Text	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	This setting contains the text that is used for the group box label. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.

Table 4-17 • Settings for a Group Box Control (cont.)

Setting	Project Type	Description
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Hyperlink Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

To learn how to add an HTML control to a dialog in an InstallScript project or in an InstallScript MSI project, see Using an HTML Control on a Dialog.

Use the hyperlink control to add a hyperlink to a dialog in your project. The hyperlink control displays an HTML link; clicking the link at run time opens a page in the default browser on the target system.

Important • *Windows Installer 5 and later include support for the hyperlink control. If this control is used on a dialog that is displayed on a system that has an earlier version of Windows Installer, run-time error 2885 occurs, and the installation aborts. Therefore, if you want to use the hyperlink control on a dialog but your installation targets systems that have Windows Installer 4.5 or earlier, it is recommended that you include two versions of the dialog in your project: one with the hyperlink control, and one without it. Add conditions to the dialogs to show or hide them, depending on the version of Windows Installer that is present.*

Following is a sample condition that you could use for the dialog that contains the hyperlink control:

```
VersionMsi >= "5.00"
```

Following is a sample condition that you could use for the alternate dialog that does not contain any hyperlink control:

```
VersionMsi < "5.00"
```

When you select a hyperlink control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-18 • Settings for a Hyperlink Control

Setting	Description
Name	Enter a name for this hyperlink control. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Code Page	If you want the control to use fonts from the code page that is defined in the installation's package, select Database. If you want the control to use fonts from the target system's default code page, select User's System.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Format as Bytes	If you want the installation to attempt to display the value that is entered in the Text setting in bytes, select True. If you select True, the Text setting must contain only a number, without the unit. Then, at run time, it is divided by 512 and displayed as the correct number of kilobytes, megabytes, or gigabytes, depending on the size.
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).

Table 4-18 • Settings for a Hyperlink Control (cont.)

Setting	Description
No Prefix	If the Text setting contains an ampersand that should be displayed as an ampersand character (&), select True. If you are using the ampersand in the Text setting to indicate that the letter that follows the ampersand should be underlined (for example, `&Click` would be displayed as Click), select False.
No Text Wrap	Indicate whether you want to allow the text to wrap in this control. If you select True and the text expands beyond the width of the text area, the end of the string is cut off and replaced with an ellipsis button (...). Otherwise, the text wraps and can extend beyond the height of the text area, if it is not long enough.
Property	Enter the name of a property that is set when an end user clicks this hyperlink. This property can be unique to this control; it does not need to be present in the Property Manager view.
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.

Table 4-18 • Settings for a Hyperlink Control (cont.)

Setting	Description
Text	This setting contains the text that is used for the control. Use HTML markup in this setting for your hyperlink. Following is a sample entry for this setting: `To learn about the latest offerings from ABC Company, visit the <a href="http://www.abccompany.com">ABC Company Web site</a>.` For this sample, the **ABC Company Web site** text is displayed as a hyperlink that points to the **http://www.abccompany.com** Web site. Note that the only protocol that is supported for the hyperlink is HTML. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Transparent	If you want the background to show through this control, select True. Note that you may want to avoid making this control transparent if you are placing it on top of a colored bitmap. The text may not be visible if end users change the color scheme of their display. For example, the text in this control may become invisible if an end user sets the high-contrast parameter for accessibility reasons.
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Icon Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The icon control displays a picture of an icon.

When you select an icon control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-19 • Settings for an Icon Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this icon. The name must be unique among all of the controls in your project.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.

Table 4-19 • Settings for an Icon Control (cont.)

Setting	Project Type	Description
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
File Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter the path to and the name of the icon file that you want to use for this control, or click the ellipsis button (...) in this setting to browse to it. InstallShield adds the file to your release at build time. The file must be stored as a binary resource in the installation.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Icon Size	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assuming that your icon file has more than one resource, specify the size of the image that you want to use for the control. The **Use first image** option causes the first image in the file to be displayed and makes it stretch to fit the size of the control, regardless of what you specify for the Stretch to Fit setting.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Stretch to Fit	Basic MSI, Merge Module	If you want the icon to be resized to fill the area of the control, select True. To have the icon centered if it is smaller than the control or to have the icon cropped if it is bigger than the control, select False.

Table 4-19 • Settings for an Icon Control (cont.)

Setting	Project Type	Description
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.

Table 4-19 • Settings for an Icon Control (cont.)

Setting	Project Type	Description
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Line Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The line control creates lines of adjustable length and thickness. You can use lines on a dialog to separate areas of the dialog or add graphical touches.

When you select a line control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-20 • Settings for a Line Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this line. The name must be unique among all of the controls in your project.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.

Table 4-20 • Settings for a Line Control (cont.)

Setting	Project Type	Description
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.

Table 4-20 • Settings for a Line Control (cont.)

Setting	Project Type	Description
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

List Box Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

- *Merge Module*

The list box control is a standard list box that lets end users select a single option from a list of predetermined options.

When you select a list box control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Project • *(For Basic MSI and Merge Module projects) When you first draw this type of control on a dialog, InstallShield prompts you for the name of a Windows Installer property that identifies all of the items that are displayed in this list box. InstallShield uses the name that you enter as the value for this control's Property setting. At run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.*

Table 4-21 • Settings for a List Box Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this list box. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Code Page	Basic MSI, Merge Module	If you want the control to use fonts from the code page that is defined in the installation's package, select Database. If you want the control to use fonts from the target system's default code page, select User's System.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.

Table 4-21 • Settings for a List Box Control (cont.)

Setting	Project Type	Description
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Indirect Property	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Items	Basic MSI, Merge Module	To specify the options that you want to be listed in this control, click the ellipsis button (...) in this setting; this opens the List Items dialog box. To add a new item to the list, click the Add button on the List Items dialog box. For each item, you must enter the text that is displayed in the list box, and a value, which is the value that is assigned to the property if this item is selected.

Table 4-21 • Settings for a List Box Control (cont.)

Setting	Project Type	Description
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Property	Basic MSI, Merge Module	Enter the name of a property that is set when an end user selects an option from this control. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the text of the default selection.
Property Is Integer	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property for this control (specified in the Property setting) has an integer value, select True. If the property's value is a string, select False.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.

Table 4-21 • Settings for a List Box Control (cont.)

Setting	Project Type	Description
Sorted	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Selecting True causes the items in the list box to be sorted alphabetically. A value of False makes them retain the order that you set for each item in the List Items dialog box.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, Merge Module	This setting contains the text that is used for screen readers. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.

Table 4-21 • Settings for a List Box Control (cont.)

Setting	Project Type	Description
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

List View Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The list view control displays a single column of options; an icon is displayed next to each option.

When you select a list view control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Project • *(For Basic MSI and Merge Module projects) When you first draw this type of control on a dialog, InstallShield prompts you for the name of a Windows Installer property that identifies all of the items that are displayed in this list view. InstallShield uses the name that you enter as the value for this control's Property setting. At*

run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.

Table 4-22 • Settings for a List View Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this list view. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).

Table 4-22 • Settings for a List View Control (cont.)

Setting	Project Type	Description
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Icon Size	Basic MSI, Merge Module	Assuming that your icon file has more than one resource, specify the size of the image that you want to use for the control. The **Use first image** option causes the first image in the file to be displayed and makes it stretch to fit the size of the control, regardless of what you specify for the Stretch to Fit setting.
Indirect Property	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Items	Basic MSI, Merge Module	To specify the options that you want to be listed in this control, click the ellipsis button (...) in this setting; this opens the List Items dialog box. To add a new item to the list, click the Add button on the List Items dialog box. For each item, you must enter the text that is displayed in the list view control, and a value, which is the value that is assigned to the property if this item is selected.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.

Table 4-22 • Settings for a List View Control (cont.)

Setting	Project Type	Description
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Property	Basic MSI, Merge Module	Enter the name of a property that is set when an end user selects a value from this control. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.
Property Is Integer	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property for this control (specified in the Property setting) has an integer value, select True. If the property's value is a string, select False.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sorted	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Selecting True causes the items in the combo box to be sorted alphabetically. A value of False makes them retain the order that you set for each item in the List Items dialog box.
Stretch to Fit	Basic MSI, Merge Module	If you want the image to be resized to fill the area of the control, select True. To have the image centered if it is smaller than the control or to have the image cropped if it is bigger than the control, select False.

Table 4-22 • Settings for a List View Control (cont.)

Setting	Project Type	Description
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, Merge Module	This setting contains the text that is used in the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).

Table 4-22 • Settings for a List View Control (cont.)

Setting	Project Type	Description
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Masked Edit Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

The masked edit control is essentially an edit field control that lets end users enter information in a specified format.

When you select a masked edit control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-23 • Settings for a Masked Edit Control

Setting	Description
Name	Enter a name for this masked edit control. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.

Table 4-23 • Settings for a Masked Edit Control (cont.)

Setting	Description
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Indirect Property	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Mask	Enter the formatting for the mask. To learn more, see MaskedEdit Control in the Windows Installer Help Library.
Max. Length	Specify the maximum number of characters that the end user can enter in this control.
Property	Enter the name of a property that is set with the value that an end user enters in the masked edit control. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.

Table 4-23 • Settings for a Masked Edit Control (cont.)

Setting	Description
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Path Edit Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

A path edit control is used in conjunction with a directory combo control and a directory list control to create a browse dialog. The path edit displays the complete path that is assembled from selections that the end user makes in the directory combo and directory list, along with or instead of edits that the end user makes.

When you select a path edit control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-24 • Settings for a Path Edit Control

Setting	Description
Name	Enter a name for this path edit control. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This property is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Indirect Property	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).

Table 4-24 • Settings for a Path Edit Control (cont.)

Setting	Description
Property	Enter the name of a property that is set when an end user enters a value into this path edit or selects one from the directory list. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	This setting contains the text that is used for the control's label. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.

Table 4-24 • Settings for a Path Edit Control (cont.)

Setting	Description
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Progress Bar Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A progress bar is a dynamic, graphical bar that fills up in response to control events.

When you select a progress bar control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-25 • Settings for a Progress Bar Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this progress bar. The name must be unique among all of the controls in your project.

Table 4-25 • Settings for a Progress Bar Control (cont.)

Setting	Project Type	Description
Appearance	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Select the appropriate option: • **Continuous**—The moving progress bar consists of a continuous bar. • **Segmented**—The progress bar consists of a series of rectangles.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).

Table 4-25 • Settings for a Progress Bar Control (cont.)

Setting	Project Type	Description
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, Merge Module	This setting contains the text that is displayed by the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.

Table 4-25 • Settings for a Progress Bar Control (cont.)

Setting	Project Type	Description
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Push Button Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A push button control is a button that carries out a command when an end user clicks it.

When you select a push button control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-26 • Settings for a Push Button Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this push button. The name must be unique among all of the controls in your project.

Table 4-26 • Settings for a Push Button Control (cont.)

Setting	Project Type	Description
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting. This setting is enabled if Text is selected for the Control Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Control Style	Basic MSI, Merge Module	Specify whether this control is marked with a text label, an icon, or a bitmap.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).

Table 4-26 • Settings for a Push Button Control (cont.)

Setting	Project Type	Description
File Name	Basic MSI, Merge Module	Enter the path to and the name of the image file that you want to use for this control, or click the ellipsis button (...) in this setting to browse to it. InstallShield adds the file to your release at build time. The file must be stored as a binary resource in the installation. This setting is enabled if you select Bitmap or Icon for the Control Style setting. This setting is enabled if Bitmap or Icon are selected for the Control Style setting.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Icon Size	Basic MSI, Merge Module	Assuming that your icon file has more than one resource, specify the size of the image that you want to use for the control. The **Use first image** option causes the first image in the file to be displayed and makes it stretch to fit the size of the control, regardless of what you specify for the Stretch to Fit setting. This setting is enabled if Bitmap or Icon are selected for the Control Style setting.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.

Table 4-26 • Settings for a Push Button Control (cont.)

Setting	Project Type	Description
Show UAC Shield Icon	Basic MSI, Merge Module	If you want the control to include a User Account Control (UAC) shield icon when end users run the installation on Windows Vista or later systems, select True. The shield icon signals to end users that elevated privileges may be required. If the UAC shield icon should not be included on the control, select False.
Stretch to Fit	Basic MSI, Merge Module	If you want the image to be resized to fill the area of the control, select True. To have the image centered if it is smaller than the control or to have the image cropped if it is bigger than the control, select False. This setting is enabled if Bitmap or Icon are selected for the Control Style setting.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	This setting contains the text that is used on the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield. This setting is enabled if Text is selected for the Control Style setting.

Table 4-26 • Settings for a Push Button Control (cont.)

Setting	Project Type	Description
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting is enabled if Text is selected for the Control Style setting.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Radio Button Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A radio button control is one of two or more mutually exclusive options that end users can select. A radio button must be inserted into a radio button group; it functions as part of that control.

A radio button group and its radio buttons behave as a single control. It is not possible to hide or disable individual buttons within a radio button group. All the buttons in a group must be the same style—for example, either all of them have text or all of them have bitmaps.

Note that when you delete a radio button group, all of its radio buttons are also deleted. In addition, when you change the name of the radio button group control, all of its radio buttons are deleted.

When you select a radio button control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-27 • Settings for a Radio Button Control

Setting	Project Type	Description
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default. The control identifier for the first radio button in a group is the control identifier for the radio button group. The control for each subsequent radio button is the radio button group identifier incremented by one.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.

Table 4-27 • Settings for a Radio Button Control (cont.)

Setting	Project Type	Description
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Order	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the number that indicates the order in which this radio button is listed in the radio button group. This setting must contain a unique, positive integer, but it does not need to be consecutive with the Order setting of the other radio buttons in this group.
Text	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	This setting contains the text that is used for the radio button's label. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).

Table 4-27 • Settings for a Radio Button Control (cont.)

