP2 or later, Windows Server 2003 SP1 or later
Windows Installer 4.0 **(This is not available as a redistributable.)**	Windows Vista, Windows Server 2008
Windows Installer 3.1	Windows 2000 SP3 or later, Windows Server 2003 or later
Windows Installer 3.0	Windows 2000 SP3 or later, Windows Server 2003 or later
Windows Installer 2.0	Windows 95 or later (Note that InstallShield does not include support for Windows 95, Windows 98, Windows NT 4, or Windows Me.)
Suite/Advanced UI	Windows XP SP3 or later, Windows Server 2003 SP2 or later
Advanced UI	Windows XP SP3 or later, Windows Server 2003 SP2 or later
InstallScript	Windows XP or later, Windows Server 2003 or later

For more information about Windows Installer redistributables, see Adding Windows Installer Redistributables to Projects.

Targeting 64-Bit Operating Systems

Microsoft designed 64-bit versions of Windows to allow existing 32-bit applications to continue to work seamlessly. They also designed 64-bit versions of Windows in such a way to allow a recompiled version of the same code to work seamlessly as a 64-bit application. To provide this support, 64-bit versions of Windows isolate the 32-bit and 64-bit from each other in two main ways: their files are stored in separate locations (Program Files vs. Program Files (x86); System32 vs. SysWow64), and their registry keys are separated (HKLM\Software vs. HKLM\Software\Wow6432Node).

In some cases, such as installation, what is normally a beneficial separation becomes a challenge. Typically installations are 32-bit applications themselves (in order to run on 32-bit machines), and accessing 64-bit locations to install a 64-bit application is more complex than a standard file copy or registry write. Each project type that is available in InstallShield handles this complexity in different ways.

Windows Installer–based installations disallow access to 64-bit locations except when the installation targets only 64-bit systems; however, they support running 64-bit DLL code whenever running on a 64-bit system. Note that some target systems—such as Windows Server Core systems—may not have 32-bit Windows-on-Windows (WOW64) support. InstallShield lets you create pure 64-bit installations that work on those systems. For more information, see Targeting 64-Bit Operating Systems with Basic MSI and InstallScript MSI Installations.

InstallScript installations are always 32 bit so they can run only 32-bit DLL code (or launch 32-bit or 64-bit .exe files). However, all InstallScript installations support accessing 64-bit locations through the 64-bit component setting, as well as through other methods. For additional details, see Targeting 64-Bit Operating Systems with InstallScript Installations.

Suite/Advanced UI and Advanced UI installations enable you to reference either 32-bit or 64-bit locations, and they can launch 32-bit or 64-bit installations, depending on the target system. However, all extension DLL code in a Suite/Advanced UI or Advanced UI project must be 32 bit. To learn more, see Targeting 64-Bit Operating Systems with Suite/Advanced UI and Advanced UI Installations.

Targeting 64-Bit Operating Systems with Basic MSI and InstallScript MSI Installations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Note that if you create an InstallScript MSI project and change the Template Summary property from Intel to x64, InstallShield creates a 64-bit MSI installation combined with a 32-bit InstallScript MSI installation at build time.

Also note that InstallScript MSI projects do not have support for architecture validation.

If you are writing applications for 64-bit Windows-based systems, you will need a way to install your 64-bit files and other data. Although 32-bit Windows Installer–based installations can run on most 64-bit machines, they cannot install to 64-bit locations. The Windows Installer service provides support for 64-bit installations. These installations can be designed and built on 32-bit machines, but they can run only on 64-bit machines. Through the use of release flags, you can build two installations (one 32 bit and one 64 bit) from a single project.

Configuring the Template Summary Property

The Template Summary property determines whether an .msi package is a 32-bit package or a 64-bit package.

If your installation targets 64-bit systems, configure the Template Summary property with the appropriate 64-bit value (x64 or Intel64). This allows end users to install your product in 64-bit locations on 64-bit systems; it also prevents end users from installing your product on 32-bit systems.

You can use the Template Summary setting in the General Information view to configure the Template Summary property. You can also set the Template Summary setting for a product configuration in the Releases view. Any value entered in the Releases view overrides the value set in the General Information view.

To learn more, see Using the Template Summary Property.

Creating 64-Bit Components

To specify that a component is 64 bit, select Yes for the component's 64-Bit Component setting. If you build a release that has at least one 64-bit component and the Template Summary property is set to a 64-bit value, the result is a 64-bit package.

For more information about the 64-Bit Component setting, as well as additional component settings, see Component Settings.

Extracting COM Data from 64-Bit COM Servers

If you are using InstallShield on a 64-bit operating system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit.

Note that if you use InstallShield on a 32-bit system, 64-bit COM extraction is not available.

To learn about extracting COM data, see Extracting COM Information from a COM Server.

Self-Registering 64-Bit COM Servers

InstallShield supports 64-bit self-registration of COM servers. If you mark a component as 64 bit and then add a file to that component, you can select the file's Self Register check box to enable 64-bit self-registration of that file during installation. The Self Register check box is on the file's Properties dialog box.

InstallShield also supports 64-bit self-registration of dynamically linked COM servers. To enable this, select the **Self-Register all files** check box on the Dynamic File Link Settings dialog box when you add the files dynamically to a 64-bit component. For more information, see Adding Dynamic File Links to Components.

Enabling or Disabling Registry Reflection

InstallShield includes support for the Windows Installer 4.0 and later attribute msidbComponentAttributesDisableRegistryReflection in the **Component** table. To use this attribute, set the Disable Registry Reflection setting for a selected component in the Components view to Yes. Registry reflection keeps the 32-bit registry view and the 64-bit registry view in sync on a target machine. Only 64-bit systems with Windows Installer 4.0 and later support this setting. Other systems ignore it. For more specific information, see Enabling and Disabling Registry Reflection.

Adding Other 64-Bit Elements

InstallShield includes support for additional 64-bit elements. For example, InstallShield includes 64-bit .NET Framework redistributables that you can add to your project. Custom actions can include 64-bit JScript or VBScript code, and 64-bit folder properties give you access to essential operating system folders such as the 64-bit Program Files folder. In addition, you can use the Setup Prerequisite Editor to configure setup prerequisites that have conditions that check for 64-bit requirements on the target system.

Note • *64-bit support requires Windows Installer version 2.0 or later.*

Specifying the Appropriate Architecture Validation

Basic MSI projects include a product configuration setting that lets you specify whether you want to use architecture validation at build time. Architecture validation enables you to detect potentially problematic cases in which your installation may try to install product files or use run-time binaries that may not match the architecture of a target system.

For example, if end users may run your installation on 64-bit Windows Server Core systems that do not have 32-bit Windows-on-Windows (WOW64) support, architecture validation can help you identify any 32-bit product files or 32-bit custom action files in your installation; 32-bit binaries cannot be loaded on 64-bit target systems without WOW64 support.

Architecture validation also enables you to generate pure 32-bit .msi packages that contain only 32-bit versions of the built-in InstallShield custom action DLLs, or pure 64-bit .msi packages that contain only 64-bit versions of the built-in InstallShield custom action DLLs.

To specify what type of architecture validation you want to use at build time and identify whether you want to build a pure 32-bit or 64-bit package, use the Architecture Validation setting for a product configuration in the Releases view.

For more details, see Selecting the Appropriate Type of Architecture Validation for Builds.

Tips for Building Two Installations—One 32 Bit and One 64 Bit—from a Single Project

If you want to be able to build two installations (one 32 bit and one 64 bit) from a single project, consider using release flags. You can assign release flags to features, InstallShield prerequisites, and chained .msi packages, as necessary, to differentiate the 32-bit items from the 64-bit items. Then you can configure each release or product configuration in the Releases view to include or exclude certain items that have a particular release flag at build time. You can also conditionally launch certain custom actions based on release flags, so that 32-bit custom actions are launched during a 32-bit installation and 64-bit custom actions are launched during a 64-bit installation.

To learn more, see:

- Release Flags
- Filtering Based on Release Flags
- Conditionally Launching Custom Actions Based on Release Flags

InstallShield lets you override the values of your project's path variables for each release in your project. This functionality enables you to essentially replace certain files and folders in your project with others at build time, depending on the particular release that you are building.

For example, you might use this functionality to swap out the binaries for custom actions. If you have set up separate releases for 32-bit and 64-bit target systems, you can override the path variable that is used to refer to the DLL that is selected for a custom action. Then InstallShield could include a 32-bit DLL for your 32-bit release and a 64-bit DLL for you 64-bit release. Note that overriding path variables to swap out files that your installation is installing is not recommended. This is because you should use separate components for 32-bit and 64-bit versions of a file.

To override one or more path variables in your project, use the Path Variables Overrides setting, which is on the Build tab for a release in the Releases view. For more information, see Build Tab for a Release.

Targeting 64-Bit Operating Systems with InstallScript Installations

Project • *This information applies to InstallScript projects.*

With a single InstallScript project, you can create one installation that installs to 32-bit locations on 32-bit systems, and to 64-bit and 32-bit locations as needed on 64-bit systems.

InstallScript installations are always 32-bit so they can run only 32-bit DLL code (or launch 32-bit or 64-bit .exe files). However, all InstallScript installations support accessing 64-bit locations through the 64-bit component setting, as well as through other methods.

Reading from and Writing to the 64-Bit System32 Folder

InstallScript includes the following system variables that let you choose between 32-bit and 64-bit System32 folders on target systems:

- WINSYSDIR
- WINSYSDIR64

Although the WINSYSDIR64 variable is set to the 64-bit Windows folder, 64-bit Windows includes functionality to automatically redirect 32-bit applications (such as the InstallScript engine) to the 32-bit System32 folder (SysWOW64). Therefore, if you are installing files or folders to WINSYSDIR64, you can disable file system redirection by placing the folders or files in a component that is marked as 64 bit. To specify that a component is 64 bit, select Yes for the component's 64-Bit Component setting. For more information about the 64-Bit Component setting, as well as additional component settings, see Component Settings.

As an alternative, you can use the constant WOW64FSREDIRECTION with the functions Disable and Enable to disable 64-bit Windows file system redirection while writing to or reading from the WINSYSDIR64 folder through your InstallScript code, and then re-enable it once the write or read is complete. Since some Windows functionality that could be used by the installation requires that redirection be enabled to work, Windows documentation recommends that you disable redirection only for as long as necessary.

Reading from and Writing to Other 64-Bit Destination Folders

InstallScript includes several addition system variables that let you choose between other 32-bit and 64-bit locations on target systems:

- COMMONFILES
- COMMONFILES64
- FOLDER_APPLICATIONS
- FOLDER_APPLICATIONS64
- PROGRAMFILES
- PROGRAMFILES64

Reading from and Writing to 64-Bit Registry Locations

The 64-bit version of Windows includes functionality that maps some 64-bit registry locations to 32-bit equivalents. For example, on a 64-bit version of Windows, HKEY_LOCAL_MACHINE\Software\Wow6432Node is the 32-bit equivalent of HKEY_LOCAL_MACHINE\Software.

If you want to install registry data to a 64-bit area of the registry without having it redirected to a 32-bit area, you can place the registry data in a component that is marked as 64 bit. To specify that a component is 64 bit, select Yes for the component's 64-Bit Component setting. For more information about the 64-Bit Component setting, as well as additional component settings, see Component Settings.

As an alternative, you can use the REGDB_OPTION_WOW64_64KEY option with the REGDB_OPTIONS variable to avoid registry redirection while editing the registry or reading from the registry through your InstallScript code, and then use the REGDB_OPTION_USE_DEFAULT_OPTIONS option with REGDB_OPTIONS to enable changes to the 32-bit area of the registry. Since some Windows functionality that could be used by the installation requires that redirection be enabled to work, Windows documentation recommends that you disable redirection only for as long as necessary.

Installing Self-Registering 64-Bit COM Servers

InstallShield supports 64-bit self-registration of COM servers. For the component that contains the self-registering DLL, .exe, .tlb, or .olb file, select Yes for the component's Self-Register setting.

Note that 32-bit self-registering files should not be installed to the 64-bit System32 folder, since file system redirection cannot be disabled for self-registration. Thus, if you have a 32-bit self-registering COM server that needs to be installed to the 32-bit System32 folder, ensure that No is selected for the 64-Bit Component setting of the component that contains the COM server.

About Add or Remove Programs Information

InstallScript installations do not support reading or writing Add or Remove Programs information in the 64-bit part of the registry. Therefore, InstallScript installations always install Add or Remove Programs information in the 32-bit part of the registry. In addition, the REGDB_OPTION_WOW64_64KEY option does not disable registry reflection for registry functions such as **CreateInstallationInfo**, **MaintenanceStart**, **RegDBGetItem**, **RegDBSetItem**, **RegDBGetAppInfo**, **RegDBSetAppInfo**, and **RegGetUninstCmdLine**.

Targeting 64-Bit Operating Systems with Suite/Advanced UI and Advanced UI Installations

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Note that Suite/Advanced UI and Advanced UI installations are always 32-bit. Therefore, they can run 32-bit DLL code, but they cannot run 64-bit DLL code.

Suite/Advanced UI and Advanced UI installations enable you to reference either 32-bit or 64-bit locations, and they can launch 32-bit or 64-bit installations, depending on the target system.

For example, if you include in your Suite/Advanced UI project one installation that should target 32-bit systems, and another installation that should target 64-bit systems, you could create an eligibility condition in the Packages view for both of these packages; for the 32-bit package, the eligibility condition would contain a platform condition that checks for the x86 architecture, and for the 64-bit package the eligibility condition would contain a platform condition that checks for the x64 or IA64 architecture. For more information, see Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects.

Launching InstallShield with vs. Without Administrative Privileges

If you launch InstallShield without administrative privileges, the following functionality is not available:

- **COM extraction**—Extracting COM information from a COM server requires administrative privileges.

  If you specify that you want to have COM information extracted from a COM server in your project, and then you try to build a release while running InstallShield without administrative privileges, build error -6017 occurs.

- **Redistributable downloading**—Downloading redistributables from within the Redistributables view requires administrative privileges. This is because InstallShield tries to download the files to a per-machine location, which requires administrative privileges.

  If you try to download a redistributable from within the Redistributables view but you do not have administrative privileges, InstallShield displays the following message:

  ```
  The download failed; make sure you are running as Administrator, and that your machine
      is connected to the Internet. Would you like to try again?
  ```

- **Ability to specify All Users locations for InstallShield prerequisites**—The Prerequisites tab on the Options dialog box is where you specify the folders that contain the InstallShield prerequisites that should be displayed in the Redistributables view and the Prerequisites view. Modifying the All Users location on that tab requires administrative privileges, since InstallShield writes the information to a per-machine location in the registry. Therefore, the All Users location on that tab is disabled if you are running InstallShield without administrative privileges.

- **Ability to specify All Users locations for merge modules**—The Merge Module tab on the Options dialog box is where you specify the folders that contain the merge modules that should be displayed in the Redistributables view. Modifying the All Users location on that tab requires administrative privileges, since InstallShield writes the information to a per-machine location in the registry. Therefore, the All Users location on that tab is disabled if you are running InstallShield without administrative privileges.

- **Ability to edit the locations for Regasm.exe and InstallUtilLib.dll**—The .NET tab on the Options dialog box is where you specify the locations of `Regasm.exe` and `InstallUtilLib.dll` files, which are utilities that are included with the .NET Framework. These utilities are used for COM interop and .NET custom actions. Modifying these locations on the .NET tab requires administrative privileges, since InstallShield writes the information to a per-machine location in the registry. Therefore, these location settings on that tab are disabled if you are running InstallShield without administrative privileges.

- **Ability to specify the frequency for checking for InstallShield updates**—The **Check for software updates** option on the Updates tab of the Options dialog box is where you specify how often you want InstallShield to check for software updates. Modifying the frequency on that tab requires administrative privileges, since InstallShield writes the information to a per-machine location in the registry. Therefore, the **Check for software updates** option on that tab is disabled if you are running InstallShield without administrative privileges.

If you switch between full Administrator and non-Administrator contexts and you use mapped-drive locations in your projects, you may encounter issues. For example, if you map a drive letter to a shared network folder through Windows Explorer without administrative privileges, you can access this drive letter in a non-administrative instance of InstallShield, but not in an administrative instance. Likewise, if you map a drive letter to a shared network folder through Windows Explorer with administrative privileges, you can access this location in an administrative instance of InstallShield, but not in a non-administrative instance. Thus, if you want to reference network locations in your project, consider using UNC paths (such as \\server\share) or mapping drive letters both with and without administrative privileges.

Note that if you are using InstallShield from within Visual Studio, you may not have administrative privileges. By default, if you launch Visual Studio by double-clicking its shortcut on a Windows Vista or later system, you will not have administrative privileges.

Task: ***To run InstallShield from within Visual Studio with administrative privileges on a Windows Vista or later system:***

1. On the Start Menu, right-click the Visual Studio shortcut and then click **Run as administrator**.
2. Create a new InstallShield project or open an existing one. For more information, see one of the following:
   - Creating InstallShield Projects in Microsoft Visual Studio
   - Opening InstallShield Projects in Microsoft Visual Studio

Developing and Building Installations on 32-Bit vs. 64-Bit Systems

InstallShield is a 32-bit application that runs on both 32-bit and 64-bit systems. In some cases, InstallShield behaves differently, depending on whether you are using it on a 32-bit system or a 64-bit system; you may also encounter differences depending on which operating system you are using. The following sections explain these differences.

Note that like InstallShield, the command-line build (`ISCmdBld.exe`), the Standalone Build, and the automation interface are also 32-bit applications. Therefore, the same platform-specific differences occur for these tools.

Loading the Automation Interface

The automation interface is a 32-bit interface; therefore, it must be loaded from a 32-bit process. If you are using the automation interface on a 64-bit machine, you may need to load the automation interface through a 32-bit executable file. Otherwise, you may encounter errors.

For more information, see Using the Automation Interface on a 64-Bit System.

Adding System Files to Your Project

If you are using InstallShield on a 64-bit system and you want to manually add to your project a system file that is located in the 64-bit System folder (System32) on your development machine, consider using the Components view or the Setup Design view instead of the Files and Folders view. On 64-bit systems, the System32 folder is reserved for 64-bit applications. When you try to view your development machine's 64-bit System folder from within the Files and Folders view in InstallShield, Windows redirects the view to instead display the SysWOW64 folder—the 32-bit version of the folder. You can use the Components view or the Setup Design view to work around this redirection and instead see the contents of the actual 64-bit System32 folder. The following instructions explain how.

Task: ***To add a system file through the Components view or the Setup Design view on a development system that has 64-bit Windows Vista or later or 64-bit Windows Server 2008 or later:***

1. Expand the node that contains the component that you want to contain the system file.
2. Depending on what project type you are using, click the **Files** node or the **Static File Links** node under that component node.
3. Right-click the **Files** pane and then click **Add**. The **Open** dialog box opens.
4. Specify the following path (but replace the drive letter with the applicable drive letter if appropriate):

   ```
   C:\Windows\Sysnative
   ```

5. Select the appropriate file that you want to add to your project, and then click the **Open** button. InstallShield adds the file to your project. InstallShield uses the Sysnative folder as part of the path for the source file that you added.

This procedure works on development and build machines that have 64-bit Windows Vista or later or 64-bit Windows Server 2008 or later. It may also work on machines that have 64-bit Windows XP or 64-bit Windows Server 2003 if the hotfix that is available in Microsoft KB 942589 is applied. (Microsoft KB 942589 adds Sysnative support to Windows XP and Windows Server 2003 machines.) Use of the Sysnative folder is not supported on 32-bit machines. If you use the Sysnative folder in an InstallShield project on a 64-bit system that has Sysnative support but then you try to build a release in that InstallShield project on a system that does not have Sysnative support, InstallShield generates one or more build errors or warnings informing you that it could not find the source file.

If you are using the automation interface with InstallShield or the Standalone Build to create, edit, or build an installation on a 64-bit machine that has Sysnative support, you can use the Sysnative folder in paths when you are specifying the source folder for system files that are in the 64-bit System folder.

Note that in many cases, including system files in an installation is not recommended, since the system folder is protected by Windows. In these cases, the preferred way to deliver and update system files is to use a Microsoft merge module, if one is available for the technology, or to have end users obtain the updates through Windows Update.

Extracting COM Data from 64-Bit COM Servers

If you want to extract COM data from a 64-bit COM server at design time or at build time, you must be using InstallShield on a 64-bit operating system. If you use InstallShield on a 32-bit system, 64-bit COM extraction is not available.

To learn about extracting COM data, see Extracting COM Registration Data at Build Time.

Scanning 64-Bit Files for Dependencies

If you use the dependency scanners in InstallShield to help you identify dependencies that you may need to add to your project, these scanners can check 64-bit files in your project for dependencies only if you are using InstallShield on a 64-bit operating system.

If you are using InstallShield on a 32-bit system, the dependency scanners in InstallShield cannot check 64-bit files in your project for dependencies. To add 64-bit dependencies to a project on a 32-bit system, consider manually adding the required files and merge modules to your project.

To learn about scanning files for dependencies, see Identifying Application Dependencies.

Scanning 64-Bit .NET Assemblies for Dependencies and Properties

If you use InstallShield on a 64-bit version of Windows Vista or later or a 64-bit version of Windows Server 2008 or later, and you use one of the built-in methods for detecting dependencies, InstallShield can scan for 64-bit dependencies of the 64-bit .NET assemblies in your project.

These methods also scan for 32-bit dependencies of the 32-bit .NET assemblies in your project.

Note that if you use InstallShield on a 32-bit version of Windows, these built-in scans can check for only 32-bit dependencies of the 32-bit files in your project. If your project includes 64-bit files, you can manually add any dependencies to the project as needed.

To learn more, see the following:

- Identifying Properties and Dependencies of .NET Assemblies
- Scanning 64-Bit .NET Assemblies for Dependencies

Using 64-Bit .NET Installer Classes and COM Interop

If you are using InstallShield on a 64-bit version of Windows, the .NET tab on the Options dialog box—which is displayed when you click Options on the Tools menu in InstallShield—lets you specify different paths for the 32-bit and 64-bit locations of the `Regasm.exe` and `InstallUtilLib.dll` files that are included with the .NET Framework. InstallShield uses the paths that you specify at build time for releases that include .NET installer classes and COM interop.

If you are building from the command line with `ISCmdBld.exe` on a 64-bit version of Windows, and you use the existing `-t` parameter to specify the path of the 32-bit version of the .NET Framework, `ISCmdBld.exe` uses the 64-bit location of `Regasm.exe` and `InstallUtilLib.dll` for 64-bit .NET installer classes and COM interop.

If you are building through MSBuild or Team Foundation Server (TFS) and you use the existing DotNetUtilPath parameter on the InstallShield task to specify the path of the 32-bit version of the .NET Framework, the build uses the 64-bit location of `Regasm.exe` and `InstallUtilLib.dll` for 64-bit .NET installer cases and COM interop.

Note that if you are using InstallShield on a 32-bit operating system, the setting for the 64-bit location is disabled, and only 32-bit support for .NET installer cases and COM interop is available. This support also applies to building from the command line with `ISCmdBld.exe`, and building through MSBuild or TFS.

To learn more, see:

- .NET Tab (on the Options dialog box)
- ISCmdBld.exe
- Microsoft Build Engine (MSBuild)

Using Help

Flexera Software understands the importance of having useful information and help resources at your fingertips. In addition to the inline help embedded within various views of the InstallShield interface, InstallShield includes the Help Library (the online help library that is installed with InstallShield) and HelpNet.

InstallShield Help Library

When you have questions about your product, first consult the InstallShield Help Library. The Help Library is the complete user's guide for using InstallShield.

You can access the InstallShield Help Library from the Help menu in InstallShield, by pressing F1, or by clicking Help buttons in the interface.

No Internet connectivity is required to view the online help. Essentially, the online help viewer is a tool that you can use to display, search, and filter technical information based on your personal needs.

Web-Based Online Help

Web-based online help is available to you 24 hours a day, seven days a week, on our Web site at http://helpnet.installshield.com. This help resource center provides near real time updates to documentation.

Help Conventions

In this documentation, reader alert and style conventions are used to bring your attention to specific information or help you identify information.

Reader Alert Conventions

Reader alerts are used throughout this documentation to notify you of both supplementary and essential information. The following table explains the meaning of each alert.

Table 1-3 • Reader Alert Conventions

Image	Alert Name	Description
	**Best Practices**	Best Practices alerts instruct you on the best way to accomplish a task.
	**Caution**	Cautions indicate that this information is critical to the success of the desired feature or product functionality.
	**Edition-Specific Note**	Edition-specific notes indicate that the information applies to a specific edition of a product (such as Professional or Premier edition).
	**Important Note**	Important notes are used for information that is essential for users to read.
	**Note**	Notes are used to draw attention to pieces of information that should stand out.
	**Project-Specific Note**	Project-specific notes are used to highlight information that may vary depending on the project type used (such as a Basic MSI or Merge Module project).
	**Security**	Security alerts identify security issues.
	**Task**	The Task graphic indicates that procedural instructions follow.
	**Tip**	Tips are used to indicate helpful information that could assist you in better using the desired function or feature.
	**Version-Specific Note**	Version-specific notes indicate that the information applies to a specific version of a product (such as Version 9.0 or Version 11.0).
	**Windows Logo Guideline**	Windows Logo Guideline alerts accompany Microsoft logo compliance requirements and recommendations.

Style Conventions

The following style conventions are used throughout this documentation.

Table 1-4 • Style Conventions

Style	Example	Description
User Interface Elements	On the **File** menu, click **Open**.	User interface elements appear in bold when referenced in tasks.
Variables	*fileName*	Variables appear in italics.
Code	`#define HWND_BROADCAST 0xffff`	Code snippets appear in a monospace typeface.
User Inputted Text	Type `$D(install)`.	Text that is to be entered as a literal value is displayed in a monospace typeface, in bold, and in blue.
File Name and Directory Paths	My files are located in the `C:\MyDocuments\SampleCode` directory.	File names and directory paths are presented in a monospace typeface.
.INI File Text	Insert the line `LimitedUI=Y` into the file to display only the Welcome dialog box when the Windows Installer package is run.	Text in .INI files is presented in a monospace typeface.
Command-Line Statements	To run the installation silently, enter: `Setup.exe /s /v/qn`	Command-line statements and parameters are presented in a monospace typeface.
Environment Variables	Set the value of the `windir` environment variable to your	Environment variables are presented in a monospace typeface.
Examples	Create two groups, one called **Admins** and the other called **General**.	Examples are presented in bold.
Functions	**FeatureAddItem** adds a new feature to a script-created feature set.	Functions are presented in bold.
Properties	In the **Name** property, enter a name for this custom control that is unique among all of the controls in your project.	Properties are presented in bold.
Screen Output	If you type an incorrect parameter, the message `The system cannot find the path specified.` is displayed.	Screen output (from a log file or from the console) is displayed in a monospace typeface, and in blue.

Using Context-Sensitive Help

While working on a project, clicking a software object displays its help information in the Help window. This is also called “context-sensitive” help.

Help information is also available for each of the properties of a selected software object displayed in the Explorer window, which provides instructions for setting that property.

Contacting Us

Flexera Software is headquartered in Schaumburg, Illinois, and has offices worldwide.

For more information about Flexera Software, including office locations and contact information, visit http://www.installshield.com.

Getting Started

InstallShield provides powerful features and time-saving tools that make authoring reliable Windows Installer and InstallScript installations easy. The InstallShield Help Library is a resource that will help you harness the full potential of InstallShield. The help topics you might want to read first depend upon your previous experience with InstallShield installation-authoring software. The table below directs you to various topics based on your level of experience.

Table 2-1 • Getting Started Road Map

Level of Familiarity	Top Help Topics
You have not created installations previously.	To learn general information about installations, refer to the following topics: • Installation Fundamentals • Application Lifecycle
You are new to InstallShield.	If you have created installations previously but you do not have experience using InstallShield, see the following topics: • Working with the InstallShield Interface • Working with Projects • Basic MSI Project Tutorial • Globalization Tutorial • InstallScript Project Tutorial • Run-Time Language Support in InstallShield • Supported Application Programming Languages

Table 2-1 • Getting Started Road Map (cont.)

Level of Familiarity	Top Help Topics
You have used other Flexera Software products.	If you have used other products from Flexera Software, refer to any of the following topics: • Upgrading from Earlier InstallShield Versions • Upgrading from Other InstallShield Editions • Project Assistant • Installation Projects Overview
You are an intermediate-level or advanced-level user of InstallShield.	If you are familiar with InstallShield, you may want to review the following topics: • Command-Line Tools • Errors and Warnings • InstallScript Language Reference • Running Installations in Silent Mode • Configuring Advanced Settings for InstallShield

Installation Fundamentals

An installation, in its simplest terms, is the “package” used to install your files and programs onto your user’s machine. It is a complete collection of the application files, as well as logic that interacts with the installer engine. The primary task of any installation is to transfer the application files from the source medium to the end user’s computer. The complexities of the Windows operating system make it anything but simple to create an effective, coherent installation without the aid of a utility such as InstallShield.

An installation is divided into three levels: products, features, and components. The following diagram illustrates this hierarchy:

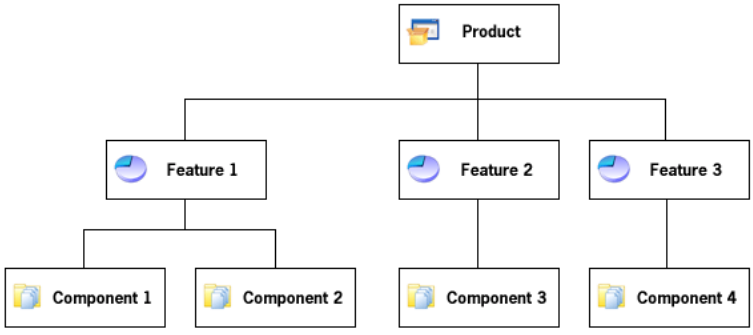

Figure 2-1: Installation Hierarchy

A *product* is the highest level of organization in an installation project. A product is usually one main application (for example, a word processor) and all of the files and data that the application requires; a suite of applications may also be a product.

A *feature* is the smallest installable part of a product, from the end user's perspective. As the designer of an installation program, you usually allow the user to choose which features to install and which features to leave on the source media. In a word processor product, the main executable may be one feature, and optional dictionaries may be a separate feature. A feature should be self-contained, in the sense that a feature should not require sibling features. For example, a thesaurus feature should not require a dictionary feature that the user can choose not to install. However, you can design features to contain subfeatures, which allow the end user finer control over which files and data to install.

Each feature in a project is made up of one or more *components*. A component is the smallest installable part of a product from the installation developer's perspective; components are invisible to the end user. Each component contains files (and other resources) with similar properties. For example, all of the files in a component will be installed in the same directory on an end user's machine, and all of the files in a component should apply to the same operating system or language. A dictionary feature might contain several language-specific dictionary components. In addition to containing files, components generally contain registry data, shortcuts, file extension information, and other system data to write to a user's machine.

When you are designing an installation, the overall task is to separate the product's files into components based on the files' destination, operating system, language, and other properties, and to associate each component with one or more features.

Application Lifecycle

Your application lifecycle should not end when your customer installs your application. As a software vendor, the success of your application goes well beyond the initial installation on the customer's desktop. Customers expect to have easy access to product updates, enhancements, and critical information. Your ability to communicate with your customers and monitor the health of your application is vital to your ongoing growth and profitability.

Too often, software vendors require their customers to initiate communication. Vendors who are not proactively creating an ongoing dialog are missing a tremendous opportunity. Unless the customer is an active visitor to your Web site or public user communities, they miss important information about updates, upgrades, hot fixes, and general technical bulletins. You miss revenue and service opportunities.

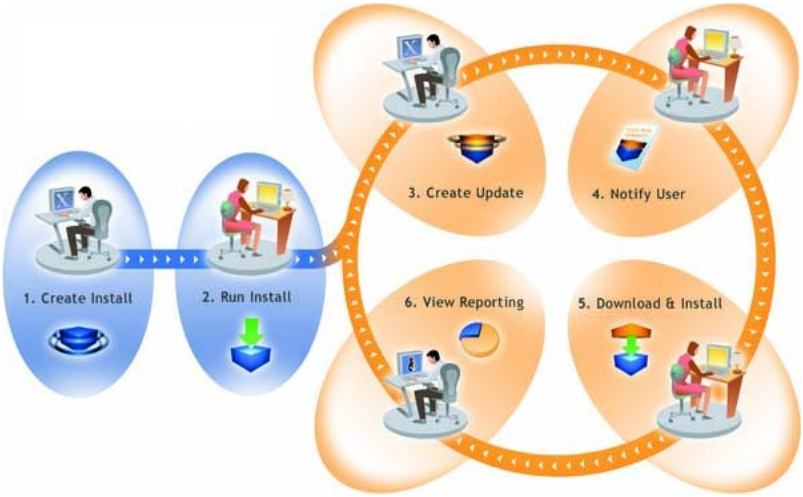

Figure 2-2: How FlexNet Connect Manages the Application Lifecycle

The above diagram illustrates how FlexNet Connect is used to manage the application lifecycle:

1. **Create Install—**InstallShield makes it easy for software developers to create installations that run on any platform.
2. **Run Install—**Installations created with InstallShield technology have successfully installed on over 400 million machines worldwide.
3. **Create Update—**InstallShield enables software developers to rapidly build patches and updates.
4. **Notify User—**FlexNet Connect notifies every user that a new update is ready to be installed.
5. **Download & Install—**FlexNet Connect downloads the update and installs it in one seamless, integrated process.
6. **View Reporting—**FlexNet Connect provides immediate feedback on the update's adoption rate.

Starting InstallShield

Each time you open InstallShield (with the exception of the initial launch after installing the product), you are taken directly to the InstallShield Start Page. The Start Page provides quick access to product information, to recently opened projects, and to InstallShield resources.

InstallShield Start Page

The InstallShield Start Page provides quick access to product information, to recently opened projects, and to InstallShield resources. The Start Page includes the following sections:

Table 2-2 • Sections on the Start Page

Section	Description
Project Tasks	Click a project task to quickly create a new project, open an existing project, or browse to one of the sample projects included with the InstallShield installation.
Help Topics	Frequently accessed help topics are listed in this section. To access the entire InstallShield Help Library from the Start Page, press F1 or click the Help Library link in the Resources section.
(Recently Opened Projects)	The section in the middle of the Start Page lists your most recently accessed projects, the project types, and the dates on which they were last modified.
Getting Started	Click the Getting Started heading for guidance on what areas of the InstallShield Help Library to read, based on your level of experience with InstallShield and installation-authoring tools.
Resources	The Resources section contains a number of links to connect you to helpful InstallShield information. • **Help Library**—Displays the InstallShield documentation. • **InstallShield Community**—Provides a Web-based forum where you can join other InstallShield users, post questions, and search for answers. • **Webinars**—Directs you to free Web-based seminars that help you evaluate InstallShield and gain the most from your Flexera Software products. • **Downloads**—Offers a place where you can download the latest InstallShield prerequisites, InstallShield merge modules, and objects; service packs; patches; and more for the version of InstallShield that you are using. • **Release Notes**—Connects you to the release notes that are posted to the Knowledge Base on the Flexera Software Web site. • **Known Issues**—Displays the Knowledge Base article that lists the known issues for the version of InstallShield that you are using and provides information about workarounds and resolutions. • **Upgrade Alerts**—Displays the Knowledge Base article that provides information about possible issues that may occur when you upgrade projects that were created with earlier versions of InstallShield to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from earlier versions. • **RSS Feeds**—Directs you to the Web page where you can subscribe to RSS feeds of InstallShield Knowledge Base articles.

Contact Us	To access the Support area of the Flexera Software Web site or join the Customer Experience Improvement Program, click one of the links listed in this section.

Working with Projects

An InstallShield project specifies the files, folders, and operations that make up the project's output. A project's output is one of the following (depending on the project type):

- Installation: creates or updates a copy of your application on the target system
- Redistributable (merge module or InstallShield object): contains logic and files needed to install distinct pieces of functionality when included in an installation
- Transform: enables an administrator to apply modified settings to an Windows Installer installation when deploying the installation

A project can be as simple or as complex as you need to meet your requirements. A simple project might consist of files, components, features, and registry entries. More complex projects might consist of these items plus redistributables, initialization file changes, and calls to external DLL functions.

Installation Projects Overview

With InstallShield, you have the ability to choose between a variety of different installation project types—those that use InstallShield's powerful InstallScript programming language (InstallScript), those that use the Windows Installer database (Basic MSI), or a combination of the two (InstallScript MSI).

The installation project type you choose depends on the needs of your software installation. InstallShield provides the same intuitive user interface for all project types, so your application's needs can dictate the project type and your authoring experience does not change. Additionally, the knowledge gained by learning how to create projects of one type is applicable to projects of the other types.

Similarities Between Project Types

All InstallShield installation project types create installations that have the same professional, industry-standard look and feel that your end users have come to expect from InstallShield. All enable you to create customized installations to meet the needs and expectations of your end users.

Despite the similarities in the project types' feature sets, there are some important differences between them—especially between the InstallScript and Basic MSI projects. See Determining Which Installation Project Is Right for You to learn which of these project types is right for your software installation needs.

Determining Which Installation Project Is Right for You

InstallShield enables you to create different types of projects, but for the beginner there is just one significant choice to make: Do you want to build your installation with Windows Installer or InstallScript technology? Deciding which project type is right for you depends on your experience with InstallShield software and installation development and on your installation and deployment needs. The three main project types are described below.

Basic MSI Projects

Basic MSI projects use the Windows Installer service to drive the entire installation, including calls to any custom actions (InstallScript, VBScript, JScript, .exe files, .dll files, managed code). The Basic MSI project type is recommended when you want to do any of the following:

- You want to meet the Windows logo program requirements.
- You want to maximize compatibility with administrative tools such as Microsoft System Center Configuration Manager, or if your software will be customized by corporate system administrators prior to deployment. The Basic MSI project type gives them the flexibility to create transforms for the installation package and its associated properties, without repackaging your installation.
- You want to avoid writing scripting code and want to instead set properties and make table entries.
- You want to upgrade an existing Basic MSI project.

InstallScript Projects

InstallScript projects use InstallScript to control the installation. This project type is recommended for any of the following scenarios:

- You have advanced requirements for the end-user experience (the end-user dialogs), such as multimedia elements.
- You want to use full-screen billboards during the run time of your installation.
- You prefer authoring the project using a procedural language at its core rather than a set of database tables.
- You want to perform actions before or after the main installation has been run.
- You want to upgrade an existing InstallScript project.

InstallScript MSI Projects

InstallScript MSI projects use both the Windows Installer engine and the InstallScript engine to drive the installation. This project type is the most complicated since it uses both of those engines for the installation; it is not recommended for beginners. This project type may be recommended in the following scenarios:

- You want to meet the Windows logo program requirements.
- You have advanced requirements for the end-user experience (the end-user dialogs), such as multimedia elements.
- You prefer authoring the project using a procedural language at its core rather than a set of database tables.
- You want to perform actions before or after the main installation has been run.

- You want to upgrade an existing InstallScript MSI project.

Tip • *Repackager is a project conversion tool that is available in AdminStudio. You can use this tool to convert InstallScript projects and InstallScript MSI projects to Basic MSI projects.*

Project Types

InstallShield offers a number of different project types to assist you in creating the optimal project for your end users.

Table 2-3 • Project Type Descriptions

Project Type	Icon	Description
Advanced UI		 ***Edition*** • *This project type is available in the Professional edition of InstallShield. If you open this type of project in the Premier edition of InstallShield, it opens as a Suite/Advanced UI project.* An Advanced UI project lets you create a bootstrap application with a contemporary, customizable user interface for a single .msi package, .msp package, or InstallScript package, as well as multiple InstallShield prerequisites. An Advanced UI installation uses a setup launcher (`Setup.exe`) to conditionally launch packages on target systems as needed.
Basic MSI		A Basic MSI project uses Windows Installer to provide the user interface for the installation. When you choose this project type, you need to create features and components, and specify all application files and other distributable data.
DIM		A DIM project is targeted toward engineering teams who want to foster collaboration, enable distributed installation development, and maximize efficiency in their organizations. A developer installation manifest (DIM) is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete, logically separated portion of a product installation. You can incorporate one or more DIMs into Basic MSI projects.
InstallScript		The InstallScript installation project provides the flexibility afforded by the InstallScript language and is driven by the proven InstallScript engine.

Table 2-3 • Project Type Descriptions (cont.)

Project Type	Icon	Description
InstallScript MSI		An InstallScript MSI project uses both InstallScript and Windows Installer tables. With this project type, you need to create features and components, and specify all application files and other distributable data.
InstallScript Object		Using the InstallScript Object project, you can create an InstallShield merge module that uses InstallScript. This type of merge module, however, can be consumed only by InstallShield.
Merge Module		Select this option to create your own merge modules. You need to create any components and file associations.
MSI Database		Select MSI Database to edit your installation project in Direct Edit mode. This means that you can directly edit the Windows Installer tables within InstallShield to configure your installation.
MSM Database		Select MSM Database to edit your merge module in Direct Edit mode. This means that you can directly edit the Windows Installer tables within InstallShield to configure your merge module.
QuickPatch		This project type is recommended for installation authors who want to ship small, single updates to their end users. QuickPatch authoring provides an alternative to creating a patch configuration in the Patch Design view even though it provides less customization. Creation of a QuickPatch begins with the Create New QuickPatch Wizard.
Suite/Advanced UI		 ***Edition*** • *This project type is available in the Premier edition of InstallShield.* A Suite/Advanced UI project lets you create a bootstrap application with a contemporary, customizable user interface for multiple .msi packages, .msp packages, InstallScript packages, .exe packages, sideloading app packages (.appx), and Windows Installer transactions, as well as multiple InstallShield prerequisites. A Suite/Advanced UI installation packages together multiple separate installations as a single installation while providing a unified user interface; it uses a setup launcher (`Setup.exe`) to conditionally launch packages on target systems as needed.
Transform		A transform (.mst file) is a simplified Windows Installer database that contains the differences between two Windows Installer databases. Creating a new transform project launches the Open Transform Wizard.

Table 2-3 • Project Type Descriptions (cont.)

Project Type	Icon	Description
Visual Basic .NET Wizard		Select this option to launch the Visual Studio .NET Wizard for Visual Basic .NET, C# .NET, and Visual C++ .NET.
C# .NET Wizard		Select this option to launch the Visual Studio .NET Wizard for Visual Basic .NET, C# .NET, and Visual C++ .NET.
Visual C++ .NET Wizard		Select this option to launch the Visual Studio .NET Wizard for Visual Basic .NET, C# .NET, and Visual C++ .NET.

Advanced UI and Suite/Advanced UI Projects

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Advanced UI and Suite/Advanced UI installations are bootstrap applications that package together installations and InstallShield prerequisites as a single installation while providing a unified, fully customizable user interface. They use a setup launcher (`Setup.exe`) to conditionally launch packages on target systems as needed.

Note that Advanced UI and Suite/Advanced UI installations require Windows XP SP3 or later or Windows Server 2003 SP2 or later.

Also note that the ability to create and build a Suite/Advanced UI installation that includes a sideloading app package (.appx) requires Windows Vista or later or Windows Server 2008 or later on the machine that has InstallShield or the Standalone Build.

Basic MSI Installation Projects

Basic MSI is the Windows Installer–based project type in InstallShield. Basic MSI projects are recommended in cases where the Windows Installer service should drive the entire installation. They allow you to author your installation using only the native Windows Installer feature set. The geometry of your end user dialogs as well as the flow of your setup user interface (UI) is authored directly in the MSI package, and the Windows Installer Service uses its native user interface rendering capabilities to display the UI to your end users. The advantages of this project type are fully realized if you need to author your installation in an open format.

Note • *Create a Basic MSI project if your software will be customized by corporate systems administrators prior to deployment. It gives them the flexibility to create transforms for the installation package and its associated properties, without repackaging your installation.*

Basic MSI projects have the ability to run InstallScript code in the form of custom actions. As with InstallScript projects, Basic MSI projects take advantage of other robust features provided by InstallShield such as dialog authoring, the ability to call custom actions in standard Windows .dll files, and the ability to specify support files.

Run-Time Behavior for Basic MSI Installations with InstallScript Custom Actions

For InstallShield 12 and Later Projects

The following steps outline the run-time behavior for Basic MSI installations that include InstallScript custom actions:

1. The package is launched by the Windows Installer service.
2. Any sequenced InstallScript custom actions execute as follows.
   a. The Windows Installer calls the relevant entry point in `ISSetup.dll` (loaded from the **Binary** table).
   b. `ISSetup.dll` extracts its `Setup.inx` resource to a temporary location.
   c. `ISSetup.dll` executes relevant script code.
   d. Windows Installer unloads `ISSetup.dll`.

The run-time behavior for InstallShield 12 and later Basic MSI projects that have InstallScript custom actions is much different than the behavior for InstallShield 11.5 and earlier because of some architecture enhancements. For more information about the enhancements, see Upgrading Projects from InstallShield 11.5 or Earlier.

For InstallShield 11.5 and Earlier Projects

For installations created with InstallShield 11.5 and earlier, the run-time behavior is as follows:

1. `Setup.exe` installs `ISScript.msi`.
2. `Setup.exe` launches `MsiExec.exe` to install the primary .msi file. (`Setup.exe` must be included in the installation, or it must already be present on the target system.)
3. ISMsiServerStartup (immediate custom action) starts and initializes `IDriver.exe`.
4. Any sequenced InstallScript custom actions execute as follows.
   a. The Windows Installer finds the relevant entry point in `ISScriptBridge.dll`.
   b. `ISScriptBridge.dll` finds the running `IDriver.exe` instance using the running object table (ROT).
   c. IDriver.exe executes relevant script code.
5. ISCleanUpSuccess shuts down `IDriver.exe`.

If you upgrade an InstallShield 11.5 or earlier project to InstallShield 2013, the run-time behavior is updated to the behavior described for InstallShield 12 and later projects.

DIM Projects

The DIM support in InstallShield is targeted toward engineering teams who want to foster collaboration, enable distributed installation development, and maximize efficiency in their organizations. A developer installation manifest (DIM) is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete, logically separated portion of a product installation. Some benefits of using DIMs are as follows:

- Working with DIMs enables multiple team members to contribute to the development of the installation simultaneously. Each software developer or other team member can work on a separate DIM that the release engineer can reference in one or more installation projects.
- Release engineers can reuse DIMs in multiple installation projects, enabling efficiency.
- DIMs include support for virtually the same functionality that is available in Basic MSI projects. This gives authors of DIMs all of the flexibility that they need to develop their portions of an installation.

InstallScript Installation Projects

The InstallScript installation project type provides the power and flexibility of the InstallScript programming language and the familiarity of the InstallShield Professional project. Windows Installer is not used at all. The installation is completely script driven and very flexible, and it uses the InstallScript engine, the same trusted engine used by InstallShield Professional.

Note • *InstallScript installations are generally less desirable to systems administrators because they require the use of Setup.exe, rather than being self-contained in an .msi file, and may not be fully customizable prior to deployment. If your software will be customized by corporate systems administrators prior to deployment, create a Basic MSI installation project.*

The InstallScript Engine

With InstallScript projects, the run-time user interface is rendered and its flow controlled by InstallScript, and the changes that are made to the target operating system are done through InstallShield's trusted InstallScript engine, with no reliance on Windows Installer.

Using InstallScript as the installation driver has many benefits. The first is that InstallScript's event model enables you to create a script-driven installation without writing a single line of code. If you want to add custom functionality, you need to implement only the events whose functionality you want to change.

The user interface abilities for Basic MSI projects are somewhat limited with regard to the types of controls you can use or the kind of control you have over dialog events. InstallScript projects have no such limitation—offering a wide range of standard controls along with the ability to add custom dialog controls. Dialog messaging in the script enables you to have complete control over how your end-user dialogs behave.

Upgrading Projects Created Using InstallShield Professional

Installation projects created using InstallShield Professional (version 5.5 and later) upgrade to the InstallScript project type.

Additional Features for InstallScript Projects

InstallScript projects provide a few additional features that are not available in Basic MSI projects:

Table 2-4 • Additional InstallScript Project Features

Feature	Description
Setup Types view	This view enables you to easily create different installation configurations for your application. This view also lets you select the defaults for the Custom setup type.
Billboard Support	Run-time billboard support is available only for InstallScript projects. Billboards let you show bitmaps to the end user while files are being transferred to their machine. You can use these bitmaps to entertain or educate user.

InstallScript MSI Installation Projects

InstallScript MSI installations use two different installer engines:

- The Windows Installer engine runs the standard Execute sequence of the .msi package. This is the sequence that typically modifies the target system.
- The InstallScript engine serves as the custom user interface (UI) handler of the installation. It also executes the InstallScript code. The advantage of using the InstallScript engine for the UI is that it offers support for highly customized run-time dialogs.

In addition, InstallShield offers two different styles for the UI of InstallScript MSI installations:

- **Traditional style**—This style lets you use the InstallScript engine as an external UI handler for your InstallScript MSI installation. With this style, your installation must include a `Setup.exe` setup launcher. The setup launcher serves as a bootstrap application that initiates the InstallScript engine to display the UI and run the InstallScript code, and the Windows Installer to run the Execute sequence of the .msi package.
- **New style**—This style lets you use the InstallScript engine as an embedded UI handler for your InstallScript MSI installation. For this style, InstallShield embeds the InstallScript engine within the .msi package. The Windows Installer calls the InstallScript engine to display the UI. The Windows Installer also runs the Execute sequence of the .msi package.

  This option requires Windows Installer 4.5 on the target machine. This option also has some limitations that require careful planning if you decide to use this style.

For detailed information about these two styles, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

Note • *Because this project type uses two different engines, it is more complex than pure InstallScript or Basic MSI installation projects. It is recommended only for advanced users.*

Traditional-style InstallScript MSI installations are less desirable to systems administrators than Basic MSI installations or new-style InstallScript MSI installations. That is because traditional-style InstallScript MSI installations require the use of `Setup.exe`, rather than being self-contained in an .msi package, and they may not be fully customizable prior to deployment. If your software will be customized by corporate systems administrators prior to deployment, create a Basic MSI project. As an alternative, you could consider using the new-style InstallScript MSI installations, but your must ensure that any system changes that need to be made are done with custom actions in the Installation Execute sequence. To ensure that sufficient privileges are available, custom actions should have an in-script execution setting of deferred in system context.

Additional Features for InstallScript MSI Projects

InstallScript MSI projects provide a few additional features that are not available in Basic MSI projects:

Table 2-5 • Additional InstallScript MSI Project Features

Feature	Description
Setup Types view	This view enables you to easily create different predefined installation configurations for your application, such as Typical or Compact. This view also enables you to select the defaults for the Custom setup type.
Billboard Support	Run-time billboard support is available for InstallScript MSI installations, but not Basic MSI installations. Billboards enable you to show bitmaps while files are being transferred to an end user's machine. You can use these bitmaps to entertain or educate end users.

Run-Time Behavior for InstallScript MSI Installations

For InstallShield 12 and Later Projects

The following steps outline the run-time behavior for InstallScript MSI installations:

1. `Setup.exe` initializes `ISSetup.dll`.
2. `ISSetup.dll` does the following:
    a. Loads `Setup.inx`.
    b. Executes pre-installation InstallScript events (for example, OnBegin).
    c. Launches the Windows Installer (and the InstallScript engine for the external user interface).
    d. Each InstallShield custom action executes as follows (for example, OnMoved). (Note that this essentially the same mechanism that is used in Basic MSI with InstallScript custom actions.)
        i. The Windows Installer calls the relevant entry point in `ISSetup.dll`. (This is a different instance of `ISSetup.dll`, loaded from the **Binary** table.)
        ii. `ISSetup.dll` extracts its `Setup.inx` resource to a temporary location.
        iii. `ISSetup.dll` executes relevant script code.

iv. Executes post-installation InstallScript events (for example, OnEnd).

The run-time behavior for InstallShield 12 and later InstallScript MSI projects is much different than the behavior for InstallShield 11.5 and earlier because of some architecture enhancements. For more information about the enhancements, see Upgrading Projects from InstallShield 11.5 or Earlier.

For InstallShield 11.5 and Earlier Projects

For InstallScript MSI installations created with InstallShield 11.5 and earlier, the run-time behavior is as follows:

1. `Setup.exe` installs `ISScript.msi`.
2. `Setup.exe` launches `IDriver.exe`.
3. `IDriver.exe` does the following:
   a. Loads `Setup.inx`.
   b. Executes pre-installation InstallScript events (for example, OnBegin).
   c. Launches the Windows Installer (and the InstallScript engine for the external user interface).

      Each InstallScript custom action executes as follows (for example, OnMoved). (Note that this is the same mechanism used in Basic MSI installations with custom actions.)

      i. The Windows Installer calls the relevant entry point in `ISScriptBridge.dll`.
      ii. `ISScriptBridge.dll` finds the running `IDriver.exe` instance using the running object table (ROT).
      iii. `IDriver.exe` executes relevant script code.
   d. Executes post-installation InstallScript events (for example, OnEnd).

Merge Module Projects

Merge modules allow you to add existing pieces of functionality to your installation. For example, if your application requires the VB Run-Time DLL, you can add Microsoft's Visual Basic Virtual Machine module to your setup application. Traditionally, you would have to create registry entries, set the target folders, custom actions and any other necessary steps yourself. With merge modules, all you need to do is associate an existing merge module with your installation and move on to your next task.

InstallShield provides you with the ability to create your own merge modules to distribute with your installations or give away to other developers. This can be useful if you are going to include certain pieces of functionality in all of your installation projects. Rather than having to recreate that part of the installation every time, you can create it once as a merge module and then associate that module with all of your installation projects.

InstallScript Custom Actions in Merge Module Projects

Merge modules can contain InstallScript custom actions. However, you must manually create the **Module**Sequence** table entries to make sure that the custom actions are merged properly.

How Merge Modules Work

When a merge module is associated with an installation project, it is merged into the .msi database at build time. As a result, you are merging two distinct projects (your new installation and the existing merge module) into one .msi file. The merge module behaves like a component in that it is not installed unless the feature with which it is associated is installed. Therefore, if you have a feature that requires VB run-time DLLs, and that feature is not selected for installation, the VB merge module will not be installed.

MSI Database and MSM Database Projects

The MSI Database and MSM Database project types allow you to edit Windows Installer installation databases and merge module databases directly, rather than working through an intermediate project format (.ism file). These project types extend the Direct Editor functionality to include different views that are supported in standard installation and merge module projects. The views that are supported in these project types are intended to function as they do for an .ism project.

Project • *There is no string entry or path variable support in an MSI Database or MSM Database project.*

You can directly edit an existing .msi file or .msm file, or directly create a new database by opening a new MSI Database or MSM Database project. The data in this file should match what you would get if you created a blank Basic MSI or Merge Module project and built a database from that project.

InstallScript Object Projects

Using InstallShield objects, you can easily install key Windows technologies. To install a technology, simply include the corresponding InstallShield object in your installation. If a technology is required by a particular component, you can associate the corresponding InstallShield object with the feature.

QuickPatch Projects

A QuickPatch project is a specific type of project recommended for installation authors who want to ship small, single updates to their users. Changes that are more extensive such as adding custom actions and changing .ini data typically require a standard patch.

QuickPatch authoring provides a simple alternative to creating a patch configuration in the Patch Design view, even though it provides less customization. Fundamentally, both patch creation methods produce the same deliverable types: .msp and .exe files.

With a QuickPatch, you can do any of the following:

- Add new files to the original installation or an earlier QuickPatch.
- Delete files in the original installation.
- Delete files that were added with a previous QuickPatch.
- Perform the same set of above operations on registry entries.

- Remove custom actions that were included with the original installation but that do not apply to the current QuickPatch project.

The creation of a QuickPatch project always begins with the Create New QuickPatch Wizard. After you have completed the wizard, you can configure the QuickPatch project settings once the project opens in InstallShield.

Transform Projects

A transform (.mst file) is a simplified Windows Installer database that contains the differences between two .msi databases. Transforms enable an administrator to apply modified settings to a database when deploying an installation package.

InstallShield has a transform project type that enables you to edit .msi packages without having to convert them to an InstallShield (.ism) project. You can save the changes made as a transform (.mst) file.

When you create a transform project or open a transform in InstallShield, the Open Transform Wizard launches to gather information about the base .msi file and any additional transform files that you want applied to the base .msi file.

Using Projects

InstallShield allows you to create, edit, upgrade, and save numerous project types—from installation projects to InstallShield object projects that allow you to reuse functionality within InstallShield.

The pages in this section cover a variety of topics, including how to create a particular project type, how to create project templates, and what to expect when you upgrade from a different InstallShield product.

Creating New Projects

There are a number of ways to create a new InstallShield project.

Task: ***To create a new project, do one of the following:***

- Click the **New Project** button on the toolbar or on the InstallShield Start Page.
- Press Ctrl+N.
- On the **File** menu, click **New**.

Any of these steps launches the New Project dialog box, from which you can select the project that you want to create.

Using a Template to Create a New Project

Your project templates are listed in the New Project dialog box on the appropriate tab. For more information, see Basing New Projects on Templates.

Creating a Project From Within Microsoft Visual Studio

You can create an InstallShield project from within the Microsoft Visual Studio workspace. For more information, see Creating InstallShield Projects in Microsoft Visual Studio.

Opening Projects

Task: ***To open an existing InstallShield project, do one of the following:***

- Click the **Open Project** button on the toolbar.
- On the **File** menu, click **Open**. In the **Open** dialog box, navigate to the project file.
- Press Ctrl+O.
- Click the **Open an existing project** link or click a recently opened project link on the InstallShield Start Page.
- Double-click a project file (.ism) on the desktop or in Windows Explorer.

With the exception of clicking a specific file or file link, all of the above options launch the Open dialog box, which enables you to browse to your project file.

Opening Projects from Source Code Control

An option on the Open dialog box enables you to get the latest version of a project folder from your source control application.

Task: ***To open a project from source control:***

1. On the **File** menu, click **Open**. The **Open** dialog box opens.
2. Click the **Source Control** button. A login dialog box for your source control program opens.
3. Log on to your source control program and browse to your project folder or database.

InstallShield gets the latest versions of every file in that project to a working directory.

Note • *If you do not have a source control application on the system that has InstallShield, the Open dialog box does not display the Source Control button.*

Opening Patch Creation Properties Files in Direct Edit Mode

You can open a previously created patch creation properties file from the Open dialog box.

Task: ***To open a patch creation properties (.pcp file):***

1. On the **File** menu, click **Open**. The **Open** dialog box opens.
2. In the **Files of type** list, click **Patch Creation Properties Files (*.pcp)**.
3. Select the .pcp file you want to edit and click **Open**.

Your patch project file opens in the Direct Editor.

Opening Windows Installer Packages

InstallShield provides the option to either edit MSI packages directly in the IDE in Direct Edit Mode or convert it to an InstallShield project (.ism), and then edit it as a Basic MSI project in the IDE.

Note • *Some functionality may be limited when editing an MSI package in Direct Edit Mode.*

Task: ***To open an MSI package in Direct Edit Mode of the IDE:***

1. Click the **Open Project** button on the toolbar. A browse dialog opens.
2. Select **Windows Installer Packages (*.msi)** from the **Files of Type** list.
3. Select the MSI package that you want to open.
4. Ensure that the **Open as** field is set to Auto, and click **Open**.

Note • *By default, the IDE opens an MSI package in Direct Edit Mode.*

The Open MSI/MSM Wizard can convert an existing Windows installer (.msi) package to an InstallShield project (.ism) file, and open the new project to modify in the IDE.

Note • *You can also open Patch Creation Project files (.pcp files) in InstallShield and edit them in the Direct Editor.*

Opening Merge Modules

The Open MSI/MSM Wizard can convert an existing Windows Installer merge module (.msm file) to an InstallShield project (.ism) file, and open the new project in the InstallShield IDE.

Task: ***To launch the Open MSI/MSM Wizard:***

1. Click the **Open Project** button on the toolbar. A browse dialog opens.
2. Select **Windows Installer Modules (*.msm)** from the **Files of Type** list.
3. Go to the merge module and click **Open**.

The Open MSI/MSM Wizard prompts for specific information about the project you are creating, and then opens your new merge module project in the IDE.

Opening Object Projects

You can open an object project (.ipo or .ipr) that you created using InstallShield Professional. When you open this project in InstallShield, it is migrated to a merge module (.msm) project.

Placing Merge Modules in the Redistributables View

To associate your merge module with InstallShield installation projects, you can automatically place your merge module project in the Modules folder so it is available in the Redistributables view for use in setup projects.

Task: ***To automatically place your merge module project in the Modules folder:***

Select the “Add to local merge module catalog” option in the Merge Module Options panel of the Release Wizard.

Saving Projects

When you create a new project, it is saved automatically with the name and location that you provide in the New Project dialog box.

InstallShield enables you to save a copy of the open project as a template or as a new project with a different name and location.

Saving a Project with a New Name and Location

When you save your project with a new name and location, a copy of the renamed project file and all of its associated files and folders are saved in the new location. The next time that you save your project, all changes are saved to this new location.

Task: ***To save your project with a new name and location:***

1. On the **File** menu, click **Save As**. The **Save As** dialog box opens.
2. In the **Save in** box, select the appropriate location.

3. Select or clear the **Create 'Project Name' subfolder and save the project in the created folder** check box as appropriate. In both cases, a <*Project Name*> subfolder is created in the **Project Location** box (on the **File Locations** tab of the **Options** dialog box).

   If you select the **Create 'Project Name' subfolder and save the project in the created folder** check box, the project file (.ism) is saved in the <*Project Name*> subfolder. If you clear the check box, the project file is saved in the location specified in the **Project Location** box.

4. If the new project's GUID should be different than the GUID of the original project, select the **Create and assign a new project GUID to the saved projec**t check box. If the new project's GUID should be the same GUID of the original project, clear this check box.

5. To use the name that you specified in the **File name** box as the value for the **Product Name** setting (in the **General Information** view) of the new project, select the **Update the project settings appropriately based on the new project name** check box. If the new project's **Name** property should be the same as that of the original project, clear this check box.

Note • *When you save a project with external dependencies, such as InstallScript files, your new project points to the original copies of these files. Duplicate copies are not made. Therefore, before you delete your original project, ensure that you do not delete any files that may be used by the new project.*

Converting from One Project Type to Another Project Type

InstallShield offers support for converting some types of projects to other types of projects.

Table 2-6 • Project Converters

Project Converter	How-To Information
Convert Basic MSI project to InstallScript MSI project	See Converting a Basic MSI Project to an InstallScript MSI Project.
Convert InstallScript MSI project to InstallScript project	See Converting an InstallScript MSI Project to an InstallScript Project.
Convert InstallScript project to Basic MSI project	Use Repackager to convert an InstallScript project to a Basic MSI project.  ***Edition*** • *Repackager is included with AdminStudio.*
Convert InstallScript MSI project to Basic MSI project	Use Repackager to convert an InstallScript MSI project to a Basic MSI project.  ***Edition*** • *Repackager is included with AdminStudio.*

Table 2-6 • Project Converters

Project Converter	How-To Information
Convert InstallScript project to InstallScript MSI project	This conversion is a two-step process: 1. Use Repackager to convert an InstallScript project to a Basic MSI project. 2. Use InstallShield to convert the Basic MSI project to an InstallScript MSI project. See Converting a Basic MSI Project to an InstallScript MSI Project.  ***Edition*** • *Repackager is included with AdminStudio.*
Convert Visual Studio setup project to InstallShield Basic MSI project	See Converting or Importing Visual Studio Projects into InstallShield Projects.
Convert Visual Studio merge module project to InstallShield Merge Module project	See Converting or Importing Visual Studio Projects into InstallShield Projects.

Converting a Basic MSI Project to an InstallScript MSI Project

Converting your Basic MSI project to an InstallScript MSI project allows you to take full advantage of the scripting capabilities that are available in InstallShield.

Caution • *This conversion is irreversible. After you convert your Basic MSI project to an InstallScript MSI project and save it, you cannot easily convert your project back to a Basic MSI project. Before you convert your Basic MSI project, it is generally good practice to first create a back-up copy of it.*

Converting Projects

Task: ***To convert your Basic MSI project to an InstallScript MSI project:***

1. Open your Basic MSI project.
2. On the **Project** menu, point to **Project Converters**, and click **Convert to InstallScript MSI project**.

Converting Dialogs

Because an InstallScript MSI project uses resource-based dialogs—instead of using the Windows Installer dialog–related tables—no Windows Installer–based dialogs from your original project are available after the migration. You need to manually add any custom dialogs.

Your converted installation project contains the default InstallScript MSI dialogs. To review the default dialogs, go to the InstallScript view and view the dialogs displayed in the OnFirstUIBefore and OnFirstUIAfter events.

Converting an InstallScript MSI Project to an InstallScript Project

InstallScript MSI projects created using InstallShield, InstallShield DevStudio, or InstallShield Developer can be easily converted to the InstallScript project type.

Task: ***To convert an existing InstallScript MSI project to an InstallScript project:***

1. Open the InstallScript MSI project.
2. On the **Project** menu, point to **Project Converters**, and click **Convert to InstallScript project**.

GUIDs

GUID stands for *globally unique identifier*. A GUID is 128 bits long, and the algorithm used to generate a GUID guarantees each GUID to be unique. Because GUIDs are guaranteed to be unique, they can be used to identify COM classes, Product Codes, and various other codes.

For example, after a product is installed, a key is created under HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall and is named after the installation's Product Code. At one time, this key was named after the Product Name. However, this caused a potential conflict. If two installations were installed on the same machine, and both shared the same Product Name, they would also share the same registry key. Because a GUID is now used, it guarantees that this conflict does not occur.

An example GUID is {5D607F6A-AF48-4003-AFA8-69E019A4496F}. Any letters in a GUID must be in uppercase.

GUIDs in Your Project

When you create an installation project, there are a number of different GUIDs that are relevant to your project.

Table 2-7 • GUIDs

GUID Name	Description
Product Code	The product GUID uniquely identifies your application.
Package Code	The package code uniquely identifies your installation package.  ***Project*** • *This GUID is available in the following project types: Basic MSI, InstallScript MSI, and QuickPatch.*

Table 2-7 • GUIDs (cont.)

GUID Name	Description
Package GUID	The package GUID uniquely identifies the installation package in the Advanced UI or Suite/Advanced UI installation.  ***Project*** *• This GUID is available in Advanced UI and Suite/Advanced UI projects.*
Patch GUID	The patch GUID uniquely identifies a patch package.  ***Project*** *• This GUID is available in the following project types: Basic MSI, InstallScript MSI, and QuickPatch.*
Suite GUID	The Suite code uniquely identifies your Advanced UI or Suite/Advanced UI installation.  ***Project*** *• This GUID is available in Advanced UI and Suite/Advanced UI projects.*
Upgrade Code or Upgrade GUID	The upgrade GUID uniquely identifies a family of products for upgrade purposes. It is important for major upgrades.  ***Project*** *• This GUID is available in the following project types: Basic MSI, InstallScript MSI, and QuickPatch.*

Project *• For information on when you need to change GUIDs in a Basic MSI or InstallScript MSI project, see Major Upgrade vs. Minor Upgrade vs. Small Update.*

Changing the Default Project Location

All new projects are saved by default in the following location:

```
C:\InstallShield 2013 Projects
```

To specify a new default location for your installation projects, use the **File Locations** tab on the **Options** dialog box.

Note *• Although this folder is used for all new installation projects, any existing projects remain in the previous location.*

Reusing Project Elements

You can save several elements in your project to reuse in another project. In some cases, the data must be saved to an intermediary file and in others you can export it directly to another .ism file. The manner in which you can reuse each element is described below.

Entire Projects

By saving a project as an InstallShield project template, you can create a project from the template that is almost identical to the original project.

Registry Entries

When you export registry entries to a REG file, you can import that file into another component's registry data in the same project or an entirely different one.

String Entries

You can export a project's string entries for a specific language to a tab-delimited text file. Typically, you would send the text file out for translation and then import the string entries back into the project for another language. However, you could also add the exported string entries to another project by importing the file into the other project.

End-User Dialogs

You can save all of your dialogs to an .rc file, export them individually to InstallShield dialog template files, or export them directly to another project.

Components

To export a component to another project, right-click on the component and select Export Components Wizard. Follow through wizard and the component and all of its data are added to the specified project.

Custom Actions

You can export a custom action to another project by right-clicking on the custom action in the Custom Actions explorer and clicking Export. The Custom Actions explorer is in the Custom Actions and Sequences view (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) and the Custom Actions view (in DIM, Merge Module, and MSM Database projects).

Using a Repository to Share Project Elements

InstallShield supports the use of repositories. A repository is a collection of common elements that can be shared and reused in different installation projects. Elements that can be stored in a repository include:

- End-user dialogs
- InstallScript files
- Merge modules
- Project templates
- SQL scripts
- System searches

Repositories provide you with the ability to reuse project elements in multiple projects and strive for consistency. They also save you from having to duplicate work. For example, if many of the installations for your organization's products include a particular custom dialog, you can create that custom dialog once and then publish it to your repository. Any time you want to use that dialog in another installation, simply add the dialog from your repository to your project.

Two types of repositories are available in InstallShield:

- Local repository—A local repository is your own collection of installation elements that you want to be able to reuse in multiple projects. A local repository is stored on your local machine, and it is *not* available to other installation authors.
- Network repository—A network repository is a collection of installation elements that multiple installation authors can access and reuse in their projects as needed. A network repository fosters collaboration among installation authors; it is stored on a network. For information on configuring a network repository, see Setting up a Network Repository.

Edition *• Network repositories are available in the Premier edition of InstallShield only. Local repositories are available in both the Premier and Professional editions of InstallShield.*

Setting up a Network Repository

Edition *• Network repositories are available in the Premier edition of InstallShield only.*

To configure a network repository, or to change the network repository settings, use the Repository tab on the Options dialog box.

Project Templates

A project template contains all of the default settings and design elements that you want to use as a starting point when you create an installation project or merge module project.

You can open a template in InstallShield and edit it as you would a project. To create a template, save any project as a template. For more information, see Creating Project Templates.

For instructions on starting a new project based on a template, see Basing New Projects on Templates.

InstallShield project templates serve only as a starting point for new projects. After you have created a project based on a template, there is no link between the current project and the existing template. If you change an element in the template, it does not affect the project that you created based on that template. However, you can modify the template and create another project based on the updated version of the template.

Creating Project Templates

The procedure for creating a template file varies, depending on whether you are creating a template for a project type that uses .ism project files (Basic MSI, InstallScript, InstallScript MSI, Merge Module), or for a project type that uses .issuite project files.

Creating a Project Template File for Projects that Use .ism Project Files

You can create a project template from any .ism project file; this includes installation projects and merge module projects. When you create a template from an .ism project file, the template file has an .ist file extension.

Task: ***To create a template (.ist) from an .ism project file:***

1. Edit the project to include the desired default settings, user interface, features, and so on.
2. On the **File** menu, click **Save As**. The **Save As** dialog box opens.
3. In the **Save As** type box, select **InstallShield Template (*.ist)**.
4. Type a file name (with the .ist extension) and select a location for the new template. The recommended location for templates is a Templates folder within the project location folder.
5. Click **OK**.

You can open the template in InstallShield and make additional changes. You can use the final version of your template to create a new project.

Creating a Project Template File for Projects that Use .issuite Project Files

You can designate any Advanced UI or Suite Advanced UI project (.issuite) to be a template. Project files and template files for these project types have the same file extension: .issuite.

Task: ***To designate that an .issuite project file is a template file and make the template available for selection in the New Project dialog box:***

Right-click in the **All Types** tab on the **New Project** dialog box and then click **Add New Template**. InstallShield lets you browse to the .issuite file that you want to use as a template, and it adds a new icon for it to the **All Types** tab.

Basing New Projects on Templates

To save time, you can base multiple projects on a single project template that contains default settings and design elements. The template can be stored somewhere on your system. It can also be stored in a repository.

Task: ***To create a project using a template as a starting point:***

1. On the **File** menu, click **New**. The **New Project** dialog box opens.
2. Click the **All Types** tab.
3. Select the template that you want to use.

   Note • *To display templates that are stored in a repository, right-click in the box of project types and ensure that* ***Show Templates in Repository*** *is enabled. To add a template to the tab, right-click in the box of project types and then click* ***Add New Template****. Then browse to the desired template file (.ist file).*
4. In the **Project Name** box, type a name for your project.
5. In the **Location** box, type the path to the directory where you want to store your template, or click the **Browse** button to find it.
6. Click **OK**. InstallShield creates the new project based on the template that you selected, and the new project is opened in InstallShield.

The new project is virtually identical to the project template, except that InstallShield generates a new product code (for installation projects), package code, and upgrade code (for Windows Installer–based installation projects), and a module ID for merge module projects.

Publishing Project Templates to a Repository

If you have an existing template that you would like to reuse for other projects or share with other users, you can publish it to a repository.

Task: ***To publish a template to a repository:***

1. On the **File** menu, click **New**. The **New Project** dialog box opens.
2. Click the **All Types** tab.
3. Right-click the template that you want to publish and then click **Publish Template to Repository**. The **Publish Wizard** opens.
4. Complete the panels in the Publish Wizard.

After you have created a project that is based on a template in your repository, there is no link between the current project and the existing repository template. If you make a change to the template and then republish it to the repository, it does not affect the project that you created based on the template. However, you can create a new project based on the updated version of the template in the repository.

Sample Projects

A number of example project (.ism) files have been included with the InstallShield installation. These projects are stored in the Samples folder. The default location is:

```
C:\Program Files\InstallShield\2013\Samples
```

These projects show you how a certain aspect of an installation project—such as release flags—can be implemented.

Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

InstallShield provides a Project Assistant to help you quickly and easily build a basic installation project. The Project Assistant provides a framework of installation project tasks to guide you through the project creation process and provides pertinent information along the way.

How the Project Assistant Works

When you create a new installation project or transform, the Project Assistant view automatically opens.

Information that you enter in the Project Assistant is saved directly to the underlying project file. Therefore, you can switch to the Installation Designer (described below) and view or modify your information using the full power of the InstallShield Installation Development Environment (IDE). In this way, you can use the Project Assistant to create the foundation for a more advanced installation where you use the Installation Designer, as needed, to customize your installation.

Integration with the Installation Designer

The Installation Designer tab displays all of the views in the InstallShield interface that are available for your project type. Here you can add more complex and powerful elements to your installation project. You can create your installation project using the Project Assistant and then use the Installation Designer to fine-tune project elements.

The Installation Designer and the Project Assistant run simultaneously. Any changes that you make in one are reflected instantly in the other. For example, if you remove a feature while using the Installation Designer tab, that feature is no longer present in your installation project and does not appear in the Project Assistant.

Using the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

When you create a new installation project, the Project Assistant is automatically displayed. The home page has an installation design diagram to help you visualize the steps that are involved in creating an installation. You can work within the Project Assistant to create your project or click the Installation Designer tab to further define a basic installation project.

Using the More Options, Other Places, and Help Links Sections in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The left column on each Project Assistant page contains one or more lists of links to help you in creating your installation and finding information:

- **More Options**—Provides additional configuration options relating to the specific area on the Project Assistant page. These are less common options that complete the functionality of the Project Assistant.
- **Other Places**—The view in the Installation Designer that corresponds to the current Project Assistant page. Clicking the link launches the full Installation Designer and activates that view.
- **Help Links**—This list provides links to help topics pertinent to the current Project Assistant page.

Navigating in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To navigate from one page of the Project Assistant to another, do one of the following:***

- To navigate directly to a specific page, click the appropriate icon in the navigation bar at the bottom of the page.
- To follow the Project Assistant steps sequentially, do one of the following:
  - Click the Next or Back arrow buttons to move forward or backward.
  - Press CTRL+TAB to move to the next page and CTRL+SHIFT+TAB to move to the previous page.
- To move back to the Home page and view the installation design diagram, click the Home button on the navigation bar.

Opening the Installation Designer

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Installation Designer tab displays the views in the InstallShield Installation Development Environment (IDE). You can use this tab to add more complex and powerful elements to your installation project than you can with the Project Assistant. To open a view in the Installation Designer, click the Installation Designer tab.

Note • *The Installation Designer and the Project Assistant run simultaneously. Any changes that you make in one are reflected instantly in the other.*

Showing or Hiding the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Project Assistant provides a simplified view of installation project tasks. You can perform all of the same tasks—and also further customize your project—through the Installation Designer.

If you prefer to create your InstallShield project entirely from within the Installation Designer, you can hide the Project Assistant so that its tab is not displayed in the InstallShield interface. Similarly, if the Project Assistant is hidden, you can choose to display it.

Task: ***To show or hide the Project Assistant:***

On the **View** menu, click **Project Assistant**.

When the Project Assistant command has a check mark next to it, the tab for the Project Assistant is shown in the InstallShield interface. When the check mark is not displayed, the Project Assistant is hidden.

If the Project Assistant command does not have a check mark, the Installation Designer becomes the default tab whenever you create a new project.

Application Information Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Application Information page is where you specify general information about the application your project will install, including the application's name and version, your company's name and Web address, and the application icon.

Add or Remove Programs in the Control Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Add or Remove Programs in the Control Panel provides a list of the applications that are installed on a computer system. You can view information about particular programs and add, modify, or remove programs from Add or Remove Programs.

The information you provide in the Application Information page of the Project Assistant is used to populate information for your application's Add or Remove Programs information when your application is installed.

Company Name and Product Name in Your Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Your company name and product name are used in several places in your installation project.

How Your Company Name Is Used Throughout Your Installation Project

Your company name is used to set the default installation directory for your application. It is also used in Add or Remove Programs in the Control Panel for your application on the end user's system.

How Your Product Name Is Used Throughout the Installation Project

Your product name is used in your application's entry in Add or Remove Programs (in the support information link) on the target system. It is also used in setting the default installation directory.

Installation Requirements Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Installation Requirements page enables you to easily set installation requirements for the target system. For example, if your application requires a specific operating system in order to run properly, you can indicate that in the first section of this page.

Specifying Operating System Requirements in the Project Assistant

Project • *The ability to specify operating system requirements in the Project Assistant is available in the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

When you specify operating system requirements on the Installation Requirements page of the Project Assistant, InstallShield creates launch conditions. These conditions are added to the **LaunchCondition** table of your .msi file; you can view and edit this table in the Direct Editor.

How InstallShield Creates the Operating System Launch Conditions

When you specify operating system requirements on the Installation Requirements page, you are essentially excluding operating systems that do not support your application.

For example, if you select only the check box for the latest Windows operating system, InstallShield creates a launch condition to exclude the operating systems that you did not select on the Installation Requirements page. With this type of launch condition, future versions of Windows operating systems are supported automatically because they are not excluded in the launch condition.

When Does the Installation Check for Requirements?

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

To ensure that the required software or operating system is present on the target system, the installation checks for these requirements in the beginning of the installation before any files are transferred.

Modifying the Run-Time Message for Software Requirements

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

If your installation has software requirements and the target system does not have the selected software, a run-time message is displayed during the installation. You can modify the message that is displayed.

Task: ***To modify the run-time message:***

1. In the Project Assistant, open the **Installation Requirements** page.
2. Select **Yes** in answer to the software requirements question.
3. Select the software that your application requires. The default run-time message is displayed to the right.
4. Click the run-time message to edit it.

Creating Custom Installation Requirements

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

You can create customized installation requirements in the Installation Designer by using the product's Install Condition setting. For this setting, you can create conditions that the Windows Installer must evaluate before launching the installation. For more information, see Setting Product Conditions.

You can also use the System Search Wizard to search for a particular file, folder, registry key, or .ini value on the target system. The System Search Wizard enables you to create a condition with the search value.

Installation Architecture Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Installation Architecture page lets you specify the features you want your installation program to display to the end user. A feature is the smallest separately installable piece of your product from the end user's standpoint. Individual features are visible to end users when they select a Custom setup type during installation.

Note • *Features can contain subfeatures, subsubfeatures, and so forth, to as many levels as your installation program requires.*

Adding Features in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To add a feature:***

1. In the Project Assistant, open the **Installation Architecture** page.
2. Select **Yes** in answer to **Do you want to customize your Installation Architecture?**
3. To add a main feature, click the **Installation Architecture** explorer. To add a subfeature, click the feature that you want to be the parent feature, and then click **New**. The Project Assistant creates the new feature.
4. Name the feature or click **Rename** to name it later.

Determining Whether to Create a Multiple-Feature Installation

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Features are the building blocks of an installation, from the end user's perspective. Because of this, features should represent distinct and discrete pieces of functionality within your installation.

If your application has different blocks of functionality, you should create a multiple-feature installation. For example, if your installation contains your application (.exe file) and a help library (.hlp file), your installation project should contain at least two features—one for each piece of functionality.

To learn more about creating a multiple-feature installation within the Project Assistant, see Creating Installations with Multiple Features.

Creating Installations with Multiple Features

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

You can create an installation with multiple features using the Project Assistant or in the Installation Designer (IDE).

Task: ***To create a multiple-feature installation in the Project Assistant:***

1. In the Project Assistant, open the **Installation Architecture** page.
2. Select **Yes** to indicate you want to customize your installation architecture.
3. Click the **Installation Architecture** explorer and then click **New**. The Project Assistant creates a new feature.
4. Press F2 or right-click the feature and select **Rename** to provide a name for the new feature.
5. To add another feature at the same level, click the **Installation Architecture** explorer and then click **New**. To create a subfeature, click the feature that you want to be the parent feature, and then click **New**. The Project Assistant creates the new feature.

6. Continue adding features and subfeatures as needed.

To learn about working with features in the Installation Designer, see Creating Features.

Default Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The *default feature* concept exists only in the Project Assistant. All resources (for example, files or registry data) that are added to an installation project need to be associated with a feature. If a resource is not associated with a feature, it is not installed to the target system at run time.

Using a default feature simplifies the authoring experience in the Project Assistant. You do not need to worry about associating project resources with a feature to ensure that they are installed. When you add registry data, create new shortcuts, or add files when All Application Data is selected, all of these resources are added to the default feature.

Setting the Default Feature

You can set the default feature in the Installation Architecture page of the Project Assistant.

What Happens If There Are No Features or No Default Feature Is Selected?

When you navigate to the Installation Architecture page or add data to the Application Files, Application Shortcuts, or Application Registry pages, InstallShield selects the first root feature as the default feature. If there are no features, InstallShield creates one silently.

Defining Feature Hierarchy

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Top-level features are the highest level in the feature hierarchy. Top-level features might include the application you want to install, a help library feature, and a sample projects feature.

Beneath the top-level features are subfeatures or *child* features. This is a feature that is dependent upon another feature for installation purposes. If the *parent* (or top-level) feature is not installed to the target system, the child feature is not installed.

Application Files Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Application Files page lets you specify the files you want to associate with each of your features.

Adding Files to Features in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To add a file to a feature:***

1. In the Project Assistant, open the **Application Files** page.
2. In the feature list at the top of the page, select the feature that should contain the file.
3. In **Destination Computer** explorer, select the folder to which you want to add the file.
4. Click **Add Files**. The **Open** dialog box opens.
5. Browse to the file that you want to add.
6. Click **Open** to add the file to the selected feature. The message “The file you have added ... may have dependencies” appears.

7. Click **Yes** if you want to have those dependencies automatically added to your installation project.

Removing Files from Features in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To remove a file from a feature:***

1. In the Project Assistant, open the **Application Files** page.
2. Click the file you want to remove and press **Delete**.

Adding Files to a Fixed Folder Location

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

If you know exactly where you want the installation to install your project files on the target system, you can hard-code a fixed folder destination.

Task: ***To add files to a fixed folder location in the Project Assistant:***

1. In the Project Assistant, open the **Application Files** page.
2. Right-click **Destination Computer** and click **New Folder**.
3. For the new folder's name, type the drive in which the destination is located—for example, **C:**.
4. Beneath the drive letter folder, further define the destination path by adding subfolders.

Viewing Additional Predefined Folders

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Project Assistant's Application Files page displays the more commonly used predefined folders. You can view and hide predefined folders in this page.

Task: ***To display additional predefined folders:***

1. In the Project Assistant, open the **Application Files** page.
2. Right-click **Destination Computer** and click **Show Predefined Folder**.
3. In the list of predefined folders, select the folder you want to display.

Tip • *To hide predefined folders, deselect them in the list of predefined folders.*

Application Shortcuts Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Application Shortcuts page lets you specify shortcuts for your application's files on the target system's desktop or Start menu. By default, this page displays a shortcut for each executable file that you have added to your project through the Project Assistant. You can delete these, and add shortcuts to other files that you have included in your installation project.

File Extensions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

File name–extension associations, or file associations, are registry settings that tell Windows what application to use to open files of a certain type. For example, Windows typically opens text files (files with the .txt extension) with Windows Notepad, and opens bitmap files (files with the .bmp extension) with Microsoft Paint.

A file extension allows someone to identify the type of file without accessing the file. A suffix (**.abc**) is appended to the file name. The file extension is also useful in that another application can recognize whether the application can work with the file (for example, open the file or modify it), based on the extension.

In InstallShield, you can register your own file extensions by configuring the settings in the Advanced Settings area of a component in the Components view or the Setup Design view. Registering your file extension instructs the target machine's operating system to use your application to open files with your file extension when an end user clicks on a file.

Creating Shortcuts to Files That Are Not Included in the Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

You can configure your installation to create a shortcut that points to a file that already exists on the target system. This file does not have to be included in your installation project.

Task: ***To create a shortcut to a file that is not included in the installation:***

1. Open the Installation Designer.
2. In the View List under **System Configuration**, click **Shortcuts**.
3. In the **Shortcuts** explorer, right-click the destination directory that you want to contain the shortcut and then click **New Shortcut to Preexisting File**. The **Browse for Shortcut Target** dialog opens.

4. Browse to the target file's location and enter the file's name in the **File Name** setting.
5. Click **OK**.
6. Configure the shortcut's settings.

Modifying a Default Shortcut in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To modify a default shortcut:***

1. In the **Project Assistant**, open the **Application Shortcuts** page.
2. Select the shortcut that you want to modify.
3. Make the required changes as needed.

Associating a Shortcut's Target with a File Extension in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

You can associate a shortcut's target with a file extension. When you do this, Windows will use the target file to launch files with the specified file extension. For example, if you enter .txt, when the end user opens a .txt file, the target file of this shortcut is launched to open the .txt file.

Task: ***To associate a shortcut's target with a file extension:***

1. In the **Project Assistant**, open the **Application Shortcuts** page.
2. Click the shortcut to activate the shortcut options.
3. Select the **Associate shortcut with file extension** option.
4. Type the file extension that you want to associate with this shortcut's target—for example, **txt**. You can add multiple extensions by separating them with a comma.

Application Registry Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Application Registry page lets you specify any registry data that your application requires.

Updating the Registry

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The registry is a database for your computer's configuration information. Information included in a computer's registry includes user profiles, hardware and software installed on the computer, and property settings.

How Do I Know What Registry Data My Application Requires?

The application developer should be able to provide registry information for you. Specifically, you will need to know if the application you are installing requires any user-specific (HKEY_CURRENT_USER) or machine-specific (HKEY_LOCAL_MACHINE) settings.

The developer can provide a .reg file that you add to your installation. InstallShield allows you to import .reg files into your installation project.

Configuring Registry Data in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To configure registry data:***

1. In the **Project Assistant**, open the **Application Registry** page.
2. Select **Yes** in answer to the question about configuring registry data.
3. Right-click the registry item to which you want to add the data, select **New**, and point to **Key**.
4. Name the key.
5. Right-click the key, select **New**, and point to the appropriate command. You can pick Default Value, String Value, Binary Value, DWORD Value, Multi-String Value, or Expandable String Value, depending on the type of data you want to register.

Modifying Registry Data Values in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To modify registry data:***

1. In the **Project Assistant**, open the **Application Registry** page.
2. Double-click the data.

If you double-clicked a multi-line string, the **Multi-Line String Value** dialog box opens. If you double-clicked any other type of registry data, the **Edit Data** dialog box opens.

3. Edit the data and click **OK**.

Associating Registry Data with Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

All the registry data that you add in the Project Assistant's Application Registry page is added to your project's default feature. You can associate your registry data with another feature in the Installation Designer.

Task: ***To use the Installation Designer to associate registry data with a feature other than the default feature:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **View Filter** list, select the feature with which you want to associate the registry data.
3. Create or drag and drop the registry data in the appropriate registry location.

Using Variable Data Types in Registry Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

InstallShield allows you to use variable data types or properties when creating registry data for your installation project.

Task: ***To use INSTALLDIR as a variable in the registry (Windows Installer-based projects only):***

1. In the **Project Assistant**, open the **Application Registry** page.
2. Select **Yes** to indicate that you want to configure the registry data that your application will install.
3. Right-click **HKEY_CLASSES_ROOT**, point to **New**, and select **Key**.
4. Name the key **Installation Location**.
5. Right-click the **Installation Location** key, point to **New**, and select **String Value.**
6. Name the string value **My Installation Location**.
7. Double-click the **My Installation Location** key. The **Edit Data** dialog box opens.
8. In the **Value Data** field, type `[INSTALLDIR]`.

At run time, the value of **[INSTALLDIR]** is replaced with the installation directory.

Application Paths

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The application path registry key contains data that Windows uses as a private search path for the specified application's .dll files. If you install an application's .dll files into a directory not found in the PATH environment variable (and not into the application's directory), you should set the appropriate application path to include the .dll file directory during installation. Application path information is stored in the registry under HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths\AppName.exe.

Installation Interview Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *MSI Database*

The Installation Interview page lets you specify the dialogs you want the end user to see when your installation program runs. Based on your answers to the questions on this page, the Project Assistant adds the corresponding dialog to your installation project.

Specifying Dialogs for Your Installation in the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *MSI Database*

Note that the option for launching your application when the installation completes is not available in InstallScript projects.

The questions that are displayed on the Installation Interview page of the Project Assistant help you specify which dialogs you want the end user to see when your installation program runs.

Task: ***To specify dialogs for your installation:***

1. **Do you want to display a License Agreement Dialog?—**Select **Yes** to browse to your license agreement file.
2. **Do you want to prompt users to enter their company name and user name?—**Select **Yes** to display a dialog requesting this information.
3. **Do you want your users to be prompted to modify the installation location of your application?**—Select **Yes** to present a dialog that allows end users to change the installation location. See Allowing End Users to Modify the Installation Location for more information.
4. **Do you want users to be able to selectively install only certain parts of your application?—**Select **Yes** to allow end users to select which parts of the application they want to install. See Creating Selectively Installable Installations for more information.
5. **Do you want to give users the option to launch your application when the installation completes?—**Select **Yes** and browse to your application file. When this option is set to **Yes**, the final dialog in the installation presents a check box that allows end users to immediately launch your application upon clicking the **Finish** button.

Tip • *To add a custom graphic to your installation dialogs, click the link in the More Options section of this page to launch the Dialog Images dialog box.*

Allowing End Users to Modify the Installation Location

If you want to provide end users with control over where your software is installed on their system, you can allow them to modify the installation location.

In a Windows Installer-based installation, the Windows Installer property **INSTALLDIR** serves as the default installation directory. When you allow users to modify the installation location, the CustomSetup dialog is presented during the installation.

In an InstallScript project, TARGETDIR serves as the default installation directory. When you allow users to modify the installation location, the SdSetupType2 dialog is presented during the installation.

License Agreements

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *MSI Database*

In order to install your product, you may require that your end users agree to certain legal requirements. For example, most software vendors do not allow end users to copy or distribute their software to others.

Your installation can present an End User License Agreement (EULA) in the License Agreement dialog at run time. The EULA is a legal contract between you and the end user, with regard to the use of your product.

The License Agreement dialog displays your license agreement text and contains a radio button group (Yes or No). If the end user does not agree to accept the EULA, your software is not installed and the installation ends.

Task: ***To add a License Agreement dialog to your project in the Project Assistant:***

1. In the **Project Assistant**, open the **Installation Interview** page.
2. Select **Yes** to indicate that you want to add a **License Agreement** dialog.
3. Type the path to your license agreement file or browse to the file.

Project • *For Basic MSI and MSI Database projects, the file must be a rich text file (.rtf).*

For InstallScript projects, the file type depends on which license dialog that you are using and which parameters you are passing to it. The SdLicenseEx and SdLicense2Ex functions have support for .rtf files and text files (.txt).

Creating Selectively Installable Installations

You can allow your end users to select which portions of your installation they want to install to their systems. This is a custom installation, which provides a list of the available features within your installation. The end user can select the features to install in a dialog presented at run time.

For example, your installation might contain your application's executable (.exe) file, a documentation (.chm) file, and a samples file. All of these files are contained in different features, which are provided in an option list to the end user. If the end user needs only the application, they can select to install the executable file, but not the documentation or samples file.

Installation Localization Page

Edition • *Multilingual language support is available in the Premier edition of InstallShield.*

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The Installation Localization page lets you specify the languages your installation supports, and specify string values and associated identifiers, which you can use in your end user interface to make your installation more easily localizable in other languages.

Note • *You can specify the set of string data that you want to edit in the drop-down menu at the top of the page.*

Localizing String Data from the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Much of the text in your installation project is stored as string entries. To make localizing your installation easier, InstallShield provides the capability to export your strings for translation and import the translated strings back into your project.

Task: ***To export all of the string data in your project for translation:***

1. In the **Project Assistant**, open the **Installation Localization** page.
2. In the data list at the top of the page, select **All String Data**.
3. In the list of languages, select a language.
4. In the **More Options** area, click **Export localizable strings**. The **File Name** dialog box opens.
5. Save the text (.txt) file to the location you want.
6. Send the text file to your translation company or department.

Task: ***After the strings in your text file are translated, you can import the strings back into your project:***

1. In the **Project Assistant**, open the **Installation Localization** page.
2. In the data list at the top of the page, select **All String Data**.
3. In the list of languages, click the language that matches the strings that you want to import.
4. In the **More Options** area, click **Import localizable strings**. The **File Name** dialog box opens.
5. Browse to your .txt file and click **Open**. The translated strings are imported back into your project.

How Localized String Data Is Used in the Installation

There are two types of string data in an installation project—string data that is specific to your installation and string data that is specific to your application.

The majority of the string data in an InstallShield project is used at run time when an end user runs the installation. However, some of the string data is installed to the target system. For example, a localized shortcut is localized string data that is installed to the end user's system.

Build Installation Page

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Tip • *The following information applies to releases that are built within InstallShield (without integration with Visual Studio). For information on building an InstallShield release from within Visual Studio, see Building Releases in Microsoft Visual Studio.*

The Build Installation page lets you specify what type of distribution you want to build and, optionally, the location to which you want to copy the distribution files. It also enables you to digitally sign the package.

Building Your Installation from the Project Assistant

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Tip • *The following information applies to releases that are built within InstallShield (without integration with Visual Studio). For information on building an InstallShield release from within Visual Studio, see Building Releases in Microsoft Visual Studio.*

Task: ***To build your installation:***

1. In the **Project Assistant**, open the **Build Installation** page.
2. Select the installation image types you want to build.

   

   Note • *The **Single MSI Package** option should be selected for machines that already have Windows Installer installed them since no attempt will be made to check and install the engine if it is not there.*

3. If you want InstallShield to automatically copy your installation to another location after the build finishes, click the **Optional distribution settings** link for each build option and specify the location.

   If you want InstallShield to distribute your installation after the build finishes, click the **Optional distribution settings** link for each build option and select the **Distribute After Build** check box.
4. To digitally sign your `Setup.exe` file to assure your end users that the code within your application has not been modified or corrupted, click the **Digitally Sign Setup hyperlink**. The **Digitally Sign Setup** dialog box opens. Configure the settings as needed.
5. Click **Build Installations**.

The Output window opens, and the Build tab displays information about the progress of the build. The build is finished when the Build tab displays the log file information.

Tip *• The Signing tab in the Installation Designer lets you specify which portions of your installation should be digitally signed at build time. InstallShield enables you to sign any and all of the following files in a release, depending on what type of project you are using:*

- *Windows Installer package (.msi file or .msm file) for Basic MSI, InstallScript MSI, and Merge Module projects*
- *`Setup.exe` file for Basic MSI and InstallScript MSI projects*
- *Media header file for InstallScript projects*
- *Package (self-extracting single-executable file) for InstallScript projects*
- *Any files in your release, including your application files*

To learn more, see Digitally Signing a Release and Its Files at Build Time.

Windows Logo *• All executable files (including .exe, .dll, .ocx, .sys, .cpl, .drv, and .scr files) in an installation must be digitally signed for the Windows logo program.*

After Completing the Project Assistant: Next Steps

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

After going through the Project Assistant pages and completing the fields, you have an installation project framework that you can use as a functional installation or you can further customize to fit your needs.

Further Customizing Your Project

The Installation Designer provides an easy way to access all of the installation creation views available in InstallShield. Click the Installation Designer tab at the top of the Project Assistant workspace to display the views.

Within the Installation Designer, you can see the View List, which is a list of all available views for the project type that you are creating. To display the View List on the left side of the workspace, press F4.

Learning About InstallShield Views

For detailed information about each of the InstallShield views, refer to the topics in the View List section of the InstallShield Help Library.

Working with the InstallShield Interface

The InstallShield interface is a graphical user interface with conventional Windows-based elements such as a menu bar, a toolbar, and dialog boxes. This section includes topics that explain how to perform basic tasks using these elements and how to customize the interface.

Displaying the View List

Task: ***To see the View List in the InstallShield interface:***

1. Click the **Installation Designer** tab at the top of the InstallShield interface.
2. Do one of the following to display the View List:
   - On the **View** menu, click **View List**. The **View List** appears on the left side of the InstallShield interface.
   - Click the toolbar's **View List** button.
   - Press F4 to hide or show the **View List**.

Opening Views in the InstallShield User Interface

The first step in many InstallShield procedures is to open a particular view in the Installation Development Environment (IDE).

Task: ***To open a view:***

1. Click the **Installation Designer** tab. The **View List** is displayed along the left side of the IDE. If the **View List** is not displayed, see Displaying the View List.
2. In the **View List**, select the view you want to open. To see all available views, expand the View List folders.

Working with the Group Box Area in Various Views

A number of views in InstallShield have a group box area that lets you organize the rows in the view. The views that contain this group box support multiple levels of grouping simply by dragging the column headers and dropping them onto the group box (the area that says, "Drag a column header here to group that column"). InstallShield displays the rows in the view hierarchically according to column arrangement in the group box. Examples of views that contain the group box are the String Editor, Property Manager, the Redistributables, Prerequisites, and Path Variables views.

Note the following tips for working with the group box:

- To move a column header to the group box area, drag the column header and drop it onto the group box.

- To copy a column header onto the group box area, press CTRL while dragging the column header and dropping it onto the group box. When you do this, the column header is displayed as a column header, and in the group box.
- When you are dropping group box headers onto the group box area, you can drop them onto other column headers. This enables you to organize rows hierarchically.
- To remove a column header from the group box, drag it from the group box area and drop it onto the row of column headers. When you are dragging it over the row of column headers, InstallShield displays arrows to indicate where in the row the column header would be displayed if you dropped it.
- To sort the items in the grid by a particular column header, click the column header in the group box or in the row of column headers.

The following examples demonstrate different ways for using the group box to organize content in views.

Default Behavior: Empty Group Box Area

By default, no column headers are displayed in the group box. The following screen shot shows part of the Redistributables view. Items are sorted by the Name column.

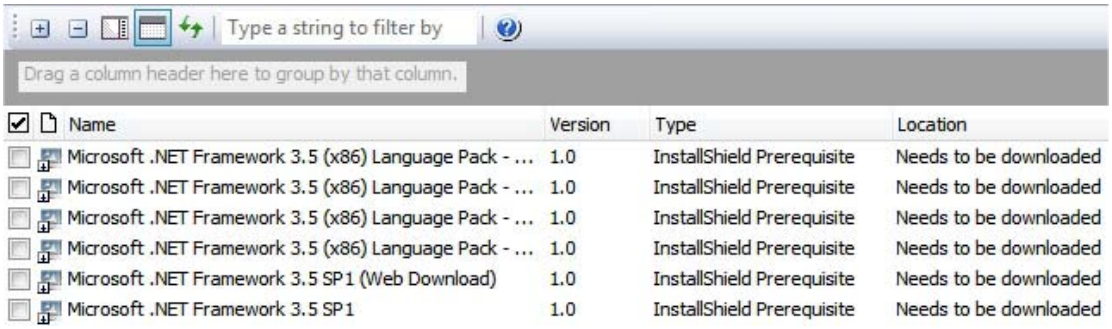

Figure 2-3: Empty Group Box Area

Grouping by One Column Header

If you press CTRL while dragging and dropping one column header onto the group box, InstallShield arranges the rows in the grid into groups of items. The following screen shot shows part of the String Editor view. Rows are organized to help identify the recently added and modified strings that need to be translated.

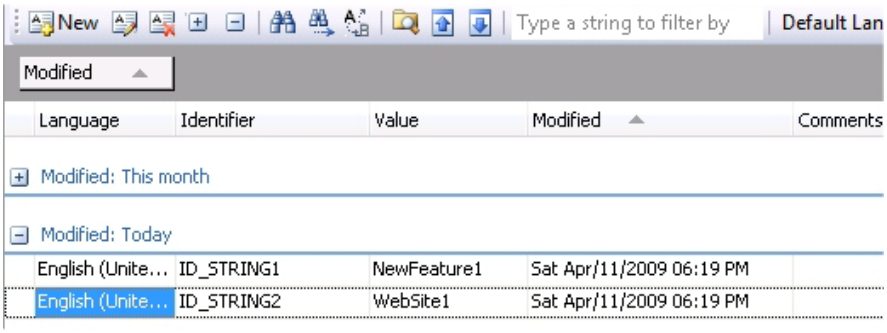

Figure 2-4: Grouping Rows by One Column Header

Grouping by Two Column Headers

If you press CTRL while dragging and dropping one column header onto another column header in the group box, InstallShield arranges the rows in the grid into multiple groups of items. The following screen shot shows part of the Redistributables view. Rows are organized to help identify the InstallShield prerequisites and merge modules that have been added to the project.

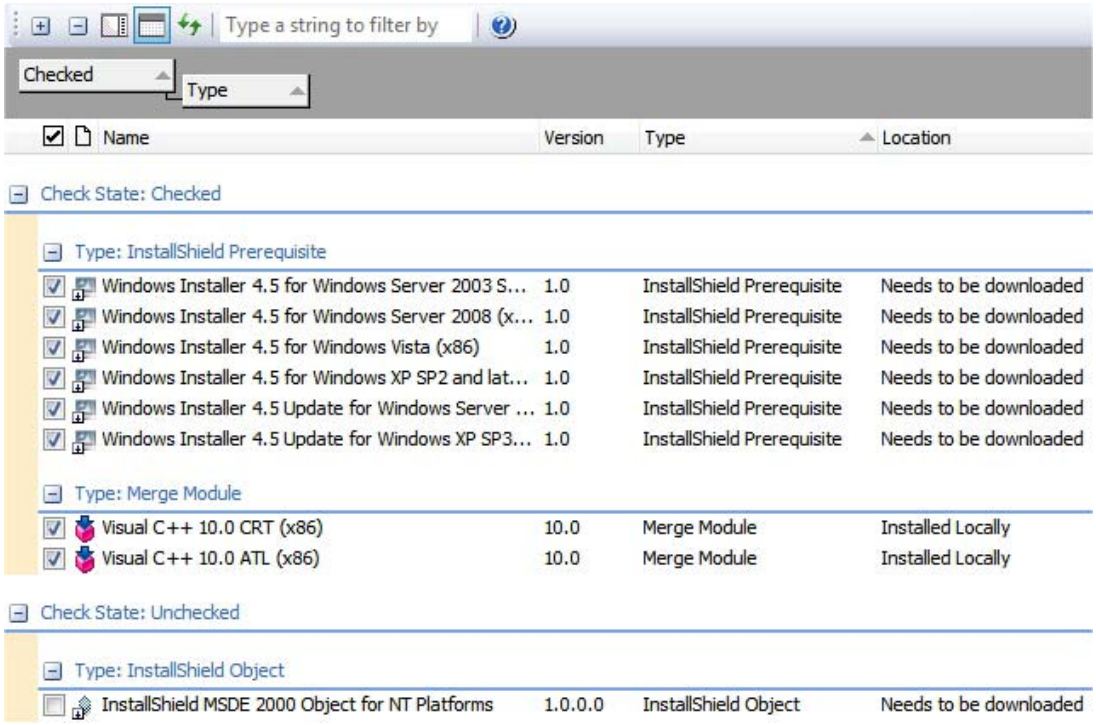

Figure 2-5: Sorting Rows by the Check Box Column and Then the Type Column

Showing or Hiding Toolbars

Task: ***To show or hide a toolbar, do one of the following:***

- Right-click a toolbar and select the toolbar that you want to be displayed or hidden.
- On the **Tools** menu, click **Customize**. The **Customize** dialog box opens. Select the check box for each toolbar that you want to be displayed. Clear the check box for each toolbar that you want to be hidden.

Adding Buttons and Menus to a Toolbar

Task: ***To add a button or menu to a toolbar:***

1. Ensure that the toolbar that you want to change is visible.
2. On the **Tools** menu, click **Customize**. The **Customize** dialog box opens.
3. Click the **Commands** tab.
4. In the **Categories** box, click the category for the button or menu that you want to add.
5. Drag the button or menu from the **Commands** box to the appropriate toolbar.

Tip • *To create your own custom toolbar, drag the button or menu to the empty gray area near the toolbars.*

Removing Buttons and Menus from a Toolbar

Task: ***To remove a button or menu from a toolbar:***

1. Ensure that the toolbar that you want to change is visible.
2. On the **Tools** menu, click **Customize**. The **Customize** dialog box opens.
3. Right-click the button or menu that you want to remove, and then click **Delete**.

Creating Custom Toolbars

Task: ***To create a custom toolbar:***

1. On the **Tools** menu, click **Customize**. The **Customize** dialog box opens.
2. Click the **Toolbars** tab.
3. Click the **New** button. The **New Toolbar** dialog box opens.
4. In the **Toolbar name** box, enter a descriptive name for the toolbar, and click **OK**.
5. Customize the new toolbar by adding menus or buttons.

Docking or Undocking the Output Window

The Output window or its individual tabs can be docked to any side of the workspace in InstallShield, or they can be dragged to free-floating positions.

If you drag the Output window or one of its tabs to the edge of the InstallShield interface, it becomes a docked window. If you drag the Output window or one of its tabs away from any of the edges of the InstallShield interface, it becomes undocked.

Task: ***To undock the Output window:***

Drag the title bar of the Output window to the new location. Resize the Output window as needed.

Task: ***To dock the Output window:***

Drag the title bar of the Output window to the left, right, top, or bottom edge of the InstallShield interface.

Task: ***To undock a tab on the Output window:***

Drag the tab to the new location. Resize the Output window as needed.

Task: ***To dock one of the Output window tabs:***

Drag the tab to the left, right, top, or bottom edge of the InstallShield interface.

Working with the Script Editor Pane in Various Views

Several views in InstallShield have a script editor pane that you can use to write code for your projects. Examples of views that contain the script editor pane are:

- **InstallScript view**—When you select a script file in this view, InstallShield displays a script editor pane where you can write InstallScript code.
- **SQL Scripts view**—When you select a SQL script in this view, the Script tab shows a script editor pane that lets you edit your SQL file.
- **Custom Actions and Sequences view**—When you select a VBScript or JScript custom action in this view, the Script tab shows a script editor pane that lets you edit your VBScript or JScript file.

This section of the documentation describes how to use the script editors in InstallShield.

Using Bookmarks in the Script Editors

Bookmarks are markers that let you jump to specific lines within your script with a minimum number of keystrokes. Bookmarks are visible in the left margin of the script editor. Note that InstallShield does not save bookmarks when you close your project.

Task: ***To add a new bookmark or clear an existing bookmark:***

1. Do one of the following:
   - Place the insertion point in the line of your script that you want to contain a bookmark.
   - Place the insertion point in the line of your script that contains the bookmark that you want to
2. Press ALT+K.

Task: ***To move the insertion point to the next line that contains a bookmark:***

Press CTRL+K.

Task: ***To move the insertion point to the previous line that contains a bookmark:***

Press CTRL+SHIFT+K.

Enabling or Disabling Auto Completion in the Script Editors

InstallShield lets you specify whether you want to be able to use automatic completion when you are typing in the script editor in various views (for example, the InstallScript view and the SQL Scripts view). If auto completion is enabled, InstallShield displays a pop-up list of alphabetically ordered functions, keywords, constants, and string identifiers that begin with the letters that you are typing in the script editor. Instead of manually typing the entire word, you can select it in the pop-up list, and InstallShield adds it to your script.

Auto completion can increase your efficiency because it can reduce the time that you spend typing code. It can also help you avoid typographical errors in your code.

Tip • *Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same auto completion settings are used for all script editors. If you change the settings in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether auto completion should be available in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Auto completion** setting, select the appropriate option:
   - **Yes**—InstallShield displays a pop-up list of available functions, keywords, constants, and string identifiers that begin with the letters that you are typing code in the script editors. This is the default option.
   - **No**—InstallShield does not display a pop-up list when you are typing code in the script editors.
3. In the **Include local variables** setting, select the appropriate option:
   - **Yes**—InstallShield adds local variables that are defined in InstallScript to the pop-up list of available functions and other script words that begin with the letters that you are typing code in the InstallScript editor. This is the default option.
   - **No**—InstallShield does not include local variables in the pop-up list when you are typing code in the InstallScript editor.

     Note that if you select No, the Functions, Properties, and Methods folders in the center pane of the InstallScript view do not list any functions, properties, or methods from your script files.

     If Yes is selected for this setting and you notice performance issues when you are typing code in the InstallScript view, you might want to change this setting to No.

     Note • *The **Include local variables** setting applies to the script editor in the InstallScript view; it does not have any effect on the script editors in other views, such as the SQL Scripts view. This setting is ignored if you select **No** for the **Auto completion** setting.*
4. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield enables or disables auto completion in the InstallScript editor as needed.

For details about how auto completion works, see Using Auto Completion when Writing Code in the Script Editors.

Using Auto Completion when Writing Code in the Script Editors

If auto completion is enabled for the script editors in InstallShield, InstallShield displays a pop-up list of alphabetically ordered functions, keywords, constants, and string identifiers that begin with the letters that you are typing in the script editor. The pop-up list contains language-appropriate options, depending on which view you are using. For example, the script editor in the InstallScript view supports auto completion of InstallScript code. The VBScript script editor in the Custom Actions and Sequences view supports auto completion of VBScript.

In addition, if auto completion for local variables is enabled, the pop-up list in the script editor of the InstallScript view also contains local variables.

To learn how to enable auto completion, see Enabling or Disabling Auto Completion in the Script Editors.

Task: ***To use auto completion for a function name, a keyword, a constant, or string identifier:***

1. Open the view that contains the appropriate script editor, and select the script that you want to edit.
2. Place the insertion point where you want to enter code in your script.
3. Do one of the following:
   - Type the first characters of the function name, keyword, or other script word.

     Depending on the view that you are using and the language that is entered in the script editor in that view, InstallShield displays a pop-up list of alphabetically ordered functions, keywords, and other script words that begin with the letters that you are typing in the script editor. The first word that matches the characters that you typed is selected in the list. If no word matches the characters that you typed, no word in the list is selected.
   - If you are using the script editor in the InstallScript view and you want to use auto completion for a list of available string identifiers, enter the string constant operator (@). InstallShield displays a pop-up list of alphabetically ordered string identifiers.
4. If the selected word is not the one you want (or no word is selected), select another word in one of the following ways:
   - To navigate through the list, use the pop-up list's scroll bar; then, click the desired word to select it.
   - To change the selection to the previous or next word, use the UP ARROW and DOWN ARROW keys.
5. To paste the selected word into your script, double-click the word, or press the ENTER key or the TAB key.

To close the list without pasting the selected word, press ESC or click outside the pop-up list.

Enabling or Disabling InstallScript Function Call Tips in the Script Editor

InstallShield lets you specify whether you want InstallShield to display an InstallScript function call tip—a type of tooltip—when you are entering a function call in your script in the InstallScript view. A function call tip shows a built-in function's parameter information. It also shows a description of the built-in function, as well as a description of the parameter that you are entering.

Function call tips let you see language information within the script editor, without requiring you to switch to a different window.

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same auto completion settings are used for all script editors. If you change the settings in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether function call tips should be shown in the script editor of the InstallScript view:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Show function call tips** setting, select the appropriate option:
   - **Yes**—InstallShield displays function call tips when you are entering function calls in your script. This is the default option.
   - **No**—InstallShield does not display function call tips when you are entering function calls in your script.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield enables or disables function call tips in the InstallScript editor as needed.

For details about how function call tips work, see Viewing Function Call Tips for an InstallScript Function in the Script Editor.

Viewing Function Call Tips for an InstallScript Function in the Script Editor

If function call tips are enabled, InstallShield shows InstallScript function call tips—a type of tooltip—when you are entering function calls in your script in the InstallScript view. A function call tip shows a built-in function's parameter information. It also shows a description of the built-in function, as well as a description of the parameter that you are entering.

To learn how to enable function call tips, see Enabling or Disabling InstallScript Function Call Tips in the Script Editor.

Task: ***To view a description of a function, as well as parameter details about that function:***

1. Enter a function name in your script by typing it or using automatic function name completion, as described earlier.
2. Type a left parenthesis—`(`—after the function name. InstallShield displays a function call tip that shows a complete call to the function, including all of its parameters. The tip also includes a description of the function, as well as a description of the next parameter that you need to enter. The first parameter appears in blue, by default.
3. Type the parameters as indicated by the call tip. Each time that you type a comma, the next parameter in the function syntax appears in blue, by default.
4. To close the call tip, type the right parenthesis—`)`. Or, press ESC or click in the script editor pane outside the call tip.

Tip • *To view additional details about a particular built-in function, constant, or other InstallScript word, place the insertion point within that word, and then press F1. The InstallShield Help Library opens, enabling you to learn more about that particular word.*

Enabling or Disabling Syntax Highlighting in the Script Editors

InstallShield lets you specify whether you want the script editors in various views in InstallShield to display script files with color attributes that identify keywords, comments, strings, and other script elements. Each category is displayed in a different color so that you can easily identify them.

This functionality—called *syntax highlighting*—helps to improve the readability and context of code. In addition, it can help you avoid errors that are caused, for example, when you attempt to use a reserved word as a user-defined identifier. It can also help you locate other errors in your script, such as misspelled keywords, missing quotation marks at the end of a string, and missing comment characters.

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same syntax highlighting and color settings are used for all script editors. If you change the settings in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether syntax highlighting should be enabled in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Syntax highlighting** setting, select the appropriate option:
   - **Yes**—InstallShield uses the syntax highlighting that is defined in the **Colors** area of the **Script Editor Properties** dialog box in all of the script editors. This is the default option.
   - **No**—InstallShield does not use any syntax highlighting in any of the script editors.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield enables or disables syntax highlighting in the script editors as needed.

InstallShield lets you define the foreground color and background color that is used for each script word category. To learn how, see Changing Colors for Syntax Highlighting in the Script Editors.

Changing Colors for Syntax Highlighting in the Script Editors

InstallShield lets you change the colors that are used to differentiate among different script elements in the script editor in various views (for example, the InstallScript view and the SQL Scripts view). You can change the foreground color (the color that is used for the text), as well as the background color, for script elements such as comments, functions, and strings.

This functionality—called *syntax highlighting*—helps to improve the readability and context of code. In addition, it can help you avoid errors caused, for example, when you attempt to use a reserved word as a user-defined identifier. It can also help you locate other errors in your script, such as misspelled keywords, missing quotation marks at the end of a string, and missing comment characters.

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same syntax coloring settings are used for all script editors. If you change the settings in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To change the syntax highlighting that is used in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Colors** area, click the setting for the script element that you want to configure. InstallShield displays foreground and background buttons in the setting.
3. Do one of the following:
   - Click the foreground button or the background button. The **Colors** dialog box opens, enabling you to select the color that you want to use.
   - Enter the RGB values for the color that you want to use for the foreground or the background. For example, the entry **0; 0; 0** / **255; 255; 255** indicates that InstallShield should use black (which has an RGB value of 0; 0; 0) for the foreground and white (255; 255; 255) for the background. If you do not want to set a color for a particular area, you can use dashes (-;-;-).
4. Click **OK**. The **Script Editor Properties** dialog box closes.

If script highlighting is enabled, InstallShield changes the colors that are used to display text in the script editor as needed. To learn more, see Enabling or Disabling Syntax Highlighting in the Script Editors.

To make the best use of this functionality, note the following:

- Misspelled reserved words are not recognized by the editor and are not displayed with syntax coloring. If you see in your script a “reserved word” that is not displayed with indicating attributes, it is possible that it is misspelled.
- Coloring of string literals includes both the opening and closing quotation marks. If the closing quotation mark is missing, string coloring will extend to the end of the line; in that case, text that should have followed the quotation will be displayed as though it were part of the string literal.
- Syntax coloring makes it easy to identify comments that open with `/*` and are not closed properly with `*/`. In that case, all of the text that follows the comment is displayed with the comment color attribute.
- In lines that include comments starting with two slashes (`//`), all text from the comment character to the end of the line is recognized as a comment.
- In the script editor that is displayed in the InstallScript view, InstallShield does not use syntax coloring for files that have an extension other than .rul or .h (for example, log or report files).

Changing the Font that Is Used to Display Text in the Script Editors

InstallShield lets you change the font that is used in the script editor in various views (for example, the InstallScript view and the SQL Scripts view).

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same font is used for all script editors. If you change the font in the SQL Scripts view, the font is also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To change the font, font style, or font size that is used to display text in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **General** area, click the **Font** setting, and then click the ellipsis button (**...**) in this setting. The **Font** dialog box opens.
3. Specify the font changes as needed.
4. Click **OK**. The **Font** dialog box closes.
5. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield changes the font that is used to display text in the script editor as needed.

Showing or Hiding Line Numbering in the Script Editors

InstallShield lets you specify whether you want the left margin of the script editors in InstallShield to contain line numbers.

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same line numbering setting is used for all script editors. If you change the setting in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether line numbering should be enabled in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Line numbering** setting, select the appropriate option:
   - **Yes**—InstallShield adds line numbers to the left margin of all of the script editors.
   - **No**—InstallShield does not show any line numbers in the left margin of any of the script editors. This is the default option.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield shows or hides line numbering in the script editors as needed.

Going to a Line Number in a Script that Is Displayed in a Script Editor

Task: ***To move the insertion point to a specific line number in your script:***

1. On the **Edit** menu, click **Go To**. The **Go To Line** dialog box opens.
2. In the **Line** box, type the number of the line where you want to move the insertion point.
3. Click **OK**.

Enabling or Disabling Automatic Indentation in the Script Editors

InstallShield lets you specify whether you want to use automatic indentation in the script editors when you are writing code. Auto indentation may help improve readability.

If automatic indentation is enabled, InstallShield indents a new line according to the indentation that is used in the previous line. When you press ENTER in the script editor pane, the insertion point appears on a new line, positioned directly beneath the first character of the previous line. To stop indenting a new line, press BACKSPACE; doing so removes the indentation.

If automatic indention is disabled, a new line is not indented—that is, the insertion point is placed in the first column of the new line.

Tip • *Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same automatic indentation setting is used for all script editors. If you change the setting in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether automatic indentation should be enabled in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Automatic indentation** setting, select the appropriate option:
   - **Yes**—InstallShield adds support for automatic indentation in all of the script editors. This is the default option.
   - **No**—InstallShield does not use automatic indentation in any of the script editors.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield enables or disables automatic indentation in the script editors as needed.

Setting the Tab Width for the Script Editors

InstallShield lets you specify the width of tabs in the script editor in various views (for example, the InstallScript view and the SQL Scripts view).

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same tab setting is used for all script editors. If you change the setting in the SQL Scripts view, the settings are also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify the width that InstallShield should use for tabs that are entered in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Tab width** setting, enter the width—as a multiple of the character space size—that you want for tabs in your scripts. The default value is **4**.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield adjusts the widths of the tabs in your script as needed.

Enabling or Disabling Syntax Folding in the Script Editors

InstallShield lets you specify whether you want the script editors in various views in InstallShield to include support for syntax folding. When syntax folding is enabled, InstallShield adds a plus sign (+) or a minus sign (–) in the margin next to each line of code that starts an expandable or collapsible block of script. You can click a plus sign to expand hidden code, or a minus sign to hide code.

Syntax folding can help you minimize the clutter of large scripts and focus on the code that is relevant to the work that you are currently doing. It can also help you see the overall structure of a script.

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same syntax folding setting is used for all script editors. If you change the setting in the SQL Scripts view, the setting is also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether syntax folding should be enabled in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Syntax folding** setting, select the appropriate option:
   - **Yes**—InstallShield uses the syntax folding in all of the script editors.
   - **No**—InstallShield does not use any syntax folding in any of the script editors. This is the default option.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield enables or disables syntax folding in the script editors as needed.

Showing or Hiding Whitespace in the Script Editors

InstallShield lets you specify whether you want the script editors in various views in InstallShield to display a symbol or other mark in place of each instance of whitespace in your script. For example, if you select Yes, InstallShield displays each space character in the script as a middle dot (·) and each tab character as an arrow. InstallShield also identifies line breaks when whitespace is enabled.

Tip *• Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same whitespace setting is used for all script editors. If you change the setting in the SQL Scripts view, the setting is also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

Task: ***To specify whether whitespace should be shown or hidden in the script editors:***

1. Right-click in the script editor pane and click **Properties**. The **Script Editor Properties** dialog box opens.
2. In the **Show whitespace** setting, select the appropriate option:
   - **Yes**—InstallShield shows whitespace characters and symbols in all of the script editors.
   - **No**—InstallShield does not show whitespace characters and symbols in any of the script editors. This is the default option.
3. Click **OK**. The **Script Editor Properties** dialog box closes.

InstallShield shows or hides whitespace characters and symbols in the script editors as needed.

Dragging and Dropping Text in the Script Editors

The script editors in InstallShield support drag-and-drop text editing, enabling you to move or copy selected text from one location in your code to another.

Moving Text

Task: ***To move text:***

1. Select the text that you want to move.
2. Place the mouse pointer over the selected text.
3. Press and hold down the left mouse button.
4. When you see a small rectangle appear beneath the mouse pointer, move the pointer to the location in your script to which you want to move the selected text. Continue to hold down the left mouse button while you move the pointer.

5. When the pointer is at the location in which you want to move the text, release the left mouse button.

Copying Text

Task: ***To copy selected text using the drag and drop method:***

1. Select the text that you want to move.
2. Place the mouse pointer over the selected text.
3. Press CTRL, and then press and hold down the left mouse button.
4. When you see a small rectangle and a plus sign beneath the mouse pointer, move the pointer to the location in your script to which you want to copy the selected text. Continue to hold down CTRL and the left mouse button while you move the pointer.
5. When the pointer is at the location in which you want to move the text, release the left mouse button.

Printing a Script File from Within a Script Editor

InstallShield lets you print a script that is displayed in the script editors in various views (for example, the InstallScript view and the SQL Scripts view).

Task: ***To print the script that is displayed in the active script editor pane:***

1. On the **File** menu, click **Print**. Note that this command is enabled only if the insertion point is in the script editor pane. The **Print** dialog box opens.
2. Specify the options that you prefer.
3. Click **OK**.

Keyboard Shortcuts for the Script Editors

The script editors in InstallShield include support for the following keyboard shortcuts.

Table 2-8 • Keyboard Shortcuts for the Script Editors

Keyboard Shortcut	Description
CTRL+C CTRL+INSERT	Copies the selected text to the Clipboard.
CTRL+X SHIFT+DELETE	Deletes the selected text and puts it in the Clipboard.

Table 2-8 • Keyboard Shortcuts for the Script Editors (cont.)

Keyboard Shortcut	Description
CTRL+F	Finds the specified text.
CTRL+H	Displays the Replace dialog box, which lets you search for text or other characters and replace them.
CTRL+G	Moves to a specified line.
TAB	Indents the selected text to the right one tab stop.
CTRL+U	Changes the selected text to all lowercase.
CTRL+V SHIFT+INSERT	Inserts the Clipboard contents at the insertion point.
CTRL+Y	Redoes the previously undone action.
CTRL+A	Selects all of the text in the entire document.
CTRL+Z ALT+BACKSPACE	Undoes the last action.
SHIFT+TAB	Outdents the selected text.
CTRL+SHIFT+U	Changes the selected text to all uppercase.
CTRL+M	Maximize the width of the script editor or restore it to its previous width.
CTRL+I	Opens the Function Wizard, which helps you add a function call at the insertion point in the script that is displayed in the InstallScript view.
ALT+K	Switches between adding and removing a bookmark in the line of script that currently contains the insertion point.
CTRL+K	Moves to the line in the script that contains the next bookmark.
CTRL+SHIFT+K	Moves to the line in the script that contains the previous bookmark.

Configuring Advanced Settings for InstallShield

One of the InstallShield program files is a file called `Settings.xml`. This file exposes some advanced machine-wide settings for InstallShield. When you install InstallShield, `Settings.xml` is installed to one of the following locations, depending on which language version of InstallShield you are using:

- **English**—*`InstallShield Program Files Folder`*\Support\0409
- **Japanese**—*`InstallShield Program Files Folder`*\Support\0411

The `Settings.xml` file for the Standalone build is installed in one of the following locations:

- **English**—*`Standalone Build Program Files Folder`*\Support\0409
- **Japanese**—*`Standalone Build Program Files Folder`*\Support\0411

In most cases, you should not modify the `Settings.xml` file. However, in some cases, you may need to make changes in this file. This section of the documentation describes some scenarios that would require `Settings.xml` changes:

- Changing the Timestamp Server for Digital Signatures
- Configuring the Compression Level for Files that Are Streamed into Setup.exe and ISSetup.dll
- Configuring the Maximum Size for .cab Files
- Modifying the List of Portable Executable Files for the Standalone Build
- Adding Support for XML Encoding Options
- Specifying the Location Where All Virtual Packages Should Be Built

Caution *• The `Settings.xml` file contains critical data; if this file is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Changing the Timestamp Server for Digital Signatures

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *QuickPatch*

When you specify digital signature information for a release, InstallShield uses VeriSign's server (**http://timestamp.verisign.com/scripts/timstamp.dll**) as the default timestamp server during builds. InstallShield includes a machine-wide setting that lets you replace that default server with a different timestamp server. The setting also lets you disable timestamping.

Caution • *The following instructions require that you modify the `Settings.xml` file that is installed with InstallShield. This file contains critical data; if it is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Task: ***To configure the timestamp server for digital signatures:***

1. Close InstallShield.
2. Find the `Settings.xml` file that is installed with InstallShield. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:
   - **English**—*`InstallShield Program Files Folder`*\Support\0409
   - **Japanese**—*`InstallShield Program Files Folder`*\Support\0411
3. Create a back-up copy of the `Settings.xml` file, in case you later need to revert to the original version.
4. Use a text editor or XML file editor to open the `Settings.xml` file.
5. Search for the <DigitalSignature> element. It looks something like this:

   ```
   <DigitalSignature Timestamp="http://timestamp.verisign.com/scripts/timstamp.dll"/>
   ```

6. To override the timestamp server with a different one, set the value of the Timestamp attribute to the appropriate URL.

   To disable timestamping, use an empty value for the Timestamp attribute:

   ```
   <DigitalSignature Timestamp=""/>
   ```

   

   Note • *Disabling timestamping may affect how long your digital signature is considered to be valid.*

7. Save the `Settings.xml` file.
8. Ensure that your XML code is well formed; if it is not well formed, you may have problems using InstallShield. In most cases, you can identify improperly formed XML code by opening the `Settings.xml` file in Internet Explorer. You should be able to expand and contract the major elements of the file; if you cannot, check the code for errors.

Whenever you build a release that includes digital signature information, InstallShield sets the timestamp according to the setting that you configured.

Tip • *If you use the Standalone Build to build a release, update the `Settings.xml` file that is installed with the Standalone Build. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:*

- ***English***—*`Standalone Build Program Files Folder\Support\0409`*
- ***Japanese***—*`Standalone Build Program Files Folder\Support\0411`*

Configuring the Compression Level for Files that Are Streamed into Setup.exe and ISSetup.dll

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

This information does not apply to custom compression, where only the files that are associated with one or more features are compressed into .cab files.

InstallShield includes a machine-wide setting that lets you specify the compression level that you want to use for files that are streamed into `Setup.exe` files and `ISSetup.dll` files at build time. Following are examples of files that may be streamed into the `Setup.exe` files and `ISSetup.dll` files:

- All of your product's files (if the release is one in which all of the files are compressed into the `Setup.exe` setup launcher)
- InstallShield prerequisite installations that have a location of Extract From Setup.exe
- The .NET Framework installation if it has a location of Extract From Setup.exe
- The Windows Installer installation if it has a location of Extract Engine From Setup.exe

InstallShield also lets you specify particular files (with or without wild-card characters) that should not be compressed when they are streamed into `Setup.exe` files or `ISSetup.dll` files.

Caution • *The following instructions require that you modify the `Settings.xml` file that is installed with InstallShield. This file contains critical data; if it is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Task: ***To configure compression settings for streamed files:***

1. Close InstallShield.
2. Find the `Settings.xml` file that is installed with InstallShield. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:

- **English**—*InstallShield Program Files Folder*\Support\0409
- **Japanese**—*InstallShield Program Files Folder*\Support\0411

3. Create a back-up copy of the `Settings.xml` file, in case you later need to revert to the original version.
4. Use a text editor or XML file editor to open the `Settings.xml` file.
5. Search for the <StreamCompression> element. It looks something like this:

   ```
   <StreamCompression exclude="*.CAB" compressionlevel="-1"/>
   ```

6. To prevent certain files or file types from being compressed when they are streamed into `Setup.exe` files or `ISSetup.dll` files, set the value of the exclude attribute to the names of those files. Note the following guidelines:

   - To specify more than one file, separate each file name with a comma.
   - To indicate a wild-card character, use an asterisk (*).

   For example, to specify that .cab files, .exe files, and a file called **test.txt** should not be compressed, set the value of the exclude attribute to as follows:

   ```
   <StreamCompression exclude="*.CAB,*EXE,test.txt" compressionlevel="-1"/>
   ```

   The default value is ***.CAB**, since .cab files are a compressed type of file.

7. Do one of the following:

   - If you want to use a compression level that offers a balance between the size of the compressed file and the time that is required to extract the compressed files at run time, set the value of the compressionlevel attribute to `-1`. This is the default value.
   - To specify a particular compression level, set the value of the compressionlevel attribute to a number from 0 to 9, where 0 indicates no compression and 9 indicates maximum compression.

     In general, when you specify a number from 0 to 9, the higher the number that you specify, the smaller the resulting compressed file is, and the longer it may take to extract the files at run time.

8. Save the `Settings.xml` file.
9. Ensure that your XML code is well formed; if it is not well formed, you may have problems using InstallShield. In most cases, you can identify improperly formed XML code by opening the `Settings.xml` file in Internet Explorer. You should be able to expand and contract the major elements of the file; if you cannot, check the code for errors.

Whenever you build a compressed release for one of the applicable project types, InstallShield streams files into `Setup.exe` files and `ISSetup.dll` files according to the settings that you configured.

Tip • *If you use the Standalone Build to build a release, update the `Settings.xml` file that is installed with the Standalone Build. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:*

- ***English***—*Standalone Build Program Files Folder\Support\0409*
- ***Japanese***—*Standalone Build Program Files Folder\Support\0411*

Configuring the Maximum Size for .cab Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

In addition, it is applicable only if you are building a compressed network image release in which all of the files are embedded in the single-file .msi package or the `Setup.exe` *setup launcher.*

This information does not apply to custom compression, where only the files that are associated with one or more features are compressed into .cab files.

The .cab file type has some limitations. For example, the maximum size of a single .cab file is 2 GB. In addition, some users have had trouble signing large .cab files and verifying the digital signature of large signed .cab files.

To work around these limitations, InstallShield enables you to specify on a machine-wide basis the maximum size for each .cab file that is built for a compressed network image release. When InstallShield is creating the .cab files for your release and it reaches the .cab file threshold that you configured, it splits the data into two or more .cab files, creating multi-part .cab files. Note that if you do not want InstallShield to create multi-part .cab files, you can configure InstallShield to store the data in a single .cab file.

Caution • *The following instructions require that you modify the* `Settings.xml` *file that is installed with InstallShield. This file contains critical data; if it is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Task: ***To specify whether InstallShield should create multi-part .cab files and—if appropriate—specify the maximum .cab file size:***

1. Close InstallShield.
2. Find the `Settings.xml` file that is installed with InstallShield. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:
   - **English**—*`InstallShield Program Files Folder`*\Support\0409
   - **Japanese**—*`InstallShield Program Files Folder`*\Support\0411
3. Create a back-up copy of the `Settings.xml` file, in case you later need to revert to the original version.
4. Use a text editor or XML file editor to open the `Settings.xml` file.
5. Search for the <CompressedNetworkCABSize> element. It looks something like this:

   ```
   <CompressedNetworkCABSize default="600"/>
   ```

6. Do one of the following:

- To specify the maximum size for .cab files, type the size in MB as the value of the default attribute. In the aforementioned example, the maximum size is **600**. The value should be 2048 or less, since the maximum size of a .cab file is 2 GB (2048 MB).

  The default value is `600`.

- If you do not want InstallShield to create multi-part .cab files, set the value of the default attribute to `-1`.

7. Save the `Settings.xml` file.
8. Ensure that your XML code is well formed; if it is not well formed, you may have problems using InstallShield. In most cases, you can identify improperly formed XML code by opening the `Settings.xml` file in Internet Explorer. You should be able to expand and contract the major elements of the file; if you cannot, check the code for errors.

Whenever you build a compressed network image release for one of the applicable project types, InstallShield creates the .cab files according to the requirement that you configured in the `Settings.xml` file. Depending on the value that you specified in the `Settings.xml` file, the **Media** table of the .msi package lists one or more .cab files.

Tip *• If you use the Standalone Build to build a release, update the `Settings.xml` file that is installed with the Standalone Build. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:*

- ***English***—*`Standalone Build Program Files Folder`\Support\0409*
- ***Japanese***—*`Standalone Build Program Files Folder`\Support\0411*

Modifying the List of Portable Executable Files for the Standalone Build

The File Extensions tab on the Options dialog box in InstallShield lets you modify the file extensions that you would like InstallShield to consider to be portable executable (PE) files. InstallShield uses this list to determine how it should create components for dynamically linked files that adhere to the best practice component creation method.

If you are using the Standalone Build to build a release, the Options dialog box is not available. However, you can modify one of the files that is installed in a subfolder of the InstallShield Standalone Build Program Files folder if you want to modify the list of file extensions that the Standalone Build considers to be PE files. The following instructions explain how.

Caution *• The following instructions require that you modify the `Settings.xml` file that is installed with InstallShield. This file contains critical data; if it is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Task: ***To modify the list of file extensions that the Standalone Build considers to be PE files:***

1. Close the Standalone Build.
2. Find the `Settings.xml` file that is installed with InstallShield. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:
   - **English**—*Standalone Build Program Files Folder*\Support\0409
   - **Japanese**—*Standalone Build Program Files Folder*\Support\0411
3. Create a back-up copy of the `Settings.xml` file, in case you later need to revert to the original version.
4. Use a text editor or XML file editor to open the `Settings.xml` file.
5. Search for the PEFileExtensions element. It looks something like this:

   ```
   <PEFileExtensions default="EXE|DLL|OCX|VXD|CHM|HLB|TLB|AX">
   ```

6. Modify the list of file extensions for the default attribute as needed. Note that each file extension is separated with a vertical bar (|).
7. Save the `Settings.xml` file.
8. Ensure that your XML code is well formed; if it is not well formed, you may have problems using InstallShield. In most cases, you can identify improperly formed XML code by opening the `Settings.xml` file in Internet Explorer. You should be able to expand and contract the major elements of the file; if you cannot, check the code for errors.

The next time that you use the Standalone Build, it will use the updated list of file extensions.

Adding Support for XML Encoding Options

InstallShield lets you specify what type of encoding should be used for an XML file. This setting is available on the Advanced tab when you select the XML file in the XML File Changes view. If the type of encoding that you want to use is not included in the list of available encoding options, you can modify one of the files that is installed in a subfolder of the InstallShield Program Files folder to add additional options. You can add any encoding that is supported by MSXML. The following instructions explain how.

Caution • *The following instructions require that you modify the `Settings.xml` file that is installed with InstallShield. This file contains critical data; if it is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Task: ***To add additional encoding options to the Encoding list on the Advanced tab in the XML File Changes view:***

1. Close InstallShield.
2. Find the `Settings.xml` file that is installed with InstallShield. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:
   - **English**—*InstallShield Program Files Folder*\System\0409
   - **Japanese**—*InstallShield Program Files Folder*\System\0411
3. Create a back-up copy of the `Settings.xml` file, in case you later need to revert to the original version.
4. Use a text editor or XML file editor to open the `Settings.xml` file.
5. Search for the ISXML element and its child elements. They look something like this:

```
<ISXML>
  <Encodings>
    <Encoding>WINDOWS-1250</Encoding>
    <Encoding>WINDOWS-1251</Encoding>
    <Encoding>WINDOWS-1252</Encoding>
    <Encoding>WINDOWS-1253</Encoding>
    <Encoding>WINDOWS-1254</Encoding>
    <Encoding>WINDOWS-1255</Encoding>
    <Encoding>WINDOWS-1256</Encoding>
    <Encoding>WINDOWS-1257</Encoding>
    <Encoding>WINDOWS-1258</Encoding>
    <Encoding>ISO-8859-1</Encoding>
    <Encoding>ISO-8859-2</Encoding>
    <Encoding>ISO-8859-3</Encoding>
    <Encoding>ISO-8859-4</Encoding>
    <Encoding>ISO-8859-5</Encoding>
    <Encoding>ISO-8859-6</Encoding>
    <Encoding>ISO-8859-7</Encoding>
    <Encoding>ISO-8859-8</Encoding>
    <Encoding>ISO-8859-9</Encoding>
    <Encoding>US-ASCII</Encoding>
    <Encoding>UNICODE-1-1-UTF-8</Encoding>
    <Encoding>UNICODE-2-0-UTF-16</Encoding>
    <Encoding>UNICODE-2-0-UTF-8</Encoding>
    <Encoding>ISO-10646-UCS-2</Encoding>
    <Encoding>UCS-4</Encoding>
    <Encoding>UCS-2</Encoding>
    <Encoding>UTF-16</Encoding>
    <Encoding Default="true">UTF-8</Encoding>
  </Encodings>
</ISXML>
```

6. Between the opening and closing Encodings tags, add a new line such as this:

   `<Encoding>Type_of_Encoding</Encoding>`

where *Type_of_Encoding* indicates the encoding that you want to be available. This should be the value that InstallShield should use for the encoding attribute of your XML document.

7. Save the `Settings.xml` file.
8. Ensure that your XML code is well formed; if it is not well formed, you may have problems using InstallShield. In most cases, you can identify improperly formed XML code by opening the `Settings.xml` file in Internet Explorer. You should be able to expand and contract the <ISXML> and <Encodings> elements; if you cannot, check the code for errors.

The next time that you open the XML File Changes view in InstallShield, you will see the encoding type that you added as one of the available options in the **Encoding used for a new file** list on the Advanced tab for an XML file in the XML File Changes view.

Specifying the Location Where All Virtual Packages Should Be Built

Edition • *Support for virtualization is included in the Virtualization Pack.*

When InstallShield converts an .msi package to a virtual package, it saves the virtual package in a subfolder of the folder that contains the .msi file by default. In some cases, you may want to specify a different location for generating all of the virtual packages. For example, if the .msi packages that you are converting are in a read-only location, you may need to override the default virtual package location with an existing writable location.

InstallShield includes a machine-wide setting that lets you specify an existing writable location where all virtual packages should be built. The following instructions explain how to configure this global setting.

Caution • *The following instructions require that you modify the `Settings.xml` file that is installed with InstallShield. This file contains critical data; if it is edited incorrectly, it can cause InstallShield to fail to work. Use extreme care when editing this file.*

Task: ***To specify the location where all virtual packages should be built:***

1. Close InstallShield.
2. Find the `Settings.xml` file that is installed with InstallShield. `Settings.xml` is installed in one of the following locations, depending on which language version of InstallShield you are using:
   - **English**—*InstallShield Program Files Folder*\System\0409
   - **Japanese**—*InstallShield Program Files Folder*\System\0411
3. Create a back-up copy of the `Settings.xml` file, in case you later need to revert to the original version.
4. Use a text editor or XML file editor to open the `Settings.xml` file.

5. Search for the <Virtualization> element and its child element. They look something like this:

```
<Virtualization>
  <!-- Instructions on how to specify a global path -->
  <GlobalBuildRedirectFolder></GlobalBuildRedirectFolder>
</Virtualization>
```

6. Enter the global path as the text content for the <GlobalBuildRedirectFolder> element. For example, to create the virtual packages in a subfolder of **NetworkFolder****VirtualPackages**, use the following:

```
<GlobalBuildRedirectFolder>\\NetworkFolder\VirtualPackages</
    GlobalBuildRedirectFolder>
```

   Note that the path must already exist. Do not enclose the path within quotation marks.

7. Save the `Settings.xml` file.

8. Ensure that your XML code is well formed; if it is not well formed, you may have problems using InstallShield. In most cases, you can identify improperly formed XML code by opening the `Settings.xml` file in Internet Explorer. You should be able to expand and contract the <Virtualization> element; if you cannot, check the code for errors.

Whenever you convert an .msi package to a virtual package in InstallShield, InstallShield uses the path that you specified.

Upgrading from Earlier InstallShield Versions

When you start using InstallShield 2013, you can upgrade installation projects that you created using earlier versions or different InstallShield products. This section discusses those upgrades.

Upgrading Projects from InstallShield 2012 Spring or Earlier

The following information describes possible upgrade issues that may occur when you upgrade projects that were created with InstallShield 2012 Spring and earlier to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from InstallShield 2012 Spring or earlier to InstallShield 2013.

General Information about Upgrading Projects that Were Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open an project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .773 (for an .ism project) or .2012.4 (for an .issuite project) before converting it. Delete the .773 or .2012.4 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2013: InstallShield 2012 Spring and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2013.

Changes that Affect All Projects (New and Upgraded Projects)

This section describes changes that affect both new projects and projects that are upgraded from earlier versions of InstallShield.

Change in Requirements for Target Systems

InstallShield no longer supports the creation of installations for Windows 2000 systems. If end users have Windows 2000 on their machine and they try to run an installation that was built with InstallShield 2013, the installation may run successfully. Or, unexpected results may occur, unless the project includes launch conditions that prevent end users from running the installation on this legacy operating system.

For Basic MSI and InstallScript MSI projects, you may want to consider adding a launch condition that displays a message if end users are running your installation on a Windows 2000 system. For InstallScript projects, you may want to consider adding InstallScript code that uses the SYSINFO structure variable to check for Windows 2000 systems, and then display a message if appropriate.

Advanced UI and Suite/Advanced UI installations now require at least Windows XP SP3 or Windows Server 2003 SP2.

InstallShield no longer supports the creation of installations for mobile devices. Thus, the Mobile Devices view, the Smart Device project type, the Palm OS Object, and the Windows Mobile Object are no longer included in InstallShield. If you try to upgrade a Smart Device project from InstallShield 2012 Spring or earlier to InstallShield 2013, InstallShield 2013 displays an error message and fails to open the project. If you upgrade a project from InstallShield 2012 Spring or earlier to InstallShield 2013, and if the project targets desktop platforms and contains other mobile device support, InstallShield removes the mobile device support during the upgrade and logs a warning.

Change in Requirements for Systems Running InstallShield

The minimum operating system requirement for running InstallShield, the Standalone Build, and the InstallShield Developer Installation Manifest (DIM) Editor is now Windows XP SP3 or Windows Server 2003 SP2. Previously, the minimum operating system requirement was an RTM version of either of these operating systems.

Changes for the Virtualization Pack

The Virtualization Pack is now available as part of the standalone version of InstallShield Premier Edition. It is no longer available as an add-on for the Professional edition of InstallShield.

Repackager Project Conversion Tool No Longer Included

The Repackager is no longer included in the Premier edition of InstallShield. Repackager is now available only with AdminStudio.