Setting	Project Type	Description
Value	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter the value that you want to be associated with this radio button when end users select it. ***Project*** *• For Basic MSI projects: To make one of the radio buttons selected by default, enter the radio button group's Windows Installer property in the Property Manager view. Type the property in all uppercase letters if you want it to be public in scope.Then, specify the value of the button that you want to appear as the default. For example, if one of your radio buttons has a value of 104 and the radio button group uses the property* ***GRP_PROPERTY1****, enter the following information in the Property Manager view to make this radio button the default selection.* • *Name: GRP_PROPERTY1* • *Value: 104*
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Radio Button Group Control

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

Note that in Basic MSI and Merge Module projects, it is not possible to hide or disable individual buttons within a radio button group. All the buttons in a group must be the same style—for example, either all of them have text or all of them have bitmaps.

A radio button group control is a container for radio button controls. A radio button group and its radio buttons behave as a single control. Note that when you delete a radio button group, all of its radio buttons are also deleted. In addition, when you change the name of the radio button group control, all of its radio buttons are deleted.

When you select a radio button group control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Project • *(For Basic MSI and Merge Module projects) When you first draw this type of control on a dialog, InstallShield prompts you for the name of a Windows Installer property that identifies all of the buttons that are displayed in this radio button group. InstallShield uses the name that you enter as the value for this control's Property setting. At run time, the installation sets the value of this property based on the end user's selection. For more details, see Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties.*

Table 4-28 • Settings for a Radio Button Group Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this radio button group. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting. This setting has no effect on a radio button group with an image for a label.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default. The control identifier for the first radio button in a group is the control identifier for the radio button group. The control for each subsequent radio button is the radio button group identifier incremented by one.

Table 4-28 • Settings for a Radio Button Group Control (cont.)

Setting	Project Type	Description
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Has Border	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To display a border around the radio button group, select True. To omit a border, select False. Use the Sunken setting to further modify the appearance of the border.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Indirect Property	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.

Table 4-28 • Settings for a Radio Button Group Control (cont.)

Setting	Project Type	Description
Property	Basic MSI, Merge Module	Enter the name of a property that is set when an end user selects one of the radio buttons in this group. This property can be unique to this control; it does not need to be present in the Property Manager view. For information on using this setting to set a default selection in the radio button group, see the radio button's Value setting.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.

Table 4-28 • Settings for a Radio Button Group Control (cont.)

Setting	Project Type	Description
Text	Basic MSI, Merge Module	This setting contains the text that is used for the radio button group's label. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield. This setting has no effect on a radio button group with an image for a label.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting has no effect on a radio button group with an image for a label.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Scrollable Text Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

A scrollable text control displays a long string of text that cannot fit on the dialog; the control includes scroll bars that enable end users to scroll through the text. The LicenseAgreement dialog is an example of a dialog that typically contains a scrollable text control.

When you select a scrollable text control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Note • *Unlike the text values for most controls, Windows Installer does not resolve property names or other values within the Scrollable Text control. As a result, the text in the file is displayed exactly as it is written.*

Table 4-29 • Settings for a Scrollable Text Control

Setting	Description
Name	Enter a name for this scrollable text control. The name must be unique among all of the controls in your project.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).

Table 4-29 • Settings for a Scrollable Text Control (cont.)

Setting	Description
File Name	Enter the path to and the name of the .rtf file that you want to use for this control, or click the ellipsis button (...) in this setting to browse to it. InstallShield adds the file to your release at build time. The file must be stored as a binary resource in the installation.
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).

Table 4-29 • Settings for a Scrollable Text Control (cont.)

Setting	Description
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Selection Tree Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A selection tree is a special control that lets end users change the selection state of your features, like in the CustomSetup dialog.

When you select a selection tree control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-30 • Settings for a Selection Tree Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this selection tree. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the control's label if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.

Table 4-30 • Settings for a Selection Tree Control (cont.)

Setting	Project Type	Description
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Indirect Property	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).

Table 4-30 • Settings for a Selection Tree Control (cont.)

Setting	Project Type	Description
Left Scrollbar	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.
Property	Basic MSI, Merge Module	Enter the name of a property for the selection tree. The end user can set the property in a browse dialog (a dialog that uses a path edit, directory combo, and directory list control).
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.

Table 4-30 • Settings for a Selection Tree Control (cont.)

Setting	Project Type	Description
Text	Basic MSI, Merge Module	This setting contains the text that is used for screen readers. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting is enabled if Text is selected for the Control Style setting.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Text Area Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

A text area control displays text.

When you select a text area control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-31 • Settings for a Text Area Control

Setting	Project Type	Description
Name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Enter a name for this text area. The name must be unique among all of the controls in your project.
Base Text Style	Basic MSI, Merge Module	This font style is used for the text if you specify nothing for the Text Style setting.
Cancel	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Code Page	Basic MSI, Merge Module	If you want the control to use fonts from the code page that is defined in the installation's package, select Database. If you want the control to use fonts from the target system's default code page, select User's System.
Context Help	Basic MSI, Merge Module	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.

Table 4-31 • Settings for a Text Area Control (cont.)

Setting	Project Type	Description
Control Identifier	InstallScript, InstallScript MSI, InstallScript Object	This setting contains a numeric identifier for the control that is unique within the dialog. This identifier is the same as a resource identifier in Visual C++. You should not change the control identifiers for any of the controls that are included with a dialog by default.
Default	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Format as Bytes	Basic MSI, Merge Module	If you want the installation to attempt to display the value that is entered in the Text setting in bytes, select True. If you select True, the Text setting must contain only a number, without the unit. Then, at run time, it is divided by 512 and displayed as the correct number of kilobytes, megabytes, or gigabytes, depending on the size.
Height	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the height of the control in dialog units.
Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Other Window Styles	InstallScript, InstallScript MSI, InstallScript Object	Click the ellipsis button (...) to display the Other Window Styles dialog box.

Table 4-31 • Settings for a Text Area Control (cont.)

Setting	Project Type	Description
No Prefix	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If the Text setting contains an ampersand that should be displayed as an ampersand character (&), select True. If you are using the ampersand in the Text setting to indicate that the letter that follows the ampersand should be underlined (for example, `&Click` would be displayed as Click), select False.
No Text Wrap	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether you want to allow the text to wrap in this control. If you select True and the text expands beyond the width of the text area, the end of the string is cut off and replaced with an ellipsis button (...). Otherwise, the text wraps and can extend beyond the height of the text area, if it is not long enough.
Property	Basic MSI, Merge Module	Enter the name of a property that can supply the initial value for the text. This property can be unique to this control; it does not need to be present in the Property Manager view.
Right-Aligned	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Sunken	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.

Table 4-31 • Settings for a Text Area Control (cont.)

Setting	Project Type	Description
Tab Stop	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	This setting contains the text that is shown inside the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Basic MSI, Merge Module	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting is enabled if Text is selected for the Control Style setting.
Tooltip	Basic MSI, Merge Module	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Transparent	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	If you want the background to show through this control, select True. Note that you may want to avoid making this control transparent if you are placing it on top of a colored bitmap. The text may not be visible if end users change the color scheme of their display. For example, the text in this control may become invisible if an end user sets the high-contrast parameter for accessibility reasons.

Table 4-31 • Settings for a Text Area Control (cont.)

Setting	Project Type	Description
Visible	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	For Basic MSI and Merge Module projects: Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font). For InstallScript, InstallScript MSI, and InstallScript Object projects: Specify the width of the control in dialog units.

Volume Cost List Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

A volume cost list control displays the disk space requirements that are associated with each volume or drive.

The list has five possible columns. The headings for each column are configurable in the **UIText** table, which you can access in the Direct Editor view. The **UIText** table identifies the values of string entries so that localized strings are displayed at run time when appropriate. Following is a list of the keys in the **UIText** table for each column, along with their default English values:

- VolumeCostVolume—Volume
- VolumeCostSize—Disk Size
- VolumeCostAvailable—Available
- VolumeCostRequired—Required
- VolumeCostDifference—Differences

When you select a volume list cost control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-32 • Settings for a Volume Cost List Control

Setting	Description
Name	Enter a name for this volume cost list. The name must be unique among all of the controls in your project.

Table 4-32 • Settings for a Volume Cost List Control (cont.)

Setting	Description
Available Col Width	Specify the default width in installer units (1/12 of the height of the system font) for the Available column. This column is hidden if the value is the number 0 or it is left blank.
Base Text Style	This font style is used for the contents of the volume cost list if you specify nothing for the Text Style setting.
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Differences Col Width	Specify the default width in installer units (1/12 of the height of the system font) for the Differences column. This column is hidden if the value is the number 0 or it is left blank.
Disk Size Col Width	Specify the default width in installer units (1/12 of the height of the system font) for the Disk Size column. This column is hidden if the value is the number 0 or it is left blank.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.

Table 4-32 • Settings for a Volume Cost List Control (cont.)

Setting	Description
Required Col Width	Specify the default width in installer units (1/12 of the height of the system font) for the Required column. This column is hidden if the value is the number 0 or it is left blank.
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Show CD-ROM	To include CD-ROM volumes in the control, select True.
Show Fixed	To include hard drives in the control, select True.
Show Floppy	To include floppy drives in the control, select True.
Show RAMDisk	To include RAM volumes in the control, select True.
Show Remote	To include mapped network drives in the control, select True.
Show Removable	To include removable drives in the control, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	This setting contains the text that is used for the control's label. Although you cannot see the label, it is available for screen readers. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting is enabled if Text is selected for the Control Style setting.

Table 4-32 • Settings for a Volume Cost List Control (cont.)

Setting	Description
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Volume Col Width	Specify the default width in installer units (1/12 of the height of the system font) for the Volume column. This column is hidden if the value is the number 0 or it is left blank.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Volume Select Combo Control

Project • *This information applies to the following project types:*

- *Basic MSI*
- *Merge Module*

A volume select combo control enables the end user to select from an alphabetical list of volumes, or drives.

When you select a volume select combo control in a dialog of the Dialogs view, InstallShield displays the following settings in the right pane.

Table 4-33 • Settings for a Volume Select Combo Control

Setting	Description
Name	Enter a name for this volume select combo. The name must be unique among all of the controls in your project.
Base Text Style	This font style is used for the control's text if you specify nothing for the Text Style setting.

Table 4-33 • Settings for a Volume Select Combo Control (cont.)

Setting	Description
Cancel	If this is the only control on the dialog that will dismiss the dialog, select True. Clicking the cancel control has the same effect as pressing the ESC key or clicking the Close button on the title bar. The Cancel or Finish button is usually the cancel control. This value is ignored if True is selected for the ErrorDialog setting of the dialog that contains this control.
Context Help	This setting is reserved for future use. Windows Installer does not currently support launching context-sensitive help topics from the installation.
Default	If this is the only control on the dialog that you want to be the default control, which means that it is activated when the end user presses the ENTER key, select True. The Next or OK button is usually the default control.
Enabled	Indicate whether the control is enabled. True means that this control is available (the end user can interact with it). False means that it is not available (grayed out).
Height	Specify the height of the control in Windows Installer user interface units (1/12 of the height of the system font).
Indirect Property	If the property that is associated with this control is referenced indirectly, select True; otherwise, select False. When True is selected for an indirect property is set to True, Windows Installer resolves the referenced property at run time. For example, this check box might use the property **_BROWSE**, whose value is INSTALLDIR. If you select True for the Indirect Property setting, the value of **_BROWSE** will be the current value of the **INSTALLDIR** property. If you select False for the Indirect Property setting, the value of _BROWSE will contain the string INSTALLDIR.
Left	Specify the distance from the left edge of the dialog to the start of the control in installer units (1/12 of the height of the system font).
Left Scrollbar	If you want the arrow and vertical scrollbar to be displayed on the left side of the control, select True. This option should be selected only when True is selected for the Right-to-Left setting.
Property	Enter the name of a property that is set when an end user selects a value from this control. This control populates the first part of the path that is displayed in the directory list, so you must use the same property for the volume select combo, the directory list, and path edit when using them together in a browse dialog. This property can be unique to this control; it does not need to be present in the Property Manager view. To set a default value for this control, make sure the property is a public property by giving it a name that contains only uppercase letters, use the Property Manager view to add the public property, and then assign to it the value of the default selection.

Table 4-33 • Settings for a Volume Select Combo Control (cont.)

Setting	Description
Right-Aligned	The default value of False aligns the text to the left of the control. Set it to True to align the text to the right.
Right-to-Left	For English and other languages that are written from left to right, select False. For Hebrew and those languages that are read from right to left, select True.
Show CD-ROM	To include CD-ROM volumes in the control, select True.
Show Fixed	To include hard drives in the control, select True.
Show Floppy	To include floppy drives in the control, select True.
Show RAMDisk	To include RAM volumes in the control, select True.
Show Remote	To include mapped network drives in the control, select True.
Show Removable	To include removable drives in the control, select True.
Sunken	To give the control's edges a recessed, three-dimensional appearance, select True. To use the default visual style for the control, select False.
Tab Index	Assign an integer that—along with the other controls on this dialog but excluding controls such as static text—specifies the order in which each control on the dialog receives focus when the end user presses the TAB key. The lowest tab index that you can use is the number 0.
Tab Stop	Indicate whether this control receives focus within the tab order. True indicates that the control receives focus; False indicates that the control does not receive focus.
Text	This setting contains the text that is used in the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Text Style	Select the font style, size, and color (if available) in which you want the control's label to be displayed. Leaving the value as <Default> displays the font that is contained in the **DefaultUIFont** property. This setting is enabled if Text is selected for the Control Style setting.

Table 4-33 • Settings for a Volume Select Combo Control (cont.)

Setting	Description
Tooltip	Enter the text that you want to be displayed when the end user places the mouse pointer over the control. When you type a value for this setting, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield.
Top	Specify the distance from the top of the dialog to the top of the control in installer units (1/12 of the height of the system font).
Visible	True means that the control is visible, and False means that it is hidden. You can also make the control visible by editing its condition in the Behavior area for the dialog.
Width	Specify the width of the control in Windows Installer user interface units (1/12 of the height of the system font).

Copying and Pasting Controls

In the Dialog Editor, you can copy and paste controls within a dialog or from one dialog to another by using standard Windows keyboard shortcuts or context menus.

Task: ***To copy a push button from one dialog to another:***

1. Open the layout for the dialog that contains the button you want to copy.
2. Select the push button and press CTRL+C.
3. Open the second dialog in the Dialog Editor and press CTRL+V to paste the control in the dialog.

The push button is pasted with the same relative size and position as the original. Its other properties are also identical to the original's. The copy of the push button is given a unique name based on the type of control it is. However, you must edit the new control's behavior, since that information is not copied over (Basic MSI projects).

Note • *Radio button groups are a special case. When you copy the group, all of its radio buttons are copied for you. You cannot copy a radio button by itself.*

Cutting and Pasting Controls

In the Dialog Editor, you can move a control from one dialog to another by using standard Windows keyboard shortcuts or context menus.

Task: ***To cut a control from one dialog and paste in another:***

1. Right-click the control and click **Cut**, or press CTRL+X. A **Delete Control** dialog box opens to inform you that deleting the control also deletes any associated conditions and actions.
2. Click **Yes** to continue cutting the control from the current dialog.
3. Open the second dialog in the Dialog Editor and press CTRL+V to paste the control in the dialog.

When you are done pasting the control into the new location, specify the control's properties and behavior.

Working with the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

This section of the documentation covers aspects of working with the wizard interface of Advanced UI and Suite/Advanced UI projects. The elements of the wizard interface consist of wizard pages and secondary windows (also known as pop-up windows). InstallShield lets you define and customize various styles to make formatting the wizard interface efficient. InstallShield also lets you add, modify, and delete wizard pages and secondary windows, and schedule when each should be displayed.

Using Styles to Customize the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you define and customize various user interface–related styles to easily change the look and feel of the wizard interface without requiring you to manually edit each user interface element individually. Using styles helps to ensure that the wizard interface is formatted consistently throughout the installation.

Wizard Interface Basics

The following two screen shots show the basic elements of the wizard interface.

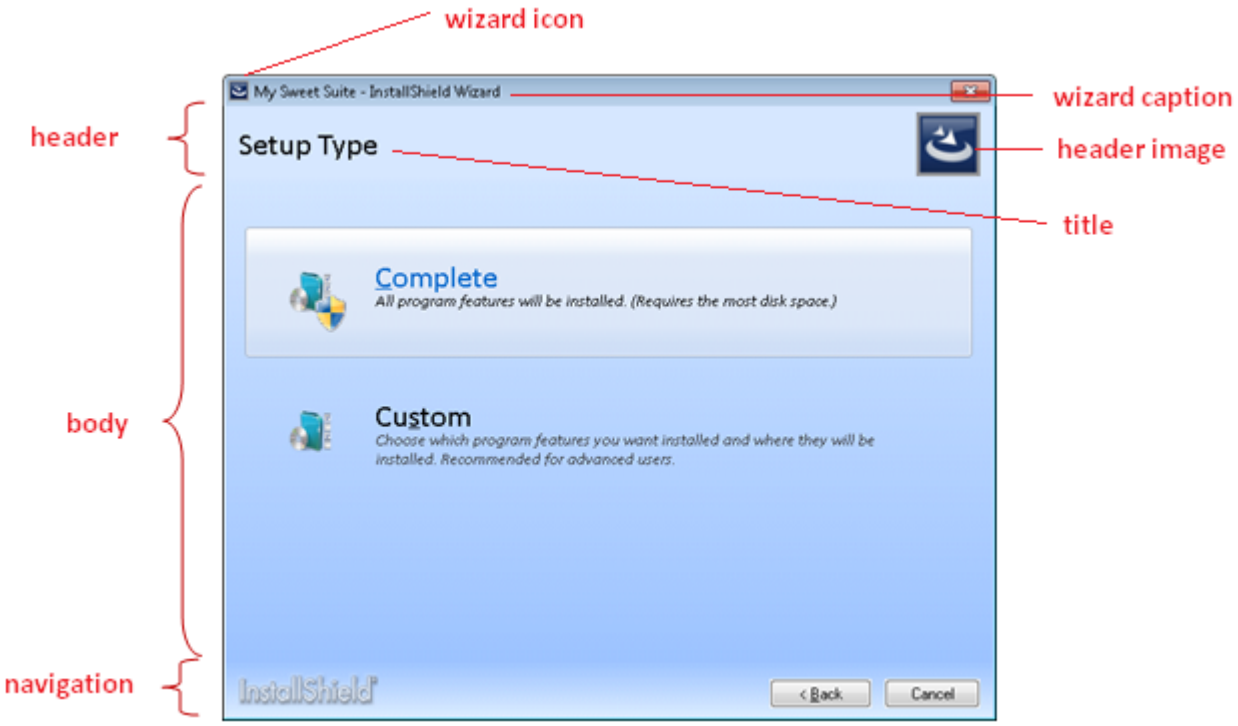

Figure 4-26: Sample Wizard Page in an Advanced UI or Suite/Advanced UI Installation

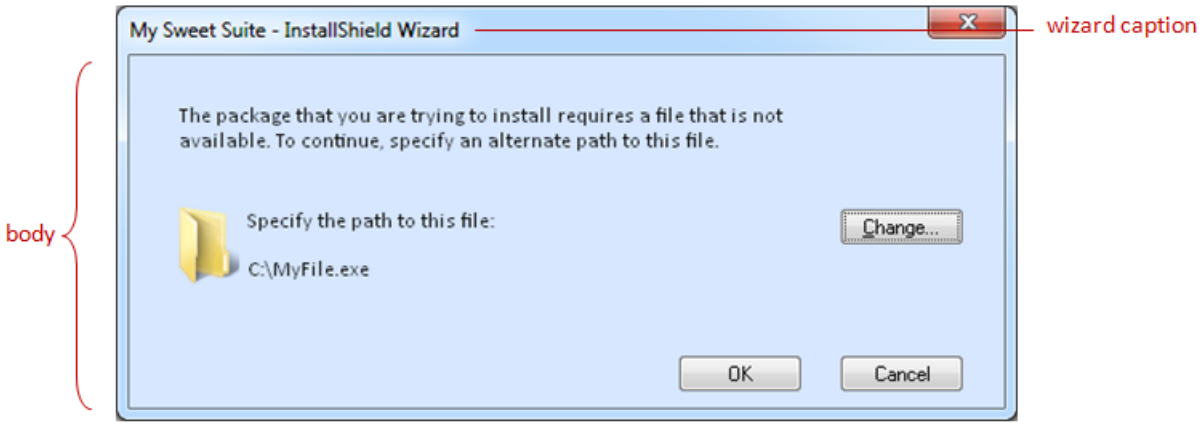

Figure 4-27: Sample Secondary Window in an Advanced UI and Suite/Advanced UI Installation

InstallShield lets you use your own wizard icon, header image, and wizard caption. InstallShield also lets you define and customize styles for the header, body, and navigation areas of the user interface of an Advanced UI or Suite/Advanced UI project.

Wizard Interface Styles

InstallShield contains a number of built-in text styles that define text attributes such as color, size, and font name for the text on the wizard UI. In addition, InstallShield contains one font set, which is a collection of fonts (including attributes such as font name, size, and weight). For each font in a font set, you can specify to which language the font is applicable. This enables you to select a different font for each language that your project supports. Font sets work in conjunction with text styles. Text styles reference a font set but can optionally override various font attributes that are defined at the font set level.

InstallShield also contains several built-in brush styles. A brush style specifies a solid color, a gradient, or an image for various elements of the wizard interface, such as the background of wizard pages and controls. You can edit any of the settings for these built-in styles, or define your own styles, through the Wizard Interface view in your Advanced UI or Suite/Advanced UI project.

The Wizard Pages node in the Wizard Interface view lets you select default project-wide text styles and brush styles; this view also lets you override the default values for the wizard caption, wizard icon, and header image.

Use page-specific and control-specific settings such as the Body Background setting that is available for specific wizard pages, secondary windows, and wizard controls if you want to override a specific use of a style. For example, the Body Background setting for the InstallationWelcome wizard page lets you override the project's default background on just the InstallationWelcome wizard page.

Defining a Custom Style for the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you add custom font sets, text styles, and brush styles to your project and then apply those styles to various wizard interface elements.

Task: ***To define a custom style:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, right-click **Styles** and then click **Add Font Set**, **Add Text Style**, or **Add Brush Style**. InstallShield adds a a new style under **Styles**. Rename the style as needed.
3. Select the style and then configure its settings in the right pane.

Once you have added a font set, you can select it for the Font List setting of any of the text styles that are defined in the Wizard Interface view. If you later want to change the list of fonts that are used for text styles that are based on that font set, select the font set and edit its settings.

Once you have added a text style or a brush style, you can select it for various style-related settings in the Wizard Interface view. If you later want to change the appearance of the wizard interface elements that use that style, select the style and edit the values for its settings.

Changes that you make to a style affect all of the wizard interface elements that use that style.

Selecting the Format for the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you select from several different wizard formats for your installation's wizard interface:

- **Glass**—The installation uses user-chosen system colors to display the caption bar, header, and navigation areas of the wizard interface. It also uses the glass effect (translucency) that was introduced in Windows Vista for these same areas of the wizard interface. Note that with this format, the installation ignores any brush styles that you have defined for the caption bar, header, and navigation areas of your wizard interface.

  Note that some operating systems do not fully support this format. Thus, in some cases, the installation may use the Wizard 97 format instead of the Glass format.

  This is the default option.

- **Aero**—This format typically has the same look and feel as the Glass format.

  Note that some operating systems do not fully support this format. Thus, in some cases, the installation may use the Wizard 97 format instead of the Aero format.

- **Wizard 97**—This format is the traditional wizard format. The installation uses the brush styles that you have defined for the various areas of your wizard interface.
- **Wizard Lite**—This format is similar to the Wizard 97 format, except that it does not include a header (the area that shows the title, plus sometimes an image near the upper corner of the wizard page). The installation uses the brush styles that you have defined for the other areas of your wizard interface.

Note that in some scenarios, an installation uses the Wizard 97 format instead of the Glass or Aero formats:

- Windows 8 and Windows Server 2012 systems do not have translucency support. On these systems, a Glass-formatted wizard interface uses the Wizard 97 format. However, an Aero-formatted wizard interface uses Aero, but without the glass effect.
- Windows 7, Windows Vista, Windows Server 2008 R2, and Windows Server 2008 have translucency support that end users can enable or disable. On these systems, Glass-formatted wizard interfaces and Aero-formatted wizard interfaces use the Wizard 97 format if translucency is disabled. These wizard interfaces also use the Wizard 97 format if the desktop composition feature on the target system is disabled.
- On Windows XP and Windows Server 2003, Glass-formatted wizard interfaces and Aero-formatted wizard interfaces use the Wizard 97 format.

Note that the wizard interface editor in the Wizard Interface view in InstallShield does not use the Glass format or the Aero format to show editable previews of the interface. If you select either of these formats for your Advanced UI or Suite/Advanced UI project, the wizard interface editor uses the Wizard 97 format to show editable previews.

Task: ***To select the format that you want to use for wizard pages in your wizard interface:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, click **Wizard Pages**.
3. In the right pane, find the **Wizard Format** setting and select the appropriate option.

Creating a New Blank Wizard Page in an Advanced UI or Suite/Advanced UI Project

Project *• This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition *• The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield enables you to add a new blank wizard page to your project.

Task: ***To create a new blank wizard page in an Advanced UI or Suite/Advanced UI project:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, right-click **Styles** and then click **Add Text Style** or **Add Brush Style**. InstallShield adds a a new style under **Styles**. Rename the style as needed.
3. Select the style and then configure its settings in the right pane.

Once you have added a wizard page, you can configure its settings in the right pane. Use the center pane to preview it and controls to it.

Adding a Predefined Wizard Page in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield enables you to add various predefined wizard pages to your Advanced UI or Suite/Advanced UI project. Examples include:

- A page that allows end users choose the installation directory for an .msi package
- A page that lets end users enter customer information and serial numbers
- A page that shows a feature tree, as well as feature descriptions and sizes, and allows end users to select which features to install

Task: ***To add a predefined wizard page in an Advanced UI or Suite/Advanced UI project:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, right-click **Wizard Pages** and then click **Add Predefined Page**. The **User Interface Wizard** opens.
3. Complete the panels in the wizard as needed.

InstallShield adds the new predefined page to your project. Configure its settings in the right pane, and use the center pane to preview it and modify its layout.

Note • *When you add the browse-for-installation-folder type of wizard page (called BrowseFolder) to your project, InstallShield adds a placeholder image control to it so that you can display a lock image on the page. Ensure that you either configure the control's Resource setting to indicate the file that you want to display with this control, or, to exclude an image, delete the image control.*

Creating a New Blank Secondary Window in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield enables you to add a new blank secondary window to your project.

Task: ***To create a new blank secondary window in an Advanced UI or Suite/Advanced UI project:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, right-click **Secondary Windows** and then click **Add Blank Page**. InstallShield adds a new page at the end of the list of wizard pages.

Once you have added a wizard page, you can configure its settings in the right pane. Use the center pane to preview it and controls to it.

Editing the Layout and Behavior of a Wizard Page or Secondary Window

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Use the Wizard Interface view to edit the layout and behavior of wizard pages and secondary windows in your installation.

Specifying the Background for the Header, Body, and Navigation Areas of the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

By default, InstallShield enables you to use different brush styles for the header, body, and navigation areas of your wizard pages. In some cases, though, you may want to use only one brush style (for example, a single background image or a vertical gradient) that spans all three of those areas. The following instructions explain how to customize using three different brush styles or one brush style.