Changes to the XML Schema for Advanced UI and Suite/Advanced UI Project Files (.issuite)

Advanced UI and Suite/Advanced UI project files (.issuite) are XML-based files. The underlying XML schema for the user interface part of the file has changed significantly in InstallShield 2013. Many attributes have been moved to child elements. Conditions, actions, and validations are fundamentally different: element collections are used instead of attribute strings. The new schema is more explicit about what is configured for the user interface of the installation.

If you create a new Advanced UI or Suite/Advanced UI project in InstallShield 2013, InstallShield automatically uses the new XML schema for the .issuite file. If you upgrade a project from InstallShield 2012 Spring or earlier to InstallShield 2013, InstallShield automatically updates the XML schema.

New Predefined Path Variables for Built-in DLL Custom Actions

InstallShield includes two new predefined path variables in projects: ISRedistPlatformDependentFolder and ISRedistPlatformDependentExpressFolder. The default values for these folders refer to subfolders in the *InstallShield Program Files Folder*\Redist folder, which contains 32-bit versions of built-in InstallShield custom action DLLs. If you create a new InstallShield 2013 project or upgrade an InstallShield 2012 Spring or later project to InstallShield 2013, InstallShield automatically includes these two predefined path variables in your project. In addition, InstallShield also uses these path variables in paths such as the source location of built-in InstallShield DLL custom actions; this applies to new projects as well as upgraded projects. Previously, InstallShield used either of the following locations as the folder that contained the DLL files: <ISProductFolder>\Redist\Language Independent\i386 or <ISProductFolder>\Redist\Language Independent\i386 Express. This change is noted for informational purposes.

Automation Interface Changes

If you use the automation interface with InstallShield or the Standalone Build, update your existing code to reflect the new ProgID: IswiAuto20.ISWiProject. The Standalone Automation Interface uses the same ISWiAutomation20.dll file that InstallShield uses, but it is installed to a different location.

Note that if you install the Standalone Build on the same machine as InstallShield, the last ISWiAutomation20.dll file that is registered is the one that is used.

Changes that Affect New Projects but Not Upgraded Projects

This section describes changes to InstallShield that may affect new projects but not projects that are upgraded from earlier versions. Note that you may need to make manual changes to upgraded projects.

Changes to the Default Wizard Format for the Suite/Advanced UI and Advanced UI Wizard Interface

If you create a new Suite/Advanced UI or Advanced UI project in InstallShield 2013, the default value for the Wizard Format setting is Glass, a new option. If you upgrade a Suite/Advanced UI or Advanced UI project from an earlier version of InstallShield to InstallShield 2013, InstallShield does not change the value of the Wizard Format setting; it leaves whatever value was selected in the earlier version of InstallShield.

You can configure your project to use to a different wizard format if appropriate. To do so, change the value of the Wizard Format setting that is displayed in the Wizard Interface view when the Wizard Pages node is selected.

For more information, see Selecting the Format for the Wizard Interface.

Changes to the Font Color of Navigation Button Text in Advanced UI and Suite/Advanced UI Installations

In some scenarios, if you upgrade an Advanced UI or Suite/Advanced UI project from InstallShield 2012 Spring or earlier to InstallShield 2013, the text on the navigation buttons may no longer be legible: the colors for the text and the buttons may not have enough contrast. This may occur if light font color is specified for the text style that is used for navigation button text, and if the target system's colors are configured to use a light color for buttons on windows.

Beginning with InstallShield 2013, Advanced UI and Suite/Advanced UI installations no longer ignore the font color that is specified for the text style of text that is used on navigation buttons. Thus, when you upgrade your Advanced UI or Suite/Advanced UI project to InstallShield 2013, you may need to adjust the color of the text style that is used for the navigation button text. To do so, in the Wizard Interface view, click the Wizard Pages node, and note the text style that is selected for the Navigation Text Style setting. Then, find that text style under the Styles node in this view, and adjust its settings as needed.

In InstallShield 2012 Spring or earlier, Advanced UI and Suite/Advanced UI projects ignored the text style color for navigation button text. At run time, the installation used the font color that Windows used for navigation buttons; the color was typically black.

New Support for Shell Properties of Shortcuts

The Shortcuts view in InstallShield now has built-in support for setting several Windows Shell properties of shortcuts:

- The Pin to Windows 8 Start Screen setting sets the System.AppUserModel.StartPinOption property by using the following GUID and property ID combination:

  9F4C2855-9F79-4B39-A8D0-E1D42DE1D5F3, 12

- The Prevent Pinning option in the Shell Properties setting sets the System.AppUserModel.PreventPinning property by using the following GUID and property ID combination:

  9F4C2855-9F79-4B39-A8D0-E1D42DE1D5F3, 9

- The Do Not Highlight as New option in the Shell Properties setting sets the System.AppUserModel.ExcludeFromShowInNewInstall property by using the following GUID and property ID combination:

  9F4C2855-9F79-4B39-A8D0-E1D42DE1D5F3, 8

Windows Installer may generate errors if one or more of these property names (instead of the GUID and property ID) are used in a package that is run on a version of Windows that does not have support for these properties.

If you used the Shell Properties setting in InstallShield 2012 Spring or earlier to configure Shell properties for a shortcut, and you upgrade the project to InstallShield 2013, InstallShield does not automatically replace the property names with the appropriate GUID and property ID combinations. To quickly switch to the GUID and property ID combination, consider deleting the old configuration in the Shell Properties view after upgrading your project, and then using the new support to reconfigure one or more of these properties. As an alternative, you can manually override the entry with the appropriate GUID and property ID. To learn more about the built-in support in InstallShield, see Setting Shell Properties for a Shortcut.

This support is available for the following project types: Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

Upgrading Projects from InstallShield 2012 or Earlier

The following information describes possible upgrade issues that may occur when you upgrade projects that were created with InstallShield 2012 and earlier to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from InstallShield 2012 or earlier to InstallShield 2013.

General Information about Upgrading Projects that Were Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open an project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .772 (for an .ism project) or .2012 (for an .issuite project) before converting it. Delete the .772 or .2012 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2013: InstallShield 2012 and earlier, InstallShield 12 and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2013.

Changes that Affect All Projects (New and Upgraded Projects)

This section describes changes that affect both new projects and projects that are upgraded from earlier versions of InstallShield.

New Default Behavior When Launching an Earlier Version or the Same Version of a Suite/Advanced UI Installation on Target Systems

InstallShield now includes two Suite Installed conditions in each Advanced UI and Suite/Advanced UI project by default:

- A new Suite Installed exit condition prevents end users from being able to install the current version of the Advanced UI or Suite/Advanced UI installation over a future newer version of the same Advanced UI or Suite/Advanced UI installation.
- A new Suite Installed mode condition now causes the Advanced UI or Suite/Advanced UI installation to run in first-time installation mode if end users install a new version of the Advanced UI or Suite/Advanced UI installation over an older version of the same Advanced UI or Suite/Advanced UI installation.

These new default conditions are available in all new Suite/Advanced UI projects. If you upgrade an InstallShield 2012 Suite project to InstallShield 2013, InstallShield automatically adds these default conditions to the project. To learn more about these conditions, see Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed.

Previously, if an end user installed a particular version of a Suite installation on a target system on which a newer version of the Suite was already installed, the installation could permit the end user to install the older Suite version over the newer version. In addition, if an end user installed a particular version of a Suite installation on a target

system on which the same version of the Suite was already installed, the Suite installation could run in first-time installation mode. Furthermore, if an end user installed a new version of a Suite installation on a target system on which an older version of the Suite was already installed, the Suite installation could run in maintenance mode.

Automation Interface Changes

If you use the automation interface with InstallShield or the Standalone Build, update your existing code to reflect the new ProgID: IswiAuto20.ISWiProject. The Standalone Automation Interface uses the same ISWiAutomation20.dll file that InstallShield uses, but it is installed to a different location.

Note that if you install the Standalone Build on the same machine as InstallShield, the last ISWiAutomation20.dll file that is registered is the one that is used.

Changes that Affect New Projects but Not Upgraded Projects

This section describes changes to InstallShield that may affect new projects but not projects that are upgraded from earlier versions. Note that you may need to make manual changes to upgraded projects.

Changes to the Default Behavior of New Combo Boxes in the Wizard Interface of Suite/Advanced UI Projects

If you create a new combo box control on a wizard page or a secondary window in a Suite/Advanced UI project in InstallShield 2013, the control is a box that contains a drop-down list of predefined values. The box is also a text box that lets end users enter a custom value. Previously, if you added a new combo box control in InstallShield 2012, the control contained a drop-down list, but it was not also a text box; that is, end users could not enter a custom value.

If you upgrade the project from InstallShield 2012 to InstallShield 2013, and if the Suite/Advanced UI wizard interface includes a combo box, the combo box is left as a drop-down list of predefined values, but it is not also a text box. To change the control to a drop-down list with the text box, set the CBS_DROPDOWNLIST style for this control to False.

Upgrading Projects from InstallShield 2011 or Earlier

The following information describes possible upgrade issues that may occur when you upgrade projects that were created with InstallShield 2011 and earlier to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from InstallShield 2011 or earlier to InstallShield 2013.

General Information about Upgrading Projects that Were Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open a project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .771 before converting it. Delete the .771 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2013: InstallShield 2011 and earlier, InstallShield 12 and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2013.

Changes that Affect All Projects (New and Upgraded Projects)

This section describes changes that affect both new projects and projects that are upgraded from earlier versions of InstallShield.

Changes in Behavior for Some MSI APIs That Are Called in InstallScript Custom Actions

A change was made to how the InstallScript engine calls Windows Installer API such as **MsiGetProperty**. The engine now calls the Windows Installer APIs directly instead of using wrapper APIs that in turn call the Windows Installer APIs. This change was made to resolve issues with buffer handling and buffer sizes. It applies to all new projects that you create in InstallShield 2013, as well as projects that you have upgraded from earlier versions of InstallShield to InstallShield 2013.

As a result of this change, you can use the MSI install handle that is passed to a custom action function with all Windows Installer APIs that require an install handle. Previously, the handle was managed by the InstallScript engine, and it could not be passed directly to Windows Installer APIs.

Also as a result of this change, any Windows Installer APIs that require a buffer size to be specified now fail if the buffer size is not correctly specified. Note that 0 is not a valid size; thus, ensure that your code does not pass a zero value for the size of the buffer.

If you have existing InstallScript custom actions that call Windows Installer APIs, ensure that a large enough buffer size is specified; if it is not, unexpected results could occur.

The following sample code demonstrates how to retrieve the value of a Windows Installer property value string in InstallScript and increase the size of the buffer if necessary.

```
prototype STRING MyGetProperty (HWND, STRING);
////////////////////////////////////////////////////////////////////////////
//   MyGetProperty
//
//   Return an MSI property string value
//   Input Parameters:
//        hMSIHandle:      Handle to the currently running MSI database
//        szPropertyName:  Name of property to retrieve
//    Output:
//        String containing the property value
////////////////////////////////////////////////////////////////////////////

function STRING MyGetProperty (hMSIHandle, szPropertyName)
    NUMBER  nvBuf, nResult;
    STRING  szReturn;
begin

//Retrieve the size of the property value
    szReturn = "";

    nResult = MsiGetProperty (hMSIHandle, szPropertyName, szReturn, nvBuf);
```

```
    if (ERROR_MORE_DATA = nResult) then
        nvBuf = nvBuf + 1;   //increment buffer size for terminating null

        //Retrieve the property value
        nResult = MsiGetProperty (hMSIHandle, szPropertyName, szReturn, nvBuf);

        if (nResult != ERROR_SUCCESS) then
            szReturn = "";
        endif;
    endif;
    return szReturn;
end;
```

Note that if the script had used **if (ERROR_SUCCESS == nResult) then** instead of **if (ERROR_MORE_DATA == nResult) then**, unexpected results could occur.

Build Warning -7235 for Basic MSI Projects

By default, software identification tagging is enabled in all Basic MSI projects. This applies to new projects that you create in InstallShield 2013, as well as projects that you have upgraded from earlier versions of InstallShield to InstallShield 2013.

If you build a release in a Basic MSI project without entering data in the required identification tag settings (the Unique ID, Tag Creator, and Tag Creator ID settings in the General Information view), and you leave tagging enabled in the project, build warning -7235 occurs. This build warning explains that the software identification tag could not be created and included in the installation because a specific required setting was left blank. To resolve this warning, enter appropriate value in each specific setting, or select No for the Use Software Identification Tag setting in the General Information view.

COM Extraction Changes

InstallShield supports a new monitoring method for COM extraction. If you are using InstallShield on a Windows Vista or later system or a Windows Server 2008 or later system, this new method is used by default. The method uses a kernel driver to monitor the areas of the registry that are modified during dynamic COM extraction at build time and static COM extraction at design time. It combines the advantages that the earlier methods provided, allowing the DLL to read existing registries entries and preventing changes to the build machine.

If necessary, you can switch between the three different COM extraction methods by setting the value data of the UseAPIRegistryHooks registry value, which is in the registry key HKEY_LOCAL_MACHINE\SOFTWARE\InstallShield\RegSpy (on 32-bit machines) or HKEY_LOCAL_MACHINE\SOFTWARE\Wow6432Node\InstallShield\RegSpy (on 64-bit machines). Possible REG_DWORD value data are:

- **0**—Use API hooking to read existing registry entries for the DLL.
- **1**—Use registry redirection to prevent making changes to the registered DLLs on the build machine. If the value is not set, this is the default behavior on Windows XP and Windows Server 2003 systems.
- **2**—Use the new kernel mode monitoring, which combines the advantages of both of the other methods. If the value is not set, this is the default behavior on Windows Vista and later systems and on Windows Server 2008 and later systems.

This functionality applies to the following project types: Basic MSI, DIM, InstallScript MSI, and Merge Module.

String Entries in Merge Module Projects

Each string identifier that is created in a Merge Module project now contains the Merge Module's module ID GUID. This applies to all new string identifiers that are created in all new Merge Module projects, as well as new string identifiers that are created in existing Merge Module projects that were upgraded from InstallShield 2011 or earlier to InstallShield 2013. Note that if you upgrade a Merge Module project from InstallShield 2011 or earlier to InstallShield 2013, the module ID GUID is not added to the string identifiers of any existing string entries.

The use of the GUID in string identifiers of Merge Module project string entries helps to minimize or eliminate conflicts that would occur if the same string identifier is used in a Merge Module project and also in an installation project that contains that Merge Module, and if different values are assigned to those two string identifiers.

Upgrading Projects from InstallShield 2010 or Earlier

The following information describes possible upgrade issues that may occur when you upgrade projects that were created with InstallShield 2010 and earlier to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from InstallShield 2010 or earlier to InstallShield 2013.

General Information about Upgrading Projects that Were Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open a project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .770 before converting it. Delete the .770 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2013: InstallShield 2010 and earlier, InstallShield 12 and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2013.

Changes that Affect All Projects (New and Upgraded Projects)

This section describes changes that affect both new projects and projects that are upgraded from earlier versions of InstallShield.

End of Integration Support for Visual Studio 2003 and Earlier

If you want to create, edit, and build your InstallShield projects directly within Visual Studio, you must use Visual Studio 2005 or later. InstallShield can no longer be integrated with Visual Studio 2003 or earlier.

Deprecation of InstallScript Objects

InstallScript objects have been deprecated in favor of InstallShield prerequisites. In a future release, InstallShield will no longer be able to create or consume InstallScript objects, and no predefined InstallScript objects will be provided. Furthermore, the Merge Module Holder Object will not be available. The recommended alternative for InstallScript objects is InstallShield prerequisites. You can use the InstallShield Prerequisite Editor to begin creating

your own InstallShield prerequisites so that you are ready to use them once the InstallScript object technology becomes obsolete. You can share these InstallShield prerequisites among InstallScript, InstallScript MSI, and Basic MSI projects.

InstallShield Builds Only Unicode Versions of Setup.exe and Update.exe; Ability to Create ANSI Versions Is No Longer Available

Now all `Setup.exe` and `Update.exe` files that are built in all project types in InstallShield are Unicode. This applies to all new Basic MSI, InstallScript, InstallScript MSI, and QuickPatch projects that you create in InstallShield 2013. It also applies to all projects that you have upgraded from earlier versions of InstallShield to InstallShield 2013. Therefore, the settings that previously enabled you to specify whether you wanted to build a Unicode version or an ANSI version of the setup launcher have been removed:

- The Setup Launcher Type setting on the Setup.exe tab for a release in the Releases view has been removed from Basic MSI projects.
- The Update Launcher Type setting was removed from Basic MSI, InstallScript MSI, and QuickPatch projects.

  In Basic MSI and InstallScript MSI projects, this setting was on the Advanced tab for a patch configuration in the Patch Design view.

  In QuickPatch projects, this setting was on the Advanced tab in the Build Settings area of the General Information view.

Changes to Win32 API Definitions

Now that the InstallScript engine has been updated to support Unicode, the Win32 API functions that are prototyped in the InstallScript header file `ISRTWindows.h` have been updated. Where applicable, wide (W) versions of API prototypes have been added in addition to existing ANSI (A) definitions. For some prototypes, no A or W version is specified; in these cases, the engine now attempt to use the W version. Previously, the A version was used.

If you upgrade an InstallShield 2010 or earlier project to InstallShield 2013, it is possible that these new prototypes could conflict with user-defined prototypes of the same APIs. It is recommended that the InstallScript-provided prototypes be used if possible. However, if you want to use your own prototypes for these Windows APIs instead of the ones that are now prototyped for InstallScript, add ISINCLUDE_NO_WINAPI_H to the list of preprocessor definitions: On the Build menu, click Settings. On the Compile/Link tab, in the Preprocessor Defines box, enter ISINCLUDE_NO_WINAPI_H. Otherwise, you may encounter compile errors.

Ensuring that Your InstallScript Code Supports Unicode

If you use any user-defined Win32 APIs or other external DLL prototypes in your InstallScript code, and the APIs have versions that support Unicode string input, update the prototypes to use BYVAL/BYREF WSTRING or WPOINTER. In addition, review the API functions in your code that accept structures as input to ensure that those that contain string or string pointer members are declared as Unicode as appropriate, if the API requires it.

Update your script to call W versions of Win32 APIs if it is currently calling A versions.

Differential Release Support in InstallScript Projects

A differential release that is created in an InstallShield 2011 or later InstallScript project can update a product only if its earlier InstallScript installation was also created in InstallShield 2011 or later. If you want to use InstallShield 2011 or later to create an update for a product whose earlier InstallScript installation was created with InstallShield 2010 or earlier, you should create a full release, instead of a differential release.

This requirement is necessary because of the Unicode support that is new in the InstallShield 2011 InstallScript engine. After a differential release is used to update an earlier version of a product on a target system, the earlier version of the installation (along with the earlier engine run time) is used to run any maintenance operations. Because the InstallShield 2010 and earlier versions of the InstallScript engine cannot read the new Unicode storage format, the installation fails.

Uninstalling 64-Bit Registry Entries that Were Installed by the InstallScript Engine

By default, the InstallScript engine now logs the changes that it makes to the 64-bit part of the registry during an InstallScript or InstallScript MSI installation on 64-bit target systems. Furthermore, the 64-bit registry changes that are logged by the InstallScript engine are now uninstalled during uninstallation.

Note that if you created an InstallShield 2010 or earlier installation that wrote 64-bit registry data and you create an upgrade for your product in InstallShield 2013, the existing 64-bit registry entries that were logged by the base installation are not removed when the product is uninstalled from a target system. The only way to work around this limitation is to manually remove the registry data during uninstallation.

Script Editor Changes

Pressing CTRL+SPACEBAR from within the script editor pane in the InstallScript view no longer displays a list of built-in InstallScript functions that are available for auto completion, as it did in InstallShield 2010 and earlier. Now if you want to see a list of built-in InstallScript functions for auto completion, you simply need to start typing the first letter or letters of that function. The pop-up list also contains other InstallScript keywords. To learn more, see Using Auto Completion when Writing Code in the Script Editors.

The context menu that is displayed when you right-click in a script editor pane is now different than it was in InstallShield 2010 and earlier:

- The context menu no longer contains a Show Whitespace command. To show or hide whitespace characters and symbols in the script editors, use the Script Editor Properties dialog box. This dialog box also lets you modify other settings in the script editors, such as font, syntax colors, and line numbering. To access this dialog box, right-click in a script editor and then click Properties.
- The context menu no longer contains a Make Uppercase command or a Make Lowercase command. To make text in the script editor uppercase, select it and then press CTRL+SHIFT+U. To make it lowercase, select it and then press CTRL+U.
- The context menu no longer contains a Find command or a Replace command. To perform a search in a script, press CTRL+F, and then specify the text that you want to find. To search for a string and replace it with something else, press CTRL+H and then specify the appropriate information. As an alternative, you can use the Find and Replace commands on the Edit menu.

For more keyboard shortcuts, see Keyboard Shortcuts for the Script Editors.

The views that contain the revised script editor are the InstallScript view, the SQL Scripts view, and the Custom Actions and Sequences view (when you are viewing a VBScript or JScript file in this view).

InstallScript Debugger Changes

If you copy the InstallScript Debugger (`ISDbg.exe`) from your installation development machine to a debug machine so that you can debug InstallScript code, you must also now copy the file called `SciLexer.dll` to the same folder on the debug machine. You can find `SciLexer.dll` on your installation development machine in the same folder as the `ISDbg.exe` file (*`InstallShield Program Files Folder`*`\System`).

For more information, see Debugging an Installation on Any Computer.

Changes that Affect New Projects but Not Upgraded Projects

This section describes changes to InstallShield that may affect new projects but not projects that are upgraded from earlier versions. Note that you may need to make manual changes to upgraded projects.

DPI Changes and Their Effect on InstallScript Dialogs

If you have an InstallShield 2010 or earlier InstallScript or InstallScript MSI project that contains one or more edited InstallScript dialogs and you want to upgrade the project to InstallShield 2013 or later, ensure that your machine uses the same DPI value that was selected when the InstallScript dialogs were edited. Otherwise, the dialogs may be sized incorrectly at run time.

Note that once you have upgraded the project, you can change the DPI value on your machine at any time as needed; if you do, the dialogs are sized correctly at run time. Also note that if you upgrade an InstallShield 2013 or later project that contains one or more edited InstallScript dialogs to a future version of InstallShield, you do not need to use the same DPI value during the upgrade.

Changing Design-Time and Build-Time Locations of Existing InstallShield Prerequisites in Existing Projects

InstallShield now lets you specify the folders where InstallShield should search for InstallShield prerequisite files (.prq files), their associated data files, and their dependencies. Previously, InstallShield searched for .prq files in the following location only: *`InstallShield Program Files Folder`*`\SetupPrerequisites`.

If you move any InstallShield prerequisites from the *`InstallShield Program Files Folder`*`\SetupPrerequisites` folder to a new custom location that you have defined on the Prerequisites tab of the Options dialog box (or any of the other places where search paths can be defined now), you may need to perform the following steps in InstallShield 2010 or earlier projects when you upgrade them to InstallShield 2013:

1. In the Redistributables view or the Prerequisites view, clear the check box for each InstallShield prerequisite that is included in your project but is located in a custom location. Also clear the check box for each InstallShield prerequisite whose data files or dependencies were moved from the default location to a custom location.
2. Click the new Refresh button.
3. Select the check box for each InstallShield prerequisite that you removed from your project in step 1.

InstallShield removes the path of the prerequisite from the **ISSetupPrerequisites** table of your project. The full path was stored in this table in InstallShield 2010 and earlier projects. Note that if you only clear a prerequisite's check box and then reselect it without clicking the Refresh button, InstallShield continues to use the full path, rather than just the file name, in the **ISSetupPrerequisites** table.

If you upgrade an InstallShield 2010 or earlier project to InstallShield 2013, change the location of an InstallShield prerequisite, and then add that prerequisite to your project, you do not need to perform the refresh procedure. Also, if you create a new project in InstallShield 2013, you do not need to perform the refresh procedure. In both cases, InstallShield does not include the path in the **ISSetupPrerequisites** table of your project, which enables you to use the custom search path, instead of the default path.

Preventing an InstallScript MSI Installation from Overwriting a Future Major Version of the Same Product

The Upgrades view in new InstallScript MSI projects now contains a major upgrade item called ISPreventDowngrade. This item prevents end users from being able to install the current version of your product over a future major version of the same product. If you upgrade an InstallScript MSI project from InstallShield 2010 or earlier to InstallShield 2013, the ISPreventDowngrade item is not added automatically. You can manually add an ISPreventDowngrade item if appropriate. To learn how, see the Preventing the Current Installation from Overwriting a Future Major Version of the Same Product.

Upgrading Projects from InstallShield 2009 or Earlier

The following information describes possible upgrade issues that may occur when you upgrade projects that were created with InstallShield 2009 and earlier to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from InstallShield 2009 or earlier to InstallShield 2013.

General Information about Upgrading Projects that Were Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open a project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .768 before converting it. Delete the .768 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2013: InstallShield 2009 and earlier, InstallShield 12 and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2013.

Installing More than One Edition of InstallShield

Only one edition of InstallShield 2013—Premier, Professional, or Express—can be installed on a system at a time. Previously, it was possible to install the Express edition on the same system that had the Premier or Professional edition of the same InstallShield version.

Change to the List of Supported Operating Systems for Running InstallShield

The minimum operating system requirement for systems that run InstallShield (the authoring environment) is now Windows XP or Windows Server 2003. Previously, the minimum operating system requirement was Windows 2000 SP3.

Changes that Affect All Projects (New and Upgraded Projects)

This section describes changes that affect both new projects and projects that are upgraded from earlier versions of InstallShield.

Setup.exe No Longer Runs on Windows 9x, Windows NT 4, or Windows Me Systems

`Setup.exe` installations that are created in InstallShield can no longer be run on Windows 9x, Windows NT 4, or Windows Me. If an end user tries to launch `Setup.exe` on a Windows 9x or Windows Me system, Windows displays a message box with the following error: "The *`FullSetup.exePathAndFileName`* file expects a newer version of Windows. Upgrade your Windows version." On Windows NT 4 systems, Windows displays a message box with the following error: "*`FullSetup.exePathAndFileName`* is not a valid Windows NT application."

InstallShield no longer lists these legacy operating systems in any of the areas where target operating systems can be selected. For example, the Installation Requirements tab of the Project Assistant in Basic MSI and InstallScript MSI projects no longer lists these operating systems. In InstallScript projects, the Platforms tab on the Project Settings dialog box no longer lists these operating systems.

If you upgrade an InstallScript project that was created in InstallShield 2009 or earlier to InstallShield 2013, and if the operating system settings in the earlier project contained references to only these legacy operating systems, InstallShield replaces the legacy operating system options with the option for targeting all supported platforms.

Windows Installer 1.x Redistributables Are No Longer Available

InstallShield no longer includes Windows Installer 1.x redistributables, since they target only legacy versions of Windows that are no longer supported. Previously, it was possible to add Windows Installer 1.x redistributables to a project through the Releases view, or through the Release Wizard.

Redistributable for VBScript Runtime Files Is No Longer Available

InstallShield no longer includes the InstallShield object for VBScript Runtime Files. This redistributable targets only legacy versions of Windows that are no longer supported.

InstallScript Dialog Source Code Changes

The InstallScript code for built-in InstallScript dialogs has been moved from individual InstallScript script files (.rul) to a single `ISRTScriptDialogs.rul` file. In addition, the event class drop-down list in the InstallScript view has a new Dialog Source option. If you select this option, the event handler drop-down list shows all of the built-in InstallScript dialogs. You can select any dialog in this list to customize its code.

InstallShield supports backwards compatibility: If you imported dialog source code into an InstallShield 2009 or earlier project and then you upgrade the project to InstallShield 2013, you can still use that dialog code. However, if you want to use the dialog sources that are now available when you select the dialogs in the event handler drop-down list, you must first make some changes to your upgraded project. Otherwise, you may encounter compile errors. In order to use the dialog code: On the Build menu, click Settings. On the Compile/Link tab, in the Preprocessor Defines box, enter the following:

```
_ISSCRIPT_NEW_STYLE_DLG_DEFS
```

After this definition has been added, if any dialogs had previously been imported into the project in earlier versions of InstallShield, the code in these imported .rul files may cause compile errors. These errors would need to be resolved.

If _ISSCRIPT_NEW_STYLE_DLG_DEFS is not defined, a warning message is displayed when the Dialog Source option is selected in the event class drop-down list in the InstallScript view.

The _ISSCRIPT_NEW_STYLE_DLG_DEFS definition is automatically added to all new projects that are created in InstallShield 2013.

This functionality applies to the following project types: InstallScript, InstallScript MSI, and InstallScript Object.

InstallScript Header File Changes

The InstallScript header files (.h) have been reorganized. As a result, some of the .h files are obsolete. If an InstallScript file (.rul) in your project references one or more of these obsolete .h files, a compile warning is displayed whenever you compile your script or build a release. To resolve the warnings, remove any #include statements that reference the obsolete .h files, and rebuild the release. Also, ensure that `ifx.h` is referenced in an #include statement in your `Setup.rul` file or in other script files that are referenced by `Setup.rul`.

InstallScript Changes for Windows API Prototypes

The service-related Windows API prototypes (such as CreateServiceA, StartServiceA, and ControlService) are now prototyped in `ISRTWindows.h` for all InstallScript, InstallScript MSI, and InstallScript Object projects. They are also now prototyped in `ISRTWindows.h` for all Basic MSI and Merge Module projects that include InstallScript custom actions.

If you want to use your own definitions for these Windows APIs instead of the ones that are now prototyped for InstallScript, add **`ISINCLUDE_NO_SERVICEAPI`** to the list of preprocessor definitions: On the Build menu, click Settings. On the Compile/Link tab, in the Preprocessor Defines box, enter **`ISINCLUDE_NO_SERVICEAPI`**. Otherwise, you may encounter compile errors.

Note that the constant ISINCLUDE_NO_WINAPI_H now suppresses only Windows API prototypes, not Windows constants or Windows structure definitions.

Patch Creation (Basic MSI, InstallScript MSI)

InstallShield now uses the Windows Installer 4.5 patching technology to create patches. This change is reported for informational purposes.

New Custom Actions and Database Tables for IIS Support in Basic MSI and InstallScript MSI Projects

If you add IIS support through the Internet Information Services view in a Basic MSI or InstallScript MSI project in InstallShield, InstallShield automatically adds several DLL custom actions to your project to support the IIS functionality. In InstallShield 2013, these custom actions have been enhanced to enable you to add applications to Web sites. In addition, these actions have been renamed to reflect standard naming conventions:

- **ISIISCosting**—This custom action replaces the caExtractIISSuppFiles action.
- **ISIISRollback**—This custom action replaces the caRlbackVRoots action.
- **ISIISUninstall**—This custom action replaces the caRemoveVRoots action.
- **ISIISInstall**—This custom action replaces the caCreateVRoots action.
- **ISIISCleanup**—This custom action replaces the caIISCleanup action.

The entry points of each of the DLL custom actions have been renamed to match the corresponding custom action names.

Note that IIS functionality requires administrative privileges. Therefore, each of these DLL custom actions checks the Privileged property value. The value must be 1; if it is not, an error is displayed at run time. In InstallShield 2009 and earlier, each of the IIS custom actions had a Privileged = 1 condition. In InstallShield 2013, this condition is no longer set when you add new IIS Web sites or other IIS data to your project, since the custom actions check the Privileged property value.

If you upgrade a Basic MSI or InstallScript MSI project that contains IIS support from InstallShield 2009 or earlier to InstallShield 2013, InstallShield automatically updates and renames the custom actions accordingly. In addition, if the condition for an old custom action was not modified from the default condition, InstallShield also removes the Privileged = 1 condition. If a condition was modified, InstallShield leaves the existing condition as is. You can manually modify any of the conditions if appropriate.

In InstallShield 2013, all of the IIS data is stored in the **ISIISItem** and **ISIISProperty** tables. In InstallShield 2009 and earlier, the IIS data was stored in the following tables: **ISIISAppPool**, **ISIISCommon**, **ISIISMetaData**, **ISIISWebServiceExtension**, **ISVRoot**, **ISVRootAppMaps**, and **ISWebSite**. If you upgrade a Basic MSI or InstallScript MSI project that contains IIS support from InstallShield 2009 or earlier to InstallShield 2013, InstallShield automatically moves the IIS data to the new tables; InstallShield also deletes the old tables from the project.

For more information, see:

- Managing Internet Information Services
- InstallShield Custom Action Reference

Changes for the Redistributables View

The Redistributables view has a new toolbar and group box area that provide robust search and organizational functionality. Use the new Show Details button in this view to show or hide the details pane for the selected redistributable in this view. The details pane provides information such as which files a redistributable installs. The Show Details button replaces the Show Details and Hide Details links that were previously available in the upper-right corner of this view.

The new group box area is below the new toolbar in the Redistributables view. You can drag and drop column headings onto this group box area to organize the list of redistributables in a hierarchical format. If you want InstallShield to separate all of the redistributables in the view into two groups—one whose check box is selected and one whose check box is cleared—drag the check box column to the group box area. This enables you to easily identify all of the redistributables that are included in your project. The result is similar to the behavior that previously occurred if you right-clicked any redistributable and then clicked Show Only Selected Items. Note that the Show Only Selected Items command is no longer available in the Redistributables view.

For more information, see Working with the Group Box Area in Various Views.

Limiting the UI Level of a Chained .msi Package to that of the Main .msi Package

The UI level for a chained .msi package is now limited to be no higher than that of the parent package's current UI level. For example, in the following scenario, the chained .msi package is launched silently: you add a chained .msi package to your project in the Releases view and select Full UI (/qf) for its UI level setting, but the main installation

is launched silently (/qn). Previously, the chained package showed exactly the UI level that was authored in the Releases view of the main installation; to restore this behavior, set the property **ISChainExceedUILevel** equal to the value 1.

Encoding and Related Differences for XML File Changes

If you use the XML File Changes view to configure changes for a file that is already present on the target machine, or that is being installed as part of your installation, the installation now uses the encoding that is specified in that XML file, rather than the encoding that is specified in the XML File Changes view. This applies to new projects that are created in InstallShield 2013, as well as projects that are upgraded from InstallShield 2009 or earlier.

In addition, if the "Always create this element if it does not already exist" check box is cleared for an element that is not present in the target file, its child elements are no longer created. Thus, for an XML file such as //**A**/**B**/**C**, C is not created on the target system if B is neither present nor set to be created.

Changes to the Major and Minor Version Registry Entries for the Uninstall Key of InstallScript Installations

InstallScript installations now always create VersionMajor and VersionMinor registry values in the Uninstall key; the names of these values now match the entries that are created during Basic MSI and InstallScript MSI installations. This applies to new installations that are created in InstallShield 2013, as well as installations that are upgraded from InstallShield 2009 or earlier. Previously, in InstallShield 2009 and earlier, the names of the values that InstallScript installations created were MajorVersion and MinorVersion; these are no longer created.

In order to use the new registry values, the values of the following InstallScript constants have been changed:

- REGDB_VALUENAME_UNINSTALL_MAJORVERSION is now VersionMajor instead of MajorVersion.
- REGDB_VALUENAME_UNINSTALL_MINORVERSION is now VersionMinor instead of MinorVersion.

When the **MaintenanceStart** function is called, it creates the updated value names in the registry. By default, it also deletes the old value names if they exist. If you do not want the old value names to be deleted from target systems, you can use the new REGDB_OPTIONS option called REGDB_OPTION_NO_DELETE_OLD_MAJMIN_VERSION. If you want to continue using only the old value names, you must delete the new versions after **MaintenanceStart** returns.

If REGDB_UNINSTALL_MAJOR_VERSION or REGDB_UNINSTALL_MINOR_VERSION is used with the **RegDBGetItem** function, **RegDBGetItem** first checks for the new value; if the new value is found, the function returns the value data from the new value. If the new value is not found, the function automatically checks for the old value; if the old value is found, the function returns the value data from the old value.

To provide backwards compatibility, the following new constants are available:

- REGDB_UNINSTALL_MAJOR_VERSION_OLD
- REGDB_UNINSTALL_MINOR_VERSION_OLD

You can specify these constants with the **RegDBGetItem**, **RegDBSetItem**, and **RegDBDeleteItem** functions to get, set, and delete the old values.

The following new string constants are also available:

- REGDB_VALUENAME_UNINSTALL_MAJORVERSION_OLD is defined as MajorVersion.

- REGDB_VALUENAME_UNINSTALL_MINORVERSION_OLD is defined as MinorVersion.

For more information, see the following:

- REGDB_VALUENAME_UNINSTALL_MAJORVERSION
- REGDB_VALUENAME_UNINSTALL_MAJORVERSION_OLD
- REGDB_VALUENAME_UNINSTALL_MINORVERSION
- REGDB_VALUENAME_UNINSTALL_MINORVERSION_OLD
- REGDB_UNINSTALL_MAJOR_VERSION_OLD
- REGDB_UNINSTALL_MINOR_VERSION_OLD
- REGDB_OPTIONS
- RegDBSetItem
- RegDBGetItem
- RegDBDeleteItem

Removal of the SdShowMsg Dialog from the List of Editable Dialogs

The Dialog Editor does not currently support dialogs, such as **SdShowMsg**, that do not have a title bar; if you try to customize the **SdShowMsg** dialog, it may get corrupted. Therefore, this dialog is no longer displayed in the Dialogs view as one of the dialogs that you can edit. To customize this dialog, you should use the **SdShowMsg** call, not the Dialog Editor.

Automation Interface Changes

The value of the eosAll constant for the OSFilter, which is a member of the ISWiComponent and ISWiRelease objects in the automation interface, has been changed. The new value is 64028880; previously, it was 5308624. If you are using the value of this constant to configure the list of operating systems for a component or a release through the automation interface, you must update your script to use the new value.

For more information, see the following:

- ISWiComponent Object
- ISWiRelease Object

Changes for the Locations of InstallScript Run-Time Script, Library, and Header Files

The InstallScript run-time library files that are installed with InstallShield have been consolidated into a central location, instead of several separate subdirectories. The script, library, and header files are now installed in Src, Lib, and Include folders in the following directory:

InstallShield Program Files Folder\Script\Isrt

The following folders are no longer installed, since the files within them are consolidated in the above location:

InstallShield Program Files Folder\Script\IISRuntime

InstallShield Program Files Folder\Script\SQLRuntime

InstallShield Program Files Folder\Script\XMLRuntime

Note that because of a name conflict, the Assert.h file in the following location is being renamed as ISAssert.h:

InstallShield Program Files Folder\Script\Isrt\Include

If you create a new project in InstallShield 2013, it uses the new locations of the files. If you upgrade a project from InstallShield 2009 or earlier to InstallShield 2013, InstallShield updates the projects to use the new locations.

Changes in the Way that Linked Libraries and Their Locations Are Specified

The Compile/Link tab on the Settings dialog box has a new Additional Library Paths box that lets you specify the locations where the InstallScript compiler should search for InstallScript libraries (.obl files) that are not one of the standard InstallShield locations. For InstallScript and InstallScript Object projects, the standard locations are:

- <ISProductFolder>\Script\Ifx\Lib
- <ISProductFolder>\Script\Isrt\Lib

For Basic MSI and InstallScript MSI projects, the standard locations are:

- <ISProductFolder>\Script\Iswi\Lib
- <ISProductFolder>\Script\Isrt\Lib

If you create a new project in InstallShield 2013, InstallShield automatically lists the standard InstallShield script libraries such as ISRT.obl in the Libraries (.obl) box on the Compile/Link tab. However, InstallShield no longer includes the full path in that box. If you want to add your own custom libraries, you can specify the library file name in the Libraries (.obl) box, and the path in the Additional Library Paths box. You do not need to specify the full path and file name in the Libraries (.obl) box.

If you upgrade a project that was created in InstallShield 2009 or earlier to InstallShield 2013, InstallShield automatically removes the path of the standard script libraries that are listed in the Libraries (.obl) box. For more information, see Compile/Link Tab.

Removal of the InstallScript Structure Definition for ISOSVERSIONINFO

The definition of the ISOSVERSIONINFO structure, as well as the corresponding unused global instances of this structure, has been removed. The equivalent OSVERSIONINFO structure is still available. This definition removal does not cause any functionality changes; however, if you attempt to use the ISOSVERSIONINFO structure definition or global structure instances, a compiler error results.

To avoid a compiler error, do either of the following:

- Update the script to use the equivalent OSVERSIONINFO structure, and declare a local instance of this structure if needed. Update the script to use the appropriate structure member names. (Note that the OSVERSIONINFO member names are different than the ISOSVERSIONINFO member names.) Following is the definition of OSVERSIONINFO:

```
typedef OSVERSIONINFO
    begin
        NUMBER nOSVersionInfoSize;
        NUMBER nMajorVersion;
        NUMBER nMinorVersion;
        NUMBER nBuildNumber;
        NUMBER nPlatformId;
```

```
        STRING szCSDVersion[128];
    end;
```

- Declare the structure and structure instances locally as follows:

```
// Data structure that contains operating system version information.
// Used by ISCompareServicePack.
typedef ISOSVERSIONINFO // define a structure
begin
    LONG ISIOSVersionInfoSize;    // Size in bytes of this data structure
    LONG ISIMajorVersion;         // Major version number of the OS.
    LONG ISIMinorVersion;         // Minor version number of the OS.
    LONG ISIBuildNumber;          // Build number of the OS.
    LONG ISIPlatformId;           // Operating system platform.
    STRING szISCSDVersion [128];  // Additional information about OS.
end;

// Variable for the operating system version information data structure.
// Used by ISCompareServicePack.
ISOSVERSIONINFO ISVersion;

// Pointer that points to the OS version information variable.
// Used by ISCompareServicePack.
ISOSVERSIONINFO POINTER pISVersion;
```

Obsolete Keys Are No Longer Written to Setup.ini for InstallScript Projects

The following keys are obsolete and are no longer written to the `Setup.ini` file for InstallScript projects: Resource, EngineVersion, and EngineBinding.

ISCab.exe Is No Longer Available

`ISCab.exe` is no longer supported. Therefore, it is no longer included with InstallShield.

Changes that Affect New Projects but Not Upgraded Projects

This section describes changes to InstallShield that may affect new projects but not projects that are upgraded from earlier versions. Note that you may need to make manual changes to upgraded projects.

Changes to Support for Securing Permissions for Files, Folders, and Registry Keys

The General Information view has a new Locked-Down Permissions setting that lets you specify whether you want to use the new custom InstallShield handling or the traditional Windows Installer handling for all new permissions that you set for files, folders, and registry keys in your project. The new custom InstallShield handling option offers several advantages over the traditional Windows Installer handling option.

In all new projects, the default value for this setting is the custom InstallShield handling option. If you upgrade a project from InstallShield 2009 or earlier to InstallShield 2013, the traditional Windows Installer handling option is the default value of this setting.

This new setting is available in the following project types: Basic MSI, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform.

For more information, see the following:

- Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment
- Selecting the Locked-Down Permissions Type for a Project

Changes to the ReadyToInstall Dialog for Beta Windows Installer 5 Support of Per-User Installations

The General Information view has a new Show Per-User Option setting. This setting lets you specify whether you want the ReadyToInstall dialog—in certain scenarios—to include buttons that let end users indicate how they want to install the product: for the current user or for all users. The per-user button sets the new Windows Installer property **MSIINSTALLPERUSER** equal to 1 to indicate that the package should be installed for the current user. The **MSIINSTALLPERUSER** property is available with the beta of Windows Installer 5.

If you create a new Basic MSI project in InstallShield 2013, the ReadyToInstall dialog includes support for the per-user and per-machine buttons; these buttons are displayed or hidden at run time if appropriate. If you upgrade a Basic MSI project from InstallShield 2009 or earlier to InstallShield 2013, the ReadyToInstall dialog does not have this support automatically. You can manually add these buttons and their associated conditions to the ReadyToInstall dialog if appropriate; use the ReadyToInstall dialog in a new InstallShield 2013 project as a guideline.

Public Directory Properties for Feature Destinations Are Added to SecureCustomProperties

When you specify a location for the Destination setting of a feature and the location includes a public directory property, InstallShield now adds that property to the **SecureCustomProperties** property to allow end users to change the destination after the product has been advertised. This occurs in new projects that are created in InstallShield 2013. The change is also made for all feature destinations if you upgrade a project from InstallShield 2009 or earlier to InstallShield 2013.

This change applies to the following project types: Basic MSI and InstallScript MSI.

Changes to the Conditions for the InstallWelcome Dialog and the ResolveSource Action

The condition on the InstallWelcome dialog and the ResolveSource action has been changed to `Not Installed` for all new Basic MSI projects that are created in InstallShield 2013. The conditions were changed so that the InstallWelcome dialog and the ResolveSource action can be used for a first-time installation with a patch. If you upgrade a Basic MSI project from InstallShield 2009 or earlier to InstallShield 2013, the conditions are not changed automatically. If you want the dialog and action to be used for a first-time installation with a patch, you can change the conditions in your upgraded project to `Not Installed`.

Improvements to the .rtf File Size Limit for the SdLicenseRtf and SdLicense2Rtf Functions

The file size limit for the .rtf files that are used with the InstallScript dialog functions **SdLicenseRtf** and **SdLicense2Rtf** is now 16 MB instead of 64 KB. Previously, if the file size was more than 64 KB, part of the EULA text was missing from the license dialog at run time.

Note that if you had overridden the **SdLicenseRtf** or **SdLicense2Rtf** functions in your script in InstallShield 2009 or earlier and then upgraded that project to InstallShield 2013, you would need to manually change the size limit by updating the **SendMessage** call with the EM_EXLIMITTEXT message in DLG_INIT. The iParam parameter (the fourth parameter) of the **SendMessage** call needs to be changed. The **SendMessage** call should be changed to this:

```
SendMessage( hEdit, EM_EXLIMITTEXT, 0, 0xffffff );
```

Previously, the code contained this:

```
SendMessage( hEdit, EM_EXLIMITTEXT, 0, 0 );
```

Removal of the OnResolveSource Event Handler from InstallScript MSI Installations

The InstallScript event handler OnResolveSource has been removed from InstallScript MSI projects. The Windows Installer now handles all source resolution. If you added the OnResolveSource event to an InstallScript MSI project in InstallShield 2009 or earlier and then you upgrade that project to InstallShield 2013, that event will no longer be called.

Changes to the Way that a Log File Is Displayed from the SetupCompleteSuccess Dialog in Basic MSI Installations

The ShowMsiLog custom action now launches `Notepad.exe` from the SystemFolder directory, instead of from the WindowsFolder directory. Thus, if your installation is run on Windows Vista or later and the end user indicates on the SetupCompleteSuccess dialog that they want to view the log file, the installation launches `Notepad.exe` from the SystemFolder directory. This change was made because on Windows Server 2008 Standard Edition, `Notepad.exe` is available in the System32 directory, but not the Windows directory.

Note that behavior is available by default in all new Basic MSI projects that are created in InstallShield. If you upgrade an InstallShield 2009 or earlier Basic MSI project to InstallShield 2013, InstallShield does not automatically change the behavior. You can manually change the behavior if necessary: In the Custom Actions and Sequences view, click the ShowMsiLog action. (If this action is not displayed, right-click the Custom Actions node and then click Show All Custom Actions.) Set the Filename & Commandline setting as follows:

```
[SystemFolder]notepad.exe "[MsiLogFileLocation]"
```

Thus, the value should contain [SystemFolder] instead of [WindowsFolder].

Changes for ALLUSERS Property in InstallScript MSI Installations

Beginning with InstallShield 2010, the **ALLUSERS** property is set to 1 by default in all new InstallScript MSI projects. This is the recommended implementation, since most installations must be run in a per-machine context with administrative privileges. This value is also recommended to help avoid **ALLUSERS**-related issues when an InstallScript MSI installation is run silently.

If you upgrade a project that was created with InstallShield 2009 or earlier to InstallShield 2013, InstallShield does not automatically change the value of the **ALLUSERS** property or add this property if it was not defined in the earlier project.

InstallScript Installations No Longer Include _Setup.dll

InstallScript installations no longer include `_Setup.dll`. Some earlier versions (DevStudio 9 and InstallShield X) did not log `_Setup.dll` for uninstallation. As a result, this file was left behind in the Disk1 folder location (DISK1TARGET) after uninstallation. If an update was created with a later InstallShield version (InstallShield 10.5 through InstallShield 2009) and the update was for an original installation that was created with DevStudio 9 or InstallShield X, `_Setup.dll` was deleted during uninstallation because `_Setup.dll` was logged by the update. Since `_Setup.dll` is not included in InstallScript installations that are created with InstallShield 2013, the

_Setup.dll file may now be left behind. Therefore, if you are updating from an installation that was created with DevStudio 9 or InstallShield X, you may need to delete the _Setup.dll file manually (DISK1TARGET ^ "_Setup.dll") during uninstallation to ensure that the uninstallation is complete.

Saving a Project as an Earlier Version

InstallShield no longer has support for downgrading a project. That is, you cannot save an InstallShield 2013 project as an InstallShield 2009 or earlier project.

Trialware Support

The only edition of InstallShield that includes the Trialware view is the Premier edition. This edition lets you create the Try and Die type of trialware. InstallShield no longer includes support for creating the Try and Buy/Product Activation type of trialware.

Web Projects

The Web project type is no longer listed as one of the types of new projects that you can create in InstallShield. To use the same functionality that was available with a Web project in InstallShield 2009 and earlier, create a Basic MSI project, and then add a Web site in the Internet Information Services view.

The only difference between a Web project and a Basic MSI project was that a new Web project automatically contained a predefined folder for the **IISROOTFOLDER** directory in the Files and Folders view. All of the files that you add to the **IISROOTFOLDER** directory are installed to the Web server's root directory on the target system. InstallShield adds predefined folder for the IISROOTFOLDER directory to a Basic MSI project when you add a Web site to the project. Thus, a Basic MSI project that contains at least one Web site configured in the Internet Information Services view is equivalent to a Web project that was created in InstallShield 2009 or earlier.

Compact Projects

InstallShield no longer has support for Compact projects.

Visual Studio Integration

Microsoft Visual Studio can be integrated with only one version of InstallShield Premier Edition or InstallShield Professional Edition at a time. The last version of InstallShield that is installed or repaired on a system is the one that is used for Visual Studio integration.

Upgrading Projects from InstallShield 2008 or Earlier

The following information describes possible upgrade issues that may occur when you upgrade projects that were created with InstallShield 2008 and earlier to InstallShield 2013. It also alerts you to possible changes in behavior that you may notice between new InstallShield 2013 projects and projects that are upgraded from InstallShield 2008 or earlier to InstallShield 2013.

General Information about Upgrading Projects that Were Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open a project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .766 before converting it. Delete the .766 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2013: InstallShield 2008, InstallShield 12 and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2013.

Changes that Affect All Projects (New and Upgraded Projects)

This section describes changes that affect both new projects and projects that are upgraded from earlier versions of InstallShield.

New Default Setup Launcher Value for New Releases: Windows Installer Is Not Included

When you create a new release in a Basic MSI or InstallScript MSI project, the redistributable for the Windows Installer engine is no longer included by default:

- If you use the Release Wizard to create a new release, the Setup Launcher panel is where you specify whether to include the Windows Installer. The default value for the **Support these operating systems** setting is **Do not install Windows Installer**. Previously, the default value was **Both Windows 9X and NT**.
- If you create a new release by right-clicking the Releases explorer in the Releases view, the default value for the Setup Launcher setting on the Setup.exe tab is now **Yes (no MSI engine included)**. Previously, the default value for this setting was **Yes (include Windows NT & Windows 9x MSI engine)**.

This change applies to all new releases that are created in new InstallShield 2013 projects.

If you upgrade a project from InstallShield 2008 or earlier to InstallShield 2013, this change applies to all new releases; InstallShield does not automatically change the value for releases that were originally created in the earlier InstallShield version.

Upgrade and Patch Validation

When you build QuickPatch projects, InstallShield now runs patch and upgrade validation. Therefore, when you build a QuickPatch package in InstallShield 2013, you may see validation errors and warnings. If you built a QuickPatch project in InstallShield 2008 or earlier, InstallShield did not run the upgrade and patch validation; thus, patch or upgrade validation errors or warnings were never displayed at build time.

In addition, the Val0015 warning now checks the **ISSelfReg** table in QuickPatch projects and in patches that are created through the Patch Design view in Basic MSI and InstallScript MSI projects. If a QuickPatch or patch project adds a row to the **ISSelfReg** table, Val0015 warns you that the patch will be uninstallable. Previously, Val0015 did not check for entries in this table.

File Compression for Files that Are Streamed into Setup.exe and ISSetup.dll at Build Time

If you build a release that uses a `Setup.exe` setup launcher or a `ISSetup.dll` file, InstallShield now compresses files that it streams into the `Setup.exe` file or the `ISSetup.dll` file at build time. The default compression level that InstallShield uses offers a balance between file size and time that is required to extract the compressed files at run time. This applies to new Basic MSI and InstallScript MSI projects as well as existing Basic MSI and InstallScript MSI projects that are upgraded from InstallShield 2008 or earlier to InstallShield 2013.

If you want to change the compression level or you do not want to use any compression, you can override the default level through a machine-wide setting. For more information, see Configuring the Compression Level for Files that Are Streamed into Setup.exe and ISSetup.dll.

Previously, InstallShield did not include any support for compressing files that were streamed into the `Setup.exe` file or the `ISSetup.dll` file at build time. Thus, if you compare a release that was built in InstallShield 2008 or earlier with the same release that is built with the default compression level in InstallShield 2013, you may notice that the file size of `Setup.exe` or `ISSetup.dll` is slightly different. In addition, the time that is required to extract files may be slightly different.

Multi-Part .cab Files

InstallShield now has a default limit of 600 MB for each .cab file that it creates at build time for a network image release in which the compression type is the standard compression type (not custom compression) and all of the files are embedded in a single-file .msi package or a `Setup.exe` setup launcher. When InstallShield is creating the .cab files for this type of release and it reaches this limit, it splits the data into two or more .cab files, creating multi-part .cab files. This applies to new Basic MSI and InstallScript MSI projects as well as existing Basic MSI and InstallScript MSI projects that are upgraded from InstallShield 2008 or earlier to InstallShield 2013.

You can modify the .cab size limit if necessary. In addition, if you do not want InstallShield to create multi-part .cab files, you can configure it to create single .cab files. For more information, see Configuring the Maximum Size for .cab Files.

Previously, InstallShield did not create multi-part .cab files, and there was no built-in limit for the .cab file size.

Automation Interface and Standalone Build

If you have existing automation scripts that work with the InstallShield Automation Interface, you no longer need to change the library name from IswiAuto*N* to SAAuto*N* (where *N* indicates the version number) throughout the scripts in order to use them with the Standalone Automation Interface.

The Standalone Build that is available with InstallShield Premier Edition now uses the same directory structure that InstallShield uses.

The `ISCmdBld.exe` file that is used for command-line builds with InstallShield is now installed with the Standalone Build. Previously, the Standalone Build used `IsSaBld.exe`, a different file, for command-line builds.

FlexNet Connect Support in InstallScript Projects

InstallScript projects no longer include an Update Notifications view, which is used to add FlexNet Connect support to an installation. Note that this view is still available in Basic MSI and InstallScript MSI projects.

Note the following details about FlexNet Connect support in InstallScript projects:

- InstallShield does not add `ISUS.obl` to the list of libraries (or enable any other FlexNet Connect functionality) when ISEnableUpdateService is changed to 1 in the **InstallShield** table. The `ISUS.obl` library is no longer supported.
- If you upgrade an InstallScript project from InstallShield 2008 or earlier to InstallShield 2013, InstallShield automatically disables FlexNet Connect support and removes the `ISUS.obl` from the list of linked script libraries.
- The InstallScript constants and functions for FlexNet Connect still compile. However, all of the functions—except for **UpdateServiceGetAgentTarget**—now return ISERR_NOT_IMPLEMENTED. **UpdateServiceGetAgentTarget** returns null ("").
- All calls to the InstallScript functions for FlexNet Connect were removed from the default InstallScript code. In the OnUpdateUIBefore event handler, the code for **UpdateServiceOnEnabledStateChange** was removed. In the OnMoveData event handler, the code blocks for **UpdateServiceRegisterProduct** and **UpdateServiceCreateShortcut** were removed.

  Note that if you upgrade an InstallScript project from InstallShield 2008 or earlier to InstallShield 2013 and you had overridden these events in the earlier version of your project, the aforementioned functions are called. This should not cause any problems. The functions now return ISERR_NOT_IMPLEMENTED.

  Also, the OnFirstUIAfter event handler was updated to not include the option of calling **SdFinishUpdate**, which was disabled previously by default.
- All FlexNet Connect–related run-after-reboot functionality was removed. Therefore, the product is not registered with FlexNet Connect after a reboot.
- When you build an InstallScript project, InstallShield no longer adds any FlexNet Connect–related files to the media.
- ISUS.obl will no longer be supported and thus will not be provided with the product.

FlexNet Connect Support in InstallScript MSI Projects

The following FlexNet Connect–related functions have been deprecated for InstallScript MSI projects:

- **GetUpdateStatus**—This function always returns FALSE.
- **SetUpdateStatus**—This function returns ISERR_NOT_IMPL.
- **GetUpdateStatusReboot**—This function always return FALSE.
- **SetUpdateStatusReboot**—This function returns ISERR_NOT_IMPL.

All calls to the **SetUpdateStatus** and **SetUpdateStatusReboot** functions were removed from the default InstallScript code.

Multilanguage Support in Basic MSI and InstallScript MSI Projects

If an installation includes multilanguage support and end users launch Setup.exe again (after the product is already installed) to run the installation in maintenance mode, the language selection dialog is no longer displayed. The maintenance dialogs are displayed in the same language that was used to originally install the product.

Similarly, if a multilanguage minor upgrade or small update is run to update an earlier version of an already installed product, the language selection dialog is not displayed. The upgrade dialogs are displayed in the same language that was used to originally install the product.

This behavior helps ensure that the same language that was used to run the original installation and install its features is also used to repair the original installation, as well as to add other features that were not originally installed but are installed during maintenance mode or upgrades.

InstallScript Multi-Instance Support

For an InstallScript multilanguage, multi-instance installation that displays the language selection dialog, the instance selection dialog is now displayed before the language selection dialog. The dialog order change enables end users to select a different language for a new instance of the product. If end users specify in the instance selection dialog that they want to maintain an existing instance, the language selection dialog is not displayed. Note that when the instance selection dialog is displayed, it is displayed in the same language that would be used to display the language selection dialog.

If multiple instances of a non-multi-instance installation are installed through the `Setup.exe /ig` command-line parameter, the language selection dialog is displayed only during a first-time installation; it is not displayed during maintenance mode. This helps ensure that the same language that was used to run the original installation and install its features is also used to repair the original installation, as well as to add other features that were not originally installed but are installed during maintenance mode.

During an InstallScript full-release installation that does not display the instance selection dialog—such as an installation that is run in silent mode or with the `Setup.exe -hide_usd` command-line parameter—the installation automatically installs a new instance. This behavior occurs for all new InstallShield 2013 projects, as well as projects that are upgraded from earlier versions to InstallShield 2013. In InstallShield 2008, `/hide_usd` resulted in the first installed instance being maintained, and silent mode resulted in a new instance being installed. In InstallShield 12 and earlier, the first installed instance would be maintained in both the `/hide_usd` and silent mode scenarios.

For a differential media, the first instance read is updated.

During a non-multi-instance installation on a system where two or more instances are installed (using the `Setup.exe /ig` command-line parameter), the instance selection dialog is displayed. The instance selection dialog does not allow a new instance to be installed during a non-multi-instance installation because a non-multi-instance installation does not generate a new random GUID for the new instance. The instance selection dialog includes the “default” instance (the instance whose GUID matches the product code) if it installed and it is one of the instances that can be maintained. This behavior applies to all new InstallShield 2013 projects, as well as projects that are upgraded from earlier versions of InstallShield.

If a single instance is installed, the installation automatically attempts to maintain the installed instance; it does not show the instance selection dialog. Note that is true even if the installed instance is not the default instance. As a result of this behavior, if the default instance is not installed but a non-default instance is installed (using the `/ig` parameter), it is not possible to install or maintain the default instance without (a) first uninstalling the non-default instance or (b) specifying the GUID of the default instance through the `/ig` parameter. Therefore, if you support using the `/ig` parameter to install multiple instances, it is recommended that you always use this parameter. This behavior applies to all new InstallShield 2013 projects, as well as projects that are upgraded from earlier versions of InstallShield.

For InstallShield 2008, if a non-multi-instance installation was run on a target system that had multiple instances installed, the instance selection dialog was not displayed; in this case, the default instance was always used. For InstallShield 12 and earlier, if a non-multi-instance installation was run on a target system that had multiple instances installed, the instance selection dialog was displayed; this dialog did not allow a new instance to be displayed (because a non-multi-instance installation does not generate a new random GUID for the new instance). However, the title bar of the dialog indicated that the end user should select an instance to update; it should have indicated that the end user should select an instance to update or maintain.

Changes for SdRegisterUser, SdRegisterUserEx, SdCustomerInformation, and SdCustomerInformationEx in InstallScript MSI Installations

In an InstallScript MSI installation, the following InstallScript text substitutions now map directly to Windows Installer properties:

- IFX_PRODUCT_REGISTEREDOWNER maps to the Windows Installer property USERNAME.
- IFX_PRODUCT_REGISTEREDCOMPANY maps to the Windows Installer property COMPANYNAME.

Therefore, when these InstallScript variables are set and retrieved, the corresponding Windows Installer properties are set and retrieved. The default values for these variables are no longer read from the registry; instead the Windows Installer properties are used by default. To use the previous functionality, you can set the variables manually through the following sample code:

```
// Registered Owner (Only load from registry if pre-loaded value (from log file) is "")
if( !StrLengthChars( IFX_PRODUCT_REGISTEREDOWNER ) ) then
    szValue = "";
    RegDBGetItem( REGDB_WINCURRVER_REGOWNER, szValue );
    if( StrLengthChars( szValue ) ) then
        IFX_PRODUCT_REGISTEREDOWNER = szValue;
    endif;
endif;

// Registered Company (Only load from registry if pre-loaded value (from log file) is "")
if( !StrLengthChars( IFX_PRODUCT_REGISTEREDCOMPANY ) ) then
        szValue = "";
        RegDBGetItem( REGDB_WINCURRVER_REGORGANIZATION, szValue );
        if( StrLengthChars( szValue ) ) then
            IFX_PRODUCT_REGISTEREDCOMPANY = szValue;
        endif;
endif;
```

In an InstallScript MSI installation, the various registration-related dialogs—**SdRegisterUser**, **SdRegisterUserEx**, **SdCustomerInformation**, and **SdCustomerInformationEx**—now set IFX_PRODUCT_REGISTEREDOWNER, IFX_PRODUCT_REGISTEREDCOMPANY, and IFX_PRODUCT_REGISTEREDCOMPANY as appropriate based on the end users' selections. This automatically updates the corresponding Windows Installer properties.

When a null string ("") is specified for either svName or svCompany for the any of the registration-related dialog functions (**SdRegisterUser**, **SdRegisterUserEx**, **SdCustomerInformation**, or **SdCustomerInformationEx**), the functions use the appropriate variable (determined from the corresponding Windows Installer property) as the default. Previously, the variables were used only if both svName and svCompany were null; for **SdCustomerInformation** and **SdCustomerInformationEx**, the values were read directly from the Windows Installer properties, bypassing the script variables.

If a null string ("") is specified for the svSerial parameter, the default value for the serial number field is now set to IFX_PRODUCT_REGISTEREDSERIALNUM. Previously in this case, the dialog displayed no value.

The following InstallScript variables are new or have been changed:

- **DISABLE_PERUSERBTN**—This existing variable indicates that the per-user radio button should be disabled (or hidden) in cases that it would normally be enabled. This variable is always initialized to FALSE. Previously, this value was initialized to TRUE on Windows 9x systems; otherwise, it was FALSE.
- **DISABLE_ALLUSERBTN**—This existing variable indicates that the all-user radio button should be disabled (or hidden) in cases that it would normally be enabled. This variable is always initialized to FALSE. Previously, this value was initialized to TRUE if the operating system was not Windows 9x and the end user was not an administrator or power user.
- **HIDE_DISABLED_BTNS**—This new variable indicates that the all-user and per-user radio buttons should be hidden instead of being disabled. The default value is TRUE. Note that if this variable is set to TRUE, both radio buttons are hidden if either button is determined to be disabled.

The registration dialogs now automatically disable (or hide) the per-user radio button on Windows 9x regardless of the value of DISABLE_ALLUSERBTN. Previously, the per-user radio button was disabled only if DISABLE_PERUSERBTN was FALSE.

Note also that the registration dialogs automatically disable (or hide) the all-users radio button if the end user is not an administrator or power user, regardless of the value of DISABLE_ALLUSERBTN. This behavior has not changed.

These changes apply to all new InstallScript MSI projects that are created in InstallShield 2013, as well as InstallScript MSI projects that were created in earlier versions of InstallShield and then upgraded to InstallShield 2013.

Proxy Server Support

You may want to configure your installation to download certain files only if they are needed on the target system. For example, the Windows Installer engine, the .NET Framework, and some InstallShield prerequisites may already be present on some or most target systems. Instead of embedding these files in your installation (which would increase your overall installation size), you can configure your project so that only the ones that are needed are downloaded at run time.

If your end users access the Internet through a proxy server and your installation is configured to download files, the installation now uses the system proxy settings that are manually configured in Internet Explorer during the download. This occurs even if another browser on the target system is the default browser.

Note that InstallShield does not include support for the Automatically Detect Settings functionality in Internet Explorer. (If end users have the Automatically Detect Settings check box selected in Internet Explorer for their LAN connection and the installation needs to download files, the installation fails because the files cannot be downloaded. If it is possible that your end users may have the Automatically Detect Settings check box selected in Internet Explorer for their LAN connections, you may want to embed all of the files in your installation rather than configure them to be downloaded; if the files are embedded, the failures can be avoided.) However, InstallShield does support the Automatic Configuration Script functionality that is set up for LAN connections in Internet Explorer.

This is the behavior for all new projects in InstallShield 2013, as well as all projects that are created in earlier versions and then upgraded to InstallShield 2013.

In InstallShield 2008 and earlier, the installation attempted to use the proxy server settings that were configured in whatever browser was the default browser. However, this was not always possible, and it caused some problems:

- If Netscape 6 or 7 was the default browser, the Netscape 4 settings were used. If Netscape 8 or 9 was the default browser, the system (Internet Explorer) settings were used.
- If Netscape 4 settings were used, only the proxy server list was read and imported correctly. The proxy bypass list was read, but it was not imported correctly.
- Non–Internet Explorer 4 compatible settings such as the auto-proxy script setting were not imported.
- The method that the installation used for determining the default browser was not compatible on Windows Vista. Therefore, on Windows Vista systems, an installation may not have detected the default browser correctly.

Web Downloader Option to Wrap a 1.x .msi Package into a .cab File Is No Longer Available

InstallShield no longer includes an option to specify that an .msi package should be wrapped into a .cab file. This option was previously available for the Web Downloader type of media in Basic MSI and InstallScript MSI projects in which the Windows Installer 1.1 or 1.2 was included. The recommended method is to use Windows Installer 2.0 or later and to digitally sign the package.

Status Text in InstallScript MSI Projects

The OnFirstUIBefore, OnMaintUIBefore, OnAdminInstallUIBefore, OnAdminPatchUIBefore, OnPatchUIBefore, OnUninstall, and OnResumeUIBefore event handlers in an InstallScript MSI project now include **SetStatusExStaticText** calls by default in all new InstallScript MSI projects. This new default code sets status text for the STATUSEX dialog; the status text that is displayed is now appropriate for the type of operation (first-time installation, maintenance, uninstallation, repair, etc.) being performed. Previously, it was necessary to manually add the **SetStatusExStaticText** calls; otherwise, the status text that was displayed did not correspond with the type of operation being performed.

Note that if you upgrade an InstallScript MSI project from InstallShield 2008 or earlier to InstallShield 2013 and you had overridden one or more of the updated events in the earlier version of your project, you must manually add the **SetStatusExStaticText** code to these events.

Changes for the InstallScript Variable SHELL_OBJECT_FOLDER

You can specify `SHELL_OBJECT_FOLDER` (for InstallScript or InstallScript MSI projects) or `<SHELL_OBJECT_FOLDER>` (for InstallScript projects) in the Display Name setting for a folder in the Shortcuts view. Then you can define the display name for the folder at run time by setting the SHELL_OBJECT_FOLDER variable in your script before the shortcut is created. The shortcut is typically created during file transfer.

To use this functionality in an InstallScript MSI installation, any letters that are specified for the Key Name setting of the folder in the Shortcuts view must be all uppercase (for example, NEWFOLDER1).

SHELL_OBJECT_FOLDER is now initialized to the same value as IFX_PRODUCT_NAME during initialization. Note that these variables are not synchronized once initialized; therefore, if you change one and want the other to change, you must change both manually.

Note that also as part of this change, the default OnFirstUIBefore event handler code in InstallScript MSI projects no longer includes the following line of code:

```
SHELL_OBJECT_FOLDER = @PRODUCT_NAME;
```

If you have an InstallScript MSI project that was created in InstallShield 2008 or earlier and you modified the default OnFirstUIBefore code, InstallShield does not remove this line from your code when you upgrade your project to InstallShield 2013.

To learn more, see SHELL_OBJECT_FOLDER.

Change in Behavior for the InstallScript Function FeatureFileEnum

If you use the question mark (?) as a wild-card character for the szQuery parameter of the InstallScript function FeatureFileEnum, the function now uses the question mark as a substitute for exactly one character. If you used the question mark as a wild-card character with **FeatureFileEnum** in a project that you created in an earlier version of InstallShield, you may need to change your InstallScript code when you upgrade it to InstallShield 2013. In earlier versions of InstallShield, the function used the question mark as a substitute for one or zero characters.

For example, if you create a new InstallScript project with default settings and add the following InstallScript code to your project, the dialog that is displayed at run time does not display anything.

```
#include "ifx.h"

   LIST listFiles;

program

   listFiles = ListCreate( STRINGLIST );
   FeatureFileEnum( MEDIA, "DefaultFeature", "Default?Component", listFiles, NO_SUBDIR );
   SdShowInfoList( "", "", listFiles );

endprogram
```

In installations that were created earlier versions of InstallShield, the dialog displayed `DefaultComponent`.

All InstallScript Installations Now Support Showing Update UI

All InstallScript projects now support showing the update user interface (UI). Previously, the General Information view and the Project Settings dialog box had a confusing option that enabled the update UI to be disabled. If the update UI was disabled, the MEDIA_FLAG_UPDATEMODE_SUPPORTED flag was not set for MEDIA_FIELD_MEDIA_FLAGS, and the OnSetUpdateMode event handler did not set the UPDATEMODE variable when appropriate. As a result, the update UI was not shown.

Note that changing the value of ISShowUpdateUI in the InstallShield table (which the previous option updated) no longer has any effect.

It is possible to duplicate the previous functionality through the following methods:

- Override the OnSetUpdateMode event and update the function to return before setting the UPDATEMODE variable. The installation never shows the update UI.
- Override the OnUpdateUIAfter event and change the call for FeatureRemoveAllInMediaAndLog to FeatureRemoveAllInMedia.

Changes for the Certified for Windows Vista Validation Suites

The two Certified for Windows Vista validation suites that help you determine whether your installation or merge module meets the requirements for the Windows Vista logo program have been revised. They now consist of only the InstallShield ICEs (ISICEs). The Microsoft-created ICEs (ICE01 through ICE99) have been removed, since they are available in the Full MSI Validation Suite for installation packages and in the Merge Module Validation Suite for merge modules.

In addition, these two suites have been renamed:

- The new name for the Certified for Windows Vista Validation Suite (plus InstallShield ICEs) is *InstallShield Certified for Windows Vista Validation Suite*.
- The new name for the Certified for Windows Vista Merge Module Validation Suite (plus InstallShield ICEs) is *InstallShield Certified for Windows Vista Merge Module Validation Suite*.

For more information about the validation and the Certified for Windows Vista program, see:

- Requirements for the Windows Logo Program
- Validating Projects

Updated InstallScript Objects and Object Templates

A number of improvements were made to the InstallScript objects and InstallScript object templates that are available for use with InstallShield 2013 InstallScript projects.

If you have an Internet connection, you can use the Check for Updates feature in InstallShield to obtain the updated InstallScript objects and object templates for the version of InstallShield that you are using. To check for updates: On the Tools menu, click Check for Updates. InstallShield launches FlexNet Connect, which checks for updates.

If you do not have an Internet connection on the computer that has InstallShield, visit the Downloads area of the http://www.installshield.com site from a computer that does have an Internet connection, download the updated InstallScript objects and templates, save them to a removable disk, and then transfer them to the computer that has InstallShield.

Changes that Affect New Projects but Not Upgraded Projects

This section describes changes to InstallShield that may affect new projects but not projects that are upgraded from earlier versions. Note that you may need to make manual changes to upgraded projects.

Unicode and ANSI Versions of the Setup.exe and Update.exe Bootstrappers

InstallShield now enables you to specify whether you want to create a Unicode version or an ANSI version of the `Setup.exe` setup launcher for a Basic MSI project. Previously, if your Basic MSI project included a setup launcher, InstallShield always built an ANSI version; it did not include support for building a Unicode version.

A Unicode setup launcher can correctly display double-byte characters in the user interface of the setup launcher, regardless of whether the target system is running the appropriate code page for the double-byte-character language. An ANSI setup launcher displays double-byte characters in the setup launcher dialogs if the target system is running the appropriate code page. However, it displays garbled characters instead of double-byte characters in those dialogs if the target system is not running the appropriate code page.

If you create a new release in a Basic MSI project in InstallShield 2013, the default setup launcher type is Unicode. In addition, if you create a new patch configuration or a new QuickPatch project in InstallShield 2013, the default update launcher type is Unicode.

If you upgrade a Basic MSI project from InstallShield 2008 or earlier to InstallShield 2013, the setup launcher type for any existing releases is ANSI. You can override the type if appropriate.

Similarly, if you upgrade a Basic MSI project or a QuickPatch project from InstallShield 2008 or earlier to InstallShield 2013, the update launcher type for any existing patch is ANSI. You can override the type if appropriate.

Dynamic File Links

When you add or modify a dynamic file link in a project, you can specify which component creation method you want InstallShield to use: a new best practice method or the previously available one-component-per-directory method. These methods are applicable to dynamic file linking in Basic MSI, InstallScript MSI, and Merge Module projects.

If you create a new dynamic file link in InstallShield 2013, InstallShield uses the best practice method by default.

All dynamic file links that are created in InstallShield 2008 or earlier use the one-component-per-directory method. If you have a project with dynamic file links and you upgrade it from InstallShield 2008 or earlier to InstallShield 2013, InstallShield continues to use the one-component-per-directory method for creating the components of those already present dynamic file links. For any new dynamic file links that you create in the upgraded project, the best practice method is used by default. For detailed information about the two component creation methods, as well as guidance on which method you should use, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.

IIS Web Sites and Associated Components

InstallShield now includes support for installing IIS Web sites without any virtual directories. In addition, InstallShield now lets you associate a Web site with a component. As a result of these enhancements, a Web site is created on a target machine if a virtual directory or a component that is associated with it is installed.

If you add a new Web site through the Internet Information Services view in InstallShield 2013, InstallShield automatically associates that Web site with a component. If you upgrade an InstallShield 2008 or earlier project that already has an IIS Web site, InstallShield does not automatically associate that Web site with a component. Use the General tab that InstallShield displays when you select a Web site in the Internet Information Services view if you want to associate the selected Web site with a component.

Note that if a Web site is associated with a component, the Web site's **Delete Web Site on Uninstall** check box now corresponds with the Permanent setting for that component in a Basic MSI or InstallScript MSI project, or with the Uninstall setting for that component in an InstallScript project. That is, if you select or clear the **Delete Web Site on Uninstall** check box for a Web site, InstallShield automatically updates the value of the component's Permanent setting or Uninstall setting, as appropriate.

Simplification of QuickPatch Packages

The new Streamline QuickPatch setting on the Advanced tab in a QuickPatch project determines how InstallShield builds QuickPatch packages. A streamlined QuickPatch package typically has fewer new subfeatures and custom actions than a non-streamlined QuickPatch package.

In some cases, InstallShield cannot streamline the QuickPatch package. For example, if you configure the QuickPatch package to remove an installed file, InstallShield cannot streamline it.

When you create a new QuickPatch project, the default value for the Streamline QuickPatch setting is Yes. However, when you upgrade a QuickPatch project from InstallShield 2008 or earlier to InstallShield 2013, the value for this setting is No. You can change this value if appropriate. For more information, see Specifying Whether to Streamline the QuickPatch Package.

Default Condition for the SetARPINSTALLLOCATION Custom Action

By default, all new Basic MSI and InstallScript MSI projects contain the built-in InstallShield custom action SetARPINSTALLLOCATION. This custom action, which sets the value of the ARPINSTALLLOCATION property to the fully qualified path for the product's primary folder, is scheduled for the Installation Execute sequence, and it has no condition. In InstallShield 2008 and earlier, the default condition for this custom action was Not Installed. With this default Not Installed condition, the custom action is not run during maintenance mode, and this results in a blank value for the ARPINSTALLLOCATION property. To avoid this behavior in a project that you upgrade from InstallShield 2008 or earlier to InstallShield 2013, open the Custom Actions and Sequences view and delete the Not Installed value from the Install Exec Condition setting for this custom action.

New Sequence Location for the MigrateFeatureStates Action

By default, the MigrateFeatureStates action is now sequenced immediately after the CostFinalize action in all new Basic MSI and InstallScript MSI projects. If you use the SQL Scripts view to add SQL support to the new project, InstallShield now schedules the InstallShield built-in custom action ISSQLServerFilteredList after the MigrateFeatureStates action. In InstallShield 2008 and earlier, the ISSQLServerFilteredList was sequenced before the MigrateFeatureStates action, and this caused run-time error 2601. To avoid this error in a project that you upgrade from InstallShield 2008 or earlier to InstallShield 2013, open the Custom Actions and Sequences view and move the ISSQLServerFilteredList action after the MigrateFeatureStates in the Installation User Interface sequence.

Template Summary Property Changes

You can specify a value for the Template Summary property in the General Information view or for a product configuration in the Releases view. If you try to enter an invalid value (for example, if you indicate multiple platforms or you use more than one semicolon), InstallShield displays a warning message box and does not allow you to change the value for the property.

Earlier versions of InstallShield permitted you to enter invalid values. If you upgrade an InstallShield 2008 or earlier project to InstallShield 2013, InstallShield does not automatically change the invalid value. However, you can manually update the value if appropriate. For more information, see Using the Template Summary Property.

Welcome Assistant Removed

The Welcome Assistant, which was displayed the first time that you opened InstallShield, is no longer included.

InstallShield MSIPackageDiff Replaced by InstallShield MSI Diff

The tool called InstallShield MSIPackageDiff is no longer included with InstallShield. It has been replaced by a more powerful tool called InstallShield MSI Diff. You can launch InstallShield MSI Diff from within InstallShield: On the Tools menu, point to Difference, and then click InstallShield MSI Diff.

For more information, see InstallShield MSI Diff.

Upgrading Projects from InstallShield 12 or Earlier

The following information describes changes that may affect projects that are upgraded from InstallShield 12 or earlier to InstallShield 2013.

Upgrading Projects Created in Earlier Versions of InstallShield

If you use InstallShield 2013 to open a project that was created with an earlier version, InstallShield 2013 displays a message box that asks you if you want to convert the project to the new version. If you reply that you do want to convert it, InstallShield creates a backup copy of the project with a file extension such as .765 before converting it. Delete the .765 part from the original project's file name if you want to reopen the project in the earlier version of InstallShield. Note that you cannot open InstallShield 2013 projects in earlier versions of InstallShield.

You can upgrade projects that were created with the following versions of InstallShield to InstallShield 2008: InstallShield 12 and earlier, InstallShield DevStudio, InstallShield Professional 7 and earlier, and InstallShield Developer 8 and earlier. Note that projects that were created with InstallShield MultiPlatform or InstallShield Universal cannot be upgraded to InstallShield 2008.

End of Support for Windows 9x, Windows NT 4, and Windows Me on Target Systems

InstallShield no longer supports the creation of installations for Windows 9x, Windows NT 4, and Windows Me systems. If end users have one of these operating systems on their computer and they try to run an installation that was built with InstallShield 2013, unexpected results may occur, unless the project includes launch conditions that prevent end users from running the installation on any of these legacy operating systems.

For Basic MSI and InstallScript MSI projects, you may want to consider adding launch conditions that display a message if end users are running your installation on any of the legacy systems. For InstallScript projects, you may want to consider adding InstallScript code that uses the SYSINFO structure variable to check for these legacy systems, and then display a message if any of these legacy systems are present.

To learn more, see:

- Specifying Operating System Requirements in the Project Assistant
- Platforms Tab
- Platforms Dialog Box
- Modify Property Dialog Box/Release Wizard—Platforms Panel

COM Extraction

When you use InstallShield to extract COM information from a COM server, InstallShield puts the data in the Registry table, instead of in the **TypeLib** table. Microsoft strongly advises against using the TypeLib table, as described in the TypeLib Table topic on the MSDN Web site.

Unused Directories Automatically Removed from .msi File at Build Time by Default

Note that if you upgrade a Basic MSI, InstallScript MSI, or Merge Module project that was created in InstallShield 12 or earlier to InstallShield 2013, the new Keep Unused Directories setting on the Build tab in the Releases view is set to No. Therefore, if a directory that is listed in the Directory column of the Directory table is not referenced in any known location in the .msi file, InstallShield removes it from the Directory table of the .msi file that it creates at build

time. For Basic MSI and InstallScript MSI projects, this occurs after any merge modules are merged, but only directories that are present in the .msi file are removed; therefore, if a merge module contains new unused directories in its Directory table, the new unused directories are added to the installation.

Changes for ALLUSERS and for the CustomerInformation Dialog

Beginning with InstallShield 2008, the **ALLUSERS** property is set to 1 by default in all new Basic MSI projects. This is the recommended implementation, since most installations must be run in a per-machine context with administrative privileges.

If you upgrade a project that was created with InstallShield 12 or earlier to InstallShield 2013, InstallShield does not automatically change the value of the **ALLUSERS** property or add this property if it was not defined in the earlier project.

Also new with InstallShield 2008, by default, the CustomerInformation dialog in all new Basic MSI projects does not display the radio button group that enables end users to specify whether they want to install the product for all users or for only the current user. This is the recommended implementation for this dialog.

If you upgrade a project that was created with InstallShield 12 or earlier to InstallShield 2013, InstallShield does not automatically change the CustomerInformation dialog.

To learn more, see:

- Per-User vs. Per-Machine Installations
- ALLUSERS

Windows Server 2003 Conditions and 64-Bit Windows XP Conditions for Setup Prerequisites

The operating system version number is 5.2 for both Windows Server 2003 and 64-bit Windows XP. As a result, prerequisites that were created in InstallShield 12 and that required Windows Server 2003 could be installed on 64-bit Windows XP systems, and those that required Windows XP could not be installed on 64-bit Windows XP systems.

To resolve this issue, the Setup Prerequisite Editor in InstallShield 2008 has been enhanced to enable you to specify whether the target system is required to be a workstation, a server, or a domain controller.

To resolve this issue for an existing prerequisite that includes a Windows Server 2003 requirement or a 64-bit Windows XP requirement, open the prerequisite in the Setup Prerequisite Editor in InstallShield 2008. On the Conditions tab, select the condition that needs to be corrected and click Modify. In the **Select which platform the prerequisite should be run on** box, select the appropriate operating system requirement. Doing this correctly sets the new Product (OS) Type setting to the appropriate workstation, server, or domain controller value.

Automation Interface

The Display Save Options dialog setting was removed from the Releases view. Therefore, the WebSaveOptionsDlg property, which corresponds with that setting, is no longer available for the ISWiRelease object of automation interface.

New Default Value for the Cache Path Setting for a Release

The default value for the Cache Path setting for a compressed release in the Releases view is now set to `[LocalAppDataFolder]Downloaded Installations`. The previous default value was `[WindowsFolder]Downloaded Installations`, which may not be available to users on locked-down systems. If you migrate a project from InstallShield 12 or earlier to InstallShield 2013, the Cache Path setting is not automatically changed. Therefore, you may want to change that value.

InstallScript One-Click Install Installations

`Setup.exe` is no longer used as the setup player for InstallScript One-Click Install installations; `Setup.ocx` is now used instead. In order for a `Setup.ocx` file to be included in an installation, the new Generate One-Click Install setting in the Releases view must be set to Yes. If you upgrade an InstallScript project from InstallShield 12 or earlier to InstallShield 2013 and the Create Default Web Page setting in the Releases view is set to Yes, InstallShield sets the Generate One-Click Install setting to Yes automatically during the upgrade. However, if the Create Default Web Page setting is set to No and you intend to distribute the installation over the Internet, you must manually select Yes for the Generate One-Click Install setting after upgrading the project.

All functionality that is related to the Save And/or Run Setup dialog box has been removed from InstallShield. If you want to give end users the option of downloading and saving the installation (or creating an icon on the desktop), you need to implement this within your installation's Web page, and handle the download and save operations through the Web page.

To pass data to a launched One-Click Install installation, use the is::CmdLine parameter and the CMDLINE script variable. Previously, it was possible to pass data from the Web page to the installation; however, this support has been removed. Note that the only valid value for the first parameter of SetProperty is now is::CmdLine.

To learn more about One-Click Install installations, see One-Click Install Installations in InstallScript Projects.

Patch Creation for Basic MSI and InstallScript MSI Projects

InstallShield now uses version 3.1 of Patchwiz.dll to create patches.

DemoShield Support

DemoShield is no longer being sold. In addition, it is no longer supported. Therefore, InstallShield no longer includes any DemoShield integration.

Changes for the Windows Vista Validation Suites

The validation suites that help you determine whether your installation meets installation requirements for the Windows Vista logo program have been renamed:

- The new name for the Windows Vista Quality Validation Suite (plus InstallShield ICEs) is *Certified for Windows Vista Validation Suite (plus InstallShield ICEs)*.
- The new name for the Windows Vista Quality Merge Module Validation Suite (plus InstallShield ICEs) is *Certified for Windows Vista Merge Module Validation Suite (plus InstallShield ICEs)*.

In addition, three of the InstallShield ICEs have been moved to the InstallShield Best Practice Suite.

For more information about the validation and the Certified for Windows Vista program, see:

- Requirements for the Windows Logo Program
- Validating Projects

To learn about the validators that are now available as InstallShield Best Practices, see:

- ISBP17 (which was previously known as ISICE13)
- ISBP18 (which was previously known as ISICE14)
- ISBP19 (which was previously known as ISICE15)

Upgrading Projects from InstallShield 11.5 or Earlier

For InstallShield 12, a number of improvements were made to the InstallScript MSI architecture to resolve issues with security (COM/DCOM) and other areas that can cause some installations to fail for various reasons. The architecture was improved for InstallShield 12 to resolve these issues and to make InstallScript MSI a more reliable project type. The improvements also help increase the reliability of InstallScript projects, as well as Basic MSI projects that include InstallScript custom actions.

The following table compares the earlier design with the current design:

Table 2-9 • Architecture Changes

In InstallShield 11.5 and Earlier	In InstallShield 12 and Later
Each InstallScript custom action is handled by `ISScriptBridge.dll` (a C++ MSI DLL), which forwards actual script execution to the ongoing `IDriver.exe` process.	Each InstallScript custom action is handled by `ISSetup.dll` (a single C++ MSI DLL), which contains the full InstallScript engine.
A set of engine files is required. They must be installed by `ISScript.msi` before the primary installation begins.	No engine files or `ISScript.msi` file is required. `ISSetup.dll` is self-contained.
All InstallScript custom actions execute in a shared `IDriver.exe` process. The `IDriver.exe` process remains resident until a final shutdown custom action is required.	Each InstallScript custom action is independent and has its own self-contained lifecycle. From the custom action entry point, `ISSetup.dll` starts the script engine, executes the relevant script, and shuts down the engine.

Advantages of the Architecture Changes That Were Introduced in InstallShield 12

The architecture in InstallShield 12 and later has several advantages over the earlier architecture:

- End users no longer encounter error 1607, error 1608, or other COM/DCOM run-time errors that are related to finding the running `IDriver.exe` file. When these errors occurred under the earlier model, they were difficult to resolve, often requiring changes to DCOM settings. Also, the reliance on the running object table made the model brittle across the spectrum of usage scenarios, including Fast User Switching and Windows Terminal Services.

- The engine binding is static. No shared engine files are installed to `Program Files\Common Files\InstallShield`. The reliance in InstallShield 11.5 and earlier on shared engine files made the model brittle because separate installations were not isolated. Changes to one engine version could break an existing installation. Isolation, especially for an installer, is one key to reliability.
- The `ISScript.msi` file (the InstallScript engine installer) is no longer needed. The earlier model required an `ISScript.msi` file to execute prior to the primary .msi file. Because the full application was not contained in a single .msi file, the installation essentially required a bootstrap for Basic MSI installations that had InstallScript custom actions. This was very inflexible for enterprises that use Active Directory for managed environments. Also, it was confusing for advanced users who expect the main .msi file to be self-contained. InstallScript MSI installations still require a bootstrap, so that requirement is no different than the earlier architecture; however, Basic MSI installations with InstallScript custom actions no longer require a bootstrap.
- Fewer InstallShield custom actions are needed to run the installation. The earlier model relied on a deep coupling between startup and shutdown custom actions that could easily fail. If one of the required custom actions was deleted or moved, the installation would not work properly.

Disadvantages of the Architecture Changes That Were Introduced in InstallShield 12

The disadvantages of the architecture in InstallShield 12 and later include the following:

- InstallScript events are not available in Basic MSI and merge module projects; therefore, all InstallScript code for these project types must be run by InstallScript custom actions. Global variables do not share state between these custom action invocations. Therefore, you can declare a global variable in one InstallScript custom action script and then use that global variable throughout the script. However, if your Basic MSI installation has a second InstallScript custom action, the global variable declared in the first script is not available to the second script.

  With the earlier model, InstallScript developers were able to use script code in any of the InstallScript events in Basic MSI projects, and any InstallScript global variables shared state. This allowed setup authors to write custom actions with a more holistic view and sense of continuity across the installation. However, because global variables are generally discouraged in programming, the new limitation should actually result in better-written InstallScript code.
- In-memory objects must be serialized in order to be shared between custom action invocations. With the earlier model, InstallScript developers could store complex object-based data in global variables. As with the aforementioned disadvantage, this may actually result in better InstallScript code.

Upgrading InstallShield 11.5 and Earlier Projects

The extensive rearchitecture that has been introduced in InstallShield 12 may require some manual changes when you upgrade projects that were created with InstallShield 11.5 or earlier to InstallShield 2013.

Task: ***To upgrade your project:***

1. Before you convert your project, create a backup version of your project file and any InstallScript files.
2. Open InstallShield 2013.

3. On the **File** menu, click **Open**. The **Open** dialog box opens.
4. Browse to select the project file (.ism) of the InstallShield 11.5 or earlier project that you want to upgrade. A dialog box opens, prompting you to specify whether you want to upgrade the project.
5. Click Yes.

InstallShield upgrades your project and saves a backup copy of the project file (.ism).

To learn about possible manual changes that you may need to make to upgraded projects, see the following:

- Upgrading InstallShield 11.5 or Earlier Basic MSI Projects that Have InstallScript Custom Actions
- Upgrading InstallShield 11.5 or Earlier InstallScript MSI Projects
- Upgrading InstallShield 11.5 or Earlier InstallScript Projects
- Upgrading InstallShield 11.5 or Earlier QuickPatch Projects that Have InstallScript Custom Actions
- Creating Standard Patches for InstallShield 11.5 and Earlier InstallScript MSI Projects
- Upgrading InstallShield 11.5 or Earlier InstallScript MSI Object Projects or Projects that Contain This Type of Object

Upgrading InstallShield 11.5 or Earlier Basic MSI Projects that Have InstallScript Custom Actions

The following sections explain details about upgrading Basic MSI projects that were created in InstallShield 11.5 or earlier to InstallShield 2013.

Global Variables, Global Pointers, and SUPPORTDIR

With InstallShield 12 and later, when a Basic MSI installation executes an InstallScript custom action, the compiled InstallScript is loaded before the action is called, and it is unloaded after the action completes. Thus, each InstallScript custom action executes in its own session with complete InstallScript engine loading and unloading. This behavior is different than with InstallShield 11.5 and earlier: the compiled InstallScript was loaded once before the first InstallScript custom action that was used by the InstallScript was executed, and it was unloaded at the end of the installation after all InstallScript custom actions were completed.

A major implication of this change in behavior is that global variables and pointers are no longer maintained between individual InstallScript custom action calls:

- If you need to store a value across multiple custom action calls, you must use some external mechanism such as the registry, Windows Installer properties, or an external data file to store the information between calls. If you choose to use Windows Installer properties in deferred, commit, or rollback InstallScript custom actions, see the guidelines in Windows Installer Properties and Deferred, Commit, and Rollback InstallScript Custom Actions.
- If you need to use a COM object or some other global object across custom action calls, you must initialize the object for each individual custom action call in order for the object to be valid.

Another implication of this change is that each custom action initializes and uses its own individual **SUPPORTDIR**. Therefore, you cannot share information across individual calls using files in **SUPPORTDIR**, since each custom action invocation will have its own unique **SUPPORTDIR**. You can share information using **FOLDER_TEMP** or some other file location.

Note that **FOLDER_TEMP** may not be the same path for all of your InstallScript custom actions. If you have some InstallScript custom actions that run in system context and some that do not, they will have different temp paths if the package is running in an elevated state. The InstallScript custom actions run in the context of a different user, so storing files in the temp directory and retrieving it later may not work in certain scenarios.

Windows Installer Properties and Deferred, Commit, and Rollback InstallScript Custom Actions

Deferred, commit, and rollback InstallScript custom actions in Basic MSI installations have access to only some of the built-in Windows Installer properties: **CustomActionData**, **ProductCode**, and **UserSID**. If you want an InstallScript custom action to access any other properties (such as **SUPPORTDIR**) during deferred, commit, or rollback execution, you need to pass them as **CustomActionData**. You can do so by scheduling an immediate set-a-property type of custom action (or, for example, an immediate InstallScript custom action with the **MsiSetProperty** function) to set a property that matches the name of the custom action. The value of this property is then available in the **CustomActionData** property within the deferred custom action.

For example, if you want to access a property such as **SUPPORTDIR**, you could create an immediate custom action that is called MyCustomActionName and that sets the MyCustomActionName property to [SUPPORTDIR], and then substitute "SUPPORTDIR" with "CutomActionData" in the MsiGetProperty call:

```
MsiGetProperty(hMSI, "CustomActionData", szSupportDir, nLen)
```

For more details, see the following:

- Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions
- Obtaining Context Information for Deferred Execution Custom Actions

Note that failure to compensate for an unavailable Windows Installer property may cause unexpected results during installation. For example, since in a deferred action, `MsiGetProperty(hMSI, "INSTALLDIR", szInstallDir, nLen)` sets szInstallDir to the empty string, szInstallDir ^ szFile may refer to a file in the current directory instead of a file in [INSTALLDIR]. The current directory for a deferred custom action is often [SystemFolder].

Deferred, commit, and rollback InstallScript custom actions do not have access to the **ProductLanguage** property. If your installation includes multilanguage support and it also has a deferred, commit, or rollback InstallScript custom action that needs access to the language in which the end user is running the installation, the installation assumes that this language is the installation's default language. This could be a problem if an end user runs the installation in a language other than the default language. However, deferred, commit, and rollback custom actions do not typically display any user interface, so this would usually not be a problem.

Predefined InstallScript Event Handler Functions

The predefined InstallScript event handler functions are no longer available in Basic MSI projects with InstallScript custom actions. In InstallShield 11.5 and earlier, the following InstallScript event handler functions were available for Basic MSI projects:

- OnBegin

- OnMoving
- OnMoved
- OnEnd

InstallShield no longer supports these event handler functions for Basic MSI projects that have InstallScript custom actions. They are not called once the project is rebuilt with InstallShield 12 and later. Note that these event handler functions still compile in InstallShield 12 and later; they are just not called.

If you use these event handler functions in your project, you need to manually schedule custom actions that call these functions. To learn how, see Creating and Scheduling InstallScript Custom Actions that Call InstallScript Event Handlers for Basic MSI Projects.

InstallShield InstallScript Scripting Engine Merge Module

Beginning with InstallShield 12, the InstallShield scripting engine merge module is no longer available for inclusion in Basic MSI projects. In InstallShield 11.5 and earlier, you could use this merge module to distribute the InstallScript engine for installations that did not include `Setup.exe`. InstallShield 12 and later automatically includes the InstallScript engine as part of `ISSetup.dll` in Basic MSI installations that have InstallScript custom actions, regardless of whether `Setup.exe` is used. Therefore, you do not need this merge module in InstallShield 2013 projects.

If you use InstallShield 2013 to try to build a release for a project that has this merge module, you may encounter a build error such as the following one:

```
ISDEV : error -4075: File not found. An error occurred merging Module
    'InstallShieldScriptingEngine.4F635B62_07BF_4779_B74E_D80C29D508E3:0' for Feature 'NewFeature1'.
```

To resolve this build error, remove this merge module from your project; you can do so by clearing its check box in the Redistributables view.

Changes to the InstallScript Engine Files

With InstallShield 12 and later, Basic MSI installations that include InstallScript custom actions no longer install InstallScript engine files to the following directory:

`<COMMONFILES>\InstallShield\Driver\<Version>\Intel 32`

For InstallShield 11.5 and earlier Basic MSI projects with InstallScript custom actions, several files were stored in the **Binary** table:

- `Setup.inx`
- `Isconfig.ini`
- `Isrt.dll`
- `ISScriptBridge.dll`
- `_isresXXXX.dll` (where XXXX is the language—one .dll was included for each language included in the installation)
- `StringxXXXX.txt` (where XXX is the language—one .txt was included for each language in the installation)

For InstallShield 12 and later, all of these files (except `ISScriptBridge.dll`, which is no longer used) are stored inside the `ISSetup.dll` file, and that is the only file that is stored in the **Binary** table.

The InstallScript engine file changes have not been known to cause any upgrade issues. These changes are reported for informational purposes.

Creating and Scheduling InstallScript Custom Actions that Call InstallScript Event Handlers for Basic MSI Projects

For InstallShield 12 and later, the predefined InstallScript event handler functions are no longer available in Basic MSI projects with InstallScript custom actions. In InstallShield 11.5 and earlier, the following InstallScript event handler functions were available for Basic MSI projects and InstallScript MSI object projects:

- OnBegin
- OnMoving
- OnMoved
- OnEnd

InstallShield no longer supports these event handler functions for Basic MSI projects that have InstallScript custom actions. They are not called once the project is rebuilt with InstallShield 2013. Note that these event handler functions still compile in InstallShield 2013; they are just not called.

Similarly, these same predefined InstallScript event handler functions are not supported in InstallScript MSI object projects that are converted to merge module projects automatically when they are opened in InstallShield 2013. The functions are not called once the converted merge module project is built in InstallShield 2013.

If you have these events in your Basic MSI or InstallScript MSI object project and you upgrade your project to InstallShield 2013, you need to manually schedule custom actions that call the event handler functions. The following instructions explain how to do so.

Task: ***To manually schedule InstallScript custom actions that call the predefined InstallScript event handler functions:***

1. Open the upgraded project in InstallShield 2013.
2. Make the appropriate changes to your InstallScript file:
    a. In the View List under **Behavior and Logic**, click **InstallScript**.
    b. Find the OnBegin, OnMoving, OnMoved, and OnEnd event handler functions in your script. You can quickly find a function by clicking the function name in the center pane of the view.
    c. Rename the functions to an alternate name to avoid conflicts with existing function prototypes automatically included in `ifx.h`. For example:
        - MyOnBegin
        - MyOnMoving
        - MyOnMoved

- MyOnEnd

d. Update the existing functions to take a single HWND parameter. For example:

```
function MyOnBegin(hMSI) begin end;
```

e. Add appropriate prototypes for these new functions:

```
export prototype MyOnBegin(HWND);
export prototype MyOnEnd(HWND);
export prototype MyOnMoved(HWND);
export prototype MyOnMoving(HWND);
```

3. Add InstallScript custom actions that call your renamed InstallScript event handler functions:

a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI projects) or **Custom Actions** (in merge module projects).

b. In the center pane, right-click the **Custom Actions** explorer and then click **New InstallScript**. InstallShield adds an InstallScript custom action.

c. Type a name for the custom action; use the same name that you used to rename the InstallScript functions. For example:

- MyOnBegin
- MyOnMoving
- MyOnMoved
- MyOnEnd

d. Select the new InstallScript custom action that you created.

e. Set the **Function Name** setting to the name of the InstallScript function.

f. For the **In-Script Execution** setting, specify the value that is indicated in the table below.

4. Schedule the InstallScript custom action for the appropriate part of the installation:

a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.

b. Right-click the action or dialog that you want your InstallScript custom action to follow and click **Insert**. The **Insert Action** dialog box opens, providing a list of all the actions and dialogs that are currently associated with your project.

c. Select the InstallScript custom action that you created. If appropriate, enter a condition in the **Condition** box for launching the InstallScript event.

d. Click **OK**.

To match the previous functionality as closely as possible, set the in-script execution in step 3f and schedule the InstallScript custom actions in step 4b as follows:

Table 2-10 • Scheduling the Custom Actions

Custom Action	In-Script Execution	Location in the Sequence
MyOnBegin	Immediate (default)	One of the first actions in the Installation User Interface sequence.
MyOnMoving	Deferred in system context	In the Installation Execution sequence, between the InstallInitialize and AllocateRegistrySpace actions.
MyOnMoved	Deferred in system context	In the Installation Execute sequence, between the ScheduleReboot and InstallFinalize actions.
MyOnEnd	Immediate (default)	The last event in the Installation Execute sequence after the InstallFinalize action. (In previous releases, OnEnd was called after all other events as a result of the installation completing.)

Note the following:

- Global variables and pointers are no longer maintained between individual InstallScript custom action calls. In addition, each InstallScript custom action initializes and uses its own individual **SUPPORTDIR**. Therefore, you cannot share information across individual calls using files in **SUPPORTDIR**. For more information, see Global Variables, Global Pointers, and SUPPORTDIR.
- Most Windows Installer properties are not available to deferred, commit, and rollback InstallScript custom actions. For more information, see Windows Installer Properties and Deferred, Commit, and Rollback InstallScript Custom Actions.

Upgrading InstallShield 11.5 or Earlier InstallScript MSI Projects

The following sections explain details about upgrading InstallScript MSI projects that were created in InstallShield 11.5 or earlier to InstallShield 2013.

Global Variables, Global Pointers, and SUPPORTDIR

With InstallShield 2013 and earlier versions, when an InstallScript MSI installation initializes, it loads the compiled InstallScript file, and it calls InstallScript events in this “main” loaded InstallScript file as necessary during the installation.

However, for InstallShield 12 and later, when a function within the InstallScript is called by the Windows Installer engine as an InstallScript custom action, the custom action behaves like an InstallScript custom action in a Basic MSI installation. That is, the function is executed in a completely separately loaded script instance; the script is loaded before the action is called and unloaded after the action completes. Thus, each InstallScript function that is called by the Windows Installer engine as an InstallScript custom action executes in its own session with complete

InstallScript engine loading and unloading. This behavior is different than with InstallShield 11.5 and earlier: the custom actions were called in the single main loaded script file instance that was loaded during initialization and unloaded at the end of the installation.

A major implication of this change in behavior is that InstallScript functions that are called as InstallScript custom actions no longer have access to global variables and pointers that are maintained by the main executing script file:

- If you need to interact with the main executing InstallScript file to perform tasks such as using or changing global variables or modifying objects that are maintained by the main executing script file (which includes updating the status bar or logging script operations for uninstallation), your function must be called from an InstallScript event—not as an InstallScript custom action. Functions that are called from InstallScript events are executed in the main InstallScript instance. (Exception: Some InstallScript error events such as OnFilesInUse are called as a result of an error message from the Windows Installer engine. The Windows Installer engine launches these InstallScript error events as InstallScript custom actions; thus, the limitations of InstallScript custom actions also apply to these InstallScript events.)
- If you need to store a value across multiple InstallScript custom action calls, you must use some external mechanism such as the registry, Windows Installer properties, or an external data file to store the information between calls. If you choose to use Windows Installer properties in deferred, commit, or rollback InstallScript custom actions, see the guidelines in Windows Installer Properties and Deferred, Commit, and Rollback InstallScript Custom Actions.
- If you need to use a COM object or some other global object across custom action calls, you must initialize the object for each individual custom action call in order for the object to be valid.

Another implication of this change is that each custom action initializes and uses its own individual **SUPPORTDIR**. Therefore, you cannot share information across individual calls using files in **SUPPORTDIR**, since each custom action invocation will have its own unique **SUPPORTDIR**. You can share information using **FOLDER_TEMP** or some other file location.

Note that **FOLDER_TEMP** may not be the same path for all of your InstallScript custom actions. If you have some InstallScript custom actions that run in system context and some that do not, they will have different temp paths if the package is running in an elevated state. The InstallScript custom actions run in the context of a different user, so storing files in the temp directory and retrieving it later may not work in certain scenarios.

Windows Installer Properties and Deferred, Commit, and Rollback InstallScript Custom Actions

Deferred, commit, and rollback InstallScript custom actions in InstallScript MSI installations have access to only some of the built-in Windows Installer properties: **CustomActionData**, **ProductCode**, and **UserSID**. If you want an InstallScript custom action to access any other properties (such as **SUPPORTDIR**) during deferred, commit, or rollback execution, you need to pass them as **CustomActionData**. You can do so by scheduling an immediate set-a-property type of custom action (or, for example, an immediate InstallScript custom action with the MsiSetProperty function) to set a property that matches the name of the custom action. The value of this property is then available in the **CustomActionData** property within the deferred custom action.

For example, if you want to access a property such as **SUPPORTDIR**, you could create an immediate custom action that is called MyCustomActionName and that sets the MyCustomActionName property to [SUPPORTDIR], and then substitute "SUPPORTDIR" with "CutomActionData" in the MsiGetProperty call:

```
MsiGetProperty(hMSI, "CustomActionData", szSupportDir, nLen)
```

For more details, see the following:

- Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions
- Obtaining Context Information for Deferred Execution Custom Actions

Note that failure to compensate for an unavailable Windows Installer property may cause unexpected results during installation. For example, since in a deferred action, `MsiGetProperty(hMSI, "INSTALLDIR", szInstallDir, nLen)` sets szInstallDir to the empty string, szInstallDir ^ szFile may refer to a file in the current directory instead of a file in [INSTALLDIR]. The current directory for a deferred custom action is often [SystemFolder].

Deferred, commit, and rollback InstallScript custom actions do not have access to the **ProductLanguage** property. If your installation includes multilanguage support and it also has a deferred, commit, or rollback InstallScript custom action that needs access to the language in which the end user is running the installation, the installation assumes that this language is the installation's default language. This could be a problem if an end user runs the installation in a language other than the default language. However, deferred, commit, and rollback custom actions do not typically display any user interface, so this would usually not be a problem.

Changes to the DoInstall Function

The **DoInstall** function now launches the setup executable file of the child installation instead of using the already-running installation engine to run the child installation. This change should be automatic; that is, it should not require any changes to existing InstallScript code. The child installation may take slightly longer to initialize than in previous versions because the installation executable file needs to initialize. For more information, see DoInstall.

Note that now calling **DoInstall** is similar to calling **LaunchAppAndWait**. When the installation is run from any removable media, such as a CD-ROM or a floppy disk, the `Setup.exe` file on Disk1 may not be available during the entire installation. (If `Setup.exe` becomes unavailable while it is running, the operating system sometimes displays a prompt to request that the end user insert the correct disk, and this may cause the installation to fail.) Therefore, to avoid this problem, the `Setup.exe` file is copied to a Temp folder, and the installation is relaunched from there. The original `Setup.exe` then terminates. However, when this happens, **DoInstall** (or **LaunchAppAndWait**, if it is called) behaves as if the installation has completed, and it does not wait.

Several workarounds for this issue exist. One method is to use the `/clone_wait` parameter when you are launching the child installation; as a result of this workaround, the launched installation keeps the original launched process running, and the parent installation then waits. Note, however, that this may cause problems if the original CD containing `Setup.exe` is not available throughout the entire installation. This includes multiple-CD installations, where the first CD is not available during some parts of the installation.

The only other way to avoid this problem is to add code that determines the ID of the child processes of the launched process and wait for the child process to complete.

Changes to Disk1 Files

InstallShield no longer places the following file on the Disk1 image of the built installation because it is no longer needed:

```
ISScript<version>.msi
```

In InstallShield 12 and later, the following file is placed on the Disk1 image of the built installation:

`ISSetup.dll`

The Disk1 file changes have not been known to cause any upgrade issues. These changes are reported for informational purposes.

Changes to the InstallScript Engine Files

With InstallShield 12 and later, InstallScript MSI installations no longer install InstallScript engine files to the following directory:

`<COMMONFILES>\InstallShield\Professional\Runtime\<MajorVersion>\<MinorVersion>\Intel32`

For InstallShield 11.5 and earlier InstallScript MSI projects, several files were stored in the **Binary** table:

- `Setup.inx`
- `Isconfig.ini`
- `Isrt.dll`
- `ISScriptBridge.dll`
- `_isresXXXX.dll` (where XXXX is the language—one .dll was included for each language included in the installation)
- `StringxXXXX.txt` (where XXX is the language—one .txt was included for each language in the installation)

For InstallShield 12 and later, all of these files (except `ISScriptBridge.dll`, which is no longer used) are stored inside the `ISSetup.dll` file, and that is the only file that is stored in the **Binary** table.

The InstallScript engine file changes have not been known to cause any upgrade issues. These changes are reported for informational purposes.

InstallScript-Related Custom Actions

Several built-in InstallScript-related custom actions were eliminated in InstallShield 12 for InstallScript MSI projects. If you upgrade an InstallScript MSI project from InstallShield 11.5 or earlier to InstallShield 2013, InstallShield removes these built-in custom actions from your project. Because these custom actions have been removed, some existing InstallScript event handler functions that were previously called by the custom actions are now called directly from InstallScript. For more information, see Creating and Scheduling InstallScript Custom Actions that Call InstallScript Event Handlers for InstallScript MSI Projects.

Changes for Deploying an InstallScript MSI Installation Without a Setup.exe File

To allow InstallScript MSI installations to be run without the `Setup.exe` file so that the packages can be deployed through technologies such as Active Directory, you may be able to use the instructions that are described in Knowledge Base article Q108166 - HOWTO: Deploying an MSI Wrapped with an InstallShield Script-Based Setup.exe. However, if you follow the procedure that is described in that article and users launch the .msi file directly, some of the InstallScript events (such as OnMoved) are never called. The reason that they are not called is that some of the InstallScript event handler functions that were previously called by built-in InstallScript-related custom actions are not called, since the InstallScript-related custom actions have been removed.

For more information, see Creating and Scheduling InstallScript Custom Actions that Call InstallScript Event Handlers for InstallScript MSI Projects.

Creating and Scheduling InstallScript Custom Actions that Call InstallScript Event Handlers for InstallScript MSI Projects

Several built-in InstallScript-related custom actions were eliminated in InstallShield 12 for InstallScript MSI projects. If you upgrade an InstallScript MSI project from InstallShield 11.5 or earlier to InstallShield 2013, InstallShield removes these built-in custom actions from your project. Because these custom actions have been removed, some existing InstallScript events that were previously called by the custom actions are now called directly from InstallScript. This article identifies the eliminated custom actions and explains how add custom actions that call these InstallScript events so that the scheduling is similar to the scheduling used in InstallShield 11.5 and earlier.

The eliminated custom actions also may affect your InstallScript MSI installation if you allow the installation to run without the `Setup.exe` file so that the packages can be deployed through technologies such as Active Directory. The procedure for implementing this is described in Knowledge Base article Q108166 - HOWTO: Deploying an MSI Wrapped with an InstallShield Script-Based Setup.exe. Note that if you follow the procedure that is described in that article and end users launch the .msi file directly, some of the InstallScript events are never called. The reason that they are not called is that some of the InstallScript event handler functions that were previously called by built-in InstallScript-related custom actions are not called, since the InstallScript-related custom actions have been removed. If you configure your installation according to the Q108166 article, you may also need to follow the instructions below to add custom actions that call the built-in InstallScript events.

The following built-in InstallScript-related custom actions were eliminated in InstallShield 12. They are removed from InstallScript MSI projects when they are upgraded from InstallShield 11.5 or earlier to InstallShield 2013:

- ISCleanupSuccess
- ISCleanUpSuspend
- ISCleanUpUserTerminate
- ISCleanupFatalExit
- ISMsiServerStartup
- ISRebootPatchHandler
- ISRollbackCleanup
- ISStartup
- OnCheckSilentInstall (For details about changes for this custom action, see OnCheckSilentInstall.)
- OnFeaturesInstalled
- OnFeaturesInstalling
- OnInstallFilesActionAfter
- OnInstallFilesActionBefore
- OnMoved
- OnMoving

Because these custom actions have been removed, some existing InstallScript event handlers that were previously called by the custom actions are now called directly from InstallScript. This includes the following InstallScript event handlers that are called immediately before file transfer:

- Feature functions for Installing and Uninstalling
- OnGeneratedMSIScript
- OnGeneratingMSIScript
- OnInstallFilesActionBefore
- OnMoving

It also includes the following InstallScript event handlers that are called immediately after file transfer:

- Feature functions for Installed and Uninstalled
- OnMoved
- OnInstallFilesActionAfter

These changes were made to make global variables and global pointers available for these InstallScript event handler functions. However, because previously the events were called from custom actions, the sequence of these events in relation to other custom actions that are called directly by Windows Installer has changed. Therefore, you may need to adjust your InstallScript code appropriately to account for these changes.

Except in the case of the feature event handlers, it is also possible to add custom actions that call these event handler functions so that the scheduling is similar to the scheduling used in InstallShield 11.5 and earlier. However, global variables and global pointers are not maintained between calls, as discussed in the Global Variables, Global Pointers, and SUPPORTDIR section.

Calling OnFeatureInstalling, OnFeatureUninstalling, OnFeatureInstalled, or OnFeatureUninstalled from a custom action during file transfer does not have any effect on the installation. This is because these functions are called from InstallScript just before file transfer, and they do not have any effect when they are called more than once.

Task: ***To manually schedule an InstallScript custom action that calls a predefined InstallScript event handler function:***

1. Open the upgraded project in InstallShield 2013.
2. Make the appropriate changes to your InstallScript file:
   a. In the View List under **Behavior and Logic**, click **InstallScript**.
   b. Find the event handler function in your script. You can quickly find a function by clicking the function name in the center pane of the view.
   c. Rename the function to an alternate name to avoid conflicts with existing function prototypes automatically included in ifx.h. For example:
      - MyOnGeneratingMSIScript
      - MyOnMoving
      - MyOnMoved
   d. Update the existing function to take a single HWND parameter. For example:

```
function MyOnGeneratingMSIScript(hMSI) begin end;
```

e. Add appropriate prototypes for this new function:

```
export prototype MyOnGeneratingMSIScript(HWND);
```

3. Add an InstallScript custom action that calls your renamed InstallScript event handler function:

   a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.

   b. In the center pane, right-click the **Custom Actions** explorer and then click **New InstallScript**. InstallShield adds an InstallScript custom action.

   c. Type a name for the custom action; use the same name that you used to rename the InstallScript function. For example:

      - MyOnGeneratingMSIScript
      - MyOnMoving
      - MyOnMoved

   d. Select the new InstallScript custom action that you created.

   e. Set the **Function Name** setting to the name of the InstallScript function.

   f. For the **In-Script Execution** setting, specify the value that is indicated in the table below.

4. Schedule the InstallScript custom action for the appropriate part of the installation:

   a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.

   b. Right-click the action or dialog that you want your InstallScript custom action to follow and click **Insert**. The **Insert Action** dialog box opens, providing a list of all the actions and dialogs that are currently associated with your project.

   c. Select the InstallScript custom action that you created. If appropriate, enter a condition in the **Condition** box for launching the InstallScript event.

   d. Click **OK**.

To match the previous functionality as closely as possible, set the in-script execution in step 3f and schedule the InstallScript custom actions in step 4b as follows:

Table 2-11 • Scheduling the Custom Actions

Custom Action	In-Script Execution	Location in the Sequence
OnGeneratingMSIScript	Immediate (default)	In the Installation Execute sequence between the RemoveExistingProducts and InstallInitialize actions
OnMoving	Deferred in system context	In the Installation Execute sequence between the InstallInitialize and AllocateRegistrySpace actions

Table 2-11 • Scheduling the Custom Actions (cont.)

Custom Action	In-Script Execution	Location in the Sequence
OnFeaturesInstalling, which calls all the feature Installing and Uninstalling events that are defined. Note: This will not have any effect, as explained above.	Deferred in system context	In the Installation Execute sequence between the InstallInitialize and AllocateRegistrySpace actions (after OnMoving)
OnInstallFilesActionBefore	Deferred in system context	In the Installation Execute sequence between the MoveFiles and InstallFiles actions
OnFeaturesInstalled, which calls all the feature Installed and Uninstalled events that are defined. Note: This will not have any effect, as explained above.	Deferred in system context	In the Installation Execute sequence between the ScheduleReboot and InstallFinalize actions (before OnMoved)
OnMoved	Deferred in system context	In the Installation Execute sequence between the ScheduleReboot and InstallFinalize actions (before OnGeneratedMSIScript)
OnInstallFilesActionAfter	Deferred in system context	In the Installation Execute sequence between the InstallFiles and PatchFiles actions
OnGeneratedMSIScript	Immediate (default)	In the Installation Execute sequence between the ScheduleReboot and InstallFinalize actions (after OnMoved)

Note the following:

- Global variables and pointers are no longer maintained between individual InstallScript custom action calls. In addition, each InstallScript custom action initializes and uses its own individual **SUPPORTDIR**. Therefore, you cannot share information across individual calls using files in **SUPPORTDIR**. For more information, see Global Variables, Global Pointers, and SUPPORTDIR.
- Most Windows Installer properties are not available to deferred, commit, and rollback InstallScript custom actions. For more information, see Windows Installer Properties and Deferred, Commit, and Rollback InstallScript Custom Actions.

OnCheckSilentInstall

In InstallShield 11.5 and earlier, the OnCheckSilentInstall custom action automatically called the OnMsiSilentInstall InstallScript event if the InstallScript MSI installation was being installed silently without using `Setup.exe` (for example, if the following command-line was used: `Msi.exe /i<Package> /qn`). In InstallShield 12 and later, this event is not called in InstallScript MSI installations. However, you can add a custom action that calls the OnMsiSilentInstall event handler function. To do so, use the aforementioned instructions, noting the following scheduling requirements in steps 3f and 4b:

Table 2-12 • Scheduling the OnCheckSilentInstall Custom Action

Custom Action	In-Script Execution	Location in the Sequence
OnCheckSilentInstall	Immediate (default)	As the first action in the Installation Execute sequence

Also, to require that the InstallScript event run only in the expected scenario, add the following code to the event:

```
cchValueBuf = MAX_PATH;
// Check whether Setup.exe is being used, if so just return.
MsiGetProperty(nHandle, "ISSETUPDRIVEN", szValueBuf, cchValueBuf);
if(StrLengthChars(szValueBuf)) then
   return ISERR_SUCCESS;
endif;
```

Upgrading InstallShield 11.5 or Earlier InstallScript Projects

The following sections explain details about upgrading InstallScript projects that were created in InstallShield 11.5 or earlier to InstallShield 2013.

Including InstallScript Objects in InstallScript Projects

InstallScript installations created in InstallShield 2013 cannot consume objects that were created with InstallShield 11.5 or earlier.

If you upgrade an InstallScript project to InstallShield 2013, all references to any InstallShield objects are updated to point to the InstallShield 2013 versions of the objects. If the new version object is not present on the system, an error indicating that the object could not be found is displayed at build time.

For instructions on acquiring the InstallShield 2013 objects, see Obtaining Updates for InstallShield.

Changes to the DoInstall Function

The **DoInstall** function now launches the setup executable file of the child installation instead of using the already-running installation engine to run the child installation. This change should be automatic; that is, it should not require any changes to existing InstallScript code. The child installation may take slightly longer to initialize than in previous versions because the installation executable file needs to initialize. For more information, see DoInstall.

Note that now calling **DoInstall** is similar to calling **LaunchAppAndWait**. When the installation is run from any removable media, such as a CD-ROM or a DVD, the `Setup.exe` file on Disk1 may not be available during the entire installation. (If `Setup.exe` becomes unavailable while it is running, the operating system sometimes displays a prompt to request that the end user insert the correct disk, and this may cause the installation to fail.) Therefore, to avoid this problem, the `Setup.exe` file is copied to a Temp folder, and the installation is relaunched from there. The original `Setup.exe` then terminates. However, when this happens, **DoInstall** (or **LaunchAppAndWait**, if it is called) behaves as if the installation has completed, and it does not wait.

Several workarounds for this issue exist. One method is to use the `/clone_wait` parameter when you are launching the child installation; as a result of this workaround, the launched installation keeps the original launched process running, and the parent installation then waits. Note, however, that this may cause problems if the original CD containing `Setup.exe` is not available throughout the entire installation. This includes multiple-CD installations, where the first CD is not available during some parts of the installation.

The only other way to avoid this problem is to add code that determines the ID of the child processes of the launched process and wait for the child process to complete.

Setup.exe Changes

The `/deleter` command-line parameter for `Setup.exe` is no longer needed. If you specify this parameter, the installation will not run. Note that InstallScript installations no longer clone the installation immediately when they are launched (unless, for example, the installation is running from the temp folder because the `/runfromtemp` parameter is specified), so `/deleter` is no longer needed.

The `/clone_nowait` command-line parameter for `Setup.exe` is no longer needed. If you specify this parameter, `Setup.exe` ignores it. Note that InstallScript installations no longer wait for the cloned installation to complete by default unless the `/clone_wait` parameter is specified. For more information on `/clone_wait`, see Setup.exe and Update.exe Command-Line Parameters.

Like InstallScript MSI and Basic MSI installations, InstallScript's `Setup.exe` file returns meaningful return codes. Therefore, if you are checking the return value of `Setup.exe`, in InstallShield 11.5 and earlier, it would always be 0; in InstallShield 12 and later, `Setup.exe` returns an appropriate return value. For details on the possible return codes, see Setup.exe Return Values and Run-Time Errors (InstallScript Projects).

Changes to Disk1 Files

InstallShield no longer places the following files on the Disk1 image of the built installation because they are no longer needed:

- `Engine32.cab`
- `Setup.ibt`

In InstallShield 12 and later, the following files are placed on the Disk1 image of the built installation:

- `ISSetup.dll`
- `_Setup.dll`

The Disk1 file changes have not been known to cause any upgrade issues. These changes are reported for informational purposes.

Changes to the InstallScript Engine Files

With InstallShield 12 and later, InstallScript installations no longer install InstallScript engine files to the following directory:

```
<COMMONFILES>\InstallShield\Professional\Runtime\<MajorVersion>\<MinorVersion>\Intel32
```

This change has not been known to cause any upgrade issues. This change is reported for informational purposes.

Upgrading InstallShield 11.5 or Earlier QuickPatch Projects that Have InstallScript Custom Actions

QuickPatch projects that are created in InstallShield 12 and later for InstallScript MSI projects can only patch media that were also created with InstallShield 12 and later. If you want to use InstallShield 2013 to create an update for an application whose previous InstallScript MSI installation was created with InstallShield 11.5 or earlier, you should create a create a minor-upgrade package instead of a QuickPatch, and use the Patch Design view to create a standard patch. Subsequent patches from this version can be created as QuickPatch projects.

Creating a QuickPatch for a Basic MSI project (with or without InstallScript custom actions) has not been known to cause any issues.

Creating Standard Patches for InstallShield 11.5 and Earlier InstallScript MSI Projects

InstallShield 12 and later does not support the creation of InstallScript MSI patches (using the Patch Design view) where both the latest and previous setups were created with InstallShield 11.5 or earlier. Creating a patch where the latest setup is created with InstallShield 12 or later and the previous setup was created with InstallShield 11.5 or earlier has not been known to cause any issues.

Upgrading InstallShield 11.5 or Earlier InstallScript MSI Object Projects or Projects that Contain This Type of Object

InstallShield 11.5 and earlier included the InstallScript MSI Object type of project. This project type is no longer available in InstallShield.

Upgrading InstallScript MSI Object Projects

If you open an InstallScript MSI Object project in InstallShield 2013, InstallShield will convert it to a merge module project.

Predefined InstallScript event handlers are not available in merge module projects that have InstallScript custom actions. Therefore, if you have an InstallShield 11.5 or earlier InstallScript MSI object project that uses InstallScript event handler functions, you must manually schedule custom actions that call these functions when the project is converted to a merge module project in InstallShield 2013. To learn how, see Creating and Scheduling InstallScript Custom Actions that Call InstallScript Event Handlers for Basic MSI Projects.

Note that InstallShield 2013, as well as earlier and later versions of InstallShield, can consume InstallShield 2013 merge modules that have InstallScript custom actions.

Upgrading Projects that Contain InstallScript MSI Objects

Building upgraded projects that contain already-built InstallScript MSI objects (.imm files) will fail; these objects cannot be consumed in InstallShield 2013. If you try to do so, a build error such as the following one occurs:

```
ISDEV : error -4075: File not found. An error occurred merging Module
    'InstallShieldMSIObjectName.4F635B62_07BF_4779_B74E_D80C29D508E3:0' for Feature 'NewFeature1'.
```

where “InstallShieldMSIObjectName.4F635B62_07BF_4779_B74E_D80C29D508E3:0” is information that is specific to the missing InstallScript MSI object. To resolve this build error, remove this InstallScript MSI object from your project; you can do so by clearing its check box in the Redistributables view.

Upgrading Projects Created with InstallShield Express

If you have an InstallShield project that was created using versions 2.1 through 5.x of InstallShield Express, that project is automatically upgraded to a Basic MSI project when you open it in InstallShield 2013. InstallShield 2013 converts InstallShield Express projects to a Basic MSI project because it is the comparable project type.

To learn how to convert your upgraded project to an InstallScript MSI project, see Converting a Basic MSI Project to an InstallScript MSI Project.

Task: ***To upgrade an Express project:***

Open the project in InstallShield. A dialog box opens to ask if you would like to upgrade your project.

- Click **Yes** to upgrade your project. Your project opens in InstallShield.
- Click **No** to leave the project unopened.

A backup copy of your original project is created and stored in the location specified in the dialog box.

InstallShield 2013 preserves the logic and dialog of the Setup Types view when it migrates Express 2.x projects (.iwz) to a Basic MSI project in InstallShield 2013. In earlier versions of Express, setup types were based on components. In Express 2.x projects (.iwz), components were replaced by features, and file groups are now mapped to destination folders instead of components.

When you upgrade an Express 2.x project (.iwz) to a Basic MSI project in InstallShield 2013, you can edit setup types by changing a feature’s Install Level property and dialog control events.

Note *• Billboard properties from Express projects will not be migrated since they are not supported in Basic MSI projects. You will receive warning 701 when the billboards property is specified in earlier Express projects.*

If you migrate an Express project with a language that is not installed with your current version of InstallShield, you will lose support for that language. Language support is available in the Premier edition of InstallShield.

Upgrading Projects Created with InstallShield Professional

You can upgrade projects that were created using InstallShield Professional. When you are using InstallShield 2013 and you open an installation project that was created with InstallShield Professional, your project is automatically upgraded. This enables you to immediately work with your project in InstallShield 2013.

Projects that were created using InstallShield Professional were composed of several .ini files referenced by an .ipr file. In InstallShield 2013, your installation project is one file—an .ism file.

First Step: Opening Your Installation Project

Task: ***To open an installation project created in InstallShield Professional:***

1. Open InstallShield.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the InstallShield Professional project file (.ipr) that you would like to open.
4. Click **Open**.

Your project opens in InstallShield, and the extension changes from .ipr to .ism. A backup of your original .ipr project is saved as *ProjectName*.ipr.bak in the same folder.

Next Steps: Modifying Your Installation Project

After you upgrade your installation project, you can use the views, menus, wizards, and other parts of the InstallShield user interface to modify your project settings.

You may also need to make changes to the upgraded project; see Migrating from InstallShield Professional 6.x and Migrating from InstallShield Professional 5.x.

Note • *In InstallShield 2013, support files are linked to a subfolder of the project folder; in InstallShield Professional, support files were physically copied to a subfolder of the project folder.*

Migrating from InstallShield Professional 6.x

When you upgrade an InstallShield Professional 6.x installation to InstallShield 2013, note the following:

- You can quickly convert a script that uses a program...endprogram block to an event-based script that calls all appropriate event handler functions except the user interface and file transfer functions. For details, see OnShowUI.
- The new simplified model for Internet installations eliminates many of the Ether object's methods and all of its properties and subobjects (while providing InstallScript enhancements that let you handle any Internet-

specific requirements). If your Internet installation used any of these properties and methods, see Replacing Obsolete Properties and Methods.

- Installations created in version 6.x contained a number of automatically created string entries; the installation used these string entries to get information. These string entries were redundant—they contained the same information contained in the Project Settings property sheet. InstallShield 2013 simplifies matters by allowing the information specified in the project settings to be used at runtime.

  Note that using this information is not required; you can continue using your existing string entries as before by simply leaving them intact in your project.

  If you want your migrated installation to automatically use the information from your project's Project Settings property sheet, delete the following string entries from your project:

  COMPANY_NAME

  PRODUCT_NAME

  PRODUCT_KEY

  PRODUCT_VERSION

  TITLE_CAPTIONBAR

  FOLDER_NAME

  TITLE_MAIN

  Also, update any script code that may be using one of these string entries to use the new corresponding system variable instead, as shown in the following table:

  Table 2-13 • String Entries and Corresponding New System Variables

String Entry	System Variable
COMPANY_NAME	IFX_COMPANY _NAME
PRODUCT_NAME	IFX_PRODUCT_NAME
PRODUCT_KEY	IFX_PRODUCT_KEY
PRODUCT_VERSION	IFX_PRODUCT_VERSION
TITLE_CAPTIONBAR	IFX_SETUP_TITLE
FOLDER_NAME	IFX_PRODUCT_NAME
TITLE_MAIN	IFX_SETUP_TITLE

  Note that you can remove only a subset of these string values if you want some values to be read from the string entries and some to be read from the project settings. If you retain any of these string values, be sure to modify them as required, rather than changing the unused project settings; in particular, when creating an update installation, be sure to update the value of the PRODUCT_VERSION string entry if it exists.

- If your installation uses an event-based script and you have overridden the default OnSetUpdateMode event handler code, a message such as the following may be displayed at run time: "The installed version of the application could not be determined. The setup will now terminate." If this error occurs, add code that manually sets IFX_INSTALLED_VERSION during the OnSetUpdateMode event. For sample code, see the default code that is included in the OnSetUpdateMode event of a new InstallShield 2013 InstallScript project.

- If your installation uses an event-based script and you have overridden the default OnFirstUIBefore event handler code, you must replace the following code (from the 6.x version of OnFirstUIBefore) in order to install files to the appropriate default location:

  ```
  TARGETDIR = PROGRAMFILES ^ @COMPANY_NAME ^ @PRODUCT_NAME;
  ```

  with the following code (from the new default OnFirstUIBefore code) to set TARGETDIR:

  ```
  /* Handles both end users with administrative or power user privileges and
  end users without such privileges. */
  if ( ALLUSERS ) then
      TARGETDIR = PROGRAMFILES ^ IFX_COMPANY_NAME ^ IFX_PRODUCT_NAME;
  else
      TARGETDIR = FOLDER_APPDATA ^ IFX_COMPANY_NAME ^ IFX_PRODUCT_NAME;
  endif;

  /* Handles both standard and multi-instance installations. */
  if( MAINT_OPTION = MAINT_OPTION_MULTI_INSTANCE && MULTI_INSTANCE_COUNT > 0) then
      nLoop = 1;
      svDir = TARGETDIR;
      while(ExistsDir(TARGETDIR) = EXISTS)
          NumToStr(szTargetDirAppendix,nLoop);
          TARGETDIR = svDir + szTargetDirAppendix;
          nLoop = nLoop + 1;
      endwhile;
  endif;
  ```

  If you are using a procedural script (one with a program…endprogram block), you need to update the code in which you set TARGETDIR in order to set the default target directory appropriately for users without administrator privileges.

- If your installation uses an event-based script and you have overridden the default OnMaintUIBefore event handler code, and during uninstallation you want to remove all features including those that are not listed in the media but only in the log file (see FeatureRemoveAllInMediaAndLog for more information), then you must replace the following code (from the 6.x version of OnMaintUIBefore):

  ```
  case REMOVEALL: ComponentRemoveAll();
  ```

  with the following code (from the new default OnMaintUIBefore code):

  ```
  MediaGetData( MEDIA, MEDIA_FIELD_MEDIA_FLAGS, nMediaFlags, szIgnore );

  case REMOVEALL:
      /* Properly handles updating. */
      if( nMediaFlags & MEDIA_FLAG_UPDATEMODE_SUPPORTED ) then
          FeatureRemoveAllInMediaAndLog();
      else
          FeatureRemoveAllInMedia();
      endif;
  ```

If you are using a procedural script that supports script-based uninstallation you need to update your call to ComponentRemoveAll appropriately.

- If your script calls RegDBSetItem to alter the registry entries that are created by MaintenanceStart (or DeinstallStart), and it makes those calls to RegDBSetItem in an event handler that is called before the OnMoved handler (for example, OnMoving or <feature name>_OnInstalled), you must move those calls to RegDBSetItem. MaintenanceStart is now called in the OnMoveData event handler's default code, whereas previously MaintenanceStart was called automatically immediately after the maintenance/uninstallation feature was installed and before any other features were installed.
- The InstallShield Professional 6.x default event handler code included the following lines in both OnFirstUIBefore and OnMaintUIBefore:

  ```
  SetStatusWindow( 0, "" );
  Enable( STATUSEX );
  StatusUpdate( ON, 100 );
  ```

  In InstallShield 2013, this code has been relocated to the default OnMoveData event handler code, so you have the following options:

  - If you have not customized this code, you do not need to do anything because the redundant calls will not cause a problem. You can safely remove this code from OnFirstUIBefore and OnMaintUIBefore if you want to avoid code duplication.
  - If you have customized this code and you want these customizations to apply regardless of what user interface (UI) event is called, you should remove the code from OnFirstUIBefore and OnMaintUIBefore, then override the OnMoveData event and place the customized code in place of the default code.
  - If you have customized the code and you want specific code depending on what UI event is called, you should override OnMoveData, comment out the default code, and continue to use your existing code. Note that in this case, if your installation supports updating you may also want to customize OnUpdateUIBefore.
- The 6.x default event handler code included the following commented-out code in the OnFirstUIBefore and OnMaintUIBefore events:

  ```
  // TO DO: if you want to enable background, window title, and caption bar title
  // SetTitle( @TITLE_MAIN, 24, WHITE );
  // SetTitle( @TITLE_CAPTIONBAR, 0, BACKGROUNDCAPTION );
  // Enable( FULLWINDOWMODE );
  // Enable( BACKGROUND );
  // SetColor( BACKGROUND, RGB( 0, 128, 128 ) );
  ```

  If you activated this code and would like to provide a consistent UI experience regardless of what UI event is called, you can remove this code from OnFirstUIBefore and OnMaintUIBefore and then override OnShowUI and customize the code appropriately.
- Many Windows API functions are declared in included header files (.h files) in InstallShield 2013. If any of these functions are also explicitly declared in your script code, do one of the following:
  - Remove your function declaration and use the declaration provided by InstallShield Professional.
  - If you are creating a script that needs to be compilable in both InstallShield 2013 and earlier versions, surround your declaration with code like the following:

```
#if _ISCRIPT_VER < 0x700
prototype ...
#endif
```

You may also need to update code that calls a Windows API function, if the declaration defined by InstallShield Professional is different than your declaration.

- In order that the end user interface flows smoothly, by default the installation initialization dialog box remains displayed until the script displays a dialog box. To close the installation initialization dialog box, call Disable(DIALOGCACHE) or any dialog box function.

Migrating from InstallShield Professional 5.x

Project • *This information applies to InstallScript Object projects.*

Script Changes

The basic structure of an InstallShield Professional 5.x script is supported in the InstallScript project type in InstallShield 2013. To compile a Professional 5.x script in InstallShield, you must first make the following changes:

Preprocessor Directives

- Include the following statement at the beginning of your script:

  ```
  #include "ifx.h"
  ```

- Remove any #define statements for SD_SINGLE_DIALOGS and its associated SD_<dialog name> constants.
- You may need to remove some #define statements that define Windows constants if those statements result in compiler errors. Many Windows constants are defined in `Ifx.h` (which is in the *`InstallShield Program Files Folder`*`\Script\Isrt\Include` subfolder) or its included files.

Built-In Functions

- Remove the following functions, which were supported in Professional 5.x but are not supported in InstallShield 2013. Some of these functions will compile, but they will not give the expected results. Where possible, supported alternatives are suggested.

Table 2-14 • Obsolete Professional 5.x Functions

Professional 5.x Function	Suggested Alternative
AppCommand	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)
AddProgItemEx	AddFolderIcon
CmdGetMsg	Windows API function GetMessage (call CmdGetHwndDlg to get the dialog handle)

Table 2-14 • Obsolete Professional 5.x Functions (cont.)

Professional 5.x Function	Suggested Alternative
CmdGetParam1	Windows API function GetMessage (call CmdGetHwndDlg to get the dialog handle)
CmdGetParam2	Windows API function GetMessage (call CmdGetHwndDlg to get the dialog handle)
CommitSharedFiles	The actions performed by this function in Professional 5.x are done automatically in InstallShield 2013.
CreateProgGroupEx	AddFolderIcon
DeleteGroup	DeleteProgramFolder
DeleteProgItem	DeleteFolderIcon
ExitProgMan	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)
GetGroupNameList	GetFolderNameList
GetItemNameList	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)
QueryProgGroup	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)
RegDBCreateKey	RegDBCreateKeyEx
RegDBCreateKeyValue	RegDBCreateKeyValueEx
RegDBGetKeyValue	RegDBGetKeyValueEx
RegDBSetKeyValue	RegDBSetKeyValueEx
ReloadProgGroup	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)
ReplaceProgItem	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)
ShowGroup	None. (Appropriate only for platforms using the Program Manager shell, which are no longer supported.)

- Call Disable(LOGGING) before any code that makes changes to the target system that you do not want logged for uninstallation, and call Enable(LOGGING) after that code. This is necessary because logging of changes for uninstallation is automatically enabled before any script code is executed.

  Note that this is different from Professional 5.x installations in which logging did not begin until DeInstallStart was called. If you have any installation actions that previously were not logged because they occurred before DeInstallStart, you will need to add an additional Disable(LOGGING) call before these installation actions to disable logging manually.

  If you want your installation to display a background, you must call Enable(BACKGROUND). In InstallShield 2013, the background is disabled by default, whereas in Professional 5.x it was enabled by default. (In event-based scripts, code for customizing and displaying a background exists in comment lines at the beginning of the default code for OnFirstUIBefore. To activate this code, remove the slash characters at the beginnings of the desired lines.)

  Note that some user-interface functions, such as PlaceBitmap, will not work properly (nor return a negative value to let you know they failed) if the installation background is not enabled.

- It is no longer necessary to call RegDBSetItem with the argument REGDB_UNINSTALL_NAME to set the value of [DisplayName] under the uninstallation key. This is now done when MaintenanceStart or DeinstallStart is called.

- Calling SetColor with STATUSBAR as its argument will not have any effect in InstallShield 2013; status bars are drawn using system colors.

- When you call StrGetTokens, if the first (or last) character of szString matches a character in szDelimiterSet, a null string ("") is not inserted in the list as the first (or last) element. Instead, the characters between the first and second (or last and next to last) delimiters are inserted in the list as the first (or last) element.

- When you call StrGetTokens, if a wildcard character is included in the filename specified by szSrcFile, the filename part of szTargetFile is not ignored as in previous versions of InstallShield Professional; instead, all of szTargetFile is treated as the target path to which each source file is copied to with its existing name. For example, CopyFile("C:*.*", "D:\\File.txt") copies files to a folder named File.txt on the D drive.

- WaitOnDialog now returns IDCANCEL when the end user selects the system menu's Close command or clicks the title bar's Close button from a custom dialog. In previous versions, DLG_CLOSE was returned in these cases.

- If you pass GetSystemInfo a first argument of DRIVE and a third argument that is a UNC path, the function correctly returns a negative value. Previously it returned zero, falsely indicating success, although due to operating system limitations UNC paths are not supported in that case.

- When you call ParsePath with its third argument set to PATH and its second argument set to a UNC path that includes only a server name without a trailing backslash (for example, "\\\\TheServer"), the function correctly sets the first argument equal to a double backslash ("\\\\"). In Professional 5.x, the function would set the first argument equal to a single backslash ("\\").

- The Professional 5.x Help Library listed specific numeric return values, other than 0 (zero) for success, for some functions. Some of these numeric values have changed for InstallShield 2013; a script used in InstallShield 2013 should compare a function's return value only to the constants that are currently listed in that function's help.

- In order for the end-user interface to flow smoothly, by default the installation initialization dialog remains displayed until the script displays a dialog. To close the installation initialization dialog, call Disable(DIALOGCACHE) or any dialog function.
- ComponentMoveData's second argument no longer returns useful data.
- Passing a pointer to a string as the fourth argument of SendMessage no longer gives the expected result. To pass string data to SendMessage, see the Additional Information section of the SendMessage topic.

Predefined Constants

- Remove the following constants, which were supported in Professional 5.x but are not supported in InstallShield 2013:

  COMPONENT_VALUE_ALWAYSOVERWRITE

  COMPONENT_VALUE_NEVEROVERWRITE

  COMPONENT_VALUE_NEWERDATE

  COMPONENT_VALUE_NEWERVERSION

  COMPONENT_VALUE_OLDERDATE

  COMPONENT_VALUE_OLDERVERSION

  COMPONENT_VALUE_SAMEORNEWDATE

  COMPONENT_VALUE_SAMEORNEWERVERSION

  COMPONENT_FIELD_DESTINATION

  COMPONENT_FIELD_OVERWRITE

- Remove statements that assign values to the following predefined variables (for example, TARGETDISK="C:\\";). Such statements will not compile in InstallShield 2013; these constants are now read-only.

  CMDLINE

  COMMONFILES

  ERRORFILENAME

  FOLDER_DESKTOP

  FOLDER_PROGRAMS

  FOLDER_STARTMENU

  FOLDER_STARTUP

  ISRES

  ISUSER

  ISVERSION

  MODE

PROGRAMFILES

SUPPORTDIR

TARGETDISK (The value of this variable is automatically updated when TARGETDIR is changed.)

UNINST

WINDIR

WINDISK

WINSYSDIR

WINSYSDISK

DLLs

- When you called a DLL function in Professional 5.x, all string arguments were passed by reference; in InstallShield 2013, you can pass a string argument by value. To specify the method for passing an argument, in the function prototype, precede the argument's data type with the BYREF or BYVAL keyword; for example, MyDLL.MyFunc(BYREF NUMBER, BYVAL STRING). The InstallShield 2013 compiler includes the following compiler warnings to encourage the use of the appropriate keyword.
  - If your script includes DLL function calls where neither BYREF nor BYVAL has been specified, you receive compiler warning W7507. To eliminate this warning, add the appropriate keyword to the function prototype.
  - If you specify a literal string for a string argument that is passed by reference, you receive compiler warning W7511. To eliminate this warning, add the BYVAL keyword to the function prototype.

  When you call a function in an external DLL, make sure the same calling convention is used in the script and the DLL. In Professional 5.x, the installation engine always used the stdcall convention but would sometimes overlook an inconsistent DLL convention. The InstallShield 2013 engine does not; it generates an error (exception 0x80040704) when the wrong calling convention is used.