Tip • *For information on defining brush styles, see Defining a Custom Style for the Wizard Interface.*

Using Three Different Brush Styles for the Header, Body, and Navigation Areas

Task: ***To use three different brush styles for the header, body, and navigation areas:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, click **Wizard Pages**. The global wizard interface settings are available in the right pane.
3. In the **Default Body Background** setting, select the brush style that you want to use as the background for the body area of the wizard interface.
4. In the **Header Background** setting, select the brush style that you want to use as the background for the header area of the wizard interface.

5. In the **Navigation Background** setting, select the brush style that you want to use as the background for the navigation area of the wizard interface.

Important • *Note that if you select a brush style in the aforementioned background settings, you should delete any value in the Full Wizard Background setting. The wizard interface supports use of a single brush style for the full wizard background, or separate brush styles for the header, body, and navigation areas; it does not support specification of brush styles for all four of those areas simultaneously.*

Using One Brush Style that Spans the Header, Body, and Navigation Areas

Task: ***To use a single brush style for the header, body, and navigation areas:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, click **Wizard Pages**. The global wizard interface settings are available in the right pane.
3. In the **Full Wizard Background** setting, select the brush style that you want to use as the background for the navigation, body, and navigation areas of the wizard interface.

Important • *Note that if you select a brush style in the aforementioned setting, you should delete any values from the other background settings: Default Body Background, Header Background, and Navigation Background. The wizard interface supports use of a single brush style for the full wizard background, or separate brush styles for the header, body, and navigation areas; it does not support specification of brush styles for all four of those areas simultaneously.*

Adding a Control to a Wizard Page or Secondary Window

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

If you select a wizard page or secondary window in the Wizard Interface view, the toolbar that InstallShield shows directly above the wizard interface preview pane includes several different buttons and other controls that let you add new controls.

Task: ***To add a control to the wizard interface:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, click the wizard page or secondary window that you want to modify. The wizard editor in the center pane shows the page or secondary window.
3. In the toolbar above the wizard interface preview pane, click the appropriate New Control button (the Label, Text Box, Button, or **Combo Box** button), or select one of the control types that are listed in the drop-down list next to the control buttons. For information about each of the available types of controls, see Wizard Interface View Toolbar.

   InstallShield adds the control near the upper-left corner of the body area of the page or secondary window. In addition, InstallShield adds a subnode for the control under the selected wizard page or window.
4. Place the cursor in the middle of the control, and then drag it to move it to the appropriate location.
5. In the right pane, configure the control's settings.

Tip • *The order in which the controls are listed under the a wizard page's node matches the tab order.*

If you are using more than one group of radio button controls on a page, ensure that the Style setting includes WS_GROUP for the first radio button of each group.

Changing the Tab Order of Controls on a Wizard Page or Secondary Window

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

In most cases, end users can use the TAB key to move the focus from one control on a wizard page or window to another. By default, the tab order is the order in which the controls were added to the wizard page or window.

Task: ***To change the tab order of the controls on a wizard page or window:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, expand the node of the wizard page or secondary window whose tab order you want to modify.

   Each control on the page or window has its own subnode. The controls are listed in tab order. That is, the first control under a page node is the first control that receives focus on that page.
3. Right-click the control that you want to resequence in the tab order, and then click **Move Up** or **Move Down**.
4. Continue moving the controls as needed until the order that the controls are listed under the page reflects the appropriate tab order.

Note that in some cases, a control may not be included in the tab order. For example, a disabled control would not receive focus as an end user tabs from one control to another control.

Using Navigation Buttons on Wizard Pages

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Each wizard page in an Advanced UI or Suite/Advanced UI project can have one or more of the following built-in navigation buttons:

Table 4-34 • Built-In Navigation Buttons for Wizard Pages

Button	Description of Default Behavior
Next	Move to the next wizard page in the interface, skipping any pages whose Visible conditions evaluate to false. Clicking this button has no effect if the current wizard page is the last page in the interface. The Next navigation button behaves similarly to controls that use a Set Active Page action, which triggers a move to a specific page.

Table 4-34 • Built-In Navigation Buttons for Wizard Pages (cont.)

Button	Description of Default Behavior
Back	Move to the previous wizard page in the interface, skipping any pages whose Visible conditions evaluate to false. Clicking this button has no effect if the current wizard page is the first page in the interface. The Back navigation button behaves similarly to controls that use a Set Active Page action, which triggers a move to a specific page.
Cancel	Display a message box with question IDS_SUITE_CONFIRMCANCEL; on Yes, cancel the wizard and move to the last wizard page. In most cases, the last wizard page should not show a Cancel button, since cancelling the installation at that point does not have any effect. If a Cancel button is displayed, clicking it would result in closing the wizard.
Install	Start the installation and move to the next wizard page. The Install navigation button behaves similarly to controls that use an Install action, which start the installation and then move to a specific wizard page.
Finish	After a successful installation or maintenance, if a restart is required, ask whether to restart (message IDS_SUITE_ASKREBOOT), and then trigger the appropriate response. In either case (required or not required, immediate restart or delayed restart), close the wizard.

Including a Navigation Button on or Excluding It from a Wizard Page

When you select a wizard page in the Wizard Interface view of an Advanced UI or Suite/Advanced UI project, the grid on the right side of the view shows the settings for the selected page. The Navigation area settings let you configure the navigation buttons for the page.

Task: ***To include or exclude a navigation button:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, click the wizard page whose buttons you want to modify.
3. In the **Navigation** area of the grid on the right side of the view, do the following:
   - To include a specific button on the wizard page, select **Yes** in that button's setting, and then configure the subsettings under that button's setting as needed.
   - To exclude a specific button from a wizard page, select **No** in that button's setting, and then configure the subsettings under that button's setting as needed.

To learn about changing the default behavior of navigation buttons, see Overriding the Default Behavior of a Navigation Button on a Wizard Page.

Overriding the Default Behavior of a Navigation Button on a Wizard Page

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

If the Click event of a navigation button includes either a Set Active Page action or an Install action, and if that action moves through the wizard interface, this prevents the default behavior described above. The default behavior is prevented even if the scheduled action is skipped because of a false condition for the action.

For example, you may want to override the default behavior for the Install button: instead of moving to the next wizard page in the interface, you may want the installation to proceed to a specific wizard page. In this scenario, you must add an Install action to the Install button's Click setting, and specify the specific subsequent page. If you then add a condition to the action, and the condition prevents the Install action from running, the default behavior for the Install button is suppressed. That is, the installation does not start when the end user clicks the Install button. (Note that in this case, you may want to define a condition for the navigation button's Enabled setting to ensure that the Install button is disabled if appropriate. Otherwise, end users may become confused when they are able to click an Install button that has no effect.)

Note that extension DLLs actions cannot prevent the default action except by actually calling the corresponding methods on the ISuiteUIExtension interface. The Advanced UI or Suite/Advanced UI engine cannot determine whether the extension chose to call the method. If you need an extension action to override the default behavior, but only navigate or install under certain conditions, add a Set Active Page or Install action with a false condition such as the empty None group.

Populating Combo Box and List Box Controls in the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you add to the wizard interface one or more combo box controls and list box controls with predefined selectable options. The process involves configuring the control's settings to define the content for the selectable options. The process also involves the use of two properties: one that defines the list of options that you want to display in the control, and one that the installation uses to store the option that the end user selects at run time.

Task: ***To populate a combo box control or a list box control with predefined options:***

1. Create a property that defines the list of options that you want to display in the combo box control or the list box control:
   a. In the View List under **Behavior and Logic**, click **Property Manager**.
   b. In the toolbar above the property grid, click the **New Property** button. InstallShield adds a new row to the bottom of the grid.
   c. In the **Name** column, enter a name for the new property—for example, **CONTROLOPTIONS**.
   d. In the **Value** column, enter the options that you want to list in the combo box control or the list box control, as well as the values to which they correspond. Use the following format:

      ID_Option1\r*Value1*\n*ID_Option2*\r*Value2*\n*ID_Option3*\r*Value3*

      For more information on how to set this property value, see the Using the Proper Syntax for Identifying the Control Options Through a Property Value section below.
2. In the View List under **User Interface**, click **Wizard Interface**.
3. In the **Wizard Interface** explorer, expand the wizard page or secondary window that you want to modify, and then select the combo box control or list box control that you want to configure.
4. In the **Property** setting, enter the name of the Advanced UI or Suite/Advanced UI property—for example, **SELECTIONPROPERTY**—that you want to associate with the control. At run time, the installation uses this property to store the value that the end user selects.
5. In the **Content Property** setting, select the name of the Advanced UI or Suite/Advanced UI property that identifies the options that you want to list in this control. (That is, enter the name of the property that you created in step 1—for example, **CONTROLOPTIONS**.)

Using the Proper Syntax for Identifying the Control Options Through a Property Value

In the first step in the aforementioned procedure, it is necessary to create a new Advanced UI or Suite/Advanced UI property, and to set its value to the options that you want to be listed in the combo box control or the list box control. It is also necessary to associate each option with a corresponding value. The following format is used:

ID_Option1\r*Value1*\n*ID_Option2*\r*Value2*\n*ID_Option3*\r*Value3*

ID_Option1 corresponds with *Value1*, *ID_Option2* corresponds with *Value2*, and *ID_Option3* corresponds with *Value3*.

ID_Option1, *ID_Option2*, and *ID_Option3* represent string identifiers that are defined in the String Editor view. The strings that are associated with those string identifiers indicate the selectable options that you want to be displayed in the control; the order in which you specify these options is the same order that the installation uses to list the options in the control at run time.

\r is the separator between the name of each selectable option and the corresponding property value that you want to associate with it.

Value1, *Value2*, and *Value3* are the possible property values that you want to be stored in **SELECTIONPROPERTY**—the property that you entered in step 4.

Thus, if the end user selects **ID_Option2** in the control, the installation sets the value of **SELECTIONPROPERTY** as **Value2**.

\n is the separator between a value and the next selectable option.

Note that there are no spaces before or after the separators (\r or \n).

Tip *• If you want to specify the default option for a combo box control or a list box control, use the Property Manager view to set the value of the Advanced UI or Suite/Advanced UI property equal to the property value that corresponds with the default selectable option. Thus, if you want ID_Option3 to be selected by default, add the* ***SELECTIONPROPERTY*** *property to the Property Manager view, and set its value to Value3. To leave the control blank by default, do not define the property in the Property Manager view.*

Working with End-User Data from a Combo Box Control or a List Box Control

At run time, end users can make a single selection from the combo box or the list box; this sets the control's property (which is **SELECTIONPROPERTY** in the aforementioned procedure) to the value that is associated with the selected option—for example, *Value1*, *Value2*, or *Value3*. You can trigger different types of behavior based on the value of the **SELECTIONPROPERTY** property. Examples are:

- You can enable or disable a control on the wizard page or secondary window. To do this, use the control's Enabled setting to define a Property type of condition and tie the enabled state of the control to a particular value of the property.
- You can display or hide a particular control on a wizard page or secondary window. To do this, use the control's Visible setting to define a Property type of condition and tie the enabled state of the control to a particular value of the property.
- You can display or skip a particular wizard page or secondary window. To do this, use the wizard page's or secondary window's Visible setting to define a Property type of condition and tie the enabled state of the wizard interface to a particular value of the property.
- You can use the value of the Advanced UI or Suite/Advanced UI property to set a particular property in a package in the Advanced UI or Suite/Advanced UI installation. To do this, use the command line and silent command line settings that are available as subsettings in the Operation area of the grid in the Packages view. For more information, see Using Advanced UI and Suite/Advanced UI Properties to Dynamically Configure Command Lines.

Configuring Validation for a Control on a Wizard Page or Window

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you implement validation for some of the various wizard interface controls. For example:

- You can ensure that end users enter a serial number in a text box in a specified format.
- You can configure validation for a text box control to check whether the folder an end user specifies in the text box is valid.
- You can prevent end users from selecting certain combinations of check boxes that do not work together.

Validation for a control checks the property that is associated with that control. When an end user clicks a check box, for example, the associated property is potentially changed to one of two new values. Validation offers a method for checking whether the new value is appropriate.

Various types of controls trigger validation at different events:

Table 4-35 • Triggers for Different Types of Validation

Types of Controls	Event that Triggers Validation
Text box, **password box**	Validation occurs when the entry in the control changes.
Button, **command link,** **check box,** **radio button,** **image button**	Validation occurs when the end user clicks the control.
Combo box, **list box,** **checked list box,** **feature selection tree**	Validation occurs when the selection for the control changes.

You can use the subsettings under the Text Style setting to specify different text styles for the control to give end users a visual indication when the control is in various states (default, valid, or invalid).

You can also use the subsettings in the Events area to trigger an action when the end user clicks or uses the control. If you have actions and validation configured for a control, the validation runs before the actions. For more information about actions, see Configuring an Action for a Control on a Wizard Page or Window.

Task: ***To configure validation for a control:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, select the wizard page or secondary window that you want to modify.
3. In the wizard editor, select the control that requires validation.
4. In the **Validate** setting, click the **Validation** button and then point to the type of validation that you want to occur.

   One of the types of validation lets you call a function in a DLL file that you have created. If your project includes any DLL files in the Support Files view, InstallShield makes them available in this list, and lets you overwrite the validation function name with the function in the DLL that you want to call.

The following table describes the types of validation that are available. Note that some types of validation are applicable to only certain types of controls. For example, the value length validation is applicable only to the text box and password box controls.

Table 4-36 • Types of Validation for Wizard Interface Controls

Type of Validation	Description
Existing File	This type of validation checks whether the value of the property that is associated with this control contains the fully qualified path and name of a file that is present. The end user typically sets the value of the property when entering the path and file name in this control. This type of validation calls a function in a DLL file that you have created and added to your project through the Support Files view. For example, you can use a DLL file to check the validity of the property's value—that is, the input that the end user enters for the control.
Existing Folder	This type of validation checks whether the value of the property that is associated with this control contains the fully qualified path and name of a folder that is present. The end user typically sets the value of the property when entering the path and folder name in this control.
New File in Existing Folder	This type of validation checks whether the value of the property that is associated with this control contains the fully qualified path and name of a file that is not present. The end user typically sets the value of the property when entering the path and file name in this control. Note that the path for the file must exist for this type of validation.