  In your script, you can declare a calling convention, either cdecl or stdcall, when declaring a DLL function. For example:

  prototype cdecl MyDLL.MyFunction (INT, INT);

  If you do not explicitly declare a calling convention, InstallShield uses stdcall.
- In InstallShield 2013, InstallScript arrays are internally formatted as OLE Automation safe arrays, not native C or C++ arrays. To pass an InstallScript array to a DLL function that expects a C or C++ array, you must place the array data in the expected format by calling GetCArrayFromISArray.
- In InstallShield 2013, a string variable whose address is stored in a pointer variable cannot be changed by passing the pointer to a DLL function. To allow a DLL function to change the value of a string variable, pass the variable itself as an argument to the function, after declaring the data type of that argument specifying the BYREF operator.
- You no longer need to call the UseDLL function before calling a DLL that is located on Windows' DLL search path. The DLL search path is the following:

  1. The folder from which the application loaded.

2. The current folder.
3. The 32-bit Windows system folder.
4. The 16-bit Windows system folder.
5. The Windows folder.
6. The folders that are listed in the PATH environment variable.

Use this feature with caution; the values of the current folder and PATH environment variable on an end user's machine are not predictable.

Miscellaneous

- The undocumented array syntax ArrayName[nArrayIndex] is no longer supported. In InstallShield 2013, the syntax for all arrays is ArrayName(nArrayIndex).
- If you explicitly declare a return type for a script-defined function, you must specify the same return type in the function definition, after the keyword "function", or the script will not compile. (If you do not explicitly declare a return type, the return type is assumed to be NUMBER.) In previous versions of InstallShield Professional, return types were assumed to be NUMBER regardless of explicit specifications of other return types, so this issue did not arise.
- To place uninstall information under HKEY_CURRENT_USER, set the value of the ALLUSERS system variable to FALSE.
- To pass a literal character as an argument to a built-in or user-defined function, you must pass its numeric ASCII value.
- When processing the system variable CMDLINE, be aware that the following command line switches are no longer used by Setup.exe and so are included in CMDLINE: -SMS, -z, -c, -e, -q, -t, and -x. The -SMS switch is obsolete because now Setup.exe always stays in memory until the installation is complete. The -z switch is obsolete because now Setup.exe initializes correctly even on systems with more than 256 megabytes of memory.
- Remove Professional 5.x's ODBC Template code, which will not compile in InstallShield 2013. This is because the following function call is nested within the code:

```
ComponentGetData ( szMedia, szCompName,
   COMPONENT_FIELD_DESTINATION, nvData, svDest );
```

In InstallShield 2013 this function call does not compile because the Destination property is a file group property, not a component property.

Other Changes

- Pressing F3 no longer works to exit an installation.
- Setup.exe no longer supports the -f switch for using a renamed Setup.inx.
- InstallShield 2013 installations do not support including special billboards for low-resolution systems.
- If neither a source file nor the already-existing target file has a version number, and the source file's file group's Overwrite property is "Newer Version", "Same or Newer Version", or "Older Version", then the file on the target system is not overwritten. In Professional 5.x installations, the target file would be overwritten.

- InstallShield 2013 does not support displaying Windows 95-style dialogs.
- The Lang key in a silent installation's response (.iss) file's [Application] section no longer has any effect.
- In Professional 5.x installations, any registry key logged by the installer would be removed during uninstallation in any case. In InstallShield 2013, keys created by RegDBCreateKeyEx and non-shared keys in registry sets are removed only if the installer created the key, that is, the key did not exist when the installation was run.

Script Changes: Lexicon Conversion

Terminology Change

In InstallShield Professional, the functional building blocks of your installation from the end user's perspective were called components. With InstallShield 2013, these building blocks are called features.

Because of this change in terminology, a number of InstallScript function names have also changed. When you upgrade a project that you created using InstallShield Professional, some items in your script might undergo a lexicon change or be aliased.

- Function Names
- ComponentFileInfo (FeatureFileInfo) Flags
- ComponentSetData (FeatureSetData) and ComponentGetData (FeatureGetData) Flags

Function Names

Any InstallScript function name that referred to component now refers to feature. For example, ComponentDialog is now FeatureDialog. The parameters for these functions have not changed. Click a feature function to view the corresponding help topic.

Table 2-15 • Function Name Changes

Component Function	Feature Function
ComponentAddItem	FeatureAddItem
ComponentCompareSizeRequired	FeatureCompareSizeRequired
ComponentDialog	FeatureDialog
ComponentError	FeatureError
ComponentErrorInfo	FeatureErrorInfo
ComponentFileEnum	FeatureFileEnum
ComponentFileInfo	FeatureFileInfo
ComponentFilterLanguage	FeatureFilterLanguage

Table 2-15 • Function Name Changes (cont.)

Adding Project Assistant Dialog Support to Projects Upgraded from InstallShield Professional

When you upgrade an installation project from InstallShield Professional to InstallShield and the project contains a Setup.rul file that was created in InstallShield Professional, some questions may not be available on the Installation Interview page of the Project Assistant. This is because the Setup.rul file is missing the portions of the OnFirstUIBefore event code that InstallShield uses to key on script tags.

If you create a new InstallScript project and look at the OnFirstUIBefore event, you will see the following code that the Project Assistant requires in order to support dialog functions:

```
//{{IS_SCRIPT_TAG(FunctionName)
    InstallScript code...
//}}IS_SCRIPT_TAG(FunctionName)
```

Task: ***To add Project Assistant dialog support to your upgraded project:***

1. In the **InstallScript** view, open your Setup.rul file.
2. Comment out the OnFirstUIBefore event code.
3. In the event category list at the top of the InstallScript pane, select the OnFirstUIBefore event. InstallShield re-adds this event to your script.
4. Copy the pertinent dialog code to the commented-out code for the OnFirstUIBefore event.
5. Delete the OnFirstUIBefore event code that you added in step 3.
6. Remove the comments from the remaining OnFirstUIBefore event code.

Upgrading Projects Created with InstallShield—Windows Installer Edition

If you have an InstallShield project (.ism file) that was created using InstallShield—Windows Installer Edition, that project is automatically upgraded to a Basic MSI project when you open it in InstallShield. See Converting a Basic MSI Project to an InstallScript MSI Project to learn how to convert your upgraded project to an InstallScript MSI project.

Task: ***When you open the project, a dialog box appears to ask if you would like to upgrade your project.***

- *Click **Yes** to upgrade your project. Your project opens in the IDE.*
- *Click **No** to leave the project unopened.*

A backup copy of your original project is created and stored in the location specified in the dialog.

Upgrading a Setup from the Command Line

You can also upgrade your setup project when you build it from the command line. Use the -u parameter to upgrade your setup project from the command line without building it.

Troubleshooting Upgrade Errors

Any errors that result from the upgrade are displayed in the output panel at the bottom of the IDE. For information on these errors, see Upgrade Errors and Warnings (Upgrading from InstallShield—Windows Installer Edition).

Post-Upgrade Changes in the Property Manager

Properties in the Property Manager with an empty value (no value) are invalid for MSI. Because of this, ***DO_NOT_BUILD*** appears in place of the empty value for these properties. In this way, properties with empty values are preserved as placeholders after the upgrade, but are not built into the .msi package.

Upgrading from Other InstallShield Editions

InstallShield is available in three different editions: Premier, Professional, and Express.

Features that Are in Only the Premier Edition

Following is a list of some of the features that are available in the Premier edition but not the Professional, or Express editions:

- **Ability to create and build Suite/Advanced UI installations**—Create a bootstrap application with a contemporary, customizable user interface for multiple .msi packages, .msp packages, InstallScript packages, .exe packages, sideloading app packages (.appx), and Windows Installer transactions, as well as multiple InstallShield prerequisites. A Suite/Advanced UI installation packages together multiple separate installations as a single installation while providing a unified user interface; it uses a setup launcher (`Setup.exe`) to conditionally launch packages on target systems as needed.
- **Virtualization support**—The Microsoft App-V Assistant is included in the Virtualization Pack. Use this assistant to create customized virtual applications in the Microsoft App-V format. Virtualization enables you to isolate an application in its own environment so that it does not conflict with existing applications or modify the underlying operating system.
- **Application Virtualization Suitability Suites**—Several validation suites are available in InstallShield for helping you to determine how ready your products are for virtualization. The InstallShield virtualization internal consistency evaluators (ISVICEs) that are included in these suites let you check suitability for Microsoft App-V 4.x, Microsoft App-V 5.x, Microsoft Server App-V, VMware ThinApp, and Citrix XenApp. The validation suites can enable you to make more informed decisions about how you should build your product if you are considering offering your customers a virtualized version.
- **Support for DIM files**—The ability to create DIM projects is available in the Premier edition of InstallShield. This support is also available in the InstallShield Developer Installation Manifest Editor, a collaboration add-on. The ability to add DIM files to Basic MSI projects is available in the Premier edition of InstallShield.

A DIM project is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete portion of a product installation. Working with DIMs enables multiple team members to contribute to the development of the installation simultaneously. Each software developer or other team member can work on a separate DIM that the release engineer can reference in one or more Basic MSI projects.

- **Multilingual installations**—Create a single installation that displays end-user text in multiple languages and can handle conditional installation of language-specific files. Change dialogs and messages to any one of 34 additional languages using pre-translated strings.

  

  Project *• Note that support for two of those languages—Arabic (Saudi Arabia) and Hebrew—is available in only Basic MSI and Merge Module projects.*

- **Arabic (Saudi Arabia) and Hebrew language support**—InstallShield Premier Edition includes support for Arabic (Saudi Arabia) and Hebrew languages, which are written and read from right to left. All of the default end-user dialog strings are available in these languages.

  Since these languages are read from right to left, the Premier edition also includes support for mirroring Arabic and Hebrew dialogs; that is, InstallShield uses a right-to-left layout for Arabic and Hebrew dialogs. Thus, for example, buttons that are on the right side of dialogs in English and other left-to-right languages are moved to the left side of right-to-left-language dialogs.

- **Ability to specify commands that run before, during, and after builds**—InstallShield Premier Edition includes release settings that you can use to specify commands that you want to be run at various stages of the build process. You can schedule commands that run at the following build events: (a) before InstallShield starts building the release, (b) after InstallShield has built the .msi package and the .cab files (if your product's data files are to be stored in .cab files), but before the .msi package has been digitally signed and streamed into the `Setup.exe` file, and (c) after InstallShield has built and signed the release.

- **Extra licenses for InstallShield MSI tools**—InstallShield includes several tools: InstallShield MSI Diff, InstallShield MSI Query, InstallShield MSI Sleuth, and InstallShield MSI Grep. You can use these tools to troubleshoot issues with Windows Installer packages. InstallShield Premier Edition includes a separate installation and extra licenses that let you install just the InstallShield MSI tools, without InstallShield, on separate machines. For specific terms, see the End-User License Agreement for the InstallShield MSI tools.

- **Ability to import IIS data from existing IIS Web sites into a project**—InstallShield includes an IIS scanner (`IISscan.exe`), a command-line tool for scanning an existing IIS Web site and recording IIS data about the Web site. The IIS scanner creates an XML file that contains all of the settings for the Web site, its virtual directories, its applications, and its application pools. You can use the XML file to import the IIS data into the Internet Information Services view in InstallShield Premier Edition. Once you have imported the IIS data into a project, you can use the Internet Information Services view to make changes to the IIS settings as needed.

- **InstallShield Collaboration**—InstallShield Premier Edition includes licenses for InstallShield Collaboration for Visual Studio.

- **Network repository**—A network repository is a collection of installation elements that multiple installation authors can access and reuse in their projects as needed. A network repository fosters collaboration among installation authors; it is stored on a network.

- **InstallShield Best Practice Suite**—InstallShield includes a set of validators called the InstallShield Best Practice Suite. The InstallShield Best Practice (ISBP) validators in this suite alert you if your installation violates best-practice guidelines.
- **Additional Dialog Themes**—Several dialog themes are available only in the Premier edition of InstallShield.

Features that Are in Only the Premier and Professional Editions

Following is a list of some of the features that are available in the Premier and Professional editions but not the Express edition:

- **Ability to create and build Advanced UI installations**—Create a bootstrap application with a contemporary, customizable user interface for a single .msi package, .msp package, or InstallScript package, as well as multiple InstallShield prerequisites. An Advanced UI installation uses a setup launcher (`Setup.exe`) to conditionally launch packages on target systems as needed.

  (Note that the Suite/Advanced UI functionality in the Premier edition of InstallShield includes extended support for this functionality: The Suite/Advanced UI functionality enables you to package multiple .msi packages, .msp packages, InstallScript packages, .exe packages, sideloading app packages (.appx), and Windows Installer transactions, as well as multiple InstallShield prerequisites into a single installation with a contemporary, unified, customizable user interface.)
- **Standalone Build**—This tool, which is available with the Premier and Professional editions of InstallShield, enables you to install only the part of InstallShield that builds the installations, plus any redistributables that you want to include, on a build machine. Extra licenses of the Standalone Build are available for purchase.
- **Dialog Editor**—The Dialog Editor enables you to modify the layout of existing end-user dialogs or create new custom dialogs. Import and export dialogs to share them across projects. Construct different dialogs for each language supported in the project.
- **InstallShield MSI tools**—The Premier and Professional editions of InstallShield includes several tools: InstallShield MSI Diff, InstallShield MSI Query, InstallShield MSI Sleuth, and InstallShield MSI Grep. You can use these tools to troubleshoot issues with Windows Installer packages.
- **Automation interface**—Use script to add new files, add or delete features, change the product name and upgrade code, change release settings, change summary information stream items, change release flags, change any property, initiate the build process, and more.
- **Release customization**—Define which project segments to compress, which features to place on which disk, and which languages to include. Choose to filter application data based on language to support localization efforts.
- **Source code control integration**—Simplify the process of checking projects in and out of your source code control system and save space when differencing projects. The SCC integration in the Premier and Professional editions of InstallShield supports integration with various source code control systems.
- **Flexible localization support**—The Premier and Professional editions of InstallShield include a String Editor view, which gives you complete and centralized control over the localizable text strings that are displayed at run time during the installation process. You can use this view to edit the strings for everything from button text to feature descriptions. This view also includes support for exporting string entries (which you can have translated) and for importing translated string entries back into your project.

- **Project validation**—Use standard .cub files to validate installations and merge modules. Use the upgrade and patching validation to find out about potential upgrade problems and resolve them before you release your upgrades and patches.
- **Patch creation**—In addition to enabling you to create QuickPatch projects, the Premier and Professional editions let you create standard patches that contain updates to a previous version of your product.
- **Manage multiple product versions**—Build versions such as Evaluation, Debug, Standard, and Advanced—from a single project. Allow specific features, InstallShield prerequisites, and other elements to be chosen for inclusion in (or exclusion from) a release through user-defined flags.
- **Support for InstallScript**—The Premier and Professional editions of InstallShield include support for InstallScript, a simple but powerful programming language. You can add InstallScript custom actions to Windows Installer–based installations or create InstallScript projects, which use the InstallScript engine instead of the Windows Installer engine to control the entire installation.
- **Flexible custom action support**—The Premier and Professional editions of InstallShield include support for several custom action types that are not available in the Express edition. These extra custom action types enable you to do the following: set a property, set a directory, call a public method in a managed assembly, or display error message under certain conditions and abort the installation.
- **Flexible shortcut support**—The Premier and Professional editions of InstallShield include support for configuring various advanced settings for shortcuts that are not configurable in the Express edition. For example, the Premier and Professional editions let you prevent a shortcut in your project from being pinned to the taskbar or to the Start menu. They also let you prevent a shortcut on the Start menu from being highlighted as newly installed after end users install your product. These shortcut options are often used for tools or secondary products that are part of an installation.
- **Merge module authoring and editing**—Package pieces of a project for reuse across application installations. Reuse those you create or any of the ones included in the product. Edit and open modules for greater customization.
- **Project templates**—Create project templates that contain all of the default settings and design elements that you want to use as a starting point when you create an installation project or merge module project.
- **Multiple IIS Web sites**—The Express and Limited editions of InstallShield let you install only one Web site per installation. The Premier and Professional editions let you install more than one Web site per installation.
- **Support for IIS application pools and Web service extensions**—Install and manage IIS application pools and Web service extensions.
- **Advanced support for Windows services**—Although the Express edition of InstallShield includes some support for working with services, the Premier and Professional editions of InstallShield include additional flexibility for services. For example, the Premier and Professional editions enable you to start, stop, or delete a service during installation or uninstallation; the service can be part of your installation, or it can be already present on target systems. These editions also let you configure extended service customization options that were introduced in Windows Installer 5.
- **SQL support**—Connect to SQL servers, import database schema and data, associate SQL scripts with features, and more with SQL support.
- **Ability to modify text files or XML files**—Use the Text File Changes view or the XML File Changes view to configure files that you want to modify on the target system at run time.

- **Pure 64-bit support**—Windows Server Core supports disabling 32-bit Windows-on-Windows (WOW64) support. As this configuration becomes more popular, you may want to ensure that your 64-bit applications can install without any reliance on 32-bit functionality. To make this possible, the Premier and Professional editions of InstallShield include support for building pure 64-bit .msi packages; these can be run on 64-bit Windows-based systems that do not have WOW64 functionality.
- **InstallShield Prerequisite Editor**—Use this tool to create new InstallShield prerequisites and modify existing ones.
- **Custom icons for Setup.exe and Update.exe**—Specify a custom icon (.exe, .dll, or .ico file) that you want to use for `Setup.exe` and `Update.exe` files that you create at build time. The icon is displayed on the Properties dialog box for `Setup.exe`; this Properties dialog box opens when end users right-click the `Setup.exe` file and then click Properties. End users can also see the icon when they view your `Setup.exe` file in Windows Explorer.
- **Expiration dates for Setup.exe**—Set an expiration date, as well as an expiration message, for `Setup.exe`. If end users try to run `Setup.exe` on or after the date that you have specified in your project, the expiration message is displayed, and the installation exits.
- **Support for installation of multiple packages using transaction processing**—Windows Installer 4.5 and later include support for installing multiple packages using transaction processing. The Premier and Professional editions of InstallShield let you add chained .msi packages to an installation project. Your package, plus the added .msi packages, are chained together and processed as a single transaction. If one or more of the packages in the transaction cannot be installed successfully or if the end user cancels the installation, the Windows Installer initiates rollback for all packages to restore the system to its earlier state.
- **Ability to export and reuse various project elements**—Increase efficiency by moving pieces of an existing project (dialogs, custom actions, or features) to a merge module or another installation project.
- **Multiple-instance support**—Create an installation that lets end users install multiple instances of a product on the same machine and in the same user context.
- **Device driver support**—Device driver support in the Premier and Professional editions simplifies the process of installing device drivers from installation using the Driver Installation Frameworks for Applications (DIFxApp) from Microsoft.
- **Additional Dialog Themes**—Several dialog themes are available only in the Premier and Professional editions of InstallShield. The Limited and Express editions contain only two themes.
- **Conversion of Visual Studio merge module projects**—The Premier and Professional editions of InstallShield let you convert a Visual Studio merge module project to an InstallShield merge module project; this is necessary if you want to build a merge module for consumption in other projects.
- **COM+ application proxy support**—Manage COM+ application proxies during your installation. A COM+ application proxy consists of a subset of the attributes of the server application, and it enables remote access from a client machine to the machine where the application resides.

For additional details about the features that are included with each edition, contact InstallShield Sales, or visit http://www.installshield.com.

To learn about upgrading from one edition to another, see the appropriate topic:

- Upgrading from the Express Edition to the Professional or Premier Editions
- Upgrading from the Professional Edition to the Premier Edition

Upgrading from the Express Edition to the Professional or Premier Editions

If you have an Express project type that was created using the Express edition of InstallShield, that project is upgraded to a Basic MSI project when you open it in the Premier or Professional edition of InstallShield. This upgrade is done because Basic MSI is the comparable project type for the Express project type. QuickPatch projects created with the Express edition remain as QuickPatch projects in the Premier and Professional editions of InstallShield.

When you open any project created with the Express edition in the Premier or Professional edition, InstallShield converts the file from an .ise file to an .ism file. A backup of your .ise file is saved before the conversion takes place.

Billboard properties from Express edition projects will not be migrated since they are not supported in Basic MSI projects. You will receive warning 701 when the billboards property is specified in Express edition projects.

Task: ***To upgrade an Express edition project:***

Open the project in the Premier or Professional edition of InstallShield. A dialog box opens to ask if you would like to upgrade your project.

- Click **Yes** to upgrade your project. Your project opens in InstallShield.
- Click **No** to leave the project unopened.

A backup copy of your original project is created and stored in the location specified in the dialog box.

Upgrading from the Professional Edition to the Premier Edition

When you open a Professional edition project in the Premier edition, your project does not need to be converted. It opens seamlessly in the Premier edition, enabling you to take advantage of Premier edition–only features. To learn about the specific features, see Upgrading from Other InstallShield Editions.

For additional information about the features included with each edition, visit http://www.installshield.com.

Converting or Importing Visual Studio Projects into InstallShield Projects

Visual Studio includes limited support for creating setup and merge module projects. InstallShield lets you convert or import these types of Visual Studio projects into InstallShield projects so that you can use the advanced features and functionality in InstallShield to create installations and merge modules.

With InstallShield, you can do the following:

- Import a Visual Studio setup project (.vdproj) into an InstallShield Basic MSI or Merge Module project (.ism), or import a Visual Studio merge module project (.vdproj) into an InstallShield Basic MSI or Merge Module project (.ism). These tasks enable you to create InstallShield installation and merge module projects that contain the same data and settings that were in your Visual Studio project. During the import process, you can choose to import or ignore certain settings in the Visual Studio project.
- Convert a Visual Studio setup project to an InstallShield Basic MSI project, or convert a Visual Studio merge module project to an InstallShield merge module project. Converting a Visual Studio merge module project to an InstallShield Merge Module project is necessary if you want to build a merge module for consumption in other projects.

Note • *If your Visual Studio project contains one or more project outputs, you can use InstallShield to import that Visual Studio project into an InstallShield project; however, InstallShield cannot convert that Visual Studio project into an InstallShield project.*

The following versions of Visual Studio are supported:

- Visual Studio 2010
- Visual Studio 2008
- Visual Studio 2005
- Visual Studio .NET 2003
- Visual Studio .NET

Benefits of Using an InstallShield Project Instead of a Visual Studio Project

If you convert or import your Visual Studio project into an InstallShield project, you can use the features in InstallShield to fully customize your project.

Following is a list of a few of the tasks that you can perform in InstallShield projects but not in Visual Studio projects:

- Modify the layout of dialogs through a visual Dialog Editor.
- Manage components and features.
- Store custom actions in the **Binary** table of the .msi or .msm database. (With Visual Studio, all custom actions must be installed with the product.)
- Manage SQL-related tasks, such as connecting to a SQL server and running SQL scripts.
- Manage IIS Web sites, applications, virtual directories, application pools, and Web service extensions.
- Add billboards that are displayed during file transfer.
- Modify XML files or other text files on the target system at run time.
- Create shortcuts to pre-existing files on a target system.
- Manage COM+ applications.

Import Process

InstallShield lets you import a Visual Studio setup or merge module project into an InstallShield Basic MSI or Merge Module project.

Note • *If the Visual Studio setup or merge module project that you want to import into an InstallShield project contains one or more project outputs, the InstallShield project must be in the same Visual Studio solution that contains the Visual Studio setup or merge module project and all of its project dependencies.*

In order to import a Visual Studio project that contains project outputs, you must be using InstallShield from within Visual Studio. If your InstallShield project is open in InstallShield, but not from within Visual Studio, and you try to import a Visual Studio project that contains project outputs into the InstallShield project, an error occurs.

Task: ***To import a Visual Studio project (.vdproj) into an InstallShield project (.ism):***

1. In InstallShield, create or open the Basic MSI or Merge Module project.
2. On the **Project** menu, click the **Visual Studio Deployment Project Wizard** button.
3. Complete the panels of the Visual Studio Deployment Project Wizard.

InstallShield imports the Visual Studio project into your open InstallShield project based on the settings that you configured in the wizard. As InstallShield imports the project, it displays the status of the project import in the Output window. The Output window shows each step of the conversion process, and it lists any conversion errors and warnings.

Conversion Process

If you use InstallShield to convert a Visual Studio setup project, InstallShield creates an InstallShield Basic MSI project (.ism).

If you use InstallShield to convert a Visual Studio merge module project, InstallShield creates an InstallShield Merge Module project (.ism).

Task: ***To convert a Visual Studio project (.vdproj) to an InstallShield project (.ism):***

1. Open InstallShield.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. In the **Files of type** box, select **Visual Studio Setup Projects (*.vdproj)**.
4. Browse to the location of the Visual Studio project that you want to open, and select the project file.
5. Click the **Open** button.

InstallShield creates an InstallShield project based on the settings in the Visual Studio project. InstallShield stores the .ism file in the same folder as the .vdproj file. As InstallShield creates the .ism file, it displays the status of the project conversion in the Output window. The Output window shows each step of the conversion process, and it lists any conversion errors and warnings.

Once the conversion process finishes successfully, the new InstallShield project is displayed in InstallShield.

Post-Import and Post-Conversion Tasks

Prerequisite Tasks

Visual Studio lets you add one or more predefined prerequisites to one or more configurations in a Visual Studio setup project. The import and conversion processes in InstallShield attempt to convert all of the prerequisites in all of the configurations to equivalent InstallShield prerequisites. If InstallShield does not include a corresponding InstallShield prerequisite, warning -9071 occurs, alerting you that the prerequisite could not be converted. To resolve this warning, consider creating an InstallShield prerequisite that installs the required redistributable, and add that InstallShield prerequisite to your project. For more information, see Defining InstallShield Prerequisites and Working with InstallShield Prerequisites that Are Included in Installation Projects.

User-Interface Tasks

The import and conversion processes do not incorporate the dialogs from a Visual Studio project into the InstallShield project. Once you have imported or converted your project, you can use the Dialogs view in InstallShield to configure settings for the dialogs in your project.

Language Tasks

If you imported a Visual Studio project into an InstallShield project and the following conditions exist, InstallShield replaces the existing string entry values in your project with default string entry values for the language of your Visual Studio project:

- You indicate in the Visual Studio Deployment Project Wizard that you would like to import the language of the Visual Studio project.
- The language of your Visual Studio project does not match the default language in your InstallShield project. (In Visual Studio, the Localization property indicates the project's language. In InstallShield, the Default Language setting in the String Editor view indicates the project's default language.)
- InstallShield has support for the language that is used in your Visual Studio project. (If you are using the Professional edition of InstallShield, you may not have support for the language that is used in your Visual Studio project.)

For example, if you indicate in the Visual Studio Deployment Project Wizard that you would like to import the language of the Visual Studio project, if the language of your InstallShield project is Spanish, if the language of your Visual Studio project is German, and if you are using the Premier edition of InstallShield, InstallShield replaces the Spanish run-time strings in your project with the default German translations. Thus, if you edit a string entry value by revising a setting such as the Publisher setting in the General Information view, and then you indicate in the wizard that you want to import the language of a Visual Studio project, InstallShield overwrites the value of the Publisher setting—as well as values for other settings—with the default German string entry values.

Therefore, if you change the project language while importing your Visual Studio project, review the settings in the General Information view and the String Editor view, and modify the string entry values if appropriate.

.NET Installer Class Tasks

If your Visual Studio project includes a .NET installer class custom action, InstallShield configures the .NET installer class information for the .NET assembly's component during the conversion process, instead of creating a .NET installer class custom action. InstallShield does not include support for the Condition property of a .NET installer class custom action in Visual Studio. Therefore, if your Visual Studio project contains a .NET installer class custom action that has a condition, you may want to use the Components view in InstallShield to create a condition for the component that contains the .NET assembly after you have converted your project.

Additional Tasks

You can also use the other views in InstallShield to make additional changes to your project.

Note • *Visual Studio lets you specify a directory path that contains multiple formatted properties, such as [ProgramFilesFolder][Manufacturer]\[ProductName], for the application folder. Visual Studio projects use a directory custom action to resolve the path at run time. However, InstallShield does not support this type of directory path. Therefore, InstallShield resolves the path during the conversion process and uses the* ***INSTALLDIR*** *property for the path.*

Obtaining Updates for InstallShield

If you have an Internet connection, you can use the Check for Updates feature in InstallShield to obtain the latest InstallShield prerequisites, merge modules, and objects; service packs; patches; and other updates for the version of InstallShield that you are using.

Task: ***To check for updates:***

On the **Tools** menu, click **Check for Updates**.

InstallShield launches FlexNet Connect, which checks for updates. When an update is available, you can do the following:

- View the updates for your system.
- View descriptions about the updates.
- Download and install the updates that you select.

Run-Time Language Support in InstallShield

Important • *Language support varies, depending on the edition of InstallShield that you are using, the project type, and the language of the InstallShield interface (English or Japanese).*

Note that support for Arabic (Saudi Arabia) and Hebrew is available only in Basic MSI, Merge Module, and Suite/Advanced UI projects in the Premier edition.

The InstallShield Premier edition includes default run-time strings in 35 supported languages. When you add a supported language to a project, that language is made available in various language-related settings throughout InstallShield. In addition, InstallShield adds translated string entries for that language to your project. The string entries are for the default dialogs, messages, and other end-user interface elements. For a list of the supported languages, see Language Identifiers.

The InstallShield Premier edition also lets you add unsupported languages, beyond the built-in 35 languages, to Basic MSI, InstallScript, InstallScript MSI, and Suite/Advanced UI projects through the New Language Wizard. An unsupported language is one in which none of the default run-time strings are translated. When you add an unsupported language to a project, that language is made available in various language-related settings throughout InstallShield. In addition, InstallShield uses the strings from your project's default language as placeholders for the strings in that newly added unsupported language; you can use the String Editor view to provide translated strings for the unsupported languages.

The English version of the InstallShield Professional edition lets you select one of 33 languages (any of the supported languages, except for Arabic or Hebrew) to use as the run-time language for all of the projects that you create. The English version of the InstallShield Professional edition includes default run-time strings for the one language that you have selected.

The Japanese version of the InstallShield Professional edition lets you select English plus one additional supported language; that is, if you are using the Japanese version of the InstallShield Professional edition, you can create projects with English run-time strings as well as projects with run-time strings from one other supported language. The Japanese version of the InstallShield Professional edition includes default run-time strings in English, plus the one additional supported language that you have selected.

If you want to modify the default run-time strings or you are adding custom dialogs, messages, and other end-user interface elements to your project, you can enter the custom run-time strings directly in your InstallShield project. As an alternative, you can export a language's string entries to a file, translate the string values in the file, and then import the translated file into your project. This support is available in all editions of InstallShield.

To learn more about language support in InstallShield, see the following sections of the documentation:

- Localizing the End-User Interface
- Creating Multilingual Installations
- Code Page Requirements for Language Support
- Settings for Languages

Code Page Requirements for Language Support

If you plan on creating releases that include run-time strings in a language that includes double-byte characters (for example, Japanese, Greek, or Korean), determine whether you need to install any code pages on your build machine.

Unicode encoding is used to display run-time strings throughout InstallShield. With Unicode encoding, double-byte characters are displayed correctly within InstallShield, even if InstallShield is on a system that does not have a project's target languages installed. In addition, you can build releases on a system that does not have the release's target languages.

However, if you use ANSI encoding for run-time strings (for example, if you export the string entries from a project as an ANSI text file and then import the translated ANSI text file into your project), you need to install the code pages for those languages on your build machine. The code pages allow your system to accurately represent the characters of those languages. If your build machine does not have the code pages installed, InstallShield reports a build error when you try to build a release, and the installation does not display double-byte characters properly at run time.

Tip • *It is recommended that you use Unicode encoding instead of ANSI encoding when you are exporting string entries to a file for translation.*

Installing Supplemental Language Support on a Build Machine

The following instructions explain how to install code pages on a build machine that has Windows XP. This may be necessary if you want to build releases that contain Chinese, Japanese, and Korean languages. On later operating systems, the code pages are typically installed by default.

Task: ***To install code pages on a build machine that has Windows XP:***

1. In the **Control Panel**, launch **Regional and Language Options**.
2. Click the **Languages** tab.
3. Click the **Details** button.
4. Click the **Add** button.
5. Select the language for which you want to add a code page.
6. Click **OK**.

The following instructions explain how to install files for right-to-left languages such as Arabic and Hebrew on a build machine that has Windows XP. On later operating systems, these files are typically installed by default. If these files are not installed, the String Editor view may display the strings left to right instead of right to left.

Task: ***To install right-to-left language support on a build machine that has Windows XP:***

1. In the **Control Panel**, launch **Regional and Language Options**.
2. Click the **Languages** tab.
3. In the **Supplemental language support** area, select the **Install files for complex script and right-to-left languages** check box.

4. Click the **Add** button.
5. Select the language for which you want to add a code page.
6. Click **OK**.
7.

Supported Application Programming Languages

InstallShield allows you to create installations for applications created in *any* programming language—including applications created with Java, Pascal, C++, Visual Basic, Delphi, C# .NET, Visual Basic .NET, ASP .NET, and Cobol.

Even if you created your application using a language other than those listed above, you can use InstallShield to create an installation for your application. In addition—if you are not deploying an application, but want to package files or a database—you can use InstallShield to assist with those tasks.

3

Tutorials

This section contains tutorials that walk you through the process of creating an installation using InstallShield.

Table 3-1 • Available Tutorials

Tutorial	Description
InstallScript Project Tutorial	Leads you step-by-step through the process of creating an InstallScript installation project. The tutorial also provides information about the various tasks associated with installation projects and introduces you to the views in the InstallShield interface in which you can accomplish these tasks.
Basic MSI Project Tutorial	Teaches you how to a Basic MSI installation project. The tutorial also provides information about the various tasks associated with installation projects and introduces you to the views in the InstallShield interface in which you can accomplish these tasks.
Globalization Tutorial	Shows you how to add languages and language-specific components to your project. Additionally, it shows you how to conditionally install components based on the target system's language.  ***Note*** • *The Premier edition of InstallShield must be installed on your development system in order to successfully complete this tutorial.*

InstallScript Project Tutorial

This tutorial guides you through the process of creating, building, running, and enhancing an InstallScript installation using InstallShield.

The tutorial is divided into several steps. After the first step—Step 1: Creating, Building, and Testing Projects—the other steps can be performed independently, and in any order, so you can focus on the information relevant to your work.

In this tutorial, you will learn how to handle many of the tasks that an installation needs to address, including:

- Installing files
- Setting up shortcuts and registry data
- Conditionally installing data
- Changing the installation's user interface
- Building release images
- Testing the installation

Throughout the tutorial are links to related topics in the Help Library.

Step 1: Creating, Building, and Testing Projects

This step demonstrates how to create an installation project, build a release image, and test the installation. After completing this step, you will know how to:

- Use the Project Assistant to create a new project.
- Specify global properties of your installation project.
- Define setup types, features, components, and file links.
- Build a release image for duplication and distribution.
- Run your installation from the InstallShield user interface.

An installation is made up of three levels:

Table 3-1 • Levels Within an Installation

Level	Description
Components	A component is the smallest separately installable piece of your product from the developer's viewpoint. A component specifies files, shortcuts, registry data, and other data to be installed on the target system. The end user never directly interacts with components. A component can be placed in more than one feature, and the component's data will be installed if the user selects at least one feature associated with the component.
Features	A feature is the smallest separately installable piece of your product from the user's viewpoint. If the user selects the Custom setup type, a dialog is displayed in which the user can choose which features to install. Each feature contains components.
Setup Types	Setup types are predefined collections of features. By default, an installation offers Complete and Custom setup types, and the end user selects which setup type to install in the SetupType dialog.

The installation that you will create in this tutorial installs and configures an application called *Tutorial App*. The source files for Tutorial App are located in one of the Samples subfolders within the InstallShield Program Files folder. The default installation location is:

```
C:\Program Files\InstallShield\2013\Samples\WindowsInstaller\Tutorial Project
```

Creating a Project with the Project Assistant

After launching InstallShield, create a new InstallScript project by doing the following:

1. Open the **New Project** dialog box by doing one of the following:
   - Click the **Create a new project** link in the **Start Page's Project Tasks** section (on the left of the page).
   - On the **File** menu, click **New**.
   - Click the toolbar's **New Project** button
2. In the **New Project** dialog box, click the **InstallScript** tab.
3. In the **InstallScript tab's** list view, select the **InstallScript Project** icon.
4. In the **Project Name** edit box, type the project name *Tutorial*.
5. Click **OK**.

There are many other ways to create a project, such as updating a project created using InstallShield Professional. For more information, see Creating New Projects.

InstallShield creates a project file called *ProjectName*.ism, in this case Tutorial.ism. The project file stores all the settings you make in the InstallShield user interface. To move a project to another machine, copy the .ism file (and the installation source files) to the other system.

Tip • *You can change the directory where new project files are created by choosing Options from the Tools menu, selecting the File Locations tab, and entering the new location in the "Project Location" field.*

Your new project is opened to its Project Assistant tab. To begin using the Project Assistant, click the Next button in the lower right corner.

Tip • *You can do the Project Assistant's steps in any order, and switch at any time (by clicking the appropriate tab) between the Project Assistant and the Installation Designer, in which you can add more complex and powerful elements to your installation project.*

Specifying Application Information

The Application Information page lets you specify general information about the application that you are installing.

Task: ***For this tutorial, do the following:***

1. In the **Specify your company name** edit box, type the name *Tutorial Co*.
2. In the **Specify your application name** edit box, type the name *Tutorial App*.
3. Leave the other fields unchanged.

The value you enter in the application name field is used in dialogs displayed to the end user, as the display name for your application in Add or Remove Programs in the Control Panel. The application name and company name you enter determine the default location of application shortcuts on the Windows Start menu, and the default value for the *TARGETDIR* system variable, which specifies the default destination for components' files.

Customizing the Installation Architecture

The Installation Architecture page lets you specify the features you want to be displayed by your installation. A feature is the smallest separately installable piece of your product from the end user's standpoint. Individual features are visible to end users when they select a Custom setup type.

Note • *Features can contain subfeatures, subsubfeatures, and so forth, to as many levels as your installation requires.*

Task: ***For this tutorial, do the following:***

1. For the **Do you want to customize your Installation Architecture?** question, select **Yes**.
2. Select the existing DefaultFeature feature and rename it ProgramFiles.
3. Create a new feature called HelpFiles. To do so, click **Installation Architecture** and then click the **New** button.

Adding Files to Your Project

The Application Files page lets you specify the files you want to link with each of your features.

First, select from the list of features the feature in which you want to insert files. To add file links, click the Add Files button, and then browse for the file or files you want to include in the selected feature.

For this tutorial, add the Tutorial.exe file to the ProgramFiles feature by doing the following:

1. Select **ProgramFiles** from the list of features.
2. In the tree control (with top node Destination Computer), select **Application Target Folder**.
3. Click **Add Files**.
4. Browse for Tutorial.exe, which is located in your source directory.
5. When the "The file you have added ... may have dependencies" message appears, click **No**; Tutorial.exe has no dependencies.

Creating Shortcuts

The Application Shortcuts page lets you specify shortcuts for your application's files on the target system's desktop or Start menu. By default, this page displays a shortcut for each executable that you have included in your installation project; you can delete these, and add shortcuts to other files that you have included in your installation project.

For this tutorial, leave this page's default specifications unchanged: a shortcut to Tutorial.exe on the Start menu.

Configuring Registry Data

The Application Registry page lets you specify any registry entries that your application requires.

Note • *An InstallScript project includes script code that by default creates the application uninstallation key (Software\Microsoft\Windows\CurrentVersion\Uninstall\<GUID> under the HKEY_LOCAL_MACHINE or HKEY_CURRENT_USER root key as appropriate) and its values and data; you do not need to specify these registry entries.*

For this tutorial, do not specify any registry entries in this page. Registry entries are covered in

Step 2, Shortcuts and Registry Data, of the tutorial.

Selecting Dialogs with the Installation Interview

The Installation Interview page lets you specify the dialogs that you want the end user to see when your installation runs. Based on your answers to the questions on this page, the Project Assistant adds the corresponding dialog function to your installation script. Script changes related to dialogs are covered in Step 6 of the tutorial.

Task: ***For this tutorial, do the following:***

1. Select the **No** option button under the text "Do you want to display a License Agreement Dialog?"
2. Leave the other option buttons set to **Yes**.

Choosing a Language for Your Installation

The Installation Localization page lets you specify the languages that your installation supports. It also lets you specify string values and associated identifiers, which you can use in your end user interface to make your installation more easily localizable in other languages.

Edition • *Multilingual language support is available in the Premier edition of InstallShield.*

Task: ***For this tutorial, change the display name of the HelpFiles feature by doing the following:***

1. In the list box, select **Feature String Data**. The table on the right displays all of the feature string entries.
2. In the **Value** column, click **HelpFiles** (the value associated with the identifier IDS_FEATURE_DISPLAY_NAME2), and change it to `Help Files`; that is, add a space.

Building Your Installation

The Build Installation page lets you specify what type of distribution you want to build (and, optionally, the location to copy the distribution files to).

Task: ***For this tutorial, do the following:***

1. Select the **CD-ROM** option.
2. Click **Build Installations**.

The output window opens with the Build tab uppermost and displays information about the progress of the build. The build is finished when the Build tab displays the line "Build finished at *date and time*".

Running Your Installation

To run your installation from within InstallShield, click the Run toolbar button or press CTRL+F5.

The installation displays the dialogs that you specified in the Installation Interview Page of the Project Assistant. The values you entered in the Project Assistant are displayed to the end user in the appropriate dialogs. For example, at run time, the default value of **TARGETDIR** that you specified in the Project Assistant appears in the Choose Destination Location dialog. If the end user browses for a different destination directory, **TARGETDIR** stores the new value.

After the installation is complete, you can browse for the directory and find the files installed by your setup program. If the installation was successful, you will see the tutorial files installed.

Maintenance Mode

When a user runs an installation a second (or later) time for a product installed on their system, the installation runs in *maintenance mode*. Maintenance mode allows the user to modify feature selections from the first-time installation, repair the features already installed, or remove the entire program.

Uninstalling the Program

To uninstall the program, click the Run button (or press CTRL+F5), and select Remove from the Setup Maintenance dialog. This is the same behavior a user sees when selecting your application in Add or Remove Programs.

Now that you have created a basic installation project, click the Installation Designer tab (near the top of the window) to expand and fine-tune your installation as illustrated in the next step of the tutorial.

Working with the InstallShield Interface

Now that you have created a basic installation project, click the Installation Designer tab (near the top of the window) to expand and fine-tune your project in the InstallShield user interface. The InstallShield user interface is arranged in functional categories that help you add or edit information in your project. This and later steps of the tutorial explore several of the different InstallShield views.

After completing this step, you will know how to:

- Set display properties for your program features.
- Define your program's setup types.
- Create components and add file links.

Setting Feature Properties

First, you will set additional properties for the features you created in the Project Assistant, such as the feature display name and description. To edit the feature properties, go to the Features view in the IDE.

Task: ***To set feature properties:***

1. On the **Go** menu, point to **Organization** and click **Features**.
2. In the **Features** explorer, click the DefaultFeature feature and set its **Description** property to `This feature contains the Tutorial App program files`.
3. Select the New Feature feature and set its **Description** property to `This feature contains the Tutorial App help files`. As you enter each description, InstallShield creates a string entry—displayed as {ID_STRING*n*}—to represent each value.
4. Rename the features in the **Features** view to have the same names as their respective display names. To rename a feature, click the feature twice to highlight its name, then type the new name.

At run time, if the end user chooses the Custom setup type, the installation displays a dialog that prompts the user to select which features to install. This dialog displays features using the display name and description you specified here.

Setting Setup Type Properties

Setup types are collections of features to be installed. A typical installation offers Complete and Custom setup types—where the Complete setup type installs all features, and a Custom setup type displays a dialog that lets the end user choose which features to install.

You modify setup type properties in the Setup Types view of the IDE (under the View List's Organization node).

Task: ***For each setup type, select the features to be installed by selecting the boxes in front of the features' names:***

1. For the Complete setup type, select both features.
2. For the Custom setup type, select both features.

Creating Components and File Links

You can add links to additional files in the Files and Folders view. In this step, you will add a file to your HelpFiles feature. As you add files in the Files and Folders view, the IDE creates components for you according to Setup Best Practices rules.

Task: ***To add the source file Tutorial.html to a new component in the Help Files feature:***

1. Go to the **Files and Folders** view (under the View List's **Application Data** node).
2. Select **Help Files** from the feature list at the top of the view.

3. In the “Destination computer’s folders” area, right-click the **Destination Compute**r icon and verify that Show Components is selected.
4. Right-click the **Application Target Folder** icon and select **New Component**.
5. Rename the new component HelpComponent.
6. In the “Source computer’s folders” area, browse for the source folder containing TutorialHelp.html.
7. Drag the TutorialHelp.html icon from the “Source computer’s files” area and drop it on the **HelpComponent** icon.

This type of file linking, where the list of files linked to a component does not change, is called *static file linking*. To link to a directory (and possibly its subdirectories) whose contents might change between builds, see Dynamic File Linking.

Tip • *You can use the InstallShield dependency scanners to determine additional files required by your application that are currently not included in your project. For example, Tutorial App uses MFC, so it will be necessary to add the MFC Runtime object to your project in the Redistributables view if you intend to target systems that do not have the MFC run-time libraries installed.*

The next step of the tutorial explains how to build a release image for your installation project.

Building a Release

Before testing an installation, it is necessary to build a release. A release image contains all of the files to be distributed to the end user on a CD-ROM or floppy disk or from a network location.

The simplest way to build a new release is to use the Release Wizard. The Release Wizard is where you specify release properties, such as the type of media (CD-ROM, for example) to use and whether to compress files on the media. You can launch the Release Wizard by clicking the Release Wizard toolbar button, or by choosing Release Wizard from the Build menu.

Click Next in the Welcome panel to specify your release settings. You can click Help in any panel for more information about the current step.

Naming the Release

In the Specify a Release panel, specify a release name. The release name is used as the name of a folder in which your built release will be placed. For this example, create a new release called *cdrom*.

Selecting the Media Type and General Options

Media Type Panel

In the Media Type panel, you specify the type of media for which you are building a release. The media type you specify indicates the size of the disk image folders the Release Wizard creates: when you build a release for CD-ROM, the Release Wizard divides your disk images into folders, each of which is smaller than 650 MB.

For this tutorial, select CD-ROM.

Click Next to specify general options for your release.

General Options Panel

The General Options panel lets you do the following:

- Create a self-extracting executable file for distributing your installation
- Pass command line options to Setup.exe
- Pass preprocessor variable definitions to the compiler
- Select whether to place the compiled script file (.inx file) in a cabinet file

For this tutorial, leave the panel's default settings unchanged.

Specifying a Password and Supported Platforms

Password Panel

In the Password panel, you can specify a password for your installation, and, if you do, whether to execute the password-checking code in the OnCheckMediaPassword event handler function's default code.

For this tutorial, do not specify a password.

Click Next to specify the operating systems you want to support in the current release.

Platforms Panel

In the Platforms panel, you can specify the operating systems you want to support in the current release.

For this tutorial, do not change the default selection: **Use platforms specified by the Platforms project property**.

Specifying Setup Languages and Including Features

Setup Languages Panel

In the Setup Languages panel, you can specify the languages you want your installation to be able to run in, and whether to display a dialog that allows the end user to select the language in which they want the setup displayed.

The wizard will build into your installation only those language-specific elements, including string entries and dialogs, that you select in this panel. All language-independent resources, such as product properties and built-in actions, are included as a matter of course.

For this tutorial, leave the default selections unchanged.

Click Next to specify which features you want to include in the current release.

Features Panel

In the Features panel, you can specify which features are included in the built release.

For this tutorial, do not change the default selection: **Use the 'Include in Build' feature property to determine inclusion**.

Defining Media Layout and Dialog Appearance

Media Layout Panel

In the Media Layout panel, specify, for individual features or for all features, whether the features' files are stored in cabinet files or placed uncompressed in the disk image.

For this tutorial, do not change the default selection: "Cabinet File(s)".

User Interface Panel

In the User Interface panel, specify the look and feel of your installation's end user dialogs.

For this tutorial, leave the default selections unchanged.

Specifying Internet Options and Digitally Signing Your Application

Internet Options Panel

In the Internet Options panel, specify various Internet-related options. Any release can be run over the Internet, regardless of its media type.

For this tutorial, check the Create a default Web page for the setup box and leave the other default selections unchanged.

Digital Signature Panel

In the Digital Signature panel, you can digitally sign your application. Digitally signing your application helps to assure your end users that the code within your application has not been modified or corrupted since publication.

For this tutorial, leave the default selections unchanged.

Specifying Update and Postbuild Information

Update Panel

The Update panel lets you specify the release format and the existing releases for which the current release can be run as an update.

For this tutorial, leave the default selections unchanged.

Postbuild Options Panel

The Postbuild Options panel lets you copy disk image folders to a folder or FTP site, or execute a batch file, after the release build is complete.

For this tutorial, leave the default selections unchanged.

Reviewing Your Settings

The Summary panel displays the Release Wizard settings for the current release. If the settings are correct, select the Build the Release check box and click Finish to build your release. If not, click Back to modify the settings.

Status messages for the build in progress are displayed in the output window.

When the build is complete, the files to copy onto the CD are placed in the following directory:

`<ProjectFolder>\Tutorial\cdrom\DiskImages\DISK1.`

After making changes to your project in later steps of the tutorial, you can rebuild the latest release by clicking the Build toolbar button, choosing Build from the Build menu, or pressing F7.

You can now run the installation as you did previously in this tutorial. To run the installation as an Internet installation, click the toolbar's Open Release Folder button and launch Setup.htm.

The next step of the tutorial explains how to create shortcuts and registry data for an installation.

Troubleshooting Your Installation

After running your installation, if files are not installed, check the following parts of your project:

- Verify that TARGETDIR is set to the proper value. This is set in the General Information view.

  For this tutorial, the recommended value is as follows:

  `[ProgramFilesFolder]TutorialCo\TutorialApp`

- Verify that your setup types have features associated with them.
- Verify that your features have components and files associated with them.
- After making any changes to your installation, it is necessary to rebuild your project by clicking the Build button or pressing F7.

Step 2: Shortcuts and Registry Data

This step explains how to use the IDE to:

- Create program shortcuts
- Create registry information

Creating Shortcuts

You create and modify shortcuts in the Shortcuts view. The properties of a shortcut include its display name, its target executable and arguments, and the icon it displays. Using the Project Assistant, you have already created a shortcut to Tutorial App in the end user's Programs folder, under the Start menu.

Task: ***In this step you create a shortcut on the end user's desktop.***

1. Go to the **Shortcuts** view.
2. Right-click the **Desktop** icon and select **New Shortcut**. The **Browse for Shortcut Target** dialog box opens.
3. In the dialog box, select **Application Target Folder** from the **Look in** drop-down menu and select Tutorial.exe from the files list.
4. Click **Open** to close the **Browse for Shortcut Target** dialog box.
5. Rename the shortcut icon to an internal name such as *tutorial*.

Next, set the following properties for the shortcut:

Table 3-2 • Shortcut Properties

Property	Value	Comment
Display Name	Tutorial App	InstallShield adds the display name to the project's strings (and displays the string identifier in curly braces in the Display Name field) so that the name can be easily localized to other languages.
Target	<TARGETDIR>\Tutorial.exe	
Icon File	<TARGETDIR>\Tutorial.exe	
Icon Index	0	
Working Directory	<TARGETDIR>	

Tip • *To create a shortcut to a file already located on the user's machine, enter the path to the file—using system variables to represent the path to the file, when possible. For example, to launch a copy of Windows Notepad located in the user's Windows or WinNT folder, enter the shortcut target as <WINDIR>\Notepad.exe.*

Creating Registry Data

Another common requirement for installations is to write information to the target system's registry. To add registry data to a component, you can use the Registry view.

For example, to create a registry value called *TutorialData* under HKEY_LOCAL_MACHINE\Software\Tutorial Co\Tutorial\1.00.0000:

Task: ***To create registry data:***

1. Go to the **Registry** view.
2. In the **Destination computer's Registry view area**, right-click **Destination Computer** and select **New Registry Set**.
3. Rename the registry set *tutorial*.
4. Under the *tutorial* registry set, right-click HKEY_LOCAL_MACHINE and from the **New** submenu select **Key**.
5. Rename the key *Software*.
6. Repeat the process for subkeys named *Tutorial Co*, *Tutorial*, and *1.00.0000*.
7. In the **Destination computer's Registry data area**, right-click and select **New String Value**.
8. Rename the value *TutorialData*.
9. Double-click the TutorialData value and enter *<TARGETDIR>* in the **Value data** field.
10. Click the *tutorial* registry set, and in the **Registry Set Install Conditions** pane check DefaultComponent.

At run time, if the end user selects a setup type or collection of features that includes the Tutorial.exe component, the registry data is created on the target system.

Verifying that the Shortcut Was Created

Task: ***To verify that your installation created the shortcut:***

1. Rebuild your project by clicking the **Build** toolbar button or pressing **F7**.
2. Run the project by clicking the **Run** button or pressing CTRL+F5 (first removing any existing version of the program from your system). A shortcut to Tutorial App should be present in the **Programs** folder of your **Start** menu.

Verifying that the Registry Data Was Created

Task: ***To verify that the installation created the registry data:***

1. Launch Tutorial App from its shortcut.
2. From the **Tutorial** menu, choose **Verify Registry Data**. If the registry data was created, a message box displaying the text *<TARGETDIR>* is displayed.

The next step of the tutorial explains how to register a COM server (self-registering file).

Step 3: Registering COM Servers

For many files, the installation's only requirement is to copy the files from the source media to the target system. For others, the installer also needs to register the files with the target system. One category of file that needs extra handling is a *self-registering file*.

In this step you will create a component that installs and registers Tutorial.ocx and an HTML file that uses it.

A COM server is usually a DLL or .ocx file that requires extra information to be written to the target system's registry before applications and Web pages that use the self-registering file can find it.

Task: ***To install a self-registering file***

1. Go to the **Files and Folders** view.
2. At the top of the **Files and Folders** view, select the **Program Files** feature from the **Add new components to the feature** menu.
3. In the **Source computer's folder pane**, browse for Tutorial.ocx in your source directory.
4. Drag Tutorial.ocx from the **Source computer's folders pane** and drop it into the **Destination computer's folders pane's Application Target Folder**. The component SelfRegFiles is created under Application Target Folder; this component contains Tutorial.ocx and has its Self-Register property set to **Yes**, as you can verify by right-clicking the component and selecting **Properties**.

Next, add the HTML file to a new component also associated with the Program Files feature.

Task: ***To add the HTML file to a new component associated with the Program Files feature:***

1. In the **Destination computer's folders pane** of the **Files and Folders** view, right-click **Application Target Folder** and select **New Component**.
2. Rename the component *OcxHTML*.
3. Drag the file TutorialCtrl.html from the **Source computer's files view** into the *OcxHTML* component.

Task: ***After rebuilding your release (by pressing F7) and running the installation (by pressing CTRL+F5), you can verify that the file was registered properly:***

1. Launch Tutorial App using its shortcut in the **Programs** menu, or by double-clicking its icon.
2. Choose **COM Server Test** from the **Tutorial** menu.
3. If the COM server was registered correctly, the HTML page displays a "success" message.

The next step of the tutorial demonstrates how to install files conditionally.

Step 4: Conditions and Properties

In this step, you will learn how to conditionally install data on a target system.

A common requirement for installations is to install certain files on a system only if particular conditions are met. For example, files may be specific to an operating system or language, or should be installed only if the user has appropriate privileges.

To install a component (and its files and other data) only on particular operating systems, you can use the component's Operating Systems property. You can modify a component's properties by opening the Setup Design view, expanding the feature icon that contains the feature, and selecting the desired component.

Task: ***To create a component that will be installed only on systems that have Windows 8:***

1. Go to the **Setup Design** view.
2. Right-click the **HelpFiles** feature and select **New Component**.
3. Rename the component to *windows_8_files*.
4. Click the **Files** icon for the component and add the file ReadmeNT.txt from your source folder by right-clicking in the **Files** pane and browsing to the file.
5. Click the windows_8_files component to display the component's property grid.
6. Select the component's Operating Systems setting and click the browse button. The **Platforms** dialog opens.
7. Select the Windows 8 check box.
8. Click **OK**.

After you rebuild (by pressing F7) and run the installation (by pressing CTRL+F5), and any files or other data contained in the component will be installed only if the target system is running Windows 8.

The next step of the tutorial describes how to modify your project's script.

Step 5: Working with Scripts

InstallShield uses the InstallScript language to drive an installation. You can modify the project's script in the InstallScript view.

Tip • *Press CTRL+M to maximize the Script Editor; press CTRL+M again to restore it.*

InstallScript project scripts use an event-driven model, where a series of predefined functions are called in a specific order. For information about the built-in categories of event handlers and the order in which event handler functions are called, see Event Handlers.

The functions already defined in your script appear in the Functions tree. To view or edit an existing function, click its name in the Functions tree.

Note • *Event handler functions are called even if they do not explicitly appear in your script. If an event handler function does not appear in your script, its default code is used.*

To add and edit an event handler function, select the desired event category (such as Before Move Data) from the script editor's left drop-down list, and then select the name of the desired event (such as Begin) from the right drop-down list. Event handler functions that are already explicitly defined in your script appear in boldface text.

For example, the OnBegin event handler is the first function called in an installation script, for both a first-time installation and maintenance mode.

Task: ***To add your own code to the OnBegin event handler, begin by creating the function:***

1. Select **Before Move Data** from the event category list on the left.
2. Select **Begin** from the event handler list on the right.

The following code is added to your script:

```
////////////////////////////////////////////////////////////////////////////
//
//  FUNCTION: OnBegin
//
//  EVENT: Begin event is always sent as the first event during
//  installation.
//
////////////////////////////////////////////////////////////////////////////
function OnBegin( )
begin
    // TO DO: you may change default non-UI settings, for example
    //
    // You may also perform your custom initialization steps, check requirements, etc.
end;
```

You can place any code you want to execute at the beginning of your installation in the **OnBegin** function.

Using the Function Wizard

This example demonstrates how to use the Function Wizard to add a call to the MessageBox function. This displays a message when the user begins the installation.

Task: ***To add the MessageBox function to your OnBegin function:***

1. Delete the comments (lines beginning with //) between the lines reading begin and end;, and place the text insertion point between the lines.
2. Press CTRL+I to launch the **Function Wizard**.
3. In the **Function Category** list, select **Built-in dialog**.
4. In the **Function Name** list, select **MessageBox**.

5. Click **Next**.
6. In the **szMsg** field—which contains the message you want to display—type "*Welcome to the Tutorial installation!*" (including the quotation marks).
7. In the **nType** drop-down list—which specifies the type of message box to display—select **INFORMATION**.
8. Click **Finish** to paste your function call into the script.

Your **OnBegin** function should now appear as follows:

```
function OnBegin( )
begin
MessageBox ( "Welcome to the Tutorial installation!" , INFORMATION );
end;
```

Compiling the Script

After modifying the script, you must compile the script for the changes to take effect. Compile the script by clicking the Compile toolbar button, choosing Compile from the Build menu, or pressing CTRL+F7. Status messages are displayed during compilation in the output window of the IDE.

Tip • *If compiling the script results in any errors or warnings, you can double-click the error message to highlight the script line where the error occurred.*

When you run the installation (by clicking the Run toolbar button, or by pressing CTRL+F5), the message box appears before the Welcome dialog is displayed.

Displaying the Message only for First-Time Installation

The **OnBegin** function is called for both a first-time installation and a maintenance-mode installation, which means the message box will be displayed when the user reinstalls or removes the program. To display the message box only for a first-time installation, you can place your MessageBox call inside an if statement that determines if the user is running the installation for the first time.

InstallScript defines a system variable called *MAINTENANCE*, which is true if the installation is running in maintenance mode and false otherwise. To display your message box only for a first-time installation, change the **OnBegin** function to read as follows:

```
function OnBegin( )
begin
if (!MAINTENANCE) then
    MessageBox("Welcome to the Tutorial installation!", INFORMATION);
endif;
end;
```

After you compile and run the installation, the message box appears only for a first-time installation, and not for maintenance mode.

InstallScript

The InstallScript language contains hundreds of functions for performing installation-related tasks, such as working with the registry and INI files, testing characteristics of the target operating system, and displaying dialogs. For details and examples, see the InstallScript Language Reference.

The next step of the tutorial explains how to modify the dialogs that are displayed by your installation.

Step 6: Changing the User Interface

This step describes three ways you can modify the user interface of your installation:

1. Taking different actions based on user input.
2. Modifying user-interface-related script functions to display different dialogs.
3. Modifying the layout and properties of a dialog using the **Dialog Editor**.

Handling User Input

In your InstallScript code, the event handler functions that contain the dialog functions displayed at run time are:

- **OnFirstUIBefore**, which contains the dialogs to be displayed before data transfer for a first-time installation.
- **OnFirstUIAfter**, which contains the dialogs to be displayed after data transfer for a first-time installation.
- **OnMaintUIBefore**, which contains the dialogs to be displayed before data transfer for a maintenance-mode installation.
- **OnMaintUIAfter**, which contains the dialogs to be displayed after data transfer for a maintenance-mode installation.

Note • *The OnMaintUIBefore and OnMaintUIAfter event handler functions are not called if the project's Maintenance Experience property is set to "No uninstall or maintenance".*

A default InstallScript project created with the Project Assistant defines the **OnFirstUIBefore** event handler function, which defines the user interface for a first-time installation. **OnFirstUIBefore** calls dialog functions to display the dialogs that you specified in the Project Assistant's Installation Interview page. For example, the following code displays a dialog that prompts the end user to enter a user name and company name:

```
szMsg = "";
szTitle = "";
nResult = SdRegisterUser( szTitle, szMsg, szName, szCompany );
```

The end user's user name and company name are returned in the last two variables, which you can then use in any way you want, for example, to create a registry key or check against information you have stored in a file.

Changing the Dialogs Displayed

The InstallScript language includes many predefined dialogs that you can display in your installation's user interface.

Task: ***To replace the default user information dialog with one that also prompts the user for a serial number, you can replace the SdRegisterUser function with a call to SdRegisterUserEx:***

1. In the **InstallScript** view, select **OnFirstUIBefore** from the **Functions** node.
2. Declare the string script variable szSerial by adding the following to the declarations before begin in the **OnFirstUIBefore()** function:

   ```
   string szSerial;
   ```

3. Delete the lines containing the call to SdCustomerInformation:

   ```
   Dlg_SdRegisterUser:
          szMsg = "";
          szTitle = "";
          nResult = SdRegisterUser( szTitle, szMsg, szName, szCompany );
          if (nResult = BACK) goto Dlg_SdLicense2;
   ```

4. Replace the deleted lines with the following:

   ```
   Dlg_SdRegisterUserEx:
          szMsg = "";
          szTitle = "";
          szSerial = "";
          nResult = SdRegisterUserEx(szTitle, szMsg, szName, szCompany, szSerial );
          if (nResult = BACK) goto Dlg_SdLicense2;
   ```

5. Change goto statements that previously pointed to Dlg_SdRegisterUser to point to Dlg_SdRegisterUserEx.
6. Press CTRL+F7 to compile the script.

Using this approach, you can insert additional dialog in your installation's user interface, or replace existing ones.

Using the Dialog Editor

The Dialog Editor allows you to modify the appearance of dialog displayed by your installation.

As shown in the previous step, the serial number entered by the end user is displayed in the SdRegisterUserEx dialog as plain text.

Task: ***To modify the dialog so the password is hidden as the end user types it:***

1. In the **Dialogs** view (which is under the List View's User Interface node), right-click the **SdRegisterUserEx** icon and select **Edit**.
2. Select the **English (United States)** icon.

3. In the **Dialog Editor**, select the edit field under the **Serial Number** label.
4. Change the **Password** property of the **Edit** control from False to True.

Tip • *To maximize the Dialog Editor view, press CTRL+M.*

After rebuilding the project (by pressing F7) and running it (by pressing CTRL+F5), the serial number entered by the user will be hidden.

Tip • *To restore a dialog to its default appearance, right-click the dialog's icon and select Revert Dialog to Default.*

Basic MSI Project Tutorial

This tutorial guides you through the process of creating, building, running, and enhancing a Basic MSI installation project using InstallShield.

The tutorial is divided into several steps. After the first step—Step 1: Creating, Building, and Testing Your Project—the other steps can be performed independently, and in any order, so you can focus on the information relevant to your work.

In this tutorial, you will learn how to handle many of the tasks that an installation program needs to address, including:

- Installing files
- Setting up shortcuts and registry data
- Conditionally installing data
- Registering COM servers
- Changing the installation's user interface
- Building release images
- Testing the installation

Throughout the tutorial are links to related topics in the InstallShield Help Library.

Step 1: Creating, Building, and Testing Your Project

This step demonstrates how to create an installation project, build a release image, and test the installation program. After completing this step, you will know how to:

- Use the Project Assistant to create a new project.
- Specify global properties of your installation project.
- Define features, components, and file links.
- Build a release image for duplication and distribution.
- Run your installation program from within InstallShield.

Basic MSI Installation Building Blocks

A Basic MSI installation program is made up of two levels:

Table 3-1 • Levels Within a Basic MSI Installation

Level	Description
Components	A component is the smallest separately installable piece of your product from the developer's viewpoint. A component contains files, shortcuts, registry data, and other data to be installed on the target system. The end user never directly interacts with components. A component can be placed in more than one feature, and the component's data will be installed if the user selects at least one feature associated with the component.
Features	A feature is the smallest separately installable piece of your product, from the end user's viewpoint. If the end user selects the Custom setup type during the installation, a dialog with which the user can choose which features to install is displayed. Each feature contains components.

Tutorial Files

The installation program you will create in this tutorial installs and configures an application called *Tutorial App*. The source files for Tutorial App are located in one of the Samples subfolders within the InstallShield Program Files folder. The default installation location is:

```
C:\Program Files\InstallShield\2013\Samples\WindowsInstaller\Tutorial Project
```

Creating a New Basic MSI Project

The first step in the tutorial is to create a new Basic MSI project.

Task: ***To create a new Basic MSI project:***

1. Select **New** from the **File** menu, or click the **New Project** button in the toolbar. The **New Project** dialog appears.
2. Click the **Windows Installer** tab and select the **Basic MSI** project type.
3. In the **Project Name** field, type *Tutorial*.
4. Leave the default setting for the **Project Location** field.
5. Select the **Create the project in Project Name subfolder** option.
6. Click **OK** to create your project and launch the **Project Assistant**.

InstallShield creates a project file called *ProjectName*.ism, in this case creating the project file Tutorial.ism. The project file stores all the settings you make in the InstallShield IDE. To move a project to another machine, copy the .ism file (and the installation source files) to the other system.

Tip • *To change the default directory where new project files are created, type a new path in the Project Location field in the Options dialog (File Locations tab).*

Specifying Application Information

After you create a new project, the Project Assistant launches to help you specify project and application information. The first page in the Project Assistant provides a graphical overview of the installation creation process. To begin using the Project Assistant, click the Application Information icon at the bottom of the view.

The Application Information page is where you specify general information about the application your project will install.

Task: ***To specify application information for the tutorial:***

1. Type *TutorialCo* in the **Company Name** field. This automatically updates the information in the **Web Address** field.
2. Type *TutorialApp* in the **Application Name** field. The value that you enter in the **Application Name** field is used on dialogs displayed to the end user. It is also used as the display name for your application in Add or Remove Programs.
3. Leave the default values in the **Application Version** and **Company Web Address** fields.
4. In the **Application Icon** field, click browse button to browse to the Tutorial.exe location. The default location is `C:\Program Files\InstallShield\2013\Samples\WindowsInstaller\Tutorial Project`. Open the .exe file and select the **Icon Index:0**.

The Application Information panel will look like the following when you are finished.

Figure 3-1: Application Information Panel

The application name and company name you enter determine the default location of application shortcuts on the *Windows Start* menu, and the default value for the *INSTALLDIR* property, which specifies the default destination for your program's files.

Note • *The default value of INSTALLDIR is [ProgramFilesFolder]Your Company Name\Your Product Name. The special form [ProgramFilesFolder] expands to the location of the user's Program Files folder at run time. For a list of the other directory properties that are defined by Windows Installer, see the System Folders Set by the Installer section in Windows Installer Property Reference.*

Setting Installation Requirements

The Installation Requirements page allows you to easily set installation requirements for the target system. For example, if your application requires a specific operating system in order to run properly, you can indicate that in the first section of this panel.

Operating System Requirements

If your application required a certain version of Windows or later to run on the target system, you would select Yes and then select the operating systems with which your application can run properly.

For the tutorial, leave *No* selected

Software Requirements

If your application's installation requires that a particular piece of software be installed on the target system, select *Yes* and select the required software. To customize the run-time message that will be displayed if the required software is not present on the target system, click on the run-time message and edit.

Note • *The run-time message is not displayed in this section until a software requirement is selected.*

For the tutorial, leave *No* selected.

Customizing Installation Architecture

The Installation Architecture page lets you specify the features you want your installation program to display to the end user. A feature is the smallest separately installable piece of your product from the end user's standpoint. Individual features are visible to end users when they select a Custom setup type during installation.

Note • *Features can contain subfeatures, subsubfeatures, and so forth, to as many levels as your installation program requires.*

Your installation architecture currently contains a default feature, *Tutorial_Files*. The default feature is always installed when an end user runs your installation. In this step, you will add another feature to the installation architecture.

Task: ***For the tutorial, add a new Help_Files feature:***

1. Select **Yes** for the **Do you want to customize your Installation Architecture?** option.
2. Right-click the **Installation Architecture** node and select **New**.
3. Name the new feature *Help_Files*.

When you finish this step, your installation architecture will look like this:

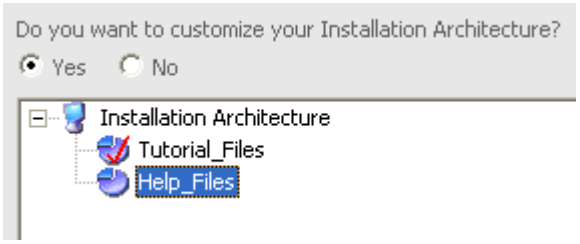

Figure 3-2: Installation Architecture

Adding Files to Your Project

The next step is to add your application's files to the installation project. The Application Files page lets you specify the files you want to associate with each of your features.

In this step, you will add the Tutorial executable file to the Tutorial_Files feature.

Task: ***To add the Tutorial executable to the Tutorial_Files feature:***

1. Select the Tutorial_Files feature from the drop-down list of features at the top of the page.
2. In the tree control (with top node Destination Computer), select the **INSTALLDIR** node.
3. Click **Add Files**. An **Open** dialog is displayed.
4. Browse to Tutorial.exe, which is located in the Tutorial Files source directory.
5. Click **Open** to add the file to the Tutorial_Files feature.
6. When the **file you have added ... may have dependencies** message appears, click **No**. Tutorial.exe has no dependencies. The file is added to the feature and appears in the file list panel on the right.

Note • *The key icon next to the file indicates that this file is the key file of the feature's component. Windows Installer requires that most components have a single key file. The Windows Installer service uses a component's key file for several purposes, including checking for the file's existence to determine if a component needs to be repaired and using the key file as the default target for a shortcut. When you add an executable file to a feature in a*

Basic MSI project, the Project Assistant automatically sets it as the key file of the component it creates behind the scenes for the file. For more information, see Setting Component Key Files.

Creating Shortcuts

The Application Shortcuts page lets you specify shortcuts for your application's files on the target system's desktop or Start menu. By default, this page displays a shortcut for each executable that you have included in your installation project. You can delete these, and add shortcuts to other files that you have included in your installation project.

Task: ***To activate the shortcut to Tutorial.exe:***

Click the Launch Tutorial.exe icon. Leave the default setting, **Create shortcut in Start menu**, selected. InstallShield will create a shortcut to Tutorial.exe on the end user's **Start** menu when the installation is run.

Configuring Registry Data

The Application Registry page lets you specify any registry entries that your application requires.

For the tutorial, do not specify any registry entries in this page. Registry entries are covered in Step 2: Shortcuts and Registry Data.

Selecting Dialogs with the Installation Interview

The Installation Interview page lets you specify the dialogs that you want the end user to see when your installation program runs. Based on your answers to the questions on this page, the Project Assistant adds the corresponding dialog to your installation project.

Task: ***To specify dialogs for the tutorial, do the following:***

1. **Do you want to display a License Agreement Dialog?**—Select **No**. If you selected **Yes** for this option, you would be able to browse to your license agreement file.
2. **Do you want to prompt users to enter their company name and user name?—**Select **Yes**. The installation displays a dialog requesting this information.
3. **Do you want your users to be prompted to modify the installation location of your application?—**Select **Yes**. For more information, see Allowing End Users to Modify the Installation Location.
4. **Do you want users to be able to selectively install only certain parts of your application?—**Select **Yes**. For more information, see Creating Selectively Installable Installations.
5. **Do you want to give users the option to launch your application when the installation completes?—**Select **Yes** and browse to the Tutorial.exe file (located in [ProgramFilesFolder]TutorialCo\Tutorial). When this option is set to **Yes**, the final dialog in the installation

presents a check box that allows the end user to immediately launch your application upon clicking the **Finish** button.

Choosing a Language for Your Installation

The Installation Localization page lets you specify the languages your installation supports, and specify string values and associated identifiers, which you can use in your end user interface to make your installation more easily localizable in other languages.

Edition • *For language options in addition to the language that you chose when you installed InstallShield, you must have the Premier edition of InstallShield.*

Task: ***For this tutorial, leave English (United States) selected and change the display names of the installation's features by doing the following:***

1. In the list box, select **Feature String Data**. The table on the right displays all of the feature string entries.
2. In the **Value** column, click **Tutorial_Files** (the value associated with the identifier IDS_FEATURE_DISPLAY_NAME2) and change it to `Tutorial Files`.
3. Click **Help_Files** (the value associated with the identifier IDS_FEATURE_DISPLAY_NAME3) and change it to `Help Files`.

Note • *For more information, see Creating Multilingual Installations.*

Building Your Installation

After defining your installation project's architecture, adding your application files, creating shortcuts, and selecting dialogs, you are ready to build the installation.

The Build Installation page lets you specify what type of distribution you want to build and, optionally, the location to which you want to copy the distribution files.

Task: ***To build the installation you have just created:***

1. Select the CD-ROM option.
2. Click **Build Installations**.

The output window opens with the **Build** tab uppermost and displays information about the progress of the build. The build is finished when the **Build** tab displays the log file information.

In the next step, you will run your installation program from the IDE.

Running Your Installation

After completing the Project Assistant steps in this tutorial, you have created a fully functional installation program that installs the Tutorial executable.

Task: ***To run your installation:***

Click the **Run** button on the toolbar or press CTRL+F5.

The installation displays the dialogs that you specified in the Installation Interview page of the Project Assistant. The values you entered in the Project Assistant are displayed to the end user in the appropriate dialogs. For example, at run time, the default value of *INSTALLDIR* that you specified in the Project Assistant appears in the Choose Destination Location dialog box. If the end user browses for a different destination directory, *INSTALLDIR* stores the new value.

After the installation is complete, you can browse for the directory and find the files installed by your installation. If the installation was successful, you will see the tutorial files installed.

Maintenance Mode

When a user runs an installation a second (or later) time for an application installed on their system, the installation runs in *maintenance mode*. Maintenance mode allows the user to modify feature selections from the first-time installation, repair the features already installed, or remove the entire application.

Uninstalling the Application

Task: ***To uninstall the Tutorial application:***

Click **Uninstall**.

Now that you have created a basic installation project, click the Installation Designer tab (near the top of the InstallShield window) to expand and fine-tune your installation as illustrated in the next step of the tutorial.

Working in the IDE

After creating a project, you set properties of the project in the InstallShield installation development environment, or *IDE*. The IDE is arranged in functional categories that help you add or edit information in your project. This and later steps of the tutorial explore several of the IDE views.

Note • *The views displayed in the IDE differ, depending on the project type you create.*

After completing this step, you will know how to:

- Set properties for your program features.
- Create components and add file links.

Setting Feature Properties

First, you will set additional properties for the features you created in the Project Assistant, such as the feature display name and description. To edit the feature properties, go to the Features view in the IDE.

Task: ***To set feature properties for this tutorial, do the following:***

1. Open the **Features** view. The **Features** view is located in the **Organization** section of the **View List**.
2. In the **Features** view, select the Tutorial_Files feature to display its property grid on the right.
3. Type the following text in the **Description** field: *This feature contains the Tutorial application files.*
4. Select the **New_Feature** feature to display its property grid.
5. Type the following text in the **Description** field: *This feature contains the Tutorial help files*

As you enter the display names and descriptions, InstallShield creates a string entry—displayed as {ID_STRING*n*}—to represent each value.

At run time, if the end user chooses the Custom setup type, the installation program displays a dialog that prompts the user to select which features to install. This dialog displays features using the display name and description you specified here.

Creating Components and File Links

You can add links to additional files in the Files and Folders view. In this step, you will add a file to your Help_Files feature. As you add files in the Files and Folders view, the IDE creates components for you according to Setup Best Practices rules.

Task: ***To add Tutorial.html to a new component in the Help_Files feature:***

1. Open the **Files and Folders** view.
2. In the **Destination computer's folders pane**, right-click the **Destination Computer** icon and verify that **Show Components** is selected.
3. Select **Help_Files** from the feature list at the top of the view.
4. Expand the tree in the **Destination computer's folders pane** to see the [INSTALLDIR] folder.
5. Right-click the [INSTALLDIR] folder and select **New Component**. Name the component *Help_Component*.
6. In the **Source computer's folders pane**, browse for the Tutorial files source folder containing TutorialHelp.html.
7. Drag the **TutorialHelp.html** icon from the **Source computer's files pane** to the **Help_Component** component in the **Destination computer's folders**. InstallShield adds the file to Help_Component component in the Help_Files feature.

8. Click the **Help_Component** icon to display the component's files in the **Destination computer's files pane**.
9. Because each component should have a key file, right-click the TutorialHelp.html file and select **Set Key File**.

This type of file linking, where the list of files linked to a component does not change, is called *static file linking*. To link to a directory (and possibly its subdirectories) whose contents might change between builds, see Dynamic File Linking.

Tip • *You can use the InstallShield dependency scanners to determine additional files required by your application that are currently not included in your project. For example, Tutorial App uses MFC, so it will be necessary to add the MFC merge module (MFC42.msm) to your project in the Redistributables view if you intend to target systems that do not have the MFC run-time libraries installed.*

The next step of the tutorial explains how to build a release image for your installation project.

Building a Release

Before testing an installation program, it is necessary to build a release to update your project settings. A release image contains all of the files to be distributed to the end user on a CD-ROM or from a network location.

The simplest way to build a release is to use the Release Wizard. The Release Wizard is where you specify release properties, such as the type of media (CD-ROM, for example) to use and whether to compress files on the media.

Task: ***To begin using the Release Wizard:***

1. Click the **Release Wizard** button on the toolbar or choose **Release Wizard** from the **Build** menu.
2. In the **Welcome** panel, click Next to begin defining your release settings.

Naming the Product Configuration and Release

Product Configuration Panel

In the Product Configuration panel, you specify the name for the current product configuration. The product configuration name is the name of a folder (inside your project folder) in which your built release will be placed.

Task: ***For the tutorial:***

1. Create a new product configuration called *Tutorial*.
2. Click **Next** to specify a release name.

Specify a Release Panel

In the **Specify a Release** panel, specify a release name. The release name is used as the name of a folder (inside the product configuration folder) in which your built release will be placed.

Task: ***For the tutorial:***

1. Create a new product release called *CDROM*.
2. Click **Next**.

Specifying Filtering Settings and Languages

Filtering Settings Panel

In the Filtering Settings panel, you can specify features or components to leave out of the current release.

Task: ***For the tutorial:***

Use the default settings (no filtering), and click **Next** to continue.

Setup Languages

In the Setup Languages panel, you specify which languages (from among the project languages) the user interface of your installation program should display, and whether to display a dialog from which the user can select the installation language.

Task: ***For the tutorial:***

Use the default settings (include English in the user interface), and click **Next** to continue.

Selecting the Media Type and Disk Spanning Options

Media Type Panel

In the Media Type panel, you specify the type of media for which you are building a release. The media type you specify indicates the size of the disk image folders the Release Wizard creates. When you build a release for CD-ROM, the Release Wizard divides your disk images into folders, each of which is smaller than 650 MB.

Task: ***For the tutorial:***

Select **CD-ROM** from the **Media Type** menu.

Disk Spanning Options Panel

The Disk Spanning Options panel lets you specify how your program files should be arranged, if multiple disk images are required. The Custom spanning type lets you specify the disk image on which to place the files in particular features.

Task: ***For the tutorial:***

Select **Automatic**, which lets the **Release Wizard** determine the disk image on which to place each feature's files.

For more information, see Spanning Installations over Multiple Disks or CDs.

Specifying Compression Settings and Setup Launcher Options

Release Configuration Panel

In the Release Configuration panel, you can specify whether to compress all, none, or some of the files in your installation project.

Task: ***For the tutorial:***

Select Compress all files.

Setup Launcher Panel

The Setup Launcher panel lets you specify whether to create a Setup.exe setup launcher, and whether to include the Windows Installer installers (InstMsiA.exe for Windows 9x and InstMsiW.exe for Windows NT and Windows 2000) with your installation program. The Windows Installer installers are necessary for target systems that do not have the Windows Installer service already, or that have older versions of the Windows Installer service.

You can also indicate which version of the Windows Installer service you want to install.

Task: ***For the tutorial:***

Leave the default settings selected.

For this step, leave all the defaults selected.

Installing Windows Installer Engine Files

This topic discusses the configurable settings in the Windows Installer Location panel.

Windows Installer Location Panel

In the Windows Installer Location panel, specify where the Windows Installer installers (InstMsiA.exe and InstMsiW.exe) are located, if you specified to include the installers in the previous Setup Launcher panel. You can specify that the installers should be downloaded from a Web site, compressed into Setup.exe, or left uncompressed on the first disk image.

Task: ***For the tutorial:***

Select **Copy from source media**.

Adding Digital Signature and Password Protection

Digital Signature Panel

The Digital Signature panel allows you to digitally sign your application. Digitally signing your application helps to assure your end users that the code within your application has not been modified or corrupted since publication.

Task: ***For the tutorial:***

Leave the default settings (no digital signature).

Password & Copyright Panel

The Password & Copyright panel allows you to activate password protection for your installation project and to indicate specific information for your application's copyright.

Task: ***For the tutorial:***

Leave the default settings (no password protection or copyright information).

Including .NET Framework Support and Choosing Advanced Settings

.NET Framework Panel

In the .NET Framework panel, specify whether to include .NET Framework support in your release.

Task: ***For the tutorial:***

Leave the default settings (do not include .NET Framework).

Advanced Settings Panel

The Advanced Settings panel lets you specify additional settings related to the current release, such as the level of compression to use and whether to create a PDF file for SMS distribution.

Task: ***For the tutorial, select the following settings:***

- Use long file names
- Optimize size
- Generate Autorun.inf—This generates a file that enables AutoPlay for your CD-ROM image.

For information about the other settings, click the Help button on the Advanced Settings panel.

Reviewing Your Settings

Summary

The Summary panel displays all of the Release Wizard settings for the current release.

Task: ***If the settings are correct:***

1. Select the **Build the Release** check box.
2. Click **Finish** to build your release.

Status messages for the build in progress are displayed in the output window. When the build is complete, the files to copy onto the CD are placed in the directory:

`<ProjectFolder>\Tutorial\cdrom\DiskImages\DISK1.`

You can have InstallShield copy your built disk images to another directory using the Events tab in the Releases view.

Rebuilding Your Project

After making changes to your project in later steps of the tutorial, you can rebuild the latest release by clicking the Build toolbar button  , choosing Build from the Build menu, or pressing F7.

The next step of the tutorial explains how to create shortcuts and registry data for an installation program.

Troubleshooting Your Installation

After running your installation, if files are not installed, check the following parts of your project:

- Verify that **INSTALLDIR** is set to the proper value. This is set in the General Information view.

  For this tutorial, the recommended value is `[ProgramFilesFolder]TutorialCo\TutorialApp`.

- Verify that your features have components and files associated with them.
- After making any changes to your installation, it is necessary to rebuild your project by clicking the Build button or pressing F7.

Step 2: Shortcuts and Registry Data

This step explains how to use the IDE to:

- Create program shortcuts
- Create registry information

The processes for creating other types of system data are similar to the items described in this step. For more information, view the topics listed below.

Creating Shortcuts

You create and modify shortcuts in the Shortcuts view. The properties of a shortcut include its display name, its target executable and arguments, and the icon it displays.

Creating the Shortcut

Task: ***In this step you will create a shortcut to Tutorial App in the user's Programs folder, under the Start menu.***

1. Open the **Shortcuts** view. The **Shortcuts** view is located in the **System Configuration** section of the **View List**.
2. Right-click the **Programs Menu** folder icon, and select **New Advertised Shortcut**. The **Browse for a Component** dialog appears.
3. In the dialog, select **Tutorial_Files** from the **Feature** drop-down menu and select Tutorial.exe from the files list and click **Open** to close the dialog.
4. Rename the shortcut icon to an internal name such as *Tutorial*.
5. Set the following shortcut properties:

Table 3-2 • Shortcut Properties

Property	Value	Comment
Display Name	Tutorial Application	To accommodate target systems that do not support long file names, the IDE will create an expression that includes a short file name, as in "TUTORI~1|Tutorial App". If you want, you can modify the short file name part of the expression, as in "TUTORIAL|Tutorial App".

Table 3-2 • Shortcut Properties (cont.)

Property	Value	Comment
Description	Launch the Tutorial application	Displayed as a tooltip.
Advertised	Yes	At run time, if the user advertises the product or the feature containing the shortcut, the shortcut is created but the component's files are not installed until the user launches the shortcut.
Target	Advertised shortcut to [INSTALLDIR]Tutorial.exe	Automatically set to the component's key file for an advertised shortcut.
Icon File	<TutorialSource>\Tutorial.exe	Browse for Tutorial.exe in the source location, and select its only icon.
Icon Index	0	The icon index identifies a particular icon if there is more than one icon resource in the executable file.
Working Directory	[INSTALLDIR]	The working directory should be set to the default directory for your Save As and Open dialogs.

Tip • *To create a shortcut to a file already located on the end user's machine, set the Advertised property to No, and enter the path to the file—using Windows Installer directory properties to represent the path to the file, when possible. For example, to launch a copy of Windows Notepad located in the user's Windows or WinNT folder, enter the shortcut target as [WindowsFolder]Notepad.exe.*

Creating Registry Data

Another common requirement for installation programs is to write information to the target system's registry. To add registry data to a component, you can use the Registry view.

Task: ***To create a registry value called TutorialData under HKEY_LOCAL_MACHINE\SOFTWARE\Tutorial Co\Tutorial\1.00.0000:***

1. Open the **Registry** view.

   The **Registry** view is located in the **System Configuration** section of the **View List**.

2. Select **Tutorial.exe** from the **View Filter** at the top of the view.

3. In the **Destination computer's Registry view pane**, right-click HKEY_LOCAL_MACHINE, select **New**, and point to **Key**.

4. Rename the key *SOFTWARE*.
5. Repeat the process for subkeys named *Tutorial Co*, *Tutorial*, and *1.00.0000*.
6. In the **Destination computer's Registry data pane**, right-click and select **New String Value**.
7. Rename the value *TutorialData*.
8. Double-click the TutorialData value and enter *[INSTALLDIR]* in the Value data field.

The **Registry** view should now appear as follows:

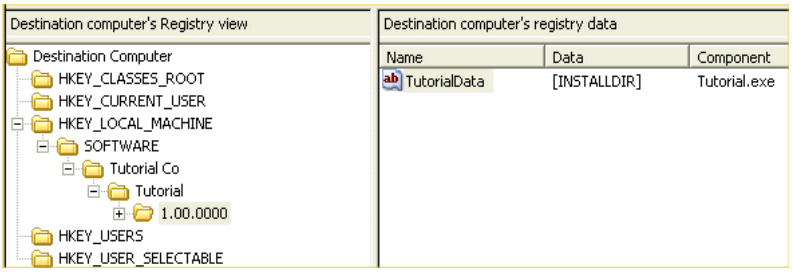

Figure 3-3: Registry View

Tip • *To write the value of a Windows Installer property to the registry, you can use the form [PropertyName]. In this example, creating a registry value whose data is [INSTALLDIR] writes the value of INSTALLDIR to the registry.*

At run time, if the end user selects a setup type or collection of features that includes the Tutorial.exe component, the registry data is created on the target system.

Verifying that the Shortcut Was Created

Task: ***To verify that your installation program created the shortcut:***

1. Rebuild your project by clicking the **Build** toolbar button or pressing **F7**.
2. Run the project by clicking the **Run** button or pressing CTRL+F5 (first removing any existing version of the program from your system). A shortcut to the Tutorial application should be present in the **Programs** folder of your **Start** menu.

Verifying that the Registry Data Was Created

Task: ***To verify that the installation program created the registry data:***

1. Launch Tutorial App from its shortcut.
2. From the **Tutorial** menu, choose **Verify Registry Data**. If the registry data was created, a message box displaying the value of *INSTALLDIR* is displayed.

The next step of the tutorial explains how to register a COM server (self-registering file).

Step 3: Registering COM Servers

For many files, the installation program's only requirement is to copy the files from the source media to the target system. For others, the installer also needs to register the files with the target system. One category of file that needs extra handling is a *COM server*, commonly known as a *self-registering file* or *ActiveX control*. A COM server is usually a DLL or OCX that requires extra information to be written to the target system's registry before applications and Web pages that use the self-registering file can find it.

Creating a COM Server Component

To install and register these and other types of files, you can use the Component Wizard. The Component Wizard creates components that copy the files, and perform any additional registration steps. In this step you will create a component that installs and registers Tutorial.ocx and an HTML file that uses it.

Task: ***To create a COM server component:***

1. Open the **Files and Folders** view. The **Files and Folders** view is located in the **Application Data** section of the **View List**.
2. At the top of the **Files and Folders** view, select the Tutorial_Files feature from the **Add new components to the feature** menu.
3. In the **Destination computer's folders pane**, right-click the **[INSTALLDIR]** folder and select **Launch Component Wizard**.
4. In the **Welcome** panel of the **Component Wizard**, select the Let me select a type and define the component myself option and click **Next**.
5. In the **Component Type** panel, select the **COM Server** icon, type *Tutorial.ocx* in the **Component Name** field, and click **Next**.
6. In the **COM Server—Destination** panel, verify that the destination is set to [INSTALLDIR].
7. In the **COM Server File** panel, click the browse button next to the **COM Server File** field and browse for Tutorial.ocx in your tutorial files source directory. Click **Next**.
8. After the Component Wizard has extracted the COM information, review the COM information and click **Finish** to create the component.

The next step is adding the HTML file to the component you just created.

Task: ***To add the HTML file to the component:***

1. In the **Destination computer's folders pane** of the **Files and Folders** view, select the new Tutorial.ocx component.
2. Drag the file TutorialCtrl.html from the **Source computer's files pane** to the **Destination computer's files pane**.
3. Verify that Tutorial.ocx is marked as the key file of its component.

Note • *See Registering COM Servers for other options for registering self-registering files, including extracting COM information each time that you rebuild the release—for COM servers with interfaces that change between builds—or calling the file's self-registration functions.*

Verifying that the COM Server Was Registered

Task: ***After rebuilding your release (by pressing F7) and running the installation (by pressing CTRL+F5), you can verify that the COM server was registered properly:***

1. Launch Tutorial App using its shortcut in the **Programs** menu, or by double-clicking its icon.
2. Choose **COM Server Test** from the **Tutorial** menu.
3. If the COM server was registered correctly, the HTML page displays a "success" message.

The Component Wizard can also create components that install and configure fonts and Windows NT services.

The next step of the tutorial demonstrates how to install files conditionally.

Step 4: Conditions and Properties

In this step, you will learn how to conditionally install data on a target system.

Operating System Conditions

A common requirement for installation programs is to install certain files on a system only if particular conditions are met. For example, files may be specific to an operating system or language, or should be installed only if the user has appropriate privileges.

To install a component (and its files and other data) only on particular operating systems, you can use the component's Operating Systems property. You can modify a component's properties by opening the Setup Design view, expanding the feature icon that contains the feature, and selecting the desired component.

Task: ***To create a component that will be installed only on systems running Windows 7 or later:***

1. Open the **Setup Design** view. The **Setup Design** view is located in the **Organization** section of the **View List**.
2. Right-click the **Help_Files** feature and select **New Component**.
3. Rename the component *Windows_7_Files*.
4. Expand the Windows_7_Files component, click the **Files** icon for the component, and add the file ReadmeNT.txt from your tutorial files source folder by right-clicking in the Files pane and browsing to the file.
5. Right-click the .txt file and select **Set Key File**.
6. Click the Windows_7_Files component to display the component's property grid.
7. Select the component's Condition property and click the browse button to launch the **Condition Builder** dialog.
8. Create the following condition: *VersionNT>=601*. For information on creating conditions, see Building Conditional Statements.
9. Click **OK** to close the **Condition Builder** dialog and add the condition.

After you rebuild (by pressing F7) and run the installation (by pressing CTRL+F5), and any files or other data contained in the component will be installed only if the target system is running Windows 7 or later.

Windows Installer Conditions

The Windows Installer service stores some global information about your installation program and about the user's operating system in properties. Some properties are built into the Property table of your MSI database, and some are created and set by the Windows Installer engine when the user launches an installation program.

Properties commonly used in conditions include:

- AdminUser, which is set if the user running your installation has administrative privileges.
- VersionNT, numeric values describing the operating system version the user is running.
- PhysicalMemory, which contains the amount of RAM—in megabytes—on the user's system.

A Windows Installer condition is a statement of logic that compares a property value against a constant value, or tests if a property exists. For example, Windows Installer defines properties called ScreenX and ScreenY, which contain the user's monitor resolution in pixels. A Windows Installer condition that checks that the user has at least 800 by 600 resolution would read "(ScreenX>=800) And (ScreenY>=600)".

Conditions can also test if a property is defined. For example, the AdminUser property is set only if the user has administrative privileges, and a condition that tests if a user has administrative privileges is simply "AdminUser".

Task: ***To create a component that will be installed only if the user has administrative privileges:***

1. Right-click the **Help_Files** feature and select **New Component**.
2. Rename the component *Admin_Component*.
3. Expand the **Admin_Component** component and click the **Files** icon.
4. Add the file AdminOnly.txt from your tutorial files source folder, and set it as the key file of the component.
5. Click the browse button in the component's **Condition** property to display the **Condition Builder** dialog.
6. In the **Condition Builder** dialog, type *AdminUser* in the **Condition(s)** field.
7. Click **OK**.

At run time, the component's data are installed only if the user has administrative privileges.

The next step of the tutorial describes how to modify your installation's user interface.

Step 5: Changing the End-User Interface

This step describes three ways you can modify the end-user interface of your installation program:

- Specifying the dialogs to be displayed during the installation.
- Modifying the layout and properties of a dialog using the Dialog Editor.

Adding a New Dialog

The Basic MSI project includes many dialogs that you can display in your installation program's user interface. The topic, Running Your Installation, in this tutorial, showed the dialogs your installation program displays based on your selections in the Project Assistant's Installation Architecture page.

Task: ***To create a new dialog:***

1. Open the **Dialogs** view. The **Dialogs** view is located in the **User Interface** section of the **View List**.
2. Right-click the **All Dialogs** explorer and then click **New Dialog**. The **Dialog Wizard** opens. Click **Next** to dismiss the **Welcome** panel.
3. In the **Dialog Template** panel, click **Interior Wizard Panel**, and select the **Let me insert this dialog in a User Interface sequence** check box.
4. In the **User Interface** panel, select **Installation** in the **User Interface Sequence** list. In the list of dialogs, select **InstallWelcome**. Based on these selections, InstallShield will insert your new dialog in sequence immediately following the **InstallWelcome** dialog.
5. In the **Dialog Position and Condition** panel, leave the default settings, and click **Finish**. Your new dialog appears in the **Dialogs** list.

6. Right-click the dialog and select **Rename**. Rename the dialog `WelcomeBitmap`.

Using the same technique, you can insert additional dialogs in your installation's user interface.

Modifying Dialog Layout in the Dialog Editor

The Dialog Editor allows you to modify the appearance of dialogs displayed by your installation program.

Task: ***In this step, you will modify the WelcomeBitmap dialog that you just created:***

1. First, create a bitmap (using a program like Microsoft Paint) that measures 300 by 150.
2. Open the **Dialogs** view.
3. Expand the WelcomeBitmap dialog's node. Click **English (United States)** to open the **Dialog Editor**.
4. Click the **Dialog Bold Title** text box at the top of the dialog. In the **Text** field, type *Welcome Bitmap*. This changes the dialog's main title.
5. Click the **Dialog Normal Description** text box at the top of the dialog. In the **Text** field, type *Displays my welcome bitmap*. This changes the dialog's description.
6. Click the **Bitmap** button on the **Dialog Control** toolbar and use the cursor to drag a box on the dialog. Set the Height to 150 and the Width to 300.
7. In the **File** field browse to the bitmap file that you created in step 1.

After rebuilding the project (by pressing F7) and running it (by pressing CTRL+F5), the Welcome Bitmap dialog will appear after the Install Welcome dialog.

Tip • *To maximize the Dialog Editor view, press CTRL+M.*

Globalization Tutorial

The Globalization tutorial introduces you to the tools and options that InstallShield provides for creating a global installation package. A global installation is one that has the potential to run in many different languages. Depending on how you choose to build your installation, you can either include all the languages in one package and let the end user select the language, or you can build individual installation packages for each language that you target. This tutorial walks you through the process of creating an all-encompassing installation.

***Edition** • The Premier edition of InstallShield must be installed on your development system in order to successfully complete this tutorial.*

If you have not already done so, you may want to run through the Basic MSI tutorial to familiarize yourself with how to create an installation package. When finished with the Basic MSI Tutorial, you will have a Basic MSI installation project that is ideal for adding additional languages. The complete project file for the Basic MSI tutorial was installed with this product in one of the Samples subfolders within the InstallShield Program Files folder. The default location is:

```
C:\Program Files\InstallShield\2013\Samples\WindowsInstaller\Tutorial Project\Tutorial
```

***Project** • Almost all of the information in the tutorial also applies to InstallScript installation projects. Differences are explicitly noted in the tutorial text.*

Opening the Project File

This tutorial uses `Othello.ism`, which is a sample project file that is installed with InstallShield.

Task: ***To begin the tutorial:***

Open `Othello.ism`, which is located in one of the Samples subfolders within the InstallShield Program Files folder. The default location is:

```
C:\Program Files\InstallShield\2013\Samples\WindowsInstaller\Basic Installation Project
```

***Project** • Othello.ism is a Basic MSI installation project. Almost all of the information in this tutorial also applies to InstallScript installation projects; differences are explicitly noted in the tutorial text.*

Selecting the Target Languages

The first step in creating a global installation is to select the languages that you want to target. For this tutorial, you will add two languages to your installation project: German and Polish.

Task: ***To add languages to your project:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Setup Languages** setting, click the ellipsis button (**...**). The **Setup Languages** dialog box opens.
3. Select the **English (United States)**, **German**, and **Polish** check boxes.

InstallShield adds string entries for English, German, and Polish to your project. Each string entry consists of a language-independent identifier and a corresponding language-specific value. The string entries include the built-in user-interface string resources that are already translated. To view all of the string entries, you can use the String Editor view. (In the View List under User Interface, click String Editor.)

Every time that you add a new string entry to your default language, a parallel entry is made to the string entries for all of the other languages that are in your project.

Editing Language-Specific String Entries

The next step is to edit string entries in your installation project. You will edit string entries for three different settings: The feature's display name, the shortcut's display name, and the shortcut's description. (The shortcut's description will be created as part of the next step in this tutorial.)

Feature Display Name

Task: ***To provide a display name for a feature:***

1. In the View List under **Organization**, click **Setup Design**.
2. In the **Setup Design** explorer, click **ProgramFiles**.
3. In the **Display Name** setting in the right pane, enter `Program Files` if it is not already there.

If you click anywhere else within the Setup Design view, you will see that the text that you entered has been preceded by a string identifier, which is enclosed within curly brackets ({}). You can view all of your project's string entries by clicking the ellipsis button (...) that is displayed when you click the Display Name setting.

Shortcut Display Name

Task: ***To add a display name for the shortcut:***

1. In the **Setup Design** explorer, expand the **ProgramFiles** feature, and then expand the **Program_Executables** component.

   The component Program_Executables contains a shortcut to the file `Othello.exe`.
2. Click the **Shortcuts** icon under the **Program_Executables** component.

3. In the **Shortcuts** explorer, click the **Othello** shortcut. InstallShield displays the shortcut's settings in the right pane.

   Currently, the **Display Name** setting is set to **Othello**. The value is preceded by a string identifier, which is enclosed within curly brackets ({}).

4. To change the display name, enter the new name in the **Display Name** setting.

Creating String Entries

Because many of your text strings might be used in multiple places in your project, it is inefficient to store each instance of these strings in the project. Instead, you can create the string once, and use it anywhere a string is needed. To help streamline the process of localizing a project, all of the text strings that may be displayed at run time during the installation process are available in one consolidated view: the String Editor view. You can use this view to create new string entries.

For the shortcut's Description setting, you are going to enter your new string entry through the String Editor view. Then, you will associate that string with the shortcut's description.

Task: ***To create a new string entry and use it for the shortcut's Description setting:***

1. In the View List under **User Interface**, click **String Editor**.
2. Do one of the following:
   - Click the **New** button.
   - Press the INSERT key.

   The **String Entry** dialog box opens.
3. In the **String Identifier** box, enter the following:

   ```
   MYSTRING
   ```

4. In the **Value** box, enter the following text:

   ```
   This is the description of the Othello shortcut.
   ```

5. In the **Comments** box, you can optionally specify an internal note about the string entry. The comments are not displayed at run time.
6. Click **OK**. InstallShield adds new rows in the String Editor view, one for each language (English, German, and Polish).
7. In the View List under **System Configuration**, click **Shortcuts**.
8. In the **Shortcuts** explorer, click the **Othello** shortcut. InstallShield displays the shortcut's settings in the right pane.
9. In the **Description** setting, click the ellipsis setting (**...**). The **Select String** dialog box opens.
10. Select the **MYSTRING** row, and then click **OK**.

Your new string is now entered as the value for the **Description** setting.

Including Language-Specific Files and Components

The next step in creating a global installation involves including language-specific files and components within your installation project. For example, although many of your program files may be language-independent, your help files and run-time strings are both language-specific. For the purpose of this exercise, you will add three new components to your project. Each component contains a Readme file that is localized in all of your supported languages.

Task: ***To add a component to your project:***

1. In the View List under **Organization**, click **Setup Design**.
2. In the **Setup Design** explorer, right-click the feature called **ProgramFiles**, and then click **New Component**.
3. Type *English_Readme* for the component's name.
4. Repeat this process two more times. Name these components *Polish_Readme* and *German_Readme*.

Translated versions of a simple Readme file are included with InstallShield. These files are located in one of the Samples subfolders within the InstallShield Program Files folder:

InstallShield Program Files Folder\Samples\WindowsInstaller\Basic Installation Project\Data Files\Readme

Task: ***To add a file to the English_Readme component:***

1. Expand the new **English_Readme** component, and then click the **Files** icon under the **English_Readme** component.
2. Right-click in the **Files** list and click **Add**.
3. Browse to the `English.txt` file, and then click **Open**.

Repeat these steps for the German and Polish components, adding `Deutsch.txt` to and `Polski.txt`, respectively.

Specifying Component Installation Conditions

Now that you have created your language-specific components, you need to include logic that will let the installer know which of these components should be installed. By specifying a component condition, you can determine the default language of the target system and then install the appropriate file. Each of the three language-specific components that you created will need a condition. If that condition evaluates to True, the component is installed.

Task: ***To create the component condition:***

1. Click the German_Readme component.
2. In the right pane, click the **Condition** setting, and then click the ellipsis button (**...**) for this setting. The **Condition Builder** dialog box opens.
3. In the **Properties** list, select **SystemLanguageID**, and then click the **Add** button.
4. In the **Operators** list, select the equals sign (**=**), and then click the **Add** button.

   The **Condition(s)** box contains **SystemLanguageID =**, which reflects the selections you previously made.
5. Next you need to provide a value that will be checked when the installation is run. Because you are currently editing the German component, enter `1031` after the equal sign. 1031 is the language ID for German. Since the component is installed only if this equation evaluates to true (that is, the target system's language is German), this component is not installed on any machine that is not running in German.

Follow the same steps from above to add a condition to the Polish_Readme component. Instead of using 1031 as the language value, use 1045, which is the language ID for Polish.

You need to choose one language as your default language. For this example, English is the default. Therefore, the condition that you use for the English_Readme component differs from the other two. The condition for the English_Readme component should appear as follows:

```
SystemLanguageID<>1045 AND SystemLanguageID<>1031
```

With this logic, if the language of the target machine is not German or Polish, the English_Readme component is installed.

Project • *To learn how to specify which language-dependent components are installed at run time for InstallScript and InstallScript object projects, see Installing Components Based on Language.*

Translating the Strings

Before you can build your installation project, you need to translate the English strings that you entered for the feature's display name, the shortcut's display name, and the shortcut's description. For this tutorial, they have been translated for you. All you have to do is enter the correct text for the German and Polish string entries. You can use the String Editor view to do this.

German String Values

Open the String Editor view. Find each of the following string identifiers for the German language. You can enter the string identifier in the Search Grid box to easily find each string. As an alternative, you can click the Identifier column heading to sort all of the string entries by identifier. Update the German values for the three string entries as follows:

Table 3-1 • German String Entries

Identifier	Value
FEAT_DISPLAYNAME	Programmdateien
SHORTCUT_DISPLAYNAME	Othello-Verknuepfung
MYSTRING	Dies ist die Beschreibung der Verknuepfung fuer Othello.

Polish String Values

Update the Polish values for the three string entries:

Table 3-2 • Polish String Entries

Identifier	Value
FEAT_DISPLAYNAME	Pliki Programu
SHORTCUT_DISPLAYNAME	Skrt do Othello
MYSTRING	Opis skrtu Othello.

In most translation situations, you export your string entries for translation. To learn more, see Translating String Entries. However, for the purposes of this tutorial, it is easier to edit the string entries within the String Editor view.

Building the Installation

Your installation project has been fully globalized and is ready to test. Before you can test the installation, however, you need to build it.

Task: ***To build your installation:***

1. Click the **Release Wizard** button on the toolbar.
2. In the first two panels, specify a product configuration and release name.
3. Accept the default settings for every other panel in the wizard except the **Setup Languages** panel.

4. The **Setup Languages** panel enables you to choose which languages to include in your installation. Only the languages that you specified in the General Information view appear in the list of available languages—English, Polish, and German. Select the check box next to each language.
5. Also, ensure that you select the **Display the Setup Languages Dialog** check box. This dialog allows end users to select the language in which they want the installation to run.
6. Accept the default settings provided in the remaining wizard panels.
7. When you reach the **Summary** panel, ensure that the **Build the Release** check box is selected, and then click the **Finish** button.
8. InstallShield builds the release.

Running the Installation

Task: ***To run your installation:***

1. Click the **Run Setup** button on the toolbar. The **Choose Setup Language** dialog appears.
2. To run your installation, select **German (Standard)** and click **OK**. From this point forward, every dialog is displayed in German.

Note • *After an installation is run in a particular language, Windows Installer caches this information and always runs the installation in that language.*

As the installation wizard progresses, you may notice that some buttons are not properly sized. You can easily fix this problem by opening the Dialog Editor and resizing the controls so the text fits in the control.

In the Custom Setup panel (in German it is called Angepasstes Setup), the feature name is now *Programmdateien*. Your localized string entries are a part of the installation.

Testing the Installation

The last step is testing the globalized installation that you created.

Task: ***To test the installation:***

1. Open the **Start** menu and select **Programs**. The Othello shortcut is displayed as Othello Verknpfung. You can see the shortcut's description, which also appears in German.
2. Navigate to the installation directory for Othello. It should be in <Program Files Folder>\Shakespeare Inc\Othello. The readme file that you installed is called Deutsch.txt.

4

Creating Installations

If you have ever installed an application onto your computer, you have seen an installation in action—from the end user's perspective. An installation's primary task is to transfer files from the source medium to the local drive. An installation often also displays a user interface to obtain end user selections, configures the target system (for example, makes any required registry entries and creates shortcuts), and enables modification or uninstallation of the installed application. Creating an installation involves performing some or all of the following tasks.

Specify Installation Information

Basic information that you enter in the General Information view is used in various parts of the installation; for example, the product name is used to create the application information registry key.

Organize and Transfer Files

File transfer involves copying files from the source medium, such as a CD or DVD, to a local drive on the end user's machine. Depending on the configuration the end user chooses—by selecting a setup type (in an InstallScript or InstallScript MSI installation) or features—all or only some of the files may be transferred to the local disk.

Organize the files to be installed into setup types and features to help your end users select the most appropriate files. Within each feature, organize the files into components according to their type and purpose, for example, files that are installed to the same target folder.

Configure the Target System

In addition to installing files, many installations need to configure the target system by creating shortcuts and program folders, modifying the registry, modifying initialization file (.ini file) data, configuring Open Database Connectivity (ODBC) resources, modifying environment variables, modifying XML files, modifying text files, schedule tasks, and install and control Windows services.

Customize Installation Behavior

InstallShield offers wide-ranging customization options. InstallScript installations are driven by InstallShield's simple but powerful InstallScript programming language, which—in addition to its built-in functions—enables you to call DLL and Windows API functions and launch child installations and other applications from your installation.

Windows Installer-based installations can use custom actions to run InstallScript, VBScript, or JavaScript code; call DLL functions; run executable files; call a managed method in a managed assembly; set a property or a directory; trigger an error and end the installation; run PowerShell scripts; terminate a process; or run other installation packages.

Define the End-User Interface

An installation's end-user interface provides information and installation configuration options to the end user. Through the user interface, an end user can choose to install only part of a product, choose to leave some files on the source medium, view a license agreement, or provide the installer information that may be necessary to properly configure the installation.

The user interface can be customized to meet the needs of your installation. For example, you can prompt a user for a serial number before starting the installation to protect your software against illegal use. During file transfer, an installation can display billboards that provide product information such as new features or usability tips. A status bar may also be displayed to show the progress of the file transfer process.

Configure Servers

A server-side installation may need to create and manage new Internet Information Services (IIS) Web sites, manage COM+ applications and components, or manage and organize SQL scripts by server connections and settings.

Prepare Installations for Update Notification via FlexNet Connect

FlexNet Connect lets you automatically notify your Web-connected end users when patches, updates, and product information for your application are ready for release. To take advantage of FlexNet Connect, you must enable FlexNet Connect in your original installation.

Prepare the Installation for Maintenance and Uninstallation

To uninstall, modify, or repair an application, the operating system must have some indication that the application is present. To accommodate this, an installation registers an application with the operating system so that it can be easily maintained or uninstalled.

Much of the information registered in this process is available to the end user through Add or Remove Programs in the Control Panel. For example, technical support contact information, product update information, product version, and product publisher information are registered in this process.

Build, Test, and Deploy the Installation

Once you have created your installation project, you will want to build, test, and deploy the installation: create the files that you will release to your users, test the installation for errors, and optionally copy the files to a local or network location or an FTP site.

Create Trialware

Offering prospective customers a free trial version of your product can be a highly effective sales tool, but it carries the risk that some will abuse the privilege and continue to use the product without paying for it. InstallShield enables you to create a protected trial version of your product without requiring you to modify the source code.

Before You Begin

The “Before You Begin” section of the InstallShield Help Library contains information that is helpful to installation authors as they create new installation projects with InstallShield. The topics provide background information on Windows Installer, the Windows logo program, INSTALLDIR, TARGETDIR, and other areas of installation development.

Requirements for the Windows Logo Program

Microsoft established a list of requirements that a product and its installation must fulfill in order to participate in the Windows 8 Desktop App Certification Program. The requirements outline criteria that help make a product more compatible, reliable, and secure when running on Windows systems. Products that meet the Windows 8 Desktop App Certification Program requirements can carry the Compatible with Windows 8 logo.

Qualifying for the Windows Logo Program

To learn how to qualify for the Windows logo program, visit MSDN. This Web site has information about the Windows logo program.

Certified for Windows Validation Suites in InstallShield

Validating your installation package or merge module may help you identify whether your product meets installation requirements for Windows logo program. If a package or merge module fails one or more validation rules, InstallShield reports the specific rules that were violated and offers additional information to help you troubleshoot the problem.

Therefore, if you are interested in being able to use the Windows logo, consider using both of the following suites to validate your installation package:

- **InstallShield Validation Suite for Windows 8**—This suite consists of a number of InstallShield internal consistency evaluators (ISICEs) that help you identify issues that may make your installation behave unexpectedly on Windows systems. This suite checks for issues that may not be revealed in the Full MSI Validation Suite.
- **Full MSI Validation Suite**—This suite consists of ICEs that Microsoft created.

If you create a merge module in InstallShield, use the following suites to validate your merge module:

- **InstallShield Merge Module Validation Suite for Windows 8**—This suite consists of a number of InstallShield ISICEs that help you identify issues that may make your merge module behave unexpectedly on Windows systems. This suite checks for issues that may not be revealed in the Merge Module Validation Suite.
- **Merge Module Validation Suite**—This suite consists of ICEs that Microsoft created.

Additional validation suites are also available.

To learn more, see Validating Projects.

Windows Logo • *The Windows Logo Guideline alert appears throughout the InstallShield Help Library whenever the information relates to complying with the Windows logo program guidelines.*

Introduction to Windows Installer

A Windows Installer installation program is distributed as an .msi package, which consists of a Windows Installer database (.msi database) and related data files (.cab files, uncompressed data files, etc.). The .msi databases, implemented as COM structured storage, contain dozens of tables that describe the changes that are to be performed on the target system. For example, some of the .msi tables are:

- **File**, which describes the files to be installed
- **Registry**, which describes the registry data to be written
- **Shortcut**, which describes shortcut settings

Other .msi database tables describe the appearance and behavior of the installation's user interface, install and configure Windows services and ODBC information, determine characteristics of the target system, and store icons and other binary data for use during installation.

From a developer's perspective, perhaps the greatest change in Windows Installer installation programs is that there is no explicit script to write. Instead, Windows Installer–based installations perform standard and custom actions, where an action displays a dialog, queries the target system, or makes changes to the target system. These actions are arranged into sequences, which are ordered collections of actions.

Windows Installer includes a collection of application program interface functions, or APIs, dedicated to managing product installations. Applications must call the Windows Installer APIs in order to take advantage of features available with Windows Installer.

An integral part of Windows operating systems, Windows Installer provides a standard format for component management as well as an interface for managing applications and system tools. Various versions of Windows Installer are available as redistributables for Windows operating systems.

Although it is possible to create a Windows Installer package by editing .msi database tables directly, the large number of tables and relationships among them makes doing so a formidable task. InstallShield organizes the process of developing an installation for Windows Installer into various views, providing graphical editors and wizards that shield the developer from much of the implementation detail that is associated with .msi databases.

For more information on Windows Installer technology, see the Windows Installer Help Library.

Minimizing the Number of User Account Control Prompts During Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Some of the specific details apply to only some of these project types. These differences are noted where appropriate.

One of the goals of Windows Vista and later, as well as User Account Control (UAC), is to allow users to run as standard users all of the time. Elevation should rarely be required; if it does occur, it should occur for as short of a duration as possible.

Several different areas of InstallShield affect whether an installation triggers UAC consent or credential prompts for elevated privileges. Understanding these different settings will help you create the appropriate UAC experience for your installation when end users run it on Windows Vista and later systems. It will also offer guidance if you are trying to minimize the number of UAC prompts that are displayed during your installation.

Depending on how it is configured, an installation that includes InstallShield prerequisites may prompt for elevated privileges on Windows Vista and later systems at several different points during the installation:

1. When the end user launches the `Setup.exe` file
2. When the `Setup.exe` file launches a setup prerequisite that requires elevated privileges
3. When the ISInstallPrerequisites custom action relaunches the `Setup.exe` file in feature prerequisite installation mode because one or more of the features being installed has an associated feature prerequisite

   Note that the ISInstallPrerequisites custom action does not verify whether any feature prerequisites require elevated privileges before the prompt for elevated privileges is displayed. In addition, the ISInstallPrerequisites custom action does not check the conditions on any of the feature prerequisites to determine whether the feature prerequisites need to be installed. The prompt for elevated privileges is always displayed.

   

   Project • *Basic MSI projects include support for feature prerequisites.*

4. When the Windows Installer begins the Execute sequence of the .msi package

   

   Project • *This last installation point applies to Basic MSI and InstallScript MSI projects, but not InstallScript projects.*

UAC-Related Settings in InstallShield

Following is a list of the InstallShield settings that help determine whether UAC prompts are displayed during an installation on Windows Vista and later systems:

- **Required Execution Level**—Use this setting in the Releases view to specify the minimum execution level required by your installation's `Setup.exe` file. InstallShield uses the value that you select (Administrator, Highest available, or Invoker) in the application manifest that it embeds in the `Setup.exe` launcher. For more information, see Specifying the Required Execution Level for Your Setup Launcher on Windows Vista and Later Platforms.

- **The prerequisite requires administrative privileges**—If you are creating or modifying an InstallShield prerequisite for your installation, use this check box to indicate whether administrative privileges are required in order to install this prerequisite. This check box is on the Behavior tab in the InstallShield Prerequisite Editor. For more information, see Specifying that an InstallShield Prerequisite Requires Administrative Privileges.
- **Require Administrative Privileges**—Use this setting in the General Information view to specify whether the Execute sequence of your installation's .msi package requires administrative privileges. If you set this to No, InstallShield sets bit 3 in the Word Count Summary property to indicate that elevated privileges are not required to install your product. For more information, see Entering Summary Information Stream Data.

Project • *The Require Administrative Privileges setting does not apply to InstallScript projects.*

- **Advertise If Prerequisites Are Elevated**—Use this setting in the Releases view to specify whether the .msi package should be advertised—and if so, whether it should be run silently or with the full user interface (UI)—after the InstallShield prerequisites in the installation have been successfully installed with elevated privileges on Windows Vista and later machines. The advertisement may allow end users to avoid the UAC prompt that would otherwise be displayed for an .msi package that requires elevated privileges. For more information, see Specifying Whether a Product Should Be Advertised If Its InstallShield Prerequisites Are Run with Elevated Privileges.

Project • *The Advertise If Prerequisites Are Elevated setting does not apply to InstallScript projects.*

In addition, the type of InstallShield prerequisite—either setup prerequisite or feature prerequisite—may affect whether UAC prompts are displayed during an installation on Windows Vista and later systems. To learn more about these two types of InstallShield prerequisites, see Setup Prerequisites vs. Feature Prerequisites.

Note the following UAC-related behavior on Windows Vista and later:

- If Required Execution Level is set to Invoker, any InstallShield prerequisites in your installation do not require administrative privileges, and Require Administrative Privileges is set to No, end users should see no UAC prompts during installation.
- If Required Execution Level is set to Invoker, your installation includes setup prerequisites that require administrative privileges, and Require Administrative Privileges is set to No, end users should see one UAC prompt—plus up to one additional UAC prompt for each reboot—during installation.
- If the full user interface of the setup launcher is displayed and the installation includes setup prerequisites that need to be installed, the setup launcher typically displays the setup prerequisite dialog before the main installation starts. If one or more of the setup prerequisites that need to be installed require administrative privileges, the Install button on the message box has the shield icon to alert the end user that elevated privileges are required.
- If the installation is continuing after a reboot and privileges must be elevated, the OK button of the continuation message box has the shield icon. If privileges do not need to be elevated, the shield button is not displayed.
- If your installation includes more than one setup prerequisite that must be installed on a target machine and one or more of those setup prerequisites requires administrative privileges, the UAC prompt is displayed before the first setup prerequisite is installed. This may allow elevated privileges to be used for all prerequisites without requiring separate UAC prompts for each prerequisite installation. Note, however, that if a setup

prerequisite installation causes a reboot, administrative privileges are lost, and a UAC prompt may be displayed if any of the remaining prerequisites require administrative privileges.

A slightly different behavior applies to feature prerequisites. If your installation is going to install any features that are associated with prerequisites, the UAC prompt is displayed when the ISInstallPrerequisites custom action relaunches `Setup.exe` in feature prerequisite installation mode. This occurs regardless of whether any of the feature prerequisites require elevated privileges. It also occurs before any of the feature prerequisites' conditions are evaluated to determine whether the feature prerequisites need to be installed. Note that if a feature prerequisite installation causes a reboot, administrative privileges are lost. After the reboot, the ReadyToInstall dialog is displayed again, and the end user needs to click the Install button to proceed with the rest of the installation. In this case, the UAC prompt is displayed again when the ISInstallPrerequisites custom action relaunches `Setup.exe` in feature prerequisite installation mode.

- Note that if Require Administrative Privileges is set to No but your .msi package tries to perform a task for which it does not have adequate privileges, Windows Installer may display a run-time error.
- If privileges are elevated at the end of an installation and the SetupCompleteSuccess dialog launches the product, elevated privileges are carried over to your product. In most cases, running an application with elevated privileges is discouraged.

Sample Scenarios

The following sections contain examples that illustrate different combinations of values for the aforementioned settings in InstallShield. The diagrams show when Windows Vista and later request elevated privileges for standard users or administrative users who have limited privileges. The examples are based on the default UAC settings on Windows Vista and later systems.

Example 1: UAC Prompt Is Displayed for a Prerequisite that Requires Administrative Privileges; .msi File Is Advertised

The example 1 diagram shows an installation that requires elevation for a setup prerequisite, a feature prerequisite, and for the Execute sequence of the .msi package. Windows Vista and later display one UAC prompt for the setup prerequisite, and another one for the feature prerequisite.

If the feature prerequisite was not included or if it was a setup prerequisite instead of a feature prerequisite, the second UAC prompt (which is labeled as *UAC prompt #2* in the diagram) would not be displayed. In these cases, UAC prompt #2 would not be needed because the .msi package is successfully advertised after the setup prerequisite is installed with elevated privileges.

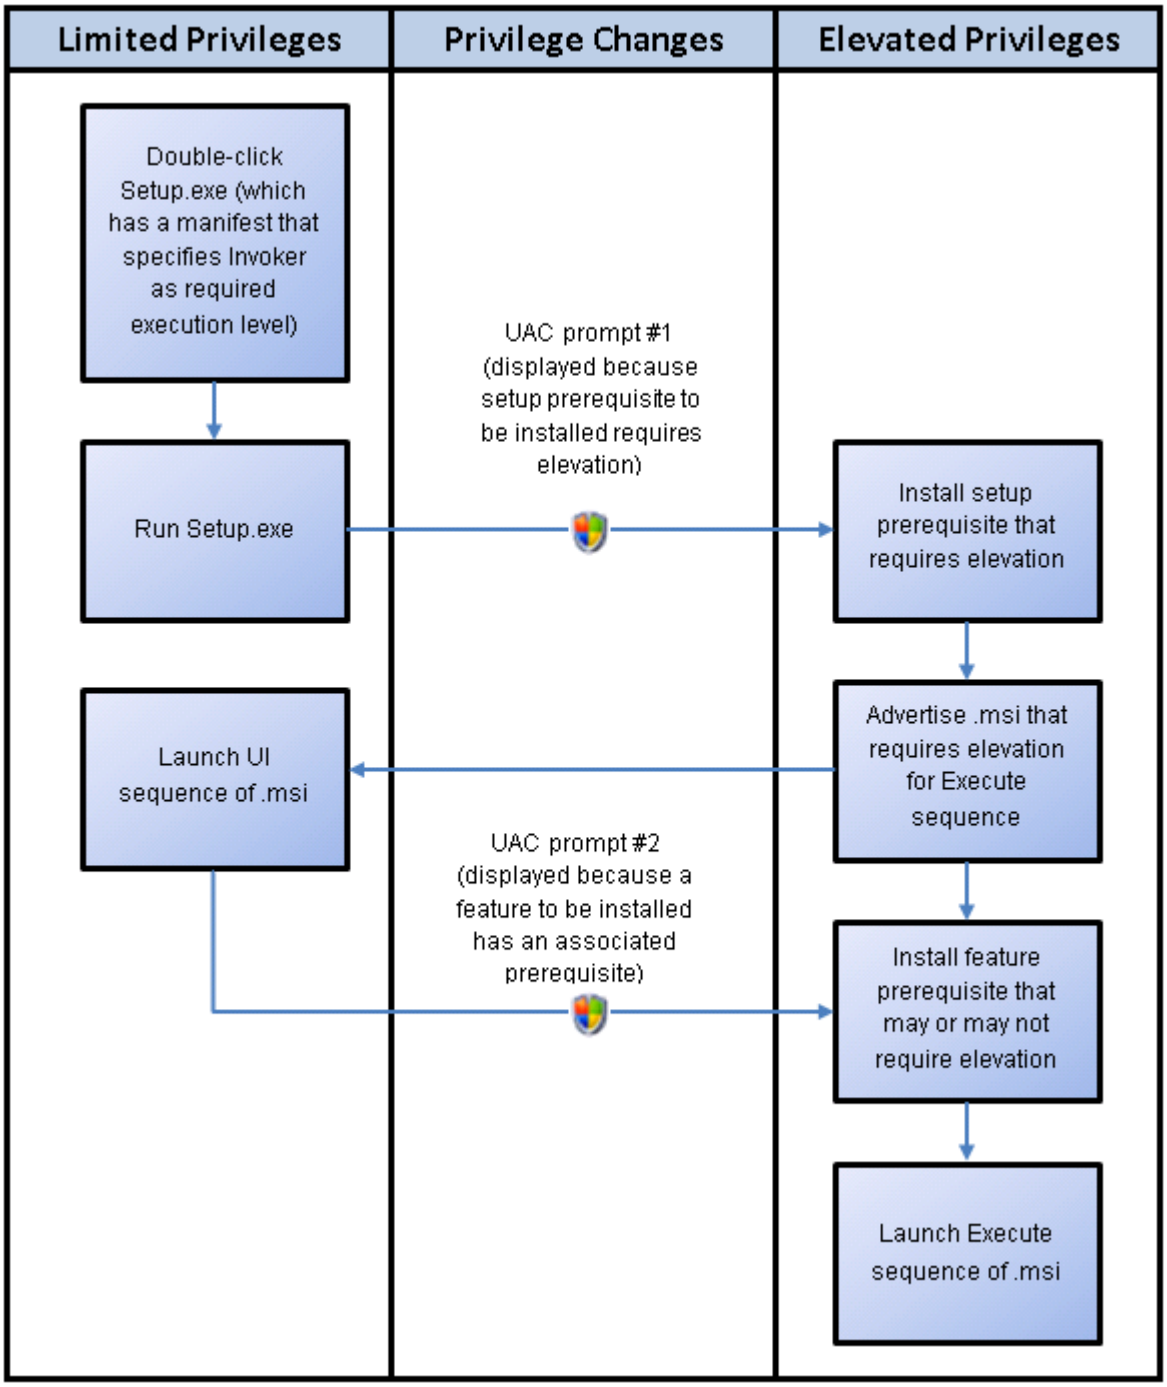

Figure 4-1: Example 1—Diagram of an Installation that Has Invoker as the Required Execution Level and that Advertises the .msi Package

Example 2: UAC Prompt Is Displayed for Setup.exe and After a Reboot for a Prerequisite that Requires Administrative Privileges

The example 2 diagram shows an installation that requires elevation for `Setup.exe`, two setup prerequisites, a feature prerequisite, and the Execute sequence of the .msi package. Because the `Setup.exe` file has a manifest that specifies Administrator as the required execution level, elevated privileges are used for each part of the installation. The second UAC prompt is displayed because elevated privileges are lost during a reboot.

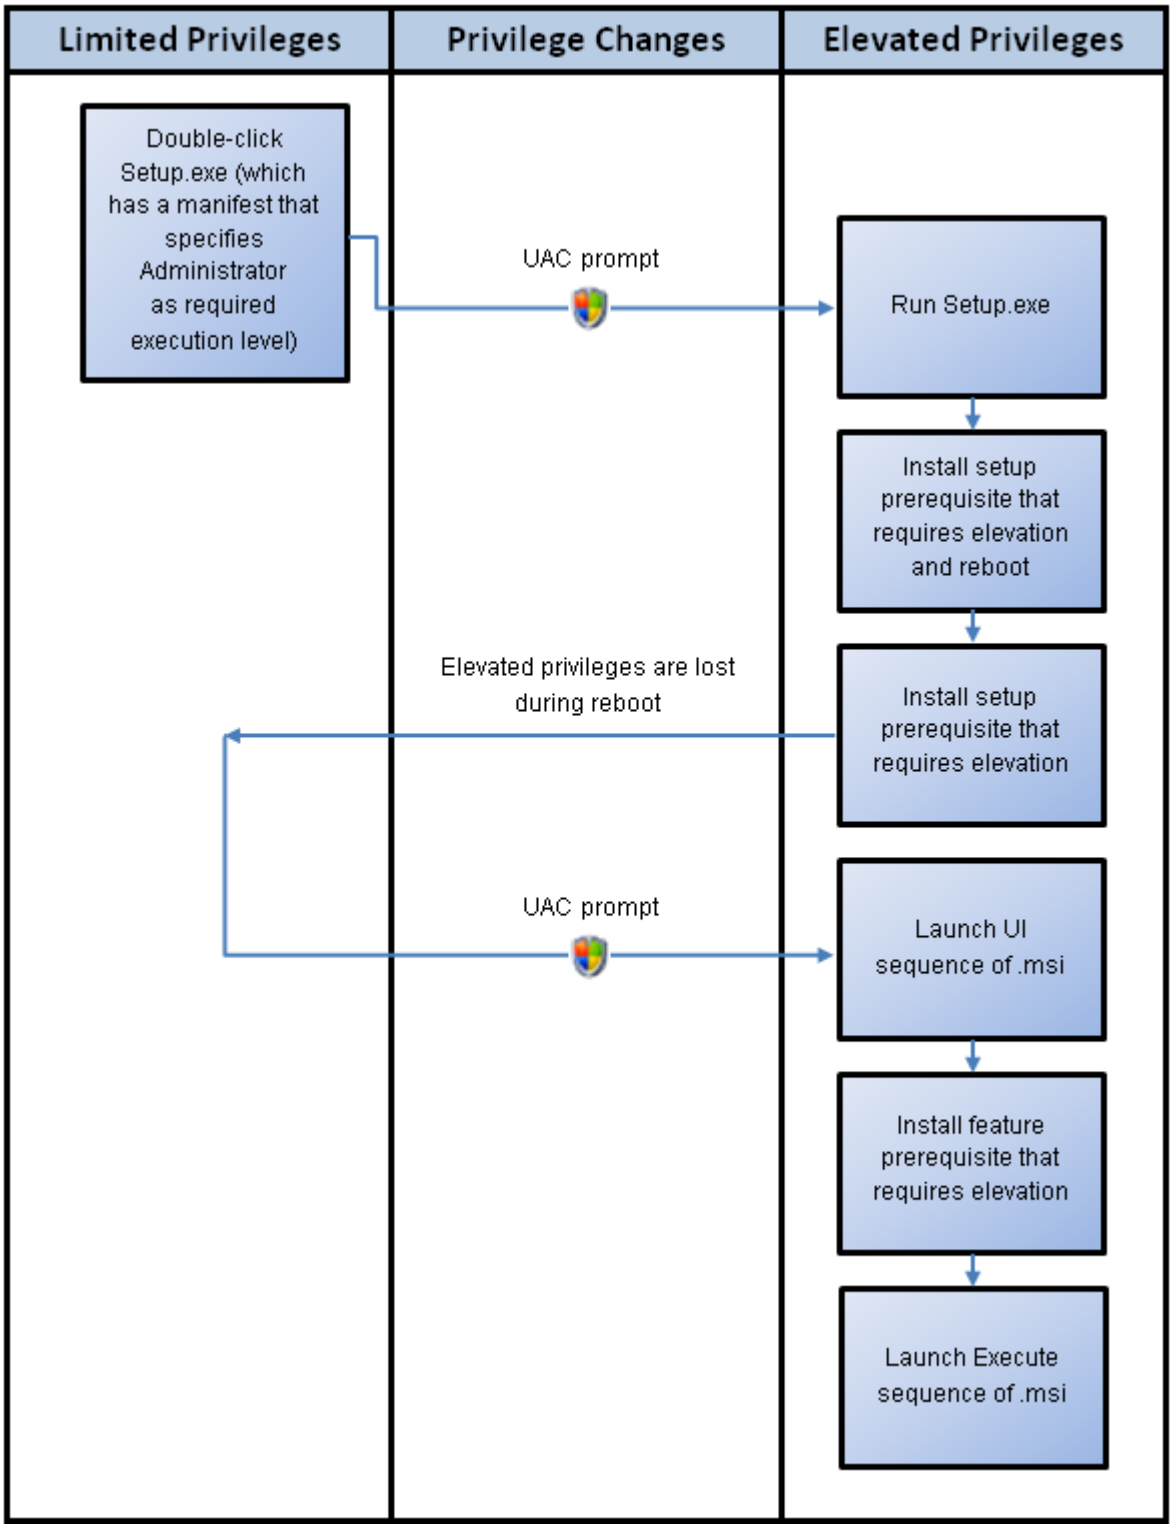

Figure 4-2: Example 2—Diagram of an Installation that Has Administrator as the Required Execution Level

Setting an Application's Disk Usage

Windows Installer uses a process called file costing to determine the total disk space a current installation requires. This encompasses costs for files that will be installed or removed, registry entries, shortcuts, and other components of an installation.

File Costing

File costing takes into account the fact that some files are overwritten by newer versions, which decreases the file cost. These values are dependent on the volume to which each file is to be installed or removed, and they are recalculated when a component's directory association is changed.

File costs are determined for each component, depending on whether it is installed locally, installed to run from the source media, such as a CD, or removed.

With InstallShield, you can set your application's disk usage. This allows you to control file costing by choosing to run your application from the source media, from the local machine, or to install it when required. Note that running your application from the source enhances application resiliency and conserves space on an end user's system.

Application Resiliency

If Windows Installer cannot provide a component, the Windows Installer technology enables applications to try to repair the component or to reinstall the component if the corresponding file is corrupted or the current file is older than the available version.

Source Resiliency

In addition to supporting application resiliency, the Windows Installer supports source resiliency through the Source List, which can include network locations, URLs, or compact discs from which applications are installed on-demand. Administrators can use the Group Policy Editor to disable this functionality.

INSTALLDIR vs. TARGETDIR

INSTALLDIR represents the main product installation directory for a Basic MSI and InstallScript MSI installations, such as the end user launching `Setup.exe` or your .msi database.

TARGETDIR represents the installation directory for an InstallScript installation, or for an administrative Windows Installer–based installation (when the user runs `Setup.exe` or `MsiExec.exe` with the `/a` command-line switch).

In an InstallScript MSI project, the InstallScript variable MSI_TARGETDIR stores the target of an administrative installation.

Preventing the Current Installation from Overwriting a Future Major Version of the Same Product

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

To prevent end users from being able to install the current version of your product over a future major version of the same product, the Upgrades view should contain a major upgrade item, the major upgrade item should be properly configured to prevent the current version of your product from being installed over a future version, and your project should include a properly configured and scheduled type 19 custom action.

When you create a new Basic MSI or InstallScript MSI project, InstallShield automatically adds support for preventing the current installation from overwriting a future major version:

- The Upgrades view contains a major upgrade item called ISPreventDowngrade.

  The **Products sharing my Upgrade Code** option is selected on the Common tab of the major upgrade item. The value of the Upgrade Code setting on the Advanced tab is {000000000000-0000-0000-0000-00000000}. When you build a release, InstallShield uses the release's upgrade code (set in the General Information view, or overridden for the release's product configuration in the Releases view) for the major upgrade item.

  InstallShield sets the Detect Property setting of this major upgrade item to ISFOUNDNEWERPRODUCTVERSION and configures the other settings as appropriate.

- The Custom Actions and Sequences view contains a custom action called ISPreventDowngrade, a type 19 custom action that Windows Installer launches when an end user tries to install the current version of your product over a future major version.

  InstallShield schedules the ISPreventDowngrade custom action for the user interface and execute sequences of the installation sequence so that Windows Installer runs it if appropriate, regardless of what user interface level is used. In addition, InstallShield uses ISFOUNDNEWERPRODUCTVERSION as the condition for this custom action.

The following instructions explain how to manually add this support for projects that you created in InstallShield 12 or earlier and then upgraded to InstallShield 2013.

Task: ***To manually add support for preventing end users from being able to install the current version of your product over a future major version:***

1. Use the **Upgrades** view to add a major upgrade item to your project.
2. On the **Common** tab, select the **Products using my Upgrade Code** option.
3. Configure the settings on the **Advanced** tab for the major upgrade item as follows:
   a. In the Minimum Version setting, specify the product version that you are using for your current project.

b. Leave the Maximum Version setting blank. If a value is listed for this setting, delete it.

c. If your project includes multiple languages, specify the language identifiers in the **Language** setting.

d. In the **Detect Only** setting, select **Yes**; for all of the other Yes-No settings, select **No**.

e. In the **Detect Property** setting, type a descriptive name such as the following one:

```
FOUNDNEWERVERSION
```

4. Add and schedule a type 19 custom action for your project to handle scenarios where an end user tries to install the current version of your product over a future major version:

a. In the **Custom Actions and Sequences** view, right-click the **Custom Actions** explorer and click **New Error**.

b. Select the new custom action.

c. In the **Error Message** setting, type the error message text that should be displayed when an end user tries to install the current version of your product over a future major version.

d. In the **Install UI Sequence** and **Install Exec Sequence** settings, select **After FindRelatedProducts**.

e. In the **Install UI Condition** and **Install Exec Condition** settings, type the value that you specified in step 3e.

Preparing Installations for Non-Administrator Patches

Windows Installer 3.0 and later enables you to create patches that can be installed by non-administrators. Non-administrator patches can be used if strict criteria are met. For example, the base installation that the patch will update must include the certificate that will be used to sign the patch package. To learn about the other criteria that must be met, see Non-Administrator Patches.

Task: ***To prepare a base installation that can later be updated by non-administrator patches:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release whose digital signature information you want to configure.
3. Click the **Signing** tab.
4. Specify the digital signature information.

InstallShield automatically adds the necessary information to the **MsiDigitalCertificate** table and the **MsiPatchCertificate** table. This enables you to create patches that can be installed by non-administrators.

Tip • *The digital signature settings are also available in the Releases view.*

The Windows Installer design enables you to sign a package with one certificate and also allow patches that are signed with a different certificate. The following instructions explain how to add to the base installation the additional certificates for the patches.

Task: ***To add additional digital certificates:***

1. Use a tool such as `Signcode.exe` to sign a dummy file. The `Signcode.exe` file is located in the following directory:

   `InstallShield Program Files Folder``\System`

2. In your original installation project, open the **Direct Editor**.
3. In the **Tables** explorer, click **MsiDigitalCertificate**.
4. Click the last row in the table to add a new entry.
5. In the **DigitalCertificate** field, type a unique name for your certificate.
6. Click the **CertData** field. The **Edit Binary Stream** dialog box opens.
7. In the **File name** box, enter the path and name of the file that you signed in step 1. You can click the browse button to find the file.
8. Click **OK**.
9. In the **Tables** explorer, click **MsiPatchCertificate**.
10. Click the last row in the table to add a new entry.
11. In the **PatchCertificate** field, type a unique name for your patch certificate.
12. In the **DigitalCertificate** field, select the entry that you created for the **MsiDigitalCertificate** table in step 4.

Settings for Platforms and Platform Suites

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Note that some of the settings apply to both of these project types, but some apply only to one of these project types.

InstallShield includes several settings for platforms, platform suites, and languages.

Specifying Platforms at the Project Level

One project-level setting enables you to specify the platforms that your project supports:

- **Platform Filtering**—Use this setting to specify the platforms that you want to be available when you select operating system requirements for components or releases in your project. In general, if a platform is not listed for this setting at the project level, you cannot designate that a particular component or release in your project is targeted for that platform.

The Platforms setting is available for InstallScript projects. To access this setting, open the General Information view. You can also configure this setting through the Project Settings dialog box: on the Project menu, click Settings, and click the Platforms tab.

Note • *Specifying platforms at the project level does not create target system requirements for running the installation. If you want to create target system requirements in an InstallScript project, use the SYSINFO structure to identify the operating platform of the target system.*

For information on how to specify target system requirements for InstallScript MSI projects, see Specifying Operating System Requirements in the Project Assistant.

Specifying Operating Systems and Platform Suites at the Component Level

Two component-level settings enable you to specify platform information for a component:

- **Operating Systems**—If a component is specific to one or more operating systems, use this setting to indicate those operating systems. If the target machine's operating system does not match one of the operating systems that are specified for this setting, the component is not installed.

  By default, components are operating system independent, meaning that none of the component's data are specific to certain operating systems.

  The Operating Systems setting is available for InstallScript and InstallScript MSI projects. To access this setting, open the Components view and select a component.

- **Platform Suite(s)**—If a component is specific to one or more platform suites, use this setting to indicate the suites. If you specify more than suite, you can indicate whether all or any of the suites must be present on the target machine in order for the component to be installed.

  By default, components are platform suite independent, meaning that none of the component's data are specific to a particular platform suite.

  This setting provides an additional layer of filtering beyond the Operating Systems setting. Set the Platform Suite(s) setting only if necessary, and be sure to select only those platform suites that are required for the proper functioning of your application. For example, if a component should be installed on both the Home and Professional editions of Windows XP, you can leave Suite Independent as the value for this setting; selecting Windows XP for the Operating Systems setting encompasses both editions.

  The Platform Suite(s) setting is available for InstallScript projects. To access this setting, open the Components view and select a component.

Specifying Platforms at the Release Level

One release-level setting enable you to specify platform information for a release:

- **Platform(s)**—If a release is specific to one or more platforms, use this setting to indicate the platforms. If the platform specified for a component does not match one of the platforms that is selected for this setting, InstallShield does not include the component in the release.

  The default value for this setting is Use Project Setting. This value indicates that the release supports the platforms that are specified at the project level.

The Platform(s) setting is available for InstallScript projects. To access this setting, open the Releases view and select a release. You can also configure this setting through the Platforms panel in the Release Wizard.

Controlling Support for Platforms and Platform Suites at Run Time for InstallScript Projects

During run time of InstallScript installations, you can control the platforms and platform suites that your installation supports by calling the **FeatureFilterOS** function.

In the **OnFilterComponents** event handler, the framework typically calls this function with the platforms and platform suites that match the target system so that only the appropriate components are installed. By calling **FeatureFilterOS**, you can override this default behavior to install or prevent the installation of components based on any platform or platform suite criteria that you specify.

For more information, see FeatureFilterOS.

Specifying Installation Information

As you begin creating your installation project, you will need to specify important installation information at the outset. This includes specifying product and project settings and configuring Add or Remove Programs settings.

Configuring General Project Settings

InstallShield stores your project settings in a single installation project file (.ism file). This file stores all of the information about your project. In the General Information view, you can edit basic information about your installation project—including the author's name, the languages that the project supports, and any comments that you want to include.

The General Information view is also where you configure general product information such as the product name, the product code (GUID), and the version number. A product is the top level of organization in an installation project. The installation is further divided into features and components, which are subsets of your product. Although an installation can contain multiple features and components, it can have only one product.

For detailed information about each of the project and projects settings that are available, see General Information View.

Saving an InstallShield Project File (.ism) in XML or Binary Format

InstallShield lets you save your .ism project file in XML or binary format.

Task: ***To specify the format of your project file:***

1. In the View List under **Installation Information**, click **General Information**.
2. In **Project File Format** setting, select the appropriate option. Available options are:
   - **Binary**—To save the project file as a database file, select this option. This format is best for the speed of opening and saving the project file.
   - **XML**—To save the project file as a hierarchical text-based format, select this option. This project file format is best for use with source code control systems.

Note • *Your InstallShield project file (.ism) retains the .ism file extension when you save it in XML or binary format.*

Advanced UI and Suite/Advanced UI projects (.issuite) are always saved as XML files.