Table 4-36 • Types of Validation for Wizard Interface Controls (cont.)

Type of Validation	Description
Value Length	This type of validation checks whether the value of the property that is associated with this control contains a certain number of characters. The end user typically sets the value of the property when entering text in this control. To configure this type of validation, specify the minimum and maximum values in the subsettings under this setting.
Value Mask	This type of validation checks whether the value of the property that is associated with this control matches a particular format. The end user typically sets the value of the property when entering information such as a serial number in this control. To configure this type of validation, specify the required format in the Pattern setting under this setting. Enter any of the following characters in place of a digit: `# % @` Enter any of the following characters in place of a character: `& ^ ? '` Any other characters that you enter must match exactly.
Browse for DLL Action	This type of validation calls a function in a DLL file that you have created and added to your project through the Support Files view. For example, you can use a DLL file to check the validity of the property's value—that is, the input that the end user enters for the control.

Configuring an Action for a Control on a Wizard Page or Window

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you define actions that an end user triggers when using some of the various wizard interface controls. For example, you can add a Print button to a LicenseAgreement wizard page, and define a print action for that button control; when an end user clicks the Print button, the Print dialog box opens, enabling the end user to print the license agreement.

If you have actions and validation configured for a control, the validation runs before the actions. The actions run for both validation success and validation failure. They also run when the splash page is dismissed, when an image button gets or loses focus, or when an end user scrolls to the bottom of a rich text box. For more information about validation, see Configuring Validation for a Control on a Wizard Page or Window.

Task: ***To configure an action for a control:***

1. In the View List under **User Interface**, click **Wizard Interface**.
2. In the **Wizard Interface** explorer, select the wizard page or secondary window that you want to modify.
3. Do one of the following:
   - To configure the action of one of the navigation controls (the Next, Back, Cancel, Install, or Finish buttons)—In the right pane, expand the settings for the control whose action you want to modify.
   - To configure the action of any of the other controls—In the wizard editor, select the control whose action you want to modify.
4. In the **Click** setting, or in an action-related setting under the **Events** setting, point to the **New Action** button, and then click the type of action that you want to configure.
5. Configure the subsettings under the action as needed.

If you enter more than one action statement, the actions are run in the order in which they are listed in the action setting.

One of the types of actions lets you call a function in a DLL file that you have created. If your project includes any DLL files in the Support Files view, InstallShield makes them available in this list, and lets you overwrite the action function name with the function in the DLL that you want to call.

The following table describes the types of actions that are available.

Table 4-37 • Control Actions

Type of Action	Description
Set Property	This type of action sets a specific property to a specific value.
Install	This type of action starts the installation and moves to a specific wizard page.
Print	This type of action launches the Print dialog box, enabling an end user to print the specified file.
Open	This type of action opens a file or Web page.

Table 4-37 • Control Actions (cont.)

Type of Action	Description
Browse for Folder	This type of action launches the Browse for Folder dialog box when an end user clicks the control. The string of instructions that are displayed on this dialog box is typically the value of a string identifier. When the end user selects a folder in this dialog box and clicks the OK button, the dialog box closes, and the installation sets the value of a specific property to the full path of the folder that the end user selected. To configure this type of action, configure the subsettings under this action.
Browse for File	This type of action launches the Browse for Files or Folders dialog box when an end user clicks the control. The string of instructions that are displayed on this dialog box is typically the value of a string identifier. When the end user selects a file in this dialog box and clicks the OK button, the dialog box closes, and the installation sets the value of a specific property to the full path and file name of the file that the end user selected. To configure this type of action, configure the subsettings under this action.
Set Active Page	This type of action moves to a specific wizard page.
Show Window	This type of action shows a secondary window as a modal window.
Browse for DLL Action	This type of action calls a function in a DLL file that you have created and added to your project through the Support Files view. For example, you can use a DLL file to trigger custom behavior.

Using Images, Text Files, and Other Objects in the Wizard Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Any images, text files (such as End-User License Agreements), and other files that you want to use in the wizard interface of your Advanced UI or Suite/Advanced UI project are included in your project as support files. Support files are files that are installed to the target system for use only during the installation process. These files are automatically removed from target system when the installation is complete.

If your project supports multiple languages, you can add language-specific support files to the appropriate language-specific areas of the Support Files view. At run time, the Advanced UI or Suite/Advanced UI installation displays the appropriate language-specific support files.

For more information, see Using Support Files.

Localizing the End-User Interface

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

InstallShield has many settings that let you specify text strings that should be displayed to end users. For example, when you enter a value for the Display Name and Description settings for a feature, you are configuring the feature name and description that may be displayed in the CustomSetup dialog at run time. Whenever you enter a value for such a setting that may need to be localized for one or more languages, InstallShield automatically creates a string entry for each language that your project supports. Each string entry consists of a language-independent identifier and a corresponding language-specific value. At run time, the installation displays the appropriate translated string values. Using string entries instead of hard-coded text enables you to keep the code for your installation completely separate from any language-specific strings that you may want to be displayed during the installation.

To help streamline the process of localizing a project, all of the text strings that may be displayed at run time during the installation process are available in one consolidated view: the String Editor view. You can use this view to edit the strings for everything from button text to feature descriptions. You can also use this view to export each language's string entries to a file, translate the values that are listed in the file, and then import the translated file into your project.

Working with String Entries in Projects that Support Multiple Languages

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Edition • *The Premier edition of InstallShield includes support for creating multilingual installations.*

Note • *To add additional languages to your project, use the Setup Language setting in the General Information view.*

Your project contains a string entry for every localizable text string and for each language that your project supports. The String Editor view shows the collection of language-independent identifiers and corresponding language-specific values for your project.

Note the following details about string entries in projects that include support for multiple languages:

- The values for all of the localizable settings throughout InstallShield—such as the Display Name and Description settings for a feature—use the project's default language (which you can specify in the String Editor view). If you edit the value of one of these localizable settings, InstallShield simultaneously updates the string entry's value in the String Editor view for the default language.

  Likewise, if you use the String Editor view to modify a string value for your project's default language, InstallShield simultaneously updates the settings in the other InstallShield views that display the value of that string entry.

- Each language that is supported by your project uses the same set of string identifiers.

  Therefore, if you add a string entry to a project, InstallShield uses the same string identifier for each language. If you rename a string identifier, InstallShield renames the string identifier for all languages. If you delete a string entry, InstallShield deletes it from each language.

- If you add a new language to your project, InstallShield adds to that language the same string identifiers that are available in the other languages that are in your project. For default string entries—that is, those that are available for the built-in dialogs and other user-interface elements—InstallShield adds the already-translated string values. For custom string entries that you have created, InstallShield uses the string values from the default language for the new language. You can modify any string values as needed for the new language.

When you finish authoring your project, you can export the string entries for each language to text files, and send the text files out for translation. Once the string entries in the text file are translated, you can import them into your project.

Using String Entries in InstallShield

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

Instead of hard-coding strings throughout your project, you can use string entries in areas of InstallShield that accept localizable text. The manner in which you select a string entry differs depending on where you need to use it.

Settings in Various Views

When you are entering the value of a setting in one of the views in InstallShield and that value is a text string that can be presented to end users, InstallShield automatically uses a string identifier for that setting. InstallShield places the string identifier in curly brackets before the string value. Following is an example of the value for the Display Name setting of a feature:

{ID_STRING24}My New Feature

In this example, **ID_STRING24** is the string identifier that is used for the Display Name setting. **My New Feature** is the string value for the project's default language.

Task: ***To work with a setting that accepts a localizable text string entry, do one of the following:***

- To enter a new text string that is not present anywhere else in the project, type the text string that you want to use. InstallShield automatically assigns a new string identifier to the value that you enter.

  If your project includes support for multiple languages, InstallShield adds the new string identifier to all of your project's languages, and uses the string value that you entered as the value for all languages.

- To look at a list of existing string entries that are used in the project, click the ellipsis button (...) that is displayed on the right when you click the setting's value. InstallShield opens the Select String dialog box, which lets you select an existing string entry or create a new string entry.

Caution • *Do not confuse editing an existing string value with entering a new string identifier by entering text in an InstallShield setting. Once you have selected a string identifier for a setting, deleting the localizable text in the setting merely deletes the current string value; it does not replace the current string identifier with a new one.*

Dialog Editor

Many of the controls in the Dialog Editor accept strings that are displayed to the end user. For example, the Text and Tooltip properties always require localizable text.

Using a string entry in the Dialog Editor is similar to selecting string identifiers in other areas of InstallShield.

Task: ***To work with the Dialog Editor and a control's property that uses localizable text, do one of the following:***

- Click the control's property sheet and edit the string. Doing so changes the value of the string entry for the current language. When you enter a text value without first selecting a string, InstallShield creates a new string identifier for your project.

  If your project includes support for multiple languages, InstallShield adds the new string identifier to all of your project's languages, and uses the string value that you entered as the value for all languages.

- When you click a localizable property's value to edit it, an ellipsis button (**...**) appears inside the property sheet. Click the ellipsis button to view the string entries for the current language.

The major difference between the dialog control properties and the settings in other views in InstallShield is that the other views always display the string value for the default language. When you edit a dialog's layout, however, you must first select the language of the dialog. Then, all strings displayed in the dialog and in the property sheet are from the current language of the dialog that you are editing.

InstallScript Script Editor Pane

If you are working in the InstallScript script editor pane in the InstallScript view, you can select and edit string entries through the Select String dialog box.

Task: ***To use a string identifier in your InstallScript:***

1. Place the cursor at the point in your script where you want the string identifier to be inserted.
2. On the **Edit** menu, point to **Insert** and click **String Entry**. The **Select String** dialog box opens.
3. Do one of the following:
   - To use an existing string entry, click the row that contains the string entry that you want to use in your script.
   - To create a new string entry, click the **New** button. The **String Entry** dialog box opens, enabling you to create a new string identifier and value.
4. Click **OK**.

InstallShield places the string identifier in your script preceded by the at (@) symbol.

For more information, see String Constant Operator (@).

Tip • *Although you can include hard-coded user-interface strings directly in InstallScript code, it is recommended that you avoid doing this. Strings that are hard coded in InstallScript code are not stored as Unicode; thus, they are displayed correctly only when the installation is run on systems that have the correct code page. Adding strings to a project through the String Editor view and referencing the associated string identifiers from InstallScript code eliminates this issue.*

What Happens with String Entries at Build Time and Run Time

InstallShield stores string entries in the **ISString** table of your InstallShield project file (.ism). At build time, InstallShield uses the string values instead of the string identifiers when it is creating your release in most cases. That is, the string identifiers are not built into the release, and the string identifiers are not available at run time.

The one exception of when InstallShield does use string identifiers in a build is if your project includes InstallScript code. In this scenario, the release that InstallShield builds includes string tables that contain all of the string entries. These string tables make it possible for you to use string identifiers in your InstallScript code instead of hard-coded text strings. At run time, the installation replaces string identifiers with string values as needed.

Adding a String Entry

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

The String Editor view lets you create a new string entry that you can later reference in one of the settings in InstallShield, in one of your project's dialogs, and in your InstallScript code.

Task: ***To add a new string entry to your project:***

1. In the View List under **User Interface**, click **String Editor**.
2. Do one of the following:
   - Click the **New String Entry** button.
   - Press the INSERT key.

   The **String Entry** dialog box opens.

3. In the **String Identifier** box, specify the language-independent string identifier that you want to use for your string entry, or leave the new default string identifier that InstallShield enters in this box for you.
4. In the **Value** box, specify the localizable text string that you want to use for the string entry.
5. In the **Comments** box, you can optionally specify an internal note about the string entry. The comments are not displayed at run time.
6. Click **OK**.

InstallShield adds a new row in the String Editor view for the new string entry.

Tip • *If your project includes support for multiple languages, InstallShield adds the string entry to all of your project's languages, and it uses the string value that you entered as the value for all languages. You can edit the string values for languages as needed.*

Note • *Since you must use a string identifier throughout InstallShield for settings that accept localizable text, InstallShield adds a new string entry to your project whenever you try typing a value into a setting without selecting an existing string identifier.*

Editing a String Entry

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

The String Editor view contains a spreadsheetlike table that lets you modify string entries in your project.

Task: ***To edit a string entry in the String Editor view:***

1. In the View List under **User Interface**, click **String Editor**.
2. Find the string entry that you want to modify.
3. Do one of the following:
   - To overwrite all of the text in a table cell, click the table cell and then type your new identifier, value, or comments.

- To place the cursor at a particular place within a table cell, double-click that place. Then type your change.

Note that if you rename a string identifier, InstallShield renames the string identifier for all languages in your project.

When you edit a string entry, InstallShield updates the Modified column with the date and time that you made the change. You can sort the string entries in the String Editor view by modified date. This is helpful if you want to identify which strings have been modified since the strings were last translated.

Tip • *If you are editing a localizable setting from within one of the other views in InstallShield, you can click the ellipsis button (...) in that setting. Doing so opens the Select String dialog box, which lets you specify which string entry you want to use for the selected setting.*

Project • *In Basic MSI, InstallScript MSI, and Merge Module projects, some of the string values contain Windows Installer properties inside square brackets—for example,* ***Install [ProductName]****. At run time, the property and brackets are replaced by the property value.*

String values may also contain font information in curly brackets—for example, ***{&MSSansBold8}OK****. The font information indicates style details that should be used to display the strings at run time.*

Searching for Instances of String Identifiers

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

String identifiers are used throughout InstallShield projects. If you want to see where a particular string identifier is used in your project, you can perform a search in the String Editor view.