Specifying a Product Name

Enter the name of your product in the Product Name setting of the General Information view. The name that you enter should be the name of the product for which you are creating an installation. This value is used throughout your project, in various instances; for example:

- The name of the source file folder under the project location
- In Basic MSI and InstallScript MSI projects: the name of the Windows Installer package (.msi file) that InstallShield builds by default
- In run-time dialogs
- Under the informational registry key in accordance with Windows logo requirements. The informational values are found in the following location and are used in Add or Remove Programs to enable an end user to change or remove your product.

  HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Uninstall*ProductCode*

Since it will be incorporated into the paths for your source files, the product name cannot contain any of the following characters: \ / : * ? " < > | . -

Tip *• In an InstallScript or InstallScript MSI project, you can use the UNINSTALL_DISPLAYNAME variable to specify a different product display name in Add or Remove Programs.*

For Basic MSI and InstallScript MSI projects—If you do not want to use the product name for the .msi package file name, you can use the MSI Package File Name setting on the General tab for a product configuration in the Releases view and specify a different .msi file name. Note that if you want to be able to release minor upgrades or small updates to update your product, the previous and latest versions of your installation must have the same .msi package name. Attempting to perform a minor upgrade or a small update when the .msi file name has changed can lead to Windows Installer run-time error 1316.

Caution *• If you want to include an ampersand (&) in your product name, you must use two ampersands (&&) to display the name properly in end user dialogs. For example, to display* ***New & Improved Product****, you should enter the product name as* `New && Improved Product`*.*

Specifying the Product Version

When you are specifying the version number for your product, you must ensure that you enter a valid product version. The version must contain only numbers. It is typically in the format *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. The maximum value for the *aaa* and *bbb* portions is 255. The maximum value for *ccccc* and *ddddd* is 65,535.

At run time, the installation registers the version number of the product that is being installed. The entire version string is displayed in Add or Remove Programs. The product version number is important because the installation engine uses it in part to determine whether to apply an upgrade.

You can configure the product version in the General Information view.

Note that although you can include the fourth field (*ddddd*) when you specify your product's version, the installation does not use this part of the product version to distinguish between different product versions.

Project • *For Advanced UI, Basic MSI, InstallScript, InstallScript MSI, and Suite/Advanced UI projects—If your release includes a* `Setup.exe` *file, the product version that you specify is displayed on the Properties dialog box for* `Setup.exe`*. For more information, see Customizing File Properties for the Setup Launcher.*

For InstallScript and InstallScript Object projects—Instead of hard-coding a value, you can use a path variable that is defined in the Path Variables view. At build time, InstallShield replaces the path variable with the appropriate value. (To use a path variable: On the Project menu, click Settings. Then select the appropriate path variable on the Application tab.)

Product Version Numbers in InstallScript and InstallScript Object Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

By default, InstallScript projects use version numbers in packed DWORD format—that is, as a four-byte value whose first byte is the major version, second byte is the minor version, and last two bytes are the build number. Packed DWORDS are entered and displayed in the format major.minor.build; for example, 1.2.3 or 255.255.65535. Packed DWORD version numbers are assumed in the default script code for registering the version number of the product that is being installed, and for comparing that version number to that of the already installed product during an update installation.

If any of these version numbers are not in packed DWORD format, you must modify the script code as discussed in the following sections.

Version Number of the Already Installed Product

The default **OnSetUpdateMode** event handler function code compares the version number of the product that is being installed, and the version numbers to which the update can be applied (as specified in the Release property sheet), to the system variable `IFX_INSTALLED_VERSION`. The installation automatically attempts to initialize the value of this system variable to the string equivalent of the data in the Version value under the application uninstallation registry key. If that value does not exist, or its data is not a packed DWORD, then the value of `IFX_INSTALLED_VERSION` is a null string (""), in which case the default **OnSetUpdateMode** code displays an error message and aborts the installation. One solution is to insert code that checks the version information on the system and sets `IFX_INSTALLED_VERSION` equal to an appropriate packed DWORD value. For example, if previous installations stored a version string in the MyVersion value under HKEY_LOCAL_MACHINE\SOFTWARE\MyCompany\MyProduct, you could insert code like the following:

```
if (IFX_INSTALLED_VERSION="") then
    /* Get the registered version information. */
    RegDBSetDefaultRoot( HKEY_LOCAL_MACHINE );
    RegDBGetKeyValueEx( "Software\\MyCompany\\MyProduct",
        "MyVersion", REGDB_STRING, szVersionString, nSize );

    /* Assign a value to IFX_INSTALLED_VERSION. */
    switch (szVersionString)
        /* A registered version string of "A" corresponds to an existing version number of 1.0.0. */
        case "A":
            IFX_INSTALLED_VERSION = "1.0.0";
        /* A registered version string of "B" corresponds to an existing version number of 1.1.0. */
        case "B":
            IFX_INSTALLED_VERSION = "1.1.0";
        /* An absent version string corresponds to an existing version number of 0.0.0. */
        default:
            IFX_INSTALLED_VERSION = "0.0.0";
    endswitch;
endif;
```

Version Number of the Product that Is Being Installed

The default **OnMoveData** event handler function code calls **RegDBSetVersion** to take the product version number that you entered in the General Information view and enter it in the target system's registry. **RegDBSetVersion** assumes that the product version is in packed DWORD format. If you want to register a product version that is not in packed DWORD format, you must replace OnMoveData's call of **RegDBSetVersion** with code like the following:

```
/* The setup automatically initializes the value of the system variable
IFX_PRODUCT_VERSION to the product version that you entered in the
Product Version setting in the General Information view. */
RegDBSetItem(REGDB_UNINSTALL_VERSION, IFX_PRODUCT_VERSION );
RegDBSetItem(REGDB_UNINSTALL_DISPLAY_VERSION, IFX_PRODUCT_VERSION );
```

RegDBSetItem must be called after **MaintenanceStart**.

Setting the Product Code in a Windows Installer–Based Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The product code is a string that uniquely identifies your product. An installation uses a product code at run time to determine whether the product has already been installed.

Enter a GUID that uniquely identifies your product, or click the **Generate a new GUID** button ({...}) in the Product Code setting in the General Information view to let InstallShield generate a new GUID. The installation registers this GUID at run time.

Caution • *Because the product code uniquely identifies your product, changing the code after distributing a release of your product is not recommended.*

Setting the Product Code in an InstallScript-Based Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The product code is a GUID string that uniquely identifies your product. An installation uses a product code at run time to determine whether the product has already been installed.

Enter a GUID that uniquely identifies your product, or click the **Generate a new GUID** button ({...}) in the Product Code setting in the General Information view to let InstallShield generate a new GUID. The installation registers this GUID at run time.

Caution • *The project GUID is used to associate uninstallation or maintenance with the original installation. A new GUID is automatically generated for each new project that you create, including copies of existing projects. Once you have changed a project's GUID, its previous GUID cannot be recovered. For these reasons, changing a project's GUID is typically not necessary and should be approached with caution.*

Setting the Upgrade Code

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *QuickPatch*
- *Transform*

The upgrade code is a GUID that identifies a related set of products. The Windows Installer uses a product's upgrade code when performing major upgrades of an installed product. The upgrade code, stored in the **UpgradeCode** property, should remain the same for all versions of a product.

To configure the GUID for a new product, use the Upgrade Code setting in the General Information view. When you are working on an upgrade for a later version of your product, enter the same upgrade GUID in the Upgrades view or in your QuickPatch project.

Setting Product Conditions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Installation Requirements page in the Project Assistant lets you specify some commonly used installation requirements for the target system. For example, if your application requires a specific operating system in order to run properly, you can indicate that on the Installation Requirements page.

InstallShield also enables you to define your own custom conditions that Windows Installer must evaluate before your product can be installed. Conditions that you create in the General Information view and on the Installation Requirements page in the Project Assistant apply to the entire product; if one or more of the conditions are false on the target system, the installation exits and an error message is displayed.

For example, if your product requires 64 MB of RAM in order to run properly, you can use the Product Condition Builder dialog box to create a condition. At run time, the Windows Installer checks the target system to determine how much RAM is installed. If it is less than 64 MB, or if any of the other product conditions are false, the Windows Installer displays an error message and exits the installation.

Tip • *You cannot guarantee the order in which Windows Installer evaluates product launch conditions. If it is necessary to control the order in which the conditions are evaluated, you can create an error custom action in the Custom Actions and Sequences view for each condition, and schedule them in the appropriate order.*

Task: ***To create a custom launch condition for your product's installation:***

1. In the View List under **Installation Information**, click **General Information**.
2. Click the **Install Condition** setting and then click the ellipsis button (**...**). The **Product Condition Builder** dialog box opens.
3. Click the **New Condition** button. InstallShield adds a new condition row to the **Conditions** box.
4. Do one of the following:
   - In the **Condition** column, type the launch condition.
   - Use the **Properties** list, the **Operators** list, and the **Add** buttons to build your conditional statement:
     a. In the **Properties** list, select a property and then click the **Add** button. InstallShield adds the property to the **Condition** column.
     b. If your conditional statement should contain an operator, select an operator in the **Operators** list and then click the **Add** button. InstallShield adds the operator to the conditional statement.

c. If your conditional statement should contain a value, double-click the condition field, press END so that the insertion point is at the end of the condition statement, and enter the value.

5. In the **Message** column, enter the error message that you would like to be displayed if the condition evaluates to false.

   When you type a value for this column, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can double-click this setting and then click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.

   

   Note • *Windows Installer dialogs, which display the text that you specify in the Message column, do not recognize the escape sequences \r (carriage return), \n (new line), or \t (tab).*

6. Click **OK**.

Important • *InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Building Conditional Statements.*

Setting the Default Product Destination Folder (INSTALLDIR)

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Your project's **INSTALLDIR** property serves as the default folder for all of your product's files. Its value is assigned to the Windows Installer folder property **INSTALLDIR**, which is the default feature and component destination folder.

Windows Logo • *According to the Windows logo program requirements, the default destination of your product's files must be a subfolder of the Program Files folder or the end user's Application Data folder, regardless of the language of the target system. If you use ProgramFilesFolder as the parent folder for your product's destination folder setting, your files are installed to the correct location. The default value for the INSTALLDIR setting is:*

`[ProgramFilesFolder]`*`Company Name\Product Name`*

Task: ***To set a product's INSTALLDIR property:***

1. In the View List under **Installation Information**, click **General Information**.
2. To use a built-in Windows Installer directory as part of your path: In the **INSTALLDIR** setting, click the ellipsis button (...) . The **Set INSTALLDIR** dialog box opens. In the **Destination Directories** box, select a destination folder.

   As an alternative, you can manually enter the path in the **INSTALLDIR** setting.

Note • *Selecting a new folder property in the Set INSTALLDIR dialog box overwrites the contents of the value in the INSTALLDIR setting. You can specify a subfolder of any folder property by separating subfolders with a backslash—for example,* ***[ProgramFilesFolder]My Company\Program****.*

Other Destination Folder Considerations (Windows Installer–based projects only)

Setting the feature's Remote Installation setting to Favor Source—or to Favor Parent when the subfeature's parent feature is set to Favor Source—means that the feature's files will not be installed on the target system, regardless of the product's **INSTALLDIR** property.

Each feature and component has a Destination setting. The feature's Destination setting overrides the product's Destination Folder setting, and the component's Destination setting overrides the feature's. Therefore, if you want all of your product's files to be installed by default to the product's destination folder, enter `[INSTALLDIR]` for all of your features' and components' Destination settings.

When using an installer folder property such as **INSTALLDIR**, you are specifying a *default* value. An end user could change this value by setting a property when launching `Msiexec.exe` at the command line or by selecting a new destination folder for a feature in the CustomSetup dialog.

Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment

InstallShield offers several ways to secure files, folders, registry keys, and Windows services for end users who run your product in a locked-down environment:

- **Traditional Windows Installer handling**—In Windows Installer–based projects, you can choose to use the built-in Windows Installer support for setting permissions for files, folders, and registry keys at run time. With this option, InstallShield stores permission information for your product in the **LockPermissions** table of the .msi database.

  This type of permission handling cannot be combined with the new Windows Installer handling; if you try to build a release that contains the **MsiLockPermissionsEx** table and the **LockPermissions** table, build error -7207 occurs.

- **New Windows Installer handling**—In Windows Installer–based projects, you can choose to use the latest Windows Installer support for setting permissions for files, folders, registry keys, and Windows services at run

time. With this option, InstallShield stores permission information for your product in the **MsiLockPermissionsEx** table of the .msi database.

This option requires Windows Installer 5 or later on the target system; earlier versions of Windows Installer ignore settings for this type of handling.

This type of permission handling cannot be combined with the traditional Windows Installer handling; if you try to build a release that contains the **MsiLockPermissionsEx** table and the **LockPermissions** table, build error -7207 occurs.

- **Custom InstallShield handling**—In Windows Installer–based projects, you can choose to use custom support for setting permissions at run time. With this option, InstallShield stores permission information for your product in the custom **ISLockPermissions** table of the .msi database. InstallShield also adds custom actions to your project.
- **SetObjectPermissions, an InstallScript Function**—You can use the **SetObjectPermissions** function in InstallScript events and InstallScript custom actions to set permissions at run time.

All of these methods enable you to assign permissions for a file, folder, or registry key to specific groups and users. For example, you may assign Read, Write, and Delete permissions for a particular file to the Administrators group, but only Read permissions for all of the users in a different group. The new Windows Installer handling option also lets you assign permissions for a Windows service.

Determining Which Option to Use

The following table compares the different types of methods for setting permissions.

Table 4-1 • Comparison of Different Ways to Secure Objects in a Locked-Down Environment

Comparison Category	Explanation of Available Support
Project type	• **Traditional Windows Installer handling, New Windows Installer handling, and Custom InstallShield handling**—Available in the following project types: Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform. • **SetObjectPermissions function**—Available in InstallScript events in the following project types: InstallScript, InstallScript MSI. Also available through InstallScript custom actions in the following project types: Basic MSI, DIM, InstallScript MSI, and Merge Module.
Well-known security identifiers (SIDs)	• **Traditional Windows Installer handling**—Supports a limited number of SIDs (Administrators, Everyone). • **New Windows Installer handling, Custom InstallShield handling, SetObjectPermissions function**—Supports many SIDs (Administrators, Authenticated Users, Creator Owner, Everyone, Guests, Interactive, Local Service, Local System, Network Service, Power Users, Remote Desktop Users, and Users).

Table 4-1 • Comparison of Different Ways to Secure Objects in a Locked-Down Environment (cont.)

Comparison Category	Explanation of Available Support
Localized names for SIDs	• **Traditional Windows Installer handling**—Does not support localized names for SIDs; if you try to use a localized name, the installation fails. • **New Windows Installer handling, Custom InstallShield handling, and SetObjectPermissions function**—Supports localized names for all of the supported well-known SIDs (Administrators, Authenticated Users, Creator Owner, Everyone, Guests, Interactive, Local Service, Local System, Network Service, Power Users, Remote Desktop Users, and Users).
Ability to deny specific permissions	• **Traditional Windows Installer handling**—Not supported. This handling lets you set specific permissions; you cannot deny permissions. Thus, you can give a user read-only access to a file. However, you cannot prevent a user from having read-only access. • **New Windows Installer handling, Custom InstallShield handling, and SetObjectPermissions function**—Supported. These options let you indicate whether you want to deny a user or group from having the permissions that you are specifying.
Effect on permissions that already exist	• **Traditional Windows Installer handling**—Existing permissions may be deleted. For example, if permissions are already set for a folder on the target system for the Everyone user, and your installation needs to set permissions for the Administrators user, this option would allow you to set permissions for the Administrators user. However, the existing permissions for Everyone would be deleted. • **New Windows Installer handling, Custom InstallShield handling, and SetObjectPermissions function**—These options let you add permissions to a file, folder, or registry key that already exists on the target system, without deleting any existing permissions for that object. For example, if permissions are already set for a folder on the target system for the Everyone user, and your installation needs to set permissions for the Administrators user, these options would allow you to set permissions for the Administrators user without deleting the existing permissions for the Everyone user.
Ability to propagate permissions to child objects (subfolders, files, and subkeys)	• **Traditional Windows Installer handling**—Not supported. If you want to configure permissions for a subfolder or a file in a folder (or a subkey under a registry key), the parent that is created on the target system automatically inherits the permissions of its child. • **New Windows Installer handling, Custom InstallShield handling, and SetObjectPermissions function**—Supported. These options let you configure permissions for a folder (or a registry key), and indicate whether you want the permissions to be applied to all of the folder's subfolders and files (or the registry key's subkeys).

Table 4-1 • Comparison of Different Ways to Secure Objects in a Locked-Down Environment (cont.)

Comparison Category	Explanation of Available Support
Ability to set permissions for objects that are not being installed as part of your installation	• **Traditional Windows Installer handling, New Windows Installer handling, and Custom InstallShield handling**—Not supported. • **SetObjectPermissions function**—Supported. You can secure permissions for a file, folder, or registry key that is installed as part of your installation, or it can be already present on the target system.
Ability to set permissions for a new user that is being created during the installation	• **Traditional Windows Installer handling**—Not supported. • **New Windows Installer handling, Custom InstallShield handling, and SetObjectPermissions function**—Supported. If a new user is created during the installation, you can configure permissions for that user.

Learning More about the Custom InstallShield Handling Option or the Traditional Windows Installer Handling Option

In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects, you need to specify whether you want to use the custom InstallShield handling or the Windows Installer handling. To learn how, see Selecting the Locked-Down Permissions Type for a Project.

To learn how to set permissions for a file or folder using either of these options, see Configuring Permissions for Files and Folders. For information on setting permissions for a registry key using either of these options, see Configuring Permissions for Registry Keys.

Learning More about the New Windows Installer Handling Option

To use the new Windows Installer handling option for a service, add a service to your project and then configure its settings. For more information, see Installing, Controlling, and Configuring Windows Services.

To use the new Windows Installer handling option for files, folders, or registry keys, use the **MsiLockPermissionsEx** table in the Direct Editor view.

Learning More about the InstallScript Function SetObjectPermissions

For information on the **SetObjectPermissions** function, see SetObjectPermissions.

Selecting the Locked-Down Permissions Type for a Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield includes a project-wide setting that lets you specify how your installation should configure permissions for files, folders, and registry keys for end users in a locked-down environment.

Task: ***Selecting the locked-down permission type for a project:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Locked-Down Permissions** setting, select the appropriate option:
   - **Custom InstallShield handling**—InstallShield adds a custom table and custom actions to your project to set permissions on the target system. This is the default value.
   - **Traditional Windows Installer handling**—InstallShield uses the **LockPermissions** table in the .msi database to store permissions information for your product.

For a detailed comparison of these two options, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.

The next time that you configure permissions for a file, folder, or registry key in your project, InstallShield uses the locked-down permission type that you selected:

- If you selected the traditional Windows Installer handling option, InstallShield uses the **LockPermissions** table in your project.
- If you selected the custom InstallShield handling option, InstallShield uses the **ISLockPermissions** table in your project; InstallShield also adds the ISLockPermissionsCost and ISLockPermissionsInstall custom actions to your project.

If you change the value of the Locked-Down Permissions setting but your project already contains permission settings for files, folders, or registry keys, InstallShield displays a message box that lets you specify whether you want to migrate the permission data to the appropriate table. If you choose to migrate the data, InstallShield moves the data to the table that corresponds with the option that you selected; if you are switching from the custom InstallShield handling option to the traditional Windows Installer handling option, InstallShield also deletes the ISLockPermissionsCost and ISLockPermissionsInstall custom actions from your project.

Specifying Whether Windows Installer Installations Should Be Logged

InstallShield enables you to specify on a project-wide basis whether Windows Installer 4.0 or later should log your installation. You can also customize the types of messages that are logged.

Task: ***To specify project-wide logging information for Windows Installer 4.0 or later:***

1. In the View List under **Installation Information**, click **General Information**.
2. Click the **Create MSI Logs** setting, and then click the ellipsis button (**...**). The **Logging Options for Windows Installer 4.0 and Later** dialog box opens.
3. Select the appropriate option. If you select the custom option, enter the MsiLogging value.

   For a list of valid parameters for the MsiLogging value, see MsiLogging Property in the Windows Installer Help Library.
4. Click **OK**.

The results vary, depending on which option you select in the Logging Options for Windows Installer 4.0 and Later dialog box:

- If you select No, installations are not logged. This is the default value.
- If you select Yes, InstallShield populates the **MsiLogging** property with the default value of *voicewarmupx*. If the installation is run on a target system that has Windows Installer 4.0, the following occurs:
  - The installer creates a log file according to the default logging mode of *voicewarmupx*.
  - The installer populates the **MsiLogFileLocation** property with the log file's path.
  - A **Show the Windows Installer log** check box is added to the SetupCompleteSuccess, SetupCompleteError, and SetupInterrupted dialogs. If the end user selects that check box and then clicks Finish, the log file is opened in a text file viewer or editor.
- If you select Custom, InstallShield populates the **MsiLogging** property with the value that you specify in the box. If the installation is run on a target system that has Windows Installer 4.0, the following occurs:
  - The installer creates a log file according to the custom value that you specified in the box.
  - The installer populates the **MsiLogFileLocation** property with the log file's path.
  - A **Show the Windows Installer log** check box is added to the SetupCompleteSuccess, SetupCompleteError, and SetupInterrupted dialogs. If the end user selects that check box and then clicks Finish, the log file is opened in a text file viewer or editor.

Earlier versions of Windows Installer ignore the MsiLogging setting. The **Show the Windows Installer log** check box is not visible in run-time dialogs that are displayed on systems running earlier versions of Windows Installer.

Important • *The **MsiLogFileLocation** property is read-only; it cannot be used to set or change the log file location.*

Running an InstallScript Installation Multiple Times

The InstallScript project type offers several options for the behavior of your installation when a target machine already has your product installed and the end user reruns the installation.

Table 4-2 • Maintenance Experience Settings

Maintenance Experience	When Maintenance UI Is Displayed	Number of Entries Created in Add or Remove Programs
Standard	Whenever the installation is rerun	One
Multi-Instance	Only when the installation is rerun from the Add or Remove Programs	Multiple—a separate entry for each instance
No uninstall or maintenance	Never	None

You can select these options from the Maintenance Experience setting in the General Information view.

For the default behavior—the standard option—the maintenance user interface is displayed if end users rerun an installation on machines.

The multi-instance option lets your end users rerun an installation multiple times as a first-time installation rather than as a maintenance installation. By default, this option lets end users install the product to a different location each time that they run the installation. Each time that they run the installation as a first-time installation, the components that they select (whether directly or by selecting a setup type) are installed.

If one or more instances of your product are present on a machine when an end user reruns the multi-instance installation with a user interface, the installation displays the Qualifying Product(s) Detected dialog. This dialog enables the end user to select the instance to which the update should be applied. However, if the end user reruns the installation silently, the installation suppresses the Qualifying Product(s) Detected dialog and creates a new instance on the machine.

Project • *For information on multiple-instance support in Basic MSI projects, see Installing Multiple Instances of Products.*

Configuring the Enable Maintenance Setting

Project • *This information applies to InstallScript MSI projects.*

Use the Enable Maintenance setting in the General Information view to indicate whether you want to display the full maintenance user interface (UI) or the uninstallation UI when end users rerun the installation on a system on which the product is already present.

The following table shows the available options for the Enable Maintenance setting.

Table 4-3 • Enable Maintenance Setting Options

Option	Description
Yes	Unless the `/removeonly` command-line parameter is passed to `Setup.exe`, the system variable REMOVEONLY is set to FALSE when an end user reruns the installation, and the standard maintenance UI is displayed.
No	The system variable REMOVEONLY is set to TRUE when an end user reruns the installation, and the uninstallation UI is displayed. ***Note*** • *Selecting No for the Enable Maintenance setting does not cause the OnUninstall event handler to be called. If you want the OnUninstall event handler to be called, you must use the `/uninst` command-line parameter for `Setup.exe`. Note that this is applicable only if the InstallScript UI style is the traditional style, which uses the InstallScript engine as an external UI handler. The `/uninst` command-line parameter is not supported if the InstallScript UI style is the new style (which uses the InstallScript engine as an embedded UI handler). To learn more, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.*

Note • *InstallScript MSI installations show separate Change and Remove buttons in Add or Remove Programs in the Control Panel by default. Clicking the Change button always displays the maintenance UI, and clicking the Remove button always displays the uninstallation UI.*

The Enable Maintenance setting has no effect on the behavior that occurs if end users initiate maintenance for your product by clicking the Change button for your product's entry in Add or Remove Programs.
If you want to prevent end users from being able to run maintenance from within Add or Remove Programs, select Yes for the Disable Change Button setting in the General Information view.

Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations

Project • *This information applies to InstallScript MSI projects.*

InstallScript MSI installations use two different installer engines:

- The Windows Installer engine runs the standard Execute sequence of the .msi package. This is the sequence that typically modifies the target system.
- The InstallScript engine serves as the custom user interface (UI) handler of the installation. It also executes the InstallScript code. The advantage of using the InstallScript engine for the UI is that it offers support for highly customized run-time dialogs.

Traditionally, Windows Installer has had support for only external custom UI handlers; therefore, InstallScript MSI installations have always required a `Setup.exe` setup launcher. The setup launcher serves as a bootstrap application that initiates the InstallScript engine to display the UI and run the InstallScript code, and the Windows Installer to run the Execute sequence of the .msi package.

Windows Installer 4.5 introduces support for embedded custom UI handlers. If the InstallScript engine is embedded within the .msi package, an InstallScript MSI installation does not require the `Setup.exe` setup launcher; end users can launch the installation by launching the .msi package. In this case, the .msi package contains the information that the Windows Installer needs to know about launching the InstallScript engine for the installation's UI.

Thus, InstallShield offers two different styles for the UI of InstallScript MSI installations:

- Traditional style (requires a `Setup.exe` setup launcher)—This style lets you use the InstallScript engine as an external UI handler for your InstallScript MSI installation. This is the default style.
- New style (requires Windows Installer 4.5 on the target machine)—This style lets you use the InstallScript engine as an embedded UI handler for your InstallScript MSI installation. With this style, InstallShield embeds the InstallScript engine within the .msi package. Note that this option has some limitations.

The following sections provide detailed information about these two styles; review this information to determine which style would best meet your requirements.

Traditional Style (InstallScript Engine as an External UI Handler)

The general flow in a traditional-style InstallScript MSI package during a first-time installation is as follows:

1. The InstallScript engine opens the .msi package.
2. All actions in the Installation UI sequence are run with the exception of the ExecuteAction. The actions are run in ascending sequence order.
3. The InstallScript engine performs its own internal component costing to determine the space required for all features and components in the installation.
4. The InstallScript engine launches the compiled script contained in `ISSetup.dll`. The event sequence for the events that are run before the .msi package installation is as follows:
    a. OnBegin
    b. On*Xxx*UIBefore (where Xxx is First, Maint, Admin, Patch, Resume, etc.)
    c. OnGeneratingMsiScript
    d. OnMoving
    e. OnFeaturesInstalling (Any feature installing and uninstalling events are run at this point.)
    f. OnInstallFilesActionBefore
    g. OnGeneratedMsiScript
5. The InstallScript engine launches the .msi package installation through **MsiInstallProduct**. The following factors determine the command line that the InstallScript engine passes through **MsiInstallProduct**: installation mode (for example, first-time installation, maintenance mode, minor upgrade, patch), internal feature selections, and current property values.

6. If the .msi package installation is successful, the InstallScript engine writes the secondary uninstall key (InstallShield_{ProductCode}) to the machine and then launches the following events:
    a. OnInstallFilesActionAfter
    b. OnFeaturesInstalled (Any feature installed and uninstalled events are run at this point.)
    c. OnMoved
    d. On*Xxx*UIAfter (where *Xxx* is First, Maint, Admin, Patch, Resume, etc.)
    e. OnEnd
7. After the script has completed, the InstallScript engine writes the InstallScript log to the machine.
8. The InstallScript engine shuts down.

New Style (InstallScript Engine as an Embedded UI Handler)

The InstallScript MSI embedded UI support attempts to follow the same general flow as traditional-style InstallScript MSI installation. However, there are certain portions of the flow that do not occur or are unnecessary. The general flow in a new-style InstallScript MSI package during a first-time installation is as follows:

1. The .msi package is launched directly or by `Setup.exe` (which then launches `Msiexec.exe`, which is the same behavior for a Basic MSI installation).
2. The Windows Installer engine extracts all files that are in the **MsiEmbeddedUI** table and calls the initialize embedded UI function in the DLL that contains the embedded UI handler attribute. (In the InstallScript MSI case, this is `ISSetup.dll`).
3. The InstallScript engine initializes and manually launches the ISSetupFilesExtract action if it is present and its condition in the InstallUISequence evaluates to true.
4. The InstallScript engine performs manual resolution of all entries in the **Directory** table.
5. The InstallScript engine performs its own internal component costing to determine the space required for all features and components in the installation.
6. The InstallScript engine launches the compiled script contained in `ISSetup.dll`. The event sequence for the events that are run before the .msi package installation is as follows:
    a. OnBegin
    b. On*Xxx*UIBefore (where *Xxx* is First, Maint, Admin, Patch, Resume, etc.)
    c. OnGeneratingMsiScript
    d. OnMoving
    e. OnFeaturesInstalling (Any feature installing and uninstalling events are run at this point.)
    f. OnInstallFilesActionBefore
    g. OnGeneratedMsiScript
7. The InstallScript engine returns control to the Windows Installer engine, which then begins running the installation's Execute sequence.

8. If the .msi package installation is successful, the Windows Installer engine calls back into `ISSetup.dll`. `ISSetup.dll` then launches the following events:
    a. OnInstallFilesActionAfter
    b. OnFeaturesInstalled (Any feature installed and uninstalled events are run at this point.)
    c. OnMoved
    d. On*Xxx*UIAfter (where *Xxx* is First, Maint, Admin, Patch, Resume, etc.)
    e. OnEnd
9. The InstallScript engine shuts down and returns control to the Windows Installer.

For the new-style InstallScript MSI installations, the Install UI sequence is not run. If any custom actions are sequenced in the Install UI sequence, they will not run, similar to how such actions would not run in a Basic MSI that is launched with `/qb` or `/qn`.

The InstallScript engine does not log any changes that are made to the system from InstallScript events.

Most command-line parameters that are supported by traditional-style InstallScript MSI installations are also supported for new-style InstallScript MSI installations. If an end user launches the .msi package directly, these parameters can be passed through the ISSCRIPTCMDLINE property.

Limitations with the Traditional Style (InstallScript Engine as an External UI Handler)

Uninstallable Patch Support

The traditional style does not have support for creating uninstallable patches.

Limitations and Known Issues with the New Style (InstallScript Engine as an Embedded UI Handler)

If you are considering the new style, note the following details.

Windows Installer 4.5 Requirement

The new style requires that Windows Installer 4.5 be present on the target system. You can add InstallShield prerequisites for Windows Installer 4.5 to your project so that Windows Installer 4.5 is installed if it is not present. If you include these InstallShield prerequisites in your installation, you need to use a `Setup.exe` setup launcher. For more information, see Adding Windows Installer Redistributables to Projects. Note that Windows Installer 4.5 cannot be installed on some of the early versions of Windows.

If Windows Installer 4.5 is not installed on a target system at run time, and the installation is launched with Setup.exe, the setup launcher displays error 1713 and indicates that the installation requires Windows Installer 4.5 or later in order to run. The installation aborts after the end user dismisses this error message. If the .msi package is launched directly, the installation displays an error indicating that the package needs to be launched from the `Setup.exe` file.

Upgrade and Patch Support

InstallShield does not include any built-in support for creating an upgrade that uses the new style if the upgrade updates a product that was installed with the traditional style. Therefore, if you use the traditional style to build a release of your product and then you later create an upgrade, consider using the traditional style again for the upgrade. This applies to all types of upgrades (major upgrades, minor upgrades, and small updates) that are packaged as full-installations or as patches.

Note that if the previous setups that a patch is targeting use the traditional style, the patch should also use the traditional style. Also note that a QuickPatch project maintains the UI style from the original installation. Therefore, if the original installation used the traditional style, the QuickPatch package also uses the traditional style. If the original installation used the new style, the QuickPatch package also uses the new style.

As a workaround for the major upgrade scenario, you could consider having your new-style major-upgrade installation read the uninstall string of the earlier product from the registry, and launching it with the InstallScript function LaunchApplication to uninstall the earlier version of your product before installing the new version. Note that you may need to set LAAW_SHELLEXECUTEVERB to `runas` before using **LaunchApplication** in your script.

MsiDoAction

Attempting to call the **MsiDoAction** function from one of the events that are run before the .msi package installation returns an error. This error occurs because of the handle that the Windows Installer passes to the InstallScript engine. The handle does not support running standard or custom actions in the .msi package. This function can be called from InstallScript custom actions if needed.

MsiGetTargetPath and MsiSetTargetPath

The Windows Installer **MsiGetTargetPath** and **MsiSetTargetPath** functions do not work correctly in the new style if they are in event-driven script. These functions rely on the Directory Manager having been initialized by the Windows Installer costing actions. In new-style InstallScript MSI installations, Windows Installer costing is not performed. Thus, **MsiGetTargetPath** fails to return any path information, and **MsiSetTargetPath** fails to set the requested target path. In both cases, Windows Installer logs messages in a verbose log if either of these functions are called.

To update installation paths, use FeatureSetTarget.

Note that **MsiGetTargetPath** and **MsiSetTargetPath** can be called through InstallScript custom actions that are sequenced after CostFinalize in the Installation Execute sequence.

FeatureTransferData and ComponentTransferData

The behavior of the InstallScript functions **FeatureTransferData** and **ComponentTransferData** is undefined for the new style of InstallScript MSI installations and should not be used.

program…endprogram

New-style InstallScript MSI installations cannot use procedural scripts (that is, those with a program…endprogram block). The program function is not called in this case. An event-driven script should be used to customize the behavior of the installation.

/uninst

New-style InstallScript MSI installations do not support the `/uninst` command-line parameter.

BATCH_INSTALL

Attempting to reboot by setting the BATCH_INSTALL variable does not work correctly. To perform a reboot, use the ScheduleReboot action or the REBOOT property.

Reboot Support

Reboots for new-style InstallScript MSI installations are handled in the same manner as they are handled for Basic MSI installations—not as they are handled for InstallScript-based installations (where the installation resumes after the restart and the **OnRebooted** event handler is called).

New-style InstallScript MSI installations should be authored similarly to Basic MSI installations to handle reboots; the installation does not run after a scheduled reboot occurs, and the **OnRebooted** event handler is not called.

Msiexec.exe /x (for Uninstallation)

If an end user tries to uninstall the product through the command line using the statement `Msiexec.exe /x {ProductCode}`, the uninstallation may be successful. However, the Windows Installer displays an error dialog near the end of the uninstallation. The error dialog indicates that the Windows Installer service could not be accessed.

To perform an uninstallation from the command line, the current recommended method is to use one of the following:

```
msiexec.exe /i {ProductCode} REMOVE=ALL
```

```
msiexec.exe /x {ProductCode} /qn
```

Neither of these examples triggers the Windows Installer error.

Recommendations

For new-style InstallScript MSI installations, the UI functionality may be run without administrator privileges. Therefore, the following points are recommended (and, in general, also apply to all Windows Installer–based installations):

- Do not assume that administrator privileges will be available from any InstallScript events.
- Any system changes that need to be made should be done with custom actions in the Installation Execute sequence. InstallScript custom actions can be used. To ensure that sufficient privileges are available, custom actions should have an in-script execution setting of deferred in system context.
- Custom actions that modify the system should have corresponding rollback actions that restore the system to its earlier state if the installation fails.
- Custom actions that modify the system should also have corresponding actions that run during uninstallation to remove the installed items from the system.
- If changes are made to the system from InstallScript events, the changes are not logged by the InstallScript engine and would need additional script code to clean up these resources during uninstallation.

Using InstallScript to Differentiate Between the Two Styles at Run Time

You can use the INSTALLSCRIPTMSIEEUI variable to write a single script that produces different run-time behavior for the different UI styles. To learn more, see INSTALLSCRIPTMSIEEUI.

Specifying the InstallScript User Interface Type for InstallScript MSI Installations

Project • *This information applies to InstallScript MSI projects.*

In InstallScript MSI projects, you have the choice of two different types of InstallScript user interface (UI). For detailed information about these two styles, including any limitations, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

Task: ***To specify the InstallScript user interface type for an InstallScript MSI project:***

1. In the View List under **Installation Information**, click **General Information**.
2. For the **InstallScript User Interface Type** setting, select the appropriate option.
   - **Traditional Style (Requires Setup.exe)**—If you want to use the InstallScript engine as an external UI handler for your InstallScript MSI installation, select this option. With this style, your installation must include a `Setup.exe` setup launcher. The setup launcher serves as a bootstrap application that initiates the InstallScript engine to display the UI and run the InstallScript code, and the Windows Installer to run the Execute sequence of the .msi package.

     This is the default option for this setting.
   - **New Style (Requires Windows Installer 4.5)**—If you want to use the InstallScript engine as an embedded UI handler for your InstallScript MSI installation, select this option. With this style, InstallShield embeds the InstallScript engine within the .msi package. The Windows Installer calls the InstallScript engine to display the UI. The Windows Installer also runs the Execute sequence of the .msi package.

     This option requires Windows Installer 4.5 on the target machine. This option also has some limitations that require careful planning if you decide to use this style.

Entering Summary Information Stream Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Some of the Summary Information Stream settings are available in DIM projects. In this project type, the values in these settings are not displayed or used at run time. You can use these settings in this project type as a reference for internally identifying the project.

Windows Installer databases (.msi and .msm files) are implemented as COM structured storage, and COM structured storage files usually contain a Summary Information Stream. The Summary Information Stream contains information about your company and the software being installed. For more information, see Accessing the Summary Information Stream Panel to learn how to view your file's summary information.

For a description of each Summary Information Stream setting, see General Information View.

Accessing the Summary Information Stream Panel

Task: ***To access summary information for an .msi or .msm file:***

1. Right-click the .msi file or .msm file and click **Properties**. The **Properties** dialog box opens.
2. Click the **Summary** tab to view the summary information.

Tip • *The General Information view is where you populate the information for the Properties dialog box for your installation.*

Setting Summary Information Stream Properties

Task: ***To specify summary information for the project:***

1. In the View List under **Installation Information**, click **General Information**.
2. Find the **Summary Information Stream** area of the view.
3. Modify the values of the settings as needed.

Using the Template Summary Property

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You can use the Template Summary setting in the General Information view to essentially establish conditions for processor type and language; if a target system does not meet these requirements, the installer displays an error message and exits the installation.

Tip • *You can also set the Template Summary setting for a product configuration in the Releases view. Any value entered in the Releases view overrides the value set in the General Information view.*

Syntax

List the processor type first, followed by your installation's default language. For language, enter any four-digit language ID or 0 (zero) for language neutral.

- Separate the two categories with a semicolon.
- If your installation supports multiple products and you want to have multiple entries in the language category—for example, 1033 for English and 1031 for German—separate them with a comma.

Caution • *If your installation targets 64-bit machines, do not enter both Intel and Intel64 in this field. Doing so causes your installation to fail. Also, if you enter Intel64, your installation will not run on 32-bit operating systems.*

Valid processor values include:

- Alpha (Alpha is supported by Windows Installer 1.0 only.)
- Intel
- Intel64 (Intel64 is supported by Windows Installer 2.0 only.)
- x64

Setting Conditions Based on Processor Type and Language

If your installation runs only on Intel processors and English-based systems, use the following syntax in the Template Summary property:

```
Intel;1033
```

If the processor-type condition fails, the installer displays an error message and then exits.

If your product runs on x64 processors and supports English and German, enter the following:

```
x64;1033,1031
```

To specify that the package is language-independent, you can use the syntax `Intel;` or `Intel;0`.

Setting Conditions Based on Language Only

To put a condition on the language only, start the entry with a semicolon and specify your setup's default language:

```
;1036
```

Leaving the first portion empty indicates that the package is processor-independent. If a language is not specified, InstallShield provides the release languages in the Summary Information Stream.

Configuring Add or Remove Programs Information

The settings in the Add or Remove Programs area of the General Information view describe the information that appears in Add or Remove Programs tool in the Control Panel.

If you have not entered a value for a particular Add or Remove Programs setting, a sample value appears in grey text. This value is meant to serve as an example and is not included in the final Windows Installer database.

The General Information view enables you to set much of the information that is displayed to the end user through Add or Remove Programs.

Project • *In Basic MSI and InstallScript MSI projects—Most of the values that you specify are stored in Windows Installer properties with names beginning with ARP, such as* ***ARPPRODUCTICON*** *or* ***ARPHELPLINK****. One exception to this is the Publisher setting. This value should be set with your company name and is stored in the* ***Manufacturer*** *property.*

In a Basic MSI project—To prevent your product from appearing in the Add or Remove Programs, you can set the Windows Installer property ***ARPSYSTEMCOMPONENT*** *to 1 in the Property Manager. Note that setting this property simply suppresses the display of your product in Add or Remove Programs. An end user can still remove your product by running the installation in maintenance mode or from the command line.*

In an InstallScript MSI project—To prevent your product from appearing in the Add or Remove Programs, select Yes for the Hide Add/Remove Panel Entry setting in the Releases view.

Specifying a Readme File

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Suite/Advanced UI*
- *Transform*

In the Read Me setting in the General Information view, enter the name of the Readme file for your product. On some versions of Windows, this information is displayed on the Support Info dialog box for your product's entry in Add or Remove Programs. Alternatively, you can link to a Readme file located on the Internet by specifying a valid URL.

Project • *In a Windows Installer–based project (Basic MSI or InstallScript MSI project), special formatting is required to properly display a path when the Readme file is installed as part of your installation; see the following section. In an InstallScript or InstallScript Object project, enter a hard-coded path or a URL, or specify a path relative to a system variable enclosed by angle brackets, for example,* ***<TARGETDIR>\Readme.txt****. This data is written to the target system's registry by the default* ***OnMoveData*** *event handler.*

Displaying the Readme File Path in Basic MSI and InstallScript MSI Projects

You can enter a hard-coded path or a URL for the Readme file. However, the name of a folder, such as **[MyDirectory]**, or of a component, such as **[$MyComponent]**, is not resolved. That means that the Readme value in the Support Information dialog box would be displayed as **[INSTALLDIR]Readme.txt** or **[$MyComp]Readme.htm**. The path is not resolved because this property is merely setting the initial value of the Windows Installer property ARPREADME, and formatted strings are never resolved for Windows Installer properties.

InstallShield's solution is to use a custom action to set **ARPREADME** with the value that you enter in the Read Me setting. By setting it with the SetARPReadme custom action, the path is resolved during the installation. For example, **Readme.doc** might be a file in the component Help_Files. In this case, enter `[$Help_Files]Readme.doc` for the Read Me setting. Assuming Help_Files is installed to `C:\Program Files\MyCompany\MyProduct\Help`, the path that would be displayed in Add or Remove Programs on the target system would be `C:\Program Files\MyCompany\MyProduct\Help\Readme.doc`.

Instead of the component name, you can use the file key. Do not use a folder from the **Directory** table because it will not be resolved at run time. The file key is not as reliable as the component name, because it is subject to change if the files are dynamically linked or the release uses patch optimization. Continuing the example above, if **Readme.doc** has a file key of F501_Readme.doc, enter **[#F501_Readme.doc]** for the Read Me setting. If it is installed to the same folder, Add or Remove Programs displays the following path on the target system:

```
C:\Program Files\MyCompany\MyProduct\Help\Readme.doc
```

The custom action SetARPReadme is added every time that the Read Me setting in the General Information view contains a string and the Installation Execute sequence contains the CostFinalize action. SetARPReadme is inserted into the Installation Execute and User Interface sequences directly after CostFinalize.

Including a Software Identification Tag for Your Product

Project • *This information applies to Basic MSI projects.*

ISO/IEC 19770-2 is an international standard for the creation of software identification tags. A software identification tag is a small XML-based file that contains descriptive information about the software, such as the product name, product edition, product version, and publisher. Software asset management tools collect the data in the tags to provide accurate application identification for software that is installed in an enterprise.

Software identification tagging is evolving as an industry standard, enabling independent software vendors to create smarter applications that give their customers better information for software asset management and license optimization initiatives. Including the identification tag in your product's installation makes it possible for your customers to use tools that can monitor their internal usage of your product, allowing them to understand, manage, and optimize the number of licenses of your product that they obtain from you.

Proper tag creation requires that you configure standard General Information settings such as Product Name and Product Version. It also requires that you configure a few identification-specific settings, which are also in the General Information view.

Task: ***To include a software identification tag in your installation:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Software Identification Tag** area of the view, modify the values of the settings as needed.

   The **Use Software Identification Tag** setting lets you specify whether you want to include a tag in your installation. Select **Yes**, which is the default value, and then configure the other settings in the **Software Identification Tag** area as needed.

When you use tagging in your project, InstallShield adds the tag to two new components that it creates, and it associates the components with one of your project's features. The components are:

- ISO19770_LocalTag, which has a destination of **INSTALLDIR**
- ISO19770_SystemTag, which has a destination of **CommonAppDataFolder**

Use the Setup Design view if you want to associate these components with a different feature in your project. For more information, see Component-Feature Associations.

At build time, if the following conditions are true, InstallShield includes the software identification tag with the installation that it builds:

- Yes, the default value, is selected for the Use Software Identification Tag setting in the General Information view.
- The Unique ID, Tag Creator, and Tag Creator ID settings in the General Information view have values.

Note that if tagging is enabled but you have not entered values in one or more of the three aforementioned tag identification settings, InstallShield generates a build warning to inform you that the tag could not be included in your release. To resolve this warning, configure the settings in the Software Identification Tag area of the General Information view as needed.

If you configure your project to include a software identification tag and you also configure the release in the Releases view to use a .pfx file to digitally sign your release, InstallShield digitally signs the tag at build time. Note that the .NET Framework 3.5 must be installed on your build machine in order to sign a tag file.

Including Microsoft System Center Configuration Manager Application Model Data About Your Product

Project • *This information applies to Basic MSI projects.*

Microsoft System Center 2012 Configuration Manager is a solution that helps IT administrators manage and deploy applications to users throughout an enterprise. It takes a user-centric approach to application delivery, allowing IT administrators to define each application so that it can be deployed to users on a variety of devices in the most appropriate format, with the required application dependencies.

Accurate identification of deployment metadata is necessary for migrating applications into the Configuration Manager application model. InstallShield includes the ability to specify some of the application model metadata for an application through a software identification tag. When AdminStudio users import a package into the AdminStudio Application Catalog, AdminStudio Application Manager mines package elements for deployment data such as detection methods, dependencies, requirements, as well as information in the software identification tag. AdminStudio makes this information available to users for review and tests before publishing to Microsoft System Center 2012 Configuration Manager.

Task: ***To include application model data for System Center Configuration Manager in your installation:***

1. Ensure that you are including a software identification tag in your project. For more information, see Including a Software Identification Tag for Your Product.
2. In the View List under **Installation Information**, click **General Information**.
3. In the **Add SCCM App Model Data** setting, select **Yes**.
4. Configure the subsettings under the **Add SCCM App Model Data** setting as needed. For more information, see General Information View Settings.

When you include tagging and application model data in your project, InstallShield adds the tag with the application model data to two new components that it creates, and it associates the components with one of your project's features. The components are:

- ISO19770_LocalTag, which has a destination of **INSTALLDIR**
- ISO19770_SystemTag, which has a destination of **CommonAppDataFolder**

Use the Setup Design view if you want to associate these components with a different feature in your project. For more information, see Component-Feature Associations.

At build time, if the following conditions are true, InstallShield includes the software identification tag with the installation that it builds; it also includes the application model data in the tag:

- Yes, the default value, is selected for the Use Software Identification Tag setting in the General Information view.
- The Unique ID, Tag Creator, and Tag Creator ID settings in the General Information view have values.

- Yes is selected for the Add SCCM App Model Data setting in the General Information view.

If you configure your project to include a software identification tag and you also configure the release in the Releases view to use a .pfx file to digitally sign your release, InstallShield digitally signs the tag at build time. Note that the .NET Framework 2.0 or later must be installed on your build machine in order to sign a tag file.

Organizing Files for Your Installation

The primary task of an installation is to transfer files from your distribution media to your end user's hard drive. In an InstallShield installation, files are organized in a hierarchy: files are included in components; components are associated with features (and optionally subfeatures); and, in InstallScript and InstallScript MSI installations, features are associated with setup types.

At run time, your end user simply selects the setup type—or, if you allow it, the features and subfeatures—that he or she wishes to install. End users do not see components, which you use to group your files according to their type and purpose. For example, files that are installed to the same target folder can be placed in the same component, as can self-registering files.

A file often relies on functions in other files to perform a task. However, you may not be aware of all these other files—known as dependencies—when you include your application's files in your project. To help you identify dependencies, InstallShield offers three dependency scanners that automatically add these files to your project.

In addition to including individual files in your project, you can also include redistributables (InstallShield prerequisites, merge modules, and objects), which contain logic and files needed to install distinct pieces of functionality. For example, to include the Java Runtime Environment (JRE) files in your installation, you can add the InstallShield prerequisite for JRE to your installation project.

Designing Installations

There are two main perspectives in an installation project—that of the developer and that of the end user. In InstallShield, these perspectives are addressed in detail in the Components and Features views, respectively.

Components

Components represent the developer's view of the product. They are installation authoring tools that help the developer organize similar application data—such as files, registry entries, and shortcuts—into logical groups.

To enable the end user to choose which features to install, you should divide your application into components that correspond with the features of your application.

Using InstallShield, you can also publish your project's components.

Note • *The conditions that you specify for the Publish Components, Publish Features, or Publish Product actions are not validated during design time, so use proper syntax and check to ensure that the condition produces the expected outcome.*

Features

Features are the building blocks of an application from the end user's perspective. Each feature represents a specific piece of functionality for your product—such as the help files. End users should be able to install and uninstall discrete features of your product.

For example, an end user with limited hard drive space could elect not to install a product tutorial. If the user subsequently purchases another computer or frees resources on an existing one, the previously uninstalled product tutorial could then be installed.

You should separate your application into features that correspond to the components of your application.

Separating Applications into Components

Use the following guidelines to separate an application into components.

- Identify resources that function as a group; each group can be a component.
- Windows Installer requires that every file in a component be installed to the same directory. If you need to install a directory structure, each subdirectory must correspond to a separate component.
- The resources in a component should require the same conditions.
- To take full advantage of Windows Installer repair functionality, each .exe, .dll, and .ocx file should be placed in its own component, and each should be the component's key file. The Best Practices option of the Component Wizard can create components for you using this rule.
- Similarly, each .chm or .hlp file should be placed in its own component, along with any corresponding .chi or .cnt file.
- No resource should be included in more than one component, even across products. If a component's resources are required by more than one product, consider creating a merge module with the shared resources.
- When mapping a component to one or more features, ensure that all parts of a component map to the features.
- When testing your installation, you may want to divide your application into several components to thoroughly measure its performance.

Separating Applications into Features

Use the following guidelines to separate an application into features.

- Separate your application into independent parts, such as help, clip art, and program files. This gives the end user combination options when installing your application. For instance, if your application contains a large, graphic-intensive clip art file, you could make the clip art file a feature. This gives the end user the option of installing or not installing the file—a vital ability for users with limited available resources.
- In separating your application into features, ensure that end users can recombine the parts in several ways to fulfill specific needs. When doing this, consider the needs of all users, from system administrator to customer service representative to developer and everyone in between. By addressing all groups of users, you are promoting increased distribution and usage of your application.
- Each feature should have one function—such as help files—and should be clearly defined according to this functionality to facilitate recognition and comprehension. Features should possess an independent functionality, such that users can install and use the feature by itself, if they so choose.

- If one feature requires another, make the dependent feature a child of the other.
- To eliminate confusion, keep any information pertaining to the management of the system or application transparent to the user.

Using Path Variables

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Traditionally, to link to source files in an installation project, you would need to create a reference to that file using a hard-coded path. For example, you might have a source file called Program.exe located at `C:\Work\Files` that you want to include in your installation. However, if you used hard-coded paths, you needed to enter the entire path every time that you want to associate a source file from that directory. If you moved the file to another directory, you needed to change the hard-coded path as it appears in your installation project. If your installation consisted of a small number of source files, this might not have been a problem. Unfortunately, some installations contain thousands of files that all would need to be remapped if you change the folder structure or migrate the project to a different machine.

With path variables, you can define commonly used paths in a central location so that you do not need to change every source file's path each time you move the project or change the directory structure.

All path variables can be viewed and modified in the Path Variables view. You can use path variables in almost any location in InstallShield where you link to source files, such as in the Dialog Editor, dynamic file links, and the release location. Instead of entering the path variables yourself, you can have InstallShield recommend them whenever you browse to a path. To have InstallShield automatically recommend path variables, select the Always display the Path Variable Recommendation dialog to me option on the Path Variables tab of the Options dialog box.

Note • *Path variables are used during the development of your installation project. These paths do not apply to the target machines where the application is being installed. Rather, they are used to link to source files for your installation project. When the project is built, those links are evaluated and the files they point to will be built into the installation.*

Predefined Path Variables

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Predefined path variables are variables that are set to certain standard Windows directories. These variables cannot be renamed or modified, but they can be used in your installation project to point to predefined directories. Following is a list of predefined path variables, their typical values, and the corresponding InstallScript path variables. (In an InstallScript project, InstallScript path variables are used in InstallShield, for example, as options in the list for the Destination property of a component. InstallScript path variables also correspond to system variables that can be used in the installation script.)

Table 4-1 • Predefined Path Variables

Predefined Path Variable	Value	InstallScript Path Variable
<ProgramFilesFolder>	`C:\Program Files\`	<PROGRAMFILES>
<CommonFilesFolder>	`C:\Program Files\Common Files\`	<COMMONFILES>
<WindowsFolder>	`C:\Windows\`	<WINDIR>
<SystemFolder>	`C:\Windows\System32\`	<WINSYSDIR>
<ISProjectFolder>	`C:\InstallShield 2013 Projects\`	
<ISProjectDataFolder>	`<ISProjectFolder>\ProjectName`	<ISPROJECTDIR>
<ISProductFolder>	`C:\Program Files\InstallShield\2013`	
<ISRedistPlatformDependentFolder>	`C:\Program Files\InstallShield\2013\Redist\Language Independent\i386`	

Table 4-1 • Predefined Path Variables (cont.)

Predefined Path Variable	Value	InstallScript Path Variable
<ISRedistPlatformDependentExpressFolder>	`C:\Program Files\InstallShield\2013\Redist\Language Independent\i386 Express`	

Using Predefined Path Variables

Project • *Windows Installer based projects only: The Path Variable Recommendation dialog box enables you to specify whether you want to use predefined path variables. This dialog box is launched if you enter a hard-coded path when inserting a source file into your installation and you have selected the Always display the Path Variable Recommendation dialog to me check box on the Path Variables tab of the Options dialog box. If you enter a path that is included in a predefined path variable, InstallShield suggests that you use the path variable rather than the hard-coded path.*

You can also use predefined path variables when defining the value for a standard path variable. You may want to define a standard path variable to a subfolder of a predefined variable. For example, `<ProgramFilesFolder>\InstallShield` could be used as the value for a standard path variable.

Predefined path variables are *smart* variables. This means they are set to the correct directory, even if your Windows directory is located on your D drive instead of your C drive. If you change the default project location on the File Locations tab of the Options dialog box, InstallShield updates this variable to reflect the new directory.

Creating and Defining a Path Variable

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

The Path Variables view is where you create and define standard path variables, environment variables, and registry path variables.

Task: ***To create and define a path variable:***

1. In the View List under **Media**, click **Path Variables**.
2. Do one of the following:
   - To create a standard path variable, click the **New Path Variable** button.
   - To create an environment variable, click the arrow next to the **New Path Variable** button, and then click **Environment**.
   - To create a registry variable, click the arrow next to the **New Path Variable** button, and then click **Registry**.

   InstallShield adds a new row at the bottom of the view.
3. Complete each of the settings in the new row as needed.

For descriptions of each column, see Path Variables View.

Tip • *To override the value of a user-defined path variable, an environment variable, or a registry value for a particular release at build time, use the Path Variable Overrides setting on the Build tab for that release. To learn more, see Build Tab for a Release.*

Deleting a Path Variable

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Task: ***To remove a path variable from your project:***

1. In the View List under **Media**, click **Path Variables**.
2. Select one or more path variables that you want to delete.

To select multiple consecutive path variables, select the first path variable, press and hold SHIFT, and select the last path variable. To select multiple nonconsecutive path variables, select the first path variable, press and hold CTRL, and select each additional path variable.

3. Click the **Delete Selected Path Variables** button.

Standard Path Variables

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Standard path variables are sometimes referred to as user-defined variables. These variable types are native to InstallShield. That is, they do not rely upon outside resources, as do registry or environment variables.

Using Standard Path Variables

Once you have created a standard path variable, you can use it every time you add a source file to your project. For example, you might create a variable called *<MyFiles>* and have it pointing to `C:\Work\Files`. If you add a source file to your project that contains that variable's path in its destination, it is recommended that you use the variable rather than hard-coding the path. This recommendation is displayed in the Path Variable Recommendation dialog box.

To have InstallShield automatically recommend path variables, select the Always display the Path Variable Recommendation dialog to me option on the Path Variables tab of the Options dialog box.

Tip • *To override the value of a user-defined path variable, an environment variable, or a registry value for a particular release at build time, use the Path Variable Overrides setting on the Build tab for that release. To learn more, see Build Tab for a Release.*

Registry Path Variables

Project • *This information applies to the following project types:*

- *Advanced UI*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Registry path variables enable you to define your own variables based on the default value of a specified registry key.

Once you have created a registry path variable, you can use it every time that you add a source file to your project. When you add a file to a component from a folder that contains the value of *MyRegVar*, it is recommended that you use the variable rather than hard-coding the path. This recommendation is displayed in the Path Variable Recommendation dialog box.

To have InstallShield automatically recommend path variables, select the Always display the Path Variable Recommendation dialog to me option on the Path Variables tab of the Options dialog box.

Tip • *To override the value of a user-defined path variable, an environment variable, or a registry value for a particular release at build time, use the Path Variable Overrides setting on the Build tab for that release. To learn more, see Build Tab for a Release.*

Environment Variables

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Environment path variables enable you to define your own path variables based on certain values on the **Environment** dialog box.

Task: ***To view the Environment dialog box:***

1. Right-click **My Computer** and click **Properties**. The **System Properties** dialog box opens.
2. On the **Advanced** tab, click **Environment Variables**.

A common scenario where environment path variables may be useful is when performing a build from the command line. If you do nightly builds on a machine dedicated to that purpose, you may need to change the path variables from the command line. As long as you use environment path variables, you can define the paths to your project's files from either a batch file or the command line. These paths are evaluated when the installation project is built, and the correct paths to the files will be used.

Using Environment Variables

After you have created an environment variable, you can use it every time that you add a source file to your project. For example, you might create a variable called *<MyFiles>* and have it point to `C:\Work\Files`. If you add a source file to your project that contains that variable's path in its destination, it is recommended that you use the variable rather than hard-coding the path. This recommendation is displayed in the Path Variable Recommendation dialog box.

To have InstallShield automatically recommend path variables, select the **Always display the Path Variable Recommendation dialog to me** option on the Path Variables tab of the Options dialog box.

Tip • *To override the value of a user-defined path variable, an environment variable, or a registry value for a particular release at build time, use the Path Variable Overrides setting on the Build tab for that release. To learn more, see Build Tab for a Release.*

Converting Static Links

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

You might not need to use path variables when you begin your installation project, but you may realize the benefits they provide well after you have started. Rather than going through each file link and changing it to a path variable, you can use the Converting Source Paths Wizard.

This wizard scans your project for static links and converts them all to path variables. If any of your static links can be replaced with existing path variables, the wizard does this automatically. For all other links, the wizard provides a list of the possible variables. After you choose the variables that you want to use, the wizard converts all of the links.

Task: ***To launch the Convert Source Paths Wizard:***

On the **Project** menu, click **Convert Source Paths**.

Including Files and Folders

Your files, the core of your product, are also the core of your installation. Files are added to a project only at the component level. In installation projects, components are associated with features, which are what end users see when they run your installation. If the component's feature is selected for installation, the component's files are installed to the target system.

When you are adding files to components in Windows Installer–based projects, you should be aware of Setup Best Practices. By default, the Setup Best Practices Wizard monitors your setup design and alerts you if you have violated Best Practices.

You can add files to your project in the Setup Design view (for installation projects) or the Components view, and in the Files and Folders view.

Files Explorer

The Files and Folders view contains a file explorer that allows you to drag and drop files from folders on your source machine to folders on the destination machine. The two left panes in the files explorer contain folders and the two right panes display the files located within those folders.

Note • *In installation projects (including InstallScript and Basic MSI), the Files and Folders view includes the Add new components to the feature list above the file explorer panes. This list contains all of the features in your project. When you add files in this view, new components may need to be created. From this list, select the feature with which you want to associate these new components.*

Source Computer's Folders (Top Left)

The Source computer's folders pane is similar to the left pane in Windows Explorer. This pane contains folders located either locally or on a network. From here, you can navigate to the folder that contains the files that you want to add to your installation.

Source Computer's Files (Top Right)

The Source computer's files pane displays the files contained in the currently selected folder of the Source computer's folders pane. You can drag files from this pane to a destination folder in the Destination computer's pane. The files you drop into the bottom panes are added to your installation project.

Destination Computer's Folders (Bottom Left)

In the Destination computer's folders pane, you can add files to destination folders or components, create new destination folders, or modify existing components.

Destination Computer's Files (Bottom Right)

The Destination computer's files pane displays all the files you have added to the currently selected destination folder. By right-clicking a file in this pane, you can copy, paste, or delete the file, or edit the file's properties. For Windows Installer-based projects only, you can also right-click a file to set or clear it as the key file of its component.

Working in the Files Explorer

The easiest way to add files to your installation is to use the files explorer in the Files and Folders view. Within the files explorer, you can also create new destination folders, display the components associated with the files you add to your installation, and modify component settings using the Component Properties dialog box.

Adding Files Through the Files Explorer

Task: ***To add a file:***

1. Open the **Files and Folders** view.
2. In the **Add new components to the feature** list, select the feature with which you want any new components associated. If InstallShield creates new components for the files added, these components are added to the feature selected in the **Add new components to the feature** list.
3. Windows Installer–based projects only: In the **Destination computer's folders** pane, right-click **Destination Computer**, point to **Show Predefined Folder**, and then click the predefined folder that you want to use.
4. In the **Destination computer's folders** pane, click the folder into which you want to place the file.
5. In the **Source computer's folders** pane, navigate to the folder containing the file you want to add.

   INSTALLDIR (for Windows Installer–based projects) or Application Target Folder (for InstallScript projects) is the most commonly used target location, because this is the default root directory for your application's files.
6. Select and drag the file you want to add from the **Source computer's files** pane to the **Destination computer's files** pane.

Tip • *You can specify how **INSTALLDIR** is displayed in the Destination computer's folders pane of the Files and Folders view by setting your preference on the Directory tab of the Options dialog box.*

You can also specify a hard-coded destination directory.

The Destination computer's folders pane contains a list of predefined destinations. You can add a file to either a predefined destination or to a destination that you create.

In an InstallScript project, InstallShield creates components based on the file types—for example, all self-registering files are contained in one component, all non-self-registering files in another component, and all .NET files in a different component. The components appear as subfolders in the Files and Folders view.

Creating New Destination Folders

Task: ***To create subfolders of the predefined folders:***

1. Open the **Files and Folders** view.
2. In the **Destination computer's folders** pane, right-click a folder and click **New Folder**.
3. Rename your new folder by selecting it, pressing F2, and typing the new name.

Alternately, you can drag an entire folder onto one of the destination folders, thereby adding a new subfolder to the target folder that contains the source folders files. This new subfolder has the same name as the source folder.

Displaying Components in the Files Explorer

Task: ***To display the components in your installation and the files that are associated with them:***

1. Open the **Files and Folders** view.
2. In the **Destination computer's folders** pane, right-click any folder and click **Show Components** (in Windows Installer–based projects) or **Show Components and Subfolders** (in InstallScript-based projects).

Components in installation projects that are not associated with a feature are displayed with the orphaned component icon ().

Modifying Components through the Files Explorer

In the folders explorer of the Files and Folders view, you can right-click a component and click Properties to display the Component Properties dialog box. Through this dialog box, you can modify the component's properties, add dynamic file links, and change that features contain the component.

Note • *(Windows Installer–based projects only) You can launch the Component Wizard by right-clicking a folder icon and then clicking Launch Component Wizard.*

Dragging and Dropping Files Using the Context Menu

The files explorer in the Files and Folders view enables you to drag and drop folders from your source computer to destinations on the target system. You have a number of options when you drag files from the Source computer's folders pane to the Destination computer's folders pane.

Task: ***To display the context menu:***

1. Open the **Files and Folders** view.
2. In the **Source computer's folders** pane or the **Source computer's files** pane, right-click a folder or file and drag it to the **Destination computer's folders** pane or the **Destination computer's files** pane.
3. Release the mouse button to display the context menu.

Table 4-2 • Commands Available from the Context Menu in the Files and Folders View

Command	Description
Add	Adds the folder, subfolders, and/or files selected. This is the same as the default drag-and-drop behavior.
Add Preserving Source Structure	Adds the selected folder, subfolders, and/or files while preserving the file/folder structure found on the source computer. This command is available only if the source folder matches a predefined Windows destination folder. In addition, the destination on which you drop the file or folder must be the Destination Computer.
Add Folder(s) Only	Adds only the folders selected and any subfolders contained in the selected folder. Does not add any files contained within the selected folders or subfolders.
Add Folder(s) Only Preserving Source Structure	Adds only the folders selected and any subfolders contained in the selected folder. Does not add any files contained within the selected folders or subfolders. This option also preserves the folder structure found on the source computer. This option is available only if the source folder matches a predefined Windows destination folder. In addition, the destination on which you drop the file or folder must be the Destination Computer.
Cancel	Ends the drag-and-drop operation without making any changes.

File Properties

You can set a number of properties for each file that is to be installed on the target system.

Task: ***To specify the properties for a file:***

1. Open the **Files and Folders** view.
2. In the **Destination computer's folders** pane, click the folder that contains the file whose properties you want to configure.
3. In the **Destination computer's files** pane, right-click the file and then click **Properties**. The **Properties** dialog box opens.

To see a description of each property that you can set, see File Properties Dialog Box.

Installing Self-Registering Files

The installer uses "traditional" self-registration to register your self-registering files when the files are marked as self-registering and (in a Windows Installer–based project) they are in a component that has the COM Extract at Build property set to No. The files are unregistered when they are uninstalled. The self-registration functions supported are **DllRegisterServer** and **DllUnregisterServer**.

Before setting a file's Registration property, make sure the file is self-registering. According to Setup Best Practices, there should be only one .dll file, .ocx file, or .exe file per component.

Tip • *The recommended method for installing self-registering files with Windows Installer is to write the registration information to the .msi database tables (Class, ProgID, and others). Instead of marking a file as self-registering, you can use the component's advanced settings, extract the COM information at build time, or extract the COM information when you add a file in the Files and Folders view in order to register the ProgIDs, type libraries, and so on. Using the advanced settings works whether you are installing the file in the installation or advertising it for "just-in-time installation." A further advantage is that the file can be unregistered if the installation fails.*

Even if you set the component's COM Extract at Build property to No, any information that is contained in the COM Registration advanced setting will nonetheless be registered during installation. You might want to check the COM Registration advanced setting and the component's registry data to verify that the entries are intentional and do not conflict with those made by the self-registration functions.

File Associations

Project • *This information applies to the following project types:*

- *Basic MSI*

- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

File associations are registry settings that tell Windows what application to use to open files of a certain type. For example, Windows typically launches Notepad.exe when a text (.txt) file is opened.

To view and modify registered file types on your system, open Windows Explorer, and on the Tools menu, click Folder Options. Use the File Types tab of the Folder Options dialog box to see how the file associations are configured.

Similarly, you can identify the application that is associated with a given file by right-clicking the file in Windows Explorer and then clicking Properties.

File associations are stored in both HKLM\SOFTWARE\Classes and HKCU\SOFTWARE\Classes; you can see a merged view of the data under HKEY_CLASSES_ROOT.

Creating File Associations for Your Installation Project

Best-practice guidelines recommend that you create a file association for every nonhidden type of file created or used by your product. You can quickly and easily create file associations for your installation project with the File Extensions view, which is available as an advanced setting within the Components view and the Setup Design view (for installation projects only). When an end user installs a feature that contains a file association, the file association is registered on the target machine; an entry is made in the appropriate part of the registry, and the entry links your file type to your application through the ProgID. The ProgID, which is sometimes called a file type's application identifier or tag name, uniquely identifies your application and helps the operating system recognize your file association.

Adding New File Extensions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If your application manipulates files with a unique file extension, you can register your file type. For example, if your application manipulates files with the .xyz extension, registering the file type instructs the operating system to open the file with your application when the user double-clicks its icon.

Task: ***To add a new file extension:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. In the **File Types** explorer, right-click **Extensions** and click **New Extension**. InstallShield creates a new extension with the default name **New ExtensionN**, where *N* is a unique number.
6. Type your extension without the dot (for example, enter `ext` instead of `.ext`).

Removing File Extensions

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

Task: ***To remove an extension:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. In the **File Types** explorer, right-click the extension and click **Delete**.

Setting File Extension Properties

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

The extension properties determine the registry entries for your file extension, as well as the ProgID associated with it. Detailed help is available in the help pane in InstallShield when you click each property.

Specifying Command Verbs

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

By default, the verb open is added to your file extension.

Task: ***To add a new verb and specify its properties:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. In the **File Types** explorer, right-click the extension and click **New Verb**. InstallShield creates a new verb with the default name **New VerbN**, where *N* is a unique number.
6. Type the name of your new verb. You can use any of the canonical verbs, such as `open`, `print`, `find`, and `properties`.
7. Select the new verb to edit its properties. Its property sheet opens to the right.

Removing a Verb from a File Extension

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

Task: ***To remove a verb:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. Right-click the verb and click **Delete**.

Adding New MIME Types

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

Task: ***To add a new MIME type:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.

4. Click **File Types**. The **File Types** explorer opens.
5. In the **File Types** explorer, right-click the extension and click **New MIME Type**. InstallShield creates a new MIME type with the default name **MIME TypeN**, where *N* is a unique number.
6. Type the MIME type; for example, `image/jpeg`.

Click the MIME type to view its Class ID property. Click the Class ID property to edit it in the lower pane. Press CTRL+V to paste a class ID into the property field.

Removing MIME Types

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

Task: ***To remove a MIME type:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. Right-click the MIME type and click **Delete**.

Creating ProgIDs

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

The ProgIDs item in the File Types explorer contains all of the programmatic identifiers—ProgIDs, also known as application identifiers or tag names when they support file types—that you want to associate with file extensions. A file type's ProgID is an arbitrary string, but it should be unique on the target system. One ProgID naming convention is to append the word `file` to your extension without a dot—the .ext extension might use the ProgID *extfile*. Another convention is to name a file-type ProgID after the application used to open the file type, as in SampleApp.Document.

For example, an *.xyz* file extension could point to a xyzfile ProgID, and all of the *.xyz* file-type information would be registered under xyzfile.

Task: ***To create a ProgID:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.

3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. In the **File Types** explorer, click the extension. The extension properties are displayed in the right pane.
6. In the **ProgID** property, type the name of your ProgID. InstallShield adds your ProgID under **ProgIDs** in the **File Types** explorer.
7. In the **File Types** explorer, click the new ProgID and then set its properties.

Removing ProgIDs

Project • *This information does not apply to InstallScript or InstallScript Object projects.*

Task: ***To remove a ProgID:***

1. Open the **Setup Design** view (for installation projects only) or the **Components** view.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Click **File Types**. The **File Types** explorer opens.
5. In the **File Types** explorer, click the extension. The extension properties are displayed in the right pane.
6. In the **ProgID** property, delete the ProgID.

Destination Folders

When you add files to your installation project, you do so by placing them in a destination folder. The following destination folders are provided by default. Each one is dynamic, meaning that they do not use hard-coded paths. Instead, the value for each destination folder is obtained from the operating system of the target machine.

The following folders are available only for InstallScript projects:

Table 4-3 • Default Destination Folders for InstallScript Projects

Folder Name	Description
Script-Defined Folders	This folder allows you to create folders whose location is determined in your script. Files cannot be added directly to this folder, but only to its subfolders; to create a subfolder, right-click the folder and select New Folder. Specify a folder name that is enclosed in angle brackets, for example, <MYFOLDER>; to assign the folder a location through your script, call FeatureSetTarget.

Table 4-3 • Default Destination Folders for InstallScript Projects (cont.)

Folder Name	Description
Application Target Folder	This folder's location is determined by the value of the system variable TARGETDIR.
Program Files	This folder's location is the 32-bit Program Files folder.
Program Files (64-bit)	This folder's location is the 64-bit Program Files folder.
Program Files\Common Files	This folder's location is the 32-bit Common Files folder.
Program Files (64-bit)\Common Files (64-bit)	This folder's location is the 64-bit Common Files folder.
Support Folder	This folder's location is determined by the value of the system variable SUPPORTDIR.
Windows	This folder's location is the Windows folder.
Windows\Fonts Folder	This folder's location is the Windows Fonts folder.
Windows\Windows System	This folder's location is the 32-bit Windows System folder.
Windows\Windows System (64-bit)	This folder's location is the 64-bit Windows System folder.

The following folders are available only for Basic MSI and InstallScript MSI projects:

Table 4-4 • Default Destination Folders for Basic MSI and InstallScript MSI Projects

Folder Name	Description
AdminToolsFolder	Points to the folder where administrative tools are located.
AppDataFolder	This property holds the full path to the current user's Application Data folder. A typical value of this property is: `C:\Users\`*`UserName`*`\AppData\Roaming`
CommonAppDataFolder	This is the full path to the folder containing application data for all users. A common path is: `C:\ProgramData`
CommonFiles64Folder	The value of this property is the full path to the 64-bit Common Files folder. This property requires Windows Installer version 2.0 or later.

Table 4-4 • Default Destination Folders for Basic MSI and InstallScript MSI Projects (cont.)

Folder Name	Description
CommonFilesFolder	The value of this property is the full path to the 32-bit Common Files folder.
DesktopFolder	This property is used to hold the full path to the Desktop folder for the current user. If the setup is being run for All Users, and the ALLUSERS property is set, the DesktopFolder property should hold the full path to the All Users desktop folder.
FavoritesFolder	The FavoritesFolder property contains the full path to the Favorites folder for the current user.
FontsFolder	This property holds the full path to the Fonts folder.
IISROOTFOLDER	This property stores the root directory of the Web server on a target system. If you are using IIS functionality in your installation project and you have added a Web site, then IISROOTFOLDER is automatically added. For more information, see Adding IISROOTFOLDER Support.
INSTALLDIR	This property stores the default destination folder for your installation program's files. You can set an initial value for INSTALLDIR in the General Information view.
LocalAppDataFolder	The location of locally stored application data. A typical value of this property is: `C:\Users\`*`UserName`*`\AppData\Local`
MyPicturesFolder	This property holds the full path to the current user's My Pictures folder.
PersonalFolder	This property holds the full path to the current user's Personal folder.
ProgramFiles64Folder	This property holds the full path to the 64-bit Program Files folder. This property requires Windows Installer version 2.0 or later.
ProgramFilesFolder	This property holds the full path to the 32-bit Program Files folder.
ProgramMenuFolder	This property is used to hold the full path to the Program menu for the current user. If the installation is being run for All Users, and the **ALLUSERS** property is set, the **ProgramMenuFolder** property should hold the full path to the All Users Programs menu.
SendToFolder	This property holds the full path to the current user's SendTo folder.

Table 4-4 • Default Destination Folders for Basic MSI and InstallScript MSI Projects (cont.)

Folder Name	Description
StartMenuFolder	This property is used to hold the full path the Start menu folder for the current user. If the installation is being run for All Users, and the **ALLUSERS** property is set, the **StartMenuFolder** property should hold the fully qualified path to the All Users program menu.
StartupFolder	This property is used to hold the full path to the Startup folder for the current user. If the setup is being run for All Users, and the **ALLUSERS** property is set, the StartupFolder property should hold the full path to the All Users program menu.
System16Folder	This property holds the full path to the folder containing the system's 16-bit .dll file. (In Windows Installer version 2.0, this property is no longer used.)
SystemFolder	This property holds the full path to the 32-bit Windows system folder.
System64Folder	This property holds the full path to the 64-bit Windows system folder. This property requires Windows Installer version 2.0 or later.
TempFolder	This property holds the full path to the Temp folder.
TemplateFolder	This property holds the full path to the current user's Templates folder.
WindowsFolder	This property holds the full path to the Windows folder.
WindowsVolume	This property holds the volume of the Windows folder. It is set to the drive where Windows is installed.

Creating Empty Folders

Basic MSI Projects

You can use the CreateFolder table of an .msi database—exposed in the Direct Editor—to create empty directories.

For an example, see Knowledge Base article Q103218.

InstallScript MSI Projects

The **CreateDir** function creates an empty directory.

Specifying Hard-Coded Destination Directories

In the Files and Folders view, you can specify hard-coded destination directories.

Specifying Drive Destinations

Task: ***To specify a particular drive:***

1. Open the **Files and Folders** view.
2. In the **Destination computer's folders** pane, right-click **Destination Computer** and click **New Folder**, or click **Destination Computer** and press INSERT. InstallShield adds a new folder.
3. For the name of the folder, type the drive letter followed by a colon (for example, `C:`).
4. Press ENTER.

Specifying Folders and Subfolders to Create a Destination Path

You can specify folders and subfolders beneath a drive letter folder to create a hard-coded destination path:

1. Right-click the drive folder (for example, **C:**) under which you want to add a folder or—to add a subfolder—right-click the folder under which you want to add a subfolder. You can also click the folder and press INSERT.
2. For the name of the folder, type the folder name, and then press ENTER.

Quickly Creating Destination Paths

Task: ***To quickly create a nested destination path:***

1. Right-click a folder and click **New Folder**, or click a folder and press INSERT.
2. For the name of the folder, type the destination path—for example, `a\b\c`. This creates a folder structure with `a` at the top, `b` below `a`, and `c` below `b`.

Dynamic File Linking

If you want to add the contents of an entire directory to your project, you can do so through the use of dynamic file linking. When you select a source folder for dynamic linking, InstallShield adds the files within that folder to your release at build time. InstallShield scans the source folder before every build and automatically incorporates any new or changed files into your release. Dynamic file linking is useful when the list of files in a folder—and possibly the list of files in its subfolders—might change between builds.

Important • *Dynamic file linking should be used with caution. If you inadvertently delete a dynamically linked file from the source folder that your dynamic link references, that file is not included in your release the next time you build it, and InstallShield does not display any build warning or error. Your product may install without any issues, but it may not work as expected, since the dynamically linked file that was inadvertently deleted is no longer being installed. Therefore, it is recommended that you avoid using dynamic file links for critical executable files—such as .exe, .dll, or .ocx files—especially if your product requires them in order to run successfully.*

Whenever possible, it is better to use the best practice method, instead of the by-directory method, for creating components for dynamically linked files. Note that with both methods, however, a minor upgrade, a small update, or a patch may not install correctly if a file that was present in a target image is removed from the dynamic link for the upgrade or patch.

Filtering Dynamically Linked Files

When you are configuring your dynamic file link, you can specify whether you want to include subfolders of the dynamically linked folder. To further filter the files that are dynamically linked, you can identify specific names of files that you want to be included in or excluded from the dynamic link. In addition, you can use wild cards to specify only certain files or file types to be added or excluded.

For example, if all of your image files are in one folder along with sound files and you want to dynamically link only the image files, you could specify that you would like to include only .bmp and .ico files in the dynamically linked folder. To do so, you would use an asterisk (*) in your include pattern, as in the following example:

```
*.bmp, *.ico
```

To include or exclude a specific file, you would enter the full file name in the include or exclude pattern box. For more details, see Creating a Dynamic Link.

Distinguishing Dynamically Linked Files and Folders from Static Files and Folders in the InstallShield Interface

When a dynamic file is displayed within the InstallShield interface, the lower-left corner of the file's icon includes an image that indicates that it is a dynamically linked file:

InstallShield includes that same dynamic file image on the icon of subfolders that are included in dynamic file links:

Furthermore, InstallShield adds an arrow to the folder image—in addition to the dynamic file image—on the component icon of subfolders that are included in dynamic file links:

The icons that the InstallShield interface displays for static files and folders do not include this dynamic link image.

Limitations of Dynamic File Linking

Important • *Dynamic file linking should be used with caution. If you inadvertently delete a dynamically linked file from the source folder that your dynamic link references, that file is not included in your release the next time you build it, and InstallShield does not display any build warning or error. Your product may install without any issues, but it may not work as expected, since the dynamically linked file that was inadvertently deleted is no longer being installed. Therefore, it is recommended that you avoid using dynamic file links for critical executable files—such as .exe, .dll, or .ocx files—especially if your product requires them in order to run successfully.*

Whenever possible, it is better to use the best practice method, instead of the by-directory method, for creating components for dynamically linked files. Note that with both methods, however, a minor upgrade, a small update, or a patch may not install correctly if a file that was present in a target image is removed from the dynamic link for the upgrade or patch.

Limitations for Windows Installer–Based Projects

Note the following limitations if you are considering dynamic file linking in Basic MSI, DIM, InstallScript MSI, and Merge Module projects:

- You cannot create custom actions to a dynamically linked file.
- You cannot associate a file extension with a dynamically linked file.
- You cannot extract COM information from a dynamically linked file.
- You cannot set any properties such as Shared, Permanent, or Never Overwrite for a dynamically linked file.
- You cannot use the .NET installer class functionality for a dynamically linked file.
- You cannot specify that COM interop should be enabled for a dynamically linked file.
- You cannot change default file settings (such as Read-Only or Hidden).
- You cannot set file permissions for a dynamically linked file.
- You cannot create shortcuts to a dynamically linked file.
- You cannot perform a static or dynamic scan of a dynamically linked file.
- For Basic MSI projects: You cannot launch a dynamically linked file from the SetupCompleteSuccess end-user dialog.

Any file that you add directly (not through dynamic linking) to your project has an internal name (FileKey). When you create a custom action, a file extension, shortcut, or other type of item, it actually points to this internal name.

When you add files to your project through dynamic links, the files are not physically added to the project. This means that these files do not have any FileKeys that can be associated with custom actions, file extensions, etc.

Limitations for InstallScript–Based Projects

For InstallScript and InstallScript Object projects, a single component cannot contain both static files and dynamically linked files.

Determining the Appropriate Component Creation Method for Dynamically Linked Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

- *Merge Module*

InstallShield provides two methods for creating components for dynamically linked files: the best practice method and the one-component-per-directory method.

Using the Best Practice Method

When best practices for component creation are followed, InstallShield performs the following tasks at build time for all of the files that meet the include and exclude filter criteria of your dynamic link:

- InstallShield creates a separate component for each portable executable (PE) file in the dynamically linked folder. Each PE file is the key file of its component.
- InstallShield adds all non-PE files at the root level of the dynamic link to the component that contains the link.
- If the dynamic link includes a subfolder, InstallShield creates a new component for all of the non-PE files in that subfolder. If the dynamic link includes more than one subfolder, InstallShield creates a separate component for all of the non-PE files in each subfolder.

This is the default functionality for all new dynamic links.

Tip • *The File Extensions tab on the Options dialog box is where you specify which file types are PE files.*

Using the By-Directory Method

When the by-directory method is used for component creation, InstallShield performs the following tasks at build time for all of the files that meet the include and exclude filter criteria of your dynamic link:

- InstallShield creates one component for all of the files that are in the root-level dynamically linked folder, regardless of the file types.
- If the dynamic link includes one or more subfolders, InstallShield creates a separate component for all of the files in each subfolder, regardless of the file types. The first dynamically linked file in a subfolder's component is the key file of that component.

This method of component creation is the traditional method that was available in InstallShield before the best practice method was introduced.

Determining Which Component Creation Method to Use

For most dynamic links, the preferred component creation method is the best practice method. This method enables you to create patches more easily than with the by-directory method. For minor upgrades and small updates, the components, key files, and feature-component organization need to be maintained across the earlier and later .msi databases; for patches, the **File** table keys also need to be maintained. Since each component name and component code—and possibly key files—change at each build with the by-directory method of dynamic file linking, issues may occur. The advantage of the best practice method is that it allows for greater predictability than with the by-directory method.

Tip • *When you are configuring an upgrade, use the patch optimization functionality in your build settings. Using patch optimization helps you keep component names, component codes,* ***File*** *table keys, and* ***Directory*** *table keys synchronized from the earlier release. For more information, see Upgrade Considerations.*

Note that if you want to create a patch for an earlier version of your product, and the earlier installation includes dynamic links that used the by-directory method, you must continue to use the by-directory method for the same dynamic links. However, if you add new dynamic links in your upgrade project, you can use the best practice method for those new dynamic links. That is, you can mix both types of dynamic linking in the same project and create a patch to deliver the upgrade.

Important • *Whenever possible, it is better to use the best practice method, instead of the by-directory method, for creating components for dynamically linked files. Note that with both methods, however, a minor upgrade, a small update, or a patch may not install correctly if a file that was present in a target image is removed from the dynamic link for the upgrade or patch.*

Note • *For information on the rules that Windows Installer uses when determining whether a file included in a package should overwrite a file that already exists on the target system, see Overwriting Files and Components on the Target System.*

Specifying Which Component Creation Method You Want to Use

The File Linking tab on the Component Properties dialog box is where you specify which component creation method you want to use.

Creating a Dynamic Link

Project • *The procedure for creating dynamic file links differs, depending on which project type you are using. Note that parts of the procedure apply to the following Windows Installer–based projects:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Parts of the procedure apply to the following InstallScript-based projects:

- *InstallScript*
- *InstallScript Object*

You can use the Files and Folders view to create a dynamic link.

Task: ***To create a dynamic link:***

1. In the View List under **Application Data**, click **Files and Folders**.
2. In the **Add new components to the feature** list, select the feature that should contain components with the dynamically linked files.
3. Ensure that components are displayed in the **Destination computer's folders** pane.

   If components are not displayed: In the **Destination computer's folders** pane, right-click **Destination Computer** and click **Show Components** (in Windows Installer–based projects) or **Show Components and Subfolders** (in InstallScript-based projects).
4. For a Windows Installer–based project: right-click a component and click **Dynamic File Linking**. The **Component Properties** dialog box opens, and the File Linking tab is displayed.

   For an InstallScript-based project: right-click a component and click **File Linking**. The Link Type dialog box opens.
5. Define the dynamic link and click **OK**.

Tip • *You can also use the Components view to add dynamic file links. For more information, see Adding Dynamic File Links to Components.*

Adding Dynamic File Links to Components

You can use the Components view to add dynamic file links to components in both Windows Installer–based and InstallScript-based projects. The procedure for creating dynamic file links differs, depending on which project type you are using.

Windows Installer–Based Projects

The following procedure applies to Basic MSI, DIM, InstallScript MSI, and Merge Module projects.

Task: ***To add a dynamic link to a component:***

1. In the View List under **Organization**, click **Components**.
2. In the **Components** explorer, expand the component for which you want to add dynamic file links, and then click the **Files** item under that component.
3. Right-click the **Files** pane and click **Dynamic File Linking**. The **Modify Dynamic File Links** dialog box opens.
4. Click the **New Link** button. The Dynamic File Link Settings dialog box opens. This dialog box is where you set the source folder for your link, indicate whether to include its subfolders and whether the files are self-registering, and specify which file types to include and exclude.

5. Click **OK**. Any file conflicts are resolved with prompts to overwrite existing files with the new versions. Click **Yes** to overwrite, **No** to retain the existing file version, or **Cancel** to exit the dialog box without saving any of your dynamic file link settings. You will also be warned if the folder contains no files, or if it is already in use in another dynamic link.

Your new file link details appear in the Files pane.

InstallScript-Based Projects

The following procedure applies to InstallScript and InstallScript Object projects.

Task: ***To add a dynamic link to a component:***

1. In the View List under **Organization**, click **Components**.
2. In the **Components** explorer, click the component that should contain the dynamic link.
3. Select the value of the **Link Type** property and click the ellipsis button (**...**). The Link Type dialog box opens.
4. Specify the folder that contains the files to include, and specify any other desired options.
5. Click **OK**.

Tip • *You can also use the Files and Folders view to add dynamic file links. For more information, see Creating a Dynamic Link.*

Setting a Key File for a Dynamic File Link

Project • *This information applies to dynamic links that use the one-component-per-directory method of component creation (as described in Determining the Appropriate Component Creation Method for Dynamically Linked Files) in the following Windows Installer–based projects:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

This information does not apply to dynamic links that use the best practice method of component creation.

A dynamically linked file whose component uses the one-component-per-directory method of component creation cannot be the key file of a component.

To set a key file for a component containing a dynamic link, add a static link to the desired file, and then set the static link to be the key file of the component. In the dynamic link settings, enter the full name of the key file in the **Exclude files with the following extensions** field.

For example, you might have a source directory containing several .txt files, and you want the file called Key.txt to be the key file. First, add a static link to Key.txt to a component, and set Key.txt as the key file. Next, create a dynamic link with the same source folder, setting the **Include files with the following extensions** setting to `*.txt` and the **Exclude files with the following extensions** setting to `Key.txt`.

For a dynamic link that includes subdirectories, the build process sets the first file in a subdirectory's component as the key file of the dynamically generated component.

Overwriting Files and Components on the Target System

At run time, Windows Installer considers the following questions when determining whether files should be overwritten on the target system:

- Should the component be installed?
- If the component should be installed, do its files need to be installed or updated?

The following sections explain how Windows Installer evaluates these questions.

Determining Whether a Component Needs to Be Installed

During costing, Windows Installer checks the key path of a component to determine if the component should be installed. If the component has a directory or ODBC key path, Windows Installer installs the component. In addition, if a registry key path is used for the component and both of the following conditions are true, Windows Installer installs the component:

- No is selected for the Never Overwrite setting of the component.
- The key path does not exist on the target system.

If one or both of those conditions are false for a component that has a registry key path, Windows Installer does not install the component at run time.

If a component has a key file instead of a key path, Windows Installer checks the target system for the presence of that file. Windows Installer installs the component in all of the following scenarios:

- The file is not present on the target system.
- The file is present on the target system, and the key file of the component has a higher or equal version number compared to the version number of the file on the target system.
- The file is present on the target system, and the key file of the component and the file on the target system are unversioned.

If the key file of the component has a lower version number than the file on the target system, Windows Installer does not install the component at run time. In addition, Windows Installer does not install the component at run time if the key file of the component is unversioned but the file on the target system is versioned. Thus, Windows Installer does not install a component if its key file could be downgraded at run time.

Determining Whether a File Needs to Be Installed

If Windows Installer determines that a component needs to be installed, it reviews the files for that component and determines if they need to be installed. If the name and target location of the key file matches the name and location of a file on the target system, Windows Installer uses the following rules by default to determine whether the file in your installation should overwrite the corresponding file on the target system:

- **Always Overwrite**—If the Always Overwrite check box for the file is selected, the file on the target system is overwritten, regardless of version number.
- **Versioned Files**—In all cases, the file with the highest version is maintained, even if the file already on the target system has a higher version than the one being installed. Additionally, a file of any version is maintained over unversioned files.
- **File Language**—All other things being equal, the file that is the same language as the installation is maintained over different language versions of the file. The only exception to this rule applies to multiple language files. Files with multiple languages are maintained over single language versions of a file.
- **Date**—If the modified date of a file already present on the target system is later than the creation date of that file, the file is not overwritten. This rule protects user preference files from being overwritten during an upgrade or reinstallation.

If a file is in the component that is being installed but it is not present on the target system, Windows Installer always installs that file.

Note *• The* ***REINSTALLMODE*** *property can be set to modify the default file-versioning rules. For more information, see Understanding File Overwrite Rules.*

Companion Files

Project *• This information does not apply to the following project types:*

- *InstallScript*
- *InstallScript Object*

The use of companion files enables you to bind the installation action of one file to another file. For example, if your installation project has two files—**FileA.exe** and **FileB.dat**—companion files let you bind **FileB.dat** to **FileA.exe** so that if **FileA.exe** needs to be installed or reinstalled, then **FileB.dat** is also installed or reinstalled. If **FileA.exe** needs to be uninstalled, then **FileB.dat** is also uninstalled.

Using Companion Files

This mechanism is useful when trying to override the Windows Installer's default file versioning rules. For instance, file versioning rules state that for non-versioned files, any file on the target machine that has a modified date later than its created date is considered user data and should not be overwritten. This is not always a valid assumption, so you may want to use companion files to bind a non-versioned file to a versioned file.

Creating Companion File Associations

Task: ***To create a companion file association:***

1. In the **Files and Folders** view, add the versioned file to your project.
2. Open the **Components** view.
3. In the **Components** explorer, expand the component that contains the file that you just added, and then click **Files**. Note the value in the **Key** column for that file.
4. Right-click the file and then click **Add**.
5. Select the unversioned file to add it to the selected component.
6. Right-click the second file and then click **Properties**. The Properties dialog box opens.
7. Select the **Override system version** check box.
8. In the **Version** box, type the name of the value noted in the **Key** column from step 3.

Note • *InstallShield generates a unique file key every time you add a file. Therefore, if you remove the file that you have created a binding to, it is possible that the file key will not persist. You would need to update the version of the unversioned file.*

Finding Files and Folders in Your Project

If you have added numerous folders and files to your project, you may have trouble finding a particular folder or file. You can perform a search for folders and files in the Files view; InstallShield locates any matches and highlights the first one. You can keep searching until you find all matches for your search criteria.

Task: ***To find files and folders in your project:***

1. Open the **Files and Folders** view.
2. In the **Destination computer's folders** pane, select **Destination Computer**.
3. On the **Edit** menu, click **Find**. The **Find** dialog box opens.

   As an alternative, you can press CTRL+F.
4. In the **Find What** box, type the text to be found. You can use wildcard expressions, such as `*.exe`.
5. In the **Look at** area, specify whether you want to search for files, folders, or both.
6. Specify any other desired criteria.
7. Click **Find Next**. The first item (if any) that matches your search criteria is selected in either the **Destination computer's folders** pane or the **Destination computer's files** pane.

8. To find the next item (if any) that matches your criteria, press the F3 key. Repeat this step as necessary.

Configuring Permissions for Files and Folders

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield lets you configure settings for securing files and folders for end users who run your product in a locked-down environment. You can assign permissions for a file or folder to specific groups and users. For example, you may assign Read, Write, and Delete permissions for a particular file to the Administrators group, but only Read permissions for all of the users in a different group.

Task: ***To configure the permissions for a file or folder:***

1. In the View List under **Application Data**, click **Files and Folders**.
2. For a file: In the **Destination computer's files** pane, right-click the file and then click **Properties**. The **Properties** dialog box opens.

   For a folder: In the **Destination computer's folders** pane, right-click the folder and then click **Properties**. The **Properties** dialog box opens.
3. Click the **Permissions** button. The **Permissions** dialog box opens.
4. Add, modify, and remove permissions entries as needed. For more information, see Permissions Dialog Boxes for Files and Directories.

Depending on what is selected for the Locked-Down Permissions setting in the General Information view of your project, InstallShield adds permissions data to either the **ISLockPermissions** table or the **LockPermissions** table. To learn more, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.

Tip • *You can also configure permissions for a component's destination folder. To do so, first click a component in the Components view. Next, click the value for the Destination Permissions setting, and then click the ellipsis button (...). The Permissions dialog box opens. On this dialog box, you can configure permissions as needed.*

Extracting COM Data When Files Are Added

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

When you drag and drop new files in the Files and Folders view or in the Files subview under a component, you can statically extract COM data for self-registering files. This is an alternative to extracting COM registration data at build time.

This option is also available in the COM Registration node under Advanced Settings in the Components view.

Extracting a File's COM Data

Task: ***To extract COM data on demand, rather than at build time:***

Right-click the file (or in the **COM Registration** node, right-click **COM Registration**) and click **Extract COM Data for Key File**.

Note • *This option is enabled only if the file is an .exe file or a file that is self-registering, and if the file is the component's key file.*

Tip • *If you are using InstallShield on a 64-bit system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit. To learn more about 64-bit support, see Targeting 64-Bit Operating Systems.*

Refreshing a File's COM Data

If the file's COM data has already been statically extracted, you can select Refresh COM Data for Key File. When you refresh the COM data, the old COM data is deleted from the project, then the current COM data for the file is added to the project.

Identifying Properties and Dependencies of .NET Assemblies

Project • *This information applies to the following project types:*

- *Basic MSI*

- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield offers support for identifying the properties and dependencies of .NET assemblies. The functionality depends on the project type that you are using.

Windows Installer–Based Projects

In Basic MSI, DIM, InstallScript MSI, and Merge Module projects, when you add a .NET assembly to your project, it is recommended that you set it as the key file of its component. No other .NET assemblies should be included in that component.

When a .NET assembly is the key file of its component, you can use one of the following methods to identify its dependencies:

- If you know which files and merge modules are required for the .NET assembly, you can manually add them to the same feature that contains the .NET assembly component in your project. This method is recommended, since it gives you the most control over what is included in your project.
- If you do not know which files and merge modules are required for the .NET assembly, use one of the following built-in methods:
    - To identify the .NET assembly's dependencies on demand, use the Static Scanning Wizard to detect possible dependencies. This wizard displays a list of the dependencies that it finds, and it lets you specify whether you want to include each one in your project. Note that this method is available in Basic MSI and InstallScript MSI projects, but not in DIM or Merge Module projects.
    - To identify the .NET assembly's dependencies each time that you build your project, select Dependencies and Properties for the component's .NET Scan at Build setting. If InstallShield detects any possible missing dependencies at build time, InstallShield incorporates them into the release that it generates.

Configuring the properties of a .NET assembly makes it possible for Windows Installer to update and uninstall the assembly when needed. When a .NET assembly is the key file of its component, you can use either of the following methods to identify its properties:

- Manually enter the properties and their values: In the Components view, under the Advanced Settings area for the component that contains the .NET assembly, select .NET assembly subnode under the Assembly node, and configure the properties as needed. Note that the properties and values that you enter must match the information in the assembly's manifest file. If they do not match, the assembly might be left on the target system when the feature that contains the .NET component is uninstalled.
- To identify the .NET assembly's properties each time that you build your project, select the Properties Only option or the Dependencies and Properties option for the component's .NET Scan at Build setting. If InstallShield detects any possible missing properties at build time, InstallShield incorporates them into the release that it generates.

InstallScript Projects

In InstallScript projects, when you add a .NET assembly to a component in your project, you can use the component's .NET Assembly setting to identify the assembly as a local .NET assembly. You can also use one of the following methods for identifying the dependencies of the .NET assembly:

- If you know which files and merge modules are required for the .NET assembly, you can manually add them to the same feature that contains the .NET assembly component in your project. This method is recommended, since it gives you the most control over what is included in your project.
- If you do not know which files and merge modules are required for the .NET assembly, use one of the following built-in methods:
  - To identify the .NET assembly's dependencies on demand, use the Static Scanning Wizard to detect possible dependencies. This wizard displays a list of the dependencies that it finds, and it lets you specify whether you want to include each one in your project.
  - To identify the .NET assembly's dependencies each time that you build your project, select Dependencies for the component's .NET Scan at Build setting. If InstallShield detects any possible missing dependencies at build time, InstallShield incorporates them into the release that it generates.

If Not an Assembly is selected for the component's .NET Assembly setting, InstallShield does not scan for dependencies of the component's assembly.

Note that when Local Assembly is selected for the component's .NET Assembly setting, the installation performs COM interop registration and configures .NET installer class information for the component at run time.

Scanning 64-Bit .NET Assemblies for Dependencies

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

If you use InstallShield on a 64-bit version of Windows Vista or later or a 64-bit version of Windows Server 2008 or later, and you use either of the following built-in methods for detecting dependencies, InstallShield can scan for 64-bit dependencies of the 64-bit .NET assemblies in your project:

- To identify a 64-bit .NET assembly's dependencies on demand, use the Static Scanning Wizard to detect possible dependencies. This wizard displays a list of the dependencies that it finds, and it lets you specify whether you want to include each one in your project.
- To identify a 64-bit .NET assembly's dependencies each time that you build your project, select one of the dependency options for the component's .NET Scan at Build setting. For InstallScript projects, the component's .NET Assembly setting must also be set to Local Assembly. If InstallShield detects any possible missing dependencies at build time, InstallShield incorporates them into the release that it generates.

These methods also scan for 32-bit dependencies of the 32-bit .NET assemblies in your project.

Note that if you use InstallShield on a 32-bit version of Windows, these built-in scans can check for only 32-bit dependencies of the 32-bit files in your project. If your project includes 64-bit files, you can manually add any dependencies to the project as needed.

How the Built-In Scanning Methods Detect Platform-Specific and Platform-Independent .NET Dependencies in Windows Installer–Based Projects

In Basic MSI, DIM, InstallScript MSI, and Merge Module projects, when you use either of the aforementioned built-in methods for detecting .NET dependencies, InstallShield uses a specific order for detection, as indicated in the following table.

Table 4-5 • Order for Detecting .NET Assembly Dependencies

Type of File Being Scanned	Scan Results on 32-Bit Windows Systems	Scan Results on 64-Bit Windows Systems
Platform-independent .NET assembly in the GAC	InstallShield uses the following order when scanning for dependencies: 1. 32-bit-specific .NET dependencies 2. Platform-independent .NET dependencies	InstallShield uses the following order when scanning for dependencies: 1. 64-bit-specific .NET dependencies 2. Platform-independent .NET dependencies
64-bit .NET assembly in the GAC	InstallShield does not detect any dependencies.	InstallShield uses the following order when scanning for dependencies: 1. 64-bit-specific .NET dependencies 2. Platform-independent .NET dependencies
32-bit .NET assembly in the GAC	InstallShield uses the following order when scanning for dependencies: 1. 32-bit-specific .NET dependencies 2. Platform-independent .NET dependencies	InstallShield uses the following order when scanning for dependencies: 1. 32-bit-specific .NET dependencies 2. Platform-independent .NET dependencies

If a .NET assembly is not in the GAC, InstallShield checks the same folder that contains the assembly when scanning for dependencies, and then it checks any subfolders.

Reviewing .NET Dependency Scanner Results

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield offers different built-in methods for identifying dependencies of .NET assemblies. If you use these built-in methods, the scanning may identify as a dependency a file or merge module that is not required by your product. If you are using the Static Scanning Wizard and that occurs, you can specify in the wizard that you do not want to add that dependency to your project. If you are using the .NET scan at build functionality to automatically include any possible .NET dependencies in your project at build time, you can change the values of the component's settings so that the .NET assembly is not scanned for dependencies automatically:

- In Basic MSI, InstallScript MSI, and Merge Module projects, InstallShield scans each component's .NET assembly for dependencies automatically at build time by default. You can override this default behavior by changing the value of a component's .NET Scan at Build setting as needed.
- In InstallScript projects, InstallShield does not scan each component's .NET assembly for dependencies at build time by default. You can override this default behavior by changing the values of a component's .NET Assembly setting and its .NET Scan at Build setting as needed.

In addition, InstallShield enables you to specify on a machine-wide basis any files that you want to be included or excluded automatically any time that you perform a dependency scan through InstallShield. For more information, see Filtering Files in Dependency Scanners.

To obtain the best results when you are trying to identify dependencies, it is recommended that you thoroughly test your product and its installation on a clean machine. If your product does not behave as expected, determine whether any dependencies are missing from the machine, and if so, whether they should be included in the installation.

Installing Fonts Through InstallScript and InstallScript Object Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

When you include a font file—.ttf, .ttc, or .fon file—in your installation project (using either the Components view or the Files and Folders view), the file is automatically marked internally to be registered on the target machine if you have enabled global font registration. At run time, the **OnInstalledFontFile** event handler function is called immediately after each font file is installed; the default code for this event handler function calls the **RegisterFontResource** function to register the font if it is internally marked for registration.

Font Titles

InstallShield determines the font title that the installation registers for the font in the following manner:

- For an .fon file, InstallShield—by default—reads the font title from the registry of the source system. If no title can be found in the registry, InstallShield stores the file name as the font title. For an .fon file in a component whose Link Type property is set to Static, InstallShield displays the font title in the Font title box on the file's File Properties dialog box.
- For a TrueType file (.ttf or .ttc file), by default the installation reads the font title from the file at run time, and at design time no text is displayed in the Font title box.
- For all three types of files, in a component whose Link Type property is set to Static, if you enter non-default text in the Font title box, the installation registers that text as the font title.

Installing Fonts to the Windows Fonts Folder

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

Task: ***To install a font file to the Windows Fonts folder, do either of the following:***

- In the **Files and Folders** view, place the font file in the **Destination computer's folders** pane's **Fonts Folder** folder, which is a subfolder of the **Windows** folder.
- In the **Components** view, place the font file in a component whose **Destination** property is set to **<FOLDER_FONTS>**.

Enabling or Disabling Global Font Registration

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

You can enable or disable automatic registration of font files globally.

Task: ***To enable or disable global font registration:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Font Registration** setting, specify the appropriate option:

- To enable global font registration, select **Enabled**.
- To disable global font registration, select **Disabled**.

Enabling or Disabling Registration of a Font File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

You can enable or disable automatic registration of font files for individual files.

Task: ***To enable or disable automatic registration of an individual font file:***

1. Open the **Components** view, **Setup Design** view, or **Files and Folders** view.
2. Right-click the font file and click **Properties**. The **Properties** dialog box opens.
3. To enable automatic registration of the font file, select the **Register Font File** check box.

   To disable automatic registration, clear the **Register Font File** check box.
4. Click **OK**.

Using Components

Components are elements of the application from the installation developer's perspective. Components are not visible to the end user. When the user selects a feature for installation, the installer determines which components are associated with that feature and then those components are installed. Components of an application would contain the executable binary files, data files, shortcuts, help system files, and registry entries.

You can create and modify components in the Setup Design view (for installation projects) or the Components view.

Component-Feature Relationships

Project • *Features are not used in DIM or Merge Module projects.*

Components are associated with features in the Setup Design view. For more information, see Associating New Components with Features.

Files

Expand a component's tree in the Setup Design view or the Components view and click Files to view a list of all files associated with that component. To learn how to add files, see Adding Files to Components.

Setup Best Practices

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield makes adhering to Setup Best Practices easier by alerting you to Best Practices violations while you are creating components in the Setup Design view and in the Component Wizard. By following these guidelines, you can create clean installations that distribute reusable components efficiently and avoid problems that result from file incompatibility.

When you are creating components in the Setup Design view, the Setup Best Practices Wizard monitors the files that you add to the components, alerts you when you have done anything that conflicts with Best Practices, and then gives you the opportunity to correct the action in the wizard. To turn off the wizard's automatic scanning of your setup design, select Options from the Tools menu.

InstallShield checks for compliance with the following Setup Best Practices:

Table 4-6 • Setup Best Practices that InstallShield Monitors

Best Practice	Description
Components should not contain multiple .exe, .dll, .ocx, .chm, or .hlp files	Each component should contain only one portable executable file (an .exe, .dll, or .ocx file) or WinHelp file (.hlp file). Windows Installer components are designed such that all of the advanced settings and component settings, such as the GUID code, refer ideally to a single portable executable file or help file. Place other .exe, .dll, .ocx, and .hlp files into new components. One reason for this rule is that, at run time, if the user chooses Repair for an installed product, Windows Installer checks for the existence of each installed component's key file. If the key file is missing, Windows Installer reinstalls the missing component. Therefore, if a file that is not the key file of a component is missing, it may not be restored during repair mode.

Table 4-6 • Setup Best Practices that InstallShield Monitors (cont.)

Best Practice	Description
Use merge modules	Merge modules contain all of the files, registry entries, and logic necessary to install a distinct piece of functionality. You should not distribute a file for which a merge module is available. Using merge modules also helps you comply with two related requirements—the Best Practice to avoid associating a file with more than one component and the Windows logo guideline not to ship any core components. If the Best Practices monitoring option is enabled, the Setup Best Practices Wizard alerts you whenever you try adding to a component any file that is part of the merge modules that InstallShield provides.

You should also be aware of the following component creation Setup Best Practices, to which InstallShield does not automatically alert you:

Table 4-7 • Setup Best Practices for which InstallShield Does Not Automatically Provide Alerts

Best Practice	Description
Put a shortcut target in its own component	Any file that serves as the target for a shortcut requires its own component. That file must be the key file for the component.
Group other files into components	Organize all files that do not fall into any of the above categories in components according to the files' requirements, such as a common destination folder or version checking.
Do not self-register files	Instead of calling self-registration functions to register and unregister COM server information, you should register this information for the component during installation (and the installer will unregister it during uninstallation). Self-registration is an unreliable method for registering and unregistering files. One advantage of having the installation register the information is that if the file is advertised, or not immediately installed, the registration is in place when the file is later requested from the installer. Therefore, InstallShield supports advanced settings specifically for registering COM servers.

Component Creation

InstallShield offers several methods for creating components.

- Use the Setup Design view (in installation projects only) or the Components view to create a new component and manually configure it. For more information, see Using the Setup Design or Components Views to Create a Component.

- Use the Component Wizard to allow InstallShield to define components for you according to Setup Best Practices. This wizard is available in the following project types: Basic MSI, DIM, InstallScript MSI, and Merge Module. For more information, see Using the Best Practices Option with the Component Wizard.
- If you are creating a component for a COM server, or a font, it is recommended that you use the Component Wizard. This wizard is available in the following project types: Basic MSI, DIM, InstallScript MSI, and Merge Module. For more information, see Using the Component Type Option with the Component Wizard.

Using the Setup Design or Components Views to Create a Component

For installation projects, you can create a new component in the Components view and then associate it later with a feature, or you can create a component under a specific feature in the Setup Design view, as described below. Note that the Setup Design view is not available in DIM or Merge Module projects.

Using the Setup Design View to Create a Component

For installation projects only, follow the steps below to create a component in the Setup Design view.

Task: ***To create a component in the Setup Design view:***

1. In the View List under **Organization**, click **Setup Design**.
2. In the **Setup Design** explorer, right-click a feature or subfeature and click **New Component**, or press CRTL+INSERT. InstallShield adds a new component with the default name **New Component n** (where *n* is a successive number).
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.

The new component is automatically associated with the selected feature.

Using the Components View to Create a Component

For installation projects, DIM projects, and Merge Module projects, follow the steps below to create a component in the Components view.

Task: ***To create a component in the Components view:***

1. In the View List under **Organization**, click **Components**.
2. Right-click the **Components** explorer and click **New Component**, or press INSERT. InstallShield adds a new component with the default name **New Component n** (where *n* is a successive number).
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.
4. For installation projects, associate the component with one or more features.

Note • *In installation projects, components that are not associated with a feature are displayed with the orphaned component icon (*  *).*

In InstallScript projects, the following characters are invalid in component names:

`\ / : * ? " ' < > |`

When you create a component, its property sheet is displayed to the right. You should immediately specify the component's properties, including the required Component Code (Windows Installer–based projects only) and Destination properties.

After you have created a component and specified its properties, you can associate your application's files, registry entries, and shortcuts with it.

Using the Best Practices Option with the Component Wizard

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The fastest way to create components is to launch the Component Wizard and have InstallShield organize your files into components for you. Select the **Create components for me using best practices** option to have the wizard generate components by applying Setup Best Practices to the files you specify.

Task: ***To launch the Component Wizard, do one of the following:***

- For installation projects only: Right-click a feature in the **Setup Design** view and select **Component Wizard**.
- For installation projects, DIM projects, and Merge Module projects: Right-click **Components** in the explorer of the **Components** view and click **Component Wizard**.

Best Practice Rules for Creating Components

Project • *This information applies to the following project types:*

- *Basic MSI*

- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you select the Best Practices option for creating a component through the Component Wizard, the wizard automatically organizes your files into components based on Setup Best Practices. It creates components according to the following rules:

- The wizard looks at every file that you add to see if it is already included in your project. If the file is a duplicate, the wizard does not create a component for it.
- A new component must be created for each portable executable file (.exe, .dll, or .ocx file). The component bears the name of the portable executable file. The wizard creates a GUID for the Component Code property and sets the portable executable file as the component's key file.
- The Component Wizard attempts to extract registration information for each portable executable file. If it succeeds, the wizard creates a COM server component and writes the data to the component's COM Server advanced setting.
- Every help (.hlp) file that you specify will reside in its own component along with its associated contents (.cnt) file. The component is named after its help file. The wizard creates a GUID for the Component Code property and makes the help file the component's key file. The same rule applies to HTML Help (.chm) files and the .chi files that accompany them.
- The Component Wizard puts all font (.ttf and .ttc) files into a single component called Font Files. The wizard creates a GUID for the Component Code property and sets the first file in the list as the key file. Any .fon files that you specify will automatically be included in the AllOtherFiles component that is created. Since .fon files do not have a title, they will not be added to the Font table in the .msi package. To have these files added as fonts, you will need to use the Fonts option in the Component Wizard.
- Any files that do not fall into the above categories are grouped into a single component named All Other Files. The wizard creates a GUID for the Component Code property and sets the first file in the list as the key file.

Letting InstallShield Create a COM Server Component

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If you select the **Create components for me using Best Practices** option on the Welcome panel of the Component Wizard, InstallShield automatically creates a separate component for each portable executable file that you specify. The wizard also attempts to extract registration information for each portable executable file.

If it succeeds, all of the registration information that maps to the COM Registration advanced setting is written there. The wizard creates any additional entries, such as the InProcServer32 ThreadingModel value, in the component's registry data.

Note • *If your COM server is an executable, you must put an OLESelfRegister attribute with the value of 1 into the Version section of the component's resource file.*

Letting InstallShield Create Font Components

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If you select the **Create components for me using Best Practices** option on the Welcome panel of the Component Wizard, InstallShield automatically creates a separate component for all font (.ttf and .ttc) files that you specify. Any .fon files are added to the AllOtherFiles component that is created due to the fact that these files do not have an embedded font title. To have .fon files added to your setup as fonts, use the Fonts option in the Component Wizard.

The destination folder for the font component is set to the destination folder that you chose in the Component Wizard. After the component is created, you can set its Destination Folder to the Windows Installer folder property FontsFolder (that is, use **[FontsFolder]** as the destination), the usual default location for fonts. Place square brackets around FontsFolder, as you would when specifying **[INSTALLDIR]**.

Task: ***If the font was not registered on your system, you must specify the font title by doing the following:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. In the explorer, expand the component that contains the font file and click **Files**. The **Files** view opens.
3. Right-click the font file and click **Properties**. The **Properties** dialog box opens.
4. In the **Font title** box, type a font title in the format `FontName (FontType)`—for example, `Roman (All res)`.
5. Click **OK**.

Using the Component Type Option with the Component Wizard

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If you have files with special installation requirements, using the **Let me select a type and define the component myself** option of the Component Wizard is the recommended method for organizing them into components.

Task: ***To launch the Component Wizard, do one of the following:***

- For installation projects only: In the **Setup Design** view, right-click a feature and click **Component Wizard**.
- For installation projects, DIM projects, and Merge Module projects: In the **Components** view, right-click the **Components** explorer and click **Component Wizard**.

The **Let me select a type and define the component myself** option of the Component Wizard supports the following component types:

- COM servers
- Font files
- Install services
- Control services

Note • *If you want to create a component that installs, starts, stops, or deletes a service during installation or uninstallation, you can use the Services view. You can also use this view to configure extended service customization options, which are not configurable through the Component Wizard. For more information, see* *Installing, Controlling, and Configuring Windows Services**.*

Installing COM Servers

Project • *This information applies to the following project types:*

- *Basic MSI*

- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Although you can create a component in one of several ways, the recommended method for installing a COM server (.exe, .dll, or .ocx) file in an installation is to create a COM server component in the Component Wizard.

The wizard panels displayed depend on the selections you made in previous panels. For example, the Classes panel is not displayed if the wizard succeeds in extracting the registration information in the COM Server Executable panel.

Tip • *InstallShield includes support for 64-bit COM extraction. For more information, see Targeting 64-Bit Operating Systems.*

Installing Fonts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Although you can create a component in one of several ways, the easiest way to install a font (a .ttf, .fon, or .ttc file) in an installation is to create a Fonts component in the Component Wizard.

In the Component Wizard, the panels that are displayed depend on the selections made in previous panels. For example, the Add New Fonts panel is not displayed unless you selected **I also want to add fonts not installed on this system** in the Add Installed Fonts panel.

Exporting Components to Other Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To save a component to another project:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. Right-click the component and click **Export Components Wizard**.

Tip • *You can also access the Export Components Wizard from the Project menu in InstallShield.*

When you export a component into a project, a copy of this component is added to the specified .ism file, along with all of the component's data, such as its files, shortcuts, registry entries, and advanced settings. Any string entries, properties, and path variables used in the dialog are also copied to your new project.

If the target .ism file already has a component of the same name with different properties, the Resolve Conflict dialog box opens to offer you options for resolving the conflicts.

Deleting a Component in Your Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You can permanently delete components in both the Setup Design view and the Components view.

Task: ***To delete a component:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. Right-click the component and click **Delete from project**.

The component is permanently deleted from your project.

Component-Feature Associations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Transform*

A component can be associated with as many features or subfeatures as necessary. For example, a text editor product might have two features—an editor and a spell checker. Both the editor and spell checker have dependencies that are in a System .dll files component. When designing this installation, you should associate the System .dll files component with both the editor and the spell checker features.

You can associate components with features in the Setup Design view. There are two ways to associate components with features in the Setup Design view, depending on whether or not the component already exists. For more information, see Associating New Components with Features and Associating Existing Components with Features.

Note • *Components that are not associated with a feature are displayed with the orphaned component icon:*

Associating New Components with Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Transform*

Task: ***To associate a new component with a feature:***

1. In the View List under **Organization**, click **Setup Design**.
2. Right-click the feature or subfeature and click **New Component** or **Component Wizard**. InstallShield creates a component and associates it with the selected feature.

Associating Existing Components with Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Transform*

Task: ***To associate an existing component with a feature:***

1. In the View List under **Organization**, click **Setup Design**.
2. Right-click the feature or subfeature and click **Insert Components**.
3. Select the components you want to associate with this feature from the list of components, and click **OK**.

You can move or copy existing components from one feature to another using a drag-and-drop operation:

- To move an existing component, drag the component from one feature to another.
- To copy an existing component, press CTRL while you drag the component from one feature to another.

Disassociating Components from Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Transform*

Task: ***To remove a component-feature association:***

1. In the View List under **Organization**, click **Setup Design**.
2. Right-click the component that you want to dissociate from the feature, and click **Remove from feature**.

Even though the component is no longer associated with this feature, it is still present in your project.

Adding Data to a Component

You can use the Components view to add files, registry data, and shortcuts to components.

Adding Files to Components

All of the files in a component must share the same component settings.

Criteria for Adding Files to a Component

You can add a group of files to a component only if they satisfy all of the following criteria:

- All files have the same destination folder.
- All files should be installed with the same conditions (including operating system and language).

Create new components organized around your files' installation needs and component properties. You should also be aware of Setup Best Practices when adding files to a component. Setup Best Practices helps you to write clean installations and distribute reusable components effectively.

Methods for Adding Files to Components

The way in which you add files to a component varies slightly depending on how you create your component. The sections below discuss how to associate files with components based on the way in which the component was created.

Creating a New Component in InstallShield

When you create a component by right-clicking in the Setup Design view (for installation projects) or the Components view, first select the component's Files item to view its file list.

Task: ***Use one of the following methods to associate files with this component:***

- Drag and drop files from Windows Explorer onto the file list.
- Right-click in the file list and click **Add**. In the resulting dialog box, browse to select as many files as you want to add from that folder. Click **Open**.

Creating a New Component Using the Component Wizard

If you use the Component Wizard to create a component, you can add files to the component in the Files panel.

Task: ***Use one of the following methods to associate files with this component:***

- Drag and drop files from Windows Explorer onto the file list.
- Right-click in the file list and click **Add**. In the resulting dialog box, browse to select as many files as you want to add from that folder. Click **Open**.

InstallShield creates links to your application's files. These links are used to locate the files when you build a release of your installation. If any of these links becomes invalid, File Not Found appears next to the file.

All of the above methods for adding files link the files statically, which means that the file links do not change if new files are added to or removed from the source folder. For an alternative to static linking, see Adding Dynamic File Links to Components.

Changing the Value in the Link To Column for a Component's File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

In the Components view, you can expand a component to display the Files node, which shows the files associated with that component. In the Files explorer, the Link To column provides the directory or the path variable that you used when you added the file. You can use the Direct Editor to change what appears in this column.

Task: ***To edit the directory:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, click **File**.
3. Locate the file and edit the value in the **ISBuildSourcePath** column.

Deleting a File from a Component

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To delete a file from a component:***

1. In the View List under **Organization**, click **Components**.
2. In the **Components** explorer, expand the component that contains the file that you want to delete, and then click **Files** item under it. The files associated with that component are displayed in the right pane.
3. Right-click the file that you want to delete and click **Delete**.

Adding Registry Data to Components

You can use the Registry view to add registry keys and values to a component. This information is written to the target system's registry if the component is installed. To learn how to add registry keys and values, see the following:

- Creating Registry Keys
- Dragging and Dropping Registry Entries to Create Registry Keys
- Creating Registry Values
- Importing Registry Files
- Exporting Registry Files

Creating Shortcuts in the Components View

Project • *For installation projects, you can create shortcuts in the Shortcuts view.*

Before you can create a shortcut, you must create a component that contains the file to which the shortcut is going to link.

Task: ***To create a new shortcut:***

1. In the View List under **Organization**, click **Components**.
2. In the **Components** explorer, expand the component that should be associated with the shortcut that you are creating, and then click **Shortcuts**. The **Shortcuts** explorer opens in a new pane.
3. In the **Shortcuts** explorer, right-click a destination folder and click either **New Folder** or **New Shortcut**. You can create a program folder if you want your shortcut to appear under your company name, for example.

   If you created a folder for your shortcut, create the shortcut by right-clicking your new folder and clicking **New Shortcut**.
4. Define the shortcut's properties.

Adding Subfolders to Statically Linked Components

Project • *This information applies to InstallScript projects.*

Task: ***To add a subfolder to a statically linked component:***

In the **Components** or **Setup Design** view, right-click the component's **Static File Links** subnode and then click **New Folder**.

Component Key Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

One of your component's files can serve as its key file. A key file is a file that the Windows Installer uses to detect the component's presence on the target machine and determine whether it needs to be updated. In order to create advanced component settings or shortcuts, a key file must be specified.

Caution • *If your project includes dynamically linked files, InstallShield may automatically set some of the dynamically linked files as the key file of a component. For more information, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.*

Setting Component Key Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To specify one of your component's files as the key file:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. In the explorer, expand the component and click **Files**.
3. Right-click in the files list and click **Set Key File**. The file icon ( ) for that file is replaced with a key icon ( ).

A component can have either one key file or one key path. If you have already set a key file or a key path for a component, a warning message box appears if you try to set another key file. Click Yes in the message box to replace the existing key file or key path with the new key file.

Note • *You cannot specify a key file in the Files and Folders view. Key files must be set in either the Setup Design or Components view.*

Clearing a Key File from a Component

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If you no longer want a file to serve as the component's key file, you can clear the key file from that component.

Task: ***To clear the key file from a component:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. In the explorer, expand the component and click **Files**.
3. Right-click the key file and click **Clear Key File**.

Component Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you create a component, its settings have default values, depending on whether you created the component using a view, or using a wizard.

Task: ***To edit a component's settings:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. Click the component that you want to configure, and modify its settings as needed.

For descriptions of each of the settings, see Component Settings.

Component Destination vs. Feature Destination

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Note that DIM, Merge Module, and MSM Database projects do not include features. These types of projects are added to features in Basic MSI projects. Thus, components in DIM, Merge Module, and MSM Database projects are associated with the features in the installation projects that consume them.

Both components and features have a destination setting, but there are some differences in how they are used when an end user runs your installation.

Allowing End Users to Change the Destination

You can use the feature's destination setting if you want to allow the end user to modify where the feature is installed on the target system. Because a feature's destination can be changed by the end user, you must use a public property for the feature destination. A public property has a name with only uppercase letters (for example, **INSTALLDIR**).

Note • *If you want all the components in a feature to be installed to the feature's destination, you must set all of the components' destinations to match the feature's destination.*

Setting a Specific Destination

If you want a component to go to a specific location that cannot be changed by the end user, you must set the component destination to some directory that is not used as a feature destination.

Setting a Destination Folder for the Component's Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Each component can have a different destination location for its files. The default value for the Destination setting is as follows:

- For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, and MSM Database, and Transform projects—**INSTALLDIR**, initialized to `[ProgramFilesFolder]Company Name\Product Name` in the product's **INSTALLDIR** property
- For InstallScript and InstallScript Object projects—**TARGETDIR**, initialized by default to `PROGRAMFILES ^ IFX_COMPANY_NAME ^ IFX_PRODUCT_NAME` in the default script code for the **OnFirstUIBefore** event handler function

Windows Logo • *According to Windows logo requirements, the default destination of your application's files must be a subfolder of the end user's Program Files folder. If you use **INSTALLDIR** or **ProgramFilesFolder** as the parent folder for your feature's Destination setting, your files will be installed to the correct location.*

Task: ***To change the component's destination folder:***

1. In the View List under **Organization**, click **Setup Design** (installation projects only) or **Components**.
2. Select the component whose destination you want to change.
3. In the **Destination** setting, select one of the options from the list, or click the ellipsis button (**...**) to select or create a directory.

Other Destination Folder Considerations

Project • *These considerations apply to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Component's Remote Installation Setting

Setting the component's Remote Installation setting to Favor Source (or to Optional when the component's feature is set to Favor Source) means that the component's files will not be installed on the target system, regardless of the component's Destination setting.

Feature's Remote Installation Setting

Each feature also has a Destination setting. If different, the component's Destination setting overrides the feature's destination. The feature's Destination setting is optional, but the component's is required.

INSTALLDIR as Default Destination

The assumption behind using **INSTALLDIR** as the default Destination setting for all of your features and components is that you want all of your application's files installed to the same root folder. This way, when an end user changes the destination folder for any of the features in the CustomSetup dialog, the destination folders for all of the features that are set to be installed to the path contained in **INSTALLDIR** also change.

Note • *If the component's destination is set to something other than **INSTALLDIR**, the components are installed to the destination specified for each component and changing **INSTALLDIR** has no effect on the components' destinations.*

*An installer folder property such as **INSTALLDIR** specifies a default value. An end user can change this value by setting a property when launching `Msiexec.exe` at the command line or by selecting a new destination folder for a feature in the CustomSetup dialog.*

[GlobalAssemblyCache] for Components Containing a .NET Assembly

If a component contains a .NET assembly, you can set the component's destination to **[GlobalAssemblyCache]**. When a .NET assembly is installed to a target system's Global Assembly Cache (GAC), the assembly can be accessed by other applications on the system.

In general, it is preferable to install assemblies to the local application directory. This increases application isolation.

Note • *To install an assembly to the Global Assembly Cache, the .NET Scan at Build setting for the assembly's component must be set to either Properties Only or Dependencies and Properties.*

Specifying a Component's Destination from the Script

Project • *This information applies to InstallScript projects.*

Specifying the target destination of a component's files from the script lets you change that destination at run time based on end-user input or other conditions.

Task: ***To specify the target destination of a component's files from the script:***

1. In the View List under **Application Data**, click **Files and Folders**.
2. In the **Destination computer's folders** pane, right-click **Script-defined Folders** and click **New Folder**. InstallShield adds a subfolder with the default name **<NEW VARIABLE N>**, where *N* is a successive number. You can rename this subfolder to any string that is enclosed in angle brackets; for example, `<My Script-defined Folder>`.
3. To specify the target destination of an existing component's files:
   a. In the View List under **Organization**, click **Components** or **Setup Design**.
   b. Select the component that you want to configure.
   c. In the component's property grid, click the value of the **Destination** property and in the list, select the name of the subfolder that you created in step 1.

   To create a new component and specify the target destination of its files:
   a. In the **Files and Folders** view, drag the desired file or files from the **Source computer's folders** pane and drop them on the subfolder that you created in step 1. InstallShield creates a new component with the default name **FilesN**.
   b. In your script, call **FeatureSetTarget** to assign a target location to the subfolder that you created in step 1; for example:

```
AskDestPath( "" , "Choose a location for the XYZ files." , svEndUserSelectedPath, 0 );
FeatureSetTarget( MEDIA , "<My Script-defined Folder>" , svEndUserSelectedPath);
```

Uppercase Directory Identifiers and Component Destinations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Declaring a Directory Identifier in uppercase letters makes that value a public property that can be set from the user interface. In order to allow the end user or administrator to change the destination via the user interface or from the command line, the Directory Identifier for the component's destination must be a public property.

Using mixed-case or lowercase letters for the Directory Identifier defines the directory entry as a private property. Private properties cannot be changed from the user interface.

Specifying Whether a Component's Files and Other Associated Data Are Uninstalled During Uninstallation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You may need to ensure that a component's files, registry entries, shortcuts, and other data are not uninstalled when end users uninstall your product. Following are examples of scenarios where it may be appropriate to ensure that a component's data are not uninstalled:

- You want to prevent the uninstallation of files that may be used by other products.
- The component contains a font.
- The component is being installed to [SystemFolder]. According to validation rules, if a component is installed to this location, it should not be uninstalled during uninstallation.

The setting that controls whether the component's data are uninstalled depends on which project type you are using.

Task: ***To specify whether a component's files, registry entries, and other data are uninstalled:***

1. In the **Setup Design** view (installation projects only) or the **Components** view, select the component that you want to configure. InstallShield displays its settings in the right pane.
2. In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects—Configure the **Permanent** setting as appropriate:
   - If the component data should not be uninstalled when end users uninstall the product, select **Yes**.
   - If the component data should be uninstalled, select **No**.

   In InstallScript and InstallScript Object projects—Configure the **Uninstall** setting as appropriate:
   - If the component data should not be uninstalled when end users uninstall the product, select **No**.
   - If the component data should be uninstalled, select **Yes**.

The Permanent and Uninstall settings apply to all types of data that are associated with a component. This includes files, registry entries, shortcuts, XML file changes, and SQL scripts.

Configuring Component Conditions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Conditional installation of your components can be useful if you are creating different versions of the same product—for example, a trial version and a full version. You might not want to provide full functionality in the trial version, therefore you would not install all of the components. Another use for conditional component installation is to save disk space. If the target system does not have enough disk space for all of the components, you can set non-required components to install conditionally.

Using the component's Condition setting, you can enter a statement that the installation must evaluate before setting up your component's data on the target system. The component is not installed if its condition evaluates to false. However, the component is installed or advertised if its condition evaluates to true, assuming that its feature is selected for installation.

Task: ***To set a condition for a component in your project:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. Select the component that you want to configure.
3. Click the **Condition** setting and then click the ellipsis button (**...**). The **Condition Builder** dialog box opens.
4. Do one of the following:
   - In the **Conditions** box, type the component condition.
   - Use the **Properties** list, the **Operators** list, and the **Add** buttons to build your condition:
     a. In the **Properties** list, select a property and then click the **Add** button. InstallShield adds the property to the **Condition** column.
     b. If your conditional statement should contain an operator, select an operator in the **Operators** list and then click the **Add** button. InstallShield adds the operator to the conditional statement.
     c. If your conditional statement should contain a value, enter the value.
5. Click **OK**.

Important • *InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Building Conditional Statements.*

Reevaluating Component Conditions During Reinstallation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Windows Installer evaluates a component's condition again when a product is reinstalled if you select Yes for the component's Reevaluate Condition setting. If the condition evaluates to true upon reinstallation, the component is reinstalled—or installed for the first time if the condition initially evaluated to false or if the component was never selected for installation.

Transitive Components

Components that were installed but whose conditions evaluate to false upon reinstallation are removed. Because of this special feature, which allows you, in effect, to swap components during reinstallation, components with Yes selected for the Reevaluate Condition setting are considered *transitive components*.

Consider an application that requires a different .dll file depending on whether it is installed on Windows XP or Windows Vista. You could create a component for each file and attach a condition to each component to check the version of the operating system. The component for Windows Vista would have the following condition:

```
VersionNT=600
```

The Windows XP–specific component might have the following condition:

```
VersionNT<600
```

When the product is installed on a Windows XP system, the appropriate version of the .dll file is installed and the Windows Vista version is not. What happens if the end user upgrades to Windows Vista? When the product is reinstalled, the Windows XP–specific component is uninstalled, and the Windows Vista–specific component is installed (as long as these components are both transitive).

Managing Reference Counts for Shared Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

A file's reference count (also referred to as *refcount*) is the number of products on a target system that use the file. Reference counts help to ensure that if multiple products are sharing a file, the file remains on the target system until all of the products that share it are removed.

Reference counts for shared files are stored in the following registry key:

`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\SharedDLLs`

Both Windows Installer–based projects and InstallScript-based projects include support for managing the reference counts for shared files. The functionality is slightly different, depending on the project type.

Behavior in Windows Installer–Based Installations

In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects, you can indicate that a key file is shared by selecting Yes for the Shared setting of the key file's component. If the installation installs the key file and Yes is selected for the component's Shared setting, a reference count is created in the registry—if it does not already exist—and incremented. During uninstallation of the key file, the reference count is decremented.

Windows Logo • *Windows logo guidelines require that the reference count be incremented when installing shared files and decremented when uninstalling. Core component files (which they recommend you not install) should not be reference counted.*

Behavior in InstallScript-Based Installations

In InstallScript and InstallScript Object projects, you can mark a component as shared. If the installation installs the component's files and Yes is selected for the component's Shared setting, a reference count for each file is created in the registry—if it does not already exist—and incremented. During uninstallation of the component, the reference count is decremented.

You can call the InstallScript function **GetFileInfo** with the FILE_SHARED_COUNT constant to determine an existing file's reference count.

How to Mark a Component as Shared

Task: ***To specify that a component's key file (in a Windows Installer–based project) or that a component (in an InstallScript-based project) is shared:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. Select the component that you want to configure.
3. For the **Shared** setting, select **Yes**.

Tip • *One example of when you should always mark a component as shared is if its files are to be installed to a shared directory such as the System folder or the Common Files folder.*

Note • *Note that the installation increments any existing reference count for any file in a component regardless of whether you mark the component as shared. However, if no reference count exists, the installation does not create one unless you select Yes for this Shared setting.*

Checking File Versions Before Installing

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

For InstallScript projects, this functionality is handled by the component's Overwrite setting. When you click the ellipsis button (...) in this setting, the Overwrite dialog box opens, enabling you to specify whether files of the component should overwrite existing files on the target system.

The **Never Overwrite** setting for a component enables you to indicate whether you want your installation to overwrite a file if it already exists on the target system:

- If you select Yes, the file—if it exists on the target system—is never overwritten, regardless of the file version. Selecting Yes for this setting overrides file versioning rules.
- If you select No and the file version on the target system is newer than the version being installed, the file on the target system is not overwritten. However, if the version being installed is newer, the file on the target system is overwritten.

Windows Installer checks for the existence of the component's key file when determining if it should install the component. For more information, see Overwriting Files and Components on the Target System.

Installing Files of the Same Name

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The Source Location setting for a component identifies a subfolder where the component's files will be stored in the source disk images, if the component's files are not compressed. The component's files will be copied to this subfolder in your release image.

The Source Location setting does not require a value, and in most cases, it can be left blank. If you enter a value, it must be a valid Windows folder name.

One instance where the Source Location setting could be used is when you are creating an installation that contains more than one language. In this scenario, you can have multiple files with the same name. You can create a component for each language and configure the Source Location setting as needed for each one. When you use the Source Location setting, any file with the same name can be copied onto the disk in two different locations, without the risk of being overwritten.

For example, create two components called *German* and *English*. For the first component's Source Location setting, enter **GermanVersion**. For the second component's Source Location setting, enter **EnglishVersion**. Create two files called *Test.txt*, giving them slightly different contents. Assign each file to a component.

When you build your installation with uncompressed files, two separate folders on the disk images will be created, one called *GermanVersion* and one called *EnglishVersion*. Separate versions of Test.txt will be copied to each of these folders, but neither copy will be overwritten.

Note • *The Source Location setting is not the same as the destination location. While it is conceivable that you might want to copy both versions of the file to the end user's machine, it is more likely that you would want to filter the files by language.*

Setting a Component's Remote Installation Setting

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Remote Installation setting for a component determines whether the component's files are installed on the target system or run from the source medium, such as a CD-ROM or network server. The default value for a new component is Favor Local, which means that the component's files are installed on the target system.

Task: ***To change this value so the component's files run only from the source medium:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. Select the component that you want to configure.
3. In the Remote Installation setting, select **Favor Source**. Selecting **Optional** gives this component the **Remote Installation** setting of its feature.

The component's Remote Installation setting overrides the feature's. For more information, see Component's Remote Installation Setting vs. Feature's Remote Installation Setting.

Caution • *If the component contains a Windows service, select the Favor Local option. Although an end user could change the feature's installation state through the CustomSetup dialog, the Windows Installer cannot install a service remotely.*

Component's Remote Installation Setting vs. Feature's Remote Installation Setting

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *Transform*

The component's Remote Installation setting always overrides the feature's Remote Installation setting. For example, if a component's Remote Installation setting is set to Favor Local, its files are installed on the target system regardless of the feature's Remote Installation setting.

The files are run from the source medium when a component's Remote Installation setting is set to Favor Source. If you want a component's feature to dictate whether the files run from the source medium, select Optional for the component's Remote Installation setting.

When a component is associated with more than one feature and Optional is selected for the component's Remote Installation setting, the files are installed locally if any of its features is set to Favor Local. If the component is set to Favor Local or Favor Source, the files are installed accordingly.

Extracting COM Registration Data at Build Time

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

By selecting Yes for a component's COM Extract at Build setting, you indicate that you want InstallShield to scan the component's key file for COM registration data whenever you build a release that contains that component. The extracted information is placed into the release so that Windows Installer registers the COM server when it is installed or advertised. All the necessary registry settings made by the component are extracted when you select Yes for this setting.

Unlike the Component Wizard, the build process does not write the extracted COM information to the project (.ism) file. Instead, it is dynamic, in that it is updated each time that you rebuild. It also means that you can rebuild an existing release through InstallShield or the command line even when you do not have write access to the project file.

Note • *The PATH system variable on the build machine must be set to include the directories of all of the .dll files to which the COM server links; otherwise, the file will fail to register and COM information will not be extracted.*

The build feedback (displayed in the Output window and in the build log files) details the registration information that was extracted.

Tip • *If you are using InstallShield on a 64-bit system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit. To learn more about 64-bit support, see Targeting 64-Bit Operating Systems.*

Resolving Conflicts

Despite selecting Yes for the COM Extract at Build setting, you can still specify COM information under the component's COM Registration advanced setting and in the component's Registry explorer. The existing information will always be registered when the component is installed.

If entries are detected under COM Registration, InstallShield asks you if you want to delete them if Yes is selected for the COM Extract at Build setting. If any conflicts are found during the build, you receive a warning about the item in the advanced setting that was overwritten with the dynamically acquired data.

Even with these safeguards, you might want to check the COM Registration advanced setting and the component's registry data to verify that the entries are intentional and do not conflict with the data extracted at build time.

Scanning for .NET Dependencies and Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

InstallShield lets you indicate that a component should be scanned for .NET dependencies and properties at build time. The functionality depends on the project type that you are using.

Windows Installer–Based Projects

In Basic MSI, DIM, InstallScript MSI, and Merge Module projects, you can use the .NET Scan at Build setting to indicate whether you want a component's key file to be scanned for .NET dependencies and properties at build time.

Note • *The build-time scan does not scan the key file of a component if the key file is not a .NET assembly file.*

Several options are available from the .NET Scan at Build setting for a component:

Table 4-8 • Options for the .NET Scan at Build Setting in Windows Installer–Based Projects

Option	Description
None	InstallShield does not scan the key file of this component for .NET dependencies or properties.
Properties Only	At build time, InstallShield scans the key file of this component for .NET properties. InstallShield populates the **MsiAssembly** and **MsiAssemblyName** tables with the assembly properties, as needed.
Dependencies and Properties	At build time, InstallShield scans the key file of this component for .NET dependencies and properties. InstallShield populates the **MsiAssembly** and **MsiAssemblyName** tables with the assembly properties, as needed. In addition, InstallShield adds the missing files, components, and merge modules that are required by the .NET assembly to the release.

Note • *To install an assembly to the Global Assembly Cache, the .NET Scan at Build setting must be set to either Properties Only or Dependencies and Properties.*

This setting affects how the Static Scanning Wizard scans the files in your project.

InstallScript-Based Projects

In InstallScript and InstallScript Object projects, you can use the .NET Scan at Build setting to indicate whether you want a component's files to be scanned for .NET dependencies at build time.

Several options are available from the .NET Scan at Build setting for a component:

Table 4-9 • Options for the .NET Scan at Build Setting in InstallScript-Based Projects

Option	Description
None	InstallShield does not scan the files of this component for .NET dependencies.
Dependencies	InstallShield scans the files of this component for .NET dependencies. InstallShield adds the missing dependencies to the release.

Specifying the .NET Application File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The .NET Application File setting is used when the component is scanned at build time (based on the .NET Scan at Build setting) or by the Static Scanning Wizard. The scanner uses this setting—along with the component destination—to determine the value of the File Application setting for the assembly.

The scanning algorithm works in the following way to configure the .NET assembly's File Application setting:

1. The scanning algorithm checks the component's Destination setting. If the value is **[GlobalAssemblyCache]**, the .NET assembly's File Application setting is set to null.
2. If the component's destination is something other than **[GlobalAssemblyCache]**, the scanning algorithm checks the component's .NET Application File setting. If this value is not null, the value of this setting is used to set the assembly's File Application setting.
3. If the component's destination is something other than **[GlobalAssemblyCache]** and the .NET Application File setting is null, the component's key file is used to set the assembly's File Application setting.

Reading Properties Passed to the .NET Installer Class

This is an example of a .NET class that implements the installer class and demonstrates how to read properties that are passed to the installer class from the installation.

```
using System;
using System.Configuration.Install;
using System.Windows.Forms;
using System.Collections;

namespace MyInstall
{
    ///
    /// Summary description for Class1.
    ///
    [System.ComponentModel.RunInstallerAttribute(true)]
    public class MyInstallClass : Installer
    {
        public MyInstallClass()
        {
        }
        public override void Install(IDictionary stateSaver)
        {

            base.Install(stateSaver);
            foreach(string strKey in Context.Parameters.Keys)
            {
                MessageBox.Show(strKey + " is " + Context.Parameters[strKey]);
            }
        }

        public override void Commit(IDictionary stateSaver)
        {
            base.Commit(stateSaver);
            foreach(string strKey in Context.Parameters.Keys)
            {
                MessageBox.Show(strKey + " is " + Context.Parameters[strKey]);
            }
        }

        public override void Uninstall(IDictionary stateSaver)
        {
            base.Uninstall(stateSaver);
            foreach(string strKey in Context.Parameters.Keys)
            {
                MessageBox.Show(strKey + " is " + Context.Parameters[strKey]);
            }
        }

        public override void Rollback(IDictionary stateSaver)
        {
            base.Rollback(stateSaver);
            foreach(string strKey in Context.Parameters.Keys)
            {
                MessageBox.Show(strKey + " is " + Context.Parameters[strKey]);
            }
```

```
        }
    };
}
```

Enabling and Disabling Registry Reflection

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *Transform*

Registry reflection keeps the 32-bit registry view and the 64-bit registry view in sync on the target machine.

Note • *Only 64-bit systems with Windows Installer 4 and later support registry reflection. In addition, only Windows Vista and later and Windows Server 2008 and later support it.*

If an end user installs a 64-bit application that has a component with registry reflection enabled, Windows Installer makes the associated registry changes in the 64-bit view of the registry, and the reflector copies the registry changes to the 32-bit registry view. Similarly, if an end user then installs a 32-bit application that modifies the same registry key or value, Windows Installer makes the associated registry changes in the 32-bit view of the registry, and the reflector copies the registry changes to the 64-bit registry view.

If registry reflection is disabled, Windows Installer calls the **RegDisableReflectionKey** function on each key being accessed by the component. This function disables registry reflection for the specified key. Disabling reflection for a key does not affect reflection of any subkeys.

Task: ***To enable or disable registry reflection for all new and existing registry keys that are affected by a component:***

1. In the View List under **Organization**, click **Components**.
2. In the **Components** explorer, select the component for which you want to configure the registry reflection setting.
3. To enable registry reflection, set the **Disable Registry Reflection** setting to **No**. This is the default value.

   To disable registry reflection, set the **Disable Registry Reflection** setting to **Yes**.

For more information about registry reflection, see Registry Reflection in the MSDN Library.

Specifying Whether Shared Component Patching Should Be Enabled for a Component

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

InstallShield lets you specify whether you want to enable shared component patching for a component. By default, it is disabled.

If this multiple-package sharing feature were enabled in at least one package that is installed on the target system, Windows Installer 4.5 treats the component as shared among all of those packages. If a patch that shares this component is uninstalled, Windows Installer can continue to share the highest version of the component's files on the system.

The purpose of this multiple-package component sharing is to prevent files from being downgraded during the uninstallation of a patch that contains a component that is shared with one or more other installed packages. The intent is to keep the highest version of the component's files present on the machine after uninstallation of that patch.

Note • *If the DisableSharedComponent policy is set to 1 on a target system, Windows Installer ignores this setting for all packages.*

Windows Installer 4.0 and earlier ignore this setting.

The following diagram illustrates an example of two products, ABC and XYZ, that share a component that contains a file called file.dll. An end user installs product ABC first, and version 1.0.0.0 of file.dll in the shared component is installed. Next, the end user installs product XYZ, which includes version 1.1.0.0 of file.dll. Since this version is higher than the file that was installed for product ABC, Windows Installer overwrites the current version with version 1.1.0.0. Then, the end user installs an uninstallable patch for product ABC. This patch contains version 1.2.0.0 of file.dll. Since this version is higher than the one that is already present on the target system, Windows Installer overwrites the current version with version 1.2.0.0. If the end user uninstalls the patch, either of the following results may occur:

- If the value of the Multiple Package Shared Component setting is Yes for either product ABC or product XYZ and if Windows Installer 4.5 is present, uninstalling the patch from product ABC could restore version 1.1.0.0 to the target system.
- If the value of this setting is No for product ABC and product XYZ, the file would be downgraded to version 1.0.0.0, even though product XYZ used 1.1.0.0. As a result, if product XYZ requires version 1.1.0.0, product XYZ may no longer work properly.

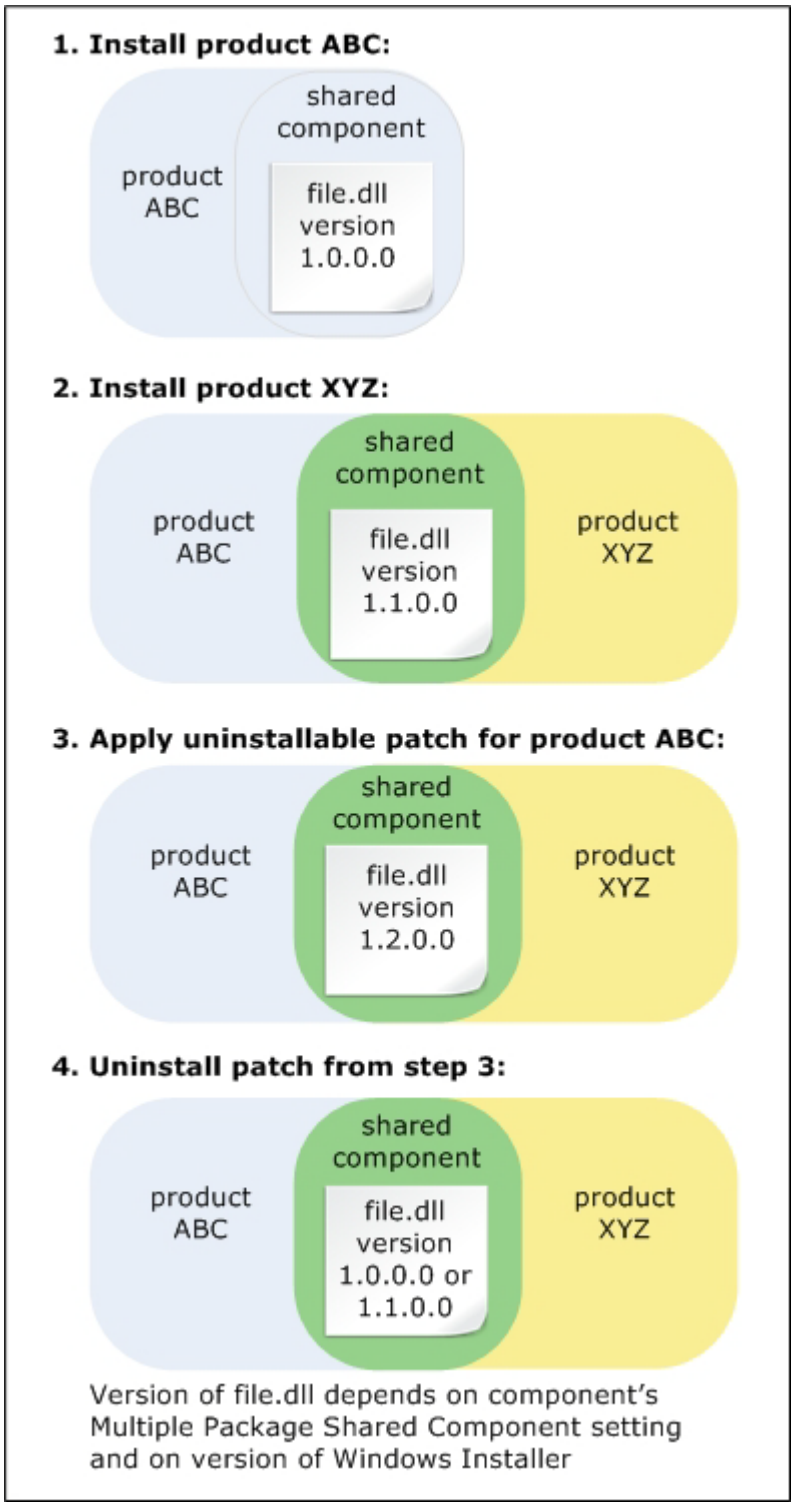

Figure 4-1: If the Multiple Package Shared Component setting for the shared component is set to Yes in either package and if Windows Installer 4.5 is present, version 1.1.0.0 of the file may be restored. Otherwise, the file may be unintentionally downgraded to version 1.0.0.0.

Task: ***To specify whether to enable shared component patching for a component:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. Select the component that you want to configure.
3. Select the appropriate value for the **Multiple Package Shared Component** setting:
   - To enable shared component patching, select **Yes**. InstallShield sets the **msidbComponentAttributesShared** attribute of the selected component to indicate that it should be shared.
   - To disable shared component patching, select **No**. InstallShield does not set the **msidbComponentAttributesShared** attribute of the selected component. However, if this component is shared with another package, the **msidbComponentAttributesShared** attribute may be set for this component in that package. Therefore, Windows Installer 4.5 would consider the multiple-package component to be shared.

Advanced Component Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Advanced Settings area under a component in the Components view (and in the Setup Design view) enables you to fulfill installation requirements for special component types. For example, when you copy an .ocx file to the target system, you must register its classes, ProgIDs, and type libraries so that the file's methods can be properly accessed. Advanced settings use Windows Installer's built-in functionality for registering COM servers; setting up ODBC drivers, data sources, and translators; installing, controlling, and configuring Windows services; and registering a file association.

By specifying the advanced settings, you can publish your component and register COM servers, file extension servers, and MIME types. If the component is selected, an advanced setting is made on the target system when the component is installed or advertised. That way, the file is ready to execute once it is installed. Publishing components—a type of advertising—is accomplished through the Publishing advanced setting.

Configuring COM Registration Settings Manually

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Important • *The recommended method for installing a COM server is to have Windows Installer register its classes, ProgIDs, and so on. Calling self-registration functions violates Setup Best Practices.*

It is recommended that you avoid using the ***TypeLib*** *table. For more information, see TypeLib Table in the Windows Installer Help Library.*

The easiest way to populate the COM Registration advanced setting is to have the Component Wizard extract the necessary information or extract COM data for a key file. (You can also have it extracted dynamically at build time, in which case you do not need to use this advanced setting.) It is recommended that you modify the COM Registration advanced setting or create COM entries in the component's Registry explorer only if you are familiar with the technical details behind your file's registration.

Task: ***To install a COM server solely through editing the component's advanced settings:***

1. Ensure that a single COM server is added to the component. The file must be a single portable executable file (such as an .exe, .dll, or .ocx file), according to Setup Best Practices.
2. Make the COM server the component's key file.
3. For the component's COM Extract at Build setting, select **No**.
4. Expand the component's **Advanced Settings** item to view all of the advanced settings.
5. Click **COM Registration** to configure COM server information.

Right-click one of the items in the COM Registration explorer to modify or to create registration information for your COM server. Right-click an item and click Rename to rename the new item.

Note • *The* PATH *system variable on the build machine must be set to include the directories of all of the .dll files to which the COM server links; otherwise, the file will fail to register and COM information will not be extracted.*

Configure the settings for each registration item or subitem that you create. More help is available in the help pane in InstallShield when you click each registration setting.

Configuring COM Classes for COM Registration Manually

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To register a class ID:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **COM Registration**. The **COM Registration** explorer appears in a separate pane.
3. In the **COM Registration** explorer, right-click **COM Classes** and click **New COM Class**.
4. Type a new name for the COM class if needed. The name that you give the COM class will be registered as the default value under HKEY_CLASSES_ROOT\CLSID\<GUID>. To give the class a new name, right-click it and click **Rename**.
5. Click the new COM class to configure its settings.
6. Specify a context type for this class. The following list tells you which server context is appropriate for which type of COM server:
   - **LocalServer32**—32-bit .exe file
   - **LocalServer**—16-bit .exe file
   - **InprocServer32**—32-bit .dll or .ocx file
   - **InprocServer**—16-bit .dll or .ocx file

If the server context is LocalServer or LocalServer32, click the context to configure the Default Inproc Handler and Argument settings.

Configuring ProgIDs for COM Registration Manually

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

A progID is a string used to identify a class in the format `Component.Class.N`.

Task: ***To specify a new programmatic identifier:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **COM Registration**. The **COM Registration** explorer appears in a separate pane.
3. In the **COM Registration** explorer, right-click **ProgIDs** and click **New ProgID**.
4. Type a new name for the ProgID. Use the format `Component.Class.N`. To give the class a new name, right-click it and click **Rename**.
5. Click the new ProgID to configure its settings.

Version-Independent ProgIDs

A version-independent progID is a string used to identify a class in the format `Component.Class`, which is constant for all versions of a class.

Task: ***To specify a new version-independent programmatic identifier:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **COM Registration**. The **COM Registration** explorer appears in a separate pane.
3. In the **COM Registration** explorer, right-click **Version-Independent ProgIDs** and click **New ProgID**.
4. Type a new name for the ProgID. Use the format `Component.Class`. To give the class a new name, right-click it and click **Rename**.

Configuring Type Libraries for COM Registration Manually

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Important • *It is recommended that you avoid using the* ***TypeLib*** *table. For more information, see TypeLib Table in the Windows Installer Help Library.*

Task: ***To specify a type library or libID:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **COM Registration**. The **COM Registration** explorer appears in a separate pane.
3. In the **COM Registration** explorer, right-click **Type Libraries** and click **New Type Library**.
4. Type a new name for the type library, or libID, referenced by this COM server. The name that you give the type library item is registered as the default value under HKEY_CLASSES_ROOT\TYPELIB\<libID>\<version>. Use the format `Component.Class`. To give the class a new name, right-click it and click **Rename**.
5. Click on the type library to configure its settings.

Registering a File Extension

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If your application manipulates files with a unique file extension, you can register your file type in the File Types area, which is available as an advanced setting within the Components view and the Setup Design view (for installation projects only). For example, if your application manipulates files with the .xyz extension, registering the file type instructs the operating system to open the file with your application when the user double-clicks its icon.

This advanced setting registers the following information about a file type on the target system when the component is installed or advertised:

Table 4-10 • File Type Information

Information Registered	Description
File Extensions	You can associate file extensions (such as .doc and .txt) with the component's key file.
ProgIDs	By setting the ProgID property in the extension, you can name a ProgID—for example, extfile—that will contain the file type registration.
Verbs	You can register command verbs (such as Open and Print) that appear in the context menu that Windows Explorer displays when an end user right-clicks a file with the current extension.
MIME Type	You can also register multipurpose Internet mail extension (MIME) types, also known as media types or content types, for the component's key file. You can also associate a MIME type with a class ID.

Note • *File associations are stored in both HKLM\SOFTWARE\Classes and HKCU\SOFTWARE\Classes; you can see a merged view of the data under HKEY_CLASSES_ROOT. It is recommended that you use the File Types editor instead of writing directly to the registry to support Windows Installer feature advertisement.*

Note also that Windows Installer writes file-extension advertisement information to the registry, which appears to be a string of random characters. This behavior is normal.

Installing Assemblies

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Note • *The recommended way to add a .NET assembly to your project is to add an assembly as a component's key file and select Properties Only for the component's .NET Scan at Build setting.*

In the Assembly section of a component's Advanced Settings, you can add a private or global Win32 assembly or .NET assembly to be registered when the current component is installed. Using assemblies helps you install products that are self-contained, without affecting other applications on the system.

Note that a component can contain only one assembly.

Adding Assemblies

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you add a .NET assembly as the key file of a component, InstallShield automatically adds values to the .NET assembly settings when the component is scanned at build time, or when you run the Static Scanning Wizard.

Task: ***To add a .NET or Win32 assembly to a component:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Right-click **Assembly** and then click **New Win32 Assembly** or **New .NET Assembly**.
5. Click the assembly and then configure the **Manifest**, **File Application**, and related settings.

InstallShield adds the information that you enter for the assembly to the **MsiAssembly** and **MsiAssemblyName** tables of your Windows Installer database. You can view and edit these tables using the Direct Editor.

Deleting Assemblies

Project • *This information applies to the following project types:*

- *Basic MSI*

- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To delete an assembly from a component:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component.
3. Click the **Advanced Settings** item to expand it.
4. Right-click the assembly and click **Delete**.

Testing for .NET Assembly Support on the Target System

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

To see if a target system supports .NET assemblies, you can test the **MsiNetAssemblySupport** property. To see if a target system supports Win32 assemblies, you can test the **MsiWin32AssemblySupport** property. (Win32 assemblies are supported only on Windows XP and later.) The assembly tables, actions, and properties require Windows Installer version 2.0 or later.

Specifying an Application Path for a Component

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

- *MSI Database*
- *MSM Database*
- *Transform*

The App Paths registry key is a useful installation-related key that helps an executable file find its .dll files without having to modify the PATH environment variable. An executable file's App Paths key looks like this:

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\App Paths*Filename*.exe

A program's App Paths key typically contains a value named Path, which should contain a semicolon-delimited list of directories where the program's .dll files could be located. Windows uses this key to find your application and its .dll files if their locations are not already in the system's path. If an end user moves or renames your application's executable file through the Explorer shell, Windows automatically updates the file's App Paths key.

Task: ***To specify an application path for your component:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. Select the component that you want to configure, and expand its **Advanced Settings** item.
3. Click the **Application Paths** item under **Advanced Settings**.
4. Select the check box of the file for which you would like to create a key.
5. In the **Application Path** column, enter the paths to the file's dependencies, or select a Windows Installer folder property from the list rather than hard-coding a path. Separate multiple paths with a semicolon (;).
6. Click **OK**.

Configuring Device Driver Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

For information on installing device drivers in InstallScript projects, see Installing Device Drivers.

Once you run the Device Driver Wizard, which adds the table and entries, custom actions, features, and components needed to include device drivers in your installation, you can set properties associated with a component that includes a device driver. The following information describes the various options that you can set within InstallShield.

The Device Driver advanced setting's Common tab within the Components view enables you to specify whether the current component includes a device driver and, if so, select desired run-time installation options. The Sequence tab enables you to specify the order in which the project's device drivers (not just the current component's device drivers) should be installed.

Publishing Components

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Publishing advanced setting for a component enables you to specify publishing information for your component. Publishing is a type of advertising (just-in-time installation) in which no user-interface elements are created for the component during installation, but the component can be installed through Add or Remove Programs or when an installed component requests the published component from the installer.

You must create at least one component ID for each advertised component.

Important • *Do not confuse the component ID with the GUID that is entered in the Component Code setting for the component; they must be unique values. The component ID that you use for the Publishing advanced setting is a category identifier that represents the category of components that are being grouped together as a qualified component.*

Each component ID must have at least one qualifier. The qualifier is a string that you can use to distinguish this language or version of the component from any other (for example, to specify a language). It must be unique for the component.

At run time, the installation registers the component IDs and qualifiers and uses these unique values to manage the published components. By calling the Windows Installer functions, your installed component—or another installed component (known as cross-product advertisement)—can request information about an advertised component and install it.

Specifying Publishing Information

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

- *Transform*

The Publishing advanced setting for a component enables you to specify publishing information for your component. Publishing is a type of advertising (just-in-time installation) in which no user-interface elements are created for the component during installation, but the component can be installed through Add or Remove Programs or when an installed component requests the published component from the installer.

Task: ***To publish a component that you have created:***

1. In the View List under **Organization**, click **Setup Design** (in installation projects only) or **Components**.
2. In the explorer, expand the component that you want to publish, and under **Advanced Settings**, select **Publishing**. The **Publishing** explorer appears in a separate pane.
3. Right-click the **Publishing** explorer and then click **New ComponentID** to generate an ID for your new component. InstallShield adds a unique componentID and a corresponding qualifier.
4. In the **Publishing** explorer, click the new qualifier and configure its value.

In the Custom Actions and Sequences view of an installation project, you can set the conditions that need to be fulfilled in order for your product to be advertised on the target system.

Task: ***To set the advertisement conditions in an installation project:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, expand the **Advertisement** item, and then the **Execute** item.
3. Click the appropriate **Execute** action, and then configure its **Conditions** setting as needed.

Adding ComponentIDs for a Component to Be Published

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You must add at least one componentID to the Publishing advanced setting of a component if you want the component to be published.

Task: ***To add a componentID:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component that should have the new componentID, and under **Advanced Settings**, select **Publishing**. The **Publishing** explorer appears in a separate pane.
3. Right-click the **Publishing** explorer and then click **New ComponentID**. InstallShield adds a unique componentID and a corresponding qualifier.

Removing ComponentIDs

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To remove a componentID:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **Publishing**. The **Publishing** explorer appears in a separate pane.
3. In the **Publishing** explorer, right-click the componentID and click **Delete**.

Adding Qualifiers to ComponentIDs

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Each componentID must have at least one qualifier. When you create a componentID, by default it has a qualifier. To rename this qualifier, right-click it and click Rename.

Task: ***To add a new qualifier:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **Publishing**. The **Publishing** explorer appears in a separate pane.
3. In the **Publishing** explorer, right-click the componentID and click **New Qualifier**. InstallShield creates a new qualifier with a default name.
4. Type a name for the qualifier.

Removing Qualifiers from ComponentIDs

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To remove a qualifier:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **Publishing**. The **Publishing** explorer appears in a separate pane.
3. In the **Publishing** explorer, right-click the qualifier and click **Delete**.

Configuring Qualifier Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You have the option of specifying an informational string, called *application data*, for each qualifier.

Task: ***To set the qualifier properties:***

1. In the View List under **Organization**, click **Setup Design** (for installation projects only) or **Components**.
2. In the explorer, expand the component, and under **Advanced Settings**, select **Publishing**. The **Publishing** explorer appears in a separate pane.
3. In the **Publishing** explorer, click the qualifier.
4. In the **Application Data** setting, enter the appropriate value.

   When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (...) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.

Defining Features

A feature is the smallest installable part of a product, from the end user's perspective. It represents a specific capability of your product—such as its help files or a part of a product suite that can be installed or uninstalled based on the end user's selections. Your entire installation should be divided into features, each of which performs a specific purpose.

Subfeatures are further divisions of a feature. Because features should be self-contained elements of a product or product suite that an end user can selectively install, it might make sense for you to organize portions of your installation as subfeatures of a parent feature.

Tip • *Although you can create many levels of subfeatures, you should keep the design as simple as possible for organizational purposes.*

Creating Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*

- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Transform*

You can use the Setup Design view or the Features view to create features, as well as subfeatures, for your project.

Task: ***To create a feature:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Right-click the top-level item in the explorer and click **New Feature**. InstallShield adds a new feature with the default name **New Feature_n** (where *n* is a successive number).
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.
4. Configure the feature's settings in the right pane.

Project • *In Basic MSI, InstallScript MSI, MSI Database, and Transform projects, feature names must contain only letters, digits, underscores (_), and periods (.), and they must begin with a letter or an underscore.*

In InstallScript and InstallScript Object projects, the following characters are invalid in feature names:
\ / : * ? " ' < > |

Tip • *To add a subfeature, right-click the parent feature and click New Feature.*

You can create multiple nested features at one time by adding a new feature and typing `Feature 1\Feature 2\Feature 3` *for the feature's name. InstallShield creates a nested feature structure where* `Feature 3` *is a subfeature of* `Feature 2`*, which is a subfeature of* `Feature 1`*.*

After you have created all of your product's features and subfeatures, you need to create components and then associate them with your features.

Configuring Feature Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *MSI Database*
- *Transform*

Task: ***To configure a feature's settings:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. Configure the settings in the grid in the right pane.

Setting a Feature's Destination

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Each feature and subfeature can have a different destination location for its files. The default value for a new feature's Destination setting is **INSTALLDIR**, which is set in the General Information view.

Windows Logo • *According to the Windows logo program requirements, the default destination of your product's files must be a subfolder of the Program Files folder or the end user's Application Data folder, regardless of the language of the target system.*

Task: ***To change the feature's destination folder:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature whose destination you want to change.
3. In the **Destination** setting, select one of the options from the list, or click the ellipsis button (**...**) to select or create a directory.

   If you want the destination to be configurable at run time, the destination folder that you select must be a public property (containing all uppercase letters).

Note • *You can leave the feature's Destination setting blank.*

Other Destination Folder Considerations

Changing Feature Destinations at Run Time

If you want to change a feature's destination directory at run time based on the end user's feature selection, you can use Windows Installer custom action type 35. For more information about changing a directory's target location, see Changing the Target Location for a Directory in the Windows Installer Help Library.

Feature's Remote Installation Setting

Setting the feature's Remote Installation setting to Favor Source (or to Favor Parent when the subfeature's parent feature is set to Favor Source) means that the feature's files will not be installed on the target system, regardless of the feature's Destination setting.

Component's Destination Setting

Each component also has a Destination setting. If the feature's Destination setting and the component's Destination setting have different values, the component's Destination setting overrides the feature's. The feature's Destination setting is optional, but the component's Destination setting is required.

INSTALLDIR as Default Destination

The assumption behind using **INSTALLDIR** as the default Destination property for all features and components is that all of your application's files should be installed to the same root folder. As a result, when an end user changes the destination folder for any of the features in the CustomSetup dialog, the destination folders for all of the features that are set to be installed to the path contained in **INSTALLDIR** also change.

Note *• If the component's destination is set to something other than **INSTALLDIR**, the component is installed to the destination that is specified for the component; changing **INSTALLDIR** has no effect on the component's destination.*

*A directory property such as **INSTALLDIR** specifies a default value. An end user can change this value by setting a property when launching* `Msiexec.exe` *at the command line or by selecting a new destination folder for a feature in the CustomSetup dialog.*

Setting Feature Conditions

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Conditional installation of your features can be useful if you are creating different versions of the same product—for example, a trial version and a full version. You might not want to provide full functionality in the trial version; therefore, you would not install all of the features. Another use for conditional feature installation is to save disk space. If the target system does not have enough disk space for all of the features, you can set non-required features to install conditionally.

Task: ***To set a condition for a feature in your project:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. Click the **Condition** setting and then click the ellipsis button (**...**). The **Feature Condition Builder** dialog box opens.
4. Click the **New Condition** button. InstallShield adds a new condition row to the **Conditions** box.
5. In the **Level** column, type the install level that should be used for the feature if the condition is met.

   Note that if the condition is met, this value overrides the value that is specified for the feature's the Install Level setting.
6. Do one of the following:
   - In the **Condition** column, type the feature condition.
   - Use the **Properties** list, the **Operators** list, and the **Add** buttons to build your condition:
     a. In the **Properties** list, select a property and then click the **Add** button. InstallShield adds the property to the **Condition** column.
     b. If your conditional statement should contain an operator, select an operator in the **Operators** list and then click the **Add** button. InstallShield adds the operator to the conditional statement.
     c. If your conditional statement should contain a value, double-click the condition field, press END so that the insertion point is at the end of the condition statement, and enter the value.
7. Click **OK**.

Important • *InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Building Conditional Statements.*

Run-Time Behavior for Feature Conditions

The default install level of a feature is the value that is configured in the Install Level setting in the Features view or the Setup Design view. This value is overridden if a feature condition evaluates as true; in this case, the install level of the feature is set to the Level value that is associated with the true conditional statement.

Each feature's install level value is compared to the value of the global public property **INSTALLLEVEL**; only those features with install level values less than or equal to **INSTALLLEVEL** are selected for installation.

For example, if you have a feature that you want to be selected by default only if the end user has elevated privileges, you can give the feature a condition of `Not Privileged` and set the install level for that condition to `200`. If the end user does not have elevated privileges, the condition is true, and the feature will be given the install level 200. Because 200 is greater than the default product install level (100), the feature will not be selected by default.

Tip • *You can conditionally hide a feature by giving the feature a condition that sets the install level to the number 0. If the condition is true, the feature will be deselected, and it will not be displayed in the CustomSetup dialog.*

Displaying Features to End Users

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

InstallShield enables you to indicate how you want a feature to be presented to the end user in the custom setup type dialog that corresponds with your project type:

- For Basic MSI, MSI Database, and Transform projects—CustomSetup dialog
- For InstallScript MSI projects—**SdFeatureDialog2**, **SdFeatureMult**, or **SdFeatureTree**

The Display setting for a feature in the Features view or the Setup Design view is where you indicate whether and how the feature should be displayed. Available options are:

Table 4-11 • Options that Are Available for the Display Setting

Option	Description
Visible and Collapsed	The feature is displayed in the run-time dialog with its subfeatures collapsed by default.
Visible and Expanded	The feature is displayed in the run-time dialog with its subfeatures expanded by default.
Not Visible	The feature and subfeatures are not displayed in the run-time dialog.

Note • *Selecting Not Visible for this setting does not have any direct impact on whether a feature is installed. A feature is not automatically installed if it is invisible—it just cannot be deselected if it would otherwise be installed, or selected if it should not be installed.*

Conditionally Selecting Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The procedure for conditionally selecting features at run time depends on the project type that you are using.

Basic MSI, MSI Database, and Transform Projects

The Condition setting for a feature enables you to specify a non-default Install Level value if the condition that you specify succeeds. If a feature's Install Level value is less than or equal to the project's **INSTALLLEVEL** property, the feature will be selected to be installed.

Task: ***For example, to deselect a feature if the end user does not have administrator privileges:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. Click the **Condition** setting and then click the ellipsis button (**...**). The **Feature Condition Builder** dialog box opens.
4. Click the **New Condition** button. InstallShield adds a new condition row to the **Conditions** box.
5. In the **Level** column, type `200`.
6. In the **Condition** column, type `Not AdminUser`.
7. Click **OK**.

At run time, if the end user does not have administrator privileges (that is, if the condition succeeds), the Install Level property for the feature is set to 200. Because the default **INSTALLLEVEL** property for a project is 100, the feature is deselected.

Task: ***You can change the INSTALLLEVEL property in the Property Manager.***

InstallScript and InstallScript MSI Projects

The **FeatureSelectItem** function enables you to select or deselect a feature displayed in a feature-selection dialog such as **SdFeatureTree**.

Conditionally Hiding Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The procedure for conditionally hiding features at run time depends on the project type that you are using.

Basic MSI, MSI Database, and Transform Projects

Any feature given an Install Level of zero will be hidden (and deselected).

Task: ***For example, to hide a feature if the end user running your installation does not have administrative privileges:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. Click the **Condition** setting and then click the ellipsis button (**...**). The **Feature Condition Builder** dialog box opens.
4. Click the **New Condition** button. InstallShield adds a new condition row to the **Conditions** box.
5. In the **Level** column, type `0`.
6. In the **Condition** column, type `Not AdminUser`.
7. Click **OK**.

After rebuilding your project and running the installation, the feature will not be displayed or installed if the end user does not have administrative privileges.

InstallScript and InstallScript MSI Projects

The **FeatureSetData** function accepts a FEATURE_FIELD_VISIBLE constant that lets you control whether a specific feature is displayed. For example, to hide a feature called HiddenFeature, include the following function call in your script:

```
FeatureSetData (MEDIA,
    "HiddenFeature",
    FEATURE_FIELD_VISIBLE, FALSE,
    "");
```

Note • *Hiding a feature does not automatically deselect it. To deselect the feature so that its data is not installed, call the following:*

```
FeatureSelectItem(MEDIA, "FeatureName", FALSE);
```

Requiring Features to Be Installed

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

When you select Yes for a feature's Required setting, the end user cannot deselect it in the CustomSetup dialog (for Basic MSI, MSI Database, and Transform projects), or the **SdFeatureDialog2**, **SdFeatureMult**, or **SdFeatureTree** dialogs (for InstallScript MSI projects). The feature will be installed to the target system.

If the value for the Required setting is No, the feature is installed by default, but the end user can deselect it.

In InstallScript MSI projects, the Required setting is applicable to root-level features during a first-time installation. It is also applicable to subfeatures in an upgrade or patch. This setting is ignored for subfeatures during a first-time InstallScript MSI installation.

Advertising Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*
- *Transform*

InstallShield enables you to selectively enable or disable a feature for advertisement. Advertised features are not installed immediately during the installation process. Instead, they are installed when requested. If the feature is assigned, the feature appears to be already installed, although it is not installed until the end user requests it. (Assigned features have their shortcuts installed, and they can be installed from Add or Remove Programs in the Control Panel. However, an assigned feature is advertised until a user requests it.) A published feature does not appear on the target system until it is requested from the installer. (Published features lack any end user–interface elements. They are installed programmatically or through an associated MIME type.)

Use the Advertised setting in the Features view to specify whether advertisement should be allowed. Available options for this setting are:

Table 4-12 • Options that Are Available for the Advertisement Setting

Option	Description
Allow Advertise	End users have the ability to select the advertisement option for this feature in the CustomSetup dialog. Although advertisement is allowed, it is not the default option when the installation is run.
Favor Advertise	The feature is advertised by default. End users can change the advertisement option for a feature in the CustomSetup dialog.
Disallow Advertise	Advertising is not allowed for this feature. End users cannot elect to have the feature advertised in the CustomSetup dialog.
Disable Advertise if Not Supported	Advertisement works only on systems with Internet Explorer 4.01 or later. If the target system does not meet this criterion, advertising is not allowed. If the target system can support advertisement, advertising is allowed.

When you allow feature advertisement, the feature is advertised, regardless of the mode in which the installation is running, as long as no other factors prevent it from being advertised. In the CustomSetup dialog, the end user can control which features are immediately installed and which are available later.

Advertisement usually requires support from the application. For example, your product's spell checker can be advertised. The application interface offers use of the spell checker through a menu command or toolbar button. You must write to check the feature's installation state and install it when the customer clicks the Spell Check command or button.

Configuring a Feature's Install Level Setting

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

For InstallScript MSI projects, this information applies only if no setup types are defined in the project.

The Install Level setting for a feature is compared against the **INSTALLLEVEL** property at run time to determine which features are available for installation. You can use this setting to create specific feature configurations.

Unless the end user deselects features in the CustomSetup dialog, all features with an install level less than or equal to the value of the package's **INSTALLLEVEL** property are installed to the target system.

Note • *You can change the package's* ***INSTALLLEVEL*** *property in the Property Manager.*

Task: ***To set a feature's Install Level property:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. For the **Install Level** setting, type an integer for this feature's install level. The recommended value is 100.

Setting a Feature's Remote Installation Setting

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Remote Installation setting for a feature determines whether the feature's files are installed on the target system or run from the source medium, such as a CD-ROM or network server. The default value for a new feature is Favor Local, which means that the files in the selected feature are installed on the target system.

Task: ***To change the Remote Installation setting so that the feature's files run only from the source medium:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. In the **Remote Installation** setting, select **Favor Source**.

Tip • *Selecting* ***Favor Parent*** *gives a subfeature the same value as its parent feature.*

Caution • *If any of the feature's components contain a Windows service, select Favor Local for the Remote Installation setting. Although an end user could change the installation state through the CustomSetup dialog, the Windows Installer cannot install a service remotely.*

Using Release Flags with Features

Project • *The following project types include support for release flags:*

- *Basic MSI*
- *InstallScript MSI*

Release flags enable you to create different versions of your product without having to create more than one project. There are two steps for filtering features according to release flags: assigning release flags and specifying which flags to include in the release.

Assigning Release Flags to Features

Project • *The following project types include support for release flags:*

- *Basic MSI*
- *InstallScript MSI*

Release flags must be set on features that you want to exclude from certain builds. For example, if you have a feature called Add-ons that should be included only in a special edition of your product, you can flag that feature and include it only when needed.

Task: ***To add a release flag to a feature:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. For the **Release Flags** setting, type a string. The string can be any combination of letters or numbers. To have more than one flag on a feature, use a comma to separate the flags.

To learn how to filter features based on release flags, see Release Flags.

Removing Release Flags

Project • *The following project types include support for release flags:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a release flag from a feature:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the feature that you want to configure.
3. In the **Release Flags** setting, delete the value.

Reordering Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

When your end users install your product, the CustomSetup dialog (in Basic MSI, MSI Database, or Transform installations) or one of the feature selection dialogs (in InstallScript or InstallScript MSI installations) displays the features in the same order that they are displayed in the Features view in InstallShield. You can change the order in which the features are displayed.

Task: ***To change the feature order:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Right-click the feature that you want to move and click **Move Up** or **Move Down**. You can also move a feature left or right, thereby making it a subfeature of another feature or a top-level feature.

Tip • *You can also reorder your features by dragging and dropping. Any feature or subfeature can be moved in this way.*

Using the Required Features Setting

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The Required Features setting enables to you specify features that are required by the selected feature. For example, you might have an installation with two features—**ProgramFiles** and **HelpFiles**. If it is necessary that end users install **ProgramFiles** whenever the **HelpFiles** feature is selected, you need to use the Required Features property.

Task: ***To arrange this feature requirement:***

1. In the View List under **Organization**, click **Setup Design** or **Features**.
2. Select the **HelpFiles** feature.
3. Click the **Required Features** property and then click the ellipsis button (**...**). The **Required Features** dialog box opens.
4. Select the **ProgramFiles** check box.
5. Click **OK**.

At run time, if the user selects a Custom setup type, feature-selection dialogs such as **SdFeatureTree** will not allow the user to deselect the **ProgramFiles** feature if the **HelpFiles** feature is selected.

Working with Setup Types

Project • *Setup types are available in the following project types:*

- *InstallScript*
- *InstallScript MSI*

To create setup types for a Basic MSI project, use the feature's Install Level setting.

Setup types enable you to provide different versions of your product to your end users. For example, the default setup types are Complete and Custom. The Complete setup type installs all of the files included in your installation. The Custom setup type lets the end user select which features are installed.

Setup types are based on features. You select the features that you would like to associate with each setup type. Then, when an end user selects a certain setup type, only those features that you associated with that setup type are installed.

By default, each project that you create contains predefined setup types. In the Setup Types view, you can add or remove setup types, rename existing setup types, and change which features are associated with each one.

Adding Setup Types

Project • *Setup types are available in the following project types:*

- *InstallScript*

- *InstallScript MSI*

To create setup types for a Basic MSI project, use the feature's Install Level setting.

Task: ***To add a setup type:***

1. In the View List under **Organization**, click **Setup Types**.
2. Right-click the **Setup Types** explorer and click **Add**. InstallShield adds a new setup type.
3. Type a new name for the setup type.

Editing Setup Types

Project • *Setup types are available in the following project types:*

- *InstallScript*
- *InstallScript MSI*

To create setup types for a Basic MSI project, use the feature's Install Level setting.

Task: ***To change which features are associated with a setup type:***

1. In the View List under **Organization**, click **Setup Types**.
2. In the **Setup Types** explorer, click the setup type that you want to edit. All of the features in your installation project appear in the lower-left pane.
3. Clear the check boxes next to the features that should not be included in the selected setup type. Select the check boxes next to those features that you want included.

Any setup types listed in the **Setup Types** pane are automatically added to your installation project.

Note • *The* ***SetupType2*** *function displays only the standard setup types—Complete and Custom—with fixed description text for both. If you want greater flexibility, call* ***SdSetupTypeEx*** *in your script instead of* ***SetupType2****. (The default code for the* ***OnFirstUIBefore*** *event handler includes a call to the* ***SetupType2*** *function.)*

Tip • *To provide an accelerator key for your setup type, include an ampersand (&) before a letter in the name. For example, the name* `Cu&stom` *becomes the label Cu*<u>s</u>*tom, and the end user can select it during installation by pressing the S key.*

Renaming Setup Types

Project • *Setup types are available in the following project types:*

- *InstallScript*
- *InstallScript MSI*

To create setup types for a Basic MSI project, use the feature's Install Level setting.

Task: ***To rename a setup type:***

1. In the View List under **Organization**, click **Setup Types**.
2. In the **Setup Types** explorer, right-click the setup type that you want to edit and then click **Rename**.
3. Type a new name for your setup type.

This updates the Display Name setting for the selected setup type. The name is displayed in the SetupTypes dialog at run time.

Deleting Setup Types

Project • *Setup types are available in the following project types:*

- *InstallScript*
- *InstallScript MSI*

To create setup types for a Basic MSI project, use the feature's Install Level setting.

Task: ***To delete a setup type:***

1. In the View List under **Organization**, click **Setup Types**.
2. In the **Setup Types** explorer, right-click the setup type that you want to delete and then click **Remove**.

Including Redistributables in Your Installation

InstallShield includes many commonly used third-party redistributables, making it easy to add support for popular technologies such as the .NET Framework to your installation. When you add redistributables to your project, the redistributables, plus all of the associated dependencies, are added to your installation. This simplifies the process of packaging redistributables and helps to facilitate consistency for internal or external use.

The Redistributables view (or in InstallScript and InstallScript Object projects, the Objects view) contains all of the InstallShield objects and third-party merge modules that are included with InstallShield. In Basic MSI and InstallScript MSI projects, this view also contains InstallShield prerequisites that you can add to your installation. In InstallScript projects, you can use the Prerequisites view to add InstallShield prerequisites to your installation.

InstallShield Prerequisites

An InstallShield prerequisite is an installation for a product or technology framework that is required by your product. You can add any of the existing InstallShield prerequisites to your installation projects and configure many of their settings. You can also create your own InstallShield prerequisites, and add them to your projects.

InstallShield includes a base set of InstallShield prerequisites. You can also use the InstallShield Prerequisite Editor in InstallShield to define custom InstallShield prerequisites or to edit settings for any existing InstallShield prerequisites.

InstallShield includes support for two types of InstallShield prerequisites:

- **Setup prerequisite**—The installation for this type of prerequisite runs before your installation runs.
- **Feature prerequisite**—This type of prerequisite is associated with one or more features. It is installed if the feature that contains the prerequisite is installed and if the prerequisite is not already installed on the system. Thus, if a feature has a condition that is not met on the target system, or if the end user chooses not to install the feature, the feature is not installed. As a result, none of its associated feature prerequisites are installed, unless the feature prerequisites are also associated with other features that are installed.

***Project** • Basic MSI projects include support for feature prerequisites.*

InstallShield also includes support for including InstallShield prerequisites as packages in Advanced UI and Suite/Advanced UI projects. For more information, see Including InstallShield Prerequisites (.prq) in an Advanced UI or Suite/Advanced UI Project.

Merge Modules

A merge module (or .msm file) contains all of the logic and files needed to install distinct pieces of functionality. For example, some applications require Microsoft C++ run-time libraries. Instead of having to include the file in a feature and figure out its installation requirements, you can simply attach the Microsoft C++ runtime library merge module to one of your project's features.

***Note** • Many of the merge modules included in the Redistributables view are authored by Microsoft or another third party. InstallShield distributes these modules as a courtesy to assist you in creating your installation project. However, InstallShield cannot modify or fix any problems that may exist within third party-authored modules. You are encouraged to contact the vendor regarding issues with specific third party-authored modules.*

Objects

Like merge modules, objects contain logic and files needed to install distinct pieces of functionality. Some objects, such as the DirectX object included with InstallShield, require customization through a wizard. As soon as you add such an object to your installation, its customization wizard opens. You can either customize your object at the time you add it, or cancel the wizard and customize your object later by right-clicking the object and selecting Change Objects Settings.

Live Redistributables Gallery

Because the file size of many of the redistributables is so large, some that are available for use in your projects are not added to your computer when you install InstallShield. However, these redistributables are still available for download from the Internet to your computer. In addition, a newer version of a redistributable that you have on your computer may be available for download.

Configurable Merge Modules

A configurable redistributable is a merge module or an object that has at least one row in the **ModuleConfiguration** table that is referenced by at least one row in the **ModuleSubstitution** table. This enables you to change a value in the redistributable. When you select a configurable module in the Redistributables view, the Merge Module Configurable Values dialog box is displayed to enable you to configure the module at the time you add it. To customize the merge module later, right-click it and select Configure merge module.

Shipping Redistributable Files

InstallShield provides third-party redistributables that you can incorporate into your installation projects. If you include redistributable technology in your projects—for example, Crystal Reports—that redistributable must be licensed from the vendor. You cannot legally redistribute these technologies without the appropriate licensing. For details, consult the vendor's documentation.

When you build releases in an InstallShield project, InstallShield includes various InstallShield redistributable files in the build output. You may use these InstallShield redistributable files in the build output according to the InstallShield End-User License Agreement. Most of these files are installed in the *InstallShield Program Files Folder*\Redist folder and included in builds as needed. Following is a list of the InstallShield redistributable files.

- _isres_LanguageID.dll
- ClrSuitePSHelper.dll
- ClrWrap.dll
- CommonHelper.dll
- corecomp.ini
- default.pal
- DLLWrap.dll
- DotNetInstaller.exe
- DRMInstallerMSI.dll

- DRMInstallerPro.dll
- EulaScrollWatcher.dll
- FileBrowse.dll
- IISHelper.dll
- InstallShield.ClrHelper.dll
- InstallShield.Interop.Msi.dll
- ISChain.exe
- ISChainPackages.dll
- ISComSrv.dll
- ISExpHlp.dll
- isexternalui.dll
- IsLockPermissions.dll
- ISNetAPI.dll
- ISNetworkShares.dll
- ISRegSvr.dll
- Isrt.dll
- ISScheduledTasks.dll
- IsSchRpl.dll
- ISSetup.dll
- ISSQLSrv.dll
- ISWindowsFeaturesAction.dll
- ISWindowsFeaturesAction64.dll
- ISXmlCfg.dll
- Layout.bin
- PowerShellWrap.dll
- PrqLaunch.dll
- QuickPatchHelper.dll
- SerialNumCAHelper.dll
- SetAllUsers.dll
- Setup.exe
- Setup.ini

- setup.inx
- setup.isn
- setup.skin
- Setup_UI.dll
- SetupSuite.exe
- SetupSuite64.exe
- SFHelper.dll
- SuiteAppxHelper.exe
- Image files that are installed in the subfolders in the *InstallShield Program Files Folder*\Support\Themes directory

Managing the Redistributables Gallery

Live Redistributables Gallery

Because the file size of many of the redistributables is so large, some that are available for use in your projects are not added to your computer when you install InstallShield. However, these redistributables are still available for download from the Internet to your computer. In addition, a newer version of a redistributable that you have on your computer may be available for download.

You can identify the status of a redistributable by its icon. Following is a list of the possible icons in the Redistributables view (or in InstallScript projects, the Objects view or the Prerequisites view) and a description of each:

Table 4-13 • Redistributable Icons

Icon	Project Type	Description
	Basic MSI, InstallScript, InstallScript MSI	This InstallShield prerequisite is installed on your computer.
	Basic MSI, InstallScript, InstallScript MSI	This InstallShield prerequisite is not installed on your computer but it is available for download.
	Basic MSI, InstallScript, InstallScript MSI	This InstallShield prerequisite is included in your project but its location is not listed in one of the directories that is specified on the Prerequisites tab of the Options dialog box.
	Basic MSI, InstallScript, InstallScript MSI	This merge module is installed on your computer.

Table 4-13 • Redistributable Icons (cont.)

Icon	Project Type	Description
	Basic MSI, InstallScript MSI	This merge module is stored in a repository and is available for inclusion in your project. For more information about repositories, see Using a Repository to Share Project Elements.
	Basic MSI, InstallScript, InstallScript MSI	This merge module is not installed on your computer but it is available for download.
	Basic MSI, InstallScript MSI	An old version of this merge module is installed on your computer. A new version is available for download.
	Basic MSI, InstallScript, InstallScript MSI	This object is installed on your computer.
	Basic MSI, InstallScript MSI	This object is not installed on your computer but it is available for download.
	Basic MSI, InstallScript MSI	An old version of this object is installed on your computer. A new version is available for download.

Project • *If you add to your project a redistributable that is not installed on your computer, one or more build errors are generated when you build a release. To eliminate the build errors, either remove the redistributable from your project or download it before rebuilding the release. If a redistributable is not installed on your computer,* ***Needs to be downloaded*** *is specified in the Location column for that redistributable.*

InstallShield does not permit you to add a redistributable in the Objects view to an InstallScript project if it is not installed on your computer.

Working with the Live Redistributables Gallery

The Redistributables view in Basic MSI and InstallScript MSI projects displays the redistributables gallery, which consists of InstallShield prerequisites, merge modules, and objects, that you can include with your installations. The Prerequisites view in InstallScript projects also displays the gallery of InstallShield prerequisites that you can add to your project.

InstallShield Prerequisites

Many InstallShield prerequisites are available in InstallShield. In addition, the InstallShield Prerequisite Editor in InstallShield enables you to modify these prerequisites and create your own. All InstallShield prerequisite (.prq) files are stored in the following location:

InstallShield Program Files Folder\SetupPrerequisites

Merge Modules

Merge modules are available from a variety of sources. Although InstallShield includes many redistributable modules, new versions may be available or other software developers may have released a module that you need. In addition, InstallShield enables you to create your own merge modules and add them to your redistributables gallery.

The source of the merge module files listed in the Redistributables view is the folder or folders specified on the Merge Modules tab of the Options dialog box. To access the Options dialog box, on the Tools menu, click Options.

The following directory is the default location for the modules that come with InstallShield:

InstallShield Program Files Folder\Modules\i386

Objects

InstallShield provides many redistributable objects and lets you create your own for inclusion in your installations. Furthermore, you may want to add to your projects the objects that other developers created with InstallShield.

The default location for the objects that come with InstallShield is:

InstallShield Program Files Folder\Objects

The objects that are included in the above location are listed in the Redistributables view.

Downloading Redistributables to Your Computer

The procedures for downloading redistributables to your computer differ, depending on what type of project you are using.

For Basic MSI and InstallScript MSI Projects

The Redistributables view enables you to download the latest InstallShield prerequisites, merge modules, and objects from the Flexera Software Web site to your computer. If a redistributable is not installed on your computer, **Needs to be downloaded** is specified in the Location column for that redistributable.

Task: ***To download a specific InstallShield prerequisite, merge module, or object:***

1. In the View List under **Application Data**, click **Redistributables**.
2. Right-click the InstallShield prerequisite, merge module, or object that you would like to download and then click **Download Selected Item**.

Task: ***To download all of the InstallShield prerequisites, merge modules, and objects that are needed for your installation project:***

1. In the View List under **Application Data**, click **Redistributables**.
2. Right-click any InstallShield prerequisite, merge module, or object and then click **Download All Required Items**.

For InstallScript Projects

The Prerequisites view enables you to download the latest InstallShield prerequisites from the Flexera Software Web site to your computer. If a redistributable is not installed on your computer, **Needs to be downloaded** is specified in the Location column for that redistributable.

Task: ***To download a specific InstallShield prerequisite:***

1. In the View List under **Application Data**, click **Prerequisites**.
2. Right-click the InstallShield prerequisite that you would like to download and then click **Download Selected Item**.

Task: ***To download all of the InstallShield prerequisites that are needed for your installation project:***

1. In the View List under **Application Data**, click **Prerequisites**.
2. Right-click any InstallShield prerequisite and then click **Download All Required Items**.

The Objects view enables you to download the latest merge modules and objects from the Flexera Software Web site to your computer. If a merge module is not installed on your computer, its icon () indicates that it is not installed. InstallShield does not permit you to add a merge module to your InstallScript project if the merge module is not installed on your computer. If an object is not installed on your computer, it is not listed in the Objects view.

Task: ***To download a specific merge module:***

1. In the View List under **Application Data**, click **Objects**.
2. In the **InstallShield Objects/Merge Modules** pane, right-click the merge module that you would like to download and then click **Download Selected Item**.

Task: ***To download objects:***

1. In the View List under **Application Data**, click **Objects**.
2. In the **InstallShield Objects/Merge Modules** pane, right-click any object and click **Check Web**. The downloads page at the Flexera Software Web site opens in an Internet browser.
3. Select the object that you would like to download and install. You are prompted during the installation to close InstallShield in order to complete the object installation.

Adding InstallShield Prerequisites to the Redistributables Gallery

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To add an InstallShield prerequisite to the redistributables gallery:***

1. Acquire the new or updated InstallShield prerequisite (.prq) file.
2. Using Windows Explorer, copy the new prerequisite to the following location:

   InstallShield Program Files Folder\SetupPrerequisites
3. Close InstallShield if it is currently open.
4. Launch InstallShield.

The modifications that you made are reflected in the Redistributables view (in Basic MSI and InstallScript MSI projects) and in the Prerequisites view (in InstallScript projects).

Removing InstallShield Prerequisites from the Redistributables Gallery

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To remove an InstallShield prerequisite from the redistributables gallery:***

1. Close InstallShield.
2. Using Windows Explorer, locate and delete the InstallShield prerequisite that you want to remove from the gallery. InstallShield prerequisites are located in the following directory:

   InstallShield Program Files Folder\SetupPrerequisites
3. Launch InstallShield.

The modifications that you made are reflected in the Redistributables view (in Basic MSI and InstallScript MSI projects) or in the Prerequisites view (in InstallScript projects).

Browsing for Merge Modules

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

If a merge module that you would like to add to your project is not listed in the Redistributables view, you can browse to find it and also add it to your project and this view.

Task: ***To browse for a merge module:***

1. In the View List under **Application Data**, click **Redistributables**.
2. Right-click an item and click **Browse for Merge Module**. The **Open** dialog box opens.
3. Browse to the merge module file.
4. Click **OK**.

What Happens When You Browse for a Merge Module

InstallShield does not maintain references to merge modules as explicit paths. Instead, it generates a key for a merge module based on the merge module GUID and the merge module locale. When InstallShield needs to access the merge module, it looks in the folders specified in the Merge Module Locations box for a file that matches that key. The Merge Module Locations box is on the Merge Modules tab of the Options dialog box.

When you browse for a merge module, the path to the folder containing the merge module is added to the list of paths in the Merge Module Locations box. In addition, a GUID:Locale key is added to your installation project based on the selected file.

Impact on Your Installation

If two merge modules in the Merge Module Locations box have the GUID:Locale key, only one is included into your installation, even if they have different file names. Because of the way InstallShield uses the Merge Module Locations box to search, it is not possible to predict which merge module will be included.

Limiting the Number of Directories in the Merge Module Locations Box

If you use a shared merge module gallery, there might be earlier or later versions of a merge module in the gallery than what exists on the target machine. For this reason, it is sometimes prudent to try and limit the number of directories in your Merge Module Locations box.

Task: ***To limit the number of directories, do one of the following:***

- Using Windows Explorer, copy the merge module that you want into one of the folders that is already listed in the **Merge Module Locations** box.
- Remove the default folders from the search path so that you are referencing only the shared location.

Adding Merge Modules to the Redistributables Gallery

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To add a merge module to the redistributables gallery:***

1. Acquire the new or updated merge module.
2. Using Windows Explorer, copy the new module to one of the folders specified on the **Merge Modules** tab of the **Options** dialog box.

   The default location for the modules that come with InstallShield is:

   InstallShield Program Files Folder\Modules\i386
3. Close InstallShield if it is currently open.
4. Launch InstallShield.

The modifications that you made are reflected in the Redistributables view (in Basic MSI and InstallScript MSI projects) and in the Objects view (in InstallScript projects).

Removing Merge Modules from the Redistributables Gallery

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To remove a module from the redistributables gallery:***

1. Close InstallShield.
2. Using Windows Explorer, locate and delete the merge module that you want to remove from the gallery. Ensure that you search each directory specified on the Merge Modules tab of the **Options** dialog box.
3. Launch InstallShield.

The modifications that you made are reflected in the Redistributables view (in Basic MSI and InstallScript MSI projects) and in the Objects view (in InstallScript projects).

Note • *If you delete a merge module that is currently associated with your installation, the message* ***[Merge Module Not Found]*** *is displayed to inform you that the module cannot be included in your installation.*

Registering Objects in InstallScript Projects

Project • *This information applies to InstallScript projects.*

When you register an object from within an InstallScript project, InstallShield adds that object to the redistributables gallery, which makes it available for inclusion in other projects.

Task: ***To register an object:***

1. In the View List under **Application Data**, click **Objects**.
2. Right-click an item, point to **Advanced**, and click **Register new object**. The **Project Settings** dialog box opens.
3. On the Language-Independent Object Properties tab, specify a media file (`Data1.hdr` file).
4. Specify any other desired settings, and click **OK**.

Incorporating InstallShield Prerequisites, Merge Modules, and Objects in Projects

InstallShield includes many third-party redistributables that are packaged as InstallShield prerequisites, merge modules, and objects. You can add these built-in redistributables to your installation projects. To learn how, see this section of the documentation.

Tip • *For information on creating your own InstallShield prerequisites, merge modules, and objects, see Designing InstallShield Prerequisites and Other Redistributables.*

Adding InstallShield Prerequisites, Merge Modules, and Objects to Basic MSI and InstallScript MSI Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding redistributables to InstallScript projects, see Adding InstallShield Prerequisites, Merge Modules, and Objects to InstallScript Projects.

Two types of redistributables—merge modules and objects—must be associated with a feature in order to be installed. You can associate a single merge module or object with as many features or subfeatures as needed. If no features exist in your installation project when you attempt to add a merge module or object, the Create a New Feature dialog box opens, enabling you to create a feature. If you do not create a feature, these two types of redistributables cannot be added to your installation project.

When you add an InstallShield prerequisite to an InstallScript MSI project, you cannot associate it with one or more features.

When you add an InstallShield prerequisite to a Basic MSI project, it is not associated with any feature by default, and it is called a *setup prerequisite*, since it is run before your main installation runs. If appropriate, you can associate an InstallShield prerequisite with one more features that are currently in your project.

Task: ***To add an InstallShield prerequisite, merge module, or object to a Basic MSI or InstallScript MSI project:***

1. In the View List under **Application Data**, click **Redistributables**.
2. If you want merge modules that have been published to a repository to be displayed, right-click a redistributable and ensure that **Show Merge Modules in Repository** is enabled.
3. Select the check box in front of the redistributable that you want to add. If you select an object, the associated wizard opens to guide you through the customization process.
4. For a merge module or an object: In the **Conditional Installation** pane, select the check box for each feature that should contain this redistributable.

   If you are working with a Basic MSI project and you want to associate a prerequisite with a feature: In the **Conditional Installation** pane, select the check box for each feature that should contain this prerequisite. If you do not want to associate the prerequisite with a feature, leave the **Install before feature selection** check box selected. This check box is selected by default when you add an InstallShield prerequisite to a Basic MSI project.

Tip • *The right pane in the Redistributables view shows details about the merge module, object, or InstallShield prerequisite that is selected in the list of available redistributables. Review this details pane to find out information such as which files a redistributable installs. You can hide or show the details pane by clicking the Show Details button in this view.*

Note • *If* ***Needs to be downloaded*** *is specified in the Location column for an InstallShield prerequisite that you added to your project, that InstallShield prerequisite is not installed on your computer. You can download the InstallShield prerequisite from the Internet to your computer if you would like to include it in your project. If you build a release without first downloading one or more required InstallShield prerequisites, and if you specify that the InstallShield prerequisites should be extracted from* `Setup.exe` *or copied from the source media (instead of being*

downloaded from the Web to the end user's computer), one or more build errors may be generated. To eliminate the build errors, remove the InstallShield prerequisite from your project, download it to your computer, or change the InstallShield prerequisite location for the release to the download option; then rebuild the release.

Obtaining InstallShield Prerequisites and Objects

Note that some of the InstallShield prerequisites and objects are not installed with InstallShield. You may need to download them. For more information, see Obtaining Updates for InstallShield.

Also note that if you have an installation (for example, a `Setup.exe` file or an .msi package) that you want to launch during your installation, you can create your own custom InstallShield prerequisite, and then add that InstallShield prerequisite to your projects as needed. To learn how to create your own InstallShield prerequisite, see Defining InstallShield Prerequisites.

Adding InstallShield Prerequisites, Merge Modules, and Objects to InstallScript Projects

Project • *This information applies to InstallScript projects.*

For information on adding redistributables to Basic MSI and InstallScript MSI projects, see Adding InstallShield Prerequisites, Merge Modules, and Objects to Basic MSI and InstallScript MSI Projects.

Merge modules and objects must be associated with a feature in order to be installed during an InstallScript installation. You can associate a single merge module or object with as many features or subfeatures as needed. If no features exist in your installation project when you attempt to add a merge module or object, the Create a New Feature dialog box opens, enabling you to create a feature. If you do not create a feature, these two types of redistributables cannot be added to your installation project.

When you add an InstallShield prerequisite to an InstallScript project, you cannot associate it with one or more features.

Task: ***To add an InstallShield prerequisite to an InstallScript project:***

1. In the View List under **Application Data**, click **Prerequisites**.
2. Select the check box in front of the InstallShield prerequisite that you want to add.

Tip • *The right pane in the Prerequisites view shows details about the InstallShield prerequisite that is selected in the list of available redistributables. Review this details pane to find out information such as which files a redistributable installs. You can hide or show the details pane by clicking the Show Details button in this view.*

Note • *If **Needs to be downloaded** is specified in the Location column for an InstallShield prerequisite that you added to your project, that InstallShield prerequisite is not installed on your computer. You can download the InstallShield prerequisite from the Internet to your computer if you would like to include it in your project. If you build*

a release without first downloading one or more required InstallShield prerequisites, and if you specify that the InstallShield prerequisites should be included with the media (instead of being downloaded from the Web to the end user's computer), one or more build errors may be generated. To eliminate the build errors, remove the InstallShield prerequisite from your project, download it to your computer, or change the InstallShield prerequisite location for the release to the download option; then rebuild the release.

Task: ***To add a merge module or object to an InstallScript project:***

1. In the View List under **Application Data**, click **Objects**.
2. In the **Features** pane, select the feature to which you want to add an object or merge module.
3. Right-click the object or merge module that you want to add and select **Add to selected feature**. (You can instead drag the object or merge module and drop it on the feature.) For some objects, an associated wizard appears to guide you through the customization process.

Note • *Merge modules that are added to a feature in an InstallScript project appear in the Features pane as subitems of the Merge Module Holder object. This object requires the Windows Installer engine. For more information, see Adding Windows Installer Redistributables to Projects.*

Tip • *To see information about an object or merge module, such as files it installs and other actions it performs, select the object or merge module name. The information is displayed in the pane on the right.*

Caution • *You should not alter another company's merge module.*

Obtaining Objects

Note that some of the objects are not installed with InstallShield. You may need to download them. For more information, see Obtaining Updates for InstallShield.

Removing InstallShield Prerequisites from a Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To remove an InstallShield prerequisite from your project:***

1. In the View List under **Application Data**, click **Redistributables** (in Basic MSI and InstallScript MSI projects) or **Prerequisites** (in InstallScript projects).
2. Clear the check box in front of the InstallShield prerequisite that you want to remove.

Tip • *If an InstallShield prerequisite is included in your installation as a dependency of another InstallShield prerequisite but you want to remove that dependency prerequisite from the installation, you must remove the corresponding dependency from the InstallShield prerequisite. For more information, see Removing a Dependency from an InstallShield Prerequisite.*

Removing Merge Modules and Objects from a Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To remove a merge module or object from your project:***

- In Basic MSI and InstallScript MSI projects: In the **Redistributables** view, clear the check box in front of the redistributable.
- In InstallScript projects: In the **Objects** view, right-click the redistributable in the **Features** window and click **Delete from project**.

InstallShield moves the merge module or object from your project. In addition, InstallShield automatically removes from the project any dependencies that are associated with that redistributable.

Determining the Files in InstallShield Prerequisites, Merge Modules, and Objects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

If you need to see a list of files in an InstallShield prerequisite, a merge module, or an object, you can do so from within the Redistributables view in Basic MSI and InstallScript MSI projects. The right pane in this view shows details about the InstallShield prerequisite, merge module, or object that is selected in the list of available redistributables. This details pane provides information such as which files a redistributable installs. You can hide or show the details pane by clicking the Show Details button in this view. Clicking the Show Details button in the Prerequisites view of an InstallScript project lets you see the files in the selected InstallShield prerequisite.

If you are using an InstallScript project and you want to see details about a merge module or object that is listed in the Objects view, select that object; InstallShield displays a list of the redistributable's files, as well as additional information, in the right pane.

Tip • *For another way to see the files contained in a merge module or object, see Knowledge Base article Q106474. This article contains a link to a downloadable Merge Module Dependency Viewer.*

Working with InstallShield Prerequisites that Are Included in Installation Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

An InstallShield prerequisite is an installation for a product or technology framework that is required by your product. Some examples of InstallShield prerequisites that are included with InstallShield are Java Runtime Environment (JRE) and SQL Server Express Edition. You can add any of the existing InstallShield prerequisites to your installation projects and configure many of their settings. You can also create your own InstallShield prerequisites, and add them to your projects.

Project • *Including InstallShield prerequisites in Windows Installer–based projects enables you to chain multiple installations together, bypassing the Windows Installer limitation that permits only one Execute sequence to be run at a time. The `Setup.exe` setup launcher serves as a bootstrap application that manages the chaining.*

Note • *Unlike Windows Installer 4.5 chaining, the InstallShield prerequisite installations are not processed as a single transaction; that is, successful installations are not rolled back after failures in later prerequisites. To learn more about Windows Installer 4.5 chaining support, see Configuring Multiple Packages for Installation Using Transaction Processing.*

The Redistributables view is where you add InstallShield prerequisites to Basic MSI and InstallScript MSI projects. The Prerequisites view is where you add InstallShield prerequisites to InstallScript projects.

Setup Prerequisites vs. Feature Prerequisites

Project • *Basic MSI projects include support for feature prerequisites.*

The following project types include support for setup prerequisites but not feature prerequisites:

- *InstallScript*
- *InstallScript MSI*

An InstallShield prerequisite that is run before the main installation's user interface sequence begins is called a *setup prerequisite*. Setup prerequisites are useful for base applications and technology frameworks that must be installed for all configurations of the installed product or that provide functionality that is used during the installation itself. When you add an InstallShield prerequisite to a project, it is the setup prerequisite type of InstallShield prerequisite by default.

Basic MSI projects enable you to associate InstallShield prerequisites with features in your main installation. When an InstallShield prerequisite is associated with one or more features, it is called a *feature prerequisite*. Feature prerequisites are installed after an end user has chosen which features to install; like merge modules, a feature prerequisite is installed only if one or more of the features that contain it are installed. Thus, feature prerequisites are useful for applications or components that are used by only some configurations of the installed product and are not used during the installation itself.

Review the following sections for more information that will help you determine which type of InstallShield prerequisite will best fit your requirements.

Special Considerations for Setup Prerequisites

Following are some tips to consider if you are including one or more setup prerequisites in your project.

.NET Framework Requirements

If your product requires that the .NET Framework be installed on the target system, you may include the .NET Framework redistributable to your project. If the target system does not have the .NET Framework, it is installed during your installation. For more details, see Adding .NET Framework Redistributables to Projects.

If your installation includes the .NET Framework redistributable and a setup prerequisite that requires that the .NET Framework be present on the target machine—for example, if it installs files to the GAC—you can specify that the .NET Framework should be installed before the setup prerequisite is installed. To learn more, see Specifying Parameters for Installing an InstallShield Prerequisite.

Displaying an Error If an End User Launches the .msi Package Instead of the Setup Launcher

If your Basic MSI or InstallScript MSI installation includes a setup prerequisite and end users launch the .msi package for your product directly, rather than launch the `Setup.exe` setup launcher, the setup prerequisite installation will not run. If the prerequisite is not already present on a target system, your product may not work as expected. This scenario may occur if you build an uncompressed release, where the .msi package is not streamed into the `Setup.exe` file.

To prevent this issue from occurring, you may want to add a type 19 custom action to your Basic MSI or InstallScript MSI project. This custom action would evaluate the same conditions that were configured for the prerequisite on the Conditions tab in the InstallShield Prerequisite Editor. The custom action would verify whether the setup prerequisite is still needed; if it is needed, the type 19 error custom action would display an error message and end the installation.

Special Considerations for Feature Prerequisites

Following are some tips to consider if you are including one or more feature prerequisites in a Basic MSI project.

Windows Installer Requirements

If your project includes a prerequisite that installs the Windows Installer, the prerequisite should be a setup prerequisite, not a feature prerequisite. That is, this prerequisite should not be associated with a feature.

.NET Framework Requirements

If your project include a prerequisite that installs the .NET Framework and your installation requires that the .NET Framework be present—for example, if your installation installs files to the GAC—the .NET Framework prerequisite should be a setup prerequisite, not a feature prerequisite. That is, this prerequisite should not be associated with a feature.

Potential Restart Issues for Feature Prerequisites

If you add an InstallShield prerequisite to your project and it may require a restart, it is recommended that you avoid associating the prerequisite with a feature. If a feature prerequisite does trigger a restart, the ReadyToInstall dialog is displayed again after the restart, and the end user will need to click the Install button again to proceed with the rest of the installation.

Calculations for Disk Space Requirements

When the Windows Installer performs the file costing–related actions, it does not automatically include the disk space that is required by any feature prerequisites. Therefore, if the CustomSetup dialog is displayed at run time, the disk space amounts that are listed for various features may be inaccurate, since they will not account for the disk space that is required by feature prerequisites. In addition, it is possible that a target system may have sufficient disk space for the main installation, but not for the feature prerequisites. In this scenario, the target system may run out of disk space midway through the installation.

To prevent file-costing issues for a feature prerequisite in your project, you may want to add a custom action that evaluates the same conditions that were configured for the feature prerequisite on the Conditions tab in the InstallShield Prerequisite Editor. This custom action would detect whether the feature prerequisite needs to be run if its associated feature is selected to be installed. If the feature prerequisite would need to be run, the custom action would add a temporary row to the ReserveCost table.

Associating an InstallShield Prerequisite with a Feature in a Basic MSI Project

Project • *Basic MSI projects include support for associating prerequisites with features.*

To learn about the differences between setup prerequisites and feature prerequisites (which are the two types of InstallShield prerequisites), see Setup Prerequisites vs. Feature Prerequisites.

If an InstallShield prerequisite is associated with a feature in a project, it is considered to be a *feature prerequisite*. If it is not associated with a feature, it is considered to be a *setup prerequisite*.

Whenever you add an InstallShield prerequisite to an installation project, it is automatically added as a setup prerequisite by default. You can make it a feature prerequisite by associating it with one or more features that already exist in your project.

Task: ***To associate an InstallShield prerequisite with a feature:***

1. In the View List under **Application Data**, click **Redistributables**.
2. In the list of redistributables, select the InstallShield prerequisite that you want to associate with a feature.

   

   Note • *The InstallShield prerequisite's check box must already be selected; this indicates that it is being included in your project. For more information, see Adding InstallShield Prerequisites, Merge Modules, and Objects to Basic MSI and InstallScript MSI Projects.*
3. In the **Conditional Installation** pane, select the check box of each feature to which you want to add this InstallShield prerequisite.

If you want to associate the prerequisite with a new feature, you must first create it. To learn how to create a new feature, see Creating Features.

If you associate a prerequisite with all of the features in your project and then you later add a new feature, InstallShield does not automatically associate the feature prerequisite with the new feature.

Note • *Feature prerequisites have some limitations that setup prerequisites do not have. For more information, see Setup Prerequisites vs. Feature Prerequisites.*

Disassociating an InstallShield Prerequisite from a Feature in a Basic MSI Project

Project • *Basic MSI projects include support for associating prerequisites with features.*

To learn about the differences between setup prerequisites and feature prerequisites (which are the two types of InstallShield prerequisites), see Setup Prerequisites vs. Feature Prerequisites.

If an InstallShield prerequisite is associated with a feature in a project, it is considered to be a *feature prerequisite*. If it is not associated with a feature, it is considered to be a *setup prerequisite*.

Task: ***To remove an InstallShield prerequisite from a feature:***

1. In the View List under **Application Data**, click **Redistributables**.
2. In the list of redistributables, select the InstallShield prerequisite that you want to disassociate from a feature.
3. In the **Conditional Installation** pane, select the **Install before feature selection** check box. This check box is selected by default when you add an InstallShield prerequisite to a Basic MSI project.

Note • *Setup prerequisites have some advantages over feature prerequisites. For more information, see Setup Prerequisites vs. Feature Prerequisites.*

Specifying the Installation Order of InstallShield Prerequisites

Project • *Basic MSI projects include support for feature prerequisites.*

The following project types include support for setup prerequisites but not feature prerequisites:

- *InstallScript*
- *InstallScript MSI*

To learn about the differences between setup prerequisites and feature prerequisites (which are the two types of InstallShield prerequisites), see Setup Prerequisites vs. Feature Prerequisites.

The Redistributables view is where you specify the order in which InstallShield prerequisites should be installed if you include more than one in a Basic MSI project or an InstallScript MSI project. The Prerequisites view is where you specify the order in which InstallShield prerequisites should be installed if you include more than one in an InstallScript project.

Task: ***To specify the order in which the InstallShield prerequisites should be installed on the target machine:***

1. In the View List under **Application Data**, click **Redistributables** (in a Basic MSI or InstallScript MSI project) or **Prerequisites** (in an InstallScript project).
2. Add the necessary InstallShield prerequisites to your project if you have not already done so.
3. Right-click any redistributable and click **Set InstallShield Prerequisite Order**. The **InstallShield Prerequisite Installation Order** dialog box opens.
4. Select a prerequisite in the list and then click the up or down arrow to move it up or down in the order for installation.

Project *• Note that when you are specifying the order in a Basic MSI project, InstallShield does not distinguish between setup prerequisites and feature prerequisites. Thus, if your project contains a mix of setup prerequisites and feature prerequisites, they are all listed in one combined list on the InstallShield Prerequisite Installation Order dialog box. At run time, before the main installation launches, the* `Setup.exe` *setup launcher evaluates only the setup prerequisites and—if appropriate—installs them in the order that you specified on the InstallShield Prerequisite Installation Order dialog box. Then later during the installation, the Windows Installer engine evaluates only the feature prerequisites and—if appropriate—installs them in the order that you specified.*

Tip *• If the Windows Installer engine, the .NET Framework, or both must be installed before an InstallShield prerequisite is installed, you can open the InstallShield prerequisite in the InstallShield Prerequisite Editor and specify this requirement. For more information, see Specifying Parameters for Installing an InstallShield Prerequisite.*

Configuring a Release that Includes InstallShield Prerequisites

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

When you package a Basic MSI or InstallScript MSI installation that includes InstallShield prerequisites, you can use any one of the following methods for supplying the InstallShield prerequisite files to end users:

- Store the InstallShield prerequisite files on the source media.
- Compress the InstallShield prerequisite files into `Setup.exe`, to be extracted at run time, as needed.
- If necessary, your installation can download the InstallShield prerequisite files that are included in your project from the URL that is specified in the InstallShield prerequisite file (.prq) for each prerequisite.

For InstallScript installations that include InstallShield prerequisites, the methods that are available are slightly different:

- Store the InstallShield prerequisite files on the source media or in `Setup.exe`, depending on how you configure the settings for the release.
- If needed, your installation can download the InstallShield prerequisite files included in your project from the URL specified in the InstallShield prerequisite (.prq) file for each prerequisite.

You can specify different methods for each InstallShield prerequisite in your project. To learn more, see Specifying a Run-Time Location for a Specific InstallShield Prerequisite.

You can also override individual methods at the release level if you want all of the InstallShield prerequisites in a release to be available through the same method. For more information, see Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level.

You can configure an InstallShield prerequisite so that it is installed either before or after any installation of the Windows Installer engine and the .NET Framework. For more information, see Specifying Parameters for Installing an InstallShield Prerequisite.

Specifying the Directories that Contain InstallShield Prerequisites

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The default location for InstallShield prerequisite files (.prq) is:

InstallShield Program Files Folder\SetupPrerequisites

InstallShield lets you specify additional or alternative locations on your local machine, or on a network. This flexibility enables you to store InstallShield prerequisites in source code control and to share a common set of InstallShield prerequisites with other team members.

InstallShield offers several ways for specifying the search paths for InstallShield prerequisite files (.prq):

- If you are editing or building from within InstallShield, use the Prerequisites tab on the Options dialog box—which is displayed when you click Options on the Tools menu—to specify a comma-delimited list of machine-wide folders and current-user folders.

  InstallShield saves the paths that you specify on the Prerequisites tab in the registry on your machine. The paths that you specify for the current user are stored in the following location:

  HKEY_CURRENT_USER\Software\InstallShield*Version*\Professional\Project Settings\PrerequisiteSearchPath

  The paths that you specify for all users are stored in the following location:

  HKEY_LOCAL_MACHINE\Software\InstallShield*Version*\Professional\PrerequisiteSearchPath

  The Options dialog box is not available if you are using the Standalone Build to build a release; however, if you want, you can manually add the paths to the registry on a machine that has the Standalone Build.

- If you are building from the command line with ISCmdBld.exe, use the `-prqpath` parameter to specify a comma-delimited list of folders.

  If you use an .ini file to specify ISCmdBld.exe parameters, you can use the PrerequisitePath parameter in the [Mode] section of your .ini file to specify a comma-delimited list of folders.

- If you are building through MSBuild or Team Foundation Server (TFS), use the PrerequisitePath parameter on the InstallShield task. This parameter is exposed as the ItemGroup InstallShieldPrerequisitePath when the default targets file is used. To specify multiple paths, use an ordered array of paths.

Instead of using hard-coded paths, you can use path variables in paths, as in the following example:

```
<ISProductFolder>\SetupPrerequisites,<ISProjectFolder>\MyCustomPrerequisites
```

The Redistributables view and the Prerequisites view list the names of the InstallShield prerequisites that correspond with the .prq files that are present in the various search paths that are specified on the Prerequisites tab of the Options dialog box. If the same .prq file is in multiple search paths, InstallShield shows only the first instance that it encounters. InstallShield first searches each path that is listed in the per-user setting on the Prerequisites tab. Then, InstallShield checks each path that is listed in the machine-wide setting.

At build time, if your project includes one or more InstallShield prerequisites, InstallShield (or the Standalone Build) searches the specified locations and includes the appropriate InstallShield prerequisites in your release as needed. If the same .prq file is in multiple search paths, InstallShield includes in the build only the first instance that it encounters. It uses the following order to search for .prq files:

1. InstallShield (or the Standalone Build) checks the paths that are specified through the `-prqpath` command-line parameter, the PrerequisitePath .ini file parameter, or the PrerequisitePath parameter on the InstallShield task.
2. InstallShield checks each path that is listed in the per-user setting on the Prerequisites tab. The paths are saved in the following location in the registry.

   HKEY_CURRENT_USER\Software\InstallShield*Version*\Professional\Project Settings\PrerequisiteSearchPath

   Note that the Prerequisites tab is not applicable to the Standalone Build, but the registry path is applicable.
3. InstallShield checks each path that is listed in the machine-wide setting on the Prerequisites tab. The paths are saved in the following location in the registry.

   HKEY_LOCAL_MACHINE\Software\InstallShield*Version*\Professional\PrerequisiteSearchPath

   Note that the Prerequisites tab is not applicable to the Standalone Build, but the registry path is applicable.
4. If no paths are specified in any of the aforementioned locations, InstallShield checks the default location (*InstallShield (or Standalone Build) Program Files Folder*\SetupPrerequisites).

Tip • *If you are using the Standalone Build to build a release that includes InstallShield prerequisites but you do not specify one or more search paths, the Standalone Build searches the default path (<ISProductFolder>\SetupPrerequisites) for the InstallShield prerequisite files. However, if you specify one or more search paths and do not explicitly include the default path, the Standalone Build does not search the default path.*

Specifying a Run-Time Location for a Specific InstallShield Prerequisite

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

InstallShield enables you to specify a different run-time location for each InstallShield prerequisite in your project.

Task: ***To specify a different run-time location for each InstallShield prerequisite in your installation:***

1. In the View List under **Application Data**, click **Redistributables** (in a Basic MSI or InstallScript MSI project) or **Prerequisites** (in an InstallScript project).
2. Select the check box for one of the InstallShield prerequisites that you want to include in your installation.
3. Right-click the InstallShield prerequisite and click **Properties**. The **InstallShield Prerequisites Properties** dialog box opens.
4. In the **Build Location** list, click the appropriate option.

Note that the location that you specify can be overridden at the release level. To avoid overriding the value that you selected for an individual InstallShield prerequisite, the InstallShield Prerequisites Location setting at the release level must be set to Follow Individual Selections. For more information, see Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level.

Tip • *If an InstallShield prerequisite is added to a project as a dependency of another prerequisite, the location for the InstallShield prerequisite dependency follows the location setting of the InstallShield prerequisite that requires it.*

Assigning Release Flags to InstallShield Prerequisites

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

You can set release flags for InstallShield prerequisites that you want to exclude from certain builds. For example, if you have an InstallShield prerequisite that should be included only in a special edition of your product that contains a special add-on that requires the InstallShield prerequisite, you can flag that InstallShield prerequisite and include it only when it is needed.

Task: ***To add a release flag to an InstallShield prerequisite that you have added to your installation project:***

1. In the View List under **Application Data**, click **Redistributables**.
2. Right-click the InstallShield prerequisite and click **Properties**. The **InstallShield Prerequisites Properties** dialog box opens.
3. In the **Release Flags** box, type a string. The string can be any combination of letters or numbers. To have more than one flag on a prerequisite, use a comma to separate the flags.

To learn more about filtering InstallShield prerequisites based on release flags, see Release Flags.

Building a Release that Includes InstallShield Prerequisites

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

When InstallShield builds a `Setup.exe` file for a project that does not include any prerequisites, it starts with the base `Setup.exe` file that is stored in the following location:

`InstallShield Program Files Folder``\redist\Language Independent\i386`

However, when InstallShield builds a `Setup.exe` file for a project that includes prerequisites, the aforementioned files cannot be used as the base because it does not have the capability of including prerequisites. A slightly larger file called `SetupPrereq.exe` is used instead. The base `SetupPrereq.exe` file is located in the same directory as the base `Setup.exe` file. Since different base files—`Setup.exe` and `SetupPrereq.exe`—are used, only installation authors who are actually including prerequisites in their projects incur the additional size overhead in the final, built `Setup.exe` file that is distributed to end users.

Run-Time Behavior for an Installation that Includes InstallShield Prerequisites

Project • *The following project types include support for both setup prerequisites and feature prerequisites:*

- *Basic MSI*

The following project types include support for setup prerequisites but not feature prerequisites:

- *InstallScript*
- *InstallScript MSI*

To learn about the differences between setup prerequisites and feature prerequisites (which are the two types of InstallShield prerequisites), see Setup Prerequisites vs. Feature Prerequisites.

Overview of an Installation that Includes InstallShield Prerequisites

The following procedure explains what typically occurs at run time when an end user launches an installation that includes setup and feature prerequisites. Note that some of the steps apply to only certain project types.

1. The setup launcher (typically called `Setup.exe`) displays the language selection dialog if appropriate.
2. The setup launcher displays the setup prerequisite dialog and launches the setup prerequisite installations if appropriate.
3. The installation displays the installation UI, which may allow the end user to select features or configure items. The installation UI shows a progress dialog.
4. In Basic MSI installations, the setup launcher launches the feature prerequisite installations if appropriate:
    a. The built-in InstallShield custom action ISInstallPrerequisites, which is scheduled between the SetupProgress dialog and the ExecuteAction action, compares the features that were selected for

installation against the list in the Windows Installer property **IsPrerequisiteFeatures**. If there are no matches, no feature prerequisites are installed.

b. The ISInstallPrerequisites action attempts to find and launch the setup launcher, and it provides the list of features that are being installed. The path to the setup launcher is identified by the Windows Installer properties **SETUPEXEDIR** and **SETUPEXENAME**:

```
[SETUPEXEDIR]\[SETUPEXENAME]
```

If ISInstallPrerequisites cannot find the setup launcher in that location, it searches elsewhere. For a first-time installation, ISInstallPrerequisites checks **SourceDir**. For maintenance mode, ISInstallPrerequisites checks paths that are related to the installation source path.

If ISInstallPrerequisites still cannot find the setup launcher, or if it finds multiple .exe files, the installation prompts the end user to browse to the setup launcher file. If the end user identifies the file, the installation continues. Otherwise, the installation ends.

c. The setup launcher evaluates the list of features to select which feature prerequisites to install, and it launches their installations as appropriate.

5. The installation finishes making changes on the target system according to the end user's selections.

6. The installation switches from the progress dialog to the SetupCompleteSuccess dialog.

The User Interface for an Installation that Includes InstallShield Prerequisites

If a target system needs one or more setup prerequisites to be installed, the setup launcher typically displays the setup prerequisite dialog before the main installation starts. This setup prerequisite lists all of the nonhidden setup prerequisites that are missing from the target system. When an end user clicks the Install button on this dialog, the setup launcher launches the necessary setup prerequisite installations. If one or more of the setup prerequisites is marked as requiring administrative privileges and the installation is run on a system on which User Account Control (UAC) is enabled, the Install button on this dialog has the shield icon to alert the end user that elevated privileges are required.

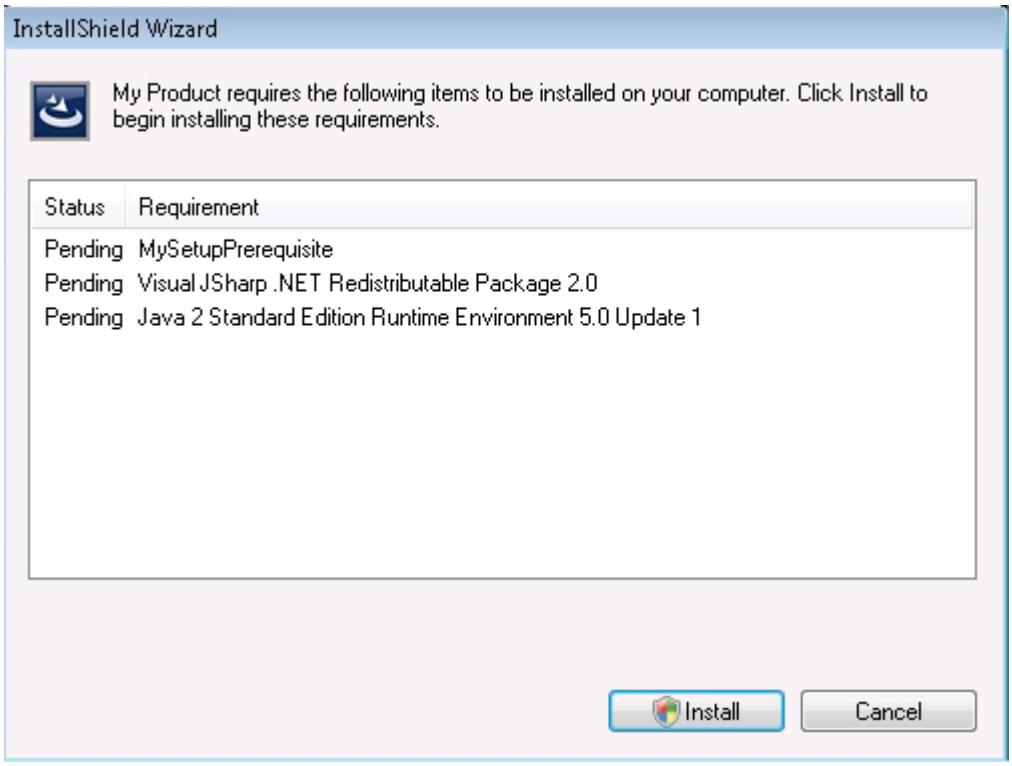

Figure 4-2: Sample Setup Prerequisite Dialog that Shows the List of Setup Prerequisites that Need to Be Installed

If a setup prerequisite is configured to be hidden, it is not listed in the setup prerequisite dialog, but it is still installed. If all of the setup prerequisites in an installation are hidden, the installation displays the setup launcher's standard initialization dialog instead of the setup prerequisite dialog.

Tip • *For instructions on how to show or hide the setup prerequisite in the setup prerequisite dialog, see Specifying Whether to Include the Name of a Prerequisite in the List of Setup Prerequisites to Be Installed on the Target System.*

If the file that a setup prerequisite installation launches is an .msi package and the prerequisite is marked to show progress, the user interface shows a status bar, along with installation progress messages from Windows Installer, while the prerequisite is being installed. This is applicable only if the main installation is a Basic MSI or InstallScript MSI installation. For more details, see Specifying Whether to Show the Progress of an InstallShield Prerequisite Installation at Run Time.

If a setup prerequisite is configured to be optionally installed by the end user, the setup launcher displays a message box that enables end users to choose whether to install the setup prerequisite. For more information, see Allowing End Users to Choose Whether to Install an InstallShield Prerequisite.

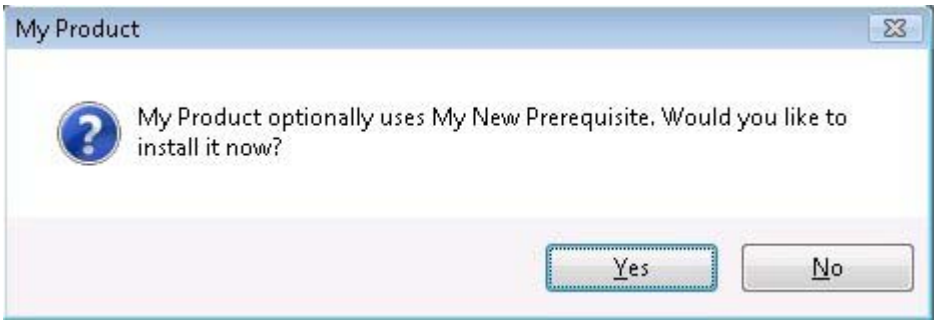

Figure 4-3: Message Box for an Optional Prerequisite

If an installation includes feature prerequisites, the setup launcher does not list them in any prerequisite dialog. However, the user interface does show progress messages if appropriate. In addition, the setup launcher displays the optional prerequisite message box if the feature prerequisite is marked as optional.

Silent Scenarios—Suppressed User Interface in Basic MSI Installations

The installation can install setup prerequisites and feature prerequisites even if the installation is run silently. That is, InstallShield prerequisites are supported in any of the following scenarios:

- **Silent setup launcher and visible .msi package**—The user interface for the setup launcher is suppressed, but the user interface for the .msi package is visible. For example, the end user might use the following command-line statement:

  ```
  Setup.exe /s
  ```

  In this scenario, the language selection dialog and the setup prerequisite dialog are not displayed.

- **Visible setup launcher and silent .msi package**—The user interface for the setup launcher is displayed, but the user interface for the .msi package is suppressed. For example, the end user might use the following command-line statement:

  ```
  Setup.exe /v"/qn"
  ```

  In this scenario, the feature selection dialog and all of the other dialogs of the main installation are not displayed. However, the end user can set Windows Installer properties such as **ADDLOCAL**, **ADDSOURCE**, **ADDDEFAULT**, and **ADVERTISE** from the command line to indicate which features should be installed.

- **Silent setup launcher and silent .msi package**—The user interface for the setup launcher and the .msi package are suppressed. For example, the end user might use the following command-line statement:

  ```
  Setup.exe /s /v"/qn"
  ```

  In this scenario, all of the setup launcher and .msi package dialogs are suppressed.

If the UI sequence of the main installation's .msi package is skipped, the setup launcher evaluates Windows Installer properties such as **ADDLOCAL**, **ADDSOURCE**, **ADDDEFAULT**, and **ADVERTISE** to determine if any feature prerequisites should be installed, and it installs feature prerequisites accordingly.

Silent Scenarios—Suppressed User Interface in InstallScript and InstallScript MSI Installations

An InstallScript or InstallScript MSI installation can install setup prerequisites even if the installation is run silently. That is, InstallShield prerequisites are supported if the end user launches the installation by entering the following command-line statement:

```
Setup.exe /s
```

Note that a response file (Setup.iss) is required. To learn more, see Creating the Response File.

The language selection dialog and the setup prerequisite dialog are not displayed.

UAC Prompts

Depending on how it is configured, an installation that includes InstallShield prerequisites may prompt for elevated privileges on Windows Vista and later systems at several different points during the installation:

1. When the end user launches the `Setup.exe` file
2. When the `Setup.exe` file launches a setup prerequisite that requires elevated privileges
3. When the `Setup.exe` file launches a feature prerequisite that requires elevated privileges
4. When the Windows Installer begins the Execute sequence of the .msi package

For more information, see Minimizing the Number of User Account Control Prompts During Installation.

Changing the Behavior of InstallShield Prerequisites

The InstallShield Prerequisite Editor enables you to modify an InstallShield prerequisite if you want to change its installation's behavior. For example, you can specify whether end users may skip the prerequisite installation, whether the prerequisite requires administrative privileges, and how the prerequisite installation should proceed if it appears that the target machine does or does not need to be restarted. To learn more, see Specifying Installation Behavior for an InstallShield Prerequisite.

You can configure an InstallShield prerequisite so that it is installed either before or after any installation of the Windows Installer engine and the .NET Framework. For more information, see Specifying Parameters for Installing an InstallShield Prerequisite.

Uninstalling an Application Whose Installation Included InstallShield Prerequisites

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Your installation may consist of your application plus one or more InstallShield prerequisites. If end users uninstall your application through Add or Remove Programs in the Control Panel, the InstallShield prerequisites are still installed on their machines. If an InstallShield prerequisite installation added an entry to Add or Remove Programs, an end user would be able to remove that InstallShield prerequisite through Add or Remove Programs.

Working with Merge Modules that Are Included in Installation Projects

This section of the documentation offers guidance for working with merge modules from within installation projects.

For information on creating or modifying your own merge modules, see Designing Merge Modules.

Specifying the Directories that Contain Merge Modules

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

InstallShield lets you specify the locations on your local machine, or on a network, where you are storing merge modules (.msm files). This flexibility enables you to store merge modules in source code control and to share a common set of merge modules with other team members.

InstallShield offers several ways for specifying the search paths for merge modules:

- If you are editing or building from within InstallShield, use the Merge Modules tab on the Options dialog box—which is displayed when you click Options on the Tools menu—to specify a comma-delimited list of machine-wide folders and current-user folders.

  InstallShield saves the paths that you specify on the Merge Modules tab in the registry on your machine. The paths that you specify for the current user are stored in the following location:

  HKEY_CURRENT_USER\Software\InstallShield*Version*\Professional\Project Settings\MMSearchPath

  The paths that you specify for all users are stored in the following location:

  HKEY_LOCAL_MACHINE\Software\InstallShield*Version*\Professional\MMSearchPath

  The Options dialog box is not available if you are using the Standalone Build to build a release; however, if you want, you can manually add the paths to the registry on a machine that has the Standalone Build.

- If you are building from the command line with ISCmdBld.exe, use the `-o` parameter to specify a comma-delimited list of folders.

  If you use an .ini file to specify ISCmdBld.exe parameters, you can use the MergeModulePath parameter in the [Mode] section of your .ini file to specify a comma-delimited list of folders.

- If you are building through MSBuild or Team Foundation Server (TFS), use the MergeModulePath parameter on the InstallShield task. This parameter is exposed as the ItemGroup InstallShieldMergeModulePath when the default targets file is used. To specify multiple paths, use an ordered array of paths.

Instead of using hard-coded paths, you can use path variables in paths, as in the following example:

```
<ISProductFolder>\MergeModules,<ISProjectFolder>\MyCustomMergeModules
```

The Redistributables view and the Objects view list the names of the merge modules that correspond with the merge modules that are present in the various search paths that are specified on the Merge Modules tab of the Options dialog box. If the same merge module is in multiple search paths, InstallShield shows only the first instance that it encounters. InstallShield first searches each path that is listed in the per-user setting on the Merge Modules tab. Then, InstallShield checks each path that is listed in the machine-wide setting.

At build time, if your project includes one or more merge modules, InstallShield (or the Standalone Build) searches the specified locations and includes the appropriate merge modules in your release as needed. If the same merge module is in multiple search paths, InstallShield includes in the build only the first instance that it encounters. It uses the following order to search for merge modules:

1. InstallShield checks each path that is listed in the per-user setting on the Merge Modules tab. The paths are saved in the following location in the registry.

   HKEY_CURRENT_USER\Software\InstallShield*Version*\Professional\Project Settings\MMSearchPath

   Note that the Merge Module tab is not applicable to the Standalone Build, but the registry path is applicable.

2. InstallShield checks each path that is listed in the machine-wide setting on the Merge Modules tab. The paths are saved in the following location in the registry.

   HKEY_LOCAL_MACHINE\Software\InstallShield*Version*\Professional\MMSearchPath

   Note that the Merge Module tab is not applicable to the Standalone Build, but the registry path is applicable.

3. InstallShield (or the Standalone Build) checks the paths that are specified through the -o command-line parameter, the MergeModulePath .ini file parameter, or the MergeModulePath parameter on the InstallShield task.

4. If no paths are specified in any of the aforementioned locations, InstallShield checks the following default directories, in order:

   a. *InstallShield (or Standalone Build) Program Files Folder*\System

   b. *InstallShield (or Standalone Build) Program Files Folder*\Modules\i386

   c. *InstallShield (or Standalone Build) Program Files Folder*\Objects

   d. *InstallShield (or Standalone Build) Program Files Folder*\Modules\i386\Japanese

   e. *InstallShield (or Standalone Build) Program Files Folder*\Modules\i386\German

   f. *Program Files Folder*\Common Files\Merge Modules

Tip • *If you are using the Standalone Build to build a release that includes merge modules but you do not specify one or more search paths through any of the user-defined methods (that is, in the registry, through the command*

line or the .ini file, or through the InstallShield task), the Standalone Build searches the aforementioned default directories for the merge modules. However, if you specify one or more search paths and do not explicitly include the default directories, the Standalone Build does not search the default directories.

Overriding a Merge Module's Destination

Although you should not alter a third-party merge module, you can override the destination for an InstallShield-created merge module and some third-party merge modules.

Note • *This procedure redirects only the **TARGETDIR** directory in the merge module, or directories that derive directly from **TARGETDIR**. If the merge module is configured to send files to a predefined folder (for example, SystemFolder), you cannot override the module's destination.*

Task: ***To override a merge module's destination:***

1. In the View List under **Application Data**, click **Redistributables**.
2. Select the check box next to the merge module to add it to your installation.
3. Right-click the module and click **Properties**. The Merge Module Properties dialog box opens.
4. In the **Destination** box, type a destination or select one from the list of predefined destinations.
5. Click **OK**.
6. In the **Conditional Installation** pane, select the feature or features that should contain the merge module.

Troubleshooting Merge Module Issues

Deleting an Associated Merge Module

If you delete a merge module that is currently associated with your installation, the message [Merge Module Not Found] is displayed, thereby making you aware that the module cannot be included in your installation.

Changing the Language Property of a Merge Module

If you change the language property of a user-defined merge module or another company's merge module after it has been added to the redistributables gallery, a build error occurs if you try to associate the changed merge module with your project. This error occurs because InstallShield uses the language identifier—along with the module identifier— to identify the module file.

If the language identifier of a merge module file is changed after the file is added to the redistributables gallery, InstallShield cannot find the file.

To locate the correct merge module file, you can browse to it from within the Redistributables view. To learn how, see Browsing for Merge Modules.

Publishing a Merge Module to a Repository from Within an Installation Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

If you have an existing merge module that you would like to reuse in Windows Installer–based installation projects or share with other users, you can publish it to a repository.

Task: ***To publish a merge module to a repository when you are working on a Windows Installer–based installation project:***

1. In the View List under **Application Data**, click **Redistributables**.
2. Right-click the merge module and then click **Publish Wizard**. The **Publish Wizard** opens.
3. Complete the panels in the Publish Wizard.

Merge modules are built into an installation at build time. If you make a change to a repository merge module and then republish it to the repository, any project that has the old version of the repository merge module will be updated the next time that a release of the project's installation is rebuilt.

Adding Windows Installer Redistributables to Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Although the Windows Installer is built into most versions of Windows, a Windows Installer–based installation may depend on certain functionality that is available in only the latest versions of Windows Installer. In addition, some InstallScript installations may require a particular version of Windows Installer.

InstallShield enables you to include a redistributable for Windows Installer in your project. The method for adding a Windows Installer redistributable to your project depends on the project type that you are using, as well as the version of Windows Installer that your installation requires.

For a list of the minimum operating system requirements for each version of Windows Installer, see Target System Requirements. For a list of which versions of Windows Installer were released with which versions of Windows, see Released Versions of Windows Installer in the Windows Installer Help Library.

Note that Windows Installer 5 and Windows Installer 4 are not available as redistributables.

Basic MSI and InstallScript MSI Projects

InstallShield gives you the option of including with your installation a Windows Installer redistributable in a self-extracting executable file called `Setup.exe`.

Windows Installer Distribution

By default, InstallShield creates a `Setup.exe` setup launcher along with your installation package. The setup launcher is required if you want your installation to install the Windows Installer engine.

If you want to include the Windows Installer redistributable in a Basic MSI or InstallScript MSI project, do one of the following:

- **For Windows Installer 4.5**—Add one or more Microsoft Windows Installer prerequisites to your project. InstallShield includes several versions that target different versions of Windows. For more information, see Including Microsoft Windows Installer Prerequisites.
- **For Windows Installer 3.1, 3.0, or 2.0**—The Setup.exe tab for a release in the Releases view is where you specify information such as whether you want to use a `Setup.exe` launcher, whether you want to include one of these versions of the Windows Installer redistributable, and which version of Windows Installer you want to include. To learn more, see Setup.exe Tab for a Release.

  As an alternative, you can add one or more Microsoft Windows Installer prerequisites to your project. For more information, see Including Microsoft Windows Installer Prerequisites.

  

  Tip • *You can also specify setup launcher requirements in the Setup Launcher panel of the Release Wizard.*

Overview of the Installation Process

At run time, `Setup.exe` determines if Windows Installer is already installed on the target system. If the Windows Installer is found on the target system and it meets the minimum version requirement, it launches your installation package. If Windows Installer is not installed, or a more recent version needs to be installed, `Setup.exe` installs Windows Installer and then launches your installation package. Note that the system may need to be restarted for Windows Installer to be updated.

InstallScript Projects

In some cases, you may want to add a Windows Installer redistributable to an InstallScript project. For example, you may be using an InstallScript project to chain together multiple Windows Installer–based installations that require a particular minimum version of Windows Installer. In addition, if you add a merge module to an InstallScript project, that merge module must be added as a subitem of the Merge Module Holder object in the Objects view. This Merge Module Holder object requires the Windows Installer engine, so if target systems may not have the Windows Installer present, you need to add the Windows Installer redistributable to your InstallScript project.

If you want to include the Windows Installer redistributable in an InstallScript project, add one or more Microsoft Windows Installer prerequisites to your project. InstallShield includes several versions that target different versions of Windows. For more information, see Including Microsoft Windows Installer Prerequisites.

Including Microsoft Windows Installer Prerequisites

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

InstallShield includes InstallShield prerequisites for several versions of Windows Installer. You can use the Redistributables view (in Basic MSI and InstallScript MSI projects) or the Prerequisites view (in InstallScript projects) to add these InstallShield prerequisites to your project.

Checking for the Presence of Windows Installer 4.5 During Basic MSI or InstallScript MSI Installations

You may want your installation to check the target system to determine if Windows Installer 4.5 is installed; if it is not installed, the installation would display an error message box and prevent the installation from continuing. This may be helpful under the following conditions:

- Your installation depends on Windows Installer 4.5 features.
- It is possible that the .msi file might be used to install your product, rather than the `Setup.exe` setup launcher (which would install Windows Installer 4.5 if appropriate).

  For example, if you deploy your installation as an uncompressed release, end users would be able to launch the .msi file directly rather than the `Setup.exe` file. In addition, if systems administrators want to customize your installation for deploying your product throughout an enterprise environment, they might create an administrative installation version and deploy that.

To determine whether Windows Installer 4.5 is installed and display an error message if it is not, create an error custom action (a type 19 custom action). The following procedure explains how.

Task: ***To determine whether Windows Installer 4.5 is installed and display an error message if it is not:***

1. In the **Custom Actions and Sequences** view, right-click the **Custom Actions** explorer and click **New Error**.
2. Select the new custom action.
3. In the **Error Message** setting, type the error message text that should be displayed when an end user launches your installation without Windows Installer 4.5 being already installed.
4. In the **Install UI Sequence** and **Install Exec Sequence** settings, select an option that would schedule the error message somewhere before the LaunchConditions action. For example, a common sequence for this error action is **<First Action>**.
5. In the **Install UI Condition** and **Install Exec Condition** settings, type the following condition:

   ```
   VersionMsi < "4.05"
   ```

Locked File/Reboot Issues

When the InstallShield prerequisite installs the Windows Installer 4.5 engine, the existing engine files are often locked. If your installation needs to use the updated engine before the target system is rebooted, be aware of the following behavior.

On Windows XP and Windows Server 2003 systems, the Windows Installer 4.5 engine files are updated immediately and the requirement for a reboot is noted and delayed until the end of the main installation (or any reboot that precedes it). The main installation uses the updated Windows Installer 4.5 engine, and it requests a reboot at the end of the installation.

On Windows Vista and Windows Server 2008 systems, the Windows Installer 4.5 engine files are not updated until after a reboot, so a reboot is requested immediately. If the end user allows the machine to be rebooted, the installation continues after the reboot. If the end user does not allow the machine to be rebooted, the installation ends. While the reboot is pending, the Windows Installer 4.5 engine appears as not installed, and subsequent attempts to run the prerequisite would result in a failure and would not allow installation to continue. Rebooting the machine completes the installation of Windows Installer 4.5 and allows the installation to continue as planned.

Adding .NET Framework Redistributables to Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

If your product requires that the .NET Framework be installed on the target system, you can add the .NET Framework redistributable to your project. If the target system does not have the .NET Framework, it is installed during your installation.

You can also include redistributables for .NET Framework language packs in your project. The language packs contain translated text, such as error messages, for languages other than English.

The method for adding the .NET Framework and .NET Framework language packs to your project depends on the project type that you are using, as well as the version of .NET Framework that your product requires.

Note • *Some .NET Framework versions include earlier .NET Framework versions:*

- *.NET Framework 3.5 includes .NET Framework 3.0 SP1 and .NET Framework 2.0 SP1.*
- *.NET 3.0 Framework SP1 includes .NET Framework 2.0 SP1.*
- *.NET 3.0 Framework RTM includes .NET Framework 2.0 RTM .*

Basic MSI and InstallScript MSI Projects

If you want to include .NET support in a Basic MSI or InstallScript MSI project, do one of the following:

- **For .NET Framework 4.5 Full, 4.5 Web, 4.0 Full, 4.0 Client, 3.5 SP1, 3.5, 3.0 SP1, 3.0, 2.0 SP2, 2.0 SP1, or 2.0 (only x64, IA64) redistributables**—Add the appropriate Microsoft .NET Framework prerequisite.

  For more information, see Including the Microsoft .NET Framework and Microsoft .NET Framework Language Pack Prerequisites.

- **For 32-bit .NET Framework 2.0, 1.1, or 1.0 redistributables**—Configure the .NET settings for the release through the .NET/J# tab in the Releases view. As an alternative, you can select the appropriate options through the Release Wizard.

  If you would prefer to distribute InstallShield prerequisites of these redistributables, you can use the InstallShield Prerequisite Editor to create them. For more information, see Defining InstallShield Prerequisites.

To test whether the .NET Framework is already installed on the target system, you can use the built-in **MsiNetAssemblySupport** property. It is set to the version of a particular .NET DLL (`fusion.dll`) if the .NET Framework is installed, and it is not set if the .NET Framework is not installed.

InstallScript Projects

InstallScript projects support two methods for adding the .NET Framework redistributables to your project:

- Use the Prerequisites view to add one or more .NET Framework prerequisites to your project.
- Use the Objects view to add the Microsoft .NET Framework object to your installation. This object also enables you to add one or more language packs to an InstallScript project. To learn more, see Microsoft .NET Framework Object Wizard.

To determine whether a particular version of the .NET Framework or a language pack is installed, use the Is function and pass the DOTNETFRAMEWORKINSTALLED predefined constant.

Obtaining InstallShield Prerequisites and Objects

Note that some of the InstallShield prerequisites and objects are not installed with InstallShield. You may need to download them. For more information, see Obtaining Updates for InstallShield.

Including the Microsoft .NET Framework and Microsoft .NET Framework Language Pack Prerequisites

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

InstallShield includes InstallShield prerequisites for some versions of the .NET Framework and the .NET Framework language packs. You can include these InstallShield prerequisites in Basic MSI, InstallScript, and InstallScript MSI projects if you want to redistribute these versions of the .NET Framework and the language packs.

Following is a list of the .NET Framework redistributables that are available as InstallShield prerequisites. The associated language pack prerequisites are included if available.

- Microsoft .NET Framework 4.5. (One InstallShield prerequisite is for the full package, and one is for the Web package. The Web package is smaller in size, but it requires an Internet connection on the target system at run time.)
- Microsoft .NET Framework 4 Full, which installs the .NET Framework runtime and associated files that are required to run and develop applications that target the .NET Framework 4. (One InstallShield prerequisite is for the full package, and one is for the Web Download package. The Web Download package is smaller in size, but it requires an Internet connection on the target system at run time.)
- Microsoft .NET Framework 4 Client, which installs the .NET Framework runtime and associated files that are required to run most client applications. (One InstallShield prerequisite is for the full package, and one is for the Web Download package. The Web Download package is smaller in size, but it requires an Internet connection on the target system at run time.)
- Microsoft .NET Framework 3.5 SP1 (One InstallShield prerequisite is for the full package, and one is for the Web Download package. The Web Download package is smaller in size, but it requires an Internet connection on the target system at run time.)
- Microsoft .NET Framework 3.5 (One InstallShield prerequisite is for the full package, and one is for the Web Download package. The Web Download package is smaller in size, but it requires an Internet connection on the target system at run time.)
- Microsoft .NET Framework 3.0 SP1 (This is a Web Download package, which requires an Internet connection on the target system at run time.)
- Microsoft .NET Framework 3.0
- Microsoft .NET Framework 3.0 (x64)
- Microsoft .NET Framework 2.0 SP2
- Microsoft .NET Framework 2.0 SP2 (x64)
- Microsoft .NET Framework 2.0 SP2 (IA64)
- Microsoft .NET Framework 2.0 SP1 (x86)
- Microsoft .NET Framework 2.0 SP1 (x64)
- Microsoft .NET Framework 2.0 SP1 (IA64)
- Microsoft .NET Framework 2.0 (x64)
- Microsoft .NET Framework 2.0 (IA64)

Tip • *For information on other versions of the .NET Framework redistributables, see Adding .NET Framework Redistributables to Projects.*

These InstallShield prerequisite installations are run in silent mode. Therefore, the language in which the .NET Framework installation runs is not an issue.

Since there currently is no way to install Windows Installer 3.x on 64-bit Itanium systems running Windows XP, and since .NET Framework 2.0 and later require Windows Installer 3.x or later, the 64-bit .NET Framework 2.0 prerequisites cannot be installed on 64-bit Itanium systems running Windows XP.

The InstallShield prerequisite installations determine if the corresponding version of the .NET Framework is already installed on the target machine by checking the Install or InstallSuccess value data for a particular HKEY_LOCAL_MACHINE key. For more details, you can open any InstallShield prerequisite in the InstallShield Prerequisite Editor and note the conditions that are set.

Including the MySQL Connector ODBC Prerequisite

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

You can include in your installation an InstallShield prerequisite that installs MySQL Connector/ODBC 3.51. It enables end users to connect to a MySQL database server that uses ODBC. Before you can add this InstallShield prerequisite to your projects, you must download the MySQL Connector/ODBC driver and configure the InstallShield prerequisite on your system.

Task: ***To add the MySQL Connector ODBC 3.51 prerequisite to your system so that you can add it to your projects:***

1. Open Windows Explorer and browse for the InstallShield prerequisite template folder. The default location is:

   `C:\Program Files\InstallShield\2013\SetupPrerequisites\Templates`

2. Copy the `MySQL Connector ODBC 3.51.prq` file that is in the Templates folder, and paste it in the InstallShield prerequisite folder. The default location is:

   `C:\Program Files\InstallShield\2013\SetupPrerequisites`

3. Visit http://dev.mysql.com/downloads/connector/odbc/3.51.html and download the MSI installer for the MySQL Connector/ODBC 3.51 driver for Windows.

4. Save the file in the following location:

   `InstallShield Program Files Folder``\Objects\MySQL\Redist`

The next time that you launch InstallShield, the MySQL Connector ODBC prerequisite is available in the Redistributables view.

If you want to change the location on your machine where you store the installer for the MySQL Connector/ODBC 3.51 driver, you can do so by opening the `MySQL Connector ODBC 3.51.prq` file in the InstallShield Prerequisite Editor and modifying the settings. To open the InstallShield Prerequisite Editor, click Prerequisite Editor on the Tools menu. For more information, see Specifying Files for an InstallShield Prerequisite.

Including the InstallShield Prerequisite for the Oracle 11g Instant Client

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

If you want to install the Oracle 11g Instant Client before your installation is run, you can include the Oracle 11g Instant Client prerequisite in your project. Before you can add this InstallShield prerequisite to your projects, you must download Oracle Instant Client and create an .msi package on your system. For more information, see Connecting to an Instance of Oracle and Running SQL Scripts.

Note • *If you want your installation to download the Oracle 11g Instant Client whenever it needs to be installed on a target system, check with Oracle to ensure that it is allowed. If it is allowed, you must host the download on your own Web site and add its download path to the InstallShield prerequisite. Flexera Software does not make this installation available for download.*

Including the DirectX 9.0 Object

DirectX provides supporting API libraries for multimedia applications and hardware, including the latest graphics cards. If your product requires DirectX to be installed on the target system, you can add the DirectX object—either the Windows Installer–based object for Basic MSI and InstallScript MSI projects, or the InstallScript object for InstallScript projects—to your project. If the target system does not have DirectX, it is installed during your installation.

After installation, the DirectX runtime cannot be uninstalled. DirectX is a system component; end users cannot uninstall it without reinstalling the operating system.

Tip • *The DirectX object is not installed with InstallShield; you need to download it. To include the DirectX object in Basic MSI or InstallScript MSI projects, obtain the MSI object download. To include the DirectX object in InstallScript projects, obtain the InstallScript object download. To learn more, see Obtaining Updates for InstallShield.*

Redistributable Files

The DirectX objects install all DirectX 9.0c core and optional components, including 32-bit- and 64-bit-specific components.

Including the DirectX Object in Basic MSI and InstallScript MSI Projects

When you add the DirectX object to a Basic MSI or InstallScript MSI project, InstallShield launches the DirectX Object Wizard.

You can use the DirectX object in compressed or uncompressed installations; the DirectX Object Wizard lets you specify whether the DirectX files should be in a folder in the Disk1 folder, or they should be streamed into the .msi file:

- If you specify that the files should be in a folder in the Disk1 folder, InstallShield creates a DirectX folder for your installation at build time and places it in the Disk1 folder of your release. InstallShield lists the DirectX folder in the Disk1 area of the Support Files view (in Basic MSI projects) or the Support Files/Billboards view (in InstallScript MSI projects).
- If you specify that the files should not be in the Disk1 folder, InstallShield embeds the files in your installation's .msi file. InstallShield lists these files in the Language Independent area of the Support Files view (in Basic MSI projects) or the Support Files/Billboards view (in InstallScript MSI projects).

***Note** • The custom action that launches the DirectX installation is sequenced in the Execute sequence and run in deferred system context so that it can be run with elevated privileges on Windows Vista and later systems.*

Updating the DirectX Object Files for Basic MSI and InstallScript MSI Projects

If you obtain updates for any of the DirectX files and you want to include them in your DirectX object, place them in the appropriate InstallShield Program Files subfolder with the other DirectX files. The location is:

InstallShield Program Files Folder\Objects\DirectX9c\Redist

You can also remove files from that folder if your product does not require them and you do not need to include them in your installation. For more information about the DirectX redistributable files, including details about any updates that Microsoft may have released since the current version of InstallShield was released, see the latest DirectX SDK or Microsoft's Web site (http://msdn.microsoft.com/directx).

At build time, InstallShield uses whatever redistributable files are in that DirectX folder to build your release.

Identifying Application Dependencies

***Project** • This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

A file often relies on functions in other files to perform a task. However, you may not be aware of all these other files—known as *dependencies*—when you include your application's files in your installation project. InstallShield offers scanning wizards to assist you in identifying and working with these files. You can access these scanners in the Dependency Scanners view.

Table 4-14 • Available Scanning Wizards

Scanner	Description
Static Scanning Wizard	Looks at portable executable files (for example, .exe, .ocx, .com, .tlb, .hlp, and .chm) in your project and checks for dependencies that they may require.
Dynamic Scanning Wizard	Monitors your system while an executable file is running and checks for .dll or .ocx files that may be required by the executable file.

Any files that are added to a Basic MSI or InstallScript MSI project through one of these scanners are added in accordance with Setup Best Practices.

If you use the Static and Dynamic scanning wizards, you can specify files that you want to be included or excluded automatically any time that you perform a static or dynamic scan through InstallShield. For more information, see Filtering Files in Dependency Scanners.

Static Scanning

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The Static Scanning Wizard enables you to scan the files already added to your project for any dependencies that they may require. This wizard scans all portable executable files (.exe, .dll, .ocx, .sys, .com, .drv, .scr, and .cpl files) in your project and checks for dependencies that they may require. The wizard displays a list of the dependencies that it finds, and it lets you specify whether you want to include each one in your project.

The new files added to your project are added to the same feature as the file that depends upon them, thereby ensuring that they are installed when needed.

How the .NET Scan at Build Setting Affects Static Scanning

In Basic MSI, InstallScript MSI, and Merge Module projects, the value that is selected for a component's.NET Scan at Build setting affects how the Static Scanning Wizard scans the files in that component:

Table 4-15 • Determining How the Static Scanning Wizard Scans Files in a Component

Value of a Component's .NET Scan at Build Setting	Description
None	The Static Scanning Wizard does not scan the .NET portion of the component for dependencies or properties. For example, if your component contains `Notepad.exe` and a .NET assembly file, the Static Scanning Wizard scans `Notepad.exe` for dependencies and does not scan the .NET assembly file for dependencies *or* properties.
Properties Only	The Static Scanning Wizard scans the entire component—all files in the component, including .NET assemblies—for properties, but it does not identify dependencies for the .NET portion of the component. For example, if your component contains `Notepad.exe` and a .NET assembly file, the Static Scanning Wizard scans both files for properties, but it does not identify dependencies for the .NET assembly file.
Dependencies and Properties	The Static Scanning Wizard scans the entire component—all files in the component, including .NET assemblies—for dependencies and properties. Any dependencies that are found during the scan are presented in the File Selection panel. If any properties are found for .NET files, InstallShield adds the properties to the .NET Assembly subnode under the Assembly node in the Advanced Settings area of a component.

Dynamic Scanning

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The Dynamic Scanning Wizard is an easy-to-use tool that monitors your system while an executable file runs. The wizard displays a list of .dll and .ocx files that may be required by the executable file, and it lets you specify whether you want to include each one in your project.

The executable file you want to scan can already be included to your project, or it can be added by the wizard.

To learn more about this wizard, see Dynamic Scanning Wizard.

Scanning for 64-Bit Dependencies

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

If you use InstallShield on a 64-bit version of Windows Vista or later or a 64-bit version of Windows Server 2008 or later, the Static Scanning Wizard and the Dynamic Scanning Wizard can scan for 64-bit dependencies of the 64-bit files in your project. These wizards can also scan for 32-bit dependencies of the 32-bit files in your project.

Note that if you use InstallShield on a 32-bit version of Windows, these wizards can scan for only 32-bit dependencies of the 32-bit files in your project. If your project includes 64-bit files, you can manually add any dependencies to the project as needed.

Reviewing Dependency Scanner Results

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The Static Scanning Wizard and the Dynamic Scanning Wizard scan your project to help you identify other files that your product may require. Each of these wizards displays a list of possible files and merge modules that you may need to add to your project. Review the scan results carefully, and determine whether it is appropriate to add each specified file and merge module to your project.

Both of the scanners works differently to identify dependencies. In some cases, one of the scanners may identify a dependency that the other does not identify. Therefore, you may want to try using both the static and dynamic scanning wizards for a more complete list of potential dependencies. In some scenarios, a dependency scanner may identify as a dependency a file or merge module that is not required by your product. If that occurs, you can exclude that file or merge module, since the wizards let you include or exclude each identified dependency as needed. In addition, InstallShield enables you to specify on a machine-wide basis any files that you want to be included or excluded automatically any time that you perform a static or dynamic scan through InstallShield. For more information, see Filtering Files in Dependency Scanners.

To obtain the best results when you are trying to identify dependencies, it is recommended that you thoroughly test your product and its installation on a clean machine. If your product does not behave as expected, determine whether any dependencies are missing from the machine, and if so, whether they should be included in the installation.

Filtering Files in Dependency Scanners

When you run the Static and Dynamic scanning wizards, you may find that they list as dependencies certain files that you do not want added to your installation. To avoid having these files added every time you run the scanner, you can edit `Filters.xml`. This file enables you to specify any files that you want the scanners to ignore or include.

`Filters.xml` is in the following location:

`InstallShield Program Files Folder``\Support`

The file must remain in this location after you edit it; otherwise, the scanners will not work properly.

Tip • *You can also use the `Filters.xml` file to control which registry items should be excluded during COM extraction. For more information, see Filtering Registry Changes for COM Extraction.*

The `Filters.xml` file also lets you control which IIS settings should be excluded when you are importing an IIS Web site. For more information, see Filtering IIS Data When Importing a Web Site and Its Settings into an InstallShield Project.

Excluding Files

The <Exclude> element in the `Filters.xml` file is where you add subelements for each of the files that you want the scanners to exclude. Any files that are listed here will not be added to your installation project by the scanners.

By default, the <Exclude> element has subelements for common system files that are present on all Windows–based machines.

Including Files

The <Include> element in the `Filters.xml` file gives you the ability to override individual files that are subelements of the <Exclude> element. Any files that are listed in subelements of the <Include> element will be added to your installation project by the scanners, even if the files are also listed in subelements of the <Exclude> element.

Note • *The following vital operating system files are never recognized by the scanner, even if you add them as subelements of the <Include> element:*

- *`kernel32.dll`*
- *`ntdll.dll`*
- *`user32.dll`*
- *`gdi32.dll`*
- *`advapi32.dll`*
- *`shell32.dll`*
- *`ole32.dll`*

Specifying Files in the <Exclude> and <Include> Elements

If you want to list a file under the <Exclude> or <Include> elements, you must add the file as a subelement. Following is a sample of a properly formatted subelement:

```
<File name="myfile.dll" path="[SystemFolder]" We="needthis"/>
```

Table 4-16 • Recognized Attributes for the <File> Subelement

Attribute	Description
name	This attribute must be lowercase. The value of this attribute (for example, **myfile.dll** in the above example) indicates the name of the file that you want to include or exclude.
path	This attribute is optional. The value of this attribute (for example, **[SystemFolder]** in the above example) indicates the path of the file.

Any other attributes are optional and are not recognized by the scanners. You may want to add additional attributes—such as the **We** attribute in the example above and the corresponding **"needthis"** value—to identify why an item is being excluded or included.

Important • *Ensure that your XML code is well formed; if its not well formed, all of the filters fail. In most cases, you can identify improperly formed XML code by opening the `Filters.xml` file in Internet Explorer. You should be able to expand and contract the <Filters>, <Include>, and <Exclude> elements; if you cannot, check the code for errors.*

If you add subelements to the <Exclude> or <Include> elements, be sure that you do not place them within the commented-out section, since InstallShield ignores that area of the `Filters.xml` file.

The following sample XML code shows the format of the `Filters.xml` file:

```
<Filters>
 <Include>
  <!--Instructions on how to add files to this element.
  -->
  <File name="mfc42.dll" We="needthis"/>
 </Include>
 <Exclude>
  <!--Instructions on how to add files to this element.
  -->
  <Registry key="HKEY_CLASSES_ROOT\Interface\{00020404-0000-0000-C000-000000000046}"/>
  <File name="12520437.cpx" path="[SystemFolder]" W2kSp4="WPF" WxpSp2="WPF" W2k3Sp1="WPF"
WinMe="WPF"/>
  <File name="12520850.cpx" path="[SystemFolder]" W2kSp4="WPF" WxpSp2="WPF" W2k3Sp1="WPF"
WinMe="WPF"/>
 </Exclude>
</Filters>
```

Registering COM Servers

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Most applications require certain COM servers in order to operate properly. In order for the operating system to recognize these COM servers, you need to register them.

With traditional COM, COM data is written directly to the registry. Registry-free COM, or Reg-Free COM, offers a simple alternative to the traditional method. With Reg-Free COM, COM data is written to an application manifest file.

Traditional COM Registration

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

InstallShield supports multiple methods for registering a COM server on a target machine. The following methods are the ones used traditionally:

- The COM information can be extracted from the file at build time (or design time) and written to the COM-related tables of your .msi database.
- The COM server's self-registration function can be called at installation time.

The first method listed—extracting the COM information and writing it to the .msi database—is preferred over the self-registration method. The first method writes the COM class information to the **Class**, **ProgID**, and **Registry** tables of the .msi database.

Determining Whether a COM Server Supports Self-Registration

Not all COM servers support self-registration. Although it is likely that you will know which files in your installation are self-registering, there may be times when you do not know. Because you must handle self-registering files differently than non-self-registering files, you need to be able to determine if a file is self-registering.

In most cases, you can determine whether a file is self-registering if you add it to an InstallShield project. InstallShield tests COM server files when they are added to a project to determine if they are self-registering files. If InstallShield determines that a COM server added to your project is self-registering:

- For Windows Installer–based projects: InstallShield sets the COM Extract at Build property of the file's component to Yes (if you have specified on the Preferences tab of the Options dialog box that COM extraction should occur at build time).
- For InstallScript-based projects: InstallShield marks the file as self-registering.

Extracting COM Information from a COM Server

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Note that for MSI Database and MSM Database projects, COM information cannot be extracted at build time; it is extracted at design time.

The recommended method for registering COM servers is to use Windows Installer tables in the .msi database to make the necessary registry entries for your COM server. With this method, Windows Installer is capable of registering files when they are advertised, and it can safely roll back the registration information in case of a failed installation.

Since each component should have only one portable executable file, the assumption is that all of the registration information belongs to a single file, marked as the key file of its component.

InstallShield supports several methods for extracting COM information from a COM server:

- Use the Component Wizard. You can use this wizard to create a new COM server component. With this method, the wizard performs a one-time scan of COM information from the component's key file.
- For a component's COM Extract at Build setting, select Yes. Since InstallShield extracts the COM data every time that you build a release, this method is helpful if your COM server's interfaces change frequently. The COM server must be the key file of its component for this method.
- Extract the information by right-clicking the file in the Files and Folders view and then clicking Extract COM Data for Key File. Use this method if you have already added the COM server file to a component.

As an alternative to having InstallShield extract the COM data, you can manually add COM information to a component in the component's Advanced Settings.

If you do not want InstallShield to extract COM information every time that you build a release, select No for the COM Extract at Build setting of the component. Use this method if you want InstallShield to register the file according to the information that is statically contained in the component's COM Registration advanced setting. This advanced setting stores information about the file's COM classes, ProgIDs, and so on, that were either extracted in the Component Wizard or entered manually in the Advanced Setting area.

When InstallShield extracts COM information from a COM server, the COM class information is written to the **Class**, **ProgId**, and **Registry** tables of the .msi database.

If you are using InstallShield on a 64-bit operating system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit. To learn more about 64-bit support, see Targeting 64-Bit Operating Systems.

InstallShield employs a special technique to find all COM information on a COM server without actually registering it. Therefore, COM extraction does not affect the system registry. However, some COM servers' registration processes depend on existing registry entry values. Although InstallShield has developed an algorithm to avoid this scenario, it may not be foolproof in some extreme cases.

Caution *• Some applications, like WinRunner, insert hook .dll files into the COM extraction engine. This causes COM extraction to fail and displays the following message: "ISRegSpy detects following module %1 hooked into this process, which causes ISRegSpy to malfunction. You need to shut the application down and restart COM extraction." If you encounter this message, shut down the application and restart COM extraction, as the dialog box instructs.*

Do not select the self-registering property for .exe files that are not self-registering. To self-register an .exe file, you need to launch the .exe file with the /regserver command. However, if the .exe file does not support the command line switch, the .exe file will be launched during extraction at build time.

Note *• The definitions of the COM-related Windows Installer tables prevent a COM server from being placed in more than one feature. If a COM server needs to be placed in more than one feature, the following are two available options:*

- *Make the second feature that requires the COM server a child of the first, and place the file in the parent feature.*
- *Use self-registration on the COM server instead of using the COM-related Windows Installer database tables.*

Filtering Registry Changes for COM Extraction

Project *• This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

To prevent InstallShield from extracting undesired COM data from a COM server (either at build or design time), you can edit the `Filters.xml` file and specify the registry keys to be excluded. `Filters.xml` is in the following location:

`InstallShield Program Files Folder``\Support`

The file must remain in this location after you edit it; otherwise, COM extraction will not work properly.

Tip *• You can also use the `Filters.xml` file to control which files should be included or excluded during dependency scanning. For more information, see Filtering Files in Dependency Scanners.*

The `Filters.xml` file also lets you control which IIS settings should be excluded when you are importing an IIS Web site. For more information, see Filtering IIS Data When Importing a Web Site and Its Settings into an InstallShield Project.

Excluding Registry Keys from COM Extraction

The <Exclude> element in the `Filters.xml` file is where you add subelements for each of the registry keys that you want the COM extraction process to exclude. Any keys that are listed here will not be uninstalled when your product is uninstalled.

By default, the <Exclude> element has subelements for common system registry keys that are required.

Specifying Registry Keys in the <Exclude> Element

If you want to list a key under the <Exclude> element, you must add the key as a registry subelement.

Following is a sample of a properly formatted registry subelement that blocks changes to an InprocServer32 registry key, all of its values, and all of its subkeys:

```
  <Registry key="HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\{00000231-0000-0010-8000-
00AA006D2EA4}\InprocServer32"/>
```

Following is a sample of a properly formatted registry subelement that blocks changes to only the default value of an InprocServer32 registry key:

```
  <Registry key="HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\{00000231-0000-0010-8000-
00AA006D2EA4}\InprocServer32" value=""/>
```

Following is a sample of a properly formatted registry subelement that blocks changes to only the ThreadingModel value name for an InprocServer32 registry key:

```
  <Registry key="HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\{00000231-0000-0010-8000-
00AA006D2EA4}\InprocServer32" value="ThreadingModel"/>
```

Table 4-17 • Recognized Attributes for the <Registry> Subelement

Attribute	Description
key	This attribute must be lowercase. The value of this attribute (for example, HKEY_LOCAL_MACHINE\SOFTWARE\Classes\CLSID\{00000231-0000-0010-8000-00AA006D2EA4}\InprocServer32 in the above examples) indicates the name of the registry key that you want to filter.
value	This attribute is optional: • To block changes to an entire registry key, do not include the value attribute. • To block changes to the default value of the specified key, set the value of this attribute to a null value. • To block changes to the name of a value of the specified key, set the value of this attribute to the name of that registry value.

Any other attributes for the <Registry> subelement are optional and are not recognized by the COM extraction process. You may want to add additional attributes to identify why an item is being excluded.

Important • *Ensure that your XML code is well formed; if its not well formed, all of the filters fail. In most cases, you can identify improperly formed XML code by opening the `Filters.xml` file in Internet Explorer. You should be able to expand and contract the <Filters>, <Include>, and <Exclude> elements; if you cannot, check the code for errors.*

If you add subelements to the <Exclude> or <Include> elements, be sure that you do not place them within the commented-out section, since InstallShield ignores that area of the `Filters.xml` file.

The following sample XML code shows the format of the `Filters.xml` file:

```
<Filters>
 <Include>
  <!--Instructions on how to add files to this element.
  -->
 </Include>
 <Exclude>
  <!--Instructions on how to add files to this element.
  -->
  <Registry key="HKEY_CLASSES_ROOT\Interface\{00020404-0000-0000-C000-000000000046}"/>
  <File name="12520437.cpx" path="[SystemFolder]" W2kSp4="WPF" WxpSp2="WPF" W2k3Sp1="WPF"
WinMe="WPF"/>
  <File name="12520850.cpx" path="[SystemFolder]" W2kSp4="WPF" WxpSp2="WPF" W2k3Sp1="WPF"
WinMe="WPF"/>
 </Exclude>
</Filters>
```

Self-Registering COM Servers

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

If you have a COM server that is self-registering, you can call the COM server's self-registration functions at installation time to register the COM server on the target machine.

InstallShield supports different methods for indicating that a COM-related file (.ocx, .dll, .exe, .tlb, or .olb) is self-registering:

- You can specify that a particular file is self-registering. For more information, see File Properties Dialog Box.
- You can specify that a dynamic link is self-registering. For more information, see Dynamic File Link Settings Dialog Box.

Tip • *If the self-registering file is part of a 64-bit component, 64-bit self-registration occurs on the target machine. For more information, see Targeting 64-Bit Operating Systems.*

When you mark a COM server .dll or .ocx file as self-registering, the file's own registration function (**DllRegisterServer**) is called during installation to register it with the target system, and its unregistration function (**DllUnregisterServer**) is called during uninstallation to unregister the file.

Registering a file with **DllRegisterServer** has several limitations:

- COM information registered with **DllRegisterServer** cannot be advertised.
- Because **DllRegisterServer** is .dll code, its effects cannot reliably be rolled back during a failed installation.
- **DllRegisterServer** cannot distinguish between per-user and per-machine COM information.
- Self-registration may require COM servers to be registered in a particular order. InstallShield self-registration (ISSelfReg) enables you to overcome this limitation.
- **DllRegisterServer** generally does not register a file with a relative path, as needed by systems that support side-by-side sharing.

In addition, if you use any type of self-registration in a patch, the patch will not be uninstallable.

When you mark one or more files as self-registering, InstallShield adds data to a table of your .msi database, and adds some custom actions related to self-registration to your installation Execute sequence. For details, see Self-Registration Methods and InstallShield Self-Registration (ISSelfReg).

Per-machine self-registration information is stored in the registry key HKLM\SOFTWARE\Classes\CLSID, and per-user self-registration information is stored in HKCU\SOFTWARE\Classes\CLSID; a merged view of the data is available under HKCR\CLSID.

Self-Registration Methods

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

On the Preferences tab of the Options dialog box, you can select whether you want to use the InstallShield self-registration method (ISSelfReg) or the Windows Installer self-registration method (SelfReg).

Note • *If you use any type of self-registration in a patch, the patch will not be uninstallable.*

Windows Installer Self-Registration

Windows Installer self-registration does the following:

- Registers only .dll and .ocx files.
- Registers files in arbitrary order.
- Can register 64-bit files if the self-registering file is part of a 64-bit component.

InstallShield Self-Registration

InstallShield self-registration does the following:

- Can register .exe, .tlb, .dll, and .ocx files.
- Uses batch mode registration to handle any registration dependencies at run time.
- Requires the inclusion of a self-registration engine that is 70 KB in overhead.
- Can register 64-bit files if the self-registering file is part of a 64-bit component.

Note • *With InstallShield self-registration, you can specify the order in which the files are registered at run time. You can set the order in the ISSelfReg table (Order column) in the Direct Editor.*

InstallShield Self-Registration (ISSelfReg)

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

If you have selected ISSelfReg as the self-registration method for COM servers, and if your project contains any files (or dynamic links) marked as self-registered, InstallShield adds information about those files to the **ISSelfReg** table of your .msi database. You can view and edit the **ISSelfReg** table in the Direct Editor. To learn about the fields in this table, see ISSelfReg Table.

In addition, if your project contains any files (or dynamic links) marked as self-registered, InstallShield adds the following custom actions to the Execute sequence of your installation.

Table 4-18 • Custom Actions Added to Projects that Have Self-Registering COM Servers

Action	Description
ISSelfRegisterCosting	Immediate-execution action that reads the **ISSelfReg** table and determines which files need to be registered or unregistered. A file will be registered when its component is scheduled to be installed, and unregistered when its component is scheduled to be uninstalled.
ISUnSelfRegisterFiles	Deferred-execution custom action that unregisters each file whose component is scheduled to be removed.
ISSelfRegisterFiles	Deferred-execution custom action that registers each file whose component is scheduled to be installed.
ISSelfRegisterFinalize	Displays error information for files that failed to self-register.

Registry-Free COM Registration

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

With Reg-Free COM, COM data is written to an application manifest file that is stored in the application folder. The manifest file is an XML file that contains information about an application and the libraries that are associated with it. Note that the Reg-Free COM manifest file, the executable file, and the COM libraries should all be installed to the same folder on the target machine.

Benefits of Reg-Free COM

Reg-Free COM has several advantages over traditional COM. For example, with Reg-Free COM, the component is defined within the scope of the application itself. Even if other applications that use the same COM component or a different version of it require that it be registered, it will not interfere with this application.

Problems may occur with traditional COM registration if multiple versions of shared libraries exist on a target system. For example, an installation may overwrite a new version of a shared library with an older version, or a new version might not be backwardly compatible with older versions. This may cause applications that require features of a specific version to crash. These types of situations are commonly known as *DLL Hell*. With Reg-Free COM, you can avoid these problems because other applications cannot access your application's COM component.

In addition, Reg-Free COM streamlines the upgrade and uninstallation processes. For an upgrade, simply replace the application folder. For an uninstallation, simply remove that folder.

Limitations of Reg-Free COM

Reg-Free COM is not appropriate for some solutions. Several limitations exist:

- Reg-Free COM works on only Windows XP or later.
- A component is not suitable for Reg-Free COM if it is a system component or part of the operating system. In addition, it is not suitable if it is a data access component such as Microsoft Data Access Components (MDAC). These types of components should not be isolated.
- A COM component can be isolated only once per application. Consider grouping COM components in a single class library as a workaround to this limitation.

Creating and Modifying Reg-Free COM Files for Your Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Use the Reg-Free COM Wizard to create and modify Reg-Free COM manifest files to be included in your installation. Before you use the Reg-Free COM Wizard, you should add the COM libraries (.dll and .ocx files) and the executable file that uses them to your InstallShield project.

The wizard extracts COM information from the libraries that you specify and adds them to the application manifest files. It also creates a new component with the manifest file set as the key file. The manifest component has the same destination and condition as the associated executable-file component.

Sample Manifest File for a Reg-Free COM File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The contents of the manifest file include the name of the executable file, the file names of the libraries that are associated with the executable files, and the COM information. For the following sample manifest file, the name of the executable file is **Sample.exe**, and the name of the library is **SampleCircle.dll**.

```
<?xml version="1.0" encoding="utf-8"?>
<assembly xsi:schemaLocation="urn:schemas-microsoft-com:asm.v1 assembly.adaptive.xsd"
manifestVersion="1.0" xmlns:asmv1="urn:schemas-microsoft-com:asm.v1" xmlns:asmv2="urn:schemas-
microsoft-com:asm.v2" xmlns:dsig="http://www.w3.org/2000/09/xmldsig#" xmlns="urn:schemas-microsoft-
com:asm.v1" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <assemblyIdentity type="win32" name="Sample.exe" version="1.0.0.10"/>
    <file asmv2:size="24576" name="SampleCircle.dll">
        <hash xmlns="urn:schemas-microsoft-com:asm.v2"> ... </hash>
        <typelib flags="HASDISKIMAGE" helpdir="" resourceid="0" tlbid="{6A2304BC-F200-49B8-955E-
0ACDE272B6E0}" version="1.0"/>
        <comClass clsid="{C621F4D3-8463-4B0C-9BEC-84D979C41385}" description="SampleCircle.Server"
progid="SampleCircle.Server" threadingModel="Apartment" tlbid="{6A2304BC-F200-49B8-955E-
0ACDE272B6E0}"/>
    </file>
</assembly>
```

On a Windows XP system, the presence of the manifest file enables the application to use methods from the COM library without the libraries having been registered in the target system's registry. Windows XP uses the COM libraries in the current directory before using any other versions of the libraries that may be registered on the target system.

Including DIMs in a Project

Project • *This information applies to Basic MSI projects.*

A developer installation manifest (DIM) is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete portion of a product installation. DIM projects enables release engineers to efficiently reuse functional portions of an installation.

Working with DIMs also enables multiple developers to contribute to the development of the installation simultaneously. Each software developer can work on a separate DIM that the release engineer can reference in one or more installation projects.

This section of the documentation explains how to include a DIM project in a Basic MSI installation project. It also offers guidance on how to work with a Basic MSI project that includes one or more DIMs.

Tip • *To learn how to create a DIM project, see Modularizing Installation Projects to Distribute Development Work and Enable Reuse.*

Determining the Appropriate Method for Incorporating DIMs in Installation Projects

Project • *This information applies to Basic MSI projects.*

A developer installation manifest (DIM) is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete portion of a product installation. Once you have created a DIM, you can add it to a Basic MSI project in one of two ways:

- **By reference**—You can add a reference for a DIM project to your Basic MSI project. With this method, the DIM elements are merged into the Basic MSI project at build time. Each time that you build the Basic MSI installation, InstallShield references the latest version of the DIM project and includes it in the installation that it generates.

  Using DIM references in Basic MSI projects enables multiple software developers to contribute to the development of the installation simultaneously. Each software developer can work on a separate DIM that the release engineer can reference in one or more installation projects.

  If you want to modify any portion of a DIM project, open the DIM project in InstallShield, make the required changes, and then rebuild any Basic MSI projects that reference that DIM.

  This method is the more commonly performed method.

  To learn more, see Referencing a DIM in a Project.

- **By import**—You can import a DIM project into your Basic MSI project. This method is a one-time, irreversible import that merges the DIM data into the Basic MSI project at design time.

  Any further changes that need to be made to the DIM data are made from within the Basic MSI project. Modifying the original DIM project does not modify the corresponding data in the Basic MSI project.

  You may want to import a DIM project to troubleshoot problems with a product or its installation. When you are importing a DIM project, you have the option to back up your Basic MSI project (.ism) before the import; this option enables you to revert back to the base Basic MSI project without the imported DIM project.

  To learn more, see Importing a DIM into a Project.

DIM projects enables developers and release engineers to reuse functional portions of an installation efficiently.

Referencing a DIM in a Project

Project • *This information applies to Basic MSI projects.*

When you add a reference for a DIM project to your Basic MSI project, the DIM elements are merged into the Basic MSI project at build time. Each time that you build the Basic MSI installation, InstallShield references the latest version of the DIM project and includes it in the installation that it generates.

Task: ***To add a reference for a DIM to a specific feature in a Basic MSI project:***

1. In the View List under **Organization**, click **Setup Design**.
2. In the **Setup Design** explorer, right-click the feature that you want to contain the DIM reference, and then click **Add DIM Reference**. The **Open** dialog box opens.
3. Browse to the DIM project file (.dim) that you want to reference, and then select that file.
4. Click the **Open** button.

InstallShield adds to the appropriate feature a component node for each component in the DIM project.

Tip • *You can also use the DIM References view to add a reference for a DIM to your Basic MSI project. In this view, right-click the DIMs explorer and then click Add DIM Reference. When you add a reference through this method, the DIM is not associated with any features in the Basic MSI project. To learn how to set up the association, see Associating a DIM Reference with a Feature. Each referenced DIM must be associated with a feature in the Basic MSI project; otherwise, InstallShield does not include it in the Basic MSI installation that it generates at build time.*

Associating a DIM Reference with a Feature

Project • *This information applies to Basic MSI projects.*

When you are including a DIM reference in a Basic MSI project, the DIM reference must be associated with at least one feature; otherwise, InstallShield does not include it in the Basic MSI installation that it generates at build time.

You can associate a DIM reference with one or more features through the DIM References view or the Setup Design view of the Basic MSI project.

Task: ***To use the DIM References view of a Basic MSI project to associate a DIM reference with a feature:***

1. In the View List under **Organization**, click **DIM References**.
2. In the **DIMs** explorer, select the DIM that you want to configure.

3. Click the **Features** tab.
4. Select the check box of each feature that you want to contain the selected DIM. Clear the check box of each feature that should not contain the selected DIM.

Task: ***To use the Setup Design view of a Basic MSI project to associate a DIM reference with a feature:***

1. In the View List under **Organization**, click **Setup Design**.
2. In the **Setup Design** explorer, right-click the feature that you want to contain the DIM reference, and then click **Associate DIM References**. The **Associate DIM References** dialog box opens; it lists all of the DIM references that are not associated with a feature in the Basic MSI project.
3. Select each DIM that you want to associate with the selected feature, and then click **OK**.

Resolving Build-Time Conflicts Between a Basic MSI Project and a DIM Reference

Project • *This information applies to Basic MSI projects.*

When you build a Basic MSI release that contains a DIM reference, InstallShield merges the DIM data into the Basic MSI release that it generates. If data conflicts exist, InstallShield needs to determine which data takes precedence: the values in the DIM project or those in the Basic MSI project.

InstallShield lets you specify how you want to resolve conflicts between settings in a DIM project with those in a Basic MSI project that contains a reference to that DIM. Following are examples of different types of conflicts that may occur:

- Both projects contain a property that has the same name but different values.
- Both projects contain a string entry that has the same string identifier but different values for a particular language.
- Both projects contain a path variable that contains the same name but different values.
- Both projects contain a component that has the same name but different values for one or more of its settings.

In most cases, conflicts do not occur, since InstallShield automatically includes a DIM project–specific GUID in the names of items such as properties, string entries, path variables, and components when you create these in a DIM project, but not in a Basic MSI project. If you create a property called **MYPROPERTY** in a Basic MSI project, the property is called **MYPROPERTY**. If you create a property called **MYPROPERTY** in a DIM project, InstallShield internally calls the property **MYPROPERTY.DIM_GUID**, where *DIM_GUID* is the identifier that is defined in the DIM GUID setting of the General Information view of the DIM project. Thus, the name of the property in the DIM becomes, for example, **MYPROPERTY.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC**. For this particular example, you can use the Direct Editor to see the internal name of the property in the **Property** table of the DIM project.

Task: ***To indicate how you want InstallShield to resolve conflicts between a Basic MSI project and one of its DIM references:***

1. In the View List under **Organization**, click **DIM References**.
2. In the **DIMs** explorer, select the DIM that you want to configure.
3. Click the **Build Options** tab.
4. For the **Conflict Resolution** setting, select the appropriate value. Available options are:
   - **Use Base Project Value**—If InstallShield encounters a conflict when merging the DIM data into the Basic MSI installation at build time, InstallShield uses the value that is in the Basic MSI project instead of the value that is in the DIM project.
   - **Use DIM Project Value**—If InstallShield encounters a conflict when merging the DIM data into the Basic MSI installation at build time, InstallShield uses the value that is in the DIM project instead of the value that is in the Basic MSI project.

One possible but unlikely scenario for encountering conflicts is if you import a DIM into a Basic MSI project, modify an item in the DIM project, and then try to add a reference to the same DIM in the Basic MSI project. In this scenario, InstallShield overrides the value of the DIM setting or the value of the Basic MSI setting, depending on how you have the Conflict Resolution setting configured, to avoid a conflict.