Task: ***To find all the occurrences of a particular string identifier within your project:***

1. In the View List under **User Interface**, click **String Editor**.
2. Select the row that contains the string identifier for which you want to search.

To select multiple consecutive rows, click the first row, and then press SHIFT while clicking the last row. To select multiple nonconsecutive rows, click the first row, and then press CTRL while clicking each additional row.

3. Click the **Search for Selected Strings in Project** button.

InstallShield displays the search results on the Results tab in the Output window. The Results tab indicates how many times the string identifier is used. In addition, it indicates the location in the Direct Editor view where the string identifier is used.

If the string identifier is not used in the project, the Results tab shows that zero occurrences were found.

Note • *InstallShield does not search the project's InstallScript files (.rul) for instances of the string identifier.*

Finding and Replacing String Entries

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

The String Editor includes support for standard find-and-replace functionality. This functionality may be useful if you want to search for specific strings in your project and replace them with revised strings.

Finding Strings in the String Editor

Task: ***To find a string in the String Editor:***

1. In the View List under **User Interface**, click **String Editor**.
2. Click the **Find String** button. The **Find** dialog box opens.
3. In the **Find what** box, type the string that you want to find.
4. Select any other options that you want.
5. Click **Find Next**.

InstallShield finds the first instance of the string that you specified.

Finding and Replacing Strings in the String Editor

Task: ***To find and replace a string in the String Editor:***

1. In the View List under **User Interface**, click **String Editor**.
2. Click the **Find and Replace** button. The **Replace** dialog box opens.
3. In the **Find what** box, type the string that you want to replace.
4. In the **Replace with** box, type the new string.
5. Select any other options that you want.
6. Click **Find Next**, **Replace**, or **Replace All**.

InstallShield replaces strings as needed.

Removing a String Entry

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

If you no longer need a particular string entry in your project, you can delete it.

Note that if you delete a string entry, InstallShield deletes it from each language in your project.

Task: ***To remove a string entry from your project:***

1. In the View List under **User Interface**, click **String Editor**.
2. Find the string entry that you want to delete.
3. Click the **Delete Selected Strings** button or press DELETE.

Removing String Identifiers from Localizable Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

When you are entering the value of a setting in one of the views in InstallShield and that value is a text string that can be presented to end users, InstallShield automatically uses a string identifier for that setting. InstallShield places the string identifier in curly brackets before the string value.

If you try to delete the setting's value, you are actually deleting the string value for the current language. In that case, the string identifier with an empty value is used for the setting.

Therefore, if you want to remove a string identifier from a localizable setting, you must replace it with a different string identifier, or add a new string identifier.

For information on replacing a string identifier, see Editing a String Entry. To learn how to create a new string identifier, see Adding a String Entry.

Displaying Billboards

Project • *Billboards are available in the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

You can add billboards to your projects to display information to end users during the installation process. The billboards can be used to communicate, advertise, educate, and entertain end users. For example, billboards can present overviews on new features of the product being installed or other products from your company. Each billboard is a file that you or your company's graphics department creates for complete control over the look and feel of the file transfer.

Project • *Support for billboards differs, depending on which project type you are using. To learn more about billboards, see the appropriate section:*

- Displaying Billboards in Basic MSI Installations

- Displaying Billboards in InstallScript and InstallScript MSI Installations

Displaying Billboards in Basic MSI Installations

Project • *This information applies to Basic MSI projects.*

You can add billboards to your projects to display information to end users during the installation process. The billboards can be used to communicate, advertise, educate, and entertain end users. For example, billboards can present overviews on new features of the product being installed or other products from your company. Each billboard is a file that you or your company's graphics department creates for complete control over the look and feel of the file transfer.

Billboard File Types for Basic MSI Projects

Project • *This information applies to Basic MSI projects.*

InstallShield supports different types of files for billboards:

- Adobe Flash application file (.swf)
- Images (.bmp, .gif, .jpg, and .jpeg)

If a target system does not have the Adobe Flash Player, which is used to display Flash application files, the installation can detect that and display image billboards in place of the Flash billboard. Therefore, if you include a Flash billboard in your project, it is recommended that you also include one or more image billboards in your project.

Note • *You can add more than one image billboard to a project, but only one Adobe Flash application file billboard.*

Types of Billboards for Basic MSI Projects

Project • *This information applies to Basic MSI projects.*

InstallShield offers support for three different billboard styles. For example, with one style, the installation displays a full-screen background, with billboards in the foreground, and a small progress box in the lower-right corner of the screen. With another style, the installation displays a standard-size dialog that shows the billboards. The bottom of this dialog shows the progress bar.

Following are descriptions and sample screen shots of each type of billboard.

Fullscreen with Small Progress (Displayed in Lower Right)

For the **Fullscreen with Small progress (displayed in lower right)** type of billboard, when the installation displays the standard end-user dialogs, it also displays a full-screen background. During file transfer, the installation shows full-screen backgrounds, with billboards in the foreground, and a small progress box in the lower-right corner of the screen.

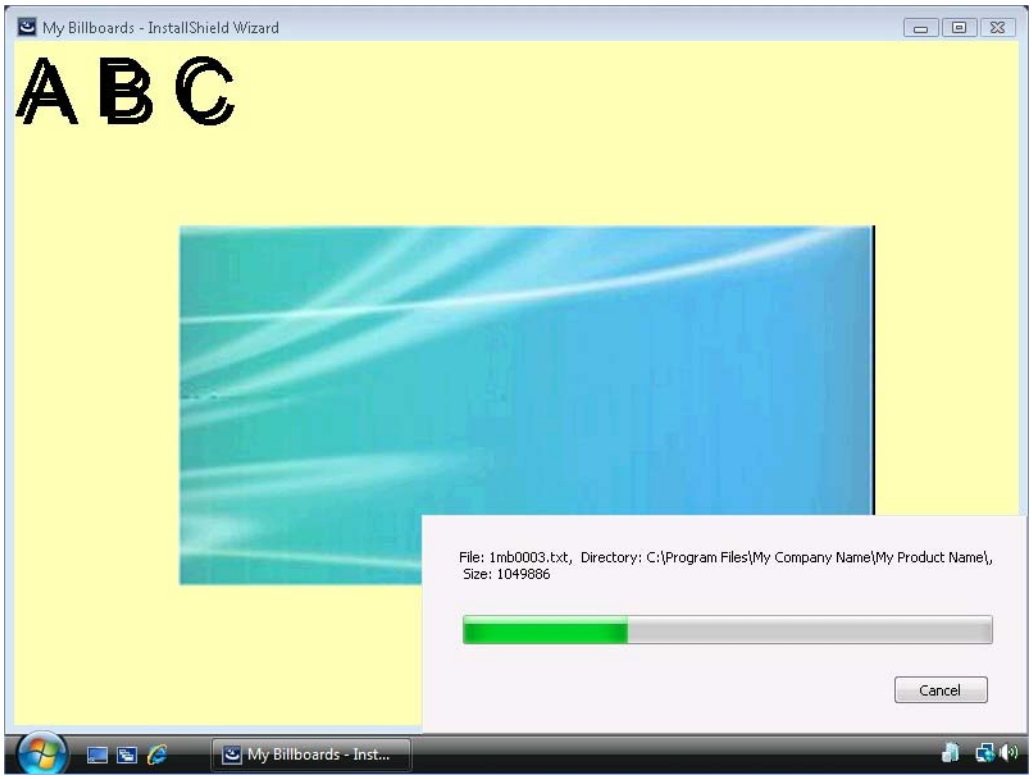

Figure 4-28: Fullscreen Billboard with Small Progress (Displayed in Lower Right)

In the sample screen shot, the billboard is the blue-green rectangle image in the center. Some of the configurable billboard settings were set as follows:

- Origin—Centered
- Title—A B C
- Font—48 pt. Arial
- Background Color—Yellow

Windowed with Standard Progress

For the **Windowed with Standard progress** type of billboard, during file transfer, the installation displays a standard-size dialog that shows the billboards. The bottom of this dialog shows the progress bar. The installation does not display a background for this style.

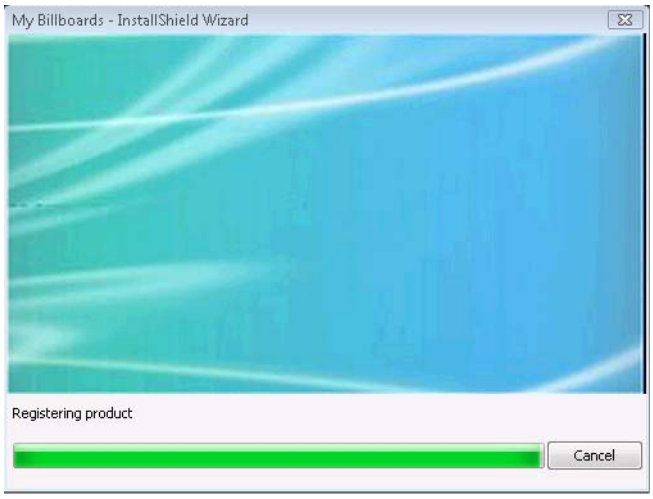

Figure 4-29: Windowed with Standard Progress

In the sample screen shot, the billboard is the blue-green rectangle image. Its size is 544 pixels wide by 281 pixels high.

Windowed with Small (Displayed in Lower Right, No Billboards)

For the **Windowed with Small (displayed in lower right, no billboards)** type of billboard, the installation displays a small progress box in the lower-right corner of the screen during file transfer. It does not display any billboards or a background.

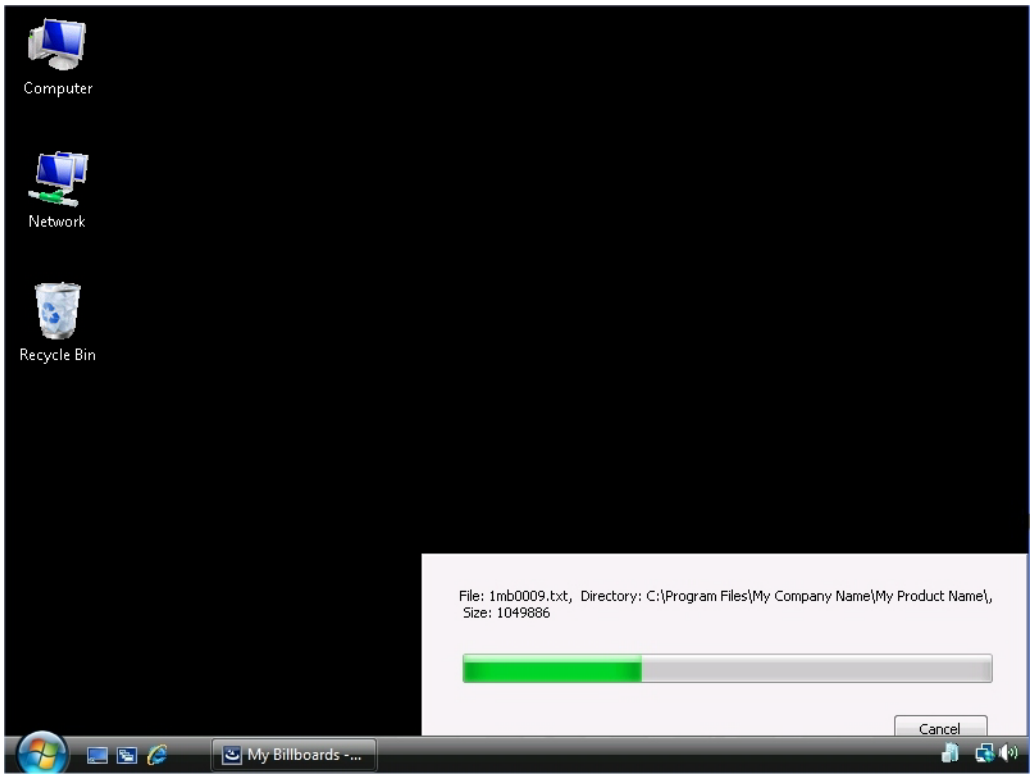

Figure 4-30: Windowed with Small (Displayed in Lower Right, No Billboards)

As shown in the sample screen shot, the progress bar is shown, but no billboard is displayed. The black background is the end user's desktop.

Specifying Which Type of Billboard to Use in a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

InstallShield offers support for different billboard styles.

Task: ***To specify which type of billboard you want to use in your installation:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the center pane, click the **Billboards** explorer. InstallShield displays the **Billboard Type** setting in the right pane.
3. In the **Billboard Type** setting, select the appropriate style of billboard.

To see samples of each type of billboard, see Types of Billboards for Basic MSI Projects.

Adding an Adobe Flash Application File Billboard to a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

InstallShield lets you display a Flash application file billboard during the file transfer process. Flash application files can consist of videos, movies, sounds, interactive interfaces, games, text, and more—anything that is supported by the .swf type of file. It is recommended that files such as Flash video files (.flv) and MP3 audio files be embedded in the .swf file so that they are available locally on the target system during file transfer. Although .swf files can reference external files that you can post on a Web site, this external implementation would require that end users have an Internet connection.

Task: ***To add an Adobe Flash Application File billboard to your installation project:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the **Billboards** explorer, right-click **Adobe Flash Application File (.swf)** and then click **New Billboard**. InstallShield adds a new billboard item with the name **NewBillboard1**.
3. Type a name for the billboard item. This name is used to help you identify the item while you are creating your installation; the name is not displayed during the installation.
4. In the right pane, configure the settings for the billboard.

Note • *If the version of Flash or other tool that you use to create your .swf file is newer than the version of the Flash Player that is installed on a target system, it is possible that some of the Flash features may not work as expected on that target system.*

If a target system does not have the Adobe Flash Player, which is used to display Flash application files, the installation can detect that and display image billboards in place of the Flash billboard. Therefore, if you include a Flash billboard in your project, it is recommended that you also include one or more image billboards in your project.