Viewing Build Instructions for a DIM Reference

Project • *This information applies to Basic MSI projects.*

If you add a DIM reference to a Basic MSI project, it is recommended that you check to see whether the author of the DIM included any build instructions that indicate guidance, tips, or other comments that may help you determine whether additional steps may be required for the specific DIM.

Task: ***To view build instructions for a DIM reference in a Basic MSI project:***

1. Open the Basic MSI project that contains the DIM reference.
2. In the View List under **Organization**, click **DIM References**.
3. In the **DIMs** explorer, select the DIM that you want to configure.
4. Click the **Instructions** tab.

On the Instructions tab, InstallShield displays any comments that the author of the DIM project entered when creating or editing it.

Overriding the Destination for a DIM Reference

Project • *This information applies to Basic MSI projects.*

If you create a DIM project, you have the ability to specify the default location on target systems for the files in the DIM project. The location is typically the value of the property **INSTALLDIR** or a subfolder of that folder. When you add a DIM reference to a Basic MSI project, you can choose to use the destination location that the author of the DIM project configured, or you can override the location and specify a different location.

Task: ***To view the default destination that is specified for a DIM reference's files and override it if appropriate in a Basic MSI project:***

1. Open the Basic MSI project that contains the DIM reference.
2. In the View List under **Organization**, click **DIM References**.
3. In the **DIMs** explorer, select the DIM that you want to configure.
4. Click the **Build Options** tab. The **Destination** setting shows the value that author of the DIM project configured.
5. To override the default value, specify the appropriate value.

   Instead of hard-coding a path, you can enter a directory property as part of the path. To select a directory property, click the ellipsis button (**...**) in this setting. This enables you to select the appropriate directory from a list, or to create a new directory within a predefined directory. Separate further levels of subdirectories with a backslash—for example, **[ProgramFilesFolder]MyApp\Bin**.

Note that it is also possible to override destinations at the feature and component levels. For more information, see Setting the Default Product Destination Folder (INSTALLDIR).

Scheduling Custom Actions and Dialogs from a DIM Reference

Project • *This information applies to Basic MSI projects.*

If you create a DIM project, you have the ability to create custom actions and dialogs. When you add a DIM reference to a Basic MSI project, you can schedule when you want the custom actions in that DIM to be run during the Basic MSI installation. You can also specify when during the Basic MSI installation the dialogs in that DIM should be run.

Task: ***To insert custom actions and dialogs from a DIM reference into a Basic MSI project:***

1. Open the Basic MSI project that contains the DIM reference.
2. In the View List under **Organization**, click **DIM References**.

3. In the **DIMs** explorer, select the DIM that you want to configure.
4. Click the **Sequences** tab.
5. In the **Sequences** explorer, right-click the action or dialog that you want your action to follow and click **Insert**. The **Insert Action** dialog box opens, providing a list of all the actions and dialogs that can be added to the sequence.
6. In the list at the top of the dialog box, select the type of action that you want to insert.
7. In the box that shows a list of actions, select the action that you want to insert.
8. Click **OK**.

Opening a Referenced DIM Project from Within an Installation Project

Project • *This information applies to Basic MSI projects.*

If you are modifying a Basic MSI project that contains one or more DIM references and you want to edit the DIM project or see detailed information about it, you can open that project with the click of a link. Note that you must be able to access the DIM project from the machine on which you are modifying the Basic MSI project.

Task: ***To open a referenced DIM project from within a Basic MSI project:***

1. In the View List under **Organization**, click **DIM References**.
2. In the **DIMs** explorer, select the DIM that you want to open.
3. On the **General** tab, click the **Launch DIM Project** link.

A new instance of InstallShield launches, and the DIM project opens within InstallShield.

Importing a DIM into a Project

Project • *This information applies to Basic MSI projects.*

When you import a DIM project into a Basic MSI project, InstallShield merges the DIM data into the Basic MSI project. The import is a one-time, irreversible action.

You may want to import a DIM project to troubleshoot problems with a product or its installation. When you are importing a DIM project, you have the option to back up your Basic MSI project (.ism) before the import; this option enables you to revert back to the base Basic MSI project without the imported DIM project.

Task: ***To import a DIM into a specific feature in a Basic MSI project:***

1. In the View List under **Organization**, click **Setup Design**.
2. In the **Setup Design** explorer, right-click the feature that you want to contain the DIM, and then click **Import DIM Wizard**. The **Import DIM Wizard** dialog box opens.
3. Complete each panel of the wizard.

Resolving Design-Time Conflicts While Importing a DIM Into a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

When you import a DIM project into an installation project, InstallShield merges the DIM data into the installation project. If data conflicts exist, InstallShield needs to determine which data takes precedence: the values in the DIM project or those in the Basic MSI project.

InstallShield lets you specify how you want to resolve conflicts between settings in the two projects when you are importing. Following are examples of different types of conflicts that may occur:

- Both projects contain a property that has the same name but different values.
- Both projects contain a string entry that has the same string identifier but different values for a particular language.
- Both projects contain a path variable that contains the same name but different values.
- Both projects contain a component that has the same name but different values for one or more of its settings.

If InstallShield encounters a conflict when importing a DIM project, the Resolve Conflict dialog box opens. This dialog box is where you specify how you want to proceed. To learn more, see Resolve Conflict Dialog Box.

In most cases, conflicts do not occur, since InstallShield automatically includes a DIM project–specific GUID in the names of items such as properties, string entries, path variables, and components when you create these in a DIM project, but not in a Basic MSI project. If you create a property called **MYPROPERTY** in a Basic MSI project, the property is called **MYPROPERTY**. If you create a property called **MYPROPERTY** in a DIM project, InstallShield internally calls the property **MYPROPERTY.DIM_GUID**, where *DIM_GUID* is the identifier that is defined in the DIM GUID setting of the General Information view of the DIM project. Thus, the name of the property in the DIM becomes, for example, **MYPROPERTY.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC**. For this particular example, you can use the Direct Editor to see the internal name of the property in the **Property** table of the DIM project.

Identifying DIM Elements in an Installation Project

Project • *This information applies to Basic MSI projects.*

When you create a DIM project in InstallShield, InstallShield assigns the project a GUID. This GUID helps to differentiate separate DIM projects. InstallShield also includes this GUID throughout various areas of the DIM project and any Basic MSI project that contains the DIM to identify the data as originating in the DIM.

For example, if you include a file called **MyFile.exe** in a DIM project that has a GUID of **8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC**, InstallShield writes the following value for this file in the **File** table of the DIM project:

MyFile.exe.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC

If you include that same `MyFile.exe` source file in a different DIM project, InstallShield would append a different GUID to the end of the file's **File** table entry. If you import the DIM project into a Basic MSI project, InstallShield also imports this file-GUID entry into the **File** table of a Basic MSI project. If you add **MyFile.exe** directly to a Basic MSI project, InstallShield does not append a GUID to the end of the file name. If you import the DIM that contains **MyFile.exe** into a Basic MSI project, you will see the

InstallShield uses the DIM GUID for files, components, path variables, and other types of installation data. This helps to make it easy to identify which parts of a Basic MSI project are included directly in the Basic MSI project, and which originate from various DIM projects that are referenced in or imported into the Basic MSI project.

The use of GUIDs also helps prevent conflicts. For example, if you use different values for a specific path variable in multiple DIM projects, import those DIMs into a Basic MSI project that uses another different value for the path variable, you will not encounter any conflicts. InstallShield uses the appropriate values for each path variable instance when building your Basic MSI installation.

Overriding Path Variables in a DIM Project for Use in an Installation Project

Project • *This information applies to Basic MSI projects.*

Depending on how the author of a DIM project defined the project's path variables, it may be necessary for you to override their values when you build a Basic MSI release that includes that DIM. Otherwise, when you build the installation, you may encounter errors because of missing files, or the wrong files may be included in your build.

InstallShield offers several ways for overriding the path variables in a DIM project:

- If you are building a Basic MSI release and you want to override a path variable for a DIM that was imported into the Basic MSI project, you can use the Path Variable Overrides setting on the Build tab in the Releases view.
- If you are building from the command line with ISCmdBld.exe, use the `-l` parameter to specify a path variable name and new value. Use this method if you are building an installation for a Basic MSI project that contains one or more DIMs.
- If you are building through MSBuild or Team Foundation Server (TFS), use the PathVariables parameter on the InstallShield task. This parameter is exposed as the ItemGroup InstallShieldPathVariableOverrides when the default targets file is used.

- You can open the DIM project and update values of path variables as needed. To learn how to open the DIM project from within an open Basic MSI project, see Opening a Referenced DIM Project from Within an Installation Project.

At build time, InstallShield (or the Standalone Build) uses the path variable overrides that you set when obtaining the source files for your project and building the release.

For more information as well as tips on using path variables in DIM projects, see Using Path Variables in a DIM.

Configuring the Target System

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

In addition, certain portions do not apply to certain types of project, as noted.

Every installation changes the target system in some way. The simplest installations might only copy files. More in-depth installations make registry changes, edit .ini files, create shortcuts, configure ODBC resources, use environment variables, modify XML files, modify text files, schedule tasks, and install and control Windows services. For more information on how to configure the target system, refer to this section of the documentation.

Creating Shortcuts and Program Folders

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You can create shortcuts and program folders on the Windows desktop and on the Start menu by using the Shortcuts explorer in the Shortcuts view. Like files, shortcuts are associated with components. In installation projects, they are created on the target system only if the feature to which the component belongs is selected for installation.

Types of Shortcuts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield offers several types of shortcuts:

Table 4-1 • Types of Shortcuts

Shortcut Type	Project Type	Description
New Shortcut	Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	Creates a new shortcut to a file that exists in your project. ***Note*** • *This option is disabled when there is no file specified for a component.*
New Advertised Shortcut	Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	Creates an advertised shortcut. The component's files are not installed to the target system until the end user launches the shortcut.
New Internet Shortcut	InstallScript	Creates an Internet shortcut (one whose Internet Shortcut setting is set to Yes) with a default value of **http://www.YourCompanyName.com** for the Target setting; change this value to the desired URL.

Table 4-1 • Types of Shortcuts (cont.)

Shortcut Type	Project Type	Description
New Shortcut to Preexisting File	Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	Creates a shortcut to a file that already exists on the target system.
New Folder	Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	Creates a program folder. You can create a program folder if you want your shortcut to appear under your company name, for example.

Creating Shortcuts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Before you create a shortcut, you should create at least one feature and component. If you have not created a component when you create your first shortcut, InstallShield creates a component for you. You can change the component to which the shortcut belongs by configuring the shortcut's Component setting.

Task: ***To create a shortcut:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, right-click one of the destination directories and then click the appropriate command. For a list of available commands, see Types of Shortcuts.

InstallShield adds a new shortcut with the default name **NewShortcutN** (where *N* is a successive number).

3. Enter a new name, or right-click it later and click **Rename** to give it a new name.
4. Configure the shortcut's settings.

For details about each of the settings that you can configure for shortcuts and folders, see:

- Shortcut Settings
- Folder Settings

Note • *You can create a program folder if you want your shortcut to appear under your company name, for example. When you have created a folder for your shortcut, you can create the shortcut by right-clicking your new folder and then clicking New Shortcut.*

You cannot create shortcuts to a dynamically linked file. For more information, see Limitations of Dynamic File Linking.

Tip • *You can also use the Components view or—in installation projects only—the Setup Design view to create a shortcut. If you use either the Components view or the Setup Design view, click the Shortcuts item in the explorer; a separate Shortcuts explorer opens in a new pane.*

Configuring Shortcut Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you have created a shortcut, you need to configure its settings. Shortcut settings enable you to link your shortcut to a file, provide a description of the shortcut, or pass arguments.

Task: ***To configure the settings for a shortcut:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, click the shortcut. The shortcut's settings are displayed in the right pane.
3. Configure the settings as needed.

For details about each of the settings that you can configure for shortcuts and folders, see:

- Shortcut Settings
- Folder Settings

Specifying the Icon for a Shortcut

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield enables you to specify the icon that should be used for a shortcut that is created on the target system at run time.

Task: ***To specify the icon for a shortcut:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, click the shortcut whose icon you want to specify. The shortcut's settings are displayed in the right pane.
3. In the **Icon File** setting, specify the file that contains the icon for the shortcut that you are creating. You must specify an .ico file or the executable file (.dll or .exe) that contains the icon resource.

   For Basic MSI, InstallScript MSI, or Merge Module projects: You can either type the fully qualified path to the file that contains the icon, or click the ellipsis (...) button to browse to it.

   For InstallScript projects: Type the fully qualified path to the file on the target system that contains the icon.

4. If the icon file that you specify contains more than one icon resource, enter the index in the **Icon Index** setting.

   A nonnegative integer refers to the order of the icon resources in the executable file. For example, 0 refers to the first icon in the file, 1 refers to the second icon, and 2 refers to the third icon.

InstallShield changes the icon that is displayed for the shortcut in the Shortcuts explorer to the one that you specified, unless either of the following conditions is true:

- The project type is InstallScript.
- The shortcut is for a pre-existing file on the target system.

For both of the aforementioned conditions, the icon file is not known until run time. Therefore, InstallShield shows the following icon for each shortcut in the Shortcuts explorer, instead of displaying the icon that is used at run time on target systems.

InstallShield also uses this icon for a shortcut in the Shortcuts explorer if the file that is selected in the Icon File setting does not contain an icon.

Project • *For Basic MSI, InstallScript MSI, and Merge Module projects: Since Windows Installer requires a separate icon when the component is advertised, InstallShield extracts the icon from any executable file that you specify.*

Tip • *For Basic MSI, InstallScript MSI, and merge module projects: You can also right-click the icon in the Shortcuts view and then click Change Shortcut icon to specify a different shortcut icon. InstallShield updates the value in the Icon settings with the values that you specify using this method.*

Creating Internet Shortcuts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

An Internet shortcut is a text file with the .url extension.

Task: ***To create an Internet shortcut that opens your Web site:***

1. Create a text file called **MySite.url** with the following contents:

   ```
   [InternetShortcut]

   URL=http://www.MySite.com
   ```

2. Add this file to a component.

Otherwise, if you simply right-click and click Add, you will add what the shortcut points to and not the shortcut itself.

When the end user launches the shortcut, the specified Web site (**www.MySite.com**) opens in the default browser.

Creating Shortcuts to Folders

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield lets you create a shortcut to a folder. The method that you use to create a shortcut to a folder depends on the project type that you are using.

Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform Projects

The Target setting of a shortcut can contain a directory identifier inside square brackets. For example, to create a shortcut to INSTALLDIR, create a shortcut with the following settings:

- Display Name: Shortcut to INSTALLDIR
- Advertised: No
- Target: [INSTALLDIR]

InstallScript and InstallScript Object Projects

The **AddFolderIcon** function creates a shortcut to a folder if you pass the path to the folder in the third (`szCommandLine`) parameter.

For example, this code creates a shortcut to the Common Files folder in the end user's Program Files folder:

```
ProgDefGroupType(COMMON)

szFolder = TARGETDIR;
LongPathToQuote(szFolder, TRUE);

AddFolderIcon(
    ProgramMenuFolder,        // where shortcut will appear
    "Shortcut to TARGETDIR",  // shortcut display name
    szFolder,        // what shortcut launches
    ""// working directory
    TARGETDIR ^ "Sample.exe", 0,       // icon file, index
    "",    // shortcut key
    NULL);              // special settings
```

InstallScript MSI Project

Use the same basic procedure as in the preceding InstallScript section, changing all occurrences of TARGETDIR to INSTALLDIR in the example code.

Specifying a Keyboard Shortcut for Accessing a Shortcut

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Keyboard shortcuts—also sometimes called hot keys—enable you to perform tasks quickly by pressing a combination of keys, such as CTRL+ALT+A, instead of using the mouse. You can assign a keyboard shortcut to your product's shortcut so that end users can press the appropriate hot keys to launch the shortcut.

Caution • *It is recommended that you avoid configuring keyboard shortcuts for your shortcuts because they may conflict with existing keyboard shortcuts on the target system.*

Task: ***To assign a keyboard shortcut to a shortcut in your project:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut for which you are specifying a hot key.
3. In the **Hot Key** setting, click the ellipsis button (**...**). The **Hot Key** dialog box opens.
4. Press the keyboard shortcut that you want to use for this shortcut.
5. Click **OK**.

In the Hot Key setting, InstallShield displays the appropriate decimal value that represents the combination of keys that you pressed.

For example, if your key combination is CTRL+ALT+A, InstallShield displays 1601 in this setting. This number is obtained by combining the hex value of CTRL (200) and the hex value of ALT (400) with the logical Or operator. Then, that number (600) is added to the hex value for the A key (41) and converted to a decimal value. In this example, the number that is converted to decimal is 641. After the conversion, it is 1601.

Renaming Shortcuts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you create a shortcut, your shortcut appears with a default internal name. This name is not displayed to end users, but you can change it to something that is relevant to your project.

Task: ***To rename a shortcut:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, right-click the shortcut that you want to rename and click **Rename**.
3. Type the new name.

Setting Shell Properties for a Shortcut

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield lets you specify one or more shortcut properties that you want the Windows Shell to set at installation run time. For example, InstallShield has built-in support for enabling you to set Shell properties that control the following behavior:

- Specifying Whether a Shortcut Should Be Pinned to the Windows 8 Start Screen
- Specifying Whether End Users Should Be Able to Pin a Shortcut to the Taskbar or Start Menu
- Preventing a Shortcut on the Start Menu from Being Highlighted as Newly Installed

InstallShield also lets you set additional properties that the Windows Shell supports. To learn more, see Setting Custom Shell Properties.

Specifying Whether a Shortcut Should Be Pinned to the Windows 8 Start Screen

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Project-specific differences are noted where applicable.

InstallShield lets you specify whether you want a shortcut to be pinned by default to the Start screen on Windows 8 target systems. If you specify that you want the pinning to be disabled, the installation sets a Windows Shell property that was introduced in Windows 8. You may want to disable pinning for shortcuts that are for tools and secondary products that are part of your installation.

Earlier versions of Windows ignore this shortcut property.

Task: ***To specify whether the shortcut should be pinned by default to the Windows 8 Start screen:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut that you want to configure. The shortcut's settings are displayed in the right pane.
3. In the **Pin to Windows 8 Start Screen** setting, specify the appropriate option:
   - **Yes**—When the shortcut is installed on Windows 8 systems, it is pinned to the Start screen. End users can optionally unpin the shortcut. This is the default option.
   - **No**—When the shortcut is installed on Windows 8 systems, it is not pinned to the Start screen. It is available in the Apps list that contains shortcuts to all of the applications on the system.

Note that Windows 8 maintains information about shortcut pinning to the Start screen after a shortcut is removed by uninstalling the application. Therefore, this setting has no effect on the target system if the shortcut has already been installed on it. Thus, when you are testing this functionality, ensure that you test on a clean machine—one on which this shortcut and its target have never been installed.

For Windows Installer–based projects (Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform), some end users have reported run-time warnings or errors with a message such as the following one when Windows Installer is installing a shortcut that configures Shell properties:

```
Property [1] for shortcut '[2].lnk' could not be set.
```

In the aforementioned message, [1] is the name of the Shell property that Windows Installer is attempting to set, and [2].lnk is the name of the shortcut file. In such cases, it appears that the .lnk file could be locked by a different process.

InstallScript Language Support

The following InstallScript functions enable you to prevent the pinning of a shortcut to the Start screen:

- CreateShortcut
- SetShortcutProperty

Specifying Whether End Users Should Be Able to Pin a Shortcut to the Taskbar or Start Menu

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

- *MSI Database*
- *MSM Database*
- *Transform*

Project-specific differences are noted where applicable.

InstallShield lets you specify whether you want the context menu commands for pinning a shortcut to the taskbar and to the Start menu to be displayed after end users install your product. You may want to disable pinning for shortcuts that are for tools and secondary products that are part of your installation. Note that if you configure the shortcut to prevent this pinning, the target of the shortcut is ineligible for inclusion in the most frequently used list on the Start menu.

If you configure a shortcut to prevent this pinning functionality, the installation sets a Windows Shell property. By default, the property is not set for new shortcuts, so end users are able to pin the shortcut to the taskbar and to the Start menu.

Note that shortcuts that contain certain strings cannot be pinned to the taskbar or the Start menu, and they cannot be displayed in the most frequently used list. Examples are:

- Documentation
- Help
- Install
- Remove
- Setup
- Support

Note that the method for hiding the context menu commands varies, depending on the project type that you are using.

Instructions for Windows Installer–Based Projects

For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects, use the Shell Properties setting to hide the context menu commands.

Task: ***To hide the context menu commands for pinning a shortcut to the taskbar or Start menu:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut that you want to configure. The shortcut's settings are displayed in the right pane.
3. In the **Shell Properties** setting, click the **Add New Shell Shortcut Property** button, and then click **Prevent Pinning**. InstallShield adds a new **Key Name** setting, plus additional rows of related settings under it, and configures them as needed.

To allow the context menu commands to be displayed, find the Key Name setting that has a Property subsetting with either of the following, and click the **Delete this shortcut shell property** button in the Key Name setting:

- System.AppUserModel.PreventPinning

- {9F4C2855-9F79-4B39-A8D0-E1D42DE1D5F3}, 9

Windows Installer 5 introduced support for this shortcut property. Earlier versions of Windows Installer ignore this setting.

Note that for Windows Installer–based installations, some end users have reported run-time warnings or errors with a message such as the following one when Windows Installer is installing a shortcut that configures Shell properties:

```
Property [1] for shortcut '[2].lnk' could not be set.
```

In the aforementioned message, [1] is the name of the Shell property that Windows Installer is attempting to set, and [2].lnk is the name of the shortcut file. In such cases, it appears that the .lnk file could be locked by a different process.

Instructions for InstallScript Projects

For InstallScript projects, use the Prevent Pinning setting.

Task: ***To hide the context menu commands for pinning a shortcut to the taskbar or Start menu:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut that you want to configure. The shortcut's settings are displayed in the right pane.
3. In the **Prevent Pinning** setting, select **Yes**.

Windows 7 introduced support for this setting. Earlier versions of Windows ignore this setting.

InstallScript Language Support

The following InstallScript functions enable you to hide the context menu commands for pinning a shortcut to the taskbar or the Start menu:

- CreateShortcut
- SetShortcutProperty

Preventing a Shortcut on the Start Menu from Being Highlighted as Newly Installed

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

- *Transform*

Project-specific differences are noted where applicable.

InstallShield lets you optionally prevent a shortcut on the Start menu from being highlighted as newly installed after end users install your product. This has the same effect as clearing the **Highlight newly installed programs** check box in the Customize Start Menu dialog box for an individual item on a target system. You may want to set this property for shortcuts that are for tools and secondary products that are part of your installation.

If you specify that you want to prevent the highlight functionality for a shortcut, the installation sets a Windows Shell property. By default, the property is not set for new shortcuts.

Note that the method for preventing the highlight behavior varies, depending on the project type that you are using.

Instructions for Windows Installer–Based Projects

For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects, use the Shell Properties setting to prevent the highlight behavior.

Task: ***To prevent the Start menu entry for a shortcut from being highlighted as newly installed:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut that you want to configure. The shortcut's settings are displayed in the right pane.
3. In the **Shell Properties** setting, click the **Add New Shell Shortcut Property** button, and then click **Do Not Highlight as New**. InstallShield adds a new **Key Name** setting, plus additional rows of related settings under it, and configures them as needed.

To enable the Start menu entry to be highlighted, find the Key Name setting that has a Property subsetting with either of the following, and click the **Delete this shortcut shell property** button in the Key Name setting:

- System.AppUserModel.ExcludeFromShowInNewInstall
- {9F4C2855-9F79-4B39-A8D0-E1D42DE1D5F3}, 8

Windows Installer 5 introduced support for this shortcut property. Earlier versions of Windows Installer ignore this property.

Note that for Windows Installer–based installations, some end users have reported run-time warnings or errors with a message such as the following one when Windows Installer is installing a shortcut that configures Shell properties:

```
Property [1] for shortcut '[2].lnk' could not be set.
```

In the aforementioned message, [1] is the name of the Shell property that Windows Installer is attempting to set, and [2].lnk is the name of the shortcut file. In such cases, it appears that the .lnk file could be locked by a different process.

Instructions for InstallScript Projects

For InstallScript projects, use the Do Not Highlight as New setting.

Task: ***To prevent the Start menu entry for a shortcut from being highlighted as newly installed:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut that you want to configure. The shortcut's settings are displayed in the right pane.
3. In the **Do Not Highlight as New** setting, select **Yes**.

Windows 7 introduced support for this setting. Earlier versions of Windows ignore this setting.

InstallScript Language Support

The following InstallScript functions enable you to prevent the highlight behavior:

- CreateShortcut
- SetShortcutProperty

Setting Custom Shell Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Project-specific differences are noted where applicable.

InstallShield lets you specify one or more shortcut properties that need to be set by the Windows Shell at run time. The properties that the Shell can set are defined in `propkey.h`, which is part of the Windows SDK.

Note that the method for preventing the highlight behavior varies, depending on the project type that you are using.

Instructions for Windows Installer–Based Projects

For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, and Transform projects, use the Shell Properties setting to set one or more Shell properties.

Task: ***To set a Shell property for a shortcut that is in your project:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, select the shortcut that you want to configure. The shortcut's settings are displayed in the right pane.
3. In the **Shell Properties** setting, click the **Add New Shell Shortcut Property** button, and then click **Custom Property**. InstallShield adds a new **Key Name** setting, plus additional rows of related settings under it, with placeholder text.
4. Configure each of the settings as needed.

You can add multiple properties for the shortcut if necessary.

Windows Installer 5 introduced support for the Shell shortcut properties. Earlier versions of Windows Installer ignore these properties.

For more information about configuring shortcut properties, see MsiShortcutProperty Table in the Windows Installer Help Library.

Note that for Windows Installer–based installations, some end users have reported run-time warnings or errors with a message such as the following one when Windows Installer is installing a shortcut that configures Shell properties:

```
Property [1] for shortcut '[2].lnk' could not be set.
```

In the aforementioned message, [1] is the name of the Shell property that Windows Installer is attempting to set, and [2].lnk is the name of the shortcut file. In such cases, it appears that the .lnk file could be locked by a different process.

InstallScript Language Support

The following InstallScript functions enable you to configure Shell properties in InstallScript projects and in other project types:

- CreateShortcut
- SetShortcutProperty

Creating Uninstallation Shortcuts for Basic MSI Projects

Project • *This information applies to Basic MSI projects.*

Windows Logo • *According to current Windows logo guidelines, best practice is to not place shortcuts to remove the application in the Start menu. An uninstallation shortcut is unnecessary because your application's uninstaller is in Add or Remove Programs.*

You can create an uninstallation shortcut to make it easier for end users to uninstall your product from their systems. When launched, the shortcut automatically starts the uninstallation process.

Task: ***To create an uninstallation shortcut:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, right-click the destination directory that should contain the uninstallation shortcut, and then click **New Shortcut to Preexisting file**. InstallShield adds a new shortcut with the default name **NewShortcutN** (where *N* is a successive number).
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.
4. In the **Arguments** field, type `/x [ProductCode]`. Separate the two arguments with a space.

   `Msiexec.exe` is the command-line engine for the Windows Installer service. The `/x` argument instructs the Windows Installer service to uninstall the product referenced by the product code.
5. Set the **Advertised** field to **No**.
6. In the **Target** field, select **[SystemFolder]**, and then append `msiexec.exe` to this location.
7. In the **Component** field, select the component with which you want this shortcut associated. If the shortcut should always be installed, associate it with the component containing your application's main executable file.

Creating Uninstallation Shortcuts for InstallScript and InstallScript MSI Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Note • *You may not want to create an uninstallation shortcut. An uninstallation shortcut is unnecessary because your application's uninstaller is in Add or Remove Programs.*

You can create an uninstallation shortcut to make it easier for end users to uninstall your product from their systems. When end users launch the shortcut, the uninstallation process automatically starts.

The following InstallScript code creates a shortcut called **Uninstall Application** on the desktop after file transfer. Launching this shortcut runs your installation in maintenance mode. This code works for both InstallScript and InstallScript MSI projects.

```
function OnMoved()
begin
   if( !REMOVEALLMODE ) then
```

```
      AddFolderIcon( FOLDER_DESKTOP, "Uninstall Application", UNINSTALL_STRING +
ADDREMOVE_STRING_REMOVEONLY, "", "", 0, "", REPLACE );
   endif;
end;
```

Tip • *If you include ADDREMOVE_STRING_REMOVEONLY, `-removeonly` is added to the command line. As a result, REMOVEONLY is set, and the OnMaintUIBefore event handler shows only the uninstallation option. To display the standard maintenance user interface, do not include ADDREMOVE_STRING_REMOVEONLY.*

Editing the Registry

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

The Windows registry is a system-wide database that contains configuration information used by applications and the operating system. The registry stores all kinds of information, including the following:

- Application information such as company name, product name, and version number
- Path information that enables your application to run
- Uninstallation information that enables end users to uninstall the application easily without interfering with other applications on the system
- System-wide file associations for documents created by an application
- License information
- Default settings for application options such as window positions

Keys, Value Names, and Values

The registry consists of a set of keys arranged hierarchically under the My Computer explorer. Just under My Computer are several root keys. An installation can add keys and values to any root key of the registry. The root keys that are typically affected by installations are:

- HKEY_LOCAL_MACHINE
- HKEY_USERS
- HKEY_CURRENT_USER
- HKEY_CLASSES_ROOT

A key is a named location in the registry. A key can contain a subkey, a value name and value pair, and a default (unnamed) value. A value name and value pair is a two-part data structure under a key. The value name identifies a value for storage under a key, and the value is the actual data associated with a value name. When a value name is unspecified for a value, that value is the default value for that key. Each key can have only one default (unnamed) value.

Note that the terms key and subkey are relative. In the registry, a key that is below another key can be referred to as a subkey or as a key, depending on how you want to refer to it relative to another key in the registry hierarchy.

InstallShield Projects and the Registry

InstallShield includes the Registry view to help you with the task of modifying the end user's registry. Use this view to create keys and values in much the same way that you use the Windows Registry Editor.

All registry data (except the <Default> registry set in a InstallScript project) must be associated with a component. In installation projects, if the component's feature is selected for installation, the component's registry data are set up on the target system.

Caution • *It is important not to modify or delete registry keys indiscriminately because the registry is a vital part of the Windows operating system, and the system may fail to function if vital registry keys are altered.*

Note • *The installer automatically creates certain registry entries based on values that you provide in the General Information view.*

Windows Logo • *These "informational keys" are required if you want to meet the requirements for the Windows logo program.*

Also, all of a component's advanced settings are used to register files on the target system.

Filtering Registry Entries by Component or Feature

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Several project types (DIM, Merge Module, and MSM Database) do not include support for features; these project types have support for by filtering by component, but not by feature.

The Registry view includes a View Filter. This filter enables you to select a component or feature whose registry data you want to display in the view.

The View Filter lists your project's hierarchy of features, subfeatures, and components. Selecting a feature shows the registry data for all of the components in that feature, but it allows you only to modify and delete existing entries. You need to select a component in order to add a new registry key.

If the feature hierarchy contains a subfeature, selecting a parent feature displays only the registry entries in that feature. It does not display the registry entries in the subfeature.

Browsing for Components

You can browse for components from within the registry explorer. Click the ellipsis button to the right of the View Filter to launch the Browse for Component dialog box. From that dialog box, you can select a feature in the Feature list and then select an existing component or click the new component button to create a new component.

If the View Filter is set to All Application Data, you can right-click a registry hive in the Destination computer's registry view pane and click Browse for Component to display the dialog box.

Viewing All Registry Entries in Your Project

To view all of the registry entries in your installation, select the All Application Data option in the View Filter. You can export registry data by selecting Export All or Export Selected Branch from the context menu after right-clicking a registry key.

Note • *You can modify, rename, or delete registry keys and values while filtering the view by All Application Data.*

When you click a registry key in the Destination computer's Registry view pane of the Registry view, InstallShield displays all of the registry data for that key in the lower-right pane of the Registry view. The Component column shows the component with which the registry data is associated. If the same value exists for more than one component, the last component that was associated with the registry data is displayed.

If you have not set a value for a key, no registry data is displayed for that key when you select All Application Data in the View Filter.

Refreshing the Registry View

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To refresh the Registry view:***

Press F12.

Creating Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To specify a registry key to be created on the target system when a component is installed:***

1. In the View List under **System Configuration**, click **Registry**.
2. *In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform, and QuickPatch projects*—In the **View Filter** list, click the component with which you want to associate the registry data.

Note • *If **All Application Data** is selected, the **Registry** view is read-only.*

In InstallScript and InstallScript Object projects—In the **Destination computer's Registry view** pane, open an existing registry set or create one by right-clicking the **Destination Computer** folder. Associate the registry set with one or more components by clicking the registry set and selecting the desired components in the **Registry Set Install Conditions** pane.

3. In the **Destination computer's Registry view** pane, right-click a registry hive or key, point to **New**, and then click **Key**. InstallShield adds a new key with the name **New Key-n** (where *n* is a successive number).
4. Enter a meaningful name to rename the key, or right-click the key and click **Rename** to give it a new name later.

InstallShield adds your new key with an empty default string value.

By default, all keys that you create are set for automatic installation and uninstallation. This means that they are installed if the component they belong to is installed, and they are uninstalled when that component in uninstalled. For more information on registry key flags, see Registry Flags.

Tip • *You can create multiple nested keys at one time by creating a new key and typing, for example,* `Key 1\Key 2\Key 3` *in the key's name. InstallShield creates a nested key structure where Key 3 is a subkey of Key 2, which is a subkey of Key 1.*

Dragging and Dropping Registry Entries to Create Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

The quickest way to add registry entries to your installation project is to drag them from one of the source panes in the Registry view and drop them into one of the destination panes. When you drop an entire key onto the **Destination computer's Registry view** pane, all of that key's subkeys and values are added to the selected component or, in a InstallScript project, to the registry set on which you drop the entry.

Using the Context Menu to Drag and Drop Keys

You can use the context menu to move multiple keys and values at one time. Right-click a registry entry, drag it to a destination, and click a command on the context menu.

Table 4-2 • Commands Available from the Registry Entry Context Menu

Option	Description
All keys & values	Adds all selected keys, subkeys, and values.
Key and its values only	Adds only the selected key and the key's values. No subkeys are added.
Only this key	Adds only the selected key, not any of its subkeys or values.
Cancel	Ends the drag and drop operation without making any changes.

Importing Data From Another Machine

A limitation of the drag-and-drop procedure is that it works only if the registry entries exist on your installation development system. If you have registry data from another machine, you can import that data with the Import REG File Wizard.

Removing Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To remove a registry key:***

1. In the View List under **System Configuration**, click **Registry**.
2. *In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform, and QuickPatch projects*—In the **View Filter** list, click the component that contains the registry key, or select **All Application Data** to view all of the registry keys for your product.

   In InstallScript and InstallScript Object projects—In the **Destination computer's Registry view** pane, open the existing registry set that contains the registry key.
3. In the **Destination computer's Registry view** pane, right-click the registry key that you want to remove and then click **Delete**.

Creating Registry Values

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To specify a registry value to be created on the target system:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, click the key to which you want to add a value. All existing registry values for that key are listed in the **Destination computer's registry data** pane.
3. Right-click in the list of values and then click the type of data you want to register. Available options are as follows:

Table 4-3 • Types of Registry Values

Option	Description
Default Value	The key's default value.

Table 4-3 • Types of Registry Values (cont.)

Option	Description
String Value	A fixed-length text string.
Binary Value	The value is interpreted and stored as a hexadecimal value.
DWORD Value	Data represented by a number that is four bytes (32 bits) long.
Multi-String Value	Multiple text strings formatted as an array of null-terminated strings, and terminated by two null characters. Selecting this command launches the Multi-Line String Value dialog box.
Expandable String Value	The value is interpreted and stored as an expandable string. According to the Microsoft Developer Network (MSDN), an expandable string registry value is a null-terminated string that contains unexpanded references to environment variables (for example, **%PATH%**).

InstallShield adds a new value with the name New Value n (where *n* is a successive number). Enter a meaningful name now to rename the value, or right-click the value name and then click Rename to give it a new name later.

Project • *In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform, and QuickPatch projects, any registry value can serve as the component's key path.*

Modifying Registry Value Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To modify the data for a registry value to be created on the target system:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, click the registry key that has the value that you want to modify. All registry values are listed in the **Destination computer's registry data** pane.
3. Double-click the value that you want to modify. The Edit Registry Data dialog box or the Multi-Line String Value dialog box opens.
4. Complete the information in the dialog box, and then click **OK**.

Project • *In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform, and QuickPatch projects—To add value data that contains square brackets ([]), you must precede each bracket with a backslash (\) and surround it with an opening and closing bracket. Otherwise, Windows Installer treats the value as a property. For example, if you wanted to write* ***[stuff]*** *to the registry, you would use* `[\[]stuff[\]]` *as the value data.*

Removing Registry Values

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To remove a registry value from your project:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, click the registry key that has the value that you want to delete. All registry values are listed in the **Destination computer's registry data** pane.
3. In the **Destination computer's Registry data** pane, right-click the registry value that you want to remove and then click **Delete**.

Registry Flags

Registry flags enable you to control the installation of your registry entries. The registry flag support differs, depending on what project type you are using.

Registry Flags in Windows Installer–Based Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

By default, your registry entries are created on the target system if the component to which they belong is installed. They are then removed from the target system when that component is removed. If you would like your registry entries to remain on the target system even after the product has been uninstalled, or if you want to create registry entries only if they do not already exist, you need to set the installation flag for that key.

In InstallShield, installation behavior is set at the subkey level. All values beneath the key must have the same installation and uninstallation behavior.

To change the registry flag of a key, right-click one of your project's keys in the Registry view, and then click any of the commands that are listed in the following table.

Table 4-4 • Types of Registry Flags in Windows Installer–Based Projects

Icon	Command	Description
	Automatic	This is the default option for all registry keys. If the key is not already present, the installation creates it. During an uninstallation, if the key is empty, it is removed.
	Install only (+)	If the key does not already exist, it is created. The key is left on the target system when the component to which this key belongs is uninstalled. This option is available only for keys that do not contain subkeys or values.
	Uninstall entire key (–)	If this flag applies to an empty key, the key is not created at installation. If this flag applies to a key that contains values and the key does not exist on the target system, the key and values are created at installation. In both cases, the key, all subkeys, and values are removed at uninstallation—even if the subkeys and values were added after the installation.

Table 4-4 • Types of Registry Flags in Windows Installer–Based Projects (cont.)

Icon	Command	Description
	Install if absent, Uninstall if present (*)	This option is similar to the default behavior (the Automatic registry flag), with one exception. For the Automatic registry flag, if the key is not empty during uninstallation, it is not removed. For the **Install if absent, Uninstall if present (*)** flag, if the registry key is present during uninstallation, the key is removed, regardless of whether its subkeys or values remain.

Registry Flags in InstallScript-Based Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

After your installation has created registry keys on the target system by installing a registry set, subkeys or values may be created under those keys by other installations or applications (or directly by the end user). You can prevent a registry key that your installation installed from being uninstalled if it has any subkeys or values that were not created by the installation. To accomplish this, you can change the registry flag of the key. To do so, right-click one of your project's keys in the Registry view and then click the following command.

Table 4-5 • Registry Flag in InstallScript-Based Projects

Icon	Command	Description
	Shared among several applications	When the component to which this key belongs is uninstalled, the key is not removed from the target system if the key has any subkeys or values. (Note that a value that was created by your installation will have already been uninstalled unless you unset its **Remove during Uninstall** flag.) If the key does not have any subkeys or values, the key is removed from the target system regardless of whether it was created by the installation—that is, whether it already existed at the time of installation.

You may want your uninstallation to leave some of your product's registry values on the end user's system—for example, registry values that are used by the operating system and are modified by your installation. To do this, right-click the key that contains the registry value that you do not want to be uninstalled. Select the **Shared among several applications** flag for that key. Then right-click the value of the key and ensure that the **Remove during Uninstall** command is not selected.

Searching for Registry Entries

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Task: ***To search for a registry entry within a certain component (in Windows Installer projects) or registry set (in InstallScript projects):***

1. In the View List under **System Configuration**, click **Registry**.
2. *In Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform, and QuickPatch projects*—In the **View Filter** list, select the component that you would like to search. Note that if **View All Entries** is selected, the **Registry** view is read only.

   In InstallScript and InstallScript Object projects—Open the registry set that you would like to search.
3. Right-click a registry entry and click **Find**. The **Find** dialog box opens.
4. Enter the string that you are searching for.
5. Click **Find** to start the search.

In a Windows Installer project, InstallShield searches only the registry entries for the current component, not all the registry data for the project.

The search starts from the top item and works its way down, regardless of which item is selected. It stops at the first match, highlighting this key. To continue the search, right-click and select Find Next, or press F3. The Find Next feature finds the next match, moving down the explorer.

Setting Uninstall Behavior for Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

- *Transform*
- *QuickPatch*

In InstallShield, uninstall behavior for registry entries is set at the key level.

Task: ***To set the uninstall behavior for a registry key:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, right-click a key and click the appropriate uninstall behavior.

Uninstall Behavior Options

In InstallShield, installation behavior is set at the subkey level. All values beneath the key must have the same installation and uninstallation behavior. For a list of available options, see Registry Flags.

Using Environment Variables in Registry Values

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

With REG_EXPAND_SZ string values, you can use environment variables for paths that are stored in the registry. These entries require special formatting in order to be recognized by the operating system as environment variables. The format for a REG_EXPAND_SZ value as it appears in the registry is %TEMP%. TEMP is the standard environment variable for the TEMP directory.

Syntax

When creating registry entries of this type, you need to begin the entry with a pound sign followed by a percent sign (#%). Then, you can enter your environment variable, complete with the beginning and ending percent sign. Therefore, if you enter **#%%TEMP%** in the Registry view in InstallShield, it appears as **%TEMP%** when written to the registry.

The Type field for this entry appears as REG_EXPAND_SZ, and the Data field is %TEMP%.

Writing Property Values to the Registry

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

For Windows Installer–based projects, you can use Windows Installer properties in registry values to store information for later use by your product. At run time, Windows Installer automatically expands expressions of the form **[PropertyName]** in registry data to the value of the property called **PropertyName**. Any property defined in the Property Manager view can be used in this way.

For example, if you would like to store the destination location of your software, create a registry value whose data is **[INSTALLDIR]**. At run time, when your installation creates the registry value, the data for that registry value is set to the location where your application is installed.

You can use the same format for registry key names and value names. For example, if you want a key name to be the name of your company, enter `[Manufacturer]` for the name of the key. When the registry key is created on the target system, the name of this key will be the value of the Publisher setting, as entered in the General Information view.

Importing Registry Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield enables you to import any existing registry (.reg) files that you may have from other installation projects or that you have created outside InstallShield

Task: ***To import a .reg file:***

1. Launch the Import REG File Wizard.
2. Follow the instructions in the wizard panels to import your .reg file.

When you import a .reg file into a component or registry set, that registry data is added to the component's or registry set's registry data and written to the end user's system if the component or registry set is installed.

Exporting Registry Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you export a registry (.reg) file, you are copying a portion of your program's registry data to a registry file.

Task: ***To export a registry file:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, right-click the registry entry that you want to export and click either **Export REG File** or **Export Selected Branch**.
   - **Export REG File** exports the entire component's registry data.
   - **Export Selected Branch** exports only the current registry key and any subkeys.

Setting Key Paths for Components

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

A key path is a unique registry value for each component that the Windows Installer uses to detect the component's presence. This value must contain a file or a folder.

Task: ***To set a component's key path:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, click the registry entry that contains the registry data that you want to use for the key path.
3. In the **Destination computer's registry data** pane, right-click the registry key's value name and then click **Set Key Path**.

The value's string, binary, or DWORD icon is replaced with a key icon.

Task: ***To remove a component's key path:***

Right-click the key path and click **Clear Key path**.

Note • *A component can have either one key path or one key file. If you have already set a key file or a key path for a component, you will get a warning prompt if you try to set another key path. Click Yes in the dialog box to replace the existing key file or key path with the new key path.*

Configuring Permissions for Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield lets you configure settings for securing registry keys for end users who run your product in a locked-down environment. You can assign permissions for a registry key to specific groups and users. For example, you may assign Read, Write, and Delete permissions for a particular registry key to the Administrators group, but only Read permissions for all of the users in a different group.

Task: ***To configure the permissions for a registry key:***

1. In the View List under **System Configuration**, click **Registry**.
2. In the **Destination computer's Registry view** pane, right-click the registry key and then click **Permissions** button. The **Permissions** dialog box opens.
3. Add, modify, and remove permissions entries as needed. For more information, see Permissions Dialog Boxes for Registry Keys.

Depending on what is selected for the Locked-Down Permissions setting in the General Information view of your project, InstallShield adds permissions data to either the **ISLockPermissions** table or the **LockPermissions** table. To learn more, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.

Primary Keys for the Registry Table

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Windows Installer requires a unique primary key for each registry key and value that you add to the **Registry** table. To enable you to create registry entries in a completely visual environment, InstallShield assigns a unique name to every entry in the database's **Registry** table at build time.

You may need to know the entry's primary key when authoring a custom action. InstallShield supports specifying a primary key on a registry key or value in the Registry Data explorer in the Setup Design view or the Components view. Note that it is not possible to assign the key or value a primary key in the Registry view.

Specifying a Primary Key for the Registry Table

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Task: ***To specify a primary key for a registry key or value:***

1. Right-click the key or value and click **MSI Value**. The MSI Value dialog box opens.
2. Enter the name of the key. Since the primary key must be a Windows Installer identifier, the name may contain only letters, numbers, underscores (_) and periods (.), and it must begin with a letter or underscore.

To view or modify the primary key, right-click the registry key or value and click MSI Value again.

If you do not specify a value, InstallShield generates a unique primary key for this entry in the **Registry** table.

Entering Multi-Line String Values for Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

The Registry view provides multi-line string support when you want to add a value to a particular registry key.

Task: ***To add a multi-line string value:***

1. Right-click the registry key to which you want to add the multi-line value, point to **New**, and click **Multi-String Value**. The Multi-Line String Value dialog box opens.
2. Select how you want to modify the registry value, and then enter a line for each null-delimited string.

3. Click **OK**.

Note • *Strings can contain just spaces, but they cannot be empty or [~], which is the delimiter for the strings.*

Writing Entries Under HKCU for a Per-User Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*
- *QuickPatch*

Since the current user may not have sufficient privileges for modifying keys under HKEY_LOCAL_MACHINE, you may need to write the entries under HKEY_CURRENT_USER.

When you select HKEY_USER_SELECTABLE in the Registry view, the entries are created under the appropriate registry hive, according to the type of installation and the end user's access rights. In a per-user installation, which means that the **ALLUSERS** property is set to 2 or that the installation is being run by someone with user-level access privileges, these entries would be made under HKEY_CURRENT_USER. In a per-machine installation, which means that **ALLUSERS** is not null and that the end user is an administrator, the entries would be written under HKEY_LOCAL_MACHINE.

Note • *Windows does not allow a new key to be created directly under HKEY_LOCAL_MACHINE. For this reason, any information that you create under HKEY_USER_SELECTABLE must be placed under the SOFTWARE subkey, which is the only subkey common to HKEY_LOCAL_MACHINE and HKEY_CURRENT_USER.*

For example, creating the key HKEY_USER_SELECTABLE\SOFTWARE\MyCompany is valid, but creating HKEY_USER_SELECTABLE\MyCompany is not.

Setting or Getting Multi-Line Strings in the Registry

Project • *This information applies to InstallScript projects.*

Setting Multi-Line Strings

To set multi-line strings, call the **RegDBSetKeyValueEx** function. The `szValue` parameter should contain the substrings to be added, separated by null characters. You must add two null characters to the end of the main string to denote its end. To create such a string, follow these steps:

1. Initialize the string to contain each of the substrings, separated by space characters.
2. Assign the ASCII value for a null string to the string positions after each line.
3. Assign an additional null character (ASCII value 0) to the end of the string.

For example:

```
svValue = "This is line one. This is line two. This is line three. ";
svValue[17] = 0;
svValue[35] = 0;
svValue[55] = 0;
svValue[56] = 0;
```

Retrieving Multi-Line Strings

To get multi-line strings, call the **RegDBGetKeyValueEx** function. The substrings will be returned in a main string, separated by null characters. To extract them, use the following code to read the strings into a string list and display them in an **SdShowInfoList** dialog:

```
// svValue is the string read in by RegDBGetKeyValueEx
listID = ListCreate( STRINGLIST );
if (listID != LIST_NULL) then
    StrGetTokens( listID, svValue, "" );
    SdShowInfoList( szTitle, szMsg, listID );
endif;
```

Working with Registry Functions

Project • *For InstallScript MSI and Basic MSI projects, it is recommended that you use the Registry view in InstallShield instead of creating registry keys and values through InstallScript code. Handling all of your registry changes in this way allows for a clean uninstallation through the Windows Installer service.*

The InstallScript language includes many built-in functions that help you configure an installation so that it accesses the registry; reads, creates, and deletes registry keys; and establishes registry-related parameters for uninstallation.

For example, you can sometimes determine if an application is present on the target system by detecting registry keys used by the application. Many applications store data in the registry key HKLM\SOFTWARE\CompanyName\ProductName\ProductVersion. To detect if a registry key exists, you can call the **RegDBKeyExist** function in your InstallScript code as follows:

```
// always set root key before calling other RegDB functions
RegDBSetDefaultRoot(HKEY_LOCAL_MACHINE);

if (RegDBKeyExist("Software\\ThisCo\\ThisApp") = 1) then
```

```
   MessageBox("ThisApp is on the system.", INFORMATION);
endif;
```

To learn more about the built-in registry functions available with InstallScript, see the following:

- Registry Functions
- Special Registry-Related Functions

Reading Data from the Registry

Basic MSI Project

The **AppSearch** and **RegLocator** tables can read a value from the registry. To read the RegisteredOwner value mentioned above, add the following record to the **AppSearch** table, using the Direct Editor:

Table 4-6 • Values for the AppSearch Table

Field	Value	Comments
Property	REGISTERED_OWNER	Must be a public property
Signature_	registry_sig	

Next, add the following record to the **RegLocator** table:

Table 4-7 • Values for the RegLocator Table

Field	Value	Comments
Signature_	registry_sig	Same signature as above
Root	2	HKEY_LOCAL_MACHINE
Key	Software\Microsoft\Windows NT\CurrentVersion	
Name	RegisteredOwner	
Type	2	Registry data

After the AppSearch action runs, the **REGISTERED_OWNER** property will contain the data read from the registry. If the value is not found, the property will be undefined (empty).

For more information regarding the **AppSearch** and **RegLocator** tables, see the Windows Installer Help Library.

For Windows Installer-based projects, you can use the System Search Wizard to find data.

InstallScript MSI Project

With InstallScript, you can use the **RegDBGetKeyValueEx** function. For example, to read the RegisteredOwner value from the key HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion, you can use code similar to the following:

```
function readRegisteredOwner( )
    STRING svRegisteredOwner;
    NUMBER nvType, nvSize;
begin
RegDBSetDefaultRoot(HKEY_LOCAL_MACHINE);

RegDBGetKeyValueEx(
    "Software\\Microsoft\\Windows NT\\CurrentVersion",
    "RegisteredOwner",
    nvType,
    svRegisteredOwner,
    nvSize);

MessageBox(
    "Registered owner is: " + svRegisteredOwner,
    INFORMATION);
end;
```

You can set a Windows Installer property equal to the value you read using the **MsiSetProperty** function.

Changing .ini File Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes .ini file functions for modifying .ini file data. You can use these functions in InstallScript projects.

Initialization (.ini) files serve as a database in which you can store and retrieve information between the uses of your applications. Some .ini files, such as `Boot.ini` and `Wininit.ini`, are used by the operating system. The INI File Changes view enables you to specify changes that should be made to .ini files on the target system. Although you can edit any .ini file found on the target system, editing system .ini files is not recommended.

Task: ***To edit an .ini file:***

1. Create an .ini file reference.
2. Add a section to the .ini file.
3. Add a keyword to the .ini file.

Before you can create an .ini file reference, you must have at least one component created. If no components exist when your .ini file reference is created, the Create a New Component dialog box is displayed, enabling you to create a component.

Creating .ini File References

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes .ini file functions for modifying .ini file data. You can use these functions in InstallScript projects.

The first step in creating an .ini file change is to create a reference to the file that you would like to edit. In order to do this, you need to know the name and location of the file on the target system that you would like to edit. If the file is not in the location that you specify, the installation cannot make changes to this file.

Task: ***To create a reference to an .ini file:***

1. In the View List under **System Configuration**, click **INI File Changes**.
2. Right-click the **INI Files** explorer and then click **Add INI File**.

InstallShield adds a new reference for the .ini file to the INI Files explorer. Configure the .ini file's settings in the right pane. For details about each setting, see .ini File Settings.

After you have created a reference to an .ini file, you can move on to the next step, which is to add a section to your .ini file.

Importing an Existing .ini File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes .ini file functions for modifying .ini file data. You can use these functions in InstallScript projects.

InstallShield lets you import an existing .ini file into your project. Once you have imported the .ini file, you can use the INI File Changes view to configure the changes that you want to be made on the target system as needed.

Task: ***To import an existing .ini file:***

1. In the View List under **System Configuration**, click **INI File Changes**.
2. Right-click the **INI Files** explorer and then click **Import INI File**. The **Open** dialog box opens.
3. Select the .ini file that you want to import, and then click **Open**.

InstallShield imports the .ini file, along with all of its sections, keywords, and values, into your project.

Specifying a Section in an .ini File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes .ini file functions for modifying .ini file data. You can use these functions in InstallScript projects.

Once you have specified the .ini file that you would like to edit, you can move onto the second step: specifying which section of that file you want to change. The .ini files are divided into sections, with each section containing keywords. Sections are identified by the square brackets surrounding them—for example, **[SectionName]**.

Task: ***To specify an .ini file section:***

1. In the View List under **System Configuration**, click **INI File Changes**.
2. Create a reference to an .ini file if it does not exist.
3. In the **INI Files** explorer, right-click the .ini file that should contain the section and click **Add Section**.

InstallShield adds a section to the INI Files explorer. Configure the section's settings in the right pane. For details about each setting, see Section Settings for an .ini File.

After you have specified a section in your .ini file, you can add a keyword.

Specifying a Keyword in an .ini File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes .ini file functions for modifying .ini file data. You can use these functions in InstallScript projects.

The keywords in an .ini file are the lowest level of organization in the .ini file. Keywords store data that must persist between uses of an application.

Once you have added an .ini file to your project and set up one or more sections, you can add keywords to the sections and then configure the keyword's properties. The properties of a keyword include the value for the keyword, as well as the action that should be performed (such as replace a data value or append to an existing data value).

Task: ***To specify a keyword for an .ini file:***

1. In the View List under **System Configuration**, click **INI File Changes**.
2. In the **INI Files** explorer, right-click a section and click **Add Keyword**.

InstallShield adds a keyword to the INI Files explorer. Configure the keyword's settings in the right pane. For details about each setting, see Keyword Settings for an .ini File.

Reading Data from .ini Files

You can use the **GetProfString** function to read data (such as key names) from an .ini file, regardless of where the .ini file is located (for example, on a network). The following example script provides a guide:

```
/*

Assuming the .ini file is called Test.ini, and contains the following:

[ProductSettings]
Key1=One
Key2=2
Key3=III
Key4=....

[OtherSettings]
Key1=Value1
Key2=Value2

*/

function OnBegin( )
    STRING svKey1Value; // filled in by GetProfString
begin

// read a single value
GetProfString(
    "\\\\Server\\Config\\Test.ini", // file name; note the double
backslash for each "real" backslash
    "ProductSettings", // section name without square brackets
    "Key1", // key name
    svKey1Value); // STRING variable to capture key value

MessageBox("Key1's value is: " + svKey1Value, INFORMATION);

end;
```

Reading All Key Names from .ini Files

To read all of the key names from a section in an .ini file, use the following script:

```
function OnBegin( )
    STRING svAllKeyNames; // filled in by GetProfString
    LIST listKeyNames; // string list containing key names
begin

// read a single value
GetProfString(
    "\\\\Server\\Config\\Test.ini", // file name; note the double
backslash for each "real" backslash
```

```
    "ProductSettings", // section name without square brackets
    "", // key name; null string "" means to get all key names
    svAllKeyNames); // STRING variable to store key names

listKeyNames = ListCreate(STRINGLIST);

// take apart string containing key names
StrGetTokens(listKeyNames, svAllKeyNames, "");

SdShowInfoList("Key names", "Here they are:", listKeyNames);

// if desired, you can loop over the key names in the list and read each
key's value...

ListDestroy(listKeyNames);

end;
```

Configuring ODBC Resources

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

One of the more complex areas of system configuration involves setting up ODBC drivers, data source names (DSNs), and translators. The ODBC resource must be properly registered on the system with all of the required attributes and, in the case of drivers and translators, install the necessary files, including any installation .dll files. This process is simplified in the ODBC Resources view, in which you can select the drivers, data sources, and translators installed on your development system.

Installing ODBC Resources

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

- *MSI Database*
- *MSM Database*
- *Transform*

All of the ODBC drivers, data source names (DSNs), and translators registered on your system are displayed in the ODBC Resources view. DSNs are shown as children of their associated driver. Expand the explorer to view all of the existing ODBC resources.

To include an ODBC resource in your installation, select the check box next to its name in the ODBC Resources pane in the upper-left corner of the view. In installation projects, the resource must then be associated with at least one feature so that it can be installed. Then, you can set the attributes for the selected resource.

Including Additional ODBC Resources

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You can also install ODBC resources not listed in the explorer. Where you add them depends on the type of resource.

Task: ***To add a driver that is not listed in the ODBC Resources explorer in the ODBC Resources view:***

1. In the **ODBC Resources** explorer, right-click **Drivers and DSNs** and click **New Driver**.
2. Enter a new name for the driver, or press the F2 key later to rename it.
3. Select the check box next to the new driver to include it in your installation.

Task: ***To add a data source that is not listed in the ODBC Resources explorer in the ODBC Resources view:***

1. In the **ODBC Resources** explorer, right-click a driver and click **New DSN**.
2. Enter a new name for the DSN, or press the F2 key later to rename it.
3. Select the check box next to the new DSN to include it in your installation.

Note • *You cannot add a translator to the list. Instead, you must install it on the development system and then select it.*

Associating ODBC Resources with Features

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Like most of the data in your project, ODBC resources must be associated with a feature. When the feature is installed to the target system, the ODBC resource is installed as a part of the feature.

After you choose to install a driver, DSN, or translator for installation, the Features list is enabled on the right side of the ODBC Resources explorer. Select all of the features to which the ODBC resource belongs. InstallShield creates a new component and associates it with each selected feature. The resource will be installed only once even if it is associated with multiple features, but the resource cannot be installed if none of its features is installed.

In an InstallScript MSI project, if no other feature exists, the resource is added to the DefaultFeature. In a Basic MSI project, if a feature does not exist when you add an ODBC resource to your installation, the Create a New Feature dialog box is displayed. This dialog box prompts you to create a feature. If only one feature is associated with an ODBC resource, it cannot be deselected until you select at least one additional feature.

Setting ODBC Resource Attributes

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When an ODBC resource is registered on the development system, its current attributes are displayed in the Properties list of the ODBC Resources view. You can edit the attributes in the Properties pane after you have selected the driver, data source name (DSN), or translator.

Adding and Deleting New Attribute Entries

Note that adding attributes to a translator is not supported.

Task: ***To add a new attribute to a driver or DSN:***

1. Open the **ODBC Resources** view.
2. In the **ODBC Resources** explorer, click the driver or DSN that should contain the new attribute entry.
3. Click in the last row of the property sheet, and add the appropriate information for the **Property** and **Value** columns.

Task: ***To delete an attribute from a driver or DSN:***

1. Open the **ODBC Resources** view.
2. In the **ODBC Resources** explorer, click the driver or DSN that should contains the attribute entry that you want to delete.
3. In the property sheet, right-click the row that you want to delete and then click **Delete**.

Using Environment Variables

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The InstallScript language includes the GetEnvVar function for retrieving the current value of an environment variable, and it enables you to create an environment variable.

Environment variables are name and value pairs that can be set on the target system with your installation and can be accessed by your application and by other running programs. Environment variables are stored in the registry.

In the Environment Variables view, you can create, set (or modify), and remove environment variables on the target system through your installation. You can also specify environment variable properties in this view.

Setting Environment Variables

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The InstallScript language includes the GetEnvVar function for retrieving the current value of an environment variable, and it enables you to create an environment variable.

Task: ***To create a new environment variable or modify the value of an existing environment variable:***

1. In the View List under **System Configuration**, click **Environment Variables**.
2. Right-click the **Environment Variables** explorer and click **Add Environment Variable**.
3. InstallShield adds a new environment variable with the default name NewEnvironmentVariable*X* (where *X* is a number). Type the name of the variable that you want to modify, remove, or create.
4. In the pane on the right, configure the environment variable's settings. For details about each setting, see Environment Variable Settings.

Environment Variables Example

```
/***************************************************************\
*  The following code creates an environment variable under Windows
*  for an entire system. You can modify the OnEnd event handler
*  function block (or any other function block) to include this example
*  code.
*
*  NOTE: The current user must have administrator privileges for this
*  code to work.
\***************************************************************/

  #define WM_WININICHANGE 0x001A
  #define HWND_BROADCAST 0xffff
  NUMBER nResult;
  STRING szKey, szEnv;
  WPOINTER pEnv;

  begin

      szKey = "SYSTEM\\CurrentControlSet\\Control\\Session Manager\\Environment";
```

```
    RegDBSetDefaultRoot(HKEY_LOCAL_MACHINE);
    nResult = RegDBSetKeyValueEx(szKey, "Fame", REGDB_STRING, "C:\\Test", -1);
    if (nResult < 0) then
        MessageBox("Failed to Set Environment Variable", WARNING);
    else
        MessageBox("Successfully Set Environment Variable", INFORMATION);
        // Flush the registry to all applications.
        szEnv = "Environment";
        pEnv = &szEnv;
        SendMessage (HWND_BROADCAST, WM_WININICHANGE, 0, pEnv );
    endif;
    // RebootDialog("", "", SYS_BOOTMACHINE);
end;

/*****************************************************************\
*  The following code creates an environment variable under Windows
*  for the current user. You can modify the OnEnd event handler
*  function block (or any other function block) to include this example
*  code.
*
*  NOTE: The current user must have administrator privileges for this
*  code to work.
\*****************************************************************/

  #define WM_WININICHANGE 0x001A
  #define HWND_BROADCAST 0xffff

  NUMBER nResult;
  STRING szKey, szEnv;
  WPOINTER pEnv;

  begin
      szKey="Environment";
      RegDBSetDefaultRoot(HKEY_CURRENT_USER);
      nResult=RegDBSetKeyValueEx(szKey,"Fame",REGDB_STRING,"C:\\test",-1);
      if (nResult < 0) then
          MessageBox("Failed to Set Environment Variable",WARNING);
      else
          MessageBox("Successfully Set Environment Variable",INFORMATION);
          // Flush the registry to all applications.
          szEnv = "Environment";
          pEnv = &szEnv;
          SendMessage (HWND_BROADCAST, WM_WININICHANGE, 0, pEnv );
      endif;
      //RebootDialog("","",SYS_BOOTMACHINE);
  end;
```

Modifying XML Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

You may need to modify .xml files that store settings related to your product, or you may need to modify standard configuration files such as `web.config` and `machine.config`. InstallShield includes support for modifying XML files on the target system at run time. The XML files can be part of your installation, or they can be files that are already present on target systems.

For instructions on how to modify an XML file during installation, consult this section of the documentation.

For background information about XML, see the following Web sites:

- World Wide Web Consortium (http://www.w3.org)
- W3 Schools (http://w3schools.com)

Tip • *Support for XML files extends into other areas of InstallShield product functionality. The System Search feature in InstallShield enables you to search for an attribute value, contents, or existence of the element in the XML file that you specify. For more information, see Searching for XML Data.*

Overview of XML File Changes

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Design-Time Tasks

The XML File Changes view enables you to define modifications that should be made to an XML file at run time. The typical process for defining those modifications is as follows:

1. If the XML file that you are modifying is part of your installation, add the base XML file to a component in your project through the Files and Folders view.
2. In the XML File Changes view, create an XML file reference for the file that you want to modify.
3. Specify the location for the XML file on the target machine.
4. Specify which feature or features should contain the XML file changes. This may be the same feature that contains the component in step 1, or it may be a different feature.
5. Configure the changes that you want to occur at run time.

You may need to add an MSXML redistributable to your project. For more information, see Run-Time Requirements for XML File Changes.

Run-Time Behavior

The XML File Changes view enables you to configure run-time behavior such as the following:

- Add a namespace mapping to an XML file, and add namespace prefixes to elements and attributes.
- Create a specified element if it does not already exist.
- Modify an element if it exists, but do not create it if it does not exist.
- Modify only the first element in the XML file that matches the specified XPath expression, or modify all matching instances.
- Remove an element during uninstallation.
- Set content for an element.
- Create a new attribute during installation, during uninstallation, or both.
- Remove an existing attribute during installation, during uninstallation, or both.
- Append a string to an existing attribute value during installation, during uninstallation, or both.
- For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, and Transform projects: Replace Windows Installer properties in elements, attributes, attribute values, and element content with the appropriate values at run time.
- For InstallScript projects: Substitute InstallScript string variables for elements, attributes, attribute values, and element content with the appropriate values at run time.

When an installation that contains XML file changes runs on a target system, MSXML parses the XML file and executes the XPath expressions that are associated with the changes that you configured. The Advanced tab in the XML File Changes view for an XML file shows the XPath expressions that are executed on target systems.

When MSXML finds an area of the XML file that matches the XPath expression, the changes that were configured in the XML File Changes view are made.

For examples of how to create some basic XPath expressions, see Using XPath Expressions to Find XML Data in an XML File.

Note • *If the XML file does not exist on the target system at run time and the* ***Always create XML file if it does not already exist*** *check box is selected on the Advanced tab for the XML file, the XML file is created with the XML data that is configured in the XML File Changes view.*

Run-Time Requirements for XML File Changes

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

The run-time functionality for XML file changes requires the presence of Microsoft XML Core Services (MSXML) 3.0 or later on the target system.

When an installation that contains XML file changes runs on a target system, MSXML parses the XML file and executes the XPath expressions that are associated with the changes that you configured. When MSXML finds an area of the XML file that matches the XPath expression, the changes that were configured in the XML File Changes view are made.

InstallShield includes redistributables for different versions of MSXML. If it is possible that target systems may not have MSXML, or they may not have the appropriate version of MSXML, you can add the appropriate MSXML redistributable to your project in either the Redistributables view (for Basic MSI and InstallScript MSI projects) or the Prerequisites view (for InstallScript projects).

For detailed information about MSXML, see the MSDN Library.

Creating an XML File Reference

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

- *Merge Module*
- *MSI Database*
- *Transform*

The recommended way to add an XML file that you want to modify at run time is to add the base XML file to a component in your project through the Files and Folders view. Then add an XML file reference to the XML File Changes view, where you can specify the changes that should be made to that file at run time. The easiest way to add the XML file reference is to import the file into the XML File Changes view.

Important *• The XML File Changes view is not designed to list a node for every node in an XML file. To improve performance, the XML File Changes view should show only the settings that differ from the base XML file:*

- *If the XML file that you are modifying is part of your installation, the XML File Changes view should list only the nodes and node sets that should be added, changed, or deleted after the XML file is installed at run time.*
- *If the XML file that you are modifying is a file that is already present on the target system, the XML File Changes view should list only the nodes and node sets that need to be added, changed, or deleted at run time.*

Therefore, when you are importing a file, import only the nodes in the XML file that you want to modify at run time. Note that the XML File Changes view does not enable you to specify the order in which new elements should be listed in the XML file. Therefore, importing only the nodes that you want to modify at run time helps to avoid issues that may occur if your product requires that the elements be listed in a particular order.

Task: ***To import an XML file into the XML File Changes view:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. Right-click the **XML Files** explorer and then click **Import**. The **Import XML Settings Wizard** opens.
3. Complete the panels in the wizard, selecting only the XML file nodes that you want to change.
4. Click **Import**.

InstallShield adds a new node for the XML file that you imported. The XML file node contains each of the nodes that you selected in the wizard. Each node represents an XPath query that occurs at run time. InstallShield also adds a new component for the XML file that you have imported through the XML File Changes view.

Now you can configure the XML file's settings and specify any element, attribute, and content changes for it.

Tip *• You can also add an XML file by right-clicking the XML Files explorer and then clicking New File. However, in most cases, you may want to create your XML file in a third-party XML editor or text editor. Next, add this file to your project through the Files and Folders view. Then, import the file, as described in the aforementioned procedure, and configure the changes that should be made to the file at run time.*

Specifying the Location of the XML File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

When you add an XML file reference in the XML File Changes view, you need to specify the location of the XML file. If the XML file is part of your installation, the location should match the destination that you specified for the base XML file when you added it to your project through the Files and Folders view.

Task: ***To specify the location of the XML file on the target system:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the XML file whose location you want to specify.
3. Click the **General** tab.
4. In the **XML File Destination** area, click the **Browse** button. The **Browse for Directory** dialog box opens.
5. In the **Destination Directories** box, select the location.
6. Click **OK**.

InstallShield adds the destination that you specified to the **Specify the location of the XML file on the target machine** box.

Associating an XML File Change Reference with a Feature

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

When you add an XML file reference in the XML File Changes view, InstallShield automatically creates a new component for it. In addition, InstallShield associates the component with the feature that is at the top of your feature list by default. To change this association, you can use the XML File Changes view.

Note • *If your project does not contain any features when you add an XML file reference, InstallShield displays the Create a New Feature dialog box, which lets you to create a new feature.*

Task: ***To associate an XML file change reference with a feature in your project:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the file whose component you want to associate with a feature.
3. Click the **General** tab.
4. In the **Select Features the XML file belongs to** box, select the check box of any feature that should contain the selected XML file change reference. This may be the same feature that contains the base XML file that you added to your project through the Files and Folders view, or it may be a different feature.

If an end user chooses to install the feature that contains the XML file changes, the XML file changes are performed at run time.

Adding a Root Element

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

If you are adding an XML file reference in the XML File Changes view, you can add a root element. Note that an XML file can contain only one root element.

Task: ***To add a root element to an XML file:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the XML file to which you want to add a new root element and click **New Root Element**.

InstallShield adds the new root element. Use the tabs that are displayed in the right pane to configure its settings.

Tip • *To add a root element and one or more levels of subelements in one step, type the name of the root element plus the subelements, with each separated by a slash. For example, to add a root element called **Root**, a **Sub** element under the **Root** element, and a **Sub2** element under the **Sub** element, type the following:*

```
Root/Sub/Sub2
```

InstallShield automatically expands it in the explorer.

Adding a New Element

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

You can add a new element to the root element or any element in your XML file.

Task: ***To add a new element:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the XML file to which you want to add a new element and click **New Element**.

InstallShield adds the new element. Rename it as appropriate, and use the tabs that are displayed in the right pane to configure its settings.

Tip • *When you are adding elements and subelements under the root element in the XML File Changes view, you can type the full XPath expression for the name of the element, and it will automatically expand in the explorer.*

*To add a root element and one or more levels of subelements in one step, type the name of the root element plus the subelements, with each separated by a slash. For example, to add a root element called **Root**, a **Sub** element under the **Root** element, and a **Sub2** element under the **Sub** element, type the following:*

```
Root/Sub/Sub2
```

InstallShield automatically expands it in the explorer so that each element has its own node.

Adding an Element for a .NET Configuration File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

If you define .NET configuration settings for your product in a web.config file, you can specify those settings through the XML File Changes view.

Task: ***To add an element for a .NET configuration file:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the XML file to which you want to add a configuration element, click **Add Predefined Element**, point to **.NET Configuration Files**, point to **Web Configuration File**, point to a given set of settings, and click the appropriate command.

InstallShield adds the new element in the explorer.

For detailed reference information about the different elements and attributes in .NET configuration files, see Configuration File Schema on the MSDN Web site.

Adding an Attribute to an Element

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

You can add attributes to an element in your XML file and then specify whether the attribute should be created at run time, the attribute should be removed at run time, or the attribute value should be appended to the existing value at run time. You can also schedule whether the task should occur during installation, uninstallation, or both.

If an attribute that you add already exists in the XML file on the target machine but the attribute has a different value than the one that you specified in the XML File Changes view, the installation updates the value at run time.

Task: ***To add an attribute to an XML element:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the XML file to which you want to add an attribute.
3. Click the **General** tab.
4. Click the **Add** button.

InstallShield adds a new row—with default values for the Attribute, Value, Operation, and Scheduling columns—to the attribute table. Change any of the settings as needed. To learn more about each of the columns, see General Tab for an XML Element.

Tip • *If you configure your installation so that the XML file remains on the target system when its component is uninstalled, you may want to create installation/uninstallation attribute pairs in the attribute table.*

For example, to add a ***key*** *attribute during installation and remove that same* ***key*** *attribute during uninstallation, add two rows with the* ***key*** *attribute to the attribute table; schedule one row for installation, and the other for uninstallation.*

Editing an Attribute's Value

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

InstallShield enables you to edit the value of an attribute if it is already present on the target machine at run time. To do so, add the attribute to the element in the XML File Changes view, and configure the value for the attribute as needed. The procedure for editing an attribute value is the same as adding an attribute value. To learn more, see Adding an Attribute to an Element.

At run time, if a different value exists for the attribute, the installation replaces the value with the one that you configured in the XML File Changes view.

Adding Content to an Element

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

XML elements can contain text content. For example, in the following XML code, **feature** is the content for the element **product**:

```
<product>feature</product>
```

Task: ***To add content to one of the elements listed in the XML File Changes view:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, select the element to which you want to add content.
3. Select the **Advanced** tab.
4. Select the **Set element content** check box.
5. In the **Content** box, type the text content.

   When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (...) next to this setting to select an existing string. For more information, see Using String Entries in InstallShield.

Using XPath Expressions to Find XML Data in an XML File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

- *Transform*

In order for your installation to add a new element or attribute to an XML file, or to perform some other change to an XML file at run time, MSXML must use the XPath expressions that are defined in the XML File Changes view to navigate through the XML file and locate the areas that need to be modified.

For detailed information about writing XPath expressions, see the following Web sites:

- World Wide Web Consortium (http://www.w3.org)
- W3 Schools (http://w3schools.com)

The following sections show examples of how to create some basic XPath expressions.

Example 1: Adding Two Elements

In example 1, the installation adds the bold lines in the following XML document:

```
<?xml version="1.0" encoding="UTF-8"?>
<Books>
   <Biographies>
      <Book Author="Bill Smith" Copyright="2007">Bill's Great Biography</Book>
      <Book Author="John Smith" Copyright="2006">John's Great Biography</Book>
   </Biographies>
</Books>
```

To add those elements, the following XPath expressions are added under the Biographies node in the XML File Changes view:

```
Book[@Author="John Smith"]
Book[@Author="Bill Smith"]
```

The following screen shots show the settings in the XML File Changes view.

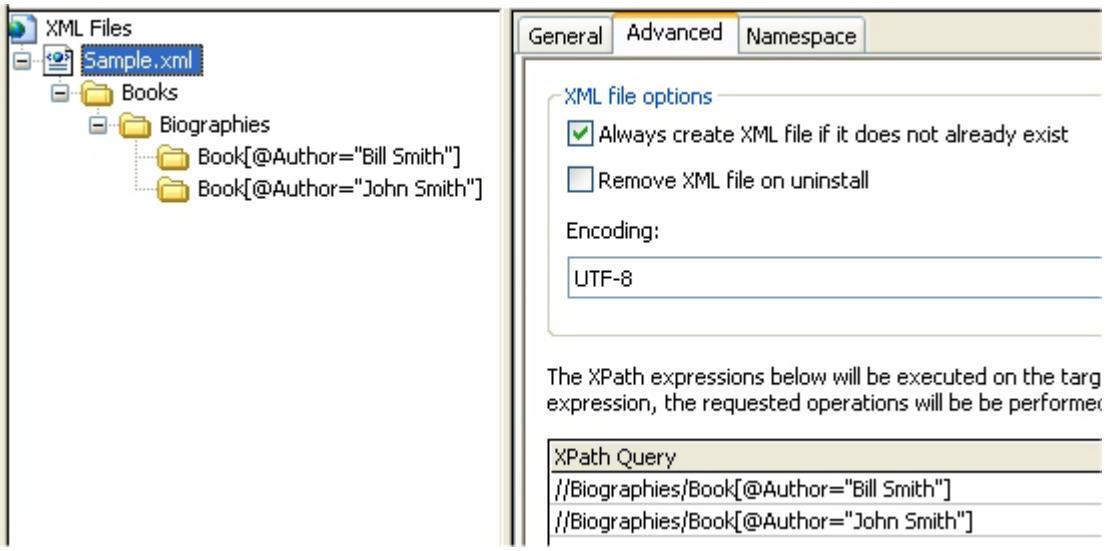

Figure 4-1: Settings for the Sample.xml File

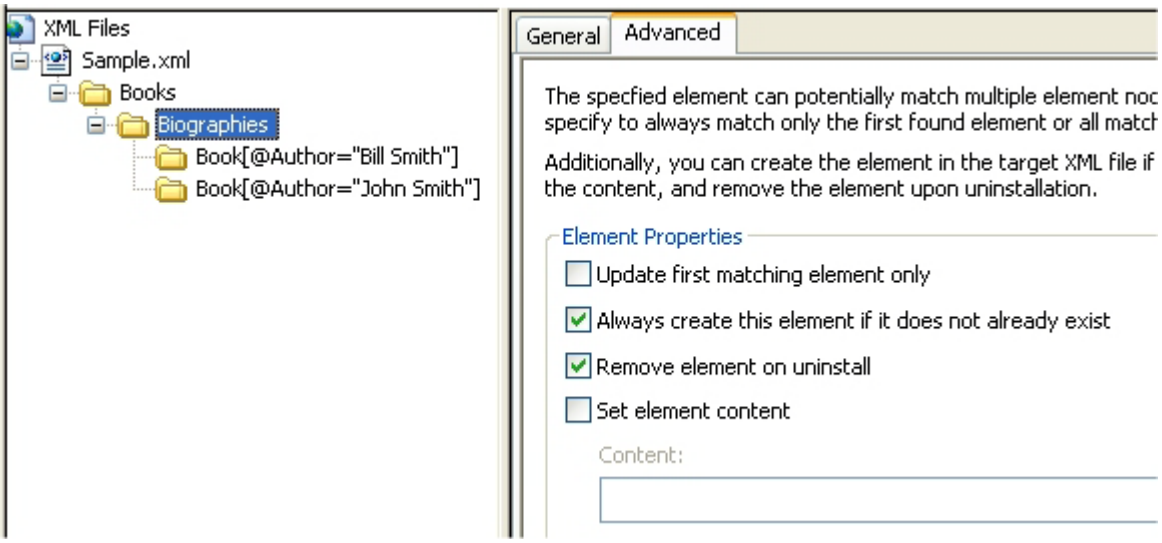

Figure 4-2: Settings for the Biographies Node, which Contains the Child Nodes to Be Added

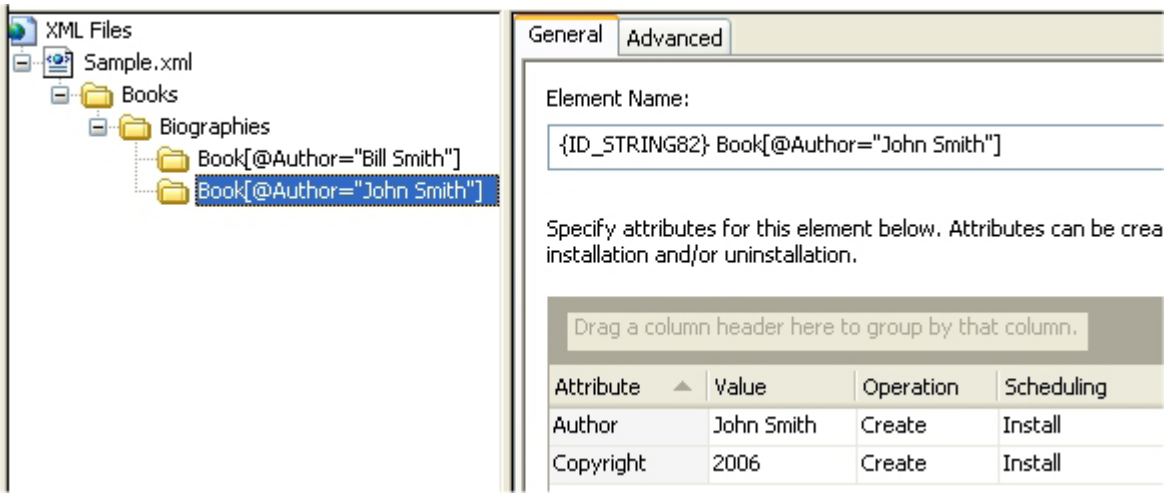

Figure 4-3: General Settings for One of the Child Nodes to Be Added

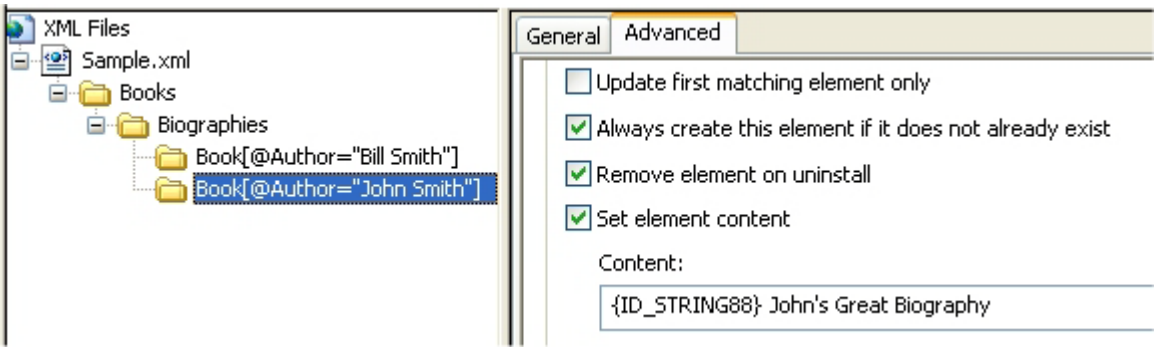

Figure 4-4: Advanced Settings for One of the Child Nodes to Be Added

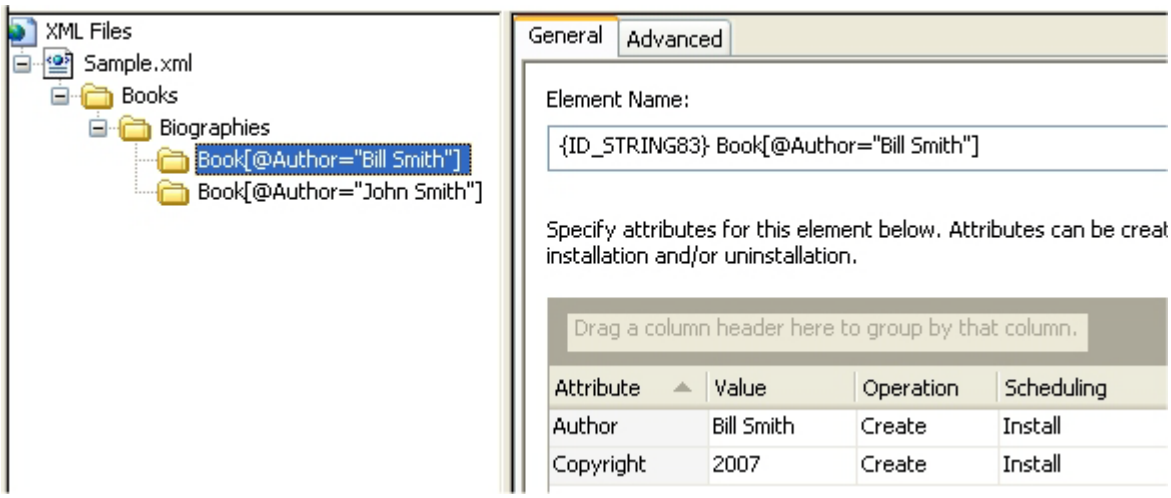

Figure 4-5: General Settings for One of the Child Nodes to Be Added

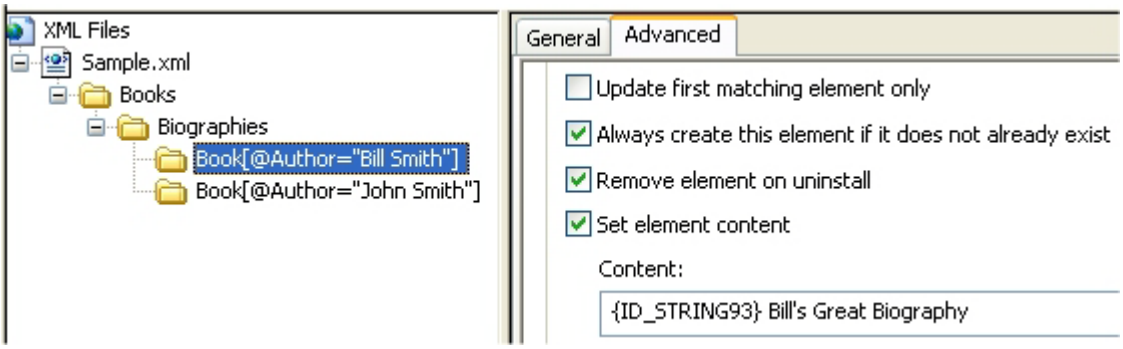

Figure 4-6: Advanced Settings for One of the Child Nodes to Be Added

Example 2: Adding Attributes to Elements

In example 2, the installation adds the bold attributes and values in the following XML document:

```
<?xml version="1.0" encoding="UTF-8"?>
<Books>
   <Biographies>
      <Book Author="Bill Smith" Copyright="2007" Publisher="Bill & John's Publish Co.">Bill's Great
Biography</Book>
      <Book Author="John Smith" Copyright="2006" Publisher="Bill & John's Publish Co.">John's Great
Biography</Book>
   </Biographies>
</Books>
```

The following screen shot shows the settings in the XML File Changes view.

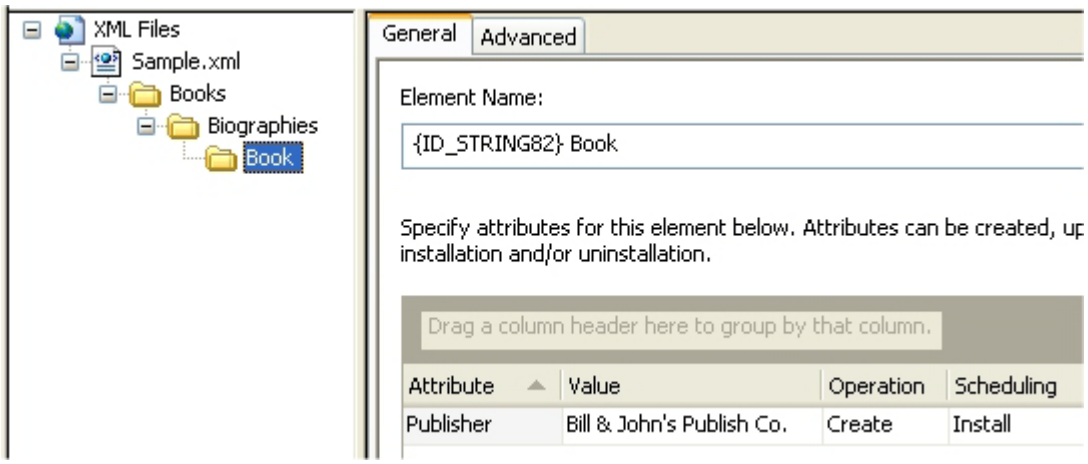

Figure 4-7: Settings for the Book Node

Example 3: Updating an Attribute's Value

In example 3, the installation searches for the attribute that has the 2006 Copyright value (as shown in bold in the following XML document) and replaces its value with a 2007 Copyright value:

```
<?xml version="1.0" encoding="UTF-8"?>
<Books>
   <Biographies>
      <Book Author="Bill Smith" Copyright="2007" Publisher="Bill & John's Publish Co.">Bill's Great
Biography</Book>
      <Book Author="John Smith" Copyright="2006" Publisher="Bill & John's Publish Co.">John's Great
Biography</Book>
   </Biographies>
</Books>
```

To update the value, the following XPath expression is added under the Biographies node in the XML File Changes view:

```
Book[@Copyright="2006"]
```

The following screen shot shows the settings in the XML File Changes view.

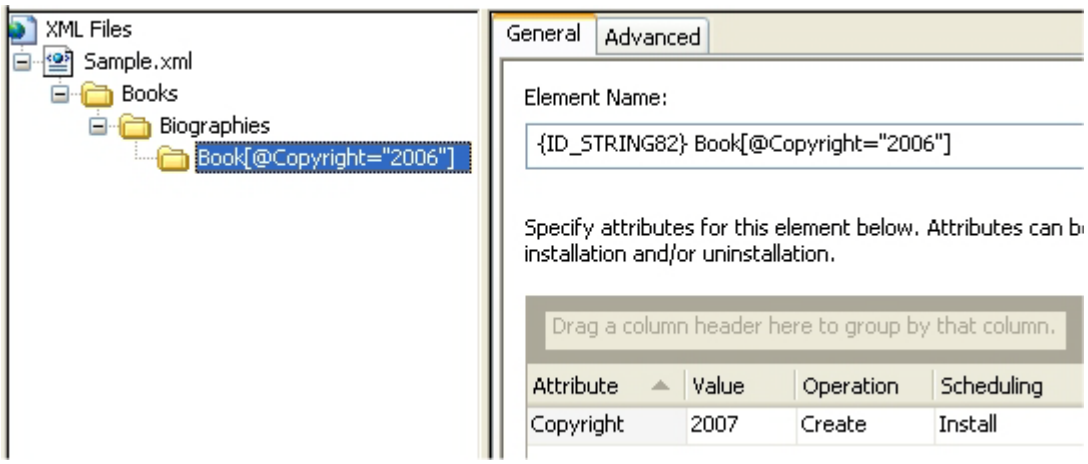

Figure 4-8: General Settings for the Attribute to Be Updated

Using Windows Installer Properties to Dynamically Modify XML Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, and Transform projects, you can use a Windows Installer property to specify an XML element, an attribute, an attribute value, or an element's content. At run time, Windows Installer uses **MsiFormatRecord** to resolve the property value, and it uses that value as the data in your XML file. This enables you to use data that end users enter in dialogs, or other configuration information that is determined during the installation, in your product's XML files.

For example, your installation may include the SQL Login dialog, which lets end users select a SQL Server. The name of the server that they select is typically stored in the **IS_SQLSERVER_SERVER** property. If you want an XML file to contain the name of the SQL server that an end user selects, you can use this property, surrounded by brackets (that is, **[IS_SQLSERVER_SERVER]**), when you configure your XML file changes in the XML File Changes view. Then at run time, Windows Installer automatically replaces the property with its associated value.

Tip • *Use a Windows Installer property for an element, an attribute, or element content only if the value of the property would make a well-formed XML document. If a property value would lead to syntax errors in the XML document, your product or installation may not behave as expected.*

*For example, if you set the name of an element to **[INSTALLDIR]**—a Windows Installer property whose value is a path on the target system—the result at run time is an element name that contains backslashes. Element names cannot contain backslashes, and XML documents that contain element names with backslashes are not valid.*

***Note** • If test your XML file from within the XML File Changes view, any Windows Installer properties that are used for XML data are not replaced with the appropriate values during testing. For more information about testing, see Testing Installation Changes to an XML File or Testing Uninstallation Changes to an XML File.*

Example

The following procedure demonstrates how to use the name of the SQL Server that an end user selects in the SQL Login dialog as the content for one of the elements in your XML file. Note that you can substitute a hard-coded value with a property for any of the elements, attributes, attribute values, or element content in the XML File Changes view. The property that you specify in this view must be enclosed within square brackets, and the property name must be in all uppercase letters; for example, **[MYPROPERTY]**.

Task: ***To use the name of the SQL Server that end users select as the content for an XML element:***

1. Configure the SQL connection and any associated SQL scripts if you have not already done so, and determine the name of the server property name:
   a. In the View List under **Server Configuration**, click **SQL Scripts**.
   b. Add a SQL connection and SQL scripts as needed. For instructions, see Configuring SQL Support.
   c. In the **SQL Scripts** explorer, click the SQL connection.
   d. Click the **Advanced** tab.
   e. Note the name that is selected for the **Target Server Property Name** setting. The default value is typically **IS_SQLSERVER_SERVER**.
2. In the View List under **System Configuration**, click **XML File Changes**.
3. In the **XML Files** explorer, select the element to which you want to add content.
4. Select the **Advanced** tab.
5. Select the **Set element content** check box.
6. In the **Content** box, type the name that is selected in step 1e, and enclose it within brackets. For example:

   ```
   [IS_SQLSERVER_SERVER]
   ```

7. Build your release.

Using InstallScript Text Substitution to Dynamically Modify XML Files

Project • *This information applies to InstallScript projects.*

For InstallScript projects, you can use a text substitution string variable for an XML element, an attribute, an attribute value, or an element's content. When the XML file changes occur at run time, the InstallScript run-time code uses the **TextSubSubstitute** function to replace the string variable with the appropriate value. This enables you to use data that end users enter in dialogs, or other configuration information that is determined during the installation, in your product's XML files.

Tip • *Use text substitution for an element, an attribute, or element content only if the value of the property would make a well-formed XML document. If a property value would lead to syntax errors in the XML document, your product or installation may not behave as expected.*

For example, if you set the name of an element to a text substitution string variable that will be replaced with text that includes one or more spaces, end users may have problems with your product or your installation. Element names cannot contain spaces, and XML documents that contain element names with spaces are not valid.

Note • *If test your XML file from within the XML File Changes view, any text substitution string variables that are used for XML data are not replaced with the appropriate values during testing. For more information about testing, see Testing Installation Changes to an XML File or Testing Uninstallation Changes to an XML File.*

Example

The following procedure demonstrates how to use the name of the SQL Server that an end user selects in the SQL Login dialog as the content for one of the elements in your XML file. Note that you can substitute a hard-coded value with a text substitution string variable for any of the elements, attributes, attribute values, or element content in the XML File Changes view. The string variable that you specify in this view must be enclosed within angle brackets; for example, **<MYPROPERTY>**. The string variable that you specify is case-sensitive.

Task: ***To use the name of the SQL Server that end users select as the content for an XML element:***

1. Configure the SQL connection and any associated SQL scripts if you have not already done so:
   a. In the View List under **Server Configuration**, click **SQL Scripts**.
   b. Add a SQL connection and SQL scripts as needed. For instructions, see Configuring SQL Support.
2. In the View List under **System Configuration**, click **XML File Changes**.
3. In the **XML Files** explorer, select the element to which you want to add content.
4. Select the **Advanced** tab.
5. Select the **Set element content** check box.

6. In the **Content** box, type the following:

   ```
   <MYPROPERTY>
   ```

7. In the View List under **Behavior and Logic**, click **InstallScript**.

8. Find the dialog code in the OnSQLLogin event for the SQL Login dialog that contains the SQL Server control, and add a call to the InstallScript function **TextSubSetValue**. For example:

   ```
   // Display login dialog (without connection name)
   // COMMENT OUT TO SWAP DIALOGS
   nResult = SQLServerSelectLogin2( szConnection, szServer, szUser, szPassword, bWinLogin, szDB,
   FALSE, TRUE );
   TextSubSetValue("<MYPROPERTY>", szServer, TRUE);
   ```

9. Build your release.

Using Reserved Characters (<, >, &, ', and ") Inside Elements

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

If you use a reserved character such as a less than symbol (<) inside an XML element, the MSXML parser converts it at run time on target systems to its predefined entity (<). Using the less than symbol instead of its entity would generate an error because XML parsers would interpret it as the start of a new element, and it would result in invalid XML code. Note that if you open the resulting XML file in a browser such as Internet Explorer, the character—not its entity—is displayed inside the XML element.

The following table lists the reserved XML characters and their entity equivalents. The table also indicates whether each reserved character is replaced by its entity at run time.

Table 4-8 • Reserved Characters and Their Predefined Entities

Character	Entity	Description	Notes
<	<	Less than	This character cannot be used as content in an XML element because it is reserved to be used to indicate the start of an XML element. This character is automatically replaced by its entity at run time.

Table 4-8 • Reserved Characters and Their Predefined Entities (cont.)

Character	Entity	Description	Notes
>	>	Greater than	This character is automatically replaced by its entity at run time.
&	&	And	This character cannot be used as content in an XML element unless it indicates the start of an entity. If this character is used as content in an XML element but it does not indicate the start of an entity, it is automatically replaced by its entity at run time.
'	'	Apostrophe	This character is not automatically replaced by its entity at run time.
"	"	Quotation mark	This character is not automatically replaced by its entity at run time.

Using Namespaces in XML Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

XML namespaces provide a method for avoiding element name conflicts. When you are specifying XML file changes in InstallShield, you can specify the namespace mappings that should be declared in the XML file and then specify namespace prefixes for any of the file's elements.

Tip • *If you use the Import XML Settings Wizard to import an XML file into the XML File Changes view, InstallShield imports any namespaces that are declared for the file.*

Declaring Namespace Mappings for an XML File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

You can declare namespace mappings for an XML file in the XML File Changes view.

Task: ***To declare a namespace mapping for an XML file:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the XML file that should contain the namespace.
3. Click the **Namespace** tab.
4. Click a row in the table to add a new namespace.
5. In the **Prefix** column, type the prefix that should be used for any elements that are associated with the corresponding namespace.
6. In the **URI** column, type a URL or a string of characters that identifies the Internet resource.

Adding a Namespace Prefix to an Element

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

If you have declared a namespace mapping for an XML file, you can associate any element in the file with that namespace by adding the corresponding prefix to the element.

Task: ***To add a namespace prefix to an element:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the element to which you want to add a prefix and then do one of the following:
   - To add a prefix to only the selected element, point to **Namespace Prefix**, and then click to the appropriate namespace mapping.
   - To add a prefix to the element and all of its subelements, point to **Namespace Prefix (include all subelements)**, and then click to the appropriate namespace mapping.

InstallShield adds the prefix to the element (and all of its subelements, if appropriate) in the XML Files explorer.

Tip • *You can also add a namespace prefix by right-clicking an element, clicking Rename, and adding the prefix and the colon (:) before the element name.*

Adding a Namespace Prefix to an Attribute

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

If you have declared a namespace mapping for an XML file, you can associate any attribute in the file with that namespace by adding the corresponding prefix to the attribute.

Task: ***To add a namespace prefix to an attribute:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the element that contains the attribute.
3. In the right pane, click the **General** tab.
4. In the grid, double-click the attribute to which you want to add the prefix, and then place the cursor at the start of the attribute name.

5. Add the prefix and a colon (:) before the attribute name.

Removing a Namespace Prefix from an Attribute

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Task: ***To remove a namespace prefix from an attribute:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the element that contains the attribute.
3. In the right pane, click the **General** tab.
4. In the grid, double-click the attribute from which you want to remove the prefix, and then place the cursor at the start of the attribute name.
5. Delete the prefix and a colon (:) before the attribute name.

Removing a Namespace Prefix from an Element

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Task: ***To remove a namespace prefix from an element:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the element whose prefix you want to remove, and then do one of the following:
   - To remove the prefix from only the selected element, point to **Namespace Prefix**, and then click **<None>**.
   - To remove the prefix from the element and all of its subelements, point to **Namespace Prefix (include all subelements)**, and then click **<None>**.

InstallShield removes the prefix from the element (and all of its subelements, if appropriate) in the XML Files explorer.

Removing Namespace Mappings from an XML File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Task: ***To remove a namespace mapping from an XML file:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, click the XML file that contains the namespace that you want to remove.
3. Click the **Namespace** tab.
4. Click the row that contains the namespace mapping that you want to remove, and then click the **Delete** button.

InstallShield removes the namespace from the table.

Testing Installation Changes to an XML File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

InstallShield enables you to test just the XML file changes that are configured for your project through the XML File Changes view without requiring you to build and run your entire installation. When you test the installation changes, InstallShield uses the latest version of MSXML that you have on your machine to parse the XML file and execute the XPath expressions that you configured. When MSXML finds an area of the XML file that matches the XPath expression, the changes that were configured in the XML File Changes view are made.

Note • *If your XML file changes include Windows Installer properties or InstallScript text substitutions, they are not replaced with the appropriate values during testing.*

Task: ***To test installation changes to an XML file:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the XML file that you want to test and then click **Test XML File Install Changes**. The **Select Test XML File** dialog box opens.
3. In the **File name** box, select the target file to which you want the installation changes applied, or specify a new target file name and location:
   - If you are modifying an XML file that is installed as part of your installation, select a copy of that file. (Do not select the actual file in your installation because testing the XML installation changes would modify it.)
   - If you are modifying an XML file that already exists on the target system, select a copy of that file.
   - To test what happens if the XML file does not exist at run time and it is not installed as part of your installation, specify a new file name and location.

   The default file name is the name of the test file that you right-clicked in step 2.
4. Click **Open**.

If the target file already exists, InstallShield applies the changes from the test file to the target file. If the target file that you specified does not exist and the **Always create XML file if it does not already exist** check box is selected on the Advanced tab for the XML file, InstallShield creates the file and applies the changes from the test file.

InstallShield displays details about the installation test on the Results tab of the Output window. The details include a hyperlink to the test file.

Tip • *If the target file is open in a browser window when you perform the testing, you may need to refresh the browser to see the test changes.*

Testing Uninstallation Changes to an XML File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

After you have tested the XML file installation changes that you have configured through the XML File Changes view, you may want to test the XML file changes that occur during uninstallation. This enables you to determine whether the changes that you configured behave as you expected during uninstallation.

When you test the uninstallation changes, InstallShield uses the latest version of MSXML that you have on your machine to parse the XML file and execute the XPath expressions that you configured. When MSXML finds an area of the XML file that matches the XPath expression, the changes that were configured in the XML File Changes view are made.

Note • *If your XML file changes include Windows Installer properties or InstallScript text substitutions, they are not replaced with the appropriate values during testing.*

Task: ***To test uninstallation changes to an XML file:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the XML file that you want to test and then click **Test XML File Uninstall Changes**. The **Select Test XML File** dialog box opens.

3. In the **File name** box, select the target file to which you want the uninstallation changes applied.

   The default value is the name of the file whose installation changes you last tested.

4. Click **Open**.

InstallShield applies the uninstallation changes that are configured in the XML File Changes view to the test file.

InstallShield displays details about the uninstallation test on the Results tab of the Output window. The details include a hyperlink to the test file. Note that if you have configured the XML file to be removed during uninstallation, the hyperlink may not work, since the file may no longer be present.

Tip • *If the target file is open in a browser window when you perform the testing, you may need to refresh the browser window to see the test changes.*

Removing an Element or an XML File from the XML File Changes View

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Task: ***To remove an element or an XML file from the XML File Changes view:***

1. In the View List under **System Configuration**, click **XML File Changes**.
2. In the **XML Files** explorer, right-click the XML file or XML element that you want to remove and click **Delete**.

If you delete an XML file, InstallShield displays a message that explains that the component associated with the XML file will be deleted along with the file itself.

Modifying Text Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

InstallShield enables you to configure search-and-replace behavior for content in text files—for example, .txt, .htm, .xml, .config, .ini, and .sql files—that you want to modify at run time on the target system. The text files can be part of your installation, or they can be files that are already present on target systems.

The Text File Changes view is where you define the changes that you want to be made to the text files. This view lets you do the following:

- Add one or more text replacement sets to your project. A text replacement set is a reference to one or more text files that you want to search at run time.
- Add one or more text replacement items to a text replacement set. A text replacement item identifies the search-and-replace criteria.

Task: ***To configure text file changes:***

1. Create a text file reference.
2. Specify the search-and-replace criteria for the text file.

For more information on how to modify a text file at run time, consult this section of the documentation.

Creating a Text File Reference

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

The first step in configuring text file changes is to create a reference to the file that you would like to edit. The file can be any non-binary file—for example, a .txt, .htm, .xml, .config, .ini, or .sql file. The file can be part of your installation (that is, one that you added to your project in the Files and Folders view), or it can be a file that is already present on target systems.

Note • *Each text file reference must be associated with a component in your project. Therefore, before you can create a text file reference, your project must have at least one component. If no components exist when you are creating a text file reference, the Create a New Component dialog box is displayed, enabling you to create a component.*

Task: ***To create a reference to one or more text files that you want to change at run time:***

1. In the View List under **System Configuration**, click **Text File Changes**.
2. Right-click the **Text File Changes** explorer and then click **Add Replacement Set**.

   InstallShield adds a new replacement set item with a default name.
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.

   The name is not displayed at run time; it is an internal name that is used to differentiate between various replacement sets in your project.
4. In the right pane, configure the settings for the replacement set. For details about each setting, see Replacement Set Settings.

After you have created a reference to a text file and configured its settings, you can move on to the next step, which is to specify the search-and-replace criteria.

Tip • *You can use Windows Installer public properties to specify the names of the text files that you want to include in or exclude from your search. This enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's text files are modified at run time. To learn more, see Using Windows Installer Properties to Dynamically Modify Text Files.*

Specifying Search-and-Replace Criteria for a Text File Change

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

Once you have specified the text file that you would like to edit, you can move onto the next step of configuring text file changes: specifying the search-and-replace criteria. Each set of criteria is known as a *replacement item*.

Task: ***To specify the search-and-replace criteria for a text file change:***

1. In the View List under **System Configuration**, click **Text File Changes**.
2. In the **Text File Changes** explorer, right-click the replacement set item whose search-and-replace criteria you want to define, and then click **Add Replacement**.

   InstallShield adds a new replacement item with a default name.
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.

   The name is not displayed at run time; it is an internal name that is used to differentiate between various replacement items in your project.
4. In the right pane, configure the settings for the replacement. For details about each setting, see Replacement Set Settings.

To modify additional strings in the text file, add additional replacement items to the replacement set in this view—one for each string change.

Tip • *You can use Windows Installer public properties to specify the search strings and the replacement strings. This enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's text files are modified at run time. To learn more, see Using Windows Installer Properties to Dynamically Modify Text Files.*

Changing the Order in Which Text File Changes Are Made

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

Text file changes are made on the target system in the order in which they are listed in the Text File Changes view.

Task: ***To change the order in which text file changes are made at run time:***

1. In the View List under **System Configuration**, click **Text File Changes**.
2. In the **Text File Changes** explorer, right-click one of the replacement set items or replacement items that you want to move, and then click either **Move Up** or **Move Down**.

Repeat the last step until all of the text file changes are correctly sorted.

Using Windows Installer Properties to Dynamically Modify Text Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

You can use a Windows Installer property to specify text strings for which you are searching or replacing. You can also use a property to specify the text files that you are including or excluding in your search.

At run time, Windows Installer uses **MsiFormatRecord** to resolve the property value, and it uses that value to modify your text file. This enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's text files are modified at run time.

Example

The following procedure demonstrates how to let end users specify during installation an IP address that must be written to an XML-based `web.config` file at run time. The `web.config` file is installed with the product to **INSTALLDIR**, and it contains XML such as the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration>
    <appSettings>
        <add key="IP Address" value="default" />
    </appSettings>
</configuration>
```

The default value in bold must be replaced by the IP address that an end user enters.

Note that you can substitute a hard-coded value with a property for the following replacement set settings in the Text File Changes view:

- Include Files

- Exclude Files

In addition, you can use a property for the following replacement item settings in the Text File Changes view:

- Find What
- Replace With

The property that you specify in any of these settings must be enclosed within square brackets, and the property name must be all uppercase; for example, **[MYPROPERTY]**.

Step 4 of the procedure is slightly different, depending on the project type, since Windows Installer controls the user interface of Basic MSI installations, and the InstallScript engine controls the user interface of InstallScript MSI installations.

Task: ***To let end users specify the IP address:***

1. In the View List under **System Configuration**, click **Text File Changes**.
2. Add and configure a replacement set item, which identifies the file for which you want the installation to search:
   a. Right-click the **Text File Changes** explorer and then click **Add Replacement Set**.

      InstallShield adds a new replacement set item. Steps 2b through 2d explain how to configure its settings, which are displayed in the right pane.

   b. In the **Target Folder** setting, select the **[INSTALLDIR]** directory property.

   c. In the **Include Files** setting, enter the following:

      ```
      web.config
      ```

   d. Leave the default values for the other settings.
3. Add and configure a replacement item, which identifies the search-and-replace criteria:
   a. In the **Text File Changes** explorer, right-click the replacement set item that you created in step 2, and then click **Add Replacement**.

      InstallShield adds a new replacement item. Steps 3b through 3d explain how to configure its settings, which are displayed in the right pane.

   b. In the **Find What** setting, enter the following:

      ```
      <add key="IP Address" value="default"
      ```

   c. In the **Replace With** setting, enter the following:

      ```
      <add key="IP Address" value="[MYPROPERTY]"
      ```

   d. Leave the default values for the other settings.
4. Use the property in a dialog. This part of the procedure depends on which project type you are using.
   - For Basic MSI projects:

a. In the View List under **User Interface**, click **Dialogs**.

b. In the **Dialogs** explorer, expand the **All Dialogs** folder, and click the language under the dialog that should contain the User Name control. As an alternative, you can add a new dialog.

c. Add an **Edit Field** control to the dialog, and set its **Property** property to the following:

```
MYPROPERTY
```

- For InstallScript MSI projects:

a. In the View List under **Behavior and Logic**, click **InstallScript**.

b. Find the dialog code in the OnFirstUIBefore event for the dialog that should contain the User Name control, and add a call to the Windows Installer API function **MsiSetProperty**. For example, if you want end users to enter the IP address in an edit box on the SdShowDlgEdit1 dialog that you have added to your project, you would add an **MsiSetProperty** call as shown in the following lines of code:

```
Dlg_SdShowDlgEdit1:
    nResult = SdShowDlgEdit1 (szTitle, szMsg, szField1, svEdit1);
    MsiSetProperty (ISMSI_HANDLE, "MYPROPERTY", svEdit1);
    if (nResult = BACK) goto Dlg_SdWelcome;
```

5. Build your release.

Tip • *If you are creating a multilanguage project and you want to use a property that can have different values based on the language that your installation uses, you can use a localizable property. For more information, see Creating a Localizable Property.*

Specifying the Code Page that Should Be Used for Opening ANSI Text Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

When an installation opens an ANSI text file to make the changes that are configured in the Text File Changes view, the installation uses the code page that is specified in the CodePage column of the **ISSearchReplaceSet** table of your project. The default value of this column is the number 0, which is CP_ACP, the code page that is currently configured to be the system Windows ANSI code page on the target system. You can use the Direct Editor view to override this value with a specific code page.

Task: ***To override the default code page that should be used to open an ANSI text file:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, click the **ISSearchReplaceSet** table. InstallShield displays the table in the right pane.
3. In the grid, find the row that corresponds with the replacement set item whose code page you want to configure.

   The ISSearchReplaceSet column in this grid shows all of the names of the replacement sets that are available in the **Text File Changes** explorer in the **Text File Changes** view.
4. Change the value of the **CodePage** field in the appropriate row.

Removing a Replacement Item or a Replacement Set from the Text File Changes View

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

This information does not apply to InstallScript projects; however, the InstallScript language includes string functions for finding and modifying string variables and literals. You can use these functions in InstallScript projects.

If you no longer want a particular search-and-replace task to be performed for a text file, you can remove its replacement item from the Text File Changes view. In addition, if you no longer want a file or group of text files to be searched, you can remove the corresponding replacement sets from the Text File Changes view.

Task: ***To remove a replacement item or a replacement set from the Text File Changes view:***

1. In the View List under **System Configuration**, click **Text File Changes**.
2. In the **Text File Changes** explorer, right-click the replacement set item or replacement item that you want to remove, and then click **Delete**.

InstallShield removes the item from the Text File Changes view.

Scheduling Tasks

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

You can have your installation create and configure automated tasks through the Windows task scheduler at run time on target systems. The scheduled tasks can launch files that are part of your installation, or files that are already present on target systems.

Adding a Scheduled Task

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Note • *Each scheduled task must be associated with a component in your project. Therefore, before you can add a scheduled task, your project must have at least one component. If no components exist when you are adding a scheduled task, the Create a New Component dialog box is displayed, enabling you to create a component.*

Task: ***To add a scheduled task to your project:***

1. In the View List under **System Configuration**, click **Scheduled Tasks**.
2. Right-click the **Scheduled Tasks** explorer and then click **Add Scheduled Task**. InstallShield adds a new task with a default name.
3. Enter a new name, or right-click it later and click **Rename** to give it a new name.

The name is not displayed at run time; it is an internal name that is used to differentiate between various scheduled tasks in your project.

4. In the right pane, configure the settings for the task. For details about each setting, see Scheduled Tasks Settings.

Using Windows Installer Properties to Dynamically Configure a Scheduled Task

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

You can use a Windows Installer property to specify information such as the account information that should be used to run the file that a scheduled task launches.

At run time, Windows Installer uses **MsiFormatRecord** to resolve the property value, and it uses that value to configure your scheduled task. This enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's scheduled tasks are created at run time.

Example

The following procedure demonstrates how to let end users specify during installation an account and password that should be used to run the scheduled task. The properties that you specify must be enclosed within square brackets, and the property names must be all uppercase; for example, **[MYPROPERTY]**.

Step 4 of the procedure is slightly different, depending on the project type, since Windows Installer controls the user interface of Basic MSI installations, and the InstallScript engine controls the user interface of InstallScript MSI installations.

Task: ***To let end users specify account and password information for the scheduled task:***

1. In the View List under **System Configuration**, click **Scheduled Tasks**.
2. In the **Scheduled Tasks** explorer, select the task that you want to configure.
3. In the **Run As** setting, enter the following:

   ```
   [DOMAINNAME]\[USERNAME]
   ```

4. In the **Password** setting, enter the following:

[PASSWORD]

5. Use the properties in a dialog. This part of the procedure depends on which project type you are using.
   - For Basic MSI projects:
     a. In the View List under **User Interface**, click **Dialogs**.
     b. In the **Dialogs** explorer, expand the **All Dialogs** folder, and click the language under the dialog that should contain Domain Name, User Name, and Password controls. As an alternative, you can add a new dialog.
     c. Add an **Edit Field** control to the dialog, and set its **Property** property to the following:

        DOMAINNAME

     d. Repeat step 5c for the USERNAME and PASSWORD properties.
   - For InstallScript MSI projects:
     a. In the View List under **Behavior and Logic**, click **InstallScript**.
     b. Find the dialog code in the OnFirstUIBefore event for the dialog that should contain the Domain Name, User Name, and Password controls, and add a call to the Windows Installer API function **MsiSetProperty**. For example, if you want end users to enter the information in edit boxes on the **SdShowDlgEdit3** dialog that you have added to your project, you would add **MsiSetProperty** calls as shown in the following lines of code:

```
Dlg_SdShowDlgEdit3:
    nResult = SdShowDlgEdit3
        (szTitle, szMsg, szField1, szField2, szField3, svEdit1, svEdit2, svEdit3);
    MsiSetProperty (ISMSI_HANDLE, "DOMAINNAME", svEdit1);
    MsiSetProperty (ISMSI_HANDLE, "USERNAME", svEdit2);
    MsiSetProperty (ISMSI_HANDLE, "PASSWORD", svEdit3);
    if (nResult = BACK) goto Dlg_SdWelcome;
```

6. Build your release.

Removing a Scheduled Task

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *Transform*

Task: ***To remove a scheduled task from your project:***

1. In the View List under **System Configuration**, click **Scheduled Tasks**.
2. In the **Scheduled Tasks** explorer, right-click the task that you want to remove and then click **Delete**.

InstallShield removes the task from your project.

Installing, Controlling, and Configuring Windows Services

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Windows services are executable files that Windows–based systems run in the background to manage various system tasks, even if no user is currently logged in. A service is an executable file, but it must be designed as a service; you cannot automatically use an arbitrary executable file as a service. Windows services can be installed to run every time that the system starts or on demand when needed. InstallShield enables you to install new Windows services and configure existing services. Windows has a Services administrative tool with which you can view and configure the services that are installed on a system.

You can use the Services view to configure a component that installs, starts, stops, or deletes a service during installation or uninstallation. You can also use this view to configure extended service customization options that are available with Windows Installer 5. As an alternative to using the Services view, you can use the Services area under the Advanced Settings node of the Components view or the Setup Design view. If you configure service information in any of these areas, the other areas are automatically updated accordingly.

Note the following details about working with services:

- The service that you are starting, stopping, deleting, or configuring can either be already present on the target system during installation or uninstallation, or it can be installed as part of your installation.
- The service executable file should be the key file of its component. For more information, see Component Key Files.
- The Remote Installation setting for the service's component must be set to Favor Local. For more information, see Setting a Component's Remote Installation Setting.

Tip • *The View Filter at the top of the Services view lets you select a component or feature whose service data you want to display in the view, and hide the ones whose service data you do not want to display in the view. The View Filter lists your project's hierarchy of features, subfeatures, and components.*

Task: ***To install, start, stop, delete, uninstall, or configure a service:***

1. If your installation is installing the service, add the service executable file to a component in your project, and make it the key file of the component. For more information, see Adding Files to Components.

   If the service is already present on target systems, skip this step.
2. In the View List under **System Configuration**, click **Services**.
3. Right-click the **Services** node and then click **Add Service**. InstallShield adds a new service.
4. Type a new name for the service now, or click it and then press F2 later to rename it.

   The name that you enter must match the name that is shown on the service's Properties dialog box. (To access an installed service's properties: In the Services administrative tool, right-click the service and then click Properties.)
5. Select the service that you added, and then configure the settings that are displayed in the right pane as needed. For information about each of the settings, see Services View.

Repeat the process for each service in this component's key file.

Note • *You must be familiar with the technical details of your service before you can configure its settings.*

Tip • *If configuring the service fails at run time, the installation may fail with an error message. ICE102 validates some of the service-related settings to help avoid such configuration failures. Therefore, it is recommended that you perform validation for your release.*

Creating Predetermined User Accounts and Groups at Run Time

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

InstallShield has support for creating one or more Windows user accounts and corresponding groups without using logon dialogs. This support requires using three Windows Installer properties for the user account, group, and password of each account that you want to be set up at run time.

Properties for Creating User Accounts

Use the following properties to create user accounts at run time:

- **ISNetApiLogonUsername**—Set the value of this property to the user account that you want the installation to create. Use either of the following formats:
  - *MachineName**UserName*
  - *DomainName**UserName*
- **ISNetApiLogonGroup**—Set the value of this property to the group to which you want the user account to belong.
- **ISNetApiLogonPassword**—Set the value of this property to the password that you want to be configured for the user account.

To configure the required properties and their values, use the Properties view. For instructions on how to do this, see Creating Properties.

Guidelines for Creating User Accounts

To create more than one user account, separate each entry for the **ISNetApiLogonUsername** property value with a tilde that is enclosed in square brackets: [~]. For example, to create a user named **User1** on a domain named **Domain1** and a user named **User2** on a machine named **Machine2**, use the following format:

Domain1\User1[~]Machine2\User2

Each user account that you specify for the **ISNetApiLogonUsername** property must have a corresponding group in the **ISNetApiLogonGroup** property and a corresponding password in the **ISNetApiLogonPassword** property. If these three properties do not have the same number of entries, a run-time error occurs.

The following table shows sample properties and their corresponding values for the creation of three different user accounts:

Table 4-9 • Properties for User Accounts and Groups

Property Name	Property Value
ISNetApiLogonUsername	Domain1\User1[~]Domain1\User2[~]Domain2\User3
ISNetApiLogonGroup	Users[~]Users[~]Administrators
ISNetApiLogonPassword	Password1![~]Password1![~]Password1!

In this example, **User1** is part of the **Users** group and has a password of **Password1**! for the **Domain1** domain. **User2** is part of the **Users** group and has a password of **Password1**! for the **Domain1** domain. **User3** is part of the **Administrators** group and has a password of **Password1**! for the **Domain2** domain.

The **ISNetApiLogonUsername**, **ISNetApiLogonGroup**, and **ISNetApiLogonPassword** properties are formatted properties. Thus, the value of these properties can be a different property, an environment variable, a file path, or a component directory path. For example:

- **[PROPERTYNAME]**—At run time, this resolves to the value of the specified property.
- **[%EnvironmentVariable]**—At run time, this resolves to the value of the specified environment variable.
- **[#FileKey]**—At run time, this resolves to the full path of the file that has the specified file key in the **File** table.
- **[$ComponentName]**—At run time, this resolves to the installation location of the specified component.

Per-User vs. Per-Machine Installations

Project • *This information applies to Basic MSI projects.*

Two Windows Installer properties, along with the current user's privileges, affect where the configuration information such as your product's shortcuts and registry entries are stored on a target machine—to the All Users profile or the current user's profile:

- ALLUSERS determines where the configuration information is stored.
- MSIINSTALLPERUSER indicates that the Windows Installer should install the package for only the current user.

  The **MSIINSTALLPERUSER** property is available with Windows Installer 5 and on Windows 7 or Windows Server 2008 R2. Earlier versions of Windows Installer and Windows ignore this property.

You can set the **ALLUSERS** and **MSIINSTALLPERUSER** properties for your project through the Property Manager. You can also set these properties using the following methods:

- At the command line
- Through a custom action
- In the CustomerInformation and ReadyToInstall dialogs

ALLUSERS, MSIINSTALLPERUSER, and Windows 7 or Windows Server 2008 R2

If the **ALLUSERS** property is set to 2 and **MSIINSTALLPERUSER** is set to 1, the Windows Installer performs a per-user installation.

During a per-machine installation, the Windows Installer requires elevated privileges, and it directs files and registry entries to per-machine locations. If User Account Control (UAC) is available on the target system, a per-machine installation typically prompts for consent or credentials, depending on the access level of the user. During a per-user installation, the Windows Installer does not prompt for credentials, and it redirects files and registry entries to per-user locations.

For more information, see Single Package Authoring on the MSDN Web site.

Effects of ALLUSERS on Windows Vista and Later

Custom actions that have an in-script execution setting of deferred in system context are used to perform an action with the rights granted to the LocalSystem account on Windows, since the Windows Installer service runs in the system context. Actions not marked as deferred in system context run with user impersonation and have the rights that the user who launches the installation has.

When a per-user installation (that is, one where **ALLUSERS** is not set) is run, deferred-in-system-context actions run in the same context in which normal deferred or immediate custom actions run, which is with user impersonation. This can potentially cause a run-time issue with the custom action in the following circumstances:

- The user who launches the Windows Installer installation is not an administrator; or the user is running the installation on Windows Vista or later, the user is part of the Administrators group, and the user does not have administrator privileges by default.
- The custom action attempts to modify a resource in a per-machine location on the machine, such as a file in the Program Files folder, or a registry key or value in HKEY_LOCAL_MACHINE.

While this may not be an issue with Windows XP or earlier versions of Windows, Windows Vista and later do not give users full administrator privileges by default. Therefore, since a deferred-in-system-context action runs with user impersonation when **ALLUSERS** is not set, the custom action could fail.

The recommended method for preventing this behavior is to specify that a per-machine installation should always be performed by setting **ALLUSERS** to 1 in the Property Manager. Per-machine installations are generally easier to manage than per-user installations.

Default Value of ALLUSERS

The **ALLUSERS** property is set to 1 by default in all Basic MSI projects. If you configure your installation so that it can be installed per user without administrative privileges, you may want to consider changing the value of the **ALLUSERS** property or removing this property from your project.

Default Controls on the ReadyToInstall Dialog

Use the Show Per-User Option setting in the General Information view to specify whether you want to give end users the option of installing your product for all users or for only the current user. Available options for the Show Per-User Option setting are:

- **No**—InstallShield does not set any related properties. At run time, the ReadyToInstall dialog does not include the buttons that let end users specify how they want to install the product. This is the default value.
- **Yes**—InstallShield sets the **ISSupportPerUser** property equal to 1.

If the following conditions are true at run time, the ReadyToInstall dialog includes the per-user and per-machine buttons:

- The **ISSupportPerUser** property is equal to 1.
- The target system has Windows 7 or later, or Windows Server 2008 R2 or later.
- The product is not already installed on the target system.

The buttons on the ReadyToInstall dialog let end users specify how they want to install the product. If elevated privileges are required, the shield icon is included on the all-users button. If an end user selects the per-user button, the **ALLUSERS** property is set to 2, and the **MSIINSTALLPERUSER** property is set to 1. If an end user selects the all-users button, the **ALLUSERS** property is set to 1, and the **MSIINSTALLPERUSER** property is not set.

Note • *Selecting No for the Show Per-User Option setting in the General Information view does not prevent end users from setting **MSIINSTALLPERUSER** from the command line when they run your installation. If your installation does not support this, you may want to add a launch condition or other run-time check to prevent this from occurring.*

Default Controls on the CustomerInformation Dialog

By default, the CustomerInformation dialog in all Basic MSI projects does not display the radio button group that enables end users to specify whether they want to install the product for all users or for only the current user. This is the recommended implementation for this dialog.

Task: ***To display the radio button group that lets end users set ALLUSERS from the CustomerInformation dialog:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, under **All Dialogs**, expand the **CustomerInformation** dialog, and then click **Behavior**. InstallShield displays the list of controls for the CustomerInformation dialog.
3. At the bottom of the lower-right pane, click the **Conditions** tab. In the upper-right pane, InstallShield displays the conditions for the selected control.
4. In the list of controls, click **DlgRadioGroupText**. InstallShield displays this control's conditions in the upper-right pane.
5. In the upper-right pane, right-click the row that contains the condition whose value is 1 and whose action is Hide, and then click **Delete**.
6. Repeat steps 4 and 5 for the **RadioGroup** control.

Running InstallScript Installations Without Administrative Privileges

Project • *This information applies to InstallScript projects.*

InstallShield enables you to create InstallScript installations that can be run by end users who do not have administrative privileges. The proper locations of registry entries, folders, and Start Menu items are dynamically determined at run time. The InstallScript system variable ALLUSERS is the key to such installations; if an installation is run by an end user who does not have administrative privileges, ALLUSERS is initialized to FALSE, and assigning it a new value in the script has no effect.

Note the following details:

- Automatic registration of files (which are included in components that have Yes selected for the Self-Register setting) requires administrative privileges.
- InstallScript objects typically require administrative privileges, since they usually install or register files in locations that require administrative privileges.
- Installing a DIFx driver requires administrative privileges.
- Installing the Setup Player for a One-Click Install installation requires administrative privileges.
- Installing a Windows service requires administrative privileges.
- Connecting to a remote registry requires administrative privileges.
- If an end user who is not an administrator or power user attempts to maintain an InstallScript installation that was installed when ALLUSERS was set to TRUE, the installation displays an error message during initialization. The error message indicates that a user with administrator rights installed the product, and similar privileges are needed to modify or uninstall the product.

Customizing Installation Behavior

An important aspect of creating an installation is customizing it for your end users' needs. The "Customizing Installation Behavior" section of the documentation discusses various features of InstallShield that help you extend the functionality of your installation. For example, you may find it useful to create custom actions to add support for something not directly supported by Windows Installer. Furthermore, you may set up custom actions to call any script that you write in the InstallScript view's script editor. Refer to this section of the documentation for more information on how you can customize the installation behavior in your project.

Using InstallScript

You can leverage the power and ease of InstallScript to extend the functionality of your installation package. The InstallScript view includes a script editor pane for you to author your InstallScript code.

Project • *You must have a file named `Setup.rul` in your project if you are using InstallScript. InstallScript and InstallScript MSI projects contain a `Setup.rul` file by default. You must add a `Setup.rul` file in Basic MSI, DIM, and Merge Module projects if you want to use InstallScript custom actions in these types of projects.*

Using Event-Driven InstallScript in InstallScript and InstallScript MSI Projects

InstallScript and InstallScript MSI projects contain an event-driven script. When you use InstallScript in these project types, many of the functions are logged for uninstallation.

Using InstallScript in Custom Actions

Basic MSI, DIM, and Merge Module Projects

In a Basic MSI, DIM, or Merge Module project, you can use custom actions to run InstallScript at run time. These project types do not support event-driven script.

InstallScript MSI Projects

In an InstallScript MSI project, you can use an InstallScript custom action to extend functionality in an execute sequence where the default event handlers are not scheduled appropriately for your installation's needs.

Creating and Using Custom Actions

Task: ***To author an InstallScript custom action and execute it in your installation:***

1. Add a blank Setup.rul to your project in the InstallScript view if it does not already exist.
2. Write an entry-point function. Note that you cannot call an entry-point function in the User Interface sequence for an InstallScript MSI installation project.
3. Compile the script.

4. Create a custom action that calls your InstallScript function.
5. Invoke the InstallScript custom action by either including it in a sequence (InstallScript MSI, Basic MSI, and merge module projects) or executing it as a control event (Basic MSI and merge module projects).
6. Debug if necessary.

Note • *As with other custom actions, changes made to the system through InstallScript custom actions are not automatically restored when the package is uninstalled. Because InstallScript custom actions are not logged and removed by the uninstaller, you must write a corresponding custom action to uninstall any changes that your custom action makes.*

Overview of ISSetup.dll

`ISSetup.dll` is a C++ MSI DLL that contains the full InstallScript scripting run-time engine. For InstallScript MSI, Basic MSI, DIM, and Merge Module projects, `ISSetup.dll` executes InstallScript custom actions. For InstallScript projects, `ISSetup.dll` must be in the Disk1 folder.

Your installation always uses the InstallScript scripting run-time engine with which it was built, even if more a more recent version is installed on a target machine by another installation.

Important • *Note the following information:*

- *`ISSetup.dll` allows you to add only 1,000 InstallScript custom actions to your InstallScript MSI, Basic MSI, DIM, or Merge Module project. If your project includes more than 1,000 InstallScript custom actions, a build error is generated.*
- *The version of `ISSetup.dll` that is used for InstallScript projects is different than the one that is used in InstallScript MSI, Basic MSI, DIM, and Merge Module projects. These two versions are not interchangeable.*

Script Files

Project • *This information applies to InstallScript projects.*

When you create an installation project, InstallShield creates two script files and stores them in the `Script Files` folder of your project folder.

- `Setup.rul` is created for global event handlers and exception handlers.
- `FeatureEvents.rul` is created for feature event handlers.

Initially, these two files are empty; the default event handlers defined by InstallShield do not appear in these files unless you select them from within the InstallScript view in InstallShield. When you do so, they are inserted into the appropriate script file and displayed in the script pane in the InstallScript view, where you can edit them.

Note that if you change the default feature event handler code in `FeatureEvents.rul`, you must put the following statement in `Setup.rul` to include your changes in the installation:

```
#include "FeatureEvents.rul"
```

Creating InstallScript Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

You must have a file named `Setup.rul` in your project if you are using InstallScript. InstallScript and InstallScript MSI projects contain a `Setup.rul` file by default. You must add a `Setup.rul` file in Basic MSI, DIM, and Merge Module projects if you want to use InstallScript custom actions in these types of projects.

Task: ***To add a new InstallScript file to your project:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, right-click **Files** and click **New Script File**.
3. Name the file.

New script files are named `Setup.rul` by default. If you already have a file called `Setup.rul`, a new file is added with the name Setup*n*.rul, where *n* is a successive number. You can rename the file by right-clicking it and then clicking Rename.

The new script file is placed in the Link To folder. InstallShield attempts to use a path variable in case you move your project. You cannot edit the Link To value.

You can also include additional header files (.h files) and script files. Repeat the above procedure to add a new script file to your project.

Opening an InstallScript File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*

- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

Task: ***To open a script file in your project so that you can edit it:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, click the file that you want to open.

Inserting and Importing Script Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

InstallShield enables you to reuse InstallScript files (.rul) and InstallScript header files (.h) in multiple projects. You can insert or import script files into a project through the InstallScript view:

- Inserting a script file creates a link to the script file in its current location.
- Importing a script file copies the script file to the folder containing the script files for your project. The script files that you import can be stored somewhere on your system, or they can be stored in a repository.

InstallShield supports all path variable types that you define in the Path Variables view for the location of these script files. However, it is important to be aware that a corresponding folder structure exists in your source code database so that your source code control software can resolve paths.

Inserting Script Files

Task: ***To insert a script file:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, right-click **Files** and then click **Insert Script Files**. The **Open** dialog box opens.
3. Select the **InstallScript** file (.rul) or InstallScript header file (.h) that you want to insert.
4. Click **Open**.

Importing Script Files

Task: ***To import a script file:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, right-click **Files** and then click **Import Script Files**. The Import InstallScript Files dialog box opens.
3. Do one of the following:
   - In the **Repository Items** box, click the InstallScript file (.rul) or InstallScript header file (.h) that you want to add to your project.
   - If the script file that you want to import is not stored in the repository, click the **Browse** button to select it.
4. Click **OK**.

Compiling Scripts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

You must compile your script before your InstallScript code can be called in your installation.

InstallShield searches only for a file named `Setup.rul` when compiling the script. You can include files with different names, but they must be included in `Setup.rul` or in an include file with the #include preprocessor statement.

Task: ***To compile your script, do one of the following:***

- On the **Build** menu, click **Compile**.
- Click the **Compile** button on the toolbar.
- Press CTRL+F7.

Before compiling, InstallShield saves any changes that you have made to your script files. The compiler's status, including any error or warning messages, is displayed in the Output window. Double-click a compiler message to go to the line in your script where the error was found.

If you compile your script file after making changes to it, it is not necessary to rebuild your release. Note that InstallShield automatically compiles your script whenever you build a release.

If your script compiled successfully, InstallShield creates `Setup.inx` (the object code that the setup engine executes) and streams it into your Windows Installer package when you build a release.

You may also need to uninstall the release that you previously ran to test your InstallScript custom action before you can see the changes to the script.

You can set compiler options on the Compile/Link tab of the Settings dialog box.

Debugging Scripts

The InstallScript Debugger is useful for stepping through your InstallScript code and checking the progress of your code.

Before you can debug your script, you must first compile it, execute it as a custom action (if applicable), and build a release.

Task: ***To debug your script directly from within InstallShield, do one of the following:***

- On the **Build** menu, click **Debug**.
- Press F5.
- Click the **Debug** button on the toolbar.

InstallShield will run the installation and open the InstallScript Debugger when the custom action is executed.

While you are in the InstallScript Debugger, press F1 at any point to view the InstallScript Debugger Help.

For information about debugging on a test system, see Debugging an Installation on any Computer.

Using Preprocessor Statements to Debug the Script

Use the #define and #ifdef statements to create an internal debugger in the script.

Task: ***To deug a script by using the preprocessor statements:***

1. Wherever you want to insert a debug statement in the script, start with the following #ifdef directive:

   ```
   #ifdef DEBUG
   ```

2. On lines that follow that directive, type the debug statements.
3. On a separate line after the debug statements, type:

   ```
   #endif
   ```

4. For debugging purposes, compile the following compiler setting:

   ```
   DDEBUG=1
   ```

Here is an example of a debugging section using an #ifdef statement:

```
#ifdef DEBUG
    if nResult < 0 then
        WriteLine (LogFileHandle, "PlaceBitmap failed");
    endif;
#endif
```

The InstallScript Debugger enables you to trace program execution and inspect variables as your installation executes.

Renaming an InstallScript File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

Task: ***To rename an InstallScript file:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, right-click the file and click **Rename**.
3. Type a new name for the file.

Project • *InstallScript projects must contain a source file named `Setup.rul`; that file is the main compilation unit of an installation script. If your InstallScript project does not include a script file with that name, error C8503 occurs when you compile your script or build a release.*

Using String Entries in Scripts

You can use string identifiers in your script in place of any value that accepts a string literal. When the custom action is executed, the installation replaces the string identifier with the corresponding string value for the language in which the installation is running.

String identifiers must follow an at symbol (@) in your script. The Select String dialog box lets you browse the list of string entries in your project. It also lets you modify string entries for the default language before inserting the selected string identifier into your script.

For example, assuming your project contains a string identifier called MSG_ACTION_SUCCEEDED, you could display its value in a message box as demonstrated below:

```
szMsg = @MSG_ACTION_SUCCEEDED;
nType = INFORMATION;
MessageBox (szMsg, nType);
```

Removing InstallScript Files from Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

When you remove a script file from your installation, you are deleting the reference to that file from your project, but not the file itself. If you later decide to insert it into your installation, you do not need to rewrite your script.

Note that the script file may, in fact, still be compiled if it is included in another file.

Task: ***To remove InstallScript files from your project:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, right-click the file and click **Remove**.

Caution • *You cannot rename a file to the name of an existing file under the project location, even if the script file has been removed through the above procedure. For example, assume you have a script file called `Setup.rul` in your project. Next, remove that file and add a new script file, called `Script1.rul` by default. You cannot rename `Script1.rul` to `Setup.rul`, because doing so would overwrite the first `Setup.rul`. To avoid this, you should move your original `Setup.rul` out of your project folder, rename it, or delete it through Windows Explorer.*

Creating Script Libraries (.obl Files)

InstallScript's built-in functions are defined in library files (.obl files) to which a script is linked when the script is compiled.

Task: ***To create a library file for functions that you have defined:***

1. Create one or more .rul files containing the definitions of your functions.
2. At the command line, for each of your .rul files, run `Compile.exe` with the `-c` switch to compile the file without linking it to any existing library file. This will create an .obs file (rather than the .inx file that is created by compiling without the `-c` switch). For example, enter the following command line to create the file `MyFunc.obs` in the current folder.

   ```
   Compile MyFunc.rul -c
   ```

   To create an .obs file with a different name or location, use the `-o` switch.
3. Run `Compile.exe` with the `-l` switch, and one or more .obs files as parameters, to create the library file. For example, enter the following command line to create the file `MyFunc.obl` in the current folder.

   ```
   Compile MyFunc.obs -l
   ```

   Entering the following command line creates the file `MyFunc1.obl` in the current folder.

   ```
   Compile MyFunc1.obs MyFunc2.obs -l
   ```

   To create an .obs file with a different name or location, use the `-o` switch.

Tip • *If you have many .obs files, you can shorten the command line by using a command file as in the following example:*

```
Compile @MyObsFiles.txt -l
```

To quickly create the command file, you can use the MS-DOS command DIR with its `/b` (bare format) switch and redirect the output to a file. For example:

```
DIR *.obs /b > MyObsFiles.txt
```

To compile an installation script using your library file, specify the library file on the command line or—when compiling within InstallShield—on the Compile/Link Tab of the Settings dialog box.

Publishing InstallScript Files (.rul and .h) to a Repository

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

If you have an existing InstallScript file (.rul) or InstallScript header file (.h) that you would like to reuse in other projects or share with other users, you can publish it to a repository.

Task: ***To publish a script file to a repository:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, right-click the script file that you would like to publish, and then click **Publish Wizard**. The **Publish Wizard** opens.
3. Complete the panels in the Publish Wizard.

After you have imported a script file from a repository into a project, there is no link between the current script file and the existing repository script file. If you make a change to the script file and then republish it to the repository, it does not affect the script file in the project to which it was imported. However, you can reimport the script file from the repository into your project.

InstallScript Lists

Lists are used to store related information, such as strings or numbers. InstallScript lists are very similar to single-linked lists in the C language. InstallScript list functions are very flexible, enabling you to return information in an order different from the order in which it was stored and access and use that information in a variety of ways.

List Functions

InstallShield provides a number of functions for creating and manipulating lists. There are three types of InstallScript list functions:

- Functions ending in **-String** that work with string lists only
- Functions ending in **-Item** that work with number lists only
- Functions that work with either string or number lists

InstallShield also has many secondary list-related functions that use or create lists.

List Structure

Lists are used to store related information—either strings or numbers. All the information in a list must be of the same data type, and the number of elements is limited only by the available memory.

An InstallScript list has two parts. The first part is the head, which InstallShield uses internally. The head of the list contains general information about the list, such as whether it contains strings or numbers. The head also contains pointers to the beginning and end of the list.

The second part of the list is the list body. The list body contains the actual strings or numbers. You can have as many strings or numbers in a list as the memory in the system will allow.

Remember that lists cannot contain both numbers and strings. A list must have only strings or only numbers.

Variables representing lists can be declared as type LIST or type LONG. Lists exist only in memory, meaning they are destroyed when the installation is complete. If a list is local to a function, the list is destroyed when the function returns control to the calling code.

Creating and Destroying Lists

Before creating a list, decide which type of list you want to build: a string list or a number (item) list. To create the list, call the **ListCreate** function:

```
// This builds the list head for a string list.
listID1 = ListCreate (STRINGLIST);
```

–or–

```
// This builds the list head for a number (item) list.
listID2 = ListCreate (NUMBERLIST);
```

ListCreate automatically builds the head of the list and returns its ID number. The ID is used in all subsequent functions that operate on the list. Therefore, you must always create a list using **ListCreate** before you use any other list function. You must store the return value from **ListCreate** in a variable of type LIST or type LONG.

This fragment creates a number list and then a string list. It also tests each one to make sure that the lists were created successfully.

```
// This creates an empty list for strings.
listID1 = ListCreate (STRINGLIST);

if (listID1 = LIST_NULL) then
      MessageBox ("Unable to create the string list", SEVERE);
endif;

// This will create an empty list for numbers.
listID2 = ListCreate (NUMBERLIST);

if (listID2 = LIST_NULL) then
    MessageBox ("Unable to create the number list", SEVERE);
endif;
```

When you are finished using a list, you will typically want to destroy the list to free the memory for other uses. **ListDestroy** destroys the list and its contents. This example creates a list referenced by listID, adds a string to the list, and then destroys the entire list.

```
listID = ListCreate (STRINGLIST);

if (listID = LIST_NULL) then
    MessageBox ("Unable to create list.", SEVERE);
    abort;
endif;

ListAddString (listID, "This is a string in the list", AFTER);
ListDestroy (listID);
```

If you do not destroy a list using **ListDestroy**, the list will be destroyed when the installation is complete. If the list is local to a function, the list is destroyed when the function returns control to the calling code.

Adding Elements to Lists

InstallShield provides several functions for adding elements to lists:

Table 4-1 • Functions that Are Used to Add Elements to Lists

Function	Description
ListAddItem	Adds an item to the list.
ListAddString	Adds a string to the list.
ListReadFromFile	Reads a text file into a list.

ListAddString and **ListAddItem** add a single element to the list that you specify. Remember that, regardless of where you place the new string in the list, it becomes the current string. Use the options BEFORE and AFTER to indicate where you want to place the new element in the list relative to the current element. If you are working with a newly created list, using either BEFORE or AFTER will add the string to the first element position in the list.

Adding elements to a list and the resulting effects on the list order and the element in the current position are most easily explained by example. The examples below use string lists and **ListAddString**, but the same principles and steps apply to using **ListAddItem** and number lists. Consider these scenarios:

- Adding an element to an empty list
- Adding an element before the current element
- Adding an element after the current element
- Adding elements before and after the current element

Adding an Element to an Empty List

The first string that you add to the list goes immediately after the head of the list. This string (*String 1* in the sample code) becomes the current string in the list. The script fragment shown below results in a list like that depicted after it:

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

// Test for a valid list
if (listID = LIST_NULL) then
    MessageBox ("List not created", SEVERE);
else
    // Add a string to the list.
    szString = "String 1";
    ListAddString (listID, szString, AFTER);
endif;
```

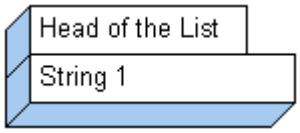

Figure 4-1: String 1 is added to a list.