Adding Image Billboards to a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

You can choose to display only one image billboard during the file transfer process, or you can include a series of image billboards, each one designed to be displayed for a specific amount of time. InstallShield includes support for .bmp, .gif, .jpg, and .jpeg image files.

Note • *Animated .gif files are not supported. If you want to use animation in a billboard, consider using an Adobe Flash application file billboard.*

Task: ***To add an image billboard to your installation:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the **Billboards** explorer, right-click **Images** and then click **New Billboard**. InstallShield adds a new billboard item with the name **NewBillboard1**.
3. Type a name for the billboard item. This name is used to help you identify the item while you are creating your installation; the name is not displayed during the installation.
4. In the right pane, configure the settings for the billboard.

Configuring Billboard Settings in a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

When you add an Adobe Flash application file billboard or an image billboard to your project, you need to configure its settings.

Task: ***To configure a billboard's settings:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the **Billboards** explorer in the center pane, click the billboard that you want to configure. InstallShield displays the billboard settings in the right pane.
3. Configure the settings as required.

For information about each of the billboard settings, see Settings for Adobe Flash Application File Billboards and Image Billboards.

Previewing Billboards Without Building and Launching a Release

Project • *This information applies to Basic MSI projects.*

InstallShield lets you preview a billboard to see how it would be displayed at run time, without requiring you to build and run a release.

Previewing a billboard lets you see how your billboard will look with the background color, position, and related settings that are currently configured for your billboard.

Task: ***To preview a billboard:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the **Billboards** explorer in the center pane, right-click the billboard that you want to preview, and then click **Preview Billboard**.

InstallShield displays a preview of the billboard as it would be displayed at run time.

To stop previewing a billboard, click the Cancel button in the preview window.

Tip • *Previewing a billboard is especially helpful if you want to see how your Flash or image billboard will look with different selected billboard types. You can preview a billboard, change the billboard type, and then preview a billboard again.*

Setting the Billboard Order in a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

Image billboards are displayed in the order in which they are listed in the Billboards view, from top to bottom.

Task: ***To change the order in which image billboards are displayed at run time:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the **Billboards** explorer, right-click one of the billboard items that you want to move, and then click either **Move Up** or **Move Down**.

Repeat the last step until all of the billboards are correctly sorted.

Run-Time Behavior of a Basic MSI Installation that Includes Billboards

Project • *This information applies to Basic MSI projects.*

Important • *If your installation includes billboards, your installation must include a `Setup.exe` setup launcher. The setup launcher is required because it displays the billboards at run time. The Setup.exe tab for a release in the*

Releases view is where you specify information such as whether you want to use a setup launcher. To learn more, see Setup.exe Tab for a Release.

If your installation includes a Flash billboard and one or more image billboards, only one billboard type is displayed at run time during the file transfer process: the Flash billboard or the image billboards.

- If the Flash Player is present on the target system, the installation displays the Flash billboard.
- If the Flash Player is not present, the installation displays the image billboards.

The run-time behavior is slightly different, depending on whether the installation is displaying a Flash billboard or image billboards:

- **If the installation is displaying a Flash billboard**—When the file transfer is complete, the installation continues showing the Flash billboard until its duration has elapsed. Once the duration has elapsed, the installation stops displaying the billboard and shows the appropriate SetupComplete dialog.

  If the file transfer takes more time than you have allocated for the duration of the Flash billboard, the installation continues displaying the Flash billboard until file transfer ends.

- **If the installation is displaying image billboards**—When the file transfer is complete, the installation stops displaying the image billboards, even if other billboards are scheduled or the current billboard's duration has not elapsed. The installation then shows the appropriate SetupComplete dialog.

  If the file transfer takes more time than you have allocated for the billboards, the installation continues displaying the billboards until file transfer ends. If No is selected for the Loop Billboard setting in the Billboards view and the installation reaches the last billboard before the file transfer ends, the installation continues displaying that last image billboard until file transfer ends. Then the installation shows the appropriate SetupComplete dialog. If Yes is selected for this setting and the installation reaches the last billboard before the file transfer ends, the installation restarts the display of billboards from the beginning. The loop continues, if necessary, until the file transfer ends, and the SetupComplete dialog is displayed.

Note • *If the version of Flash or other tool that you use to create your .swf file is newer than the version of the Flash Player that is installed on a target system, it is possible that some of the Flash features may not work as expected on that target system.*

Removing a Billboard from a Basic MSI Project

Project • *This information applies to Basic MSI projects.*

Task: ***To remove a billboard from your installation:***

1. In the View List under **User Interface**, click **Billboards**.
2. In the **Billboards** explorer, right-click the billboard that you would like to remove, and then click **Delete**.

Displaying Billboards in InstallScript and InstallScript MSI Installations

Project *• This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

You can add billboards to your projects to display information to end users during the installation process. The billboards can be used to communicate, advertise, educate, and entertain end users. For example, billboards can present overviews on new features of the product being installed or other products from your company. Each billboard is a file that you or your company's graphics department creates for complete control over the look and feel of the file transfer.

Billboard Styles and File Types for InstallScript and InstallScript MSI Projects

Project *• This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

InstallShield offers support for two different billboard styles. One includes a full-screen background window, and the other does not. Both styles show a progress bar.

Following are descriptions and sample screen shots of both types of billboard, along with applicable supported file types.

Windowed Billboards with Progress

For this style of billboard, the installation displays a standard-size dialog. During file transfer, the top of the dialog shows the billboards, and the bottom of this dialog shows the progress bar. The installation does not require a background window for this style of billboard.

You can use the following types of files for this style of billboard:

- Adobe Flash application file (.swf)
- Images (.bmp, .gif, .jpg, and .jpeg)

If a target system does not have the Adobe Flash Player, which is used to display Flash application files, the installation can detect that and display image billboards in place of the Flash billboard. Therefore, if you include a Flash billboard in your project, it is recommended that you also include one or more image billboards in your project.

Note *• For windowed billboards that show progress, you can add more than one image billboard to a project, but only one Adobe Flash application file billboard.*

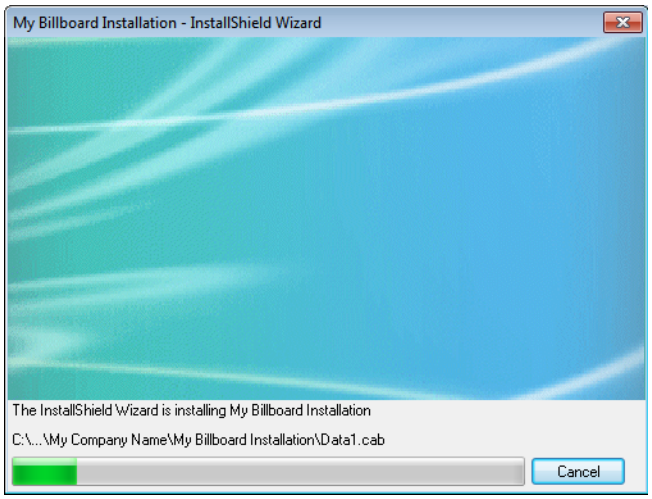

Figure 4-31: Windowed Billboard with Progress

In the sample screen shot, the billboard is the blue-green rectangle image. Its size is 544 pixels wide by 281 pixels high.

Note • *Skinned dialogs cannot display windowed billboards. To learn more about skins, see Dialog Skins.*

Billboards with a Full-Screen Background Window

For this style of billboard, when the installation displays the standard end-user dialogs, it also displays a full-screen background window. During file transfer, the billboards are displayed in front of the full-screen background window, and the standard size progress dialog is displayed in front of the billboards. This style of billboard requires a background window.

You can use image files (.bmp, .gif, .jpg, and .jpeg) for this style of billboard.

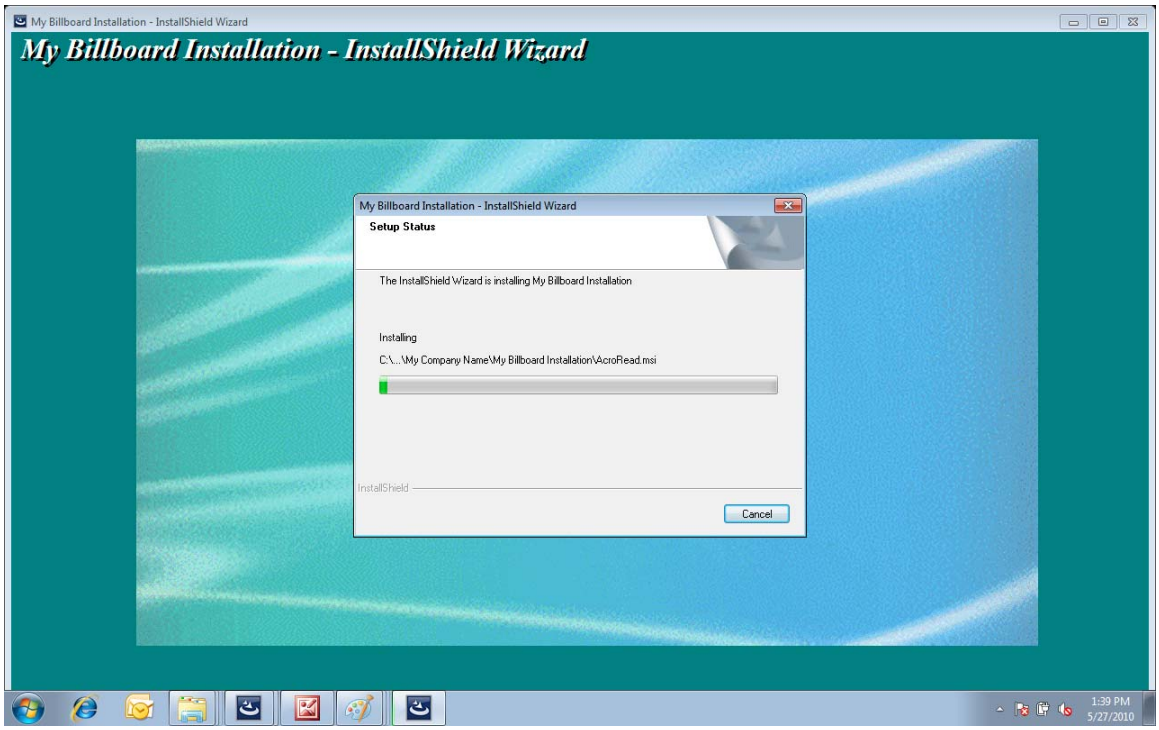

Figure 4-32: Billboard with Full-Screen Background Window

In the sample screen shot, the billboard is the blue-green rectangle image behind the progress dialog but in front of the background window.

Naming Billboard Files in an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Note • *The Adobe Flash application file support that is described here is applicable if the billboard style that you are using is the windowed style with progress, not the billboard style with a full-screen background window. If you want to use Flash file support with a full-screen background window, use the* ***PlayMMedia*** *function; with this support, the following naming conventions do not apply to the Adobe Flash file. For more information, see PlayMMedia. To learn how to display the background window for this implementation, see Displaying a Background Window in InstallScript and InstallScript MSI Installations.*

You can add more than one image billboard to a project, but only one Adobe Flash application file billboard.

Note that if a target system does not have the Adobe Flash Player, which is used to display Flash application files, the installation can detect that and display image billboards in place of the Flash billboard. Therefore, if you include a Flash billboard in your project, it is recommended that you also include one or more image billboards in your project.

The first step in adding billboards to your project is to create the Adobe Flash application file (if applicable) and image files (.bmp, .gif, .jpg, or .jpeg) that serve as your installation's billboards. When your files are properly named, you can add your billboards to your project. Note that if a target system does not have the Adobe Flash Player, which is used to display Flash application files, the installation can detect that and display image billboards in place of the Flash billboard. Therefore, if you include a Flash billboard in your project, it is recommended that you also include one or more image billboards in your project.

Billboard files must follow a designated naming convention. Each file name must begin with **bbrd**, followed by the number of the billboard (from 1 through 99); each must end with a supported file extension (.swf, .bmp, .gif, .jpg, or .jpeg). You can include a maximum of one Adobe Flash file (.swf) in your project; if you do include an .swf file, its name must contain the lowest number in the list of billboard files (for example, `bbrd1.swf`) that you are including in your project.

The billboards are displayed according to the sequential order of their file names. For example, a billboard file named `bbrd2.bmp` is displayed before `bbrd4.gif`.

Note that it is not necessary for the file name numbers to be contiguous; that is, you can add `bbrd1.jpg`, `bbrd3.jpg`, and `bbrd5.jpg` to your project, and each image is displayed at run time in order.

Tip • *The length of time that an image billboard is displayed depends upon the number of image billboards in your installation project. The percentage of the display time is approximately 1 divided by the number of billboards. For example, if you have four billboards in your installation, each billboard is displayed for 25% of the file-transfer time.*

Adding an Adobe Flash Application File Billboard to an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Note • *The Adobe Flash application file support that is described here is applicable if the billboard style that you are using is the windowed style with progress, not the billboard style with a full-screen background window. If you want to use Flash file support with a full-screen background window, use the* ***PlayMMedia*** *function. For more information, see PlayMMedia. To learn how to display the background window for this implementation, see Displaying a Background Window in InstallScript and InstallScript MSI Installations.*

InstallShield lets you display a Flash application file billboard during the file transfer process. Flash application files can consist of videos, movies, sounds, interactive interfaces, games, text, and more—anything that is supported by the .swf type of file. It is recommended that files such as Flash video files (.flv) and MP3 audio files be embedded in the .swf file so that they are available locally on the target system during file transfer. Although .swf files can reference external files that you can post on a Web site, this external implementation would require that end users have an Internet connection.