Adding an Element Before the Current Element

If the current string is the first string in the list and you add a new string before it, the new string becomes the first string in the list. The string that was formerly in the first element position now resides in the second element position. The new string at the first element position is now the current string:

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

// Test for a valid list
if (listID = LIST_NULL) then
    MessageBox ("List not created", SEVERE);
else
    // Add some strings to the list.
    szString = "String 1";
    ListAddString (listID, szString, AFTER);

    szString = "String 2";
    ListAddString (listID, szString, BEFORE);
endif;
```

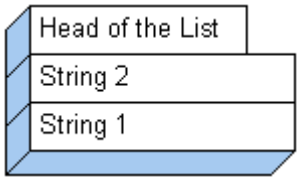

Figure 4-2: String 2 is added before String 1.

Adding an Element After the Current Element

If the current string is the first string in the list, and you add the new string after the current string, the new string becomes the second string in the list, as well as the new current string. Refer to the script fragment below and to the illustration following it:

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

// Test for a valid list
if (listID = LIST_NULL) then
    MessageBox ("List not created", SEVERE);
else
    // Add some strings to the list.
    szString = "String 1";
    ListAddString (listID, szString, AFTER);
```

```
    szString = "String 2";
    ListAddString (listID, szString, AFTER);
endif;
```

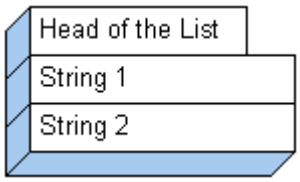

Figure 4-3: String 2 is added after String 1.

Adding Elements Before and After the Current Element

As another example, the code segment shown below creates a new list and puts String 1 in the first position. String 2 is then added before String 1, leaving String 2 in the first position as the current string. Next, String 3 is added after the current string, resulting in the list depicted below.

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

// Test for a valid list
if (listID = LIST_NULL) then
    MessageBox ("List not created", SEVERE);
else
    // Add some strings to the list.
    szString = "String 1";
    ListAddString (listID, szString, AFTER);

    szString = "String 2";
    ListAddString (listID, szString, BEFORE);

    szString = "String 3";
    ListAddString (listID, szString, AFTER);
endif;
```

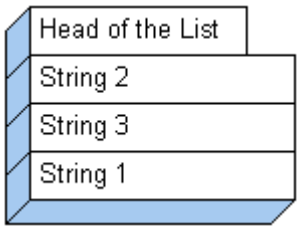

Figure 4-4: String 1 is added. Then String 2 is added before String 1. Last, String 3 is added after String 2.

In the example above, if String 3 were added before the current string, the result would be as shown below, with String 3 becoming the current string. This code segment is shown below:

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

// Test for a valid list
```

```
if (listID = LIST_NULL) then
    MessageBox ("List not created", SEVERE);
else
    // Add some strings to the list.
    szString = "String 1";
    ListAddString (listID, szString, AFTER);

    szString = "String 2";
    ListAddString (listID, szString, BEFORE);

    szString = "String 3";
    ListAddString (listID, szString, BEFORE);
endif;
```

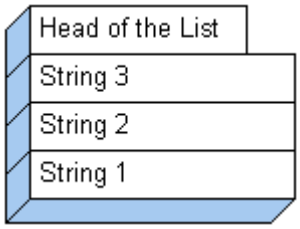

Figure 4-5: String 1 is added. Then String 2 is added before String 1. Last, String 3 is added before String 2.

Changing Existing Elements in a List

Call the **ListSetCurrentString** function to change the value of an element in a string list. Remember that only the current element may be changed, so be sure to make the string you want to update the current string in the list.

Call the **ListSetCurrentItem** function to change the value of an element in a number list. Again, the item that you want to update must be the current element in the list.

The example below demonstrates calling **ListSetCurrentItem** to change the value of the current item in a number list. The **ListSetCurrentString** function works in the same manner, but with a string list and string variables.

```
// Create a list and verify its creation.
listID = ListCreate (NUMBERLIST);
if (listID = LIST_NULL) then
    MessageBox ("Unable to create list.", SEVERE);
    abort;
endif;

// Add items (1078 and 304) to the list.
nItem = 1078;
ListAddItem (listID, nItem, AFTER);
nItem = 304;
ListAddItem (listID, nItem, AFTER);

// Current item is the second item (304).
// Now set current item to new value (305).
nItem = 305;
ListSetCurrentItem (listID, nItem);
ListDestroy (listID);
```

Deleting Elements from a List

Call the **ListDeleteString** function to delete the current string from a list. Or, call the **ListDeleteItem** function to delete the current number from a list. If there are no more elements to delete, these functions return the END_OF_LIST constant.

Note that since **ListDeleteString** and **ListDeleteItem** delete the current element, you must reset the current element to the element that you want deleted. After deletion, the next element in the list becomes the current element. You reset the element by any of the methods described in Traversing Lists.

The example below illustrates the use of several list functions, including **ListDeleteString**. The **ListDeleteItem** function is used in the same manner, except that the list is a number list and the variables are number variables.

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

if (listID = LIST_NULL) then // Test for a valid list.
    MessageBox ("List not created", SEVERE);
endif;

// Add some strings to the list.
szString = "String 1";
ListAddString (listID, szString, AFTER);
szString = "String 2";
ListAddString (listID, szString, AFTER);
szString = "String 3";
ListAddString (listID, szString, AFTER);

// Delete the current string.
ListDeleteString (listID);

// Reset the current string in the list.
lResult = ListCurrentString (listID, svString);

// svString contains "String 2."
```

Finding a Particular Element in a List

You can traverse lists non-incrementally. Call the **ListFindString** function or the **ListFindItem** function when you want to search for a specific string or number element in a list. These two functions begin their search at the current element and continue forward through the list from that point.

To start a search from the beginning of a list, call the **ListGetFirstString** or the **ListGetFirstItem** function before calling the **ListFindString** or the **ListFindItem** function.

When the **ListFindString** or the **ListFindItem** function finds the specified string or number, it becomes the current element in the list.

In the script fragment below, a number list is created, and the number 1 (in nItem) is added as the first element. Then, **ListFindItem** searches the list for the number 1, and deletes it, if found. Finally, the list is destroyed.

```
listID = ListCreate (NUMBERLIST);

if (listID = LIST_NULL) then
    MessageBox ("Unable to create list.", SEVERE);
```

```
    abort;
endif;

nItem = 1;
ListAddItem (listID, nItem, AFTER);

if (ListFindItem (listID, nItem) = 0) then
     ListDeleteItem (listID);
endif;

ListDestroy (listID);
```

Note • *The **ListFindString** and **ListFindItem** functions look for only the first instance of the specified string or number at or after the current element.*

Getting the First and Next Elements in a List

Call the **ListGetFirstString** function or the **ListGetFirstItem** function to return the first string element or number element, respectively, from a list. The element that you retrieve then becomes the current element in the list.

Call the **ListGetNextString** function or the **ListGetNextItem** function to return the string element or number element after the current element in a list. The element that you retrieve then becomes the current element in the list.

```
// Create the empty list of strings.
listID = ListCreate (STRINGLIST);

// Test for a valid list.
if (listID = LIST_NULL) then
    MessageBox ("List not created", SEVERE);
endif;

// Add some strings to the list.
ListAddString (listID, "String 1", AFTER);
ListAddString (listID, "String 2", AFTER);
ListAddString (listID, "String 3", AFTER);

// Traverse the list and display the strings in a message box.
lResult = ListGetFirstString(listID, szDriveName);

while (lResult != END_OF_LIST)
    MessageBox (szDriveName, INFORMATION);
    lResult = ListGetNextString (listID, szDriveName);
endwhile;
```

Reading a File into a List

Call the **ListReadFromFile** function to read an entire file into a string list. Each line in the file becomes an element in the list. The **ListReadFromFile** function provides an easy way to load a list, rather than building it one item at a time.

Setting an Index in a List

InstallShield provides the **ListSetIndex** function, which lets you make an element the current element using an index number. If you know the location of a particular element in a list, you can call the **ListSetIndex** function to access that element immediately. You can traverse a list in either direction by using the index to set a specific element in a list to the current element. The index of the list starts at 0 (zero).

The **ListSetIndex** function works on both string and number lists. After you set the indexed element as the current element, call either the **ListCurrentItem** function or the **ListCurrentString** function to return the value of the indexed item.

This example demonstrates traversing a list non-incrementally using **ListSetIndex**.

```
listID = ListCreate (STRINGLIST);
GetGroupNameList (listID);
nCheck = ListSetIndex (listID, LISTFIRST);

while (nCheck != END_OF_LIST)
    ListCurrentString (listID, svString);
     MessageBox (svString, INFORMATION);
     nCheck = ListSetIndex (listID, LISTNEXT);
 endwhile;

ListDestroy (listID);
```

The **ListCount** function tells you how many elements are in a list. The **ListCount** function is used mainly for general information purposes, although it can be used to establish an upper index value in conjunction with **ListSetIndex**. For example, you can call **ListCount** to get the number of elements in a list, and use that value with **ListSetIndex** to traverse a list. The above example, which uses a while loop, is rewritten below using an InstallScript for loop based on the number of elements in the list.

```
listID = ListCreate (STRINGLIST);
GetGroupNameList (listID);

// Get the number of elements in the list.
nItems = ListCount (listID);

// Display the number of elements in the list.
SprintfBox (INFORMATION, "", "i = %d", nItems);

// Loop for nItems times beginning with zero,
// displaying each list element in turn in a message box.
for i = 0 to (nItems - 1)
    ListSetIndex (listID, i);
    ListCurrentString (listID, svString);
    MessageBox (svString, INFORMATION);
    nCheck = ListSetIndex (listID, LISTNEXT);
endfor;

ListDestroy (listID);
```

Traversing Lists

InstallShield provides these functions for traversing lists incrementally and non-incrementally:

Table 4-2 • Functions that Are Used to Traverse Lists

Function	Description
ListCount	Sees how many string or numeric elements are contained in a specified list.
ListCurrentItem	Returns the current item in the list.
ListCurrentString	Returns the current string in the list.
ListFindItem	Attempts to find a numeric element in a list. If found, the element becomes the current element of the list.
ListFindString	Attempts to find a string element in a list. If found, the element becomes the current element of the list.
ListGetFirstItem	Retrieves the first element from a number list.
ListGetFirstString	Retrieves the first string from a string list.
ListGetNextItem	Retrieves the element after the current element from a number list.
ListGetNextString	Retrieves the element after the current element from a string list.
ListSetIndex	Sets the current element of the list as an index.

InstallShield uses single-linked lists, which means that unless you use functions that set indices or search for specific elements in lists, you can traverse lists incrementally in one direction only: from the first element to the last.

InstallShield allows you to traverse lists in non-incremental fashion by means of indices and by searching for particular elements in lists. Refer to the individual function descriptions for more details.

Most list traversing and list access operations are carried out relative to the current list element. Furthermore, most of the functions used to traverse and access lists establish a current element as a result of their action. Therefore, making an element the current element in a list is not an isolated action; it is a byproduct of another action.

If a list is empty, adding an element to the list will establish a current element. If a list is not empty, then making an element the current element is best accomplished by traversing the list or searching for a particular element in the list.

Tip *• Lists are often processed within while loops, usually checking for END_OF_LIST. An infinite loop can result if the list is not valid. If you are processing lists in a while loop, make sure that you have created the list with the* ***ListCreate*** *function, and that you have not destroyed the list with the* ***ListDestroy*** *function.*

Writing a List to a File

Call the **ListWriteToFile** function to write the contents of a string list to a file. Each element in the list becomes a line in the file.

The example script below reads the Autoexec.bat file into the listFile string list and then writes that string list to a file named Autoexec.bak.

```
listFile = ListCreate (STRINGLIST);
szPath = "C:\\";
szFileOld = "C:\\Autoexec.bat";
szFileNew = "C:\\Autoexec.bak";

if (ListReadFromFile (listFile, szFileOld) < 0) then
   MessageBox ("ListReadFromFile failed.", SEVERE);
endif;

ListWriteToFile (listFile, szFileNew);
```

Saving InstallScript Files

All open script files are saved automatically when you click Save on the File menu in InstallShield.

System Restore

Project *• This information applies to InstallScript projects.*

System Restore is a Windows feature that enables end users to restore PCs corrupted during software installation. The System Restore feature automatically monitors and records key system changes to the end user's PC. System Restore reduces support costs and increases customer satisfaction by letting the end user easily undo a change that may have harmed their system or revert to a time when they knew that their system was performing optimally.

InstallScript installations support System Restore by setting a *restore point* before starting the file transfer; the end user can then use System Restore to restore the system to the state it was in before the file transfer.

Note *• Installation actions (for example, registry changes and file modifications) that take place before file transfer cannot be undone by System Restore.*

Your installations are System Restore compatible by default. You can disable System Restore compatibility by placing the following code in your script's OnBegin event handler:

```
Disable( PCRESTORE );
```

If the file `Wininit.ini` exists in the target machine's `Windows` folder, the installation cannot set a restore point. To handle `Wininit.ini`, put code like the following in the **OnFirstUIBefore** and **OnMaintUIBefore** event handler functions:

```
/* Look for Wininit.ini in the Windows folder. If it is found ... */
if FindFile( WINDIR, "Wininit.ini", svResult )=0 then
    bRebootForSystemRestore = TRUE;
    /* ... get its size. */
    GetFileInfo( WINDIR ^ "Wininit.ini", FILE_SIZE, nvSize, svResult );
    /* If its size is zero bytes ... */
    if nvSize=0 then
        /* ... delete Wininit.ini. */
        if DeleteFile( WINDIR ^ "Wininit.ini" )=0 then
            bRebootForSystemRestore = FALSE;
        endif;
    endif;
    /* If Wininit.ini has a non-zero size or could not be deleted, notify the end user and allow a
reboot. */
    if bRebootForSystemRestore then
        szQuestion = "Windows System Restore lets you undo " +
            "changes to your computer. If you want to be able " +
            "to use System Restore to undo this installation, " +
            "you must reboot your computer now.\n\n" +
            "Do you want to reboot your computer now?"
        if AskYesNo( szQuestion, YES )=YES then
            System( SYS_BOOTMACHINE );
        endif;
    endif;
endif;
```

Getting and Setting Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Windows Installer properties can contain useful information about the product, the setup, the operating system, and the user. By calling **MsiGetProperty** and **MsiSetProperty**, you can directly interact with these properties in your immediate InstallScript custom action.

Note • *Note that the **MsiGetProperty** and **MsiSetProperty** properties cannot be used for deferred InstallScript custom actions, which do not have access to the active .msi database and do not recognize any Windows Installer properties. They can access only the information that has been written into the execution script.*

The following example retrieves the user name from the Windows Installer setup package, confirms the value, gives the user the opportunity to change it, and then writes the new value back into the database:

```
// Include header file for built-in functions
#include "isrt.h"
// Include header file for MSI API functions and constants
#include "iswi.h"

export prototype Func1(HWND);

function Func1(hMSI)
    STRING svName;
    NUMBER nvSize, nResponse;
begin
    // Retrieve the user's name from the MSI database
    nvSize = 256;
    MsiGetProperty (hMSI, "USERNAME", svName, nvSize);

    nResponse = AskYesNo ("Your name will be registered as " +
                          svName + ". Is this correct?", YES);

    if nResponse = NO then
        AskText ("Enter the name that will be registered for " +
                 "this product.", svName, svName);
        MsiSetProperty(hMSI, "USERNAME", svName);
    endif;
end;
```

Using Bit Flags

Project • *This information applies to InstallScript projects.*

Bit flags are one or more (up to 32) Boolean values stored in a single number variable.

Each bit flag typically has a corresponding predefined constant associated with it; this constant has the bit for this flag set to 1 and all other bits set to 0. For example, the following constant identifies the bit flag for bit 0, that is, the right-most bit in the number:

```
#define BITFLAG_EXAMPLE_1 0x00000001
```

Other bit flags could be the following:

```
#define BITFLAG_EXAMPLE_2 0x00000002
#define BITFLAG_EXAMPLE_3 0x00000004
```

Note that 0x00000003 is not a valid bit flag, since this value corresponds to two bits in the number being set to 1.

Setting Bit Flags in a Variable

To set bit flags in a variable, use the bitwise OR operator (|). For example, to assign the value BITFLAG_EXAMPLE_1 and BITFLAG_EXAMPLE_2 to the number variable *nFlags*, use code like the following:

```
nFlags = nFlags | BITFLAG_TEST_1 | BITFLAG_TEST_2;
```

Clearing a Bit Flag from a Variable

To clear a bit flag from a variable, combine the bitwise AND operator (&) with the bitwise NOT operator (~). For example, to remove the BITFLAG_TEST_1 flag from nFlags, use code such as the following:

```
nFlags = nFlags & ~BITFLAG_TEST_1;
```

Testing a Variable for a Bit Flag

To test a variable for a bit flag, use the bitwise AND operator (&) and the bit flag constant to zero all the bits other than the bit for which you are testing. For example, if *nFlags* is currently set to `BITFLAG_TEST_1 | BITFLAG_TEST_2`, the following expression evaluates to true (that is, a non-zero result):

```
nFlags & BITFLAG_TEST_1
```

All bits other than the rightmost bit are set to 0 by the & operation; the rightmost bit is 1 since it is 1 in both the constant BITFLAG_TEST_1 and *nFlags*.

The following expression evaluates to FALSE since the third bit of nFlags is 0 and all other bits are set to 0 by the & operation:

```
nFlags & BITFLAG_TEST_3
```

String Comparisons

When InstallShield compares two strings, it starts by comparing the initial character in the first string with the initial character in the second string. If those characters are equal, InstallShield then compares the characters in the next position of each string. If those characters are also equal, it moves on to the characters in the next position, continuing in sequence until it encounters one of the following conditions:

- Two characters in the same relative position in the two strings do not match. In this case, InstallShield bases its resolution on the comparison of those two characters. If the character in string one has a greater value than the character in the corresponding position of string two, then string one is greater; otherwise string two is greater.
- The end of one string is encountered without finding unequal characters in corresponding positions. In this case, the strings are of unequal length and therefore they are not equal.
- The end of both strings is reached without finding unequal characters in corresponding positions. In this case, the strings are equal in length and all characters match; therefore the strings are equal.

Consider the following example:

```
svString1 = "trusting";
    svString2 = "TRUTHFUL";

    if svString1 = svString2 then
        MessageBox("Equal", INFORMATION);
    else
        MessageBox("Not Equal", INFORMATION);
    endif;
```

String comparisons are not case-sensitive. Because an uppercase character is equal to its lowercase counterpart, InstallShield finds that the first three characters of **trusting** and the first three characters of **TRUTHFUL** are equivalent. The comparison ends with the test of the characters in the fourth position of each string. Since **s** is lower than **t** in the ASCII character table, svString1 does not equal svString2. The remaining characters are not compared and the else branch is executed.

Note • *The value of each character is based on its ASCII value. For information about the ASCII values of specific characters and symbols, refer to a basic programming manual.*

Using Null-Delimited Strings

Project • *This information applies to InstallScript projects.*

Note the following when using a null-delimited, double-null-terminated string (for example, **abc\0def\0ghi\0\0**; such strings are also sometimes referred to as *multiple null-delimited strings* or *multiple null-terminated strings*):

- When declaring a variable that will be set to a null-delimited string value, explicitly size the variable; for example:

  ```
  STRING szString[1024];
  ```

  Do not use autosizing; the installation engine expects autosized strings to not include null characters within the string.
- Do not try to create arrays of null-delimited strings; since array elements must always be autosized, string arrays do not currently support this type of string.
- The specified size of a null-delimited string should be at least the number of characters to be stored plus two for the two terminating null characters.
- Since strings are automatically initialized to all null characters, you do not need to explicitly set the second-to-last character to null (though this will not cause any adverse effects) unless you have previously set the second-to-last character to something other than null.
- The best way to determine the length of a null-delimited string is to call the **CharReplace** function to replace the null characters and then call the **StrLengthChars** function to determine the size of the resulting string.
- The **StrGetTokens** and **StrPutTokens** functions may be useful when working with null-delimited strings.
- Most InstallScript functions other than the ones noted above do not work with multiple null-delimited strings. If you want to use a multiple null-delimited string with a built-in function, use the **CharReplace** function first to replace the null characters with another character, such as an underscore (_).

Relative Path

A relative path includes all of the information necessary to locate a file by starting at the current folder on the current drive, for example, `Support\Validation`. That folder can be located along that relative path only if it exists in the current directory.

Long File Names

Windows operating systems that are 32 bit support long file names. Long file names enable end users to give directories and files more meaningful names. The term *long file name* refers to both long file names and long paths.

InstallShield provides the long file name functions to facilitate the installation of 16-bit applications and 32-bit applications that do not recognize long file names. It is your responsibility to determine your application's requirements. InstallShield provides the tools to help you install any kind of application.

Long File Names and 16-bit Applications

You can launch 16-bit applications using long file names, but you cannot pass long file names as arguments to 16-bit applications; 16-bit applications require the short file name versions of long file names to function correctly.

If your installation passes a file name to a 16-bit application, you must provide a valid short file name to the application. Long file names will not work.

If your installation writes file names to files such as .ini files, and if 16-bit applications are expected to use the files, you must write short file names that the 16-bit applications can use.

Long File Names and Double Quotation Marks

Under 32-bit operating systems, if you pass a long file name containing one or more space characters to the command line (such as in a DOS shell or in the Command Line setting for an icon), you must enclose the long file name in double quotation marks. This is necessary because the command line recognizes the space character as a delimiter separating a command from other arguments. The double quotation marks convert the long file name to a string literal, allowing the command line to receive it as a single argument.

Under 32-bit operating systems, if you pass a long file name containing one or more space characters to the command line, it must be enclosed in double quotation marks. However, due to the manner in which Windows NT accesses icon files, if a long file name in double quotation marks is used in the Command Line setting for an icon, the default Windows icon may display instead of the application's icon.

To display your product's icon, you can specify the icon's path in the parameter szIconPath of the function

AddFolderIcon when using it to add an icon to a program folder.

Double quotation marks must be removed from long file names before they can be converted to short file names in InstallShield. Refer to the LongPathToQuote and LongPathToShortPath functions.

Long File Name Format

Long file names contain names longer than the conventional 8.3 (eight characters plus a three-digit extension) short file name limit. Long file names allow the use of all the characters used in short file names. In addition, long file names can contain plus signs (+), commas (,), semicolons (;), equal signs (=), left and right square brackets ([ ]), and spaces.

Leading and trailing spaces are ignored. The fully qualified long file name (including null terminating character) can be up to 256 characters long on NTFS file systems and 260 characters long on VFAT file systems.

By default, the operating system creates a short file name for every long file name. The short file name consists of the first six characters of the long file name, a tilde (~), and a number.

Defining Constants Through the Compiler

You can define InstallScript constants on the Compile/Link tab of the Settings dialog box instead of in the script.

The following restrictions apply when defining constants on this tab:

- You can define only numeric constants.
- If you define a constant that you defined with a #define statement in the script, a compile error occurs.
- If you define a constant that you defined as a variable in the script, the value of the constant is lost at run time.

Using Windows Constants in a Script

Some Windows constants are predefined in the `ISRTWindows.h` file that is provided in the *`InstallShield Program Files Folder`*`\Script\Isrt\Include` folder. This file is automatically included in your installation when you include `Ifx.h` in your script. You do not need to redefine any constants that are defined in `ISRTWindows.h`; doing so will result in a compiler warning. To determine which constants are predefined, refer to the `ISRTWindows.h` file.

To use constants that are not defined in `ISRTWindows.h`, you must define them (using #define) in the declaration block of your installation script. You cannot simply include the `Windows.h` file that is usually part of a C++ program. The values that you need to assign to the undefined constants can generally be found in an include file that is provided with the appropriate Windows SDK or development tool. (For Microsoft Visual C++, most constants can be found in the `Winuser.h` file, which is located in the *`InstallShield Program Files Folder`*`\Script\Resource` folder.)

Coding Long String Literals

To make a very long string literal more easily readable in a script, split the long string into two or more shorter strings, place them on consecutive lines, and concatenate them. In InstallScript, concatenation is performed with the plus sign (+). The example below shows how to split a long string literal across several lines of code in this way:

```
szMonths = "January, February, March, April, " +
           "May, June, July, August, September, " +
           "October, November, December";
```

Absolute Path

Project • *This information applies to InstallScript projects.*

An absolute path includes all of the information necessary to locate a file by starting at the root directory of a specified drive. For example, `C:\Program Files\InstallShield\2013` is the absolute path to the InstallShield folder when installed on drive C.

Building Functions

Typically, functions are declared at the top of the file, and the body is defined at the bottom of the file. After you declare a function prototype, you need to define the function itself in the function block. Each function block contains only one function.

Task: ***To build a function:***

1. Start the function body with the keyword `function`.
2. Type the return value data type used in the function prototype, or type `void` if the function prototype specifies a return type of void (which indicates that the function does not return a value). If the function prototype does not specify a return type, it is not necessary to enter one here.
3. Type the function name.
4. To the right of the function name, type the names of the arguments that you are using in parentheses. The arguments must correspond in data type to the parameters that you declared in the declare block.

   

   Note • *InstallScript functions do not allow you to pass an assignment statement as a parameter. In addition, you cannot use the && or || operators within an argument to a function.*

   Steps 1 and 2 create the function header. Function headers do not end with a semicolon in InstallScript.
5. Declare any local variables that you will use in the function. Then type the keyword `begin` on a line by itself, without punctuation.
6. After the begin line, add whichever statements you need in order to accomplish your particular task.

   You can also use a return statement, particularly if you want to return a specific value from the function. See below for information on returning values from a function.
7. End your function with the keyword `end`.

A sample function block is shown below:

```
function GetPathParts(szFullPath, svDrv, svPath, svName)
    LONG lResult;
begin
    lResult = ParsePath(svDrv, szFullPath, DISK);
    if (lResult = 0) then
        lResult = ParsePath(svPath, szFullPath, DIRECTORY);
    endif;

    if (lResult = 0) then
        lResult = ParsePath(svName, szFullPath, FILENAME);
    endif;

    return lResult;
end;
```

Note • *User-defined functions can return a value with a return statement. Other types of data can be returned in parameters that have been declared with the BYREF operator.*

Calling Functions

All functions—whether user-defined, built-in, Sd, or external—are called in the same way. Type the name of the function, followed by the parameters that you want to pass to the function. For example:

```
MyFunction (MyAge, MyHeight, MyWeight);
```

Note • *InstallScript functions do not allow you to pass an assignment statement as a parameter. In addition, you cannot use the && or || operators within an argument to a function.*

An autosized string variable that is passed by reference to a function is not autosized within the called function. If the function attempts to assign a value whose length is greater than the current size of that parameter, run-time error 401 occurs. To avoid this error, declare strings with a specific size when they are to be passed by reference to a function.

Calling a DLL File Function

There are three rules you must remember when you are calling DLL file functions from your InstallScript installation script:

- The maximum length of the DLL file name is 33 characters; the maximum length of the function name is 63 characters.
- The installation cannot accept a composite parameter (that is, a parameter with a width exceeding 4 bytes) when calling a DLL file. However, a parameter can be a pointer that points to a composite structure.
- A string variable whose address is stored in a pointer variable cannot be changed by passing the pointer to a DLL file function. To allow a DLL file function to change the value of a string variable, pass the variable itself as an argument to the function, after declaring the data type of that argument specifying the BYREF operator.

Task: ***To call a DLL file function from your script:***

1. Add the DLL file to your project as a support file if you have not already done so. For more information, see Adding Support Files.
1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. In the **InstallScript** explorer, click the InstallScript file (.rul) that should call the DLL function.
3. At the beginning of the script, prototype the function using the following syntax:

   ```
   prototype [CallingConvention] [ReturnType] DLLName.FunctionName( ParamType1, ParamType2, ... );
   ```

For example:

```
prototype BOOL MyDLL.MyFunction( INT, INT, INT );
```

You can specify the calling convention to be cdecl or stdcall. If you do not specify a calling convention, InstallShield uses stdcall.

Note that the DLL file name is case-sensitive; for example, the script compiler treats *MyDLL.MyFunction* and *mydll.MyFunction* as different functions. When prototyping functions from `User.exe`, `User32.dll`, `Gdi.exe`, `Gdi32.dll`, `Krnl386.exe`, `Krnl286.exe`, or `Kernel32.dll`, you may use the keywords USER, GDI, and KERNEL in place of the DLL file name.

You can specify the return type to be any InstallScript data type except LIST. If you are declaring a DLL file function call in which a wide-character string argument or a Unicode string argument is expected, use the wstring data type. If you do not specify a return type, the installation assumes that the DLL file function returns a 4-byte value.

4. Load the DLL file by calling the **UseDLL** function. For example:

```
UseDLL( SUPPORTDIR ^ "MyDLL.dll" );
```

Note • *You do not have to load `_isuser.dll`, `_isres.dll`, or Windows API DLL files, such as `User.exe`, `User32.dll`, `Gdi.exe`, `Gdi32.dll`, `Krnl386.exe`, `Krnl286.exe`, and `Kernel32.dll`. Do not call* ***UseDLL*** *and* ***UnUseDLL*** *to load and unload these DLL files.*

5. Call the function as you would call any other function. For example:

```
bResult = MyDLL.MyFunction( nInt1, nInt2, nInt3 );
```

It is recommended that you include the DLL file name in the function call, as in the preceding example. If your script declares functions with the same name from different DLL files, calling the function without including the DLL file name results in a compiler error.

If the installation does not find the called function in the DLL file, the installation raises an exception, which you can handle by using a try...catch...endcatch block.

6. After all script calls to the DLL have been made, unload the DLL file by calling **UnUseDLL**. For example:

```
UnUseDLL( SUPPORTDIR ^ "MyDLL.dll" );
```

Note • *You can use the IS_NULLSTR_PTR variable to pass a null pointer to an external DLL function or Windows API through a parameter that has been prototyped as an InstallScript string. For more information, see IS_NULLSTR_PTR.*

Passing an Array to a DLL File Function

InstallScript arrays are internally formatted as OLE Automation safe arrays, not native C or C++ arrays. To pass an InstallScript array to a DLL function that expects a C or C++ array, you must place the array data in the expected format by calling GetCArrayFromISArray.

Declaring Functions

The first step in creating a user-defined function is to declare the function. The keyword *prototype* tells the InstallShield script compiler that the line contains a function definition.

Task: ***To declare a function:***

1. Type the keyword `prototype`.
2. Type the function's return type. (This step is optional. If you do not enter a return type, it is assumed that the function returns a NUMBER value or no value.) To specify that the function does not return a value, type `void`.
3. On the same line, enter the function name.
4. After the function name, type the data types of the parameters, and enclose them in parentheses and separate them by commas.
5. If there are no parameters, put empty parentheses to the right of the function name.
6. End the line with a semicolon (;).

In the following examples, **FunctionName** is a function containing three parameters. The arguments passed when calling **FunctionName** must be, in order, INT, STRING, and SHORT. **CopyBitmapExample** has no parameters. **FileTransfer** has five parameters—three LONG variables and two STRING variables—and returns a NUMBER value.

```
prototype FunctionName (INT, STRING, SHORT);
prototype CopyBitmapExample( );
prototype NUMBER FileTransfer (LONG, LONG, LONG, STRING, STRING);
```

When you are declaring DLL functions, use the format <DLL file name>.<function name> for the name of the DLL file function. For example:

```
prototype MyDLL.MyFunction(INT, INT);
```

The above declaration signals to the InstallScript compiler that the program will call a function named **MyFunction**, with two INT parameters, in a file named **MyDll.dll**.

You can also optionally declare a calling convention, either cdecl or stdcall, when declaring a DLL file function. For example:

```
prototype cdecl MyDLL.MyFunction(INT, INT);
```

If you do not explicitly declare a calling convention, InstallShield uses stdcall. If you explicitly declare both a calling convention and a return type, place the calling convention before the return type.

Note • *Most Windows API functions use the stdcall calling convention, but some C or C++ development environments build DLL file functions with the cdecl calling convention unless you prototype your C or C++ function with the __stdcall modifier. For more information, consult your compiler documentation.*

Many Windows API functions are declared in the header file `ISRTWindows.h`, which is automatically included when you include `Ifx.h` in your script. (You can prevent the automatic definition of Windows APIs by placing the

preprocessor constant ISINCLUDE_NO_WINAPI_H in the Preprocessor Defines box on the Compile/Link tab of the Settings dialog box.)

Returning Values from Functions

Like InstallScript's built-in functions, user-defined functions can be designed to return a value to the caller. To return a value from a function, you must include a return statement, followed by the value to be returned, before the function's end statement. If you do not include a return statement or if you do not specify a value after the keyword return, the value returned by the function is unpredictable. (If the function prototype specifies a return type of void, the function cannot return a value.)

Many programmers use return statements to return error codes that indicate the success or failure of a function call. Most of InstallScript's built-in functions use a return statement for that purpose. The return statement also is used commonly to create functions that return the result of an operation performed on parameters passed to the function, as in the example below, which returns the area of a rectangle:

```
function RectangleArea (nLength, nWidth)
    INT nVal;
begin
    nVal = (nLength * nWidth);
    return nVal;
end;
```

The keyword return can be followed by a constant, a variable, a numeric or string expression, or a function call. In the example below, **RectangleArea** has been modified to eliminate the assignment statement; the arithmetic expression follows the keyword return:

```
function RectangleArea (nLength, nWidth)
begin
    return (nLength * nWidth);
end;
```

The value returned by a function can be ignored by the calling program or function, tested in a conditional expression, or assigned to a variable. In the following example, the return value from **RectangleArea** is assigned to the variable *nArea*:

```
nArea = RectangleArea (nLong, nWide);
```

In the next example, the result of **RectangleArea** is tested in a conditional expression:

```
if (RectangleArea(nLong, nWide) > nMaxArea) then
        MessageBox("Area exceeds maximum allowed.", INFORMATION);
    endif;
```

To return more than one value or non-numeric values, use the BYREF operator to define parameters that are passed by reference.

Unsupported Functions

Some of the functions that were available in InstallShield Professional and InstallShield—Windows Installer Edition are not supported in InstallShield.

Component Functions

In InstallShield, features are the top-most level of project organization from the end user's perspective. Because of this, component functions are now feature functions. For example, **ComponentDialog** is now **FeatureDialog**. Nearly all of the component functions are available to you as feature functions in InstallShield.

Project *• Feature functions are available for use in InstallScript and InstallScript MSI project types. If you have a Basic MSI project, you must convert your project to the InstallScript MSI project type in order to use feature functions in your installation.*

PreShowComponentDlg and PostShowComponentDlg

In InstallShield—Windows Installer Edition 2.x, you had to call the **PreShowComponentDlg** and **PostShowComponentDlg** functions in order to use component-related (now feature-related) functions. In InstallShield, feature-related functions are available only for InstallScript and InstallScript MSI project types. If you have a Basic MSI project, you must convert your project to the InstallScript MSI project type in order to use feature functions in your script.

Because feature functions are not supported for use in Basic MSI projects, the **PreShowComponentDlg** and **PostShowComponentDlg** functions are no longer necessary and are not supported.

Writing Entry-Point Functions

Project *• This information applies to the following project types:*

- *Basic MSI with InstallScript custom actions*
- *InstallScript MSI with InstallScript custom actions*
- *Merge Module with InstallScript custom actions*

When Windows Installer executes an InstallScript custom action, InstallShield calls the function that you specified when you created the custom action. Every InstallScript custom action must have an exported, user-defined function as an entry point into the script.

Prototyping and Defining Functions

An entry-point function is prototyped and defined like any other function, except that it has the following requirements:

- Its prototype must include the keyword export to declare it as an exported function.
- The function can accept only one argument, which must be a handle to the .msi database.
- It should return a value meaningful to Windows Installer, if your custom action is designed to wait for a return value. These custom action return values are defined in `IsMsiQuery.h` and available to you if you include `IsMsiQuery.h` or `Iswi.h` in your script.

The following example script declares an entry-point function, which returns success if it succeeded:

```
// Include Isrt.h for built-in InstallScript function prototypes.
#include "isrt.h"

// Include Iswi.h for Windows Installer API function prototypes and constants.
#include "iswi.h"

export prototype MyFunction(HWND);

function MyFunction(hMSI)
    STRING szKey, svValue, svPath;
    NUMBER nvType, nvSize, nReturn;
begin
    RegDBSetDefaultRoot (HKEY_LOCAL_MACHINE);

    szKey = "SOFTWARE\\Microsoft\\Windows\\CurrentVersion\\App Paths\\isdev.exe";
    nReturn = RegDBGetKeyValueEx (szKey, "Path", nvType, svValue, nvSize);

    // The App Paths key contains the folder where InstallShield was
    // installed, followed by a semicolon.
    StrSub (svPath, svValue, 0, StrFind(svValue, ";"));

    if nReturn = 0 then
        MessageBox ("InstallShield is installed to " + svPath, INFORMATION);
        return ERROR_SUCCESS;
    else
        MessageBox ("Cannot determine where InstallShield is installed.", SEVERE);
        return ERROR_INSTALL_FAILURE;
    endif;
end;
```

Multiple Entry Points

Your script can have multiple entry-point functions in it to serve multiple custom actions. However, InstallShield calls only the single entry-point function specified for each InstallScript custom action.

Adding Function Calls with the Function Wizard

You can use the Function Wizard to select a function, specify its arguments, and insert the function in your script.

Declared Windows API Functions

Project • *This information applies to InstallScript projects.*

Windows API functions are declared in the header file `ISRT.h`, which is automatically included in your installation when you include `Ifx.h` in your script. If this function is also explicitly declared in your script code, do one of the following:

- Remove your function declaration and use the declaration that is provided by InstallShield.
- If you are creating a script that needs to be compatible in both InstallShield 2013 and versions of InstallShield Professional earlier than 7, surround your declaration with code such as the following:

```
#if _ISCRIPT_VER < 0x700prototype ...#endif
```

You may also need to update code that calls the Windows API function, if the declaration that is defined by InstallShield is different than your declaration.

You can prevent the automatic definition of Windows APIs by placing the preprocessor constant ISINCLUDE_NO_WINAPI_H in the Preprocessor Defines box on the Compile/Link tab of the Settings dialog box.

Specifying a Non-Default Feature Event Handler Function

By default, if the file `Setup.rul` exists in the InstallScript view and defines a function <feature name>_<event name> (for example, **NewFeature1_Installing**), then that function is the handler for that event of that feature.

You can select a different function to be the handler for the feature event. It can be any function defined in any script file in the InstallScript view, as long as it takes no arguments and is declared using the export keyword, for example:

```
export prototype MyFeatureHandler();
```

Task: ***To specify a non-default feature event handler function, do the following:***

1. Open a script file (.rul file) in the **InstallScript** view.
2. Do one of the following in the script editor pane:
   - Declare and define the function that you want to specify as a feature event handler.
   - In the Event Category and Event lists at the top of the script editor pane, select the feature and select an event handler. InstallShield automatically creates the event handler (for example, Feature1Installing).

Note • *If you put parentheses in a feature's name, event handler functions with names of the default form <feature name>_<event name> will not compile properly.*

Accessing Global Variables

Project • *This information applies to InstallScript MSI projects.*

A global variable is data declared outside of a function and available to any module in the script. By using global variables, you can share persistent data with event handlers, entry-point functions, and user-defined functions.

For example, if you retrieve the value of the operating system's version in your OnBegin event handler, you can later access that global value in an entry-point function. The following script excerpt illustrates this:

```
// Include header file for built-in functions
#include <isrt.h>
// Include header file for event handlers and MSI APIs
#include <iswi.h>
```

```
    // Declare global variable
    NUMBER nvResult;

    // Prototype entry-point function
    export prototype MyFn(HWND);

function OnBegin()
    // Declare local variable
    STRING svResult;
begin
    GetSystemInfo (WINMAJOR, nvResult, svResult);
end;

function MyFn(hMSI)
begin
    if nvResult > 4 then
        // Code for version of Windows later than 4.0
    else
        // Code for Windows 4.0
    endif;
end;
```

Important • *Global variables share state across all event handlers. However, if you create an InstallScript custom action for your project, global variables will not share state from the InstallScript custom action to the event-driven InstallScript code, or vice versa. Thus, if you declare a global variable in your event-driven InstallScript code, that variable would not be available to your InstallScript custom action. Similarly, if you declare a variable in your InstallScript custom action, that variable would not be available to your event-driven InstallScript code.*

Uninstalling Initialization (.ini) File Entries

The uninstallation removes modifications that are made with the InstallScript initialization file functions while logging is enabled. For more details, see the information in this section of the documentation.

General Limitations of Uninstalling Initialization (.ini) File Entries

The following limitations apply to uninstalling .ini file entries and modifications automatically:

- Logging must be enabled when the .ini file functions are called.
- If an .ini file was created by any of the .ini file functions, it is not removed.
- If a section name was created by any of the .ini file functions, it is not removed, even if no more keys are present.
- If a key value is completely replaced by an InstallScript function (not appended to, or prepended to), the key values that existed before the installation are not restored. In this case InstallShield considers the replaced key a newly created key and will uninstall it as if it is a new key that was created by the installation.
- The uninstallation does not restore keys or values that were deleted using **WriteProfString**.

- To append a value to existing key (for example, network under [386Enh]), the new entry must either be appended at the end or prepended in the very beginning of the existing string, but never inserted in the middle.
- Only the comma (,) and semicolon(;) are considered valid delimiters. If a string value to be uninstalled is found as a part of longer string, the value and the delimiter before or after it is also removed appropriately (based on the string's position) only if the delimiter is a comma or a semicolon. For example, if the uninstallation removes **pqr** from the string **Key=pqr,rst,uvw**, it also removes the comma after **pqr**. A character other than a comma or a semicolon in its place will not be removed. As a rule, avoid adding spaces around delimiters.

Uninstalling AddProfString's Initialization (.ini) File Entries

The uninstallation removes the keyname and value pair completely if the following conditions are true:

- The key was successfully created by **AddProfString**.
- The keyname and the value pair that exist when the uninstallation is run exactly match the installed keyname and value pair. If another installation or program modifies the installed key between the installation and uninstallation, the keyname and value pair will not be removed completely. Only the value that was created by the original installation will be removed; the key itself and any additional values will not be removed by the uninstaller.

For example, if the `System.ini` file originally read as follows:

```
[386Enh]
device=votc.386
device=*vmpcd
```

and after your call to AddProfString, it read as follows:

```
[386Enh]
device=*vmp32
device=votc.386
device=*vmpcd
```

the uninstallation would remove `device=*vmp32`.

If another installation had added a value to the existing line, only the value from the installation that is being uninstalled will be removed. The original keyname and the new value will be left in the file. For example, if you had added the line **Test Values=votc.386** in `Test.ini` under the `[Test]` section:

```
[Test]
Test Values=votc.386
Continuous Test=No
```

and another installation had added a new value to Test Values after your installation had run:

```
[Test]
Test Values=votc.386,pctcp.386
Continuous Test=No
```

when your application is uninstalled, `votc.386` will be removed and `TestValues=pctcp.386` will be left in the file:

```
[Test]
Test Values=pctcp.386
Continuous Test=No
```

Uninstalling ReplaceProfString's Initialization (.ini) File Entries

The uninstallation removes the keyname and value pair completely if the following conditions are true:

- The key was successfully created by **ReplaceProfString**.
- The key did not previously exist.
- The keyname and value pair that exist when the uninstallation is run exactly match the installed keyname and value pair. If another installation or program modifies the installed key between the installation and uninstallation, the keyname and value pair will not be removed completely. Only the value that was created by the original installation will be removed; the key itself and any additional values will not be removed by the uninstaller.

For example, if the `System.ini` file originally read:

```
[386Enh]
device=votc.386
device=*vmpcd
```

and after your call to **ReplaceProfString**, it read:

```
[386Enh]
device=*vmp32
device=votc.386
device=*vmpcd
```

the uninstallation would remove `device=*vmp32`.

Uninstalling WriteProfString's Initialization (.ini) File Entries

The uninstallation removes the keyname and value pair completely if the following conditions are true:

- The key was successfully created by **WriteProfString**.
- The key did not previously exist.
- The keyname and value pair that exist when the uninstallation is run exactly match the installed keyname and value pair. If another installation or program modifies the installed key between the installation and uninstallation, the keyname and value pair will not be removed completely. Only the value that was created by the original installation will be removed; the key itself and any additional values will not be removed by the uninstaller.

Extending Your Installation with COM Objects

Important • *Do not confuse COM objects with InstallShield objects. They are two separate features.*

Instead of using DLLs or other executable files, you can extend your installation with COM objects. COM objects can be integrated into your installation fairly easily. Use the following procedure to assign COM objects in your script.

Task: ***To assign a COM object:***

1. Declare an object variable. For example:

   ```
   OBJECT oMyCOMObject
   ```

2. Get a reference to your COM object and assign it to the variable by using the set keyword. For example:

   ```
   set oMyCOMObject = CreateObject ( szMyProgID );
   ```

The value of szMyProgID is a valid program ID for your COM object. If you leave the set keyword out, the script engine attempts to set the default property of oMyCOMObject to szProgID. Because there is no default property, since oMyCOMObject does not contain a reference to your COM object yet, the script will fail.

Important • *By default, once a COM object is loaded by the installation using* ***CoCreateObject****,* ***CoCreateObjectDotNet****,* ***CoGetObject****, or* ***DotNetCoCreateObject****, it remains loaded until the installation is finished. The COM object remains loaded regardless of whether the COM object variable goes out of scope or is set to NOTHING.*

Consequently, the library referenced by the COM object is also not released until the installation is finished. However, it is possible to unload the library referenced by the COM object by calling the Windows API ***CoFreeLibrary****.* ***CoFreeLibrary*** *unloads the library regardless of whether any object variables still reference it. Therefore, you should only call* ***CoFreeLibrary*** *after all objects that reference the library have gone out of scope or are set to NOTHING. See the following example code:*

```
prototype void ole32.CoFreeLibrary( byval int );
int hModule;

program

    // Free the library.
    hModule = GetModuleHandle( "CSharpClassLibrary.dll" );

    if( !hModule ) then
       MessageBox( "Failed to get module handle", INFORMATION );

    else

       CoFreeLibrary( hModule ); // Release the library

    endif;
```

endprogram

CoFreeUnusedLibraries *can also be used to unload the library. However, by default, the system waits 10 minutes before unloading the library, and in most cases, the installation requires the library to be unloaded immediately. If your installation will run on Windows XP and later only, you can call* ***CoFreeUnusedLibrariesEx****, which includes the option of unloading the library immediately.*

Below is an example COM object that validates a serial number. It has one method, Validate, and one property, IsEval.

```
function OnFirstUIBefore()
    OBJECT oObj;
    STRING szProgID, szMsg, szTitle, svName, svCompany, svSerial;
    BOOL bValidSerialNumber, bEval, bValidate;
    NUMBER nResult;
begin
    szProgID = "MySerialValidation";
    set oObj = CreateObject( szProgID );
    if ( !IsObject( oObj ) ) then
        MessageBox( "Object " + szProgID + " is invalid!", SEVERE );
        return ISERR_GEN_FAILURE;
    endif;

    bValidSerialNumber = FALSE;
    while (!bValidSerialNumber)
        szMsg = "Please enter your name, company name, and product serial number.";
        szTitle = "Enter info";
        nResult = SdRegisterUserEx( szTitle, szMsg, svName, svCompany, svSerial );
        if ( nResult < 0 ) then
            MessageBox( "Failed to display dialog box.", INFORMATION );
            return ISERR_GEN_FAILURE;
        endif;

        /* Check the value of the object's IsEval property. */
        bEval = oObj.IsEval;
        /* Execute the object's Validate method and
        get the return value from the method. */
        bValidate = oObj.Validate( svSerial );
        if ( bEval || bValidate ) then
            bValidSerialNumber = TRUE;
        else
            MessageBox( "Invalid serial number; please re-enter.", INFORMATION );
        endif;
    endwhile;

    return ISERR_SUCCESS;
end;
```

Note *• You can pass a data structure to your COM object as long as it has the members that your COM object expects. The following is an example of passing a data structure:*

```
#define PERSON_NAME_SIZE 1024
```

```
typedef PERSON
    begin
        STRING Name[PERSON_NAME_SIZE];
        NUMBER Age;
    end;

function OnBegin()
    PERSON pPerson;
    NUMBER nPhoneNumber;
    OBJECT oMyCOMObject;
    STRING szMyProgID;
begin
    /* Assign a value to szMyProgID in this line. */
    set oMyCOMObject = CreateObject ( szMyProgID );
    if ( !IsObject( oMyCOMObject ) ) then
        MessageBox( "Object " + szMyProgID + " is invalid!", SEVERE );
        return ISERR_GEN_FAILURE;
    endif;
    nPhoneNumber = oMyCOMObject.GetPhoneNumber( pPerson );

    return ISERR_SUCCESS;
end;
```

Note *• The standard COM return value HRESULT is not visible to an automation client such as InstallScript. To return a value from your COM object method, you should have an [out,retval] parameter in your method's parameter list, as illustrated in the following code samples.*

IDL:

```
interface IMyInterface : IDispatch
{
    [id(1)] HRESULT DoSomeWork([in] long nInputValue, [out,retval] long *pReturnValue);
}
```

C++:

```
STDMETHODIMP MyInterfaceImpl::DoSomeWork(long nInputValue, long *pReturnValue)
{
    // your implementation code
    *pReturnValue = 1; //return a value to client
    return S_OK;
}
```

InstallScript:

```
function OnBegin()
    NUMBER nObjReturn;
begin
    set oMyCOMObject = CreateObject("MyProgID");
    if (IsObject(oMyCOMObject) then
        nObjReturn = oMyCOMObject.DoSomething(10);
        /*nObjReturn will contain the value 1, returned from your implementation*/
    endif;
end;
```

Specifying Features and Subfeatures in Function Calls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Feature is a general term that refers to a set of components or subfeatures in InstallShield. A *subfeature* is a feature that is located below another feature—similar to the relationship between a folder and a subfolder.

Top-level features are the highest features in the hierarchy. Top-level features are never referred to as subfeatures.

How to Refer to Features and Subfeatures in InstallScript Code

Some feature functions and setup type dialog functions require you to refer to a single feature, while others require you to refer to multiple features.

Referring to Single Features

To refer to a single feature, use the feature's name. To refer to a subfeature, use a path-like expression where the name of each feature in the hierarchy leading to that feature is separated by double backslashes. For example, to specify the subfeature **Tutorials** under the top-level feature **Help Files**, use the following expression in your installation script:

```
szFeature = "Help Files\\Tutorials";
```

To refer to the subfeature **CBT** under **Tutorials**, use the following:

```
szFeature = "Help Files\\Tutorials\\CBT";
```

Note that the name of a feature cannot contain backslashes.

Referring to Multiple Features

In InstallScript MSI installations, some feature and setup type dialog functions, such as **SdFeatureMult**, display multiple features and their subfeatures. In these cases, you refer to multiple features by specifying the feature immediately above them in the hierarchy. To refer to multiple top-level features, use a null string ("").

For example, if you pass a null string to the **SdFeatureMult** function, the corresponding dialog displays all the top-level features in your script-created component set in the left window on the **SdFeatureMult** dialog, depending on the value of the MEDIA system variable. All subfeatures appear in the right window on this dialog.

Calling a Windows API Function

Project • *This information applies to the following project types:*

- *InstallScript*

- *InstallScript MSI*

You can call a Windows API function from within your InstallScript code.

Task: ***To call a Windows API function:***

1. At the beginning of the script, prototype the function using the following syntax:

   ```
   prototype ReturnType DLLName.FunctionName( ParamType1, ParamType2, ... )
   ```

   For example:

   ```
   prototype INT User.LoadString( INT, SHORT, BYREF WSTRING, INT );
   ```

   Use `Dumpbin.exe` with the `/EXPORTS` option to determine which functions reside in any of the Windows API DLLs `Kernel32.dll`, `User32.dll`, and `GDI32.dll`. To determine the return type and parameter types for a function, consult a Windows programming reference such as the Microsoft Development Library (MSDL).

   

   Note • *You can specify the return type to be one of the following InstallScript data types: BOOL, CHAR, HWND, INT, LONG, LPSTR, NUMBER, POINTER, or SHORT. If a return type is not specified, InstallShield assumes that the DLL function returns a 4-byte value.*

2. Call the function as you would call any other function. For example:

   ```
   nResult = LoadString( iInstance, nStringID, szMyString, MAX_SIZE );
   ```

3. To get extended error information if the function fails, check the value of the Err object's LastDllError property. (It is not possible to call the Windows API function **GetLastError** to get extended error information, since the setup itself changes this value before returning control to the script.)

Embedding Custom Transfer File Operations

In InstallShield, you can embed additional file transfer operations during the standard file transfer of the installation. Also, the progress bar is updated smoothly and appropriately during these operations. There are a few different common scenarios in which you would use this functionality.

This table provides an overview of what functions are called for each scenario.

Table 4-3 • Determining Which Functions Are Appropriate for Common Custom Transfer File Operations

Scenario Using	Function that Should Be Called
FeatureMoveData	None
XCopyFile or CopyFile	FeatureAddCost
LaunchApplication (external applications)	FeatureAddCost, FeatureSpendCost, FeatureAddUninstallCost, or FeatureSpendUninstallCost

These procedures include step-by-step information about how to use custom file transfer operations for each scenario.

Task: ***To install additional files during the standard file transfer operation using XCopyFile or CopyFile:***

1. Before file transfer, determine the size of the files to be installed, taking into account the cluster size on the target folder for the files. You can accomplish this using the **GetAndAddFileCost**, **CalculateAndAddFileCost**, and/or **GetAndAddAllFilesCost** functions.
2. Using the **FeatureAddCost** function, add the cost determined in Step 1 to the cost for the feature that these files are associated with. Note that all cost must be associated with a particular feature. Therefore, if the files to be installed are not associated with an existing feature, you must create a dummy feature or use an existing feature.
3. During file transfer, call the **XCopyFile** function to install the files. Typically, this would be done during the Installing event of the feature associated with the additional files or in the OnMoving or OnMoved events. The progress bar is updated smoothly and appropriately during the call. Note that you should disable the Cancel button in the status dialog during the `XCopyFile` operation. See the description for the XCopyFile function for more information.

Note • *There is no additional action required for the uninstallation. The files are uninstalled while the uninstallation progress is updated appropriately.*

Task: ***To call an external installation that installs additional files during the standard file transfer operation:***

1. Before file transfer, determine the size and number of the files to be installed (or other operations) by the external installation by examining the external installation and taking note of what operations occur.
2. Using the **FeatureAddCost** function, add the cost determined in Step 1 to the cost for the feature that this installation is associated with. Note that all cost must be associated with a particular feature. Therefore, if the files to be installed are not associated with an existing feature, you must create a dummy feature or use an existing feature. Review the two scenarios below.
3. If the external installation is called during uninstallation, add the number of operations and size of the operations to the uninstallation cost using **FeatureAddUninstallCost**.
4. During file transfer, use the **LaunchApplication** event to launch the installation, typically in silent mode. Typically, this would be done during the Installing event of the feature associated with the additional files or in the OnMoving or OnMoved events. Use the LAAW_USE_CALLBACK option so that your script regains control periodically during the installation and uninstallation.
5. Override the **OnLaunchAppAndWaitCallback** event, and add code to poll the running installation to determine its progress. Then call the **FeatureSpendCost** (Installation) function or the **FeatureSpendUninstallCost** (Uninstallation) function to spend the appropriate amount of cost that the installation has completed. Repeat this process while the external installation is running. The progress bar is updated smoothly and appropriately during the call. Note that you might have to adjust the

LAAW_PARAMETERS.nCallbackInterval so that the **OnLaunchAppAndWaitCallback** event is called often enough to keep the progress updated smoothly.

Expressing Large Numbers in InstallScript

When a number is stored in an InstallScript integer, only 31 bits of data are available to store the value. Therefore, the maximum value that can be expressed is 2 ^ 31 (2 GB). Note also that since InstallScript integers are always considered to be signed, the 32 bit is interpreted as the sign bit and cannot be used to store numeric data. This limits the values that can be expressed to 2 ^ 31 (2 GB) instead of 2 ^ 32 (4 GB), which could be stored in an unsigned data type.

In some cases, it is necessary or desirable to be able to specify larger values. To accomplish this in InstallShield, a number of functions support the specification of large numbers as a pair of 32-bit numbers with the sign bit (32 bit) of each number always being set to 0 to indicate a positive number. Using this format, it is possible to specify and retrieve a number with up to 62 bits of data or 2 ^ 62 of size.

Note however that since the language does not have a data type that can express the number as a single variable, the operations that can be performed on this data are limited. This data is typically passed between functions that support these values. The data can also be converted to a single value expressed in a larger size unit (such as KB or MB) using the **ConvertSizeToUnits** function or passed to an external DLL function that can handle larger data types.

When a number is specified as a high/low pair, the lower 32-bit value specifies the lower 31 bits of data (with the sign bit always set to 0 and ignored) of the full value. The upper 32-bit value specifies the upper 31 bits of data (again with the sign bit always set to 0 and ignored). For example, an upper value of 4 actually indicates 4 * 2 ^ 31 or 8589934592 (8 GB) of size. This, combined with a lower value of 100, would indicate a total size of 8589934692 units.

Note that in the case of numbers less than 2 ^ 31, the high value will always be 0 and thus can be ignored if you are sure that the size of the value will never exceed 2 ^ 31. However, it is recommended that if you need to use this data for computations, you use the **ConvertSizeToUnits** function to convert this data to a single value of the most appropriate units with minimal amount of rounding to express the data in a single value.

Note *• Note that convention differs from the unsigned high/low value pairs used by Windows in which the lower value stores the lower 32 bits of data and the high value stores the upper 32 bits of data. The* ***ConvertWinHighLowSizeToISHighLowSize*** *function is provided for easy conversion of data returned by Windows API functions.*

The following functions support high/low value pairs:

- GetDiskInfo
- GetFileInfo
- GetAndAddFileCost
- CalculateAndAddFileCost
- GetAndAddAllFilesCost

- FeatureFileInfo
- FeatureGetCostEx
- FeatureAddCost
- FeatureSpendCost
- ConvertWinHighLowSizeToISHighLowSize
- ConvertSizeToUnits

Installing Device Drivers

InstallShield supports installing device drivers in InstallScript installations using Windows Driver Install Frameworks (DIFx), which includes the DIFxAPI component. This component allows drivers to be installed or uninstalled without using the Windows Installer.

Project • *This information applies to InstallScript projects. Installing device drivers is supported in InstallScript MSI and Basic MSI projects using the DIFx Windows Installer functionality. For information on configuring device drivers using the Windows Installer, see Configuring Device Driver Settings.*

Task: ***To install a 32-bit DIFx driver in an InstallScript project:***

1. In the View List under **Installation Information**, click **General Information**.
2. For the **DIFx Support (for 32-bit platforms)** setting, select **Enabled**.
3. Add the DIFx driver files to the project.
4. Override the feature event for the feature containing the DIFx driver files and either call the **DIFxDriverPackageInstall** function for non-Plug and Play (PnP) drivers or the **DIFxDriverPackagePreinstall** function for PnP drivers.
5. Build and run the installation.

Task: ***To install a 64-bit DIFx driver in an InstallScript project:***

1. In the View List under **Installation Information**, click **General Information**.
2. For the **DIFx Support (for 64-bit Itanium platforms)** setting or the **DIFx Support (for 64-bit AMD platforms)** setting, select **Enabled**.
3. Add the DIFx driver files to the project.
4. Override the feature event for the feature containing the DIFx driver files and either call the **DIFxDriverPackageInstall** function for non-Plug and Play (PnP) drivers or the **DIFxDriverPackagePreinstall** function for PnP drivers.

5. Build and run the installation.

Checking the Compiler Version

In InstallShield, _ISCRIPT_VER is defined as 0x*VVM*, where *VV* is the major version of the product and *M* is the maintenance pack release number. For example, 0x900 evaluates as InstallShield DevStudio version 9.0 and maintenance pack 0 (the first release). This preprocessor constant was defined in InstallShield Professional 7 as 0x700 and in InstallShield Professional 6 as 0x600, but is undefined and evaluates as zero in InstallShield Professional 5.x.

You can use this constant to test whether the InstallShield compiler is being used by including code like the following in your script. This code tests for the existence of the first release of InstallShield DevStudio (version 9.0, maintenance pack number 0) or later.

```
#if _ISCRIPT_VER >= 0x900
    MessageBox( "DevStudio 9.x and above",INFORMATION );
#elif _ISCRIPT_VER >= 0x700
    MessageBox ( "This is an IS 7.x compiler.", INFORMATION );
#else
    MessageBox ( "This is an IS 6.x compiler or below.", INFORMATION );
#endif
```

Preprocessor Constants Maintained for Backwards Compatibility

The preprocessor constants _ISCRIPT_ISPRO and _ISCRIPT_ISDEV will be maintained for backwards compatibility. _ISCRIPT_ISPRO is defined for InstallScript projects (and InstallShield Professional projects). _ISCRIPT_ISDEV is defined for InstallScript MSI projects and Basic MSI projects.

Checking the Authoring Environment with _ISCRIPT_ISDEV and _ISCRIPT_ISPRO

Project • *This information applies to InstallScript projects.*

The preprocessor constant _ISCRIPT_ISPRO is defined in InstallScript projects (and in InstallShield Professional projects) but is undefined and evaluates as zero in InstallScript MSI and Basic MSI projects. The preprocessor constant _ISCRIPT_ISDEV is defined in InstallScript MSI and Basic MSI projects but is undefined and evaluates as zero in InstallScript projects (and in InstallShield Professional projects).

You can use _ISCRIPT_ISDEV and _ISCRIPT_ISPRO to write a single script that produces different behavior in the different project types by including code like the following in your script:

```
#ifdef _ISCRIPT_ISPRO
    // code specific to InstallShield Professional and InstallScript projects
#else
    #ifdef _ISCRIPT_ISDEV
        // code specific to Basic MSI and InstallScript MSI projects
    #endif
#endif
```

Launching an Installation from Another InstallScript Installation

Project • *The following information applies to InstallScript projects.*

You can launch a complete installation by calling the **LaunchApplication** function. For example, if you placed the child installation's files on a CD-ROM, you could call **LaunchApplication** as follows:

```
LaunchApplication (SRCDISK ^ "Launched Setup Folder\\Setup.exe", "", "", SW_HIDE,"",
LAAW_OPTION_WAIT);
```

As an alternative, you can include the child installation in your project as a support file. If you do this, your main installation copies the child installation to the target system, runs the installation, and deletes the installation along with any other support files. Use the SUPPORTDIR variable in the path of your child installation:

```
LaunchApplication (SUPPORTDIR ^ Setup.exe, "", "", SW_HIDE,"", LAAW_OPTION_WAIT);
```

Alternatively, you could insert links to the child installation into your file groups, install the child installation onto the target system, and then launch the installation from the target location. (With these methods, the child installation is left on the target system until the parent installation is uninstalled.)

Language Support for InstallScript

The table below shows the languages supported by the Premier edition of InstallShield. Following are descriptions of each of the columns:

- **InstallShield Language**—Name used by the InstallShield interface to refer to this language.
- **InstallScript Constant**—Language constant provided by InstallShield for filtering language-specific components.
- **Windows English Equivalent**—Name that the English version of Windows uses to refer to the language.

Table 4-4 • Supported Languages

InstallShield Language	InstallScript Constant	English Equivalent
Basque	ISLANG_BASQUE	Basque
Bulgarian	ISLANG_BULGARIAN	Bulgarian
Catalan	ISLANG_CATALAN	Catalan
Chinese (Simplified)	ISLANG_CHINESE_SIMPLIFIED	Chinese (Simplified)
Chinese (Traditional)	ISLANG_CHINESE_TRADITIONAL	Chinese (Traditional)

Table 4-4 • Supported Languages (cont.)

InstallShield Language	InstallScript Constant	English Equivalent
Croatian	ISLANG_CROATIAN Note that for backward compatibility, this constant continues to be 0x001a rather than the more logical 0x041a (in light of its relation to Serbian); you should continue to use this constant rather than ISLANG_CROATIAN_STANDARD.	Croatian
Czech	ISLANG_CZECH	Czech
Danish	ISLANG_DANISH	Danish
Dutch	ISLANG_DUTCH	Dutch (Standard)
English	ISLANG_ENGLISH	English (United States)
Finnish	ISLANG_FINNISH	Finnish
French (Canadian)	ISLANG_FRENCH_CANADIAN	French (Canadian)
French (Standard)	ISLANG_FRENCH_STANDARD	French (Standard)
German	ISLANG_GERMAN	German (Standard)
Greek	ISLANG_GREEK	Greek
Hungarian	ISLANG_HUNGARIAN	Hungarian
Indonesian	ISLANG_INDONESIAN	Indonesian
Italian	ISLANG_ITALIAN	Italian (Standard)
Japanese	ISLANG_JAPANESE	Japanese
Korean	ISLANG_KOREAN	Korean
Norwegian	ISLANG_NORWEGIAN	Norwegian (Bokmal)
Polish	ISLANG_POLISH	Polish

Table 4-4 • Supported Languages (cont.)

InstallShield Language	InstallScript Constant	English Equivalent
Portuguese (Brazilian)	ISLANG_PORTUGUESE_BRAZILIAN	Portuguese (Brazilian)
Portuguese (Standard)	ISLANG_PORTUGUESE_STANDARD	Portuguese (Standard)
Romanian	ISLANG_ROMANIAN	Romanian
Russian	ISLANG_RUSSIAN	Russian
Serbian	ISLANG_SERBIAN_CYRILLIC	Serbian (Cyrillic)
Slovak	ISLANG_SLOVAK	Slovak
Slovenian	ISLANG_SLOVENIAN	Slovene
Spanish	ISLANG_SPANISH	Spanish (Traditional Sort)
Swedish	ISLANG_SWEDISH	Swedish
Thai	ISLANG_THAI	Thai
Turkish	ISLANG_TURKISH	Turkish

Preventing Color Distortion

If you are experiencing problems with color distortion in your InstallScript custom action, it is most likely due to shifts in the color palette. This section explains how colors are apportioned on Windows systems and offers troubleshooting tips to help you minimize any distortion in your installation's end-user interface.

On systems operating in 256-color mode, there is one 256-color palette for displaying all available colors; in 16-color mode, there is a 16-color palette, regardless of the number of colors that the video driver supports. Systems operating in high-color or true-color mode do not use a color palette of any type. The colors are displayed directly, so color distortion should not occur on these systems. On systems using a color palette, entries are allocated and used as needed when an object—such as a bitmap—is displayed.

Once the current color palette has been allocated, to display a new color Windows attempts to use a color similar to one that was already allocated. Therefore, distortion may result on a 256-color system if multiple objects that contain several different colors are displayed simultaneously.

Also, Windows allocates 16 static colors (VGA colors) and four additional shades of gray during startup. These colors are used by the system to display 16-color images and are never de-allocated by Windows. See the Windows platform SDK for more information on color palette handling.

Use the tips below to minimize any color distortion related to color palette shifts. Color palette tips apply to all images that you display during installation, including the background color, .avi files, metafiles, and bitmaps.

Main Installation Window Background

- Try using a solid color background, which requires only one palette entry. Call the **SetColor** function with a solid background constant to create a solid background.
- Try using a 16-color gradient background, which requires only 16 palette entries. Call the **SetColor** function with one of the gradient color constants to create this type of background.
- Try using a tiled or a centered bitmap background. Call the **PlaceBitmap** function to create one of these backgrounds.
- Avoid using a 256-color gradient background, which requires about 80 palette entries.

Bitmaps and Metafiles

- When a bitmap is removed by calling the **PlaceBitmap** function with the REMOVE option, all color palette entries used by that bitmap that are not being used by any other currently displayed image are freed from the color palette when other colors are needed to display other objects. If you experience color distortion, always remove a bitmap once it is no longer visible (instead of covering it with another bitmap) so that its color palette entries are freed.
- Try to use similar colors (including the 16 static colors, which are always allocated) for bitmaps and billboards displayed during the installation to reduce the number of color palette entries needed.
- You can determine the maximum colors available on the target system by calling the **GetSystemInfo** function with the COLORS option. Perhaps you will want to display bitmaps of different resolutions based on the return value.
- Note that 24-bit bitmaps do not include a custom color palette in the bitmap file. When displaying a 24-bit bitmap on a 256-color system, only the currently available palette entries will be used, even if there are additional color palette entries available. If you are displaying 24-bit bitmaps in your installation and you expect it to run on 256-color systems, it is recommended that you also include 256-color versions of your bitmaps.
- Since metafiles are drawn instead of placed, additional color palette entries are not allocated when a metafile is drawn; only the existing color palette entries are used to display the metafile. If you expect your installation to run on 256 color systems, it is recommended that you use only the standard 16 static colors in your metafile, because these colors will be available, regardless of the current color palette's availability.
- Verify that the system's video driver supports 256 or more colors. If the video driver does not support 256 colors, the bitmap will not display properly, even if your video card and monitor support 256 colors.
- If a monitor is not capable of displaying 256-color bitmaps, only the 16 static colors are used. This can cause severe distortion problems. If you are using 256-color images in your installation, it is recommended that you require end users to run it on systems that support 256 colors.

Using Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield supports the use of custom actions to run InstallScript, VBScript, or JavaScript code; call DLL functions; run executable files; call a managed method in a managed assembly; set a property or a directory; trigger an error and end the installation; run PowerShell scripts; terminate a process; or run other installation packages.

Task: ***InstallShield divides the task of creating and implementing custom actions into the following steps:***

1. Create a custom action in the Custom Actions and Sequences view (or the Custom Actions view) or by using the Custom Action Wizard.
2. Decide when your custom action should run.
3. Launch a custom action by inserting it into a sequence or placing it as the result of a dialog's control event (Basic MSI projects).

For details about each of the InstallShield custom actions that are added automatically to InstallShield projects to support different functionality, see InstallShield Custom Action Reference.

Project • *Merge module projects only: You can control the launch of custom actions in a merge module by modifying the* ***ModuleInstallExecuteSequence*** *table in the Direct Editor. When you add the merge module to your installation project, all custom actions and dialogs included in the merge module are available for you to insert in the installation's sequences via the Custom Actions and Sequences view.*

Using the Custom Action Wizard

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

You can use the Custom Action Wizard to create a custom action or modify an existing one.

Task: ***To launch the Custom Action Wizard:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
2. Right-click the **Custom Actions** explorer and click **Custom Action Wizard**. The Custom Action Wizard launches.
3. Follow the wizard panels to create your custom action.

Alternatively, you can create a custom action in the Custom Actions and Sequences view (or the Custom Actions view) without using the Custom Action Wizard. For more information, see Creating Custom Actions in the Custom Actions and Sequences View (or the Custom Actions View).

To learn about displaying action information on the progress dialog and in the installation's log file, see Using Action Text.

Creating Custom Actions in the Custom Actions and Sequences View (or the Custom Actions View)

Project • *The Custom Actions and Sequences view is available in the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The view is called the Custom Actions view in the following project types:

- *DIM*
- *Merge Module*
- *MSM Database*

The recommended way to create a custom action is with the Custom Action Wizard. The wizard walks you through all the required steps to create a custom action and prompts for information. You can also create your custom action in the Custom Actions and Sequences view (or the Custom Actions view)—without using this wizard—by configuring all of its settings directly in the view.

Task: ***To add a custom action:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
2. Right-click the **Custom Actions** explorer and then click the type of custom action that you want to add.
3. Rename the new custom action by selecting it, pressing the F2 key, and typing the new name.
4. Configure the custom action's settings.

To learn about displaying action information on the progress dialog and in the installation's log file, see Using Action Text.

Cloning Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

InstallShield provides the ability to copy or *clone* your custom actions. Cloning creates a new custom action of the same type and with all of the same properties and values as the original custom action. You can use cloning to create multiple custom actions that have similar attributes without having to manually set every custom action attribute.

Note that the clone operation clones only the custom action. It does not insert the custom action into any of the installation sequences.

Task: ***To clone a custom action:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
2. In the **Custom Actions** explorer, right-click the custom action that you want to clone and click **Clone**.

InstallShield adds a copy of the cloned custom action to the Custom Actions explorer. The name of the custom action is the same name as the cloned custom action, except that the copy has a **1** at the end of the name.

Exporting Custom Actions to Other Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Task: ***To save a custom action to another project:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI and InstallScript MSI projects) or **Custom Actions** (in DIM and Merge Module projects).
2. In the **Custom Actions** explorer, right-click your custom action and click **Export**. The **Export into** dialog box opens.
3. Browse to the location of an existing InstallShield project file (.ism file). It can be either an installation project or a merge module project, but the file cannot be open in another instance of InstallShield.
4. Click **Open**.

A copy of this custom action is added to the specified .ism file. If the other .ism file already has a custom action of that name with different properties, the Resolve Conflict dialog box opens to offer you options for resolving the conflicts.

Configuring Custom Action Settings

Project • *The Custom Actions and Sequences view is available in the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The view is called the Custom Actions view in the following project types:

- *DIM*
- *Merge Module*
- *MSM Database*

When you create a custom action, you need to configure its settings. You may also need to later modify its settings. For example, you might want to edit the condition that is assigned to a custom action.

Depending on the type of custom action that you want to create, the settings for that action may have different meanings. For example, if your action calls an executable file that is stored in the .msi package, the Source setting needs to have the name of the entry in the table that points to the executable file that you want to call. The target setting is a command-line argument in this case.

Task: ***To configure the settings for a custom action:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
2. In the Custom Actions explorer, click the custom action whose settings you want to configure.
3. In the right pane, configure the settings as appropriate.

For information about each setting, see Custom Action Settings.

To learn about displaying action information on the progress dialog and in the installation's log file, see Using Action Text.

Custom Action Type Overview

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The value that is displayed in the MSI Type Number setting for a custom action represents a combination of the type of custom action (such as standard DLL, executable file, or InstallScript), the location (such as stored in the **Binary** table or installed with the product) as well as several of the custom action's settings, such as Return Processing, In-Script Execution, and Execution Scheduling. It is the decimal value that is calculated by using the OR operator to combine several bits that are available for the Type column in the Windows Installer **CustomAction** table. InstallShield also offers support for extended custom action types, such as InstallScript custom actions and standard DLL file functions.

The Windows Installer Help Library refers to custom actions by a numeric type. When you add a custom action to your project in the Custom Actions and Sequences view (or the Custom Actions view), the custom action type number is calculated automatically, and the MSI Type Number setting is set to this number. For example, launching an executable file whose fully qualified path is stored in the **Property** table is calculated as custom action type 50. To learn what value is used for any of the basic types of custom actions, see Summary List of All Custom Action Types in the Windows Installer Help Library.

For more information about each of the types of custom actions that are available in InstallShield, see Custom Action Types.

Custom Action Return Values

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Depending on your selections in the Custom Action Wizard's Additional Options panel, Windows Installer will wait for a successful return code before continuing with the installation. Your custom action must return one of these values according to its status.

Table 4-5 • Custom Action Return Values

Return Value	Description
ERROR_FUNCTION_NOT_CALLED	The custom action was not executed.
ERROR_INSTALL_FAILURE	The custom action failed.
ERROR_INSTALL_SUSPEND	The custom action was suspended, but it will be resumed later.
ERROR_INSTALL_USEREXIT	The custom action could not complete successfully because the end user aborted it.
ERROR_NO_MORE_ITEMS	The custom action succeeded, but the remaining actions should be skipped.
ERROR_SUCCESS	The custom action succeeded.

If you are authoring an InstallScript custom action, your entry-point function can return either ERROR_SUCCESS or ERROR_INSTALL_FAILURE. These constants are defined for you when you include `Iswi.h` in your script. The InstallScript engine reports any of the other exceptions to Windows Installer.

In-Script Execution

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

When you create a custom action, one setting that must be configured is the In-Script Execution setting on the Respond Options panel of the Custom Action Wizard. Actions are executed in the order in which they appear in a sequence. However, the sequences are run many times during a typical installation. The In-Script Execution setting enables you to select which iteration of the sequence will trigger your action.

(Terminal Server Aware)

If you select a Terminal Server Aware option—for example, Immediate Execution (Terminal Server Aware)—the custom action impersonates the end user during per-machine installations on terminal server machines.

Immediate Execution

As its name implies, Immediate Execution runs when the internal Windows Installer installation script is being compiled. When an .msi file is launched, the Windows Installer service converts all the tables in the installation database into an internal script. (This internal script is not the same as InstallScript code.) This script is built by cycling through all the actions in the installation in the order in which they appear. The building of this script is immediate execution. When an action is encountered whose In-Script Execution setting is set to Immediate Execution, that action is executed. Therefore, this action launches before any file transfers are encountered, possibly even before the end-user interface for the installation is fully loaded.

As a rule, custom actions scheduled for immediate execution do not modify the target system, but only set properties and query the target system (for example, to see if the target system meets your product's system requirements). Custom actions that set Windows Installer properties must be scheduled for immediate execution, and custom actions that occur in the User Interface sequence must be scheduled for immediate execution.

Because actions of this type run before any changes have been made to the system, they cannot rely on files that are being installed by the installation.

Deferred Execution

Deferred Execution takes place when the internal script generated during Immediate Execution is executed by the Windows Installer service. After that script has been fully generated, the Windows Installer service runs the newly compiled script. The script runs through all of the actions in your sequences and executes them in order. However, if an action is scheduled for immediate execution, the action does not run again during Deferred Execution.

Actions that launch during Deferred Execution have access to files being installed as part of the system. As a result, you can call a custom action that calls a function from a DLL file installed with your product during this phase of the installation. However, Deferred Execution custom actions must take place between InstallInitialize and InstallFinalize in order to work properly.

Custom actions that rely on a file being installed to the target system, or that rely on other system changes to have already been performed, must be scheduled for deferred execution.

Rollback Execution

Rollback occurs when an error is encountered by the installation or the end user cancels the installation before it has a chance to complete. The Rollback Execution option allows you to set your action to execute only during rollback. Therefore, any actions that are enabled for Rollback Execution are written to the installation script, as are Deferred Execution actions. Unlike Deferred Execution actions, Rollback Execution actions launch only during rollback. (Rollback custom actions run only if the installation fails during deferred execution.)

Any custom actions that make changes to the target system during an installation should be undone with a Rollback Execution custom action in the event of rollback. For example, if you have a custom action that creates a file, you should create a second custom action that deletes the file, and schedule the second action for rollback execution. (A rollback custom action should be scheduled before the custom action it reverses.)

Commit Execution

Commit Execution actions do not run until the InstallFinalize action completes successfully. This means that they wait until the installation has completed transferring files, registering COM servers, and creating shortcuts and registry entries. Then, any actions that are set to Commit Execution launch in the order in which they appear in the sequence.

For example, if you have a custom action that creates a temporary file, you should create a second custom action that deletes the file, and schedule it for commit execution.

Deferred Execution in System Context

Like Deferred Execution actions, these actions do not launch until the script generated by the Windows Installer service is run. However, actions of this type execute with no user impersonation.

Documenting the Behavior of Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Windows Logo • *The intended behavior of each custom action must be documented for the Windows logo program. This is especially helpful if system administrators deploy your product to enterprise environments; they sometimes need to know what the custom actions do. If you validate your installation package but you have not specified a value for the Help File Path setting, InstallShield generates validation error ISICE10. For more information, see ISICE10.*

Task: ***To document the behavior of a custom action in your project:***

1. Create a file that describes the intended behavior of the custom action. The file should be a text-based file such as a .txt, .htm, or .rtf file. Note that each custom action should have its own document.
2. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
3. In the **Custom Actions** explorer, click the action that you are documenting.
4. For the **Help File Path** setting, click the ellipsis button (**...**) to browse to the file that describes the behavior of the custom action.

Tip • *You can specify whether InstallShield should stream the contents of each of the custom action help files into the .msi file at build time. For more information, see the description of the Include Custom Action Help setting for a product configuration in the Releases view.*

Guidelines for Creating Custom Actions that Meet Requirements of the Windows Logo Program

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If you are applying for the Windows logo, your application must meet Microsoft's Windows logo program requirements. You can use the validation suite to verify whether your installation package meets most of the custom action–related logo requirements. However, some of the requirements cannot be verified through the validation suites.

Following is a list of the requirements that are not validated through the validation suites or the associated ISICEs but still must be met to achieve logo compliance for the Windows logo program:

- Do not call the Global Assembly Cache tool (`Gacutil.exe`) from a custom action. This tool was not designed to be used during installations.
- All custom actions must record success or failure in the Windows Installer log by calling **MsiProcessMessage**.
- Custom actions that change system state during installation must remove or restore the system state during uninstallation. In addition, custom actions that change system state must be written as a deferred and rollback custom action pair.

  This does not apply to custom action types 19 (displays an error, returns failure, and ends the installation), 35 (sets the installation directory), or 51 (sets a property)
- The intended behavior of each custom action in your installation must be documented. This does not apply to custom action types 19 (displays an error, returns failure, and ends the installation), 35 (sets the installation directory), or 51 (sets a property). For more information, see Documenting the Behavior of Custom Actions.

  For information about all of the InstallShield custom actions that are added automatically to InstallShield projects to support different functionality, see InstallShield Custom Action Reference.

Conditionally Launching Custom Actions Based on Release Flags

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

When your installation is built, InstallShield automatically adds a property called **ISReleaseFlags** to the **Property** table. This property contains all of the release flags that are included in the build. These flags appear exactly as they do in the Release Flags setting in the Releases view. Multiple flags are separated by a comma.

A custom action can be conditionally launched based on release flags in the following ways.

Configuring the Condition Setting

The easiest way to conditionally launch a custom action is to set the Condition setting when you insert the custom action into a sequence. In this case, you can enter a condition such as **ISReleaseFlags><"MyReleaseFlag"** in the Condition setting. This condition succeeds if the substring **"MyReleaseFlag"** is contained in the value of the **ISReleaseFlags** property.

Calling MsiGetProperty

A more robust way to set a condition on your custom action based on release flags is to author a call to **MsiGetProperty** within the custom action. In addition to determining if the action should launch, you can also indicate what code is executed by the action. For example, you can use one function from a DLL file for all scenarios, yet provide different functionality for each scenario through conditional logic within your function.

The drawback to conditionally launching your custom action in this way is that you can use only a script or DLL custom action. Additionally, your custom action still launches behind the scenes. When the custom action launches, it can check if a specified release flag has been included in the build. If that flag exists, the custom action continues. If the flag is not there, the action exits.

Placing Files in the .msi Database and Extracting Them During Run Time

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The Support Files view (in Basic MSI projects) and the Support Files/Billboards view (in InstallScript MSI projects) enable you to store temporary files that are to be used by your installation program but are not to be installed. Examples are license text files (as displayed by `SdLicense`) or DLL files called by your installation. The location to which the support files are extracted at run time is stored in the Windows Installer property **SUPPORTDIR**.

Note • *Deferred, commit, and rollback custom actions in Basic MSI and InstallScript MSI installations have access to only some of the built-in Windows Installer properties:* ***CustomActionData****,* ***ProductCode****, and* ***UserSID****. If you want a custom action to access any other properties (such as* ***SUPPORTDIR****) during deferred, commit, or rollback execution, you need to pass them as* ***CustomActionData****. To learn more, see Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions.*

Project • *Note that the value of the Windows Installer property* ***SUPPORTDIR*** *is not the same as the value of the InstallScript system variable SUPPORTDIR.*

Custom Action Script Examples

InstallScript

To access a particular support file during installation, Basic MSI projects and InstallScript MSI projects should reference the Windows Installer property **SUPPORTDIR**. You can use **MsiGetProperty** to query the path, and then append the file name to the **SUPPORTDIR** value to obtain the complete path of the file. In the settings for a custom action, this is just [SUPPORTDIR].

In an InstallScript custom action, you could use code such as the following:

```
export prototype STRING GetSupportFilePathMSI(HWND);

function STRING GetSupportFilePathMSI(hMSI)
    STRING szSupportDir[MAX_PATH + 1];
    STRING szMyFile[MAX_PATH + 1];
    NUMBER nLength;
begin
```

```
    // set initial buffer size
    nLength = MAX_PATH + 1;
    MsiGetProperty(hMSI, "SUPPORTDIR", szSupportDir, nLength);

    // reset buffer-size variable
    nLength = MAX_PATH + 1;
    MsiGetProperty(hMSI, "MYFILE", szMyFile, nLength);

    // return full file path
    return szSupportDir ^ szMyFile;
end;
```

In this example, the name of the support file that is being used is stored in the MYFILE property.

C++

In C++, you could use the following code:

```
UINT __stdcall ShowSupportdir(MSIHANDLE hInstall)
{
    TCHAR szSupportDir[MAX_PATH + 1] = {'\0'};
    DWORD dwBuff = sizeof(szSupportDir);
    MsiGetProperty(hInstall,"SUPPORTDIR",szSupportDir,&dwBuff);
    MessageBox(NULL,szSupportDir,"SUPPORTDIR is ...",MB_OK);
}
```

VBScript

In VBScript, you could use the following code:

```
dim strSupportDir
strSupportDir = Session.Property("SUPPORTDIR")
```

Accessing or Setting Windows Installer Properties Through Deferred, Commit, and Rollback Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Deferred, commit, and rollback custom actions in Basic MSI and InstallScript MSI installations have access to only some of the built-in Windows Installer properties: **CustomActionData**, **ProductCode**, and **UserSID**. If you want a custom action to access any other properties during deferred, commit, or rollback execution, you can pass them as **CustomActionData**. You can do so by scheduling an immediate set-a-property type of custom action to set a property that matches the name of the custom action. The value of this property is then available in the **CustomActionData** property within the deferred, commit, or rollback custom action.

Using CustomActionData to Access a Property

The following example shows how to access the Windows Installer property **SUPPORTDIR** through a deferred InstallScript custom action.

Task: ***To access SUPPORTDIR through a deferred InstallScript custom action:***

1. In the **Custom Actions and Sequences** view, create a set-a-property custom action (type 51) called **GetSUPPORTDIR**. Configure the **Property Name**, **Property Value**, and **Install Exec Sequence** settings for the custom action as follows, and leave all of the other settings blank.
   - Property Name: DisplaySupportDir
   - Property Value: [SUPPORTDIR]
   - Install Exec Sequence: After InstallInitialize
2. In the **InstallScript** view, create a new function called **DisplaySupportDir**.
3. Add the following code to display a message box containing the value of **SUPPORTDIR**:

```
function DisplaySupportDir(hMSI)
   STRING supportDirPath;
   NUMBER supportDirPathBuffer;
begin
   supportDirPathBuffer = MAX_PATH;
   if(MsiGetProperty(hMSI, "CustomActionData", supportDirPath, supportDirPathBuffer) ==
ERROR_SUCCESS) then
     SprintfBox(INFORMATION,"Deferred Execution","The value of SUPPORTDIR is
%s",supportDirPath);
     SprintfBox(INFORMATION,"Deferred Execution","The value of InstallScript's SUPPORTDIR is
%s",SUPPORTDIR);
   endif;
end;
```

4. In the **Custom Actions and Sequences** view, create an InstallScript custom action called **DisplaySupportDir**. Configure the **Function Name**, **In-Script Execution**, and **Install Exec Sequence** settings for the custom action as follows, and leave all of the other settings blank.
   - Function Name: DisplaySupportDir
   - In-Script Execution: Deferred Execution in System Context
   - Install Exec Sequence: After GetSUPPORTDIR

Important • *The property name that you enter in step 1 must match the name of the custom action that you create in step 4.*

Using CustomActionData to Access More Than One Property

If you want a deferred, commit, or rollback custom action to access more than one Windows Installer property, you can "pack" the properties in **CustomActionData** and then have your deferred, commit, or rollback custom action "unpack" them after retrieving the value of **CustomActionData**.

For example, if you want to retrieve the values of [INSTALLDIR], [SUPPORTDIR], and [SetupType], you would set the Property Value setting of your type 51 custom action to this:

```
[INSTALLDIR];[SUPPORTDIR];[SetupType]
```

where each property is separated by a semicolon.

You can use code such as the following VBScript to "unpack" the values from the **CustomActionData** property:

```
Dim PropArray
PropArray = Split(Session.Property("CustomActionData"), ";")
INSTALLDIR = PropArray(0)
SUPPORTDIR = PropArray(1)
SetupType = PropArray(2)
'Now do something with these variables...
```

InstallScript Custom Actions

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

In order to use your InstallScript functions in a Windows Installer installation, you first need to create a custom action that calls your script. The easiest way to create a custom action is to use the Custom Action Wizard.

The primary panels of this wizard are:

- Action Type Panel
- Action Parameters Panel
- Respond Options Panel
- Insert into Sequence Panel

When you complete the wizard, a custom action of type 65536 is created. This custom action type is not defined in the Windows Installer Help Library. Because InstallScript is not natively supported by Windows Installer, InstallShield created action type 65536.

Project *• You should not use an InstallScript custom action in the User Interface sequence of an InstallScript MSI project. You can use the event-driven script to provide the user interface in an InstallScript MSI project.*

Calling Functions in Standard DLL Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Although Windows Installer restricts the parameters that you can pass to a functions in a DLL file written for a custom action, InstallShield offers a solution that enables you to pass any number of parameters to a function and store the return value. Note that the function must use the __stdcall calling convention. Functions with more than one parameter will not work properly if this convention is not used.

You can specify that you are calling a function in a standard DLL file in the Custom Action Wizard's Action Type panel by selecting **Call a function in a standard dynamic-link library** for the Type option. The next panel, the Function Definition panel, allows you to specify the function's parameters and return value.

Note • *If you call a function in a standard DLL file that is installed with the product and the action is scheduled as deferred (for the In-Script Execution setting), the DLL file that you are calling must be the component's key file.*

A custom action that calls a function in a standard DLL file stored in the ***Binary*** *table cannot be scheduled for deferred execution.*

If you want a Windows Installer property to be set to the function's return value, the action must be configured for immediate execution. If you try to specify a return property for an action that is scheduled for deferred, rollback, or commit execution, the return property is ignored at run time.

Understanding the Parameters and Return Value as a Formatted String

When you specify the function signature for a standard DLL file action, that action's Function Signature setting in the Custom Actions and Sequences view uses the following formatting to display the function's name, arguments, return type, and return property.

```
DataType1=[PropertyName1] DllName::FuncName(in DataType2="Value", Direction
DataType3=[PropertyName2])
```

The following table describes each portion of the format.

Table 4-6 • Format for the Arguments of a Function

Argument	Description
DataType1=[PropertyName1]	`DataType1` is of type void, STRING, BOOL, NUMBER, HWND, HANDLE, or POINTER. `PropertyName1` is the name of a property from the Property Manager view. If the return type is void, `=[PropertyName1]` is omitted.
DllName	Specify the name of the DLL file, without the dot or file extension.

Table 4-6 • Format for the Arguments of a Function (cont.)

Argument	Description
FuncName	Enter the name of the function that you are calling.
in DataType2="Value"	This is the format for an argument that is a constant. `DataType1` is of type STRING, BOOL, NUMBER, HWND, HANDLE, or POINTER. `Value` is the data that you want to pass for this argument. The constant's data type is always preceded by `in`.
Direction DataType3=[PropertyName2]	This is the format for an argument that references a Windows Installer property's value. `Direction` can be *`in`*, *`inout`*, or *`out`*. For a discussion of these property types, see the Function Definition panel under the argument's source. `DataType3` can be of type STRING, BOOL, NUMBER, HWND, HANDLE, or POINTER. `PropertyName2` is the name of a property whose value will be passed to or set by the function, depending on the value of `Direction`.

Example

For the custom action created in Calling MessageBoxA in an Installation, the Target value reads:

```
void User32::MessageBoxA(in HWND=0, in STRING=[MESSAGEPROP], in STRING=[CAPTIONPROP], in NUMBER=1)
```

In this example, the data type is *`void`*, *`in HWND=0`* represents a numeric value of 0, and *`MESSAGEPROP`* is a property that contains a string that will be passed to the function MessageBoxA in `User32.dll`.

Calling Functions in Windows Installer DLL Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

A DLL file function specifically written for a Windows Installer custom action can accept only the handle to the installer database as a parameter. The steps below explain how you can retrieve information from the .msi database for use in your custom action.

You specify that your custom action resides in a Windows Installer DLL file (custom action types 1 and 17) by selecting **Call a function in a Windows Installer dynamic-link library** in the Custom Action Wizard's Action Type panel.

An alternative is to select **Call a function in a standard dynamic link library** in the Action Type panel. In this case, InstallShield allows you to specify the function's parameters.

Task: ***There are three major steps involved in passing a parameter to a function in a DLL file written for Windows Installer:***

1. Prepare your DLL file.
2. Create a custom action and insert it into one of the sequences.
3. Pass the parameter using the Property Manager view. These steps are explained in greater detail below.

Preparing DLL Files

In order for you to pass data to a DLL file function in a custom action, the function to which you are passing data needs to call the **MsiGetProperty** function, which retrieves the value of an installer property. In the example below, it retrieves the value of a public property called **MYPROPERTY**.

```
UINT __stdcall MyActionName(MSIHANDLE hInstall)
{
    TCHAR szValue[51] = {0};
    DWORD dwBuffer = 50;

    MsiGetProperty(hInstall, TEXT("MYPROPERTY"), szValue, &dwBuffer);

    MessageBox(GetForegroundWindow( ),
        szValue,
        TEXT("Value of MYPROPERTY"), MB_OK | MB_ICONINFORMATION);

    return ERROR_SUCCESS;
}
```

For more information, see MsiGetProperty in the Windows Installer Help Library.

If you use a C++ compiler to build your DLL file, ensure that the compiler does not change the function names exported from the DLL file. With Microsoft Visual C++, for example, you can create a .def file that specifies the function names to be exported from your DLL file. A typical .def (called MyActions.def) file looks like the following:

```
LIBRARY MyActions
EXPORTS
    MyActionName
```

For more information about function name decoration, see your compiler documentation.

Creating Custom Actions and Inserting them into Sequences

The second step is to create your custom action and insert it into one of the Installation sequences. To create the custom action, use the Custom Action Wizard, and to place the custom action, use the Custom Actions and Sequences view.

Passing the Parameter Using the Property Manager

Task: ***To pass the new parameter using the Property Manager:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Click the **New Property** button. InstallShield adds a new row at the bottom of the view.
3. In the **Name** column, type the name of the property that you would like to retrieve with **MsiGetProperty** (`MYPROPERTY`, in this example).
4. In the **Value** column, type the value that you want to pass. For example, if you want to pass the URL to your Web site, type `http://www.mycompany.com`.

Passing Parameters to a DLL File Function in a Custom Action

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

There are a number of reasons why you might pass a parameter to a function in a custom action. For example, you might want to pass a URL for Web registration or the UserName property for a custom user interface. However, Windows Installer does not directly support passing parameters to DLL file functions.

The entry-point function for a Windows Installer DLL file can have only one argument, which is the handle to the database. To learn about a suggestion for passing parameters to a DLL file written for Windows Installer, see Calling Functions in Windows Installer DLL Files.

Task: ***To accomplish this in InstallShield:***

1. In the Custom Wizard's **Action Type** panel, select **Call a function in a standard dynamic-link library**.
2. In the **Function Definition** panel, specify the parameters that you want InstallShield to pass to the function.

Calling a Public Method in a Managed Assembly

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The managed-code type of custom action calls a public method in a .NET assembly that is written in managed code such as Visual Basic .NET or C#.

If you include a managed-code custom action in your project, InstallShield creates a C++ Windows Installer wrapper DLL for your .NET assembly. The wrapper DLL includes your assembly, as well as the information that is required to mediate, load, and run the assembly.

Note • *If you specify that the location of your managed assembly should be the* ***Binary*** *table, InstallShield stores the wrapper DLL—which includes your assembly—in the* ***Binary*** *table.*

Run-Time Requirements for Managed-Code Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The managed-code type of custom action requires the Microsoft .NET Framework on the target system.

InstallShield includes redistributables for the .NET Framework. If it is possible that target systems may not have the .NET Framework, you can add the appropriate .NET Framework redistributable to your project. For instructions, see Adding .NET Framework Redistributables to Projects.

You can use the property **IS_CLR_VERSION** to identify a semicolon-delimited list of .NET Framework versions that the custom action should attempt to load to run your managed code. In most scenarios, this property is not set in the installation package. It is set at the command line. To specify that version 1.1 is required, use the following command-line parameter:

```
IS_CLR_VERSION=v1.1.4322
```

Note that the complete version number of the .NET Framework should be specified for the property value. If more than one version is acceptable, you can specify a semicolon-delimited list of versions. The first one that can be loaded is used. For the following example command-line parameter, the custom action attempts to load version 2.0. If that version is not present, the custom action attempts to load version 1.1. If version 1.1 is not present, the custom action fails.

```
IS_CLR_VERSION=v2.0.50727;v1.1.4322
```

To specify that the custom action should attempt to load whatever is the latest version of the .NET Framework that is installed if none of the specified versions are installed, add a semicolon to the end of the property value, as shown in the following example:

```
IS_CLR_VERSION=v2.0.50727;v1.1.4322;
```

The semicolon at the end of the property value also indicates that if none of the specified versions are present but a version of the .NET Framework is already loaded, the custom action uses the currently loaded version, even if it is not the latest version that is installed.

Note • *If the execution of your managed-code custom action is set to deferred mode, you must use the Windows Installer property* ***CustomActionData*** *to pass the* ***IS_CLR_VERSION*** *property and value. To learn more, see Specifying the Signature for a Managed Method in an Assembly Custom Action.*

Tip • *If issues with the custom action occur at run time because of .NET Framework version mismatches, you may want to instruct end users to set the* ***IS_CLR_VERSION*** *property at the command line when they run your installation. Note that for deferred custom actions, you must have already used the* ***CustomActionData*** *property to pass the* ***IS_CLR_VERSION*** *property. For more information, see Specifying the Signature for a Managed Method in an Assembly Custom Action.*

Specifying the Signature for a Managed Method in an Assembly Custom Action

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The Managed Method Definition panel in the Custom Action Wizard is where you specify arguments for the method that your managed assembly custom action should call. You can also specify this information on the Method Signature dialog box.

Using the Default Method Signature

If you use the default method signature, the custom action handles methods with up to one parameter. If the method takes a parameter, it is passed the MsiHandle, as well as any return type. If the method returns an integer, this integer is passed directly to Windows Installer. Therefore, if a method returns integer 1603 (ERROR_INSTALL_FAILURE) in this scenario, the installation aborts.

For more information, see Custom Action Return Values in the Windows Installer Help Library.

Using a Custom Method Signature for an Immediate Custom Action

If you use a custom method signature, the custom action calls the method with the arguments that you specified. If the value of a parameter is a Windows Installer property and the custom action is set for immediate execution, the method stores any by-reference and out parameter values in the passed properties. In addition, the custom action converts the return value to a string and stores it in the return property. If no return property is specified, the return value is ignored.

Note that if you use a custom signature, the custom action's return value is not passed to Windows Installer. However, if the managed code throws an unhandled exception, the custom action returns ERROR_INSTALL_FAILURE to Windows Installer. Therefore, in order for the custom action to indicate failure and for Windows Installer abort the installation, the managed code must throw an unhandled exception.

Using a Custom Method Signature for a Deferred, Commit, or Rollback Custom Action

Deferred, commit, and rollback custom actions have access to only some of the built-in Windows Installer properties: **CustomActionData**, **ProductCode**, and **UserSID**. Therefore, if you use a custom method signature and you want your managed assembly custom action to access or pass any other properties during deferred, commit, or rollback execution, you must pass them through the **CustomActionData** property. Note the following guidelines for deferred, commit, and rollback managed assembly custom actions:

- Custom signatures that pass properties need to have their values passed in as **CustomActionData** in the following format:

  ```
  PROPERTYNAME="Property Value"
  ```

  Separate multiple property name–property value pairs with a space, as in the following example:

  ```
  PROPERTYNAME1="Property Value 1" PROPERTYNAME2="Property Value 2"
  ```

- If the managed assembly for your deferred, commit, or rollback custom action is installed with the product, use **CustomActionData** to identify the location of the managed assembly, and use the following format:

  ```
  #filekey.dll="location of assembly"
  ```

  For the "location of assembly" portion, use the format `[#filekey.dll]`.

- If the path for the managed assembly references one or more properties, use **CustomActionData** to pass each of the properties and their corresponding values.

- Consider using **CustomActionData** to pass the following property and value:

  ```
  IS_CLR_VERSION="[IS_CLR_VERSION]"
  ```

  If run-time issues occur because your custom action attempts to load the wrong version of the .NET Framework to run your managed code, you can have end users set the value of the **IS_CLR_VERSION** property at the command line when they run your installation. For deferred, commit, and rollback managed-code custom actions, **IS_CLR_VERSION** must be passed to **CustomActionData** in order for end users to use this run-time override. To learn more about the **IS_CLR_VERSION** property, see Run-Time Requirements for Managed-Code Custom Actions.

Specifying Parameter Values for a Custom Method Signature

If you use a custom method signature, you can enter any of the following types of values for a parameter:

- A single property that is enclosed within square brackets—for example, **[ProductName]**. Note that immediate-mode managed assembly custom actions can update ref and out parameters. InstallShield does not support combining multiple properties or mixing properties with strings for a parameter value.

- A literal—for example, a string such as the number **1** or **1603**.

- An explicit string that is enclosed within quotation marks—for example, **"My Project Name-1"**.
- The variable *MsiHandle*, which indicates the installation handle.

At run time, after a property has been resolved or a string has been isolated from within its quotation marks, the custom action attempts to convert the string to an instance of the type of the method's appropriate parameter. A parameter of type String is passed as is, and all normal numeric types are handled by calling the public static Parse(string) method to turn the string into the type. In addition, the custom action calls any type's public static Parse(string) method and uses the return value as the passed parameter value. IntPtr is also handled despite the lack of a Parse method.

Using 32-Bit vs. 64-Bit Managed-Code Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

When you build a release that includes a managed-code custom action in your project, InstallShield attempts to determine the target architecture (32 bit or 64 bit) of the main .NET assembly that is associated with the custom action. InstallShield does this by examining the portable executable (PE) file for the assembly and determining if the PE file is 32 bit or 64 bit. If the PE file uses Microsoft intermediate language (MSIL) code, InstallShield treats it as 32 bit. InstallShield configures the release so that the appropriate version of the .NET Framework—32 bit or 64 bit—is used to run your managed code at run time.

If you want to override the built-in default behavior, use the Direct Editor view to add a new record with the following fields to the **ISCIrWrap** table.

Table 4-7 • Overriding the Default Architecture for a Managed-Code Custom Action

ISCIrWrap Table Column	Description
Action_	Enter the name of the managed-code custom action that you want to modify.
Name	Enter the following: `TargetPlatform`
Value	Specify the appropriate architecture. • To use a 32-bit version of the .NET Framework, enter the following: `x86` • To use a 64-bit version of the .NET Framework, enter the following: `x64`

Calling a Kill-Process Custom Action

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The kill-process type of custom action terminates one or more processes at run time. The following procedure describes how to include and configure this type of custom action in your project.

Task: ***To add a kill-process custom action to your project:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Right-click the **Custom Actions** explorer and then click **New Kill Process**. InstallShield adds a kill-process custom action with a default name.
3. Enter a new name, or right-click it later and click **Rename** to assign it a new name. Use a name that helps you distinguish this custom action from other actions in your project.
4. In the right-pane, configure the action's settings:
   a. In the **In-Script Execution** setting, select the iteration of the sequence that should trigger the action. For details about each option, see In-Script Execution.
   b. Use the settings in the **Sequences** area to schedule the custom action at the point where you want the process to be terminated. As an alternative, you can drag the custom action from the **Custom Actions** explorer to the appropriate node under the Sequences explorer.
   c. In the **Function Name** setting, select the appropriate function:
      - **KillProcess**—If you selected one of the immediate options in the **In-Script Execution** setting and you want to kill a process that has a particular name, select this option.
      - **KillProcessByID**—If you selected one of the immediate options in the **In-Script Execution** setting and you want to kill a process that has a particular process identifier (PID), select this option.
      - **KillProcessDeferred**—If you selected one of the deferred, commit, or rollback options in the **In-Script Execution** setting and you want to kill a process that has a particular name, select this option.
      - **KillProcessByIDDeferred**—If you selected one of the deferred, commit, or rollback options in the **In-Script Execution** setting and you want to kill a process that has a particular PID, select this option.
   d. Configure any of the action's other settings as needed.
5. In the View List under **Behavior and Logic**, click **Property Manager**.
6. Create and set a new property that identifies one or more processes that you want to terminate:
   a. Click the **New Property** button. InstallShield adds a new row at the bottom of the view.

b. In the **Name** column, enter a name for the new property. The name that you enter depends on what you selected for the **In-Script Execution** setting:

- If you selected one of the immediate options in the **In-Script Execution** setting, enter the following name:

  ```
  ISTerminateProcesses
  ```

- If you selected one of the deferred, commit, or rollback options in the **In-Script Execution** setting, enter the same name that you entered for the name of the kill-process custom action, as described in step 3. The spelling and capitalization must match exactly.

c. In the **Value** column, enter the executable file names or PIDs of the processes that you want to terminate.

Note that if you selected **KillProcess** or **KillProcessDeferred** in the **Function Name** setting, enter the executable file names of the processes. If you selected **KillProcessByID** or **KillProcessByIDDeferred**, enter the PIDs.

If you want to terminate more than one process, use a semicolon (;) to separate each file name or ID. For example, to terminate processes that have names such as **myfile1.exe** and **myfile2.exe**, enter the following:

```
myfile1.exe;myfile2.exe
```

To terminate processes that have PIDs of **3740** and **4196**, enter the following:

```
3740;4196
```

Calling a PowerShell Custom Action

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Windows PowerShell is a .NET Framework–based command-line shell and script language that enables system administrators to automate system configuration tasks. InstallShield lets you include in your installations custom actions that run PowerShell scripts (.ps1). You may want to add this type of custom action to a project to perform system configuration tasks at installation run time.

Target System Requirements for Running PowerShell Scripts

PowerShell is installed on only some operating systems by default. If an installation launches a PowerShell custom action but PowerShell is not installed, the custom action fails.

To check that PowerShell is installed on a target system, you can add the predefined system search for PowerShell to your project, and configure your PowerShell custom action to run only if the system search determines that PowerShell is installed. You can also use this system search to determine which version of PowerShell is installed, and you can include a condition for the custom action that triggers its launching only on appropriate target systems.

The PowerShell execution policy, which determines whether PowerShell scripts can be run on a target system, is set to restricted by default. This default execution policy does not permit PowerShell scripts to be run. If an installation launches a PowerShell custom action but the execution policy does not permit scripts to be run, the PowerShell custom action fails.

If you want your installation to override the target system's execution policy with an appropriate one for your installation's PowerShell custom actions, you can set the Windows Installer property **IS_PS_EXECUTIONPOLICY** equal to the name of the appropriate execution policy. Setting this property affects how the PowerShell custom actions are run in your installation; however, it does not alter the policy of the target system. Thus, any PowerShell scripts that are run subsequently outside of your installation, or during other subsequent installations, are not affected by use of the **IS_PS_EXECUTIONPOLICY** property.

Some of the execution policies require that the PowerShell script (.ps1) be digitally signed. InstallShield does not include support for digitally signing PowerShell scripts.

Tip • *You can sign your PowerShell scripts from the PowerShell command prompt. To learn more, enter the following command at the PowerShell command prompt:* `Get-Help About_Signing`

Adding a PowerShell Custom Action to Your Project

The following procedure describes how to include and configure a PowerShell custom action in your project. The procedure includes adding the PowerShell system search to your project and defining the **IS_PS_EXECUTIONPOLICY** property.

Task: ***To add a PowerShell custom action to your project:***

1. Add to your project the predefined PowerShell system search that checks to ensure that PowerShell is installed:
   a. In the View List under **Behavior and Logic**, click **System Search**.
   b. Right-click the grid in this view and then click **Add Predefined Search**. The **Add Predefined Search** dialog box opens.
   c. Select the **PowerShell** search and then click **OK**.

   If PowerShell is installed on a target system, the PowerShell system search sets the **POWERSHELLVERSION** property.
2. To indicate which execution policy you want your installation to use for your PowerShell custom actions, define the **IS_PS_EXECUTIONPOLICY** property:
   a. In the View List under **Behavior and Logic**, click **Property Manager**.
   b. Click the **New Property** button. InstallShield adds a new row at the bottom of the view.
   c. In the **Name** column, enter the following:

      ```
      IS_PS_EXECUTIONPOLICY
      ```

d. In the **Value** column, enter the name of the execution policy that you want to use to run PowerShell custom actions in your installation. Available options are:

- **AllSigned**—This policy allows only digitally signed PowerShell scripts to be run.
- **Bypass**—This policy allows all PowerShell scripts to be run, regardless of whether they are signed. No warnings or prompts are displayed.
- **RemoteSigned**—This policy allows any local PowerShell scripts to be run. PowerShell custom actions that are downloaded from the Internet must be digitally signed in order to be run.
- **Unrestricted**—This policy runs all PowerShell scripts. If your installation runs an unsigned PowerShell script that was downloaded from the Internet, the end user is prompted for permission before the custom action is run.

The default execution policy is Restricted. Although you can set **IS_PS_EXECUTIONPOLICY** equal to *Restricted*, doing so will not allow PowerShell custom actions to be run.

3. Add a PowerShell custom action to your project and configure its settings:

a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.

b. Right-click the **Custom Actions** explorer, point to **New PowerShell**, and click one of the following commands:

- **Stored in Binary table**—To have your code base stored in the **Binary** table, select this command. This location is useful if you do not want the file to be installed on the target system.
- **Installed with product**—To call code from a script file that is going to be installed on the target system, select this command.

InstallShield adds a PowerShell custom action with a default name.

c. Enter a new name, or right-click it later and click **Rename** to assign it a new name. Use a name that helps you distinguish this custom action from other actions in your project.

d. In the **PowerShell Script File Name** setting, select the PowerShell script file (.ps1) in the list of files that are stored in the **Binary** table or that are included in your project. If the location that you specified is stored in the **Binary** table, you can click this ellipsis button (...) in this setting to browse to the file.

e. In the **Sequence** area, schedule the action for the appropriate sequence. In that sequence's **Condition** setting, enter the following conditional statement to ensure that the action runs only if the system search detects that PowerShell is installed:

```
POWERSHELLVERSION
```

Tip • *If you want to ensure that the action runs only if the system search detects that specific version of PowerShell is installed, use the appropriate operator with the property and the value that you want to check. To learn more about building conditional statements, see Building Conditional Statements.*

f. Configure the action's other settings as needed.

Tip • *If PowerShell is not installed on a target system (that is, if the* ***POWERSHELLVERSION*** *property is not set, the installation skips the PowerShell custom action. If you want to prevent the entire installation from running if PowerShell is not installed, you can use the Installation Requirements page of the Project Assistant (instead of the System Search view) to add the PowerShell system search to your project. If you do that, InstallShield uses the* ***POWERSHELLVERSION*** *property in a launch condition for the installation.*

Launching Executable Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Launching an executable file from your installation is useful to install third-party tools, display a readme file, or display a Web page that contains the most up-to-date information about the product being installed. To launch an executable file from within your installation, you need to add a custom action in the Custom Actions and Sequences view (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or the Custom Actions view (in DIM, Merge Module, and MSM Database projects).

You can use the Custom Action Wizard to create the custom action that launches an executable file from your installation. Each wizard panel is listed below, with the entries that you need to make in order to launch an executable file.

Basic Information Panel

Table 4-8 • Settings for the Basic Information Panel in the Custom Action Wizard

Panel Option	Value
Name	Provide a meaningful name for your custom action. This name is used internally in your product and is for identification purposes only.
Comment	Type comments about this custom action.

Action Type

Table 4-9 • Settings for the Action Type Panel in the Custom Action Wizard

Panel Option	Value
Type	Select the type of custom action that you want to create. For this example, select Launch an executable.
Location	The selection that you make depends on where the target executable file will be during the installation. Because Notepad is on everyone's machine, it is the target for this custom action. Because Notepad is practically guaranteed to be present in the target machine's Windows folder, you can point to it using the **Directory** table. Therefore, select **Stored in the Directory** table.

Action Parameters

Table 4-10 • Settings for the Action Parameters Panel in the Custom Action Wizard

Panel Option	Value
Source	Since you choose to launch an executable file stored in the **Directory** table, you are given a list of choices that reflect all of your current entries in the **Directory** table. One of these options is **WindowsFolder**. Choose this option to point to Notepad without having to hard-code a path.
Target	For this option, you need to enter the target file within the specified directory from the Source option. Enter `Notepad.exe` and click the Next button to continue.

Additional Options

Table 4-11 • Settings for the Additional Options Panel in the Custom Action Wizard

Panel Option	Value
Return Processing	Specify how Windows Installer should control the processing of the custom action thread. You can have the main and custom action threads run synchronously (the installation waits for the custom action thread to complete before resuming the main installation thread) or asynchronously (the installation runs the custom action simultaneously as the main installation continues). In this example, select the **Synchronous (Check exit code)** option.

Respond Options

Table 4-12 • Settings for the Respond Options Panel in the Custom Action Wizard

Panel Option	Value
In-Script Execution	Select Immediate execution to have your action executed as soon as it is encountered in the script.
Execution Scheduling	Select **Always execute** so that your custom action launches every time that it is encountered.

Inserting Custom Actions into Sequences

After you have created a custom action, you must insert it into a sequence in the Custom Actions and Sequences view.

Using Msiexec.exe to Launch a Second Windows Installer Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

An alternative to launching a second .msi package using the nested installation custom action type is to create a custom action that launches **Msiexec.exe** instead. Launching a second installation in this manner causes it to run in its own process and creates the proper entries on the target system. In addition, the uninstallation process is much more effective when you launch your second installation in this way. Registry entries are properly cleaned up and reference counts are incremented and decremented accurately.

Creating a Custom Action

The first step is to create your custom action. The easiest way to do this is to use the Custom Action Wizard.

Task: ***To create a custom action using the wizard:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
2. Right-click the **Custom Actions** explorer and click **Custom Action Wizard**. The **Custom Action Wizard** opens.
3. On the **Basic Information** panel, specify a name and comment for your custom action and click **Next**.
4. On the **Action Type** panel, in the **Type** list, select **Launch an executable**. In the **Location** list, select **Stored in the Directory table**. The **Directory** table allows you to choose from predefined folders, such as SystemFolder, which is where `Msiexec.exe` is located.
5. On the **Action Parameters** panel, browse for the executable file (**Msiexec.exe**) of that you are launching. The **Target** box enables you to specify the name of the executable file that you would like to launch, as well as any command-line parameters that you would like to pass to it. For example:

   ```
   msiexec.exe /i "[SOURCEDIR]AnotherSetup\SecondSetup.msi" /qb
   ```

   The first part of this entry, **msiexec.exe**, is the name of the executable file that you would like to launch. The next section, **/i "[SOURCEDIR]AnotherSetup\SecondSetup.msi"**, tells `Msiexec.exe` which package to run. In this case, it is pointing to a file one folder below that of the source folder of the initial installation. Finally, **/qb** tells the Windows Installer service to run the installation with minimal user interface. Only a progress bar is displayed.
6. On the **Additional Options** panel, select the default options and click **Next** until you finish the wizard.

Inserting a Custom Action into a Sequence

After you have created a custom action, you need to insert it into a sequence.

Task: ***To sequence this custom action:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in Merge Module and MSM Database projects).
2. In the **Sequences** explorer, under the **Installation** sequence, expand the **User Interface** item. The actions and dialogs that are scheduled for this sequence are listed.
3. Right-click **CostFinalize** and click **Insert**. The Insert Action dialog box opens.
4. Select the new custom action.
5. Click **OK**.

Next, verify that the installation package that you want to launch is located in the folder that you specified in the Action Parameters panel, build your installation, and run it.

Note • *A custom action that launches `Msiexec.exe` must be placed in the User Interface sequence, which means that the custom action will not run if the end user runs the installation silently.*

Nested Installations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Important • *Nested installations is a deprecated feature of the Windows Installer. Applications installed with nested installations sometimes fail because they are difficult for end users to service correctly. Microsoft Corporation recommends that you avoid using nested installations and nested-installation custom actions to install products that are intended to be released to the public. To learn more, see Concurrent Installations in the Windows Installer Help Library.*

A nested installation is a type of custom action that installs or removes another .msi package (sometimes called the *child product*) from within a running installation (called the *parent product*).

Note • *Before using nested-installation custom actions, you should be aware of the following restrictions:*

- *Nested installations do not display a user interface.*
- *A child product generally does not appear in Add or Remove Programs in Control Panel on the end user's system, and it is not automatically uninstalled when the parent product is uninstalled.*

Creating Nested Installation Custom Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Important • *Nested installations is a deprecated feature of the Windows Installer. Applications installed with nested installations sometimes fail because they are difficult for end users to service correctly. Microsoft Corporation recommends that you avoid using nested installations and nested-installation custom actions to install products that are intended to be released to the public. To learn more, see Concurrent Installations in the Windows Installer Help Library.*

Task: ***To create a nested installation custom action using the wizard:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Right-click the **Custom Actions** explorer and click **Custom Action Wizard**. The **Custom Action Wizard** opens.
3. On **Basic Information** panel, specify a name and comment for your custom action and click **Next**.
4. On the **Action Type** panel, in the **Type** list, select **Launch another .msi package**. In the **Location** list, select **Included within your main setup**.
5. On the **Action Parameters** panel, browse for the location of the .msi file that you are launching. (For simplicity, assume that the child product is packaged with all files compressed into the .msi package.) The **Target** box enables you to specify command-line switches to pass to the child installation. For example, to install all of the features of the child installation with their default settings, and to use the same value for the **ALLUSERS** property used by the parent installation, type the following in the **Target** box:

   ```
   ARPSYSTEMCOMPONENT=1 ADDDEFAULT=ALL ALLUSERS=[ALLUSERS]
   ```

   You can use similar expressions to use the same value of INSTALLDIR in the child as in the parent.
6. Accept the default options on the **Additional Options** panel and click **Next** until you finish the wizard.

Inserting Nested Installation Custom Actions into Sequences

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Important • *Nested installations is a deprecated feature of the Windows Installer. Applications installed with nested installations sometimes fail because they are difficult for end users to service correctly. Microsoft Corporation recommends that you avoid using nested installations and nested-installation custom actions to install products that are intended to be released to the public. To learn more, see Concurrent Installations in the Windows Installer Help Library.*

After you have created the custom action, you need to insert it into a sequence.

Task: ***To insert a nested installation custom action into a sequence:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, under the **Installation** sequence, expand the **User Interface** item. The actions and dialogs that are scheduled for this sequence are listed.
3. Right-click **CostFinalize** and click **Insert**. The Insert Action dialog box opens.
4. Select the new custom action.
5. In the **Condition** box, type `Not Installed`. This indicates that the nested installation should be performed only the first time that the parent product is installed.
6. Click **OK**.

Removing Child Products

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Important • *Nested installations is a deprecated feature of the Windows Installer. Applications installed with nested installations sometimes fail because they are difficult for end users to service correctly. Microsoft Corporation recommends that you avoid using nested installations and nested-installation custom actions to install products that are intended to be released to the public. To learn more, see Concurrent Installations in the Windows Installer Help Library.*

A child product is not automatically removed when the parent product is removed. However, you can create a second nested-installation custom action that does this.

Task: ***To create the custom action:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Right-click the **Custom Actions** explorer and click **Custom Action Wizard**. The **Custom Action Wizard** opens.
3. On the **Basic Information** panel, specify a name and comment for your custom action and click **Next**.
4. On the **Action Type** panel, in the **Type** list, select **Launch another .msi package**. In the **Location** list, select **An application that is advertised or already installed**.
5. On the **Action Parameters** panel, browse for the location of the .msi file that you want to remove. In the **Target** box, leave the default properties:

   ```
   ALLUSERS=[ALLUSERS] REMOVE=ALL
   ```

6. Accept the default options on the **Additional Options** panel and click **Next** until you finish the wizard.

Task: ***To sequence this custom action:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, under the **Installation** sequence, expand the **Execute** item. The actions and dialogs that are scheduled for this sequence are listed.
3. Right-click **InstallValidate** and click **Insert**. The Insert Action dialog box opens.
4. Select the new custom action.
5. In the **Condition** box, type the following:

   ```
   REMOVE="ALL"
   ```

6. Click **OK**.

This custom action will uninstall the child product when the parent product is uninstalled.

Note • *When you are creating a nested-installation custom action of type Launch another .msi package with the Location setting set to* ***Stored on the source media****, be aware of the following:*

- *The child installation must not be compressed inside a `Setup.exe` installation launcher.*
- *If the child installation's files are not compressed inside the child .msi database, you must manually copy the child installation's files to the `Disk1` folder of the parent installation's release folder.*

Calling MessageBoxA in an Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To call the Windows API function MessageBoxA() in a custom action to display a message box:***

Part A: Launch the Custom Action Wizard

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Right-click the **Custom Actions** explorer and click **Custom Action Wizard**.

Part B: Start a Custom Action

1. In the **Basic Information** panel, type `CA_Example` for the custom action's name. Click **Next**.
2. In the **Action Type** panel, for the custom action's type, select **Call a function in a standard dynamic-link library**.
3. Since **MessageBoxA** is exported in `User32.dll`, which is found on every supported Windows platform, select **Destination machine search path** in the **Location** list. Click **Next** to continue.

Part C: Provide the Function Definition

MessageBoxA() has the following syntax:

```
int MessageBoxA (hWnd, lpText, lpCaption, uType);
```

Specify this information in the Function Definition panel:

1. In the **Name** box, type **MessageBoxA**.
2. Click the last row in the **Arguments** box to specify the first parameter. Edit the fields for each parameter until they mirror the following list:

   Table 4-13 • Parameters for the Arguments Box

Type	Source	Value
HWND	Constant	MsiWindowHandle
STRING	in Property	MESSAGEPROP
STRING	in Property	CAPTIONPROP
NUMBER	Constant	1

   In the **Value** list for the HWND type, select **MsiWindowHandle**. If you set the HWND type to this value, your message box will not hide behind the installation window. The properties **MESSAGEPROP** and **CAPTIONPROP** are not available in the list. When you enter these names in the **Value** list, they are added to the Property Manager.
3. In the **Return Type** list, select **void**. (Although **MessageBoxA()** does return a number, checking that value in a property is outside the scope of this example.)
4. Click **Next** to proceed to the **Action Parameters** panel.

Part D: Specify the Source for MessageBoxA

The next significant setting in the Custom Action Wizard is the Source field in the Action Parameters panel. MessageBoxA is found in `User32.dll`. Click the Browse button to locate `User32.dll` in your Windows system folder.

In the next panel of the wizard, click Next to accept the defaults, and then click Finish in the Summary panel to dismiss the wizard and add CA_Example to your project.

Part E: Initialize the Properties' Values

For the string parameters in **MessageBoxA()**, properties were provided, as described in the above procedures. The next step is to give those properties a value:

1. In the View List under **Behavior and Logic**, click **Property Manager** to view the installer properties in your project. The properties **MESSAGEPROP** and **CAPTIONPROP** were created as a result of referencing these properties in the **Custom Action Wizard**.
2. Locate **MESSAGEPROP** and click in its **Value** column to supply a value. Enter `Can you see this text?` for the value.
3. Set the CAPTIONPROP property to **Custom Action Example**.

Part F: Insert the Custom Action into a Sequence

In order to execute the custom action, you must either place it into a sequence or make it the result of a dialog's control event.

Follow the steps below to insert CA_Example into the Installation sequence of the installation project:

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, under the **Installation** sequence, expand the **User Interface** item. The actions and dialogs that are scheduled for this sequence are listed.
3. Right-click the **MigrateFeatureStates** action (the action right before the InstallWelcome dialog) and click **Insert**. The **Insert Action** dialog box opens.
4. In the list at the top of the dialog box, select **Custom Actions** (for installation projects).
5. In the list of custom actions, select **CA_Example**.
6. Click **OK**.

CA_Example is added to the Installation sequence directly after MigrateFeatureStates.

Part G: Test the Call to MessageBoxA

1. Build a release. (The Output window may show build errors if you have not added any components or files to your project.)
2. On the **Build** menu, click **Run**.

InstallShield runs your installation. After the Welcome dialog is displayed, a Custom Action Example message box opens.

Searching for Files on the Target System

System Search View

The System Search view provides the functionality for locating a particular file, folder, registry or .ini file on a target system before installing your application.

Direct Editor: Basic MSI Projects

Windows Installer uses records in the **Signature**, **AppSearch**, and "locator" tables for instructions for searching for files on the target system. The **Signature** table contains information about the file to be located, and the **AppSearch** table specifies a property to set to the full path of the located file, if found.

For example, to search for a file called **FindMe.exe**, use the Direct Editor to add the following record to the **Signature** table.

Table 4-14 • Sample Data for the Signature Table

Table Column	Sample Data
Signature	findme_sig

Table 4-14 • Sample Data for the Signature Table (cont.)

Table Column	Sample Data
FileName	FindMe.exe

Note that other fields in the **Signature** table enable you to specify optional version, size, date, and language information.

Add the following record to the **AppSearch** table.

Table 4-15 • Sample Data for the AppSearch Table

Table Column	Sample Data	Explanation
Property	LOCATION_OF_FINDME	Must be a public property.
Signature_	findme_sig	Same name used in **Signature** table.

There are four locator tables in which you can specify where Windows Installer should begin searching for the file: **CompLocator**, **RegLocator**, **IniLocator**, and **DrLocator**. To search for a file in a specific directory, use the **DrLocator** table. For example, to search for **FindMe.exe** in the user's Program Files directory, we add the following record to the **DrLocator** table.

Table 4-16 • Sample Data for the DrLocator Table

Table Column	Sample Data
Signature	findme_sig
Parent	
Path	[ProgramFilesFolder]
Depth	2

After the AppSearch action runs, the public property **LOCATION_OF_FINDME** will contain the full path to **FindMe.exe** on the end user's system if it exists; if the file is not located, this property will be undefined.

InstallScript: InstallScript MSI Projects

The **FindFile** and **FindAllFiles** functions enable you to search for existing files on the target system. For example, an implementation of the **OnAppSearch** event-handler function that searches for a file called **FindMe.exe** in the user's Program Files folder might appear as follows:

```
function OnAppSearch( )
    STRING svFoundFile;
begin
    FindAllFiles(PROGRAMFILES, "FindMe.exe", svFoundFile, RESET);
    MessageBox("Found FindMe.exe at: " + svFoundFile, INFORMATION);
end;
```

Launching the Application After the Installation Is Complete

The **LaunchApplication** function launches an executable file. For example, the following code launches a copy of **Program.exe** in the end user's INSTALLDIR folder, returning execution to the script when the end user closes the program's window.

```
LaunchApplication (INSTALLDIR ^ "Program.exe", "", "", SW_NORMAL,"", LAAW_OPTION_WAIT);
```

Project • *InstallScript projects use TARGETDIR rather than INSTALLDIR.*

Exiting the Installation from Within an InstallScript Custom Action

Project • *This information applies to the following project types:*

- *Basic MSI with InstallScript custom actions*
- *InstallScript MSI*
- *Merge Module with InstallScript custom actions*

An InstallScript entry-point function that returns the value ERROR_INSTALL_FAILURE causes the installation to exit.

Changing ODBC Properties Through Script

If you want to change ODBC properties (such as DBQ and SystemDB) through script, you must configure these options to use installer properties. Then from the script you can set those installer properties at run time. For example, you would set SystemDB to **[SYSTEM_DB_DIR]\MyDatabase** in the InstallShield interface. Then from the script, you could call **MsiSetProperty** to set the value of **SYSTEM_DB_DIR**.

Tip • *Set the property value before the OnMoving event, preferably in OnFirstUIBefore. After that, it is too late because the installer has already built up its internal script information, which cannot be modified.*

- *Use all uppercase letters for your property name.*
- *If **SYSTEM_DB_DIR** exists in the **Directory** table, omit the backslash (\) after the right bracket (]) when making your ODBC attribute settings. If you have defined it in the Property Manager, the backslash must be included.*

Using the INSTALLDIR Property in a VBScript Custom Action

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

If you need to use the **INSTALLDIR** property in a VBScript custom action, use the **Property** property of the Session object. This object is accessible in every VBScript custom action.

Following is sample code:

```
szInstallDir = Session.Property("INSTALLDIR")
```

For more information, see Session Object in the Windows Installer Help Library.

Using Action Text

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

To keep end users informed, installations commonly display text on the progress dialog to describe the installation's current activity. This usually accompanies the progress bar as a means of installation status. As each standard action and custom action is encountered, a message about the action is displayed on the progress dialog. This may be especially useful for actions that take a long time to execute. The same action text is also written to the installation's log file if one is created.

An action can also send action data that needs to be processed to the Windows Installer; once the data is processed, it can be displayed on the progress dialog.

For example, when the InstallFiles action is executing, the action text "Copying new files" is displayed by default on the progress dialog. This action text is also written to the installation's log file. If you want to provide additional detailed information about what is occurring as actions are encountered, you can add a control to the progress dialog to show action details; the control would need to subscribe to the ActionData event. For the InstallFiles action, this could include the name, directory, and size of each file as it is being installed on the target system.

Project • *InstallScript MSI installations cannot display action data on the status dialog. However, the template is written to the installation's log file.*

Specifying an Action Description and a Template for Action Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

InstallShield includes default action descriptions for standard actions and built-in InstallShield custom actions. InstallShield also includes default templates for many of those actions where appropriate. The templates indicate the format that should be used for the action data.

You may want to modify the default descriptions or templates of the standard actions and built-in InstallShield custom actions in your project. In addition, you may want to specify action text and action data format for your own custom actions.

Task: ***To specify a description and an action data template for an action in your project:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Right-click the **Action Text** explorer and click **New**. InstallShield adds a new action text item.
3. For the name of the action text item, enter the name of the action.

   

   Important • *The names of the action text items under the Action Text explorer should match the names of standard and custom actions that are in your project. If you change the name of a custom action, you must also change the name of its action text item; otherwise, the action's text is not displayed at run time or written to the installation's log file. Note, however, that you are not required to create action text for every action in your project.*
4. In the right pane, specify the description and the template. For more information, see Action Text Settings.

Tip • *If you want to edit the description or template of an action that is already listed under the Action Text explorer, select the action and then specify the appropriate values in the right pane.*

Displaying Action Descriptions on the Progress Dialog

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

In InstallScript MSI installations, the action text is automatically displayed on the progress dialog (that is, the STATUSEX dialog) if the dialog is enabled through a call to Enable (STATUSEX). This dialog is not available for editing.

By default, if a description has been specified for an action in your installation, that description is displayed above the progress bar on the progress dialog. Therefore, unless you have made some changes to this dialog in your project, you do not need to perform the following steps.

Task: ***To display action descriptions on the progress dialog:***

1. On the **SetupProgress** dialog, add a control that will display the action description:
   a. In the View List under **User Interface**, click **Dialogs**.
   b. In the **Dialogs** explorer, expand the **All Dialogs** folder, and then expand the **SetupProgress** dialog.
   c. Click a language under the **SetupProgress** dialog. The Dialog Editor in the center pane shows the dialog in the selected language.
   d. In the **Controls** toolbar, click the **Text Area** control.
   e. Draw a rectangle on the dialog in the location where you want the action description to be displayed.
2. With the control selected, configure its settings in the right pane:
   a. For the **(Name)** setting, enter the following:

      ```
      ActionText
      ```

   b. In the **Text** setting, delete the value.
3. Add a subscription for the ActionText event to the new control:
   a. In the **Dialogs** explorer under the **SetupProgress** dialog, click the **Behavior** item. The grid in the center pane shows all of the controls on the SetupProgress dialog.
   b. Select the **ActionText** control that you just created, and then click the **Subscriptions** tab in the lower-right pane.
   c. In the upper-right pane, add a record with the following information: For the **Event** field, select **ActionText**. For the **Attribute** field, enter **Text**.

At run time, if the installation is run with a full or reduced user interface, the progress dialog shows the description of each action as it is encountered. If a description has not been defined for an action, no description is displayed on the progress dialog when that action is launched.

Displaying Action Data on the Progress Dialog

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

In InstallScript MSI installations, the action data cannot be displayed on the progress dialog (that is, the STATUSEX dialog). However, you can call Enable (INDVFILESTATUS) in your InstallScript to achieve a similar result. If you call the INDVFILESTATUS constant with the ***Enable*** *function, the STATUSEX dialog shows the fully qualified file name of each file as it is transferred when* ***FeatureMoveData****,* ***CopyFile****, or* ***XCopyFile*** *is called and the progress indicator is enabled. Note that if a template is specified for an action in an InstallScript MSI project, the template is written to the installation's log file.*

If you want to provide detailed information about what is occurring as actions are launched at run time, you can add a control to the progress dialog to show action details; the control would need to subscribe to the ActionData event. For example, when the InstallFiles action is executing, the control that shows the action details could include the name, directory, and size of each file as it is being installed on the target system.

Task: ***To display the action data on the progress dialog:***

1. On the **SetupProgress** dialog, add a control that will display the action details:
   a. In the View List under **User Interface**, click **Dialogs**.
   b. In the **Dialogs** explorer, expand the **All Dialogs** folder, and then expand the **SetupProgress** dialog.
   c. Click a language under the **SetupProgress** dialog. The Dialog Editor in the center pane shows the dialog in the selected language.
   d. In the **Controls** toolbar, click the **Text Area** control.
   e. Draw a rectangle on the dialog in the location where you want the action description to be displayed.
2. With the control selected, configure its settings in the right pane:
   a. For the **(Name)** setting, enter the following:

      ```
      ActionData
      ```

   b. In the **Text** setting, delete the value.
3. Add a subscription for the ActionData event to the new control:

a. In the **Dialogs** explorer under the **SetupProgress** dialog, click the **Behavior** item. The grid in the center pane shows all of the controls on the SetupProgress dialog.

b. Select the **ActionData** control that you just created, and then click the **Subscriptions** tab in the lower-right pane.

c. In the upper-right pane, add a record with the following information: For the **Event** field, select **ActionData**. For the **Attribute** field, enter **Text**.

At run time, if the installation is run with a full user interface, the progress dialog shows the details of each action as it is launched. If a template has not been defined for an action, the details are not displayed on the progress dialog when that action is launched.

Removing an Action Description or a Template for Action Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To remove a description or an action data template for an action in your project:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Action Text** explorer, select the action whose description or template you want to delete.
3. In the **Description** setting or the **Template** setting, delete the value.

Note • *If you want neither the action description or the action template to be used, you can delete the action text record from your project: In the Action Text explorer, right-click the action text item that you want to remove, and then click Delete.*

Note that the action text for the following actions cannot be deleted:

- *GenerateScript*
- *Rollback*
- *RollbackCleanup*

In addition, the value of the Template setting for each of these actions must always be [1].

Defining Sequences

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Defining the sequences of an installation is an important part of developing an installer package. Sequences specify the order in which Windows Installer launches the standard and custom actions that control the installation process.

Project • *In Basic MSI and Transform projects, sequences also specify the order in which the dialogs are displayed.*

In InstallScript MSI projects, the user-interface dialogs are defined in the InstallScript code, and the InstallScript engine controls the user interface part of the installation.

The Custom Actions and Sequences view in InstallShield is where you define the sequences of your project. The Sequences explorer in this view lists all of the actions and dialogs in your project in chronological order, according to when they are launched during the applicable sequence. Each action and dialog is given a number in the sequence, and Windows Installer runs the sequence from the lowest number to the highest number.

Rather than having to manually provide a numeric value for every custom action and dialog that you add to your project, you can use the Custom Actions and Sequences view to insert actions or dialogs into a sequence or edit the sequence timeline. Refer to this section of the help for information about sequences.

Project • *If you create a custom action or a custom dialog in a merge module, you need to first import that module into an installation project and then add it to a sequence through the Custom Actions and Sequences view.*

Installation Sequence

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The installation sequence is the series of actions that are executed when the installation runs in the default installation mode, such as when an end user double-clicks a new .msi file. These actions are broken down into two types:

- User Interface
- Execute

Project • *The User Interface dialogs described below are those for a Basic MSI project. For an InstallScript MSI project, your InstallScript code performs the user interface of the installation.*

An InstallScript MSI project automatically includes the ISVerifyScriptingRuntime custom action. For details, see ISVerifyScriptingRuntime.

User Interface

The User Interface sequence contains all of the actions and dialogs needed to support a full user interface. This sequence is skipped if an installation is run in silent mode.

For complete technical details about each standard action, see the Standard Actions Reference in the Windows Installer Help Library.

Table 4-17 • User-Interface Actions and Dialogs in the Installation Sequence

Name of Action or Dialog	Type of Event	Description
SetupCompleteError	Dialog	This dialog is displayed at the end of an installation if that installation was terminated because of a fatal error.
SetupInterrupted	Dialog	This dialog is displayed at the end of an installation that was ended by the user.
SetupCompleteSuccess	Dialog	This dialog is displayed at the end of a successful installation.
ISSetupFilesExtract	Custom action	This custom action extracts any files that you have added in the Support Files view. For more information, see Using Support Files.
ISSetAllUsers	Custom action	The ISSetAllUsers custom action is inserted in the both the User Interface and Execute installation sequences only if one or more records are in the **Upgrade** table.
AppSearch	Standard action	This action can be used to identify and locate files on the target system. The Signature table that this action requires is available in the Direct Editor. Knowledge Base article Q103147 provides detailed information on using this action.

Table 4-17 • User-Interface Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
LaunchConditions	Standard action	This action evaluates a set of conditions that must return True if the installation is to continue. If any conditions fails, the user is presented with an error message and the installation ends. Launch conditions can be edited in the General information view.
SetupInitialization	Dialog	This dialog is displayed while the setup is preparing to begin. The default text for this dialog is "Preparing to install..."
FindRelatedProducts	Standard action	When this action is executed, the installer compares each installed product's upgrade code to that listed in the package's Upgrade table. If a match is found, the installed package's product code is added to the ActionProperty column of the Upgrade table.
CCPSearch	Standard action	The CCPSearch action allows you to check the end user's system for products qualifying for upgrade. The Signature table that this action requires is available in the Direct Editor.
RMCCPSearch	Standard action	The RMCCPSearch action allows you to check an end user's system for products qualifying for competitive upgrade. The Signature table that this action requires is available in the Direct Editor.
ValidateProductID	Standard action	Use the Validate Product ID action to set the ProductID property to the complete product identifier. This validation allows you to protect your software from illegal use by requiring users to enter the product ID.
CostInitialize	Standard action	This action is the first step in determining how much disk space is required by the current configuration of the installation. In order to complete costing, you need to use the CostInitialize action in conjunction with the CostFinalize action.
FileCost	Standard action	The FileCost action determines how much disk space is required by the current configuration of the installation. It checks to see if any files will be overwritten with later versions, and it calculates how overwriting those files affects disk space. To complete costing, you need to use the CostInitialize action in conjunction with the CostFinalize action.

Table 4-17 • User-Interface Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
IsolateComponents	Standard action	This action installs a component—usually a DLL file—into an isolated location so that it is used by only your application.
setUserProfileNT	Custom action	This custom action initializes the USERPROFILE directory identifier.
SetAllUsersProfileNT	Custom action	This custom action initializes the ALLUSERSPROFILE directory identifier.
setAllUsersProfile2K	Custom action	This custom action initializes the ALLUSERSPROFILE directory identifier.
ResolveSource	Standard action	Finds the location of the source and sets the SourceDir property.
CostFinalize	Standard action	The Calculate Disk Space action determines the total amount of disk space required by the installation in its current configuration. This action also verifies that all target directories are writable. The actions Initialize Disk Space Calculations and Initialize Dynamic Disk Space Calculations must be called before the Calculate Disk Space action; otherwise, the action will fail.
SetARPReadme	Custom action	The SetARPReadme custom action resolves the directory identifier used in the Read Me setting in the General Information view. This custom action is required because ARPREADME is a Windows Installer property and these properties do not format automatically.
MigrateFeatureStates	Standard action	This action is used during application upgrade. The feature states of the original installation are read from the target machine and applied to the upgraded features.
PatchWelcome	Dialog	The PatchWelcome dialog is displayed when a patch package is applied with a full user interface. It includes control events to set **REINSTALL** and **REINSTALLMODE** with the correct options. However, when the user interface is suppressed, you must set the properties at the command line.
InstallWelcome	Dialog	The InstallWelcome dialog displays your Welcome panel when an InstallScript MSI installation is run.

Table 4-17 • User-Interface Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
SetupResume	Dialog	This dialog opens when a previously canceled installation is resumed.
MaintenanceWelcome	Dialog	This dialog opens when the end user tries to change a program's installed features, remove the program, reinstall the program, run an installation for the second time, or select the current product in Add or Remove Programs.
SetupProgress	Dialog	This dialog displays the installation's progress.
ExecuteAction	Standard action	This action queries the **EXECUTEACTION** property to determine which top-level action should be called first, and then calls that top-level action. Top-level actions include the INSTALL, ADVERTISE, and ADMIN actions. Typically, this action starts the Installation Execute sequence.
ISSetupFilesCleanup	Custom action	This custom action appears when you add a file in the Support Files view. For more information, see Using Support Files.

Execute

The Execute sequence contains all of the actions that can change the machine's state and do not rely upon the user interface in order to function properly. These actions include file transfer, publishing components and features, and registering COM servers. Most of the Execute sequence is skipped when you run your installation in test mode, except for custom actions that have been inserted into the sequence.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence

Name of Action or Dialog	Type of Event	Description
ISSetupFilesExtract	Custom action	This custom action extracts any files that you have added in the Support Files view. For more information, see Using Support Files.
ISSetAllUsers	Custom action	The ISSetAllUsers custom action is inserted in the both the User Interface and Execute installation sequences only if one or more records are in the **Upgrade** table.
AppSearch	Standard action	This action can be used to identify and locate earlier versions of your product. The **Signature** table that this action requires is available in the Direct Editor. Knowledge Base article Q103147 provides detailed information on using this action.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
LaunchConditions	Standard action	This action evaluates a set of conditions that must return True if the installation is to continue. If any condition fails, the installation displays an error message and the installation ends. You can edit launch conditions in the General Information view.
FindRelatedProducts	Standard action	When this action is executed, the installer compares each installed product's upgrade code to that listed in the package's **Upgrade** table (supported in the Direct Editor). If a match is found, the installed package's product code is added to the **ActionProperty** column of the **Upgrade** table.
CCPSearch	Standard action	The CCPSearch action enables you to check the end user's system for products qualifying for upgrade. The **Signature** table that this action requires is available in the Direct Editor.
RMCCPSearch	Standard action	The RMCCPSearch action enables you to check an end user's system for products qualifying for competitive upgrade. The **Signature** table that this action requires is available in the Direct Editor.
ValidateProductID	Standard action	Use the ValidateProductID action to set the ProductID property to the complete product identifier. Validation allows you to protect your software from illegal use by requiring end users to enter the product ID.
CostInitialize	Standard action	This action is the first step in determining how much disk space is required by the current installation configuration.
FileCost	Standard action	This action determines how much disk space will be required by the current installation configuration. This action checks to see if any files will be overwritten with newer versions and calculates how overwriting those files will affect disk space.
IsolateComponents	Standard action	This action installs a component—usually a DLL file—into an isolated location so that it will be used by only your application.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
CostFinalize	Standard action	The CostFinalize action determines the total amount of disk space required by the current installation configuration. This action also verifies that all target directories are writable.
SetARPINSTALLLOCATION	Custom action	The SetARPINSTALLLOCATION custom action sets the value of the **ARPINSTALLLOCATION** property to the fully qualified path for the application's primary folder.
SetODBCFolders	Standard action	The SetODBCFolders action checks for existing ODBC drivers on the target system and sets the target directory of each new driver to the location of an existing driver.
MigrateFeatureStatus	Standard action	This action is used during application upgrade. The feature states of the original installation are read from the target machine and applied to the upgraded features.
InstallValidate	Standard action	The InstallValidate action determines if there is enough disk space available for the current installation configuration.
RemoveExistingProducts	Standard action	The RemoveExistingProducts action performs a silent uninstallation of any products whose code appear in OLDPRODUCTS.
InstallInitialize	Standard action	The InstallInitialize action signals the beginning of the actions that make changes to the end user's system.
AllocateRegistrySpace	Standard action	The installer makes sure that the system has at least as much free registry space available as specified in the AVAILABLEFREEREG property when it performs this action.
ProcessComponents	Standard action	The ProcessComponents action is responsible for unregistering and registering components. This action also registers or unregisters a component's key path and any other clients that the component has.
UnpublishComponents	Standard action	This action, called during uninstallation, unpublishes components that were published by your original installation, even if those components have been published by other applications.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
MsiUnpublishAssemblies	Standard action	The MsiUnpublishAssemblies action handles uninstallation of the assembly with the operating system.
UnpublishFeatures	Standard action	The UnpublishFeatures action removes all references to features that were originally published during installation. These references include registry entries that contain selection-state and feature-component mapping information.
StopServices	Standard action	This action stops the Windows services that are configured to be stopped. For more information, see Installing, Controlling, and Configuring Windows Services.
DeleteServices	Standard action	This action removes the Windows services that are configured to be deleted. For more information, see Installing, Controlling, and Configuring Windows Services.
UnregisterComPlus	Standard action	This action unregisters COM+ applications.
SelfUnregModules	Standard action	This action unregisters files registered by data in the SelfReg table.
UnregisterTypeLibraries	Standard action	During uninstallation, this action unregisters every file in the **TypeLib** table that is marked for uninstallation. This table is populated when you create a new TypeLib through the COM Registration advanced setting.
RemoveODBC	Standard action	During uninstallation, this action queries the **ODBCDataSource** table, **ODBCTranslator** table, and **ODBCDriver** table to find which ODBC resources should be removed during uninstallation. The resources that are marked for removal are uninstalled.
UnregisterFonts	Standard action	This action unregisters information about all the fonts that are set for uninstallation.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
RemoveRegistryValues	Standard action	The RemoveRegistryValues action removes values from the end user's registry if all of the following conditions are met: • The values have been authored into the **Registry** table. • The values are marked for uninstallation. • The component to which the registry entry belongs is set to run from source or is installed locally.
UnregisterClassInfo	Standard action	This action manages system registry information removal for COM classes that belong to features that are being uninstalled.
UnregisterExtensionInfo	Standard action	This action unregisters all extension-related information from the end user's system during uninstallation.
UnregisterProgIdInfo	Standard action	This action unregisters all of the ProgIDs created in the File Types advanced setting.
UnregisterMIMEInfo	Standard action	This action queries the **MIME** table of the current feature that is being uninstalled, and unregisters the MIME information for the servers found therein. This information is created through the File Types advanced setting.
RemoveIniValues	Standard action	This action removes only the .ini information that has been associated with a component in the **IniFile** table—or using the INI File Changes view. After verifying the presence in the **IniFile** table, this action removes all .ini files that are listed in the **RemoveIniFile** table if the component with which those files are associated is marked for uninstallation and the component was installed locally or set to run from source. The RemoveIniValues action also removes all .ini files that were written with the WriteIniValues action if the components with which they are associated are marked to be uninstalled.
RemoveShortcuts	Standard action	This action removes all advertised shortcuts to features that are marked for uninstallation. It also removes all non-advertised shortcuts to components that are marked for uninstallation.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
RemoveEnvironmentStrings	Standard action	When a component is removed, this action reverses any changes made to environment variables by the WriteEnvironmentStrings action during installation or reinstallation. You can specify environment variable changes using the Environment Variables view.
RemoveDuplicateFiles	Standard action	This action removes files that were created by the DuplicateFiles action. For this action to succeed, the component associated with the duplicate file must be marked for uninstallation.
RemoveFiles	Standard action	This action removes files that were originally installed by the InstallFiles action, if those files were set to run from source or installed locally, and the component with which they are associated is marked for uninstallation.
RemoveFolders	Standard action	The Remove Folders action unregisters and removes any empty folders that are associated with components that are marked for uninstallation and run from source.
CreateFolders	Standard action	This action creates empty folders for components that are set to be installed locally. These new folders are then registered with the associated component GUID (found in the component's Component Code property).
MoveFiles	Standard action	This action enables you to move or copy files that already exist on the target system. The **MoveFiles** table, used by this action, is available in the Direct Editor.
InstallFiles	Standard action	The InstallFiles action copies all of the selected feature's files to the target machine if the component feature to which those files belong is marked for installation. Only files that are associated with components that are to be installed locally are copied to the target machine.
PatchFiles	Standard action	This action queries the **Patch** table to determine which installed files have patches available. Those files undergo the bit-wise patching process.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
DuplicateFiles	Standard action	The DuplicateFiles action creates copies of certain files installed with the InstallFiles action. These files can be copied to the same directory as the original and given a different name, or they can be copied to a separate directory while maintaining the original name. The **DuplicateFiles** table, used by this action, is available in the Direct Editor.
BindImage	Standard action	Writes the virtual address of imported DLL file functions in the file's import address table, as specified in the **BindImage** table, which is available in the Direct Editor.
CreateShortcuts	Standard action	This action creates the shortcuts that you specified in the Shortcuts explorer in the Shortcut view or the Setup Design view.
RegisterClassInfo	Standard action	This action registers all of the COM class info that you specified in the COM Registration advanced setting, or which was extracted by the Component Wizard or a component's COM Extract at Build setting.
RegisterExtensionInfo	Standard action	The RegisterExtensionInfo action registers all the extensions that you specified in the File Types advanced setting.
RegisterProgIdInfo	Standard action	This action registers all of the ProgIDs that you defined in the Advanced Settings and that are linked to class servers or extension servers marked for installation.
RegisterMIMEInfo	Standard action	This action registers all of the MIME types that you defined in the File Types advanced setting that are linked to class servers or extension servers marked for installation.
WriteRegistryValues	Standard action	This action writes registry data to the target system if the associated component is marked for installation and set to run from source or installed locally. This registry information is the same data that you created in the Registry view.
WriteIniValues	Standard action	This action writes information to .ini files if the component with which this action is associated is set to be installed locally or run from source. This action and its corresponding tables are exposed in the INI File Changes view.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
WriteEnvironmentStrings	Standard action	When a component is installed, this action changes the environment variables on the system specified in the **Environment** table or the Environment Variables view.
RegisterFonts	Standard action	The RegisterFonts action registers any fonts that you included in your installation. In most cases, they were included using the Component Wizard.
InstallODBC	Standard action	This action installs all of the drivers, translators, and data sources for the ODBC resources that you specified through the ODBC Resources view.
RegisterTypeLibraries	Standard action	This action registers any type libraries that you may have created in your installation, either through the COM Registration advanced setting or the Component Wizard.
SelfRegModules	Standard action	This action registers self-registering modules listed in the **SelfReg** table. This action is performed with the default user privileges.
RegisterComPlus	Standard action	This action registers COM+ applications.
InstallServices	Standard action	This action installs the Windows services that are configured to be installed. For more information, see Installing, Controlling, and Configuring Windows Services.
MsiConfigureServices	Standard action	This action configures extended customization options for Windows services. For more information, see Installing, Controlling, and Configuring Windows Services.  ***Note*** • *This action is supported beginning with Windows Installer 5. Earlier versions of Windows Installer ignore this setting.*
StartServices	Standard action	This action starts all services that are configured to be started. For more information, see Installing, Controlling, and Configuring Windows Services.
RegisterUser	Standard action	This action registers user information to identify the user of the program.
RegisterProduct	Standard action	This action registers the product with the installer and saves the installer database on the target machine.

Table 4-18 • Execute Actions and Dialogs in the Installation Sequence (cont.)

Name of Action or Dialog	Type of Event	Description
PublishComponents	Standard action	This action publishes all components that are associated with advertised features.
PublishFeatures	Standard action	This action registers each feature's installation state. This state can be absent, advertised, or installed. If the feature is installed, the PublishFeatures action writes the feature-component relationship to the registry.
PublishProduct	Standard action	This action publishes a product if it is being advertised.
ScheduleReboot	Standard action	Insert the ScheduleReboot action into the action sequence to prompt the end user to reboot the system at the end of an installation. The ScheduleReboot action is typically placed at the end of the sequence.
InstallFinalize	Standard action	This action is the last transacted step.
RemoveExistingProducts	Standard action	This action loops through all the product codes listed in the **Upgrade** table and removes those products.
ISSetupFilesCleanup	Custom action	This custom action appears when you add a file in the Support Files view. For more information, see Using Support Files.

Advertisement Sequence

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Advertisement sequence is the list of actions that occur when an end user launches your installation with the `/j` command-line option for `MsiExec.exe`. The built-in actions in this sequence are described in the table below.

User Interface

Validation rule ICE78 requires the Advertisement User Interface sequence to be empty.

Execute

The Execute sequence contains all the actions that do not rely upon the user interface in order to function properly. These actions include file transfer, publishing components and features, and registering COM servers.

For complete technical details about each standard action, see the Standard Actions Reference in the Windows Installer Help Library.

Table 4-19 • Execute Actions in the Advertisement Sequence

Action Name	Type of Event	Description
CostInitialize	Standard action	The first step in determining how much disk space is required by the current configuration of the installation.
CostFinalize	Standard action	Determines the total amount of disk space required by the installation in its current configuration.
InstallValidate	Standard action	Determines if there is enough disk space available for the current configuration.
InstallInitialize	Standard action	Marks the beginning of the actions that make changes to the end user's system.
CreateShortcuts	Standard action	Creates the shortcuts specified in the Shortcuts view or the Setup Design view.
RegisterClassInfo	Standard action	Registers all of the COM class information specified in the COM Registration advanced setting.
RegisterExtensionInfo	Standard action	Registers all of the extensions specified in the File Types advanced setting.
RegisterProgIdInfo	Standard action	Registers all of the ProgIDs that defined in the COM Registration advanced setting if its component is being advertised.
RegisterMIMEInfo	Standard action	Registers all of the MIME types that are defined in the File Types advanced setting if its component is being advertised.
RegisterTypeLibraries	Standard action	Registers any type libraries that were created in the installation, either through the COM Registration advanced setting or the Component Wizard.
PublishComponents	Standard action	Publishes all components that are associated with features that are being advertised.

Table 4-19 • Execute Actions in the Advertisement Sequence (cont.)

Action Name	Type of Event	Description
MsiPublishAssemblies	Standard action	Manages the advertisement of common language run-time assemblies and Win32 assemblies. The action queries the MsiAssembly table to determine which assemblies have features being advertised or installed to the global assembly cache and which assemblies have a parent component being advertised or installed to a location isolated for a particular application.
PublishFeatures	Standard action	Registers each feature's installation state. This state can be absent, advertised, or installed. If the feature is installed, this action writes the feature-component relationship to the registry.
PublishProduct	Standard action	Publishes a product if it is being advertised.
InstallFinalize	Standard action	The final step of the installation or uninstallation.

Administration Sequence

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Administration sequence is the list of actions that execute when a user launches your setup program with the /a command-line option. The built-in actions and dialogs for this sequence are defined in the tables below.

User Interface

The User Interface sequence contains all of the actions and dialogs needed to support a full user interface. This sequence is skipped if an installation is run in silent mode.

Project • *The User Interface actions described below are those for a Basic MSI project. For an InstallScript MSI project, your InstallScript code performs the user interface of the installation.*

For complete technical details about each standard action, see the Standard Actions Reference in the Windows Installer Help Library.

Table 4-20 • User-Interface Actions in the Administration Sequence

Action Name	Type of Event	Description
SetupCompleteError	Dialog	This dialog is displayed at the end of an installation if it was terminated because of a fatal error.
SetupInterrupted	Dialog	This dialog is displayed at the end of an installation that was ended by the end user.
SetupCompleteSuccess	Dialog	This dialog is displayed at the end of a successful installation.
SetupInitialization	Dialog	This dialog is displayed while the installation is preparing to begin. The default text for this dialog is “Preparing to install...”
CostInitialize	Standard action	This action is the first step in determining how much disk space is required by the current configuration of the installation.
FileCost	Standard action	This action determines how much disk space will be required by the current configuration of the installation. This action checks to see if any files will be overwritten with newer versions, and it calculates how overwriting those files will affect disk space.
CostFinalize	Standard action	The CostFinalize action determines the total amount of disk space required by the installation in its current configuration. This action also verifies that all target directories are writable.
AdminWelcome	Dialog	This is the first dialog displayed during the Administration sequence.
SetupProgress	Dialog	This dialog displays the progress of the installation.
ExecuteAction	Standard action	This action runs the Administration Execute sequence.

Execute

The Execute sequence contains all the actions that do not rely upon the user interface in order to function properly. These actions include file transfer, publishing components and features, and registering COM servers.

Table 4-21 • Execute Actions and Dialogs in the Administration Sequence

Action Name	Type of Event	Description
CostInitialize	Standard action	This action is the first step in determining how much disk space is required by the current installation configuration.
FileCost	Standard action	This action determines how much disk space will be required by the current installation configuration. This action checks to see if any files will be overwritten with newer versions and calculates how overwriting those files will affect disk space.
CostFinalize	Standard action	The CostFinalize action determines the total amount of disk space required by the installation in its current configuration. This action also verifies that all target directories are writable.
InstallValidate	Standard action	The InstallValidate action determines if there is enough disk space available for the current setup configuration.
InstallInitialize	Standard action	The InstallInitialize action marks the beginning of the actions that make changes to the end user's system.
InstallAdminPackage	Standard action	This action copies the installation database to the administrative installation point.
InstallFiles	Standard action	The InstallFiles action copies all of the files to the target machine if the feature that those files belong to is slated for installation. Only files that are associated with components that are to be installed locally will be copied to the target machine.
InstallFinalize	Standard action	This action is the final step of the installation or uninstallation.

User Interface Sequence

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript MSI*
- *MSI Database*
- *Transform*

The User Interface sequence contains all of the actions and dialogs required for the default user interface. These actions and dialogs do not make changes to the target system. Generally, they gather information about the system environment and the end user for use later in the installation.

By default, the Administration and Installation sequences each contain a User Interface sequence.

Project • *InstallScript custom actions are not supported in the User Interface sequence for InstallScript MSI projects.*

Execute Sequence

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Execute sequence is executed after the User Interface sequence, unless your installation is run in silent mode. The Execute sequence contains all the standard and custom actions that change the target system. For example, file transfer is handled during the Execute sequence. Typically, this sequence is the part of the installation where changes are made to the target machine.

Each sequence (Installation, Advertisement, and Administration) has different actions that occur in the Execute sequence. This discrepancy is due to the fact that each of those sequences achieves different goals. For example, the Installation sequence installs the product on the target machine. The Advertisement sequence installs the product's advertised shortcuts, file-type information, and COM-server data on the target machine, but it does not transfer the product's files until the end user selects the shortcut, opens a registered document, or invokes an advertised COM server. As can be gathered from the name of the sequence, the product is advertised.

Inserting Actions into Sequences

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Sequences dictate when all of the actions that are associated with an installation will be executed. You can add, remove, or reorder actions in any sequence. For example, if you want to display a readme file as part of the installation, you can add to your installation a custom action that launches the readme file. This action must be inserted into a sequence.

Inserting actions into a sequence is governed by when actions in that sequence launch. Many actions rely on other actions executing before they can function. For example, if you want to launch an executable file that will be installed as part of your installation, you cannot execute the action that relies upon that executable file until the point in the sequence when the files have been installed.

Note • *InstallShield does not provide any validation on your sequences. If an action is placed in a sequence where it cannot function properly, an error will not occur until the installation is run.*

Inserting an Action

Task: ***To insert an action into a sequence:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, right-click the action or dialog that you want your action to follow and click **Insert**. The Insert Action dialog box opens, providing a list of all the actions and dialogs that can be added to the sequence.
3. In the list at the top of the dialog box, select the type of action that you want to insert.
4. In the box that shows a list of actions, select the action that you want to insert.
5. Click **OK**.

InstallShield also includes drag-and-drop support that enables you to drag and drop custom actions from the Custom Actions explorer to a sequence in the Sequences explorer.

Task: ***To insert a custom action into a sequence using the drag-and-drop method:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Drag the custom action from the **Custom Actions** explorer to the appropriate location in a sequence under the **Sequences** explorer. When you drop it, drop it onto the item that should be directly before it in the sequence.

Note • *A custom action cannot be called twice in the same sequence, since the custom action name is the key in the* ***CustomAction*** *table. Therefore, you cannot insert a custom action to a sequence that already contains that custom action.*

Determining Where to Insert the Action

There are several categories of custom actions that you can include in your installation: calling a standard or Windows Installer–ready DLL function, launching an executable file, running a script (JScript, VBScript, or InstallScript), setting a property or directory, and launching a second .msi installation. All types can be called at different times depending on the configuration of the custom action. For more information, see the following:

- Sequencing a Custom Action that Calls a Function in a DLL File
- Sequencing a Custom Action that Launches an .exe File
- Sequencing a Custom Action that Calls a Script
- Sequencing Custom Actions that Set Properties or Directory Properties
- Sequencing a Custom Action that Launches a Second .msi Package

Considerations for Custom Actions from Included Merge Modules

You can control the launch of custom actions in a merge module by modifying the **ModuleInstallExecuteSequence** table in the Direct Editor. When you add the merge module to your installation project, all custom actions and dialogs included in the merge module are available for you to insert in the installation's sequences through the Custom Actions and Sequences view.

Copying a Custom Action from One Sequence to Another

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

InstallShield enables you to copy a custom action in one sequence to another sequence through a drag-and-drop operation.

Task: ***To copy a custom action from one sequence to another:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, find the action that you want to copy.
3. Press and hold CTRL while dragging the custom action from one sequence to another sequence, and drop it onto the action or dialog that should be directly before it.

Note • *A custom action cannot be called twice in the same sequence, since the custom action name is the key in the* ***CustomAction*** *table. Therefore, you cannot move or copy a custom action to a sequence that already contains that custom action.*

Dialogs and standard actions cannot be moved to a different type of sequence through a drag-and-drop operation.

Reordering a Sequence

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The actions and dialogs in the Sequences explorer in the Custom Actions and Sequences view are organized by chronological order, according to when they are launched. Each action and item also has a number that identifies its location in the sequence in relation to other items' sequence numbers. The items are launched in order from the lowest number to the highest number.

When you add a dialog (to Basic MSI, MSI Database, and Transform projects) or a custom action to your project, you can specify when it should be launched by adding it to the appropriate place in a sequence.

Task: ***To change the order in which actions and dialogs in a sequence execute:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Do one of the following:
   - To sequence a new custom action, drag it from the **Custom Actions** explorer to the appropriate location in a sequence under the **Sequences** explorer. When you drop it, drop it onto the item that should be directly before it in the sequence.
   - To move an action or a dialog to a different point in a sequence (or from one sequence to another), drag it from the old location and drop it onto the item that should be directly before it in the sequence.

Note • *A custom action cannot be called twice in the same sequence, since the custom action name is the key in the* ***CustomAction*** *table. Therefore, you cannot move or copy a custom action to a sequence that already contains that custom action.*

Dialogs and standard actions cannot be moved to a different type of sequence through a drag-and-drop operation.

If you change a custom action after adding it to a sequence, you do not need to reassociate it with that sequence. The action that you put in the sequence is a pointer to the real action, and it is dynamically updated whenever you make changes to the action in the Custom Actions and Sequences view.

Tip *• You can also move actions and dialogs in the* ***Sequences*** *explorer using any of the following methods:*

- *Right-click the action or dialog and click* ***Move Up*** *or* ***Move Down****.*
- *Click the action or dialog and then press CTRL+SHIFT+UP ARROW or CTRL+SHIFT+DOWN ARROW.*
- *Change the position of the action or dialog by editing its Sequence Number setting, which is displayed in the grid on the right when you click the action or dialog. To move a an action or dialog to an earlier point in a sequence, give it a lower sequence number. To move it to a later point in the sequence, give it a higher sequence number.*

Removing Actions from Sequences

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Task: ***To remove an action from a sequence:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, expand the sequence that contains the action that you want to remove.
3. Right-click the action and click **Remove**.

The action is removed from that sequence only, not from all sequences or from the project. You can permanently remove an action from an installation project through the Custom Actions explorer in the Custom Actions and Sequences view.

Sequencing Rollback Custom Actions

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

- *Transform*

Any custom action that is in your installation project and that makes direct changes to the target system should have a rollback equivalent custom action. The rollback custom action can undo those changes in the event of rollback. For example, if you have a custom action that deletes files from the target system, and you do not include a rollback custom action to restore those deleted files, the computer could be left in an unstable state even after rollback has completed. Rollback custom actions behave in a similar way to deferred custom actions. That is, they do not launch when first encountered in a sequence. Instead, they are written to the rollback script, which launches only in the event of a rollback.

When inserting a rollback custom action into a sequence, note the following:

- A rollback can occur only during the Execute sequence and not at any point during the User Interface sequence. Therefore, the rollback action must be placed after InstallInitialize and before InstallFinalize in the Execute sequence.
- The rollback custom action must be sequenced before the action it rolls back. In all other instances, the Windows Installer service runs through sequences from top to bottom—the lower the sequence number, the sooner the action launches. In the rollback script, however, the service runs in the opposite direction. Therefore, to launch your rollback action when it is needed, sequence it before the action that it rolls back.

Sequencing a Custom Action that Launches an .exe File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Launching an executable file as your custom action can be a little trickier than calling a DLL file function in terms of where that action can be inserted into the sequence. You should consider things such as when the .exe file will be launched during the installation and which sequences you want the custom action to occur in.

Executable Files Stored in the .msi Package

When you are launching a .exe file that is stored in the .msi package, you can place the custom action anywhere in the sequence.

Table 4-22 • Settings for Actions that Launch an .exe File in the .msi Package

Action Type	Location	Scheduling	Sequence
Launch an executable	Stored in .msi package	Not applicable	Anywhere in the sequence

Installed Executable Files

If your .exe file is going to be installed as part of the installation, you should follow one of two sets of rules, depending on which scheduling property (Deferred Execution or Immediate Execution) you chose. For Immediate Execution, you must insert your action after the InstallFinalize action in order for it to work properly. For Deferred Execution, you need to insert the action after the InstallFiles action and before the InstallFinalize action.

Table 4-23 • Settings for Actions that Launch an Installed .exe File

Action Type	Location	Scheduling	Sequence
Launch an executable	Installed	Immediate Execution	After InstallFinalize
Launch an executable	Installed	Deferred Execution	After InstallFiles and before InstallFinalize

Local Executable Files

If the .exe file that you would like to run is already present on the system, you will need to insert your action after the CostFinalize action is called. See the table below for a clearer view.

Table 4-24 • Settings for Actions that Launch an .exe File that Is Already Installed

Action Type	Location	Scheduling	Sequence
Launch an executable	Local	Not applicable	After CostFinalize

Sequencing a Custom Action that Calls a Function in a DLL File

If you want to sequence a custom action that calls a function in a DLL file, there are three different ways to reference the DLL file, depending on where the DLL file is located during the installation:

- The DLL file can be streamed into the .msi file, but it is not installed.
- The DLL file can be in the target system's path (applies to a standard DLL file but not a Windows Installer DLL file).

- The DLL file can be installed with the rest of the installation files.

Other considerations include scheduling. The two main scheduling choices are Immediate Execution and Deferred Execution. Immediate Execution means that Windows Installer will execute your custom action as it processes the .msi file. Deferred Execution tells the installer to queue the action and perform it in sequence in the script.

DLL Files Stored in the .msi Package

When you are calling a function from a DLL file that is stored in the .msi package, you can place the custom action anywhere in the sequence.

Table 4-25 • Settings for Actions that Call a Function in a DLL File that is stored in the .msi Package

Action Type	Location	Scheduling	Sequence
DLL Function	Stored in .msi package	Not applicable	Anywhere

DLL Files Found in the System's Path

When you are calling a function from a DLL file that exists on the target system, there are also no restrictions on where you can place the custom action in the sequence.

Table 4-26 • Settings for Actions that Call a Function in a DLL File that Is Found in the System's Path

Action Type	Location	Scheduling	Sequence
DLL Function	On target system	Not applicable	Anywhere

Installed DLL Files

If you are calling a DLL function from a file that is going to be installed to the target machine during the installation and you have it scheduled to run during Immediate Execution, you can place the action only after the InstallFinalize action. If you want the action to occur during Deferred Execution, place the action after the InstallFiles action and before the InstallFinalize action. The following table illustrates this point:

Table 4-27 • Settings for Actions that Call a Function in a DLL File that Is Already Installed

Action Type	Location	Scheduling	Sequence
DLL Function	Installed	Immediate Execution	After InstallFinalize
DLL Function	Installed	Deferred Execution	Before InstallFinalize and After InstallFiles

Sequencing a Custom Action that Calls a Script

Project • *The VBScript and JScript information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The InstallScript information applies to the following project types:

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

Using script inside your custom action enables you to perform virtually any task. For example, you can launch external applications or create registry entries.

VBScript and JScript Code

Installed with the Product

If your script file is going to be installed as part of the installation, you should follow one of two sets of rules depending on which scheduling property (Deferred Execution or Immediate Execution) you chose. For Immediate Execution, you must insert your action after the InstallFinalize action in order for it to work properly. For Deferred Execution, you need to insert the action after the InstallFiles action and before the InstallFinalize action.

Table 4-28 • Settings for Actions that Call a VBScript or JScript File that Is Installed with the Product

Action Type	Location	Scheduling	Sequence
Run VBScript or JScript Code	Installed	Immediate Execution	After InstallFinalize
Run VBScript or JScript Code	Installed	Deferred Execution	After InstallFiles and before InstallFinalize

Stored in the Binary Table

If the script file that you are calling is stored in the Binary table, you can place the action anywhere in the sequence.

Table 4-29 • Settings for Actions that Call a VBScript or JScript File that Is Stored in the Binary Table

Action Type	Location	Scheduling	Sequence
Run VBScript/ JScript Code	Temporary	Not applicable	Anywhere in the sequence

Already Present on the Target System

If the script file that you want to call is already present on the system, you need to insert your action after the CostFinalize action is called.

Table 4-30 •

Action Type	Location	Scheduling	Sequence
Run VBScript/ JScript Code	Local	Not applicable	After CostFinalize

Stored Directly in the Custom Action

If you chose to place your script directly in the custom action, you can place the action anywhere in the sequence.

InstallScript Code

InstallScript custom actions differ from JScript or VBScript custom actions because the source files for InstallScript actions are always streamed into the .msi package. Therefore, the custom action can be inserted into a sequence anywhere after the action that has 2 as its sequence number. This limitation occurs because the script engine launches during sequence number 2. Therefore, if you call your script before the script engine launches, the system is not able to process it.

If your custom action contains feature functions or setup type dialog functions, you must insert the custom action after the CostInitialize, FileCost, and CostFinalize actions.

Sequencing Custom Actions that Set Properties or Directory Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

- *MSM Database*
- *Transform*

When you are sequencing a custom action that sets a property or directory, the primary guideline that you need to follow is to make sure that the custom action runs before that directory or property is needed. For example, if you want to launch an executable file that is present on the target machine, the installation will probably need to search for it first.

Once the installation finds the executable file, its path can be added to the **Directory** table, and the executable file can be launched. However, if you call the custom action after you launch the executable file, the executable file will not be found.

Some other sequencing and scheduling restrictions include:

- Validation rule ICE12 requires any type-35 custom action (called **Set a directory** in the Custom Action Wizard) to be sequenced after the standard CostFinalize action in the sequences.
- Similarly, ICE12 requires any type-51 custom action (called **Set a property** in the Custom Action Wizard) that sets the value of a property found in the **Directory** table to be scheduled before the standard CostFinalize action.
- Any custom action that sets a property should be scheduled for immediate execution.

Sequencing a Custom Action that Launches a Second .msi Package

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

Important • *Nested installations is a deprecated feature of the Windows Installer. Applications installed with nested installations sometimes fail because they are difficult for end users to service correctly. Microsoft Corporation recommends that you avoid using nested installations and nested-installation custom actions to install products that are intended to be released to the public. To learn more, see Concurrent Installations on the MSDN Web site.*

When you are sequencing a nested-installation custom action (called **Launch another .msi package** in the Custom Action Wizard), you must place the action in the Execute sequence after the standard CostFinalize action.

Additionally, ensure that the custom action launches before any of the files contained within the installation are needed by your main installation, if applicable. For example, if you later want to launch an executable file that is installed as part of the second .msi file, ensure that the package is installed before you try to launch the executable file.

ISSetAllUsers Custom Action

Why ISSetAllUsers Appears in Your Installation Package's Sequence

If you have entered one or more records in the **Upgrade** table for your installation (through the Upgrades view), InstallShield inserts a DLL custom action called ISSetAllUsers in both the User Interface and Execute portions of the installation sequence. When your product is installed as an upgrade, the ISSetAllUsers custom action checks the value of the ALLUSERS property in the installed version.

The ALLUSERS property is indicated in the Customer Information dialog (for Basic MSI projects) and in either the **SdCustomerInformation** or **SdCustomerInformationEx** dialog (for InstallScript MSI projects) by the end user during the initial installation. The ISSetAllUsers custom action compares the value in the installed version to the value in the new version. If the values differ, then ISSetAllUsers sets the **ALLUSERS** property of the new version to match that of the installed version.

Note that for upgrades, the **ALLUSERS** property is configurable only through a custom action.

The new installation's **ALLUSERS** property must match the installed version's property in order for the FindRelatedProducts action to succeed for the upgrade installation. In addition, if the previous version is installed for only one particular user and the upgrade is installed for all users, the resulting installation is corrupted and might not uninstall properly. ISSetAllUsers eliminates these problems by resetting the **ALLUSERS** property.

How ISSetAllUsers Works

The following example illustrates how the ISSetAllUsers custom action works:

1. My Application 1.0 is installed with the **ALLUSERS** property set to *1* (the end user selected **Install for All Users** in the end-user dialog during installation).
2. My Application 2.0 is authored as an upgrade to version 1.0 and has an entry in the **Upgrade** table to upgrade version 1.0.
3. The end user installs version 2.0 on the target system as an upgrade.
4. During the installation, ISSetAllUsers checks the value of the **ALLUSERS** property in the installed version and compares it to the new version's property by doing the following:
    a. ISSetAllUsers iterates through each entry in the **Upgrade** table of version 2.0.
    b. For every upgrade code in the **Upgrade** table, ISSetAllUsers searches for the related products on the target system.
    c. If the version and language constraints in the **Upgrade** table match one of the installed products (found in step 4b), ISSetAllUsers checks the **ALLUSERS** property of the installed version.
    d. If the value of **ALLUSERS** for the installed version differs from that of the new version, ISSetAllUsers sets the new installation's **ALLUSERS** property to this value.

Note • *If no matching product is installed on the target system, ISSetAllUsers does nothing.*

Using Support Files

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Suite/Advanced UI*

Support files are files that are available on the target system only during your product's installation process. Support files are copied to a temporary directory on the target system when installation begins. The support files are deleted when the installation is complete. The support directory is a dynamic file location and might be different on every target system and even on the same system for different installation instances.

In the Support Files view (in Advanced UI, Basic MSI, InstallScript Object, and Suite/Advanced UI projects) or the Support Files/Billboards view (in InstallScript projects and InstallScript MSI projects), you can add and remove files that you want to be available on the target system only during installation.

Adding Support Files

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Suite/Advanced UI*

Task: ***To add support files to your installation project:***

1. In Advanced UI, Basic MSI, InstallScript Object, and Suite/Advanced UI projects: In the View List under **Behavior and Logic**, click **Support Files**.

   In InstallScript and InstallScript MSI projects: In the View List under **Behavior and Logic**, click **Support Files**/**Billboards**.

2. In the **Support Files** explorer, click the item that should contain the support file that you are adding.
3. Right-click anywhere in the **Files** pane and then click **Insert Files**. The **Open** dialog box opens.

4. Browse to the file that you want to include. To select multiple files, hold down the CTRL key while clicking files.
5. Click **OK**.

InstallShield adds the file to the Files pane.

Tip • *You can also drag files from Windows Explorer and drop them into the Files pane.*

Adding a License File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

You can add a text file containing a license agreement in the Support Files/Billboards view.

Task: ***To add a license file:***

1. In the View List under Behavior and Logic, click **Support Files**/**Billboards**.
2. In the **Support Files** explorer, click the item that should contain the license file that you are adding.
3. Right-click anywhere in the **Files** pane and then click **Insert Files**. The **Open** dialog box opens.
4. Browse to the file that you want to include. To select multiple files, hold down the CTRL key while clicking files.
5. Call the file in the szLicenseFile parameter in one of the **SdLicense*** functions in your script.

Sorting Support Files

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *Suite/Advanced UI*

You can sort the files in the Files pane of the Support Files view (in Advanced UI, Basic MSI, and Suite/Advanced UI projects) or the Support Files/Billboards view (in InstallScript projects and InstallScript MSI projects) by clicking the heading of the column by which you want to sort the files. You can sort by any of the columns.

Adding Files and Folders to the Disk1 Folder

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

The Disk1 node enables you to indicate files and folders that you want to go on Disk1 of your installation media. These files and folders are not automatically installed to the target system when your installation is run. Rather, you can link to the installation media from your application or from the installation.

For example, you might include a large redistributable file with your application. You may want end users to be able to access the redistributable, but you do not want to include in the application installation. If this is the case, this file can be placed in the Disk1 folder.

Task: ***To add a file or folder to the Disk1 folder:***

1. In Basic MSI projects: In the View List under Behavior and Logic, click **Support Files**.

   In InstallScript and InstallScript MSI projects: In the View List under Behavior and Logic, click **Support Files**/**Billboards**.
2. In the **Support Files** explorer, click **Disk1**.
3. Right-click anywhere in the **Files** pane and then click **Insert Files**. The **Open** dialog box opens.
4. Browse to the file that you want to include. To select multiple files, hold down the CTRL key while clicking files.
5. Click **OK**.

InstallShield adds the file to the Files pane.

Removing Files or Folders from the Disk1 Folder

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Task: ***To remove a file or folder from the Disk1 folder:***

1. In Basic MSI projects: In the View List under Behavior and Logic, click **Support Files**.

   In InstallScript and InstallScript MSI projects: In the View List under Behavior and Logic, click **Support Files**/**Billboards**.
2. In the **Support Files** explorer, click **Disk1**.
3. In the **Files** pane, right-click the file or folder and then click **Delete**.

Adding Files and Folders to the Last Disk Folder

Project • *This information applies to InstallScript projects.*

The Last Disk node enables you to indicate files and folders that you want to go on the last disk of your installation media. These files or folders are not automatically installed to the target system when your installation is run. Rather, you can link to the installation media from your application or from the installation.

For example, you might include a large redistributable file with your application. You may want end users to be able to access the redistributable, but you do not want to include in the application installation. If this is the case, this file can be placed in the last disk folder.

Task: ***To add a file or folder to the last disk image folder:***

1. In the View List under Behavior and Logic, click **Support Files**/**Billboards**.
2. In the **Support Files** explorer, click **Last Disk**.
3. Right-click anywhere in the **Files** pane and then click **Insert Files**. The **Open** dialog box opens.
4. Browse to the file that you want to include. To select multiple files, hold down the CTRL key while clicking files.
5. Click **OK**.

InstallShield adds the file to the Files pane.

Removing Files or Folders from the Last Disk Folder

Project • *This information applies to InstallScript projects.*

Task: ***To remove a file or folder from the last disk image folder:***

1. In the View List under Behavior and Logic, click **Support Files/Billboards**.
2. In the **Support Files** explorer, click **Last Disk**.
3. In the **Files** pane, right-click the file or folder and then click **Delete**.

Adding Files and Folders to the Other Disk Folder

Project • *This information applies to InstallScript projects.*

The Other node enables you to indicate files or folders that you want to go on a disk of your installation media other than the first or last disk. These files or folders are not automatically installed to the target system when your installation is run. Rather, you can link to the installation media from your application or from the installation.

Task: ***To add a file or folder to a disk image folder:***

1. In the View List under Behavior and Logic, click **Support Files/Billboards**.
2. In the **Support Files** explorer, click **Other**.
3. Right-click anywhere in the **Files** pane and then click **Insert Files**. The **Open** dialog box opens.
4. Browse to the file that you want to include. To select multiple files, hold down the CTRL key while clicking files.
5. Click **OK**.

InstallShield adds the file to the Files pane.

Tip • *To specify the disk, run the Release Wizard; in the General Options panel, click the Other Disk Files button.*

Removing Files or Folders from the Other Disk Folder

Project • *This information applies to InstallScript projects.*

Task: ***To remove a file or folder from a disk image folder:***

1. In the View List under Behavior and Logic, click **Support Files/Billboards**.
2. In the **Support Files** explorer, click **Other**.

3. In the **Files** pane, right-click the file or folder and then click **Delete**.

Removing Support Files

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Suite/Advanced UI*

Task: ***To remove support files from your project:***

1. In Advanced UI, Basic MSI, InstallScript Object, and Suite/Advanced UI projects: In the View List under **Behavior and Logic**, click **Support Files**.

   In InstallScript and InstallScript MSI projects: In the View List under **Behavior and Logic**, click **Support Files**/**Billboards**.

2. In the **Support Files** explorer, click the item that contains the support file that you want to delete.
3. In the **Files** pane, right-click the file or folder and then click **Delete**.

Defining the End-User Interface

This section of the documentation covers different features of InstallShield that enable you to define different aspects of the end-user interface. Some portions of the "Defining the End-User Interface" section discuss how to create and work with dialogs for the end-user interface of your installation. Others discuss topics such as strings, which let you localize your installation.

Working with Dialogs

This section of the documentation covers some of the basic and more advanced aspects of working with end-user dialogs for various project types in InstallShield.

Project • *In Basic MSI installations, Windows Installer typically controls the run-time user interface. In InstallScript and InstallScript MSI installations, the InstallScript engine typically controls the run-time user interface. Therefore, some portions of this section of the documentation apply to Basic MSI installations, some apply to InstallScript and InstallScript MSI installations, and some apply to all three project types.*

Working with Dialogs in Any Project Type

Dialogs provide the user interface for your installation. They request information from the end user and provide feedback about the progress of the installation process.

The way in which you work with the dialogs in your project depends on the type of installation that you are creating. Adding dialogs to an InstallScript or InstallScript MSI project requires different steps than adding dialogs to a Basic MSI project.

Common Operations

Some of the dialog operations are common to Basic MSI, InstallScript, and InstallScript MSI projects.

- Using the Dialog Wizard to Create a New Dialog
- Exporting a Dialog to an .isd File for Use in Other Projects
- Importing Dialogs from an .isd File
- Exporting All Dialogs to an .rc File
- Importing Dialogs from Resource .dll Files
- Exporting Dialogs to Other Projects

Using the Dialog Wizard to Create a New Dialog

InstallShield provides a Dialog Wizard that enables you to add a new dialog to your installation and configure it by stepping through the wizard panels.

Adding the Ability to Create or Set an Existing User Account

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Project-specific differences are noted where appropriate.

Many server applications require the specification of a user account during installation. Having a user account available is often necessary because it enables a server application to access resources that are restricted to other users. InstallShield offers support for setting an existing Windows user account or creating a new one during installation by enabling you to add the appropriate run-time dialogs to your installation.

Table 4-1 • Project-Specific Details for Adding User Account Support

Project Type	Additional Information
Basic MSI	For Basic MSI projects, the specified user name, password, and group information entered in the LogonInformation dialogs are stored in the following properties: • IS_NET_API_LOGON_USERNAME • IS_NET_API_LOGON_GROUP • IS_NET_API_LOGON_PASSWORD
InstallScript	For InstallScript projects, the specified user name, password, and group information entered by the end user in the LogonInformation dialogs are stored in the following global variables: • IFX_NETAPI_USER_ACCOUNT • IFX_NETAPI_PASSWORD • IFX_NETAPI_GROUP
InstallScript MSI	For InstallScript MSI projects, the specified user account, group, and password are stored in the following global variables and properties: • IFX_NETAPI_USER_ACCOUNT • IFX_NETAPI_GROUP • IFX_NETAPI_PASSWORD • IS_NET_API_LOGON_USERNAME • IS_NET_API_LOGON_GROUP • IS_NET_API_LOGON_PASSWORD

Adding Support for the LogonInformation Dialogs to a Basic MSI Project

Task: ***To add the LogonInformation dialogs to a Basic MSI project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click **All Dialogs**, and click **New Dialog**. The **New Dialog Wizard** opens.
3. Complete each panel of the wizard. In the **Dialog Template** panel, select **Logon Information Panel and Associated Child Dialogs**.

When you are done completing each panel of the New Dialog Wizard, build and run your installation project. When the dialog sequence in which the LoginInformationDialog dialog is executed, the appropriate dialogs are displayed.

Adding Support for the LogonInformation Dialogs to an InstallScript or InstallScript MSI Project

Task: ***To add support for the LogonInformation dialogs to either an InstallScript or InstallScript MSI project:***

1. Navigate to the location in your InstallScript code where you want to insert the LogonInformation dialog set. In most situations, you will add it within **OnFirstUIBefore**. For example:

   ```
   Dlg_SdLogon:
   nResult = SdLogonUserInformation(szTitle, szMsg, szAccount, szPassword);
   if (nResult = BACK) goto Dlg_SdWelcome;
   ```

2. In InstallScript MSI projects, add the following function so that the Windows Installer properties are set to the same value as the InstallScript global variables. You can add it after calling **SdLogonUserInformation**.

   ```
   OnLogonUserSetMsiProperties();
   ```

3. On the **Build** menu, click **Settings**. The **Settings** dialog box opens.
4. Click the **Compile**/**Link** tab.
5. In the **Libraries (.obl)** box, enter the name of your new library file (*.obl):

   ```
   NetApiRT.obl
   ```

Note • *You should add the new library file name before the `isrt.obl` file name.*

Once you have added the InstallScript code, build and run your installation. When the script is executed, the appropriate dialogs are displayed.

Limitations of the LogonInformation Dialogs in Basic MSI, InstallScript, and InstallScript MSI Projects

When an end user attempts to use the LogonInformation dialogs, they may encounter a blank list of domains, or they may encounter a "Server not found" error. The following scenarios may cause this behavior:

- The target system is not on a domain.
- The Computer Browser service is not enabled on the target system.
- A firewall is configured without an exception for the Computer Browser service.
- NetBIOS over TCP/IP is not enabled on the target system.
- No master browser server is configured on the network.
- Broadcast traffic is disabled on the network.

Exporting a Dialog to an .isd File for Use in Other Projects

If you want to reuse an end-user dialog in other projects, you can export the dialog as an .isd file and then import it into other projects as needed. The .isd file contains the behavior and layout information for the dialog.

Task: ***To export a dialog to an .isd file:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog and then click **Export to Dialog File**. The **Save As** dialog box opens.
3. Browse to the folder to which you want to save the .isd file. You can rename the file if required.
4. Click **OK**.

You can now use the .isd file to import the dialog into another installation project.

Importing Dialogs from an .isd File

InstallShield enables you to import a dialog into your installation project. The file for the dialog (.isd file) can be stored in a repository, or it can be stored in some other location.

Task: ***To import a dialog into your project from an .isd file:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog and then click **Import Dialog**. The Import Dialog dialog box opens.
3. Do one of the following:
   - In the **Repository Items** box, click the dialog that you want to add to your project.

- If the file for the dialog box (.isd file) that you want to import is not stored in the repository, click the **Browse** button to select it.

4. Click **OK**.

InstallShield adds a copy for each supported language to your project.

Note • *When you import a dialog, make sure that any string identifiers, properties, and actions referenced by the dialog are present in the new installation project.*

Resolving Conflicts

When you import a dialog, InstallShield checks to make sure that the name of the dialog and its controls are unique—as required by Windows Installer. You cannot import a dialog with the same name as an existing dialog because InstallShield assumes that you are trying to import an identical dialog.

If you try to import an .isd file that uses the names of controls or string identifiers that already exist in your installation project, InstallShield asks how you want to resolve those conflicts. You can either overwrite the existing values or skip the imported values in order to leave the existing ones.

Displaying Dialogs During Installation

Adding a dialog to a project does not mean that the dialog will be displayed in the installation. For information on inserting the dialog into one or more of the project's sequences, see Displaying Dialogs During Basic MSI Installations.

Publishing a Dialog (.isd) File to a Repository

If you have an existing dialog (.isd) file that you would like to reuse in other projects or share with other users, you can publish it to a repository.

Task: ***To publish a dialog to a repository:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog and then click **Publish Wizard**. The **Publish Wizard** opens.
3. Complete the panels in the Publish Wizard.

After you have imported a dialog from a repository into a project, there is no link between the current dialog and the existing repository dialog. If you make a change to the dialog and then republish it to the repository, it does not affect the dialog in the project to which it was imported. However, you can reimport the dialog from the repository into your project.

Exporting All Dialogs to an .rc File

If you would like to edit your dialogs' resources in a resource editor such as Visual Studio, you can export the dialogs to an .rc file.

Task: ***To export a dialog to a resource script (.rc) file:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click **All Dialogs** and click **Export Dialogs to Resource Script**.

InstallShield copies all of the dialogs' resources for the default language to a file named <project name>.rc in the project location.

Every attempt is made to preserve each dialog's layout as much as possible. However, since some information in the Dialog Editor has no counterpart in a resource editor, InstallShield exports the resources as they appear in the Dialog Editor with the following exceptions:

Table 4-2 • Resources that Are Not Exported to an .rc File

Exception	Description
String entries	All strings entries are resolved to the value of the default language.
Paths	The paths, including any path variables, to any resources, such as text files or bitmaps, are preserved to make it easier to import the dialog at a later point.
Selection trees	A Windows Installer selection tree becomes a standard tree control in the .rc file.
Text style	While the Dialog Editor maintains separate properties for font information (base text style and text style) and maximum character length, these properties are grouped together as they are in the Windows Installer tables.
Behavior	Unlike .isd files, which contain complete copies of the dialog's layout and behavior, .rc files store only the resources.

Editing the Dialogs in a Resource Editor

You can edit the dialogs' geometry in a resource editor—or Notepad—as you would for any Windows dialog.

Before importing the dialogs back into your project, you must compile the .rc file into a .res file and then build it into a .dll file.

Task: ***Assuming again that you use Visual Studio, follow the steps below to build MyProject.rc into MyProject.dll:***

1. Use the Resource Compiler (`Rc.exe`) to compile **MyProject.rc** into **MyProject** with the following command-line statement:

   ```
   rc MyProject.rc
   ```

2. Run the Incremental Linker (`Link.exe`) to build a .dll file with the following command:

   ```
   link /DLL /NOENTRY /NODEFAULTLIB /MACHINE:iX86 /OUT:MyProject.dll MyProject.res
   ```

Importing Dialogs from Resource .dll Files

Task: ***To import all of the dialog resources from a .dll file:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click **All Dialogs** and click **Import Dialogs from Resource Dlls**. The **Open** dialog box opens.
3. Browse to the .dll file that contains the dialog resources that you want to import.
4. Click **Open**.

InstallShield adds each dialog to your project. Naming conflicts are resolved by adding a number to the imported dialog to make it unique.

If an imported control displays text that is already found as a string entry, InstallShield uses the existing string entry for the control's Text property.

Note • *When you are importing a dialog, ensure that any properties referenced by the dialog are present in the new installation project.*

Adding a dialog to a project does not mean that the dialog will be displayed during the installation run time. For information on inserting the dialog into one or more of the installation's sequences, see Displaying Dialogs During Basic MSI Installations.

Even though dialogs can be exported to an .rc file, you must build the resources into a .dll file before you can import them into InstallShield. For more information, see Exporting All Dialogs to an .rc File.

Exporting Dialogs to Other Projects

InstallShield enables you to insert a dialog from the current project into another existing project by exporting it.

Task: ***To export a dialog to an existing project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog and click **Export to Project File**. The **Export Into** dialog box opens.
3. Browse to the location of an existing .ism file. It can be either an installation project or a merge module project, but the file cannot be open in another instance of InstallShield.
4. Click **Save**.

A copy of this dialog is added to the specified .ism file, along with every control and all of the dialog's behavior. Any string entries, properties, and path variables used in the dialog are also copied to your new project.

If the target .ism file already has a dialog of that name with different properties, the Resolve Conflict dialog box opens to offer you options for resolving the conflicting dialogs.

You can also publish dialogs to a repository and reuse them in other installation projects. For more information, see Using a Repository to Share Project Elements.

Removing Dialogs from Projects

Basic MSI Projects

Task: ***To remove a dialog from a Basic MSI project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog and click **Delete**.

Note • *Right-clicking a dialog in the Custom Actions and Sequences view and clicking Remove does not delete the dialog from your project. It only removes it from that sequence.*

InstallScript and InstallScript MSI Projects

Task: ***To remove a dialog from an InstallScript or InstallScript MSI project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog and click **Delete**.
3. In the View List under **Behavior and Logic**, click **InstallScript**.
4. Delete the script that adds the dialog to your installation's end-user interface.

Creating and Configuring Custom Dialogs

Consider the following tips when you create and configure custom dialogs in different project types.

InstallScript and InstallScript MSI Projects

When you add a new dialog in the Dialogs view, an entry for the dialog is added to the **Dialog** table. You can directly modify data in this table in the Direct Editor.

In the Direct Editor, you can specify a value for the ISResourceId field for the new dialog. This ISResourceId value is used within the script to identify this dialog.

Once you have added the dialog to your project, you need to call functions such as **EzDefineDialog** and **WaitOnDialog** to load this dialog in memory and display it at run time. The corresponding ISResourceId value in the Dialog table is used as the fourth argument of **EzDefineDialog** to reference the custom dialog. Also, in the second argument of **EzDefineDialog**, it is advantageous to specify ISUSER as opposed to a null string. The **EzDefineDialog** function should look like the following:

```
EzDefineDialog("MyCustomDialog", ISUSER, "", 12005)
```

In the above example, 12005 is the ISResourceId of this custom dialog, as specified in the Dialog table.

Custom dialog functions can then be called to manipulate the custom dialog to your needs. These functions are documented in the InstallScript Language Reference.

Basic MSI Project

When you create a custom dialog in the Dialogs view of a Basic MSI project, a Windows Installer–type dialog is created. InstallScript custom dialog functions cannot be used with this Windows Installer–type dialog. To display this dialog in your installation, it must be placed in sequence between two dialogs by using their Next and Back controls.

Undoing Changes in the Dialog Editor

The Dialog Editor remembers up to 50 actions for each dialog and allows you to restore each change starting from the most recent one. Additionally, you can undo changes even after saving the project. However, if you close a project and reopen it, the undo history is purged.

Undoing Changes

Task: ***To undo a change, do any of the following:***

- Press CTRL+Z.
- On the **Edit** menu, click **Undo**.
- Click the **Undo** button on the toolbar.

Redoing Undone Changes

Task: ***To place an undone change back into effect, do one of the following:***

- Press CTRL+Y.
- On the **Edit** menu, click **Redo**.
- Click the **Redo** button on the toolbar.

The Undo and Redo buttons and menu commands are enabled while you are using the Dialog Editor. When you undo an action, you move back through the history of actions you performed on that dialog. When you redo, you move forward.

For example, if you resized a button and then changed its Tab Index property, clicking Undo would restore the previous value of the Tab Index property. Clicking Undo a second time returns the button to its original size. Clicking Redo twice puts the changes back into effect on the button's size and then its tab index.

Note • *You cannot undo changes made to a string entry through the Dialog Editor.*

Working with Dialogs in InstallScript and InstallScript MSI Projects

InstallShield enables you to call specific functions in your script to display end-user dialogs. The Dialogs view contains a list of standard dialogs as well as any custom dialogs that you have added to your project.

This section of the documentation discusses how to create and perform basic functions with dialogs in InstallScript and InstallScript MSI projects.

Displaying Dialogs During InstallScript and InstallScript MSI Installations

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Most of the user interface of an InstallScript or InstallScript MSI installation is defined in event handlers such as **OnFirstUIBefore** and **OnFirstUIAfter**. The following sample InstallScript code in **OnFirstUIBefore** is for the **SdWelcome** and **SdLicense2** dialogs:

```
Dlg_SdWelcome:
    szTitle = "";
    szMsg = "";
    nResult = SdWelcome( szTitle, szMsg );
    if (nResult = BACK) goto Dlg_Start;

Dlg_SdLicense2:
```

```
szTitle = "";
szOpt1 = "";
szOpt2 = "";
szLicenseFile = SUPPORTDIR ^ "License.rtf";
nResult = SdLicense2Ex( szTitle, szOpt1, szOpt2, szLicenseFile, bLicenseAccepted, TRUE );
if (nResult = BACK) then
    goto Dlg_SdWelcome;
else
    bLicenseAccepted = TRUE;
endif;
```

Every dialog function returns a constant indicating which button the end user clicked to exit the dialog. To handle the end user clicking the Back button on a dialog, directly after the dialog is an if statement that compares the dialog's return value to the constant BACK, using a goto statement to jump to a label just before the previous dialog. In the aforementioned code example, if the end user clicks the Back button on the **SdLicense2** dialog, the goto statement jumps to the Dlg_SdWelcome label, and the **SdWelcome** dialog is displayed to the end user. Therefore, if you insert a dialog function between two dialogs such as **SdWelcome** and **SdLicense2**, you need to adjust the if statements, labels, and goto statements as appropriate.

Task: ***To display a dialog to the end user as part of the installation's user interface:***

1. In the View List under **Behavior and Logic**, click **InstallScript**.
2. Add the dialog function to the appropriate script event handler.
3. Modify the dialog function's parameters according to how you want the dialog to behave.

   To learn about the available parameters, refer to the dialog function documentation:

   - Dialog Functions
   - Dialog Customization Functions
4. Use the script to direct the flow of the dialogs—for example, by using if and goto statements.

Changing the Text on Dialogs in InstallScript and InstallScript MSI Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Most dialog functions accept a string argument called szTitle that defines the text appearing in the title area of the dialog. For example, the call to **SdRegisterUser** appears as follows:

```
SdRegisterUser( szTitle, szMsg, szName, szCompany );
```

By default, the parameter szTitle is defined as a null string (""), which indicates that the dialog should use the default title text. For **SdRegisterUser**, the default title appears as shown in the following screen shot.

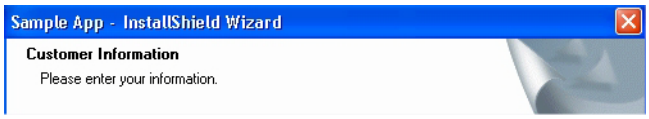

Figure 4-1: Default Title Text for the SdRegisterUser Dialog

To modify the title, you can enter specific strings to display for the `szTitle` parameter. The title is divided into two sections—the bold text at the top of the title area, and the regular text under the main title.

To specify the two sections in the value of `szTitle`, place a newline character `\n` between the two sections.

```
SdRegisterUser ("New Title\nThis is a new subtitle.",
    szMsg, szName, szCompany);
```

After recompiling the script and running the installation, the title is displayed as shown in the following sample screen shot.

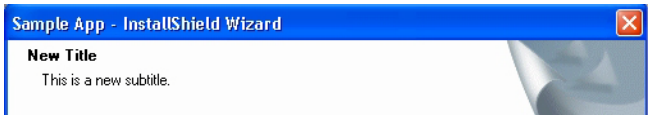

Figure 4-2: Changed Title Text for the SdRegisterUser Dialog

To change other text displayed on a dialog, there are usually one or more parameters (such as `szMsg`) that contain the text to be displayed. As with dialog box titles, a null string in a message parameter indicates that the dialog should use the default message text provided by InstallShield.

If your installation contains more than one UI language, you can use string identifiers instead of hard-coded strings in your InstallScript. For more information, see Using String Entries in InstallShield.

Creating New Custom Dialogs in InstallScript and InstallScript MSI Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

To create a custom dialog, you need to perform the following general steps:

1. Use the New Dialog Wizard to add a new custom dialog to your project. For more information, see Using the New Dialog Wizard to Add a New Custom Dialog to an InstallScript or InstallScript MSI Project.
2. Add controls to the dialog. For more information, see Adding a Control to a Dialog in an InstallScript or InstallScript MSI Project.
3. Create a script function that loads the dialog into memory, displays it on the screen, handles the end user's interaction with the dialog's controls, and closes the dialog when the user is finished with it. For more information, see Using InstallScript to Implement Custom Dialogs.

Using the New Dialog Wizard to Add a New Custom Dialog to an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Task: ***To add a new custom dialog to your project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click **All Dialogs**, and click **New Dialog**. The **New Dialog Wizard** opens.
3. Follow the wizard panels to create the new dialog. In the **Dialog Template** panel, select the **NewScriptBasedDialog** template or the **NewSkinnableDialog** template.

   The NewScriptBasedDialog and NewSkinnableDialog templates include a hidden control that has a Control Identifier value of 2. To enable end users to cancel the installation by clicking the close button in the upper-right corner of the InstallScript dialog, the dialog must have a button control whose Control Identifier property is set to this value. The Blank Dialog template does not include this control. For more information, see Using InstallScript to Implement Custom Dialogs.

Once you have added a new custom dialog to your project, you can add dialog controls.

Editing the Layout of a Dialog in an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

You can use the Dialog Editor to add, remove, and rearrange controls on a selected dialog. You can also use the Dialog Editor to modify the properties of the dialog or its controls. The InstallShield Dialog Editor functions much in the same way as other resource editors.

When you use the Dialog Editor to change the layout or appearance of a dialog, you are changing only the current project's copy of the dialog; the changes do not affect any other projects.

Task: ***To access the Dialog Editor, do one of the following:***

- In the **Dialogs** view, click a dialog and then click **Edit dialog layout** in the dialog preview pane on the right.
- In the **Dialogs** view, right-click a dialog and click **Edit**.

InstallShield displays the Dialog Editor in the center pane.

Note • *When an end user runs your installation on a Windows platform that uses a desktop display theme, the theme is used to display your installation's end-user dialogs.*

Adding a Control to a Dialog in an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

You can use the Controls toolbar in InstallShield to add controls to a dialog.

Task: ***To add a control to a dialog:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **All Dialogs** folder, and then expand the dialog item that should have the new dialog control.
3. Click a language under the dialog item that you expanded. The Dialog Editor in the center pane shows the dialog in the selected language.
4. In the **Controls** toolbar, click the control that you want to add.
5. Draw a rectangle on the dialog in the location where you want the control to be displayed.
6. In the right pane, set the control's properties.

After adding the control in the Dialog Editor, you need to use InstallScript to process the end user's interaction with the control. To learn more, see Using InstallScript to Process Dialog Controls.

Note • *For projects created in Microsoft Visual Studio, you can use the Toolbox to add dialog controls.*

Setting a Control's Properties

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The dialog itself and every control on it has a property sheet in the Dialog Editor. These properties determine such things as a control's size and position, its default text (as a string identifier), or whether the dialog is modal.

To edit one of the property sheets, select the control on the dialog, or select a control's or dialog's name from the box above the property sheet. The properties vary depending on the type of control:

- Dialog
- Check Box
- Push Button
- Edit Field
- Combo Box
- Text Area
- List Box
- Radio Button
- Bitmap
- Group Box
- Line
- Radio Button Group
- Selection Tree
- Progress Bar
- List View
- Icon

Displaying Controls on Top of a Bitmap

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

When you are setting the properties of a bitmap and other dialog controls, you can indicate that the controls should be placed on top of the bitmap.

Task: ***To display controls on top of a bitmap:***

- The value for the **Tab Index** property of the bitmap must be lower than the value for the **Tab Index** property of any controls that are to be placed on top of the bitmap. The easiest way to configure this is to set the bitmap control's **Tab Index** property to 0.

- All controls—including the bitmap—must have their **Tab Stop** properties set to **True**.

Using InstallScript to Implement Custom Dialogs

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The next step in creating a custom dialog is to write an InstallScript function that processes the end user's interaction with the dialog controls.

Task: ***To use InstallScript to implement a custom dialog in an InstallScript project:***

1. Begin by creating a new InstallScript source file to contain the custom dialog code. Name the file `CustomDialog.rul`.

   

   Tip • *To be able to use the dialog script in other projects, copy the .rul file to another location. In your other projects, open the* ***InstallScript*** *view, right-click the* ***Files*** *item in the* ***InstallScript*** *explorer, and click* ***Insert Script Files****.*

2. Inside `CustomDialog.rul`, place the prototype and implementation for your custom dialog function. Add the following code to `CustomDialog.rul`.

   ```
   prototype NUMBER CustomDialog( );
   function NUMBER CustomDialog( )
   begin
   end;
   ```

3. When you compile your script, indicate that the main script `Setup.rul` should include the code for your CustomDialog function by inserting the following line near the top of `Setup.rul`:

   ```
   #include "CustomDialog.rul"
   ```

4. In the `CustomDialog.rul` script, define the constants that store the numeric IDs of the controls that you added to the dialog. If you copied the Back, Next, and Cancel buttons from a standard dialog, you can add the following lines near the top of `CustomDialog.rul`:

   ```
   // control identifiers
   #define BUTTON_NEXT    1
   #define BUTTON_BACK   12
   ```

   In general, the numeric ID of a control on a dialog is the number listed in the control's Control Identifier property, displayed in the property list when you select the control in the Dialog Editor.

Important • *To enable end users to cancel the installation by clicking the close button in the upper-right corner of the InstallScript dialog, the dialog must have a button control with a value of 2 for the Control Identifier property. You can place this button anywhere on the dialog, and if necessary, you can make this button invisible. This is necessary because the InstallScript engine passes the WM_CLOSE message to the script only if it comes from a valid control in the dialog. If the dialog does not have a button with this identifier, the installation does not pass through the message that is generated when the dialog's close button is clicked.*

You need to define additional constants for every other control (for example, check box, edit field, or list box) with which the end user can interact.

5. Your CustomDialog function loads the custom dialog into memory using the **EzDefineDialog** function:

```
EzDefineDialog(
  "CustomDialog", // nickname for dialog
  ISUSER,         // DLL containing the dialog's resources
  "CustomDialog", // name of dialog in Dialogs view
  0);             // numeric resource ID for dialog; not used here
```

To learn which arguments you use with **EzDefineDialog**, see EzDefineDialog.

Tip • *The resource ID of a dialog is the dialog's name, as it appears in the Dialog Editor. If you need to specify a numeric resource ID, you can add a numeric ID to the* ***ISResourceId*** *column in the Dialog table for the custom dialog. You can access the Dialog table in the Direct Editor.*

6. Create a message loop in your script for the custom dialog. The message loop repeatedly calls the function **WaitOnDialog**, which returns the numeric control ID for the control with which user interacts with. A typical message loop appears as follows.

```
// repeatedly call WaitOnDialog until the user exits the dialog
// with the Next, Back, or Cancel button
while (!bDone)

// wait for the user to interact with a control,
// then return its ID
nCtrl = WaitOnDialog("CustomDialog");

// use a switch statement to handle the different controls
switch (nCtrl)

    case CONTROL1:
        // do something when user clicks CONTROL1

    case CONTROL2:
        // do something when user clicks CONTROL2

    // case statements for other controls

endswitch;

endwhile;
```

For example, CustomDialog currently contains **Next**, **Back**, and **Cancel** buttons. Its message loop might appear as follows:

```
while (!bDone)

nControl = WaitOnDialog("CustomDialog");

switch (nControl)

    case DLG_INIT:
        // Initialize the back, next, and cancel button enable/disable
        // states for this dialog and replace %P, %VS, %VI with
        // IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and
        // IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
        hwndDlg = CmdGetHwndDlg("CustomDialog");
        SdGeneralInit("CustomDialog", hwndDlg, 0, "");

    case BUTTON_BACK:
        // user clicked Back
        nReturn = BUTTON_BACK;
        bDone = TRUE;

    case BUTTON_NEXT:
        // user clicked Next
        nReturn = BUTTON_NEXT;
        bDone = TRUE;

    default:
        // check standard control handling
        if (SdIsStdButton(nControl) && SdDoStdButton(nControl)) then
            bDone = TRUE;
        endif;

endswitch;

endwhile;
```

7. When the end user exits the dialog by clicking **Back** or **Next**, you should remove the dialog from the screen and from memory using **EndDialog** and **ReleaseDialog**:

```
EndDialog("CustomDialog");
ReleaseDialog("CustomDialog");
```

To use the dialog in the main script, add a call to the CustomDialog function in, for example, the **OnFirstUIBefore** event handler of Setup.rul.

```
Dlg_SdWelcome:
    szTitle = "";
    szMsg   = "";
    nResult = SdWelcome(szTitle, szMsg);

Dlg_CustomDlg:
    nResult = CustomDialog( );
    if (nResult = BUTTON_BACK) goto Dlg_SdWelcome;

// etc.
```

If the end user clicks **Back** or **Next**, the script displays the previous or following dialog. If the user clicks **Cancel**, the standard confirmation dialog (handled by the **OnCanceling** event handler) is displayed.

Note • *For information on implementing dialog control functionality, see Using InstallScript to Process Dialog Controls.*

Special Messages

In addition to returning control identifiers, the **WaitOnDialog** function returns some special messages.

- Immediately before the dialog is displayed on the screen, **WaitOnDialog** returns the message constant DLG_INIT. In the DLG_INIT case statement, you can set the default states of check boxes and radio buttons, populate and set the current selection in a list box or combo box control, or set the initial text of an edit field.
- If an error occurs, **WaitOnDialog** returns the constant DLG_ERR.

Using InstallScript to Process Dialog Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

In InstallScript and InstallScript MSI installation projects, you use InstallScript to process the controls that you add to your custom dialogs.

Using Check Box Controls

In addition to handling button clicks, a custom dialog generally needs to be able to retrieve the end user's selections in dialog controls such as check boxes.

Note • *InstallShield has a standard dialog called AskOptions. This dialog displays up to nine check boxes or radio buttons, and therefore it is not necessary to create a custom dialog to display only check boxes to the end user.*

As with push buttons, for each check box control that you add to a dialog, you generally add a #define statement to your script that assigns a symbolic name to the numeric control ID. For example, if you add a check box control to a custom dialog, the control's numeric ID will appear in the Control Identifier property of the control. If the numeric ID is 1302, you would add the following line to your script.

```
#define MYCHECKBOX1 1302
```

For most types of controls, InstallScript defines **CtrlGet** and **CtrlSet** functions with which you can get or set the current state or data for a control. For example, you can get and set the current state of a check box control using **CtrlGetState** and **CtrlSetState**. In the DLG_INIT case of your dialog's message loop, you can call **CtrlSetState** to set the initial selection state of the check box. The following code causes the check box to appear initially selected.

```
case DLG_INIT:
    // Initialize the back, next, and cancel button enable/disable states for this dialog
    // and replace %P, %VS, %VI with IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION,
    // and IFX_INSTALLED_DISPLAY_VERSION, respectively, on control IDs 700-724 and 202.
    hwndDlg = CmdGetHwndDlg("CustomDialog");
    SdGeneralInit("CustomDialog", hwndDlg, 0, "");
    CtrlSetState("CustomDialog", MYCHECKBOX1, BUTTON_CHECKED);
```

Similarly, you can add the following code outside the dialog's message loop to detect the final selection state of the check box.

```
nState = CtrlGetState("CustomDialog", MYCHECKBOX1);
if (nState = BUTTON_CHECKED) then
    // check box selected
else
    // check box unselected
endif;
```

Using Edit Fields

You can also add edit controls to a custom dialog, which allow the end user to enter a single line of text. InstallShield has standard dialogs called **SdShowDlgEdit1**, **SdShowDlgEdit2**, and **SdShowDlgEdit3**, which display one, two, or three edit fields in which the end user can enter text.

You can read the text stored in an Edit control with **CtrlGetText**. For example, to read the text from an Edit control with resource ID 10000 into a string variable called svEdit, you can use the following code:

```
CtrlGetText("CustomDialog", 10000, svEdit);
```

Similarly, you can set the initial text stored in an Edit control (in the DLG_INIT block of the message-loop's switch statement) with **CtrlSetText**.

Tip • *You can use the **Password** attribute of an edit control to hide the characters that the end user types into the edit field. You can use the **Number** attribute to allow the end user to enter only numbers in the edit field.*

Using List Box and Combo Box Controls

List box and combo box controls need to be associated with a variable of type LIST. Before displaying the list box control, you should populate a string-list variable, and associate it with the list box or combo box control using **CtrlSetList** in the dialog's DLG_INIT handler. (For a combo box control, you will usually set the Drop-Down List property to True, and set the Height property to the height of the drop-down-list portion of the control.)

To set the initial selection in a list box or combo box control, you can call **CtrlSetCurSel** in the dialog's DLG_INIT handler; and to retrieve the user's current selection call **CtrlGetCurSel**. For example, the following code populates a list variable with the drive letters of every available drive (using GetValidDrivesList), associates the list with a combo-box control, and then reads the end user's selection from the combo box before exiting the dialog.

```
function NUMBER CustomDialog( )
  NUMBER nReturn;
  NUMBER nControl;
BOOL bDone;
       // variables for combo box list and current selection
  LIST listDrives;
```

```
  STRING svDrive;
begin
    nReturn = EzDefineDialog("CustomDialog", ISUSER, "CustomDialog", 0);

    bDone = FALSE;

    // create the list containing the combo box items
    listDrives = ListCreate(STRINGLIST);
    // fill the list with all available drive letters
    GetValidDrivesList(listDrives, -1, -1);

    while (!bDone)

    nControl = WaitOnDialog("CustomDialog");

    switch (nControl)

        case DLG_INIT:
            // Initialize the back, next, and cancel button enable/disable states
            // for this dialog and replace %P, %VS, %VI with IFX_PRODUCT_DISPLAY_NAME,
            // IFX_PRODUCT_DISPLAY_VERSION, and IFX_INSTALLED_DISPLAY_VERSION,
            // respectively, on control IDs 700-724 and 202.
            hwndDlg = CmdGetHwndDlg("CustomDialog");
            SdGeneralInit("CustomDialog", hwndDlg, 0, "");
            CtrlSetState("CustomDialog", MYCHECKBOX1, BUTTON_CHECKED);
            // associate the list with the combo box
            CtrlSetList("CustomDialog", MYCOMBOBOX1, listDrives);
            // get the first drive letter from the list...
            ListGetFirstString(listDrives, svDrive);
            // ...and make it the current selection
            CtrlSetCurSel("CustomDialog", MYCOMBOBOX1, svDrive);
        // ...cases for other controls...

    endswitch;

    endwhile;

    // get the end user's selection, and display it in a message box
    CtrlGetCurSel("CustomDialog", MYCOMBOBOX1, svDrive);
    MessageBox("You selected drive " + svDrive, INFORMATION);

    EndDialog("CustomDialog");
    ReleaseDialog("CustomDialog");

    return nReturn;
end;
```

List box and combo box controls have a Sorted property, which you can set to Yes to sort the contents of the list controls by the items' display names.

Editing Dialog Behavior in an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

To change the behavior of a dialog, you can modify the dialog function's parameters according to how you want the dialog to behave. To learn about the available parameters, refer to the dialog function documentation:

- Dialog Functions
- Dialog Customization Functions

Adding a Field That Contains a Product Name, Product Version, or Installed Version in Sd Dialog Static Text Fields

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

InstallShield enables you to place your product name, product version, or installed version globally in Sd dialog static text fields containing the placeholder %P, %VS, or %VI (sometimes appearing as an extra space). At run time, the values of the system variables IFX_PRODUCT_DISPLAY_NAME, IFX_PRODUCT_DISPLAY_VERSION, and IFX_INSTALLED_DISPLAY_VERSION are displayed in place of %P, %VS, and %VI in the static text fields.

If you are adding a static text field containing a placeholder, give the static text field a unique (to that dialog) ID in the range of 701 through 799. IDs in the 701 through 799 range instruct InstallShield to scan the static text field for the existence of the placeholders. If a placeholder is found, InstallShield replaces it with the value of the corresponding system variable.

Using an HTML Control on a Dialog

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

InstallShield includes support for HTML controls on dialogs in InstallScript and InstallScript MSI projects. HTML controls enable you to use HTML markup for dialog controls. You can include on dialogs links to Web pages, installed HTML files, and HTML support files. If an end user clicks the hyperlink on the run-time dialog, you can have the HTML page open in an Internet browser, or you can trigger other behavior that you have defined through your InstallScript code. The HTML control lets you use any valid HTML markup, including styles to control their appearance.

The HTML control also lets you display the HTML content directly on a dialog if the content is an installed HTML file or HTML support file.

To create an HTML control, you need to start with a static text control. Once you have placed the static text control on a dialog, you can convert it to be an HTML control.

Task: ***To convert any static text control on a dialog to be an HTML control, do one of the following:***

- In the Dialogs view, set the Text property of the control as follows:

  `[html]` ***`HTML Markup`***

- Use InstallScript to set the text of a control to be `[html]`, followed by the HTML markup.

At run time, the InstallScript engine converts the control to an HTML control.

Example

The following example demonstrates how to convert a static text control to an HTML control. The sample HTML code enables you to set the colors and fonts of the control so that they match those of the dialog.

Task: ***To convert a static text control to an HTML control by using the control's Text property:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click the dialog that you want to contain the HTML control, and then click **Edit**. InstallShield displays the dialog in the Dialog Editor, using the project's default language.
3. Click the static text control that you want to convert to an HTML control. InstallShield displays its properties in the right pane.
4. In the **Text** property, click the ellipsis button (**...**). InstallShield displays a list of all of the current strings in the project.
5. Click the **Edit** button.
6. Set the value of the string identifier as follows:

```
[html]<style type="text/css">html,body {padding:0; margin:0; background-color:ButtonFace} *
{font-size: 8pt; font-family: "MS Sans Serif";} </style> <a href="http://
www.MyWebSite.com">Visit my Web site</a>
```

At run time, the installation uses the default InstallScript dialog font (8 point MS Sans Serif) and sets the background color to the Windows dialog color, which is usually gray. If the content is on a dialog area that is white, you can omit the *background-color:ButtonFace* style part so that the background of the HTML control becomes white.

Tip *• As an alternative to converting the static control through the Dialogs view, you could edit the dialog's script function in the InstallScript view. For example, add the following code to the DLG_INIT case in the dialog message loop:*

```
CtrlSetText( szDlg, HTML_CTRL_ID, "[html]<style type=\"text/css\">html,body {padding:0; margin:0;
background-color:ButtonFace} * {font-size: 8pt; font-family: "MS Sans Serif";} </style><a
href=\"http://www.MyWebSite.com\">Visit my Web site</a>" );
```

For sample script, see CtrlGetUrlForLinkClicked Example.

Handling Click Events for Links in HTML Controls

If you use the **CtrlSetText** function to set HTML control content at run time and the control creation succeeds, **CtrlSetText** returns 0. If it fails, **CtrlSetText** returns ISERR_GEN_FAILURE.

To handle click events for links in HTML controls, the **WaitOnDialog** function returns the control ID of the HTML control (which is also the control ID of the original static text control). A custom dialog script function can contain a case statement that handles the HTML control ID, and then calls the **CtrlGetUrlForLinkClicked** function to obtain the URL for the link that was clicked. With this link, the script can take any action (such as launching an Internet browser to navigate to the link).

The following behavior occurs when an end user clicks a link for an HTML control that uses the anchor tag:

- If the anchor tag does not include the target attribute, or if the target value does not result in a new window, the control ID is returned to the dialog script. This allows for the script to handle link clicks itself.
- If the anchor tag does include the target attribute and its value is _blank or some other equivalent value that results in a new window, no message is sent to the script, and the URL is automatically launched.

Special Considerations for HTML Controls

If you are adding HTML controls to dialogs, note the following details.

Run-Time Requirements for HTML Controls

The HTML control requires Internet Explorer 5.5 or later for full functionality. If an earlier version is present on a target system, the only way to set the content for the HTML control is to provide an HTML file to **CtrlSetText**. Note that Internet Explorer does not need to be the default browser on the target system.

HTML Control Support for HTML Files

If you using an HTML file with an HTML control, you must specify the full path to the file through the **CtrlSetText** function. Otherwise, the InstallScript engine will not know where the file is located. Following is sample InstallScript:

```
CtrlSetText(szDlg, HTML_CTRL_ID, "[html]file://" + SUPPORTDIR^"aboutpage.htm");
```

Using an HTML Control for an Email Address

If you want to add a hyperlink that points to an email address, you can use code such as the following:

```
CtrlSetText(szDlg, HTML_CTRL_ID, "[html]<a
href=\"mailto:support@mycompany.com?Subject=Example%20Line\">Send email to Support</a>");
```

When an end user clicks such a link, a new email message is automatically opened in the target system's email application. Note that with the mailto link, no message is sent to the script.

HTML Text Content Is Not Formatted

Any content set in an HTML control is passed as is. No formatting of the content is performed. If you need to format any of the content, you can manipulate the content string in script and then pass the content string to **CtrlSetText**.

Character Count Limits for the Text Property of Static Text Controls

The Text property of static text controls has a maximum limit of 256 characters. Therefore, if you convert a static text control to an HTML control by adding `[html]` to the beginning of the text content for a control, the maximum number of characters that you can enter is 256; this includes the hyperlinked text as well as all characters for any HTML markup that you specify. If you need to enter more than 256 characters for the content, use the **CtrlSetText** function to create the control.

Reverting to the Default Dialog

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

If you have edited a dialog and you later decide that you want to undo all of your changes, you can revert back to the original default dialog.

Task: ***To revert to the default dialog:***

1. In the View List under **User Interface**, click **Dialogs**.
2. Right-click the edited dialog and click **Revert**.

Resource Compiler and Resource Linker

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

To modify dialogs in InstallScript or InstallScript MSI projects, you must have a resource compiler and resource linker installed on your system. InstallShield includes both of these types of tools.

Task: ***To view the location of the compiler and linker:***

1. On the **Tools** menu, click **Options**. The **Options** dialog box opens.
2. Click the **Resource** tab.

The Resource tab lists the locations of the compiler and linker.

Task: ***To replace the resource compiler or resource linker with one that is already on your system:***

1. On the **Tools** menu, click **Options**. The **Options** dialog box opens.
2. Click the **Resources** tab.
3. Click the Browse button next to the **Resource compiler location** box or the **Resource linker location** box to navigate to the program file.

Dialog Sampler

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The Dialog Sampler is an InstallShield wizard that displays samples of all built-in dialogs as well as dialogs called by script dialog (sd) functions in InstallScript and InstallScript MSI projects. You can launch two different varieties of the Dialog Sampler.

Task: ***To launch the Dialog Sampler:***

On the **Tools** menu, point to **InstallScript**, and then click either **Standard Dialog Sampler** or **Skinned Dialog Sampler**.

You can also launch these samplers using the shortcut in the InstallShield program folder on the Programs menu.

Dialog Skins

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Overview

Dialog skins enable you to display end-user dialogs with a different look and color scheme. Skinned dialogs are slightly larger than standard dialogs, and the controls are located differently. For skinned dialogs to display properly, the desktop area on the target machine must be at least 800 by 600 pixels (or if large fonts are used, 1024 by 768 pixels), and the system must display at least 16-bit color.

Limitations

There are limitations when using dialog skins in your project:

- A dialog skin cannot be applied to or removed from a standard dialog once you have edited that dialog in the Dialog Editor. Therefore, if you want to specify skins for dialogs that you want to modify, specify the skin first, and then edit it.
- The location of the standard navigation buttons (Next, Cancel, Back, Finish) are the same for all skins. The .skin file controls their position. Moving them in the Dialog Editor has no effect on the run-time positioning. There are also some Browse buttons on a few dialogs (for example, **SdAskDestPath**) that cannot be repositioned.
- Skinned dialogs cannot use windowed billboards. To learn more about the windowed style of billboard, see Billboard Styles and File Types for InstallScript and InstallScript MSI Projects.
- If you add custom dialogs to your project, the new dialogs should be the same size as the other end-user dialogs. If the custom dialogs are a different size, they may not be displayed correctly; for example, the navigation buttons might not be visible to the end user during run time, due to the positioning issue described above.

***Note** • If you want to specify a dialog skin for a custom dialog, you must set the skin before creating the custom dialog in the Dialog Editor in order for the skin to appear properly.*

Specifying Dialog Skins

***Project** • This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

You can use a dialog skin to change the look of the end-user dialogs in your installation. You can specify one skin per installation project. All of the dialogs in your project are displayed using the selected skin.

***Note** • A dialog skin cannot be applied to or removed from a standard dialog once you have edited that dialog in the Dialog Editor. Therefore, if you want to specify skins for dialogs that you want to modify, specify the skin first, and then edit it.*

If you want to specify a dialog skin for a custom dialog, you must set the skin before creating the custom dialog in the Dialog Editor in order for the skin to appear properly.

Selecting a Dialog Skin

Task: ***To select a dialog skin:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **Skins** item to see the available dialog skin options.
3. Click a skin to see a preview dialog displayed in the right pane.
4. To select a displayed skin, click **Select** in the preview pane. A red check mark appears on the selected skin's icon in the **Dialogs** explorer.

All of the dialog skins use .gif files for the fade graphic, with the exception of the Blue skin. The Blue skin uses a .bmp file, which results in a larger file size. The Blue skin's appearance on a 16-bit color system is not as clean as the other colors when a .gif file is used. If you want to use a Blue skin that supports 16-bit color systems and file size is not an issue, select the Blue option. For a smaller file size, select the BlueTC (True Color) option, which uses a .gif file for the graphic.

Clearing Dialog Skin Selections

Task: ***To clear the dialog skin selection:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **Skins** item to see the available dialog skin options, and select the **<None>** item.
3. Click **Select** in the preview panel.

Working with Dialogs in Basic MSI Projects

The information in this section of the documentation explains how to create and perform other basic functions with dialogs in Basic MSI projects.

Task: ***The process of creating a new dialog and displaying it in your installation can be broken down into the following tasks:***

1. Add the dialog to the project.
2. Edit the dialog's layout.
3. Define the controls' behavior (under what conditions they should be displayed, the events that their interaction should trigger, and the events that they should subscribe to).
4. Display the dialog with a NewDialog or SpawnDialog event in another dialog's control or by inserting the dialog into your project's sequences.

Displaying Dialogs During Basic MSI Installations

You can display an end-user dialog in one of two ways, as described below:

- Insert the dialog into a User Interface sequence.
- Launch the dialog through another dialog's behavior.

Inserting Dialogs into Sequences

Project • *When you create a dialog in a merge module, you cannot insert it into a sequence until you associate that module with an installation project.*

Task: ***To schedule a dialog in a sequence:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. In the **Sequences** explorer, expand one of the two high-level sequences in which dialogs are usually displayed—**Installation**, **Advertisement**, or **Administration**—to view its **User Interface** sequence.
3. Expand the **User Interface** sequence to see how the existing actions, dialogs, and custom actions are ordered.
4. Right-click the existing action or dialog that you want your dialog to follow in the sequence, and then click **Insert**. The Insert Action dialog box opens.
5. In the list, select **Dialogs**.
6. Select your new dialog from the list of dialogs.
7. Click **OK**.

When your installation runs with a full user interface (determined by the `/q` command-line parameter) and all conditions are met for this dialog, it will be displayed within the selected sequences.

While InstallShield lets you insert a dialog into an Execute sequence, doing so violates ICE13.

Launching a Dialog Through Another Dialog's Behavior

Most dialogs are displayed as a result of the NewDialog (displays another dialog in the wizard) or SpawnDialog (shows a modal dialog) control event. By selecting this event in a dialog's behavior, usually for a Next button, you can specify the dialog that succeeds it. By adding a condition to the control event, you could present different dialogs depending on the result of a selection in the preceding dialog.

Task: ***For example, to display a WelcomeBitmap dialog after the InstallWelcome dialog:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, click the **InstallWelcome** dialog.

3. Click the **Edit dialog behavior** link in the pane to the right.
4. In the **Behavior Editor**, select the **Next** button in the control list.
5. Click the **Events** tab to view and edit the Next button's control events.
6. Click the **Event** field, and then in the list click `NewDialog`.
7. Type `WelcomeBitmap` as the argument.
8. Type `1` for the condition to indicate that the dialog should be created under any circumstance.

Note • *If the InstallWelcome dialog had launched a different dialog from the Next button, you would repeat the above procedure for the WelcomeBitmap's Next button to show the next dialog.*

To learn about viewing your new dialog in the Custom Actions and Sequences view, see Viewing End-User Dialog Order in the Custom Actions and Sequences view (Basic MSI Projects).

Using Control Events in Basic MSI Dialogs

Control events allow you to provide custom functionality for each control on your dialogs. With control events, you can launch custom actions, spawn new dialogs, or display a progress bar. Many control events make use of published information. In some cases, your controls must subscribe to control-event information in order to make use of it.

Below is a comprehensive list of the control events supported by the Windows Installer service. To make use of a control event, navigate to a dialog's Behavior view. See Editing Dialog Behavior in Basic MSI Projects for more information.

Table 4-3 • Dialog Control Events Supported by Windows Installer

Event	Argument	Condition
[PropertyName]	Property value	Sets the value of the Windows Installer property called PropertyName to the value specified in the Argument field. To undefine a property, enter {} in the Argument field.
ActionData	None	Publishes data associated with the current action. A text control can subscribe to this event to display information such as the names of files being copied during the installation. For more information, see Using Action Text.

Table 4-3 • Dialog Control Events Supported by Windows Installer (cont.)

Event	Argument	Condition
ActionText	None	Publishes a description about an action. A text control can subscribe to this event to display a description of the current action that is being performed during the installation. For more information, see Using Action Text.
AddLocal	String specifying the name of a feature or ALL to specify all features.	Sets the specified feature to be run locally.
AddSource	String specifying the name of a feature or ALL to specify all features.	Sets the specified feature to be run from the source medium.
CheckExistingTargetPath	Name of the property that contains the path. You can either select this property from the list or enter the name manually. If the property is indirect, square brackets are required.	Verifies that the specified path can be written to. If the path is not writable, the installer automatically blocks any other control events associated with the current control.
CheckTargetPath	Property name containing the desired path.	Causes the installer to verify the specified path. If the path is not writable, the installer automatically blocks any other control events associated with the current control.
DirectoryListNew	None	Notifies the DirectoryList control that a new folder must be created. The installer then creates a new folder and allows the user to enter a new name for the folder.
DirectoryListOpen	None	Selects and highlights the directory the user selected in the DirectoryList control.
DirectoryListUp	None	Causes the DirectoryList control to navigate to the parent directory of the present directory.

Table 4-3 • Dialog Control Events Supported by Windows Installer (cont.)

Event	Argument	Condition
DoAction	String name of the custom action you would like to call. The Argument property contains a list of all the custom actions in your project.	Causes a custom action to launch when the selected control is activated.
EnableRollback	Boolean: True enables rollback, False disables it.	Used to turn rollback capabilities off and on.

Table 4-3 • Dialog Control Events Supported by Windows Installer (cont.)

Event	Argument	Condition
EndDialog	For standard dialogs: • **Exit**—The dialog sequence closes and control is returned to the installer with the UserExit value. This option cannot be used with child windows. • **Retry**—The dialog sequence closes and control is returned to the installer with the Suspend value. This option cannot be used with child windows. • **Ignore**—The dialog sequence closes and control is returned to the installer with the Finished value. This option cannot be used with child windows. • **Return**—The dialog exits and control is returned to the parent window. If no parent exists, control is returned to the installer with the Success value. For error dialogs: • ErrorOk • ErrorCancel • ErrorAbort • ErrorRetry • ErrorIgnore • ErrorYes • ErrorNo	Closes a dialog sequence or dialog.
IgnoreChange	None	Published by the DirectoryList control when a folder is highlighted but not opened.

Table 4-3 • Dialog Control Events Supported by Windows Installer (cont.)

Event	Argument	Condition
NewDialog	String name of the dialog you would like to launch. The Argument property contains a list of all dialogs associated with your installation. You can choose one of these dialogs, or type in the name of a yet-to-be-created dialog.	Closes the current dialog and opens the dialog specified in the Argument property.
Reinstall	String specifying the name of a feature or ALL to specify all features.	Forces the installer to reinstall the specified feature or features.
Remove	String specifying the name of a feature or ALL to specify all features.	The installer is notified of features marked for removal. The current dialog is still displayed.
Reset	None	Resets all controls on the dialog to their original state.
ScriptInProgress	None	Displays a string while execution script is compiled.
SelectionAction	None	Causes the SelectionTree control to publish a string describing the currently selected item. A text control can be used to display this description.
SelectionBrowse	Name of dialog to be spawned. The Argument property contains a list of all dialogs associated with your installation. You can choose one of these dialogs, or type in the name of a yet-to-be-created dialog.	Causes the current dialog to close and opens the dialog specified in the Argument property. This information is published by the SelectionTree control.
SelectionDescription	None	Allows you to display a feature's description in a text control. This information is published by the SelectionTree control.

Table 4-3 • Dialog Control Events Supported by Windows Installer (cont.)

Event	Argument	Condition
SelectionIcon	None	Allows you to display the icon associated with the current selection in a SelectionTree control. The SelectionTree control publishes the handle to this icon, which can be used by an Icon control to display the icon.
SelectionNoItems	None	Used by SelectionTree to remove unneeded text or disable buttons.
SelectionPath	None	This control event, which is published by the SelectionTree control, can be used to display the path of the currently selected item. A text control can be used to display this path.
SelectionPathOn	None	This Boolean is published by SelectionTree indicating the existence of a SelectionPath for the currently selected item.
SelectionSize	None	Published by a SelectionTree control to pass the size of the currently selected item. If the currently selected item is a parent, then the number of children are also published. A text control can be used to display this information.
SetInstallLevel	Integer value of the desired INSTALLLEVEL.	Installer changes installation level to specified value. By setting the **INSTALLLEVEL** property, you can create setup types. For more information, see Configuring a Feature's Install Level Setting.
SetProgress	None	Published by installer to provide installation progress. The most common application of this control event is to display a progress bar detailing the progress of the installation.

Table 4-3 • Dialog Control Events Supported by Windows Installer (cont.)

Event	Argument	Condition
SetTargetPath	Property name containing the desired path.	Causes the installer to set and check the selected path. If the path is not writable, the installer stops further control events associated with the current control.
SpawnDialog	String name of the dialog that you would like to spawn. The Argument property contains a list of all dialogs associated with your installation. You can choose one of these dialogs, or type in the name of a yet-to-be-created dialog.	Launches the dialog specified in the Argument property as a modal dialog, without closing the current dialog.
SpawnWaitDialog	String name of the dialog you would like to display. The Argument property contains a list of all dialogs associated with your installation. You can choose one of these dialogs, or type in the name of a yet-to-be-created dialog.	Launches the dialog specified in the Argument property.
TimeRemaining	None	The amount of time remaining in the installation is published by the installer. A text control can be used to display this information.
ValidateProductID	None	Sets the ProductID property to the full Product ID. If the Product ID validation fails, the installer displays an error message.

Subscriptions

The Windows Installer service provides volumes of information to the installation during the run time. One of the most useful ways to gather information during installation is to use subscriptions. To subscribe to something is commonly defined as entering one's name for a publication or service. In Windows Installer terms, actions generally publish information, and dialog controls generally subscribe to information.

Progress Bars

The best example of this relationship centers around progress bars. The InstallFiles action publishes information on the percentage of files moved and the percentage remaining to be moved. When a progress bar subscribes to this information, it is able to accurately display the progress of the installation's file transfer process.

The Windows Installer service tracks progress through what are called *ticks*. When your progress bar subscribes to this information, it is passed the **ticksSoFar** and **totalTicks** values. The progress bar uses this information to display the total progress of the installation.

Other Uses

Subscriptions are not used only for progress bars. You might have a custom action that validates a serial number as part of your installation. This action could publish the failure or success of validation. On a dialog, you could have a Next button that subscribes to this information. If the action publishes the failure of the validation, the button remains disabled. If the action publishes success, the button is enabled.

Creating New Dialogs in Basic MSI Projects

Task: ***To create a new dialog in a Basic MSI project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, right-click **All Dialogs** and click **New Dialog**. The Dialog Wizard launches to help you create a new dialog.

The next step is to edit the dialog's layout in the Dialog Editor and the controls' behavior in the Behavior Editor.

Tip • *You can also add a dialog by importing one from another project.*

Displaying a Dialog in the End-User Interface

Adding a dialog to a project does not mean that the dialog will be displayed in the installation. For information on inserting the dialog into one or more of the project's sequences, see Displaying Dialogs During Basic MSI Installations.

Editing Dialog Layout in Basic MSI Projects

Using the Dialog Editor, you can modify a dialog, edit its controls, and set display properties for the dialog and its controls, all in a visual environment.

Note • *When an end user runs your installation on a Windows platform that uses a desktop display theme, the theme is used to display your installation's end-user dialogs.*

The Dialogs view manages versions of the dialog for each of your project's supported languages. You must select a language-specific version in order to edit the layout. These versions remain identical except for changes you make to a control's size. For more information, see Modifying Dialogs for Each Language.

Opening the Dialog Editor

Task: ***To open a dialog in the Dialog Editor, do any of the following:***

- Select the language-specific version of the dialog under the dialog's name in the **Dialogs** view.
- Select the dialog's name in the **Dialogs** view. In the pane to the right under the Action Items heading, select a language from the list and click the **Edit this dialog layout** link.
- In the **Custom Actions and Sequences** view, right-click the dialog and click **Edit layout**.
- In the **Custom Actions and Sequences** view, click the name of the dialog whose behavior you want to modify. Then, click the **Edit dialog layout** link in the **Action Items** section of the right pane. If you have written your installation to run in more than one language, you must select the language you want to edit from the list.

The Dialog Editor opens in the right pane of the Dialogs view. If you need more space, you can move the property sheet so that it is no longer docked inside the editor.

Adding a Control to a Dialog in a Basic MSI Project

You can use the Controls toolbar in InstallShield to add controls to a dialog.

Task: ***To add a control to a dialog:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **All Dialogs** folder, and then expand the dialog item that should have the new dialog control.
3. Click a language under the dialog item that you expanded. The Dialog Editor in the center pane shows the dialog in the selected language.
4. In the **Controls** toolbar, click the control that you want to add.
5. Draw a rectangle on the dialog in the location where you want the control to be displayed.
6. In the right pane, set the control's properties.

Tip • *For projects created in Microsoft Visual Studio, you can use the Toolbox to add controls.*

Setting the Controls' Properties

The dialog itself and every control on it has a property sheet in the Dialog Editor. These properties determine such things as a control's size and position, its default text (as a string identifier), or whether the dialog is modal.

To edit one of the property sheets, select the control on the dialog, or select a control's or dialog's name from the drop-down box above the property sheet. The properties vary depending on the type of control:

- Bitmap
- Dialog
- Check Box
- Push Button
- Edit Field
- Combo Box
- Text Area
- List Box
- Radio Button
- Bitmap
- Group Box
- Billboard
- Line
- Radio Button Group
- Selection Tree
- Progress Bar
- List View
- Scrollable Text
- Icon
- Directory List
- Directory Combo
- Volume Cost List
- Volume Select Combo
- Masked Edit
- Path Edit

Displaying Controls on Top of a Bitmap

Task: ***To display controls on top of a bitmap:***

- The value for the **Tab Index** property of the bitmap must be lower than the value for the **Tab Index** property of any controls that are to be placed on top of the bitmap. The easiest way to configure this is to set the bitmap control's **Tab Index** property to 0.

- All controls—including the bitmap—must have their **Tab Stop** properties set to **True**.

Editing Dialog Behavior in Basic MSI Projects

Using the Behavior Editor, you can edit how controls will behave at run time.

Task: ***To launch the editor, do any of the following:***

- In the **Dialogs** view, click the name of the dialog whose behavior you want to modify. Then, click the **Edit dialog behavior** link in the **Action Items** section of the right pane.
- Double-click the dialog in the **Dialogs** view to expose its **Behavior** and language-specific items. Click the **Behavior** item.
- In the **Custom Actions and Sequences** view, right-click the dialog and click **Edit behavior**.
- In the **Custom Actions and Sequences** view, click the name of the dialog whose behavior you want to modify. Then, click the **Edit dialog behavior** link in the **Action Items** section of the right pane.

The first thing to do when you use the Behavior Editor is to select a control. All of the properties that you set in the editor apply to the selected control.

A dialog's behavior includes the following three areas:

- Events that an end user interacting with the control will trigger
- Windows Installer events that a control needs to subscribe to
- Conditions under which the control will be displayed

These aspects of a control's behavior correspond to the Events, Subscriptions, and Conditions tabs in the Behavior Editor.

Triggering Control Events in Basic MSI Dialogs

An event is a predefined action that occurs when a user interacts with a control. Events are defined in the Behavior Editor of the Dialogs view. For more information on each of the events available, see Using Control Events in Basic MSI Dialogs.

To view a control's events, select it in the list of control names and then click the **Events** tab.

Examples

The control event below dismisses the present dialog and shows the Welcome dialog only when the product is first installed:

Table 4-4 • Sample Settings for a Control Event that Shows the Welcome Dialog Under Certain Circumstances

Event	Argument	Condition
NewDialog	InstallWelcome	Not Installed

The following event launches an InstallScript custom action every time that the control is clicked:

Table 4-5 • Sample Settings for a Control Event that Launches an InstallScript Custom Action Each Time that the Control Is Clicked

Event	Argument	Condition
DoAction	MyScriptCustomAction	1

Adding New Events to a Dialog Control

Task: ***To add a new event to a dialog control:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, click the **Behavior** item for the dialog that has the control. The controls associated with that dialog are listed in the center pane.
3. Select the control that should have the new event. The events associated with that control are listed in the right pane.
4. Click the last row of the **Event** column. InstallShield displays a list of all of the standard events. Either select an event or enter the name of a Windows Installer property in brackets—for example, `[MyProperty]`.
5. Click the **Argument** column. Many of the events have a corresponding argument list that is populated with likely values. For example, if your event was **NewDialog**, the **Arguments** field will contain a list of all of the dialogs in your project. Select the appropriate argument. If your event was a property name, specify the value you want to assign to the property. Empty curly braces {} give it a null value.
6. Specify any condition that you want to check before the event is triggered. Set the condition to `1` if you want to have the installer trigger the event under any circumstance.

Reordering a Dialog Control's Events

The events launch in the order in which you see them in the Behavior Editor.

Task: ***To move an event:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, click the **Behavior** item for the dialog that has the control. The controls associated with that dialog are listed in the center pane.
3. Select the control that has the event. The events associated with that control are listed in the right pane.
4. To move an event earlier, right-click it and click **Move Up**.

   To move an event later, right-click it and click **Move Down**.

Removing an Event from a Dialog Control

Task: ***To remove an event from a control:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, click the **Behavior** item for the dialog that has the control. The controls associated with that dialog are listed in the center pane.
3. Select the control that has the event. The events associated with that control are listed in the right pane.
4. Right-click anywhere in the event's row and then click **Delete**.

Launching Custom Actions from Dialogs

To launch a custom action from a dialog, use the dialog's DoAction event. Before you can set up a DoAction event, you need to create a custom action.

When you have created a custom action, you can set up a DoAction event in a dialog to launch this action.

Task: ***To do this:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, click the dialog that you want to edit.
3. Place a new push button on this dialog. Provide a name and display text for the push button.
4. Select the Behavior view for this dialog. In this view, you can define what happens when your new button is pushed.
5. In the list of controls, select your new button. The button's events are listed in the right pane.
6. In the **Action** field, select **DoAction**.
7. In the **Argument** field, select the custom action.
8. Add a condition, if necessary.

Build and test your installation to ensure that it works as you planned.

Viewing End-User Dialog Order in the Custom Actions and Sequences view (Basic MSI Projects)

Project • *This information applies to Basic MSI projects. To view the order of your end-user dialogs in an InstallScript project or an InstallScript MSI project, use the InstallScript view to review your script.*

In the Custom Actions and Sequences view, you can view primary and next dialogs in the order in which they appear to the end user during the run time of your installation. Primary dialogs are top-level dialogs that have been inserted into the installation sequence. You can change the order of a primary dialog within the Custom Actions and Sequences view.

Next dialogs are dialogs that are triggered by the action of a previous dialog's Next button control events. Although you can view next dialogs in the Custom Actions and Sequences view, they are not a part of the installation sequence, and you cannot change their order in the Custom Actions and Sequences view. To change the order of a next dialog, you must edit the dialog's behavior in the Behavior editor.

Initial Sequences Explorer

When you first open the Custom Actions and Sequences view, the Sequences explorer lists all primary dialogs and actions in the order in which they will be executed during your installation. Many of the next dialogs have plus signs (+) next to them.

Expanded Sequences Explorer

In addition to viewing the order of primary dialogs that have been inserted into the installation sequence, you can also view next dialog order in the Sequences explorer.

When you click the plus sign (+) next to a primary dialog, the list expands to display the order in which the primary dialog's next dialogs—if any—will appear during the run time. If a particular dialog has more than one Next button control event, all possible next dialogs are displayed under the dialog.

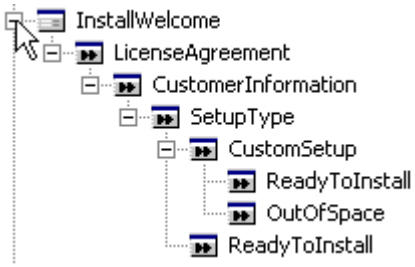

Figure 4-3: Viewing the Order of Dialogs in the Sequence

Next Dialog Information Panel

When you click a next dialog, the right pane displays information about the dialog. The right pane also has hyperlinks to the behavior and layout editors, as well as help information. More detailed information about the selected dialog is available in the Dialogs view.

Context Menu Commands

When you right-click a primary dialog, a context menu displays commands for you to edit the sequence, refresh the dialog sequence view, or edit the dialog's layout or behavior. When you right-click a next dialog, a context menu displays commands for you to edit the dialog's layout or behavior.

Refresh

After you have edited a next dialog's behavior or layout and returned to the Custom Actions and Sequences view, you can select Refresh from the context menu to refresh the dialog sequence view. This option is available only for primary dialogs.

Edit Behavior

Task: ***To move to the Dialog Behavior Editor from within the Sequences explorer in the Custom Actions and Sequences view, do either of the following:***

- Right-click the next dialog that you want to edit and click **Edit Behavior**.
- Click the name of the dialog that you want to edit. Then, in the **Action Items** section of the right pane, click **Edit dialog behavior**.

For more information, see Editing Dialog Behavior in Basic MSI Projects.

Edit Layout

Task: ***To move to the Dialog Layout Editor from within the Sequences explorer in the Custom Actions and Sequences view, do either of the following:***

- Right-click the next dialog that you want to edit and click **Edit Layout**.
- Click the name of the dialog that you want to edit. Then, in the **Action Items** section of the right pane, click **Edit dialog layout**.If you have written your installation in more than one language, you must select the appropriate language in the list.

For more information, see Editing Dialog Layout in Basic MSI Projects.

CustomSetup Dialog Options

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*
- *Transform*

The CustomSetup dialog has a sophisticated end-user interface that is tightly integrated with information about the target system, the features in your installation, and Windows Installer installation options. It provides the end user with the most control over the installation.

Many of the options and information it offers are determined by the feature properties that you set in your setup design, as described below.

Advertisement Option

Feature advertisement enables files to be installed on demand after the installation has initially run. In the CustomSetup dialog, when end users click a feature, they can specify that they want it installed later by selecting the **Will be installed when required** option.

However, that default option is present only if you select Allow Advertise or Favor Advertise for the feature's Advertised setting. To prevent Windows Installer from displaying the option to advertise the feature, select Disallow Advertise for this setting.

Hiding Features

When you set a feature's Display setting to Not Visible, the end user cannot see the feature or its subfeatures in the CustomSetup dialog and therefore cannot change any of its installation options.

Displaying All Subfeatures

The feature's Display setting also governs whether its subfeatures are expanded when the dialog first appears with the following options:

Table 4-6 • Options for the Display Setting of a Feature

Option	Description
Visible and Collapsed	The feature is displayed in the CustomSetup dialog with its subfeatures collapsed by default.
Visible and Expanded	The feature is displayed in the CustomSetup dialog with its subfeatures expanded by default.

Setting Default Destination Folders for Features

An end user can view and edit the folder to which a feature will be installed by selecting the feature in the CustomSetup dialog and clicking the Details button. The feature's Destination setting is the default value that appears, and it is reassigned to a new value if the end user enters or browses to a new path in the resulting Feature Details dialog.

For a complete discussion of the factors that affect where a feature is installed, see Setting a Feature's Destination.

Naming Features

Specify a different name to appear in the CustomSetup dialog by setting its Display Name.

Displaying Feature Descriptions

The description that is shown at the bottom of the CustomSetup dialog when you select a feature is taken from its Description setting.

Changing the Feature Order

You can change the order in which the features appear to the end user in the CustomSetup dialog. The order in which features are displayed is dictated by the order in the Setup Design view. For more information, see Reordering Features.

Requiring Features To Be Installed

If you set a feature's Required setting to Yes, the end user does not see the **Will not be available** option, meaning that the feature must be installed.

Dialog Themes

Project • *Dialog themes are available in Basic MSI projects.*

Dialog themes are predefined sets of images that give your end-user dialogs a unified and distinctive look.

With the click of a button, you can select one of the available themes for your project, and InstallShield applies that theme to all of the interior and exterior dialogs, as well as the `Setup.exe` initialization dialog, in your project. You can easily preview each dialog from within the Dialogs view to see how it looks with the selected theme.

Note • *InstallShield does not currently let you create your own dialog themes. However, InstallShield includes many themes. For more information, see Available Themes and Corresponding Dialog Sizes.*

Run-Time Requirements for the Wide Dialog Themes

Project • *Dialog themes are available in Basic MSI projects.*

If you use one of the wide dialog themes, the screen resolution on target systems must be a minimum of 800×600 pixels (or, if large fonts are used, 1024×768 pixels). If the resolution is lower than that, a horizontal scrollbar is added at run time to the bottom of each of the dialogs that is displayed with the wide theme.

Previewing a Dialog Theme

Project • *Dialog themes are available in Basic MSI projects.*

When you select a different theme for your project, InstallShield applies that theme to all of the interior and exterior dialogs in the Dialogs view. You do not need to build and run your installation in order to view the dialogs.

Task: ***To preview a theme before selecting it for your project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **Themes** folder.
3. Click one of the themes under the **Themes** folder.

In the right pane, InstallShield shows a screen shot of a sample exterior dialog with the selected theme.

Task: ***To preview how a dialog in your project looks with the selected theme:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **All Dialogs** folder, and then expand the dialog item that you want to preview.
3. Click a language under the dialog item that you expanded.

In the center pane, InstallShield displays a preview of the dialog with the selected theme applied.

Selecting or Changing a Dialog Theme

Project • *Dialog themes are available in Basic MSI projects.*

You can use a dialog theme to change the look of the end-user dialogs in your installation. You can select one theme per project.

Tip • *If you switch from one of the wide-style themes to a standard-width theme, the positions of any controls that are placed along the far left or far right sides of the dialog may change.*

If you want to change the theme for your project and you also want to add a custom exterior dialog, change the theme first, and then add the custom exterior dialog. Otherwise, the dialog may not appear properly.

Task: ***To change the dialog theme used for a project:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **Themes** folder.
3. Right-click the theme that you want to use, and then click **Select**.

InstallShield applies the selected theme to the dialogs in your project. In addition, InstallShield displays a red check mark on the selected theme's icon in the Dialogs explorer.

Tip • *You can also change the theme by clicking a button: In the Dialogs explorer, click the theme that you want to use. Then, in the right pane, click the Select button.*

Background Information on How InstallShield Applies Themes

If you switch from one dialog theme to another, InstallShield applies the theme to any dialogs in your project that match a specific width and height. Therefore, if you change the width or height of any of the dialogs in your project, and then you change the theme, InstallShield does not apply the theme to any dialogs that have a custom width or height.

For example, if you switch from a standard width theme to any other theme, InstallShield applies the theme to any dialogs that have a standard width and height: 374×266. If you switch from a wide theme to any other theme, InstallShield applies the theme to any dialogs that are 584×274.

Background Information on Which Dialogs Use the Exterior Dialog Style

By default, InstallShield uses the same style of dialog for all exterior dialogs: this style has an image on the left side of the dialogs. The InstallWelcome and SetupCompleteSuccess dialogs are examples of exterior dialogs.

If you add a custom exterior dialog to your project after you have selected a theme, InstallShield uses the selected theme for the new custom exterior dialog. However, if you later change the theme for your project, the theme may not be displayed properly in your custom exterior dialog. To resolve this type of issue, see Applying a Theme to a Custom Exterior Dialog.

Applying a Theme to a Custom Exterior Dialog

Project • *Dialog themes are available in Basic MSI projects.*

If you want to change the theme for your project and you also want to add a custom exterior dialog, it is easier to change the theme first, and then add the custom exterior dialog. Otherwise, the dialog may not appear properly; parts of newly selected theme's interior dialog images are added to your custom exterior dialog.

If you want to change the theme after you have added a custom exterior dialog to your project, you must add the name of your custom exterior dialog to the appropriate .theme file that is installed in the InstallShield Program Files folder. Then you can apply the theme to your project.

Task: ***To change the theme after you have added a custom exterior dialog to your project:***

1. Close InstallShield.
2. In the InstallShield Program Files folder, find the .theme file for the theme that you want your dialogs to use. The default location is:

   ```
   C:\Program Files\InstallShield\2013\Support\Themes
   ```

3. Open the .theme file in a text editor such as Notepad. For example, if you want to use the Global theme, open the `Global.theme` file.
4. In the **<Include>** and **<Exclude>** sections of the file, add the following line:

   `<Name>NameOfDialog</Name>`

   where *NameOfDialog* represents the name of your dialog.
5. Open your project in InstallShield.
6. In the View List under **User Interface**, click **Dialogs**.
7. In the **Dialogs** explorer, expand the **Themes** folder.
8. Right-click the theme that you want to use, and then click **Select**.

Adding a Logo or Other Image to the Exterior Dialogs

Project • *Dialog themes are available in Basic MSI projects.*

Exterior dialogs are dialogs that are displayed first and last by an installation—typically, the Welcome and Completion dialogs. The exterior dialogs for some themes have places for you to put the logo of your company or product. For example, the exterior dialogs of the Monitor theme and the Circles theme have a blank area on the left side of the dialog; you can add a bitmap control to these dialogs to customize your end-user interface.

Task: ***To add an image to an exterior dialog:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **All Dialogs** folder, and then expand the dialog item for a dialog that should have the image.
3. Click a language under the dialog item that you expanded. The Dialog Editor in the center pane shows the dialog in the selected language.
4. In the **Controls** toolbar, click the **Bitmap** button.
5. In the Dialog Editor, click where you want the bitmap control to start, and holding the left mouse button down, drag the mouse to the place where you want it to end. Then release the left mouse button.
6. Configure the bitmap control's properties in the right pane.

   Click the **File Name** property, and then click the ellipsis button (**...**) to browse to the bitmap file that you want to use.

You may want to repeat the procedure for each language and each exterior dialog in your project. The exterior dialogs that are available by default in all new Basic MSI projects are:

- AdminWelcome
- InstallWelcome

- MaintenanceWelcome
- PatchWelcome
- SetupCompleteError
- SetupCompleteSuccess
- SetupInitialization
- SetupInterrupted
- SetupResume
- SplashBitmap

Available Themes and Corresponding Dialog Sizes

Project • *Some of the themes are available in both the Premier and Professional editions of InstallShield, and some are available in only the Premier edition.*

Some of the themes set the size of the dialogs to a standard width and height: 374×266. The wide themes set the dialog size to 584×274. The following table shows the size of each dialog, plus which editions of InstallShield contain the theme.

Table 4-7 • Dialog Themes in InstallShield

Name	InstallShield Edition	Dialog Width	Dialog Height
Circles Theme (Wide)	Premier and Professional	584	274
Classic Theme	Premier and Professional	374	266
Cooperation Theme (Wide)	Premier	584	274
Filmstrip Theme (Wide)	Premier	584	274
Global Theme	Premier and Professional	374	266
InstallShield Blue Theme	Premier and Professional	374	266
InstallShield Blue Theme (Wide)	Premier and Professional	584	274
InstallShield Silver Theme	Premier	374	266

Table 4-7 • Dialog Themes in InstallShield (cont.)

Name	InstallShield Edition	Dialog Width	Dialog Height
Monitor Theme	Premier	374	266
Pastel Wheat Theme	Premier	374	266
Theater Theme (Wide)	Premier	584	274

Circles Theme (Wide)

Dialog Support for Right-to-Left Languages

Edition • *The Premier edition of InstallShield includes dialog support for languages such as Arabic and Hebrew, which are read from right to left.*

Project • *The following project types include dialog support for right-to-left languages:*

- *Basic MSI*
- *Merge Module*

InstallShield includes support for Arabic (Saudi Arabia) and Hebrew languages, which are written and read from right to left. All of the default end-user dialog strings are available in these languages.

Since these languages are read from right to left, InstallShield also includes support for mirroring Arabic and Hebrew dialogs; that is, InstallShield uses a right-to-left layout for Arabic and Hebrew dialogs. Thus, for example, buttons that are on the right side of dialogs in English and other left-to-right languages are moved to the left side of right-to-left-language dialogs. This occurs in the Dialog Editor pane in the Dialogs view of InstallShield; it also occurs at run time.

Reversed versions of the dialog images are displayed for the built-in dialog themes if appropriate. The reversed versions have *_mirror* in the image file name immediately before the .bmp or .jpg portion of the file name. For example, the name of an image for left-to-right languages might be **banner.jpg**; the name of the right-to-left equivalent for that image would be **banner_mirror.jpg**. These two files would be located in the same folder, and InstallShield would automatically use the `banner_mirror.jpg` file for the right-to-left-language versions of the dialogs. If an image should not be reversed, a *_mirror.jpg or *_mirror.bmp version of the image is not included, and the right-to-left versions of the dialogs do not show mirrored versions of the images.

Tip • *If you use custom images for your run-time dialogs and your project includes support for right-to-left languages, you may need to create mirror-image versions for those right-to-left languages. You can preview the right-to-left layout of the dialogs in the Dialogs view to see how your custom images look. Add *_mirror.jpg or *_mirror.bmp versions of your images to the folder that contains the left-to-right versions of your custom images if appropriate.*

Launching a File Open Dialog

Project • *This information applies to Basic MSI projects.*

InstallShield includes support for launching the Open dialog from one of the dialogs in your Basic MSI installation. End users click a browse button in one of your dialogs, and this launches the Open dialog. The Open dialog lets the end user browse for a file. When the end user selects the file and clicks the Open button, the Open dialog

closes, and the installation writes the full path and file name in an edit field on the dialog. The installation also sets the value of the **IS_BROWSE_FILEBROWSED** property to the path and file name of the file that the end user selected.

When you incorporate support for the Open dialog in your installation, you can define several properties to specify the following functionality:

- You can specify the string that should be displayed in the **Files of type** drop-down list on the Open dialog.
- You can specify the file extensions of the files that should be displayed when the end user is browsing through folders to select a file. All files that have other file extensions are hidden and cannot be selected to open.
- You can specify the default file extension that the Open dialog should use. If the end user does not type an extension, the Open dialog appends this default extension to the file name.

Note the following requirements for this dialog:

- The Open dialog does not allow end users to create a new file. That is, if a file does not exist, an end user cannot manually type a new file name in the Open dialog.
- If the dialog that launches the Open dialog has more than one edit field control, the edit field control that will contain the full path to the file must have the lowest value for the Tab Stop property.

Task: ***To add the Open dialog functionality to an end-user dialog:***

1. Add to your project a new MSI DLL custom action called `FileBrowse`:
   a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
   b. Right-click the **Custom Actions** explorer, point to **New MSI DLL**, and then click **Stored in Binary table**. InstallShield adds a new custom action called NewCustomAction*N*, where *N* is a successive number.
   c. Change the name of the custom action to `FileBrowse`.
   d. In the pane on the right, configure the following settings for this custom action:
      - DLL Filename: `<ISRedistPlatformDependentFolder>\FileBrowse.dll`
      - Function Name: FileBrowse
      - Return Processing: Synchronous (Ignores exit code)
      - In-Script Execution: Immediate Execution
      - Execution Scheduling: Always execute

      For all other settings, leave the default values. The value of the MSI Type Number setting should be **65**.
2. Create or edit the dialog that should launch the Open dialog, and configure its behavior and layout:
   a. In the View List under **User Interface**, click **Dialogs**.
   b. In the **Dialogs** explorer, expand the **All Dialogs** folder.
   c. Either select an existing dialog or create a new dialog.

Note that if you select an existing dialog and it has more than one edit field control, the edit field control that will contain the full path to the file must have the lowest value for the **Tab Stop** property.

d. Under this dialog, click the language whose layout you want to configure.

e. Add the edit field control that will contain the full path and file name that the end user selects at run time. When InstallShield prompts you for the property name associated with the control, enter `IS_BROWSE_FILEBROWSED`.

f. Next to the edit field control, add a pushbutton control. This is the button that will launch the Open dialog.

g. Select the pushbutton control and then edit its properties in the grid on the right as needed. For example, to specify the text that you want to be displayed on the button, add a value for the **Text** property.

h. In the **Dialogs** explorer, click the **Behavior** item under the dialog that you are configuring.

i. In the center pane that lists the dialog controls, click the pushbutton control that you just created.

j. In the bottom of the lower-right pane, click the **Events** tab to view the events for the pushbutton control if they are not already displayed.

k. In the upper-right pane, add a new event with the following settings:

- Event: DoAction
- Argument: FileBrowse
- Condition: 1

3. Configure several properties to specify behavior of the Open dialog and the dialog that launches the Open dialog:

a. In the View List under **Behavior and Logic**, click **Property Manager**.

b. Find the **IS_BROWSE_FILEBROWSED** property. Its default value is 0. Do one of the following:

- To leave the edit field control blank in your dialog when the end user first displays it, right-click the row that has the **IS_BROWSE_FILEBROWSED** property and then click **Delete Property**.
- To display a default path and file name in the edit field control, change the value of the **IS_BROWSE_FILEBROWSED** property to the path and file name.

Note • *If you do not manually change the value of this property or delete this property, the default value for the edit field control on the dialog that launches the Open dialog is set to 0.*

c. Optionally, add a property called **IS_BROWSE_FILEEXT**, and set its value to a filter string that identifies the file extensions that should be displayed when the end user is browsing through folders to select a file. All files that have other file extensions are hidden and cannot be selected to open.

A filter string can be a combination of valid file name characters and the asterisk (*) as a wild-card character.

To specify multiple file extensions, separate each with a semicolon. Do not include spaces. For example, to let end users select .exe and .dll files, enter the following string as the value of the **IS_BROWSE_FILEEXT** property:

```
*.exe;*.dll
```

In this example, the Open dialog lets end users select .exe and .dll files. It hides all other file types.

If you do not set this property, the Open dialog lets end users select any file type.

d. Optionally, add a property called **IS_BROWSE_FILETYPE**, and set its value to the string that you want to be displayed in the **Files of type** drop-down list on the Open dialog. Note that only one option can be displayed in this drop-down list.

   For example, if you want end users to be able to select .txt or .doc files, enter the following string as the value of the **IS_BROWSE_FILETYPE** property:

   ```
   Text Files (*.txt); Word documents (*.doc)
   ```

   If you do not set this property, the **Files of type** drop-down list in the Open dialog is blank.

e. Optionally, add a property called **IS_BROWSE_DEFAULTEXTENSION**, and set its value to the default file extension that the Open dialog should use. If the end user does not type an extension, the Open dialog appends this default extension to the file name. For example, to use .exe as the default file extension, enter the following string as the value of the **IS_BROWSE_DEFAULTEXTENSION** property:

   ```
   exe
   ```

At run time, when the end user clicks the new pushbutton control, the Open dialog opens. The end user can browse to and select a file. The installation sets the value of the **IS_BROWSE_FILEBROWSED** property to the path and file name of the file that the end user selected, and then it displays that path and file name in the edit field control on the dialog that launched the Open dialog.

Requiring End Users to Scroll Through the EULA in the LicenseAgreement Dialog

Project • *This information applies to Basic MSI projects.*

InstallShield includes support for disabling the Next button on the LicenseAgreement dialog until the end user reaches the end of the End-User License Agreement (EULA) text in the scrollable EULA control through one of the following methods:

- Using the scroll bar.
- Pressing PAGE DOWN when the scrollable EULA control has focus.
- Pressing CTRL+PAGE DOWN when the scrollable EULA control has focus.
- Pressing the DOWN ARROW key when the scrollable EULA control has focus.
- Right-clicking the scroll bar and then clicking Bottom.

The end user must also select the **I accept the terms in the license agreement** option before the Next button is enabled.

The LicenseAgreement dialog requires end users to select the **I accept** option by default. If you also want to require end users to reach the end of the EULA text, perform the following task.

Task: ***To require end users to reach the end of the EULA text in the scrollable EULA control:***

1. Add to your project a new MSI DLL custom action called `WatchScroll`:
   a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
   b. Right-click the **Custom Actions** explorer, point to **New MSI DLL**, and then click **Stored in Binary table**. InstallShield adds a new custom action called NewCustomAction*N*, where *N* is a successive number.
   c. Change the name of the custom action to `WatchScroll`.
   d. In the pane on the right, configure the following settings for this custom action:
      - DLL Filename: `<ISRedistPlatformDependentFolder>\EulaScrollWatcher.dll`
      - Function Name: WatchScroll
      - Return Processing: Asynchronous (Waits for exit code)
      - In-Script Execution: Immediate Execution
      - Execution Scheduling: Always execute

      For all other settings, leave the default values. The value of the MSI Type Number setting should be **129**.
2. Edit the LicenseAgreement dialog so that it launches the appropriate custom action:
   a. In the View List under **User Interface**, click **Dialogs**.
   b. In the **Dialogs** explorer, expand the **All Dialogs** folder, and expand the **LicenseAgreement** item, and then click **Behavior**.
   c. In the center pane that lists the LicenseAgreement controls, click the ScrollableText control named **Memo**. This is the control that contains the text of the EULA.
   d. In the bottom of the lower-right pane, click the **Events** tab to view the events for the Memo control if they are not already displayed.
   e. In the upper-right pane, add a new event with the following settings:
      - Event: DoAction
      - Argument: WatchScroll
      - Condition: Not LicenseViewed AND Not ISLicenseWatching
   f. In the center pane that lists the LicenseAgreement controls, click the PushButton control named **Next**.
   g. In the bottom of the lower-right pane, click the **Conditions** tab to view the conditions for the Next control.
   h. In the upper-right pane, change the Disable and Enable conditions as follows:
      - Disable: AgreeToLicense <> "Yes" OR Not LicenseViewed
      - Enable: AgreeToLicense = "Yes" AND LicenseViewed

At run time, the installation monitors the EULA control in an asynchronous custom action. While the custom action is running, the **ISLicenseWatching** property is set. Once the custom action is finished, it removes the **ISLicenseWatching** property. This avoids the hourglass flicker otherwise seen when end users scroll through the EULA text. Once the end user reaches the bottom of the EULA text, the installation sets the **LicenseViewed** property and manually enables the Next button if necessary according to the Next button's conditions. The Next button is found via its text as stored in the **Control** table; therefore, you can use the aforementioned procedure with any language transform as long as the control is named **Next**.

Adding a Print Button to a Dialog

In Basic MSI projects that are created in InstallShield X or later, the LicenseAgreement dialog includes a Print button. This button enables the end user to print the content of the dialog's ScrollableText control. This button's event executes the custom action ISPrint, which is included in a new Basic MSI project. Following are directions for adding a Print button to another dialog, and to an existing project that was created with InstallShield DevStudio 9.0 or earlier.

Adding a Print Button to Another Dialog

For the custom action ISPrint to work correctly with a dialog other than LicenseAgreement, you must set the value of the user-defined Windows Installer property **IS_PRINT_DIALOG** to the name of the dialog. (If **IS_PRINT_DIALOG** is not an existing property, ISPrint prints the content of the LicenseAgreement dialog's ScrollableText control.)

Task: ***To add a Print button to another dialog:***

1. Create a button control in the dialog and optionally set its **Text** property to `&Print`. For details, see Editing Dialog Layout in Basic MSI Projects.
2. Add a DoAction event to the Print button, and in the event's Argument field, select ISPrint. For details, see Triggering Control Events in Basic MSI Dialogs.
3. Modify the value of **IS_PRINT_DIALOG** from the events of the Back and Next buttons of the dialog and its next and previous dialogs:
    a. Determine which dialog is displayed before the dialog to which you are adding a Print button. You can do this by either checking the argument of the NewDialog event for the dialog's Back button, or viewing next dialog order in the expanded Custom Actions and Sequences view.
    b. Add an [IS_PRINT_DIALOG] event to that previous dialog's Next button, and set its argument as the name of the dialog to which you are adding a Print button.
    c. If a Print button is included on any dialog that is displayed after the dialog to which you are adding a Print button, do the following:
        i. Determine which dialog is displayed after the dialog to which you are adding a Print button. You can do this by either checking the argument of the NewDialog event for the dialog's Next button, or viewing the next dialog order in the expanded Custom Actions and Sequences view.

ii. Add an **[IS_PRINT_DIALOG]** event to that next dialog's Back button, and set its argument to the name of the dialog to which you are adding a Print button.

If the next dialog does not have a Print button, or if it is the LicenseAgreement dialog, add an **[IS_PRINT_DIALOG]** event to the Next button of the dialog to which you are adding a Print button, and set the event's argument to `LicenseAgreement`.

d. If a Print button is included on any dialog that is displayed before the dialog to which you are adding a Print button, and the previous dialog does not have a Print button or it is the LicenseAgreement dialog, add an **[IS_PRINT_DIALOG]** event to the Back button of the dialog to which you are adding a Print button, and set the event's argument to LicenseAgreement.

Adding a Print Button to an Existing Project

Task: ***To add a Print button to an existing project that was created with InstallShield DevStudio 9.0 or earlier:***

1. Create the ISPrint custom action:
   a. Launch the Custom Action Wizard.
   b. In the **Basic Information** panel's **Name** box, enter `ISPrint`.
   c. In the **Action Type** panel's **Type** box, select **Call a function in a Windows Installer dynamic-link library**.
   d. In the **Action Parameters** panel, click the **Browse** button and browse to the file `SetAllUsers.dll` in the InstallShield folder's `Redist\Language Independent\i386` subfolder. Click **Open**.

      If your project is configured to use path variables, InstallShield uses the predefined path variable `<ISRedistPlatformDependentFolder>` for part of the path.
   e. In the **Action Parameters** panel's **Target** box, enter `PrintScrollableText`.
   f. Complete the wizard, accepting all remaining default settings.
2. Create a button control in the dialog and optionally set its **Text** property to `&Print`. For details, see Editing Dialog Layout in Basic MSI Projects.
3. Add a DoAction event to the Print button, and in the event's **Argument** field, select **ISPrint**. For details, see Triggering Control Events in Basic MSI Dialogs.
4. Create the Windows Installer property **IS_PRINT_DIALOG** and set its value to the name of the dialog. For details, see Creating Properties.

Note • *If the ISPrint custom action is executed by a control event, the custom action's logging information cannot be recorded to the installer log in the usual manner (because of a Windows Installer limitation); the information is logged to the values of properties that have the form ISPrintLogmNoten.*

Minimizing Reboots on Windows Vista and Later Systems

Windows Logo • *Restarting the system after an installation is inconvenient for end users. One of the Windows logo program requirements is that all installations must contain an option that enables end users to automatically close applications and attempt to restart them after the installation is complete.*

To support this requirement, all Basic MSI projects include the MsiRMFilesInUse dialog by default. An installation displays the MsiRMFilesInUse dialog on a Windows Vista or later system if one or more files that need to be updated are currently in use during the installation. The dialog contains two options to allow end users to specify how to proceed:

- End users can choose to have the installation close the applications that are using those files and then attempt to restart the applications after the installation is complete.
- End users can avoid closing the applications. A reboot will be required at the end of the installation.

For the best end-user experience, your application should be instrumented to use the Restart Manager API; doing so allows the Restart Manager to effectively pause and resume your application exactly where the end user left it. For detailed information, see About Restart Manager and the other Restart Manager documentation on the MSDN Web site.

Dialog Controls

Whether your dialog is part of a Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, or Merge Module project, you can use many of the same controls to modify the layout and behavior of your predefined and custom dialogs.

Table 4-8 • Dialog Controls

Control Type	Project Type	Description
Billboard	Basic MSI, Merge Module	A billboard control is used to display data that can be updated in response to control events. You can use a billboard, for example, to display the progress of a protracted custom action.  ***Project*** • *If your installation includes a `Setup.exe` launcher, you can have the launcher display billboards during the file transfer process; this is an alternative to the billboard control, which is a Windows Installer control. This `Setup.exe` billboard support is available in Basic MSI, InstallScript, and InstallScript MSI installations. To learn more about this type of billboard, see Displaying Billboards.*

Table 4-8 • Dialog Controls (cont.)

Control Type	Project Type	Description
Bitmap	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A bitmap control displays an image.
Check box	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A check box control displays a check box that end user can select or clear.
Combo box	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A combo box control is a box that contains a drop-down list of predefined values; the box is also an edit field in which an end user can enter a value.
Dialog	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A dialog control is associated with a series of settings that you configure.
Directory combo	Basic MSI, Merge Module	A directory combo is used in conjunction with a directory list and a path edit control to create a browse dialog. The directory combo displays the list of drives mapped on the current system.
Directory list	Basic MSI, Merge Module	A directory list is used in conjunction with a directory combo and a path edit control to create a browse dialog. The directory list displays the folders below the drive that is selected in the directory combo control, and it populates the value of the path edit control.
Edit Field	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	An edit field control is a text box in which end users can enter a string or an integer.

Table 4-8 • Dialog Controls (cont.)

Control Type	Project Type	Description
Group box	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A group box can be used to enclose various controls in one area. A group box also provides a label that you can use to express the relationship between the controls that are contained within it.
Hyperlink	Basic MSI, Merge Module	The hyperlink control displays an HTML link; clicking the link at run time opens a page in the default browser on the target system.  ***Important*** • *Windows Installer 5 and later include support for the hyperlink control.*  ***Project*** • *To learn how to add an HTML control to a dialog in an InstallScript project or in an InstallScript MSI project, see Using an HTML Control on a Dialog.*
Icon	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The icon control displays a picture of an icon.
Line	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The line control creates lines of adjustable length and thickness. You can use lines on a dialog to separate areas of the dialog or add graphical touches.
List box	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The list box control is a standard list box that lets end users select a single option from a list of predetermined options.
List view	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The list view control displays a single column of options; an icon is displayed next to each option.

Table 4-8 • Dialog Controls (cont.)

Control Type	Project Type	Description
Masked edit	Basic MSI, Merge Module	The masked edit control is essentially an edit field control that lets end users enter information in a specified format.
Path edit	Basic MSI, Merge Module	A path edit control is used in conjunction with a directory combo control and a directory list control to create a browse dialog. The path edit displays the complete path that is assembled from selections that the end user makes in the directory combo and directory list, along with or instead of edits that the end user makes.
Progress bar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A progress bar is a dynamic, graphical bar that fills up in response to control events.
Push button	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A push button control is a button that carries out a command when an end user clicks it.
Radio button	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A radio button control is one of two or more mutually exclusive options that end users can select. A radio button must be inserted into a radio button group; it functions as part of that control.
Radio button group	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A radio button group control is a container for radio button controls. A radio button group and its radio buttons behave as a single control.
Scrollable text	Basic MSI, Merge Module	A scrollable text control displays a long string of text that cannot fit on the dialog; the control includes scroll bars that enable end users to scroll through the text. The LicenseAgreement dialog is an example of a dialog that typically contains a scrollable text control.

Table 4-8 • Dialog Controls (cont.)

Control Type	Project Type	Description
Selection tree	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A selection tree is a special control that lets end users change the selection state of your features, like in the CustomSetup dialog.
Text area	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	A text area control displays text.
Volume cost list	Basic MSI, Merge Module	A volume cost list control displays the disk space requirements that are associated with each volume or drive.
Volume select combo	Basic MSI, Merge Module	A volume select combo control enables the end user to select from an alphabetical list of volumes, or drives.

Billboard Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

If your installation includes a `Setup.exe` *launcher, you can have the launcher display billboards during the file transfer process; this is an alternative to the billboard control, which is a Windows Installer control. This* `Setup.exe` *billboard support is available in Basic MSI, InstallScript, and InstallScript MSI installations. To learn more about this type of billboard, see Displaying Billboards.*

A billboard control is used to display data that can be updated in response to control events. Billboards can contain other controls for displaying this information, but they must be static controls—including text, bitmaps, and icons—that are not linked to a Windows Installer property. You can use a billboard, for example, to display the progress of a protracted custom action.

Billboards are not fully supported in the Dialog Editor. In order to have the billboard interact with Windows Installer actions and display other controls, you must make changes to the **Billboard** and **BBControl** tables in your project; you can use the Direct Editor view to modify these tables.

When you select a billboard control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-9 • Settings for a Billboard Control

Setting	Description
Name	Enter a name for this billboard. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.

Table 4-9 • Settings for a Billboard Control (cont.)

Setting	Description
Text	This setting contains the text that is used for the initial value of the billboard's control (see the **BBControl** table). When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield. If the billboard's control contains a bitmap or icon, this value must be a foreign key into the **Binary** table to the file that is initially displayed on the control.
Text Style	Select the font style, size, and color (if available) in which you want the billboard's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Bitmap Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

- *InstallScript Object*
- *Merge Module*

A bitmap control displays an image.

When you select a bitmap control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-10 • Settings for a Bitmap Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this bitmap. The name must be unique among all of the controls in your project.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object, Merge Module	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Select True if this is the only control on the dialog that you want to be the default control, which means that it will be activated when the end user presses the ENTER key. The Next or OK button is usually the default control.
File Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter the path to and the name of the image file that you want to use for this control, or click the ellipsis button (...) in this setting to browse to it. InstallShield adds the file to your release at build time. The file must be stored as a binary resource in the installation.

Table 4-10 • Settings for a Bitmap Control (cont.)

Setting	Project Type	Description
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Stretch to Fit	Basic MSI, Merge Module	If you want the image to be resized to fill the area of the control, select True. To have the image centered if it is smaller than the control or to have the image cropped if it is bigger than the control, select False.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.

Table 4-10 • Settings for a Bitmap Control (cont.)

Setting	Project Type	Description
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Check Box Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A check box control displays a check box that end user can select or clear.

When you select a check box control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Project • *(For Basic MSI and Merge Module projects) When you first draw this type of control on a dialog, InstallShield prompts you for the name of a Windows Installer property. InstallShield uses the name that you enter as the value for this control's Property setting. At run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.*

Table 4-11 • Settings for a Check Box Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this check box. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting. This setting is enabled if Text is selected for the Control Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Control Style	Basic MSI, Merge Module	Specify whether this control is marked with a text label, an icon, or a bitmap.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.

Table 4-11 • Settings for a Check Box Control (cont.)

Setting	Project Type	Description
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
File Name	Basic MSI, Merge Module	This setting is enabled if you select Bitmap or Icon for the Control Style setting. Enter the path to and the name of the image file that you want to use for this control, or click the ellipsis button (...) in this setting to browse to it. InstallShield adds the file to your release at build time. The file must be stored as a binary resource in the installation. This setting is enabled if Bitmap or Icon are selected for the Control Style setting.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.).
Icon Size	Basic MSI, Merge Module	Assuming that your icon file has more than one resource, specify the size of the image that you want to use for the control. The **Use first image** option causes the first image in the file to be displayed and makes it stretch to fit the size of the control, regardless of what you specify for the Stretch to Fit setting. This setting is enabled if Bitmap or Icon are selected for the Control Style setting.
Indirect Property	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.

Table 4-11 • Settings for a Check Box Control (cont.)

Setting	Project Type	Description
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Property	Basic MSI, Merge Module	Enter the name of a property that is set when an end user selects this check box. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the Value setting.
Property Is Integer	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property for this control (specified in the Property setting) has an integer value, select True. If the property's value is a string, select False.
Push Button	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To turn this check box into a push button control, select True; otherwise, select False.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.

Table 4-11 • Settings for a Check Box Control (cont.)

Setting	Project Type	Description
Stretch to Fit	Basic MSI, Merge Module	If you want the image to be resized to fill the area of the control, select True. To have the image centered if it is smaller than the control or to have the image cropped if it is bigger than the control, select False. This setting is enabled if Bitmap or Icon are selected for the Control Style setting.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	This setting contains the text that is used for the control's label. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield. This setting is enabled if Text is selected for the Control Style setting.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting is enabled if Text is selected for the Control Style setting.

Table 4-11 • Settings for a Check Box Control (cont.)

Setting	Project Type	Description
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Value	Basic MSI, Merge Module	When the check box is selected, the property that is specified for the Property setting is set to this value.
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Combo Box Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A combo box control is a box that contains a drop-down list of predefined values; the box is also an edit field in which an end user can enter a value.

When you select a combo box control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Project • *(For Basic MSI and Merge Module projects) When you first draw this type of control on a dialog, InstallShield prompts you for the name of a Windows Installer property that identifies all of the items that belong to this combo box. InstallShield uses the name that you enter as the value for this control's Property setting. At run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties. (Note that Windows Installer combo boxes allow the end user to select only a single item.)*

Table 4-12 • Settings for a Combo Box Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this combo box. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Code Page	Basic MSI, Merge Module	If you want the control to use fonts from the code page that is defined in the installation's package, select Database. If you want the control to use fonts from the target system's default code page, select User's System.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.

Table 4-12 • Settings for a Combo Box Control (cont.)

Setting	Project Type	Description
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Drop-Down List	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the control to be a drop-down list, select True. If you want the control to be an editable combo box, select False.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.  ***Tip*** • *Be sure to set the Height setting to a large-enough number; this setting specifies the height of the drop-down list portion of the combo box control.*
Indirect Property	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.

Table 4-12 • Settings for a Combo Box Control (cont.)

Setting	Project Type	Description
Items	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To specify the options that you want to be listed in this control, click the ellipsis button (...) in this setting; this opens the List Items dialog box. To add a new item to the list, click the Add button on the List Items dialog box. For each item, you must enter the text that is displayed in the combo box, and a value, which is the value that is assigned to the property if this item is selected.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Max. Length	Basic MSI, Merge Module	Specify how many characters the end user can enter in the combo box.
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Property	Basic MSI, Merge Module	Enter the name of a property that is set when the end user enters a value into or selects one from this combo box. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection (specified in the Items setting).
Property Is Integer	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property for this control (specified in the Property setting) has an integer value, select True. If the property's value is a string, select False. Make sure that all of the values in the Item setting are either integers or strings, depending on the value that you select in the Property Is Integer setting.

Table 4-12 • Settings for a Combo Box Control (cont.)

Setting	Project Type	Description
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sorted	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Selecting True causes the items in the combo box to be sorted alphabetically. A value of False makes them retain the order that you set for each item in the List Items dialog box.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.

Table 4-12 • Settings for a Combo Box Control (cont.)

Setting	Project Type	Description
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Dialog Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

When you select a dialog in the Dialog Editor of the Dialogs view, InstallShield displays the following settings in the right pane.

Unlike its controls, you cannot change the name of a dialog in the Dialog Editor. To change the name, right-click the dialog in the Dialogs view and click Rename.

Table 4-13 • Settings for a Dialog Control

Setting	Project Type	Description
Caption	Basic MSI, Merge Module	Specify the name that you want to use as the title for the dialog. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Comment	Basic MSI, Merge Module	Enter comments for the dialog. Your comments are saved in the project file for your reference and are not used in the installation at any time.
Custom Palette	Basic MSI, Merge Module	A custom palette is necessary only if the dialog contains images that use a color palette that is different from the default one that is created by Windows Installer. If the dialog does not contain any images that use a different color palette, leave this value as False.
Error Dialog	Basic MSI, Merge Module	If this dialog serves as an error dialog, select True.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the height of the dialog in installer units (1/12 of the height of the system font).
Keep Modeless	Basic MSI, Merge Module	When this value is set to True and this dialog is spawned through a DoAction event, all other dialogs remain. If the Keep Modeless setting is False in this case, the other dialogs are not displayed.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the percentage from the left edge of the screen where you want the dialog to be placed. A value of 50 centers the dialog horizontally. This value is ignored if this dialog is part of an installation wizard, and the previous dialog was in a different location or was moved by the end user.

Table 4-13 • Settings for a Dialog Control (cont.)

Setting	Project Type	Description
Left Scrollbar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Select True to set the scroll bar, if present, at the left side of the dialog. The default value, False, keeps it at the right side. If you want the vertical scrollbar, if present, to be displayed on the left side of the dialog, select True. The default value, False, keeps the scrollbar on the right side.
Minimize	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the end user can minimize this dialog. False means that the option is not present on the title bar.
Modal	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Select True if this dialog is part of the installation wizard and no other dialogs should be placed on top of it.
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Resource Identifier	InstallScript, InstallScript MSI, InstallScript Object	This read-only setting shows the dialog's resource ID—the unique numeric identifier for the dialog.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the caption to the left of the control. Set it to True to align the caption to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Text Style	InstallScript, InstallScript MSI	Select a font to be used for the dialog.

Table 4-13 • Settings for a Dialog Control (cont.)

Setting	Project Type	Description
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the percentage from the top of the screen where you want the dialog to be placed. A value of 50 centers the dialog vertically. This value is ignored if this dialog is part of an installation wizard, and the previous dialog was in a different location or was moved by the end user.
Track Disk Space	Basic MSI, Merge Module	Select True if this dialog has a control that alerts the end user that a drive is out of space or that checks the value of the OutOfDiskSpace property before performing some action.
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the dialog is visible, and False means that it is hidden.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the width of the dialog in installer units (1/12 of the height of the system font).

Directory Combo Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

A directory combo is used in conjunction with a directory list and a path edit control to create a browse dialog. The directory combo displays the list of drives mapped on the current system.

When you first draw a directory combo on a dialog, InstallShield prompts you for the name of a Windows Installer property. This property should be the same for the accompanying directory list and path edit. At run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.

When you select a directory combo control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-14 • Settings for a Directory Combo Control

Setting	Description
Name	Enter a name for this directory combo. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's text if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Indirect Property	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).

Table 4-14 • Settings for a Directory Combo Control (cont.)

Setting	Description
Left Scrollbar	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Property	Enter the name of a property that is set when an end user end user selects a value from this directory combo. This control populates the first part of the path that is displayed in the directory list, so you must use the same property for the directory combo, the directory list, and path edit when using them together on a browse dialog. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Show CD-ROM	To include CD-ROM volumes in the directory combo, select True.
Show Fixed	To include hard drives in the directory combo, select True.
Show Floppy	To include floppy drives in the directory combo, select True.
Show RAMDisk	To include RAM volumes in the directory combo, select True.
Show Remote	To include mapped network drives in the directory combo, select True.
Show Removable	To include removable drives in the directory combo, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.

Table 4-14 • Settings for a Directory Combo Control (cont.)

Setting	Description
Text	This setting contains the text that is used for the control's text. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Directory List Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

A directory list is used in conjunction with a directory combo and a path edit control to create a browse dialog. The directory list displays the folders below the drive that is selected in the directory combo control, and it populates the value of the path edit control.

When you first draw a directory list on a dialog, InstallShield prompts you for the name of a Windows Installer property. This property should be the same for the accompanying directory combo and path edit. At run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.

When you select a directory list control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-15 • Settings for a Directory List Control

Setting	Description
Name	Enter a name for this directory list. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Indirect Property	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).

Table 4-15 • Settings for a Directory List Control (cont.)

Setting	Description
Left Scrollbar	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Property	Enter the name of a property that is set when an end user selects a value from this directory list. This control populates the path that is displayed in the path edit and changes depending on the selection in the directory combo, so you must use the same property for all three controls when using them together on a browse dialog. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	This setting contains the text that is used for the control's text. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.

Table 4-15 • Settings for a Directory List Control (cont.)

Setting	Description
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Edit Field Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

An edit field control is a text box in which end users can enter a string or an integer.

When you select an edit field control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Project • *(For Basic MSI and Merge Module projects) When you first draw this type of control on a dialog, InstallShield prompts you for the name of a Windows Installer property. InstallShield uses the name that you enter as the value for this control's Property setting. At run time, the installation sets the value of this property based on the*

end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.

Table 4-16 • Settings for an Edit Field Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this edit field. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).

Table 4-16 • Settings for an Edit Field Control (cont.)

Setting	Project Type	Description
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Indirect Property	Basic MSI, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Max. Length	Basic MSI, Merge Module	Specify the maximum number of characters that the end user can enter in this control.
MultiLine	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want this control to be multiline control, select True.
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.

Table 4-16 • Settings for an Edit Field Control (cont.)

Setting	Project Type	Description
Password	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want this control to behave like a password control, only showing an asterisk (*) in place of each character, select True. If you want this control to behave like a normal edit field control, select False.
Property	Basic MSI, Merge Module	Enter the name of a property that is set when an end user enters text in this control. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.
Property Is Integer	Basic MSI, Merge Module	If the property for this control (specified in the Property setting) has an integer value, select True. If the property's value is a string, select False.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.

Table 4-16 • Settings for an Edit Field Control (cont.)

Setting	Project Type	Description
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, Merge Module	This setting contains the text that is used in the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, Merge Module	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Group Box Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A group box can be used to enclose various controls in one area. To move and align the group box along with any individual control that it encloses, hold the CTRL key as you select the group box and each control that you want to select. A group box also provides a label that you can use to express the relationship between the controls that are contained within it.

When you select a group box control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-17 • Settings for a Group Box Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this group box. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.

Table 4-17 • Settings for a Group Box Control (cont.)

Setting	Project Type	Description
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.

Table 4-17 • Settings for a Group Box Control (cont.)

Setting	Project Type	Description
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