Task: ***To add an Adobe Flash Application File billboard to your installation project:***

1. In the View List under **Behavior and Logic**, click **Support Files/Billboards**.
2. In the **Support Files** explorer, click the **Billboards** item that should contain the billboard: either **Language Independent** or a language-specific item. The **Files** pane is displayed on the right.
3. Right-click anywhere in the **Files** pane and click **Insert Files**, or place your cursor in the **Files** pane and press the Insert key. The **Open** dialog opens.
4. Select your Adobe Flash application file billboard file named **bbrd1.swf**, and click **OK**.

InstallShield adds the file to your project.

Note *• If the version of Flash or other tool that you use to create your .swf file is newer than the version of the Flash Player that is installed on a target system, it is possible that some of the Flash features may not work as expected on that target system.*

If a target system does not have the Adobe Flash Player, which is used to display Flash application files, the installation can detect that and display image billboards in place of the Flash billboard. Therefore, if you include a Flash billboard in your project, it is recommended that you also include one or more image billboards in your project.

Adding an Image Billboard to an InstallScript or InstallScript MSI Project

Project *• This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

You can choose to display only one image billboard during the file transfer process, or you can include a series of image billboards, each one designed to be displayed for a specific amount of time. InstallShield includes support for .bmp, .gif, .jpg, and .jpeg image files.

Note *• Animated .gif files are not supported. If you want to use animation in a billboard, consider using an Adobe Flash application file billboard.*

Task: ***To add an image billboard to your installation project:***

1. In the View List under **Behavior and Logic**, click **Support Files**/**Billboards**.
2. In the **Support Files** explorer, click the **Billboards** item that should contain the billboard: either **Language Independent** or a language-specific item. The **Files** pane is displayed on the right.
3. Right-click anywhere in the **Files** pane and click **Insert Files**, or place your cursor in the **Files** pane and press the Insert key. The **Open** dialog opens.
4. Select a billboard file, and click **OK**.

InstallShield adds the file to your project.

Tip • *The length of time that an image billboard is displayed depends upon the number of image billboards in your installation project. The percentage of the display time is approximately 1 divided by the number of billboards. For example, if you have four billboards in your installation, each billboard is displayed for 25% of the file-transfer time.*

Adding or Modifying the Code in an InstallScript or InstallScript MSI Project to Display Billboards

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The InstallScript code that is needed to display billboards at run time varies, depending on the style of billboard that you are using.

- **Windowed Billboards with Progress**—To use windowed billboards that show progress at run time, use the STATUSBBRD constant with the **Enable** function.
- **Billboards with a Full-Screen Background Window**—To use billboards that are displayed with a full-screen background window, use the FULLWINDOWMODE and BACKGROUND constants with the **Enable** function. To learn how, see Displaying a Background Window in InstallScript and InstallScript MSI Installations.

  Note that if you want to use an Adobe Flash billboard with this style of billboard, you must also use the **PlayMMedia** function.

For details about these different styles of billboards, see Billboard Styles and File Types for InstallScript and InstallScript MSI Projects.

Setting the Billboard Order in an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Image billboards are displayed according to the numeric order of their file names. A billboard file named `bbrd2.bmp` is displayed to the end user before a file named `bbrd3.bmp`, and after a file named `bbrd1.bmp`. For specific guidelines on naming conventions, see Naming Billboard Files in an InstallScript or InstallScript MSI Project.

Task: ***To change the order in which billboards are displayed:***

1. Remove the billboard files whose order should change. (For more information, see Removing a Billboard from an InstallScript or InstallScript MSI Project.)
2. Using Windows Explorer, rename the billboard files so that they are in the appropriate numeric order.
3. Add the renamed files, as explained in Adding an Image Billboard to an InstallScript or InstallScript MSI Project.

Note that it is not necessary for the file name numbers to be contiguous; that is, you can add `bbrd1.jpg`, `bbrd3.jpg`, and `bbrd5.jpg` to your project, and each image is displayed at run time in order.

Displaying Billboards with Special Effects During an InstallScript or InstallScript MSI Installation

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The **SetDisplayEffect** function enables you to display your billboards with different special effects when they first appear on the main installation window. Choose one of this function's options before you display a bitmap with **PlaceBitmap** or display billboards during file transfer.

Moving Billboards to a Different Screen Location for an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Note • *The Adobe Flash application file support that is described here is applicable if the billboard style that you are using is the billboard style with a full-screen background window (which uses the **PlayMMedia** function), not for the windowed style with progress (which uses the STATUSBBRD constant with the **Enable** function). For more information about these two styles of billboards, see Billboard Styles and File Types for InstallScript and InstallScript MSI Projects.*

By default, the installation displays billboards in the center of the main installation window. To specify a different location, call the **PlaceWindow** function with the BILLBOARD option. For example, to place your billboards 10 pixels from the upper-left corner of the screen, make the following call:

```
PlaceWindow (BILLBOARD, 10, 10, UPPER_LEFT);
```

Since billboards are displayed only during file transfer, ensure that you call **PlaceWindow** before you begin file transfer.

Removing a Billboard from an InstallScript or InstallScript MSI Project

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Task: ***To remove a billboard from your installation project:***

1. In the View List under **Behavior and Logic**, click **Support Files/Billboards**.
2. In the **Support Files** explorer, click the **Billboards** item that contains the billboard that you want to remove: either **Language Independent** or a language-specific item. The **Files** pane is displayed on the right.
3. Right-click the billboard file and click **Delete**.

Displaying a Background Window in InstallScript and InstallScript MSI Installations

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

By default, installations do not display a background window. If you want to use the **PlayMMedia** function to display an Adobe Flash application file (.swf) or AVI files, your installation must display a background window. You may also want to display a background window for one type of billboard.

Tip • *You can display a Flash file billboard and image billboards without a background window. For more information, see Billboard Styles and File Types for InstallScript and InstallScript MSI Projects.*

The method for displaying a background window depends on which project type you are using.

InstallScript Projects

To display a background window in an InstallScript project, modify the script's **OnShowUI** event handler by removing the double slashes from the beginnings of the following lines of code:

```
//if ( LoadStringFromStringTable( "TITLE_MAIN", szTitle ) < ISERR_SUCCESS ) then // Load the title
string.
//    szTitle = IFX_SETUP_TITLE;
//endif;
//SetTitle( szTitle, 24, WHITE );
//Enable( FULLWINDOWMODE );
//Enable( BACKGROUND );
//SetColor( BACKGROUND, RGB( 0, 128, 128 ) );
```

InstallScript MSI Projects

To display a background window in an InstallScript MSI project, modify the appropriate script's UI event handler (such as **OnFirstUIBefore** or **OnMaintUIBefore**) by removing the double slashes from the beginnings of the following lines of code:

```
// SetTitle( @PRODUCT_NAME, 24, WHITE );
// SetTitle( @PRODUCT_NAME, 0, BACKGROUNDCAPTION );
// Enable( FULLWINDOWMODE );
// Enable( BACKGROUND );
// SetColor(BACKGROUND,RGB (0, 128, 128));
```

Populating List Boxes at Run Time

Basic MSI Projects

Populating a list box at run time requires you to create temporary records for the .msi database using SQL queries. For an example, see Knowledge Base article Q103295. For additional information, see InstallShield Developer Tip: Accessing the MSI Database at Run Time.

InstallScript MSI Projects

The **CtrlSetList** function associates a string list variable with a ListBox control on a dialog. For example:

```
function FillListBox( )
    LIST listDays;
begin
    listDays = ListCreate(STRINGLIST);
```

```
    ListAddString(listDays, "Monday", AFTER);
    ListAddString(listDays, "Wednesday", AFTER);
    ListAddString(listDays, "Friday", AFTER);

    CtrlSetList("DialogName", nListBoxId, listDays);
end;
```

Displaying File Browse Dialogs

For an example of calling the **GetOpenFileName** API to display a file browse dialog, see Knowledge Base article Q104325.

Displaying Network Browse Dialogs in InstallScript Installations

You can use the **SelectDirEx** function to display a dialog with which the user can browse the Network Neighborhood.

```
prototype NetBrowse( );

function NetBrowse( )
    STRING svSelectedDir[MAX_PATH + 1];
    NUMBER nReturn;
begin
    svSelectedDir = PROGRAMFILES;

    nReturn = SelectDirEx("", "Select a directory:", "", "",
        BIF_EDITBOX | BIF_RETURNONLYFSDIRS, svSelectedDir);

    if (nReturn = OK) then
        MessageBox("Selected directory was: " + svSelectedDir, INFORMATION);
    elseif (nReturn = CANCEL) then
        MessageBox("User clicked Cancel", INFORMATION);
    else
        MessageBox("Error displaying dialog", WARNING);
    endif;
end;
```

Preparing Installations for Update Notifications

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

FlexNet Connect provides a mechanism that enables you to automatically notify your Web-connected end users when patches, updates, and product information for your application are ready for release. FlexNet Connect helps you reduce the number of end users running old releases of your products and prevent them from installing the wrong updates from your Web site.

FlexNet Connect Implementation

There are two cycles of tasks that you perform when using FlexNet Connect to automatically inform end users about updates: initial deployment and update deployment. Once you have performed the initial deployment steps for your application, each time you want to distribute an update of that application to your customers, you perform the update deployment cycle of steps. To learn about the update deployment steps, see Notifying End Users about Upgrades Using FlexNet Connect.

Initial Deployment

1. Use InstallShield to create the installation project for your application. FlexNet Connect should be enabled in this project. When you enable FlexNet Connect, InstallShield includes the Software Manager in your installation. This desktop tool ships with your application and provides a tool for end users to view available updates.
2. Register your application with the FlexNet Connect Publisher site, a Web-based management portal.
3. Install your application and test it.

FlexNet Connect includes a variety of options that can be purchased together for a complete solution, or separately for a customized solution. To learn more, visit the Flexera Software Web site.

Enabling Automatic Update Notifications for a Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

Caution • *Enabling automatic update notifications in your project adds about 600 KB of files to your installation. These files must be distributed with your application in order for FlexNet Connect to work. If you cannot afford to include these files in your installation because of bandwidth limitations or other reasons, you can select* ***No*** *to disable automatic update notifications. However, FlexNet Connect cannot be used to deploy an update unless automatic notification is enabled in the original installation when you distribute it to your end users. Therefore, if you select* ***No****, you will not be able to later take advantage of the automatic update notification features.*

Task: ***To enable automatic update notification for your project:***

1. In the View List under **Installation Information**, click **Update Notifications**.
2. For the **Enable FlexNet Connect** setting, select one of the **Yes** options.
3. To register your product with FlexNet Connect, select the **Is Product/Version Registered** setting and follow the directions in the help pane.

Disabling Automatic Update Notifications for a Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

Caution • *Enabling automatic update notifications in your project adds about 600 KB of files to your installation. These files must be distributed with your application in order for FlexNet Connect to work. If you cannot afford to include these files in your installation because of bandwidth limitations or other reasons, you can select* ***No*** *to disable automatic update notifications. However, FlexNet Connect cannot be used to deploy an update unless automatic notification is enabled in the original installation when you distribute it to your end users. Therefore, if you select* ***No****, you will not be able to later take advantage of the automatic update notification features.*

Task: ***To disable automatic update notification for your project:***

1. In the View List under **Installation Information**, click **Update Notifications**.
2. For the **Enable FlexNet Connect** setting, select **No**.

InstallShield removes the FlexNet Connect files from your project.

Removing the Shortcut

If you added to your installation a shortcut that calls FlexNet Connect, you need to manually remove it.

Task: ***To remove the shortcut:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. Right-click the shortcut and select **Delete**, or select the shortcut and press the **Delete** key.

Removing the Check-for-Updates Check Box from the Last Dialog

The following instructions describe how to remove the **Yes, check for program updates (Recommended) after the setup completes** check box from the **SetupComplete** dialog.

Task: ***To remove the check-for-updates check box from the SetupComplete dialog:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Right-click the **ISENABLEDWUSFINISHDIALOG** property and select **Delete Property**.

Files that Need to Be Installed for Automatic Update Notification

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

To install with your application the ability to implement automatic notification of updates to your application, enable FlexNet Connect for your project. This is disabled by default for all new installation projects that you create.

When you enable FlexNet Connect in a Basic MSI or InstallScript MSI project, the FlexNet Connect merge module is added to your installation. When you enable FlexNet Connect in an InstallScript project, this merge module is added to your installation at build time.

The FlexNet Connect merge module includes several files that are installed on the target machine during installation of your application. These files must be distributed with your application in order for FlexNet Connect to work. Among the items that are installed:

- **Software Manager** (`ISUSPM.exe`) is an application that your end users can use to check for updates and product information. When an update is available for your application, the update is listed in the Software Manager, along with hyperlinks to download the update and view release notes.

- **Update Agent** (`Agent.exe`) is the component that handles all of the communication between the Software Manager and the notification server. Optionally, you can embed calls directly from your application to the Agent to create an update experience that is more integrated with your application. To access the FlexNet Connect documentation, see the FlexNet Connect Help Library.

Creating a Shortcut to Check for Updates

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

You can create a shortcut to launch FlexNet Connect.

Task: ***To create a shortcut to check for updates:***

1. In the View List under **System Configuration**, click **Shortcuts**.
2. In the **Shortcuts** explorer, right-click one of the destination directories and select **New Shortcut to Preexisting file**.
3. Configure the following settings for the shortcut:

Table 4-1 • Settings for a Shortcut that Checks for Updates

Setting	Value
Display Name	Check for Updates
Target	[ALLUSERSPROFILE]FlexNet\Connect\11\agent.exe
Icon File	<ISProductFolder>\redist\Language Independent\OS Independent\UpdateService.ico
Arguments	/sn[ProductCode]
Key Name	Check for Updates

Adding a Check-for-Updates Check Box to the SetupComplete Dialog

Project • *This information applies to Basic MSI projects.*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

You can add a check-for-updates check box to the last dialog of your installation. If the end user selects this **Yes, check for program updates (Recommended) after the setup completes** check box and then clicks the **Finish** button to end the installation, FlexNet Connect is launched.

Task: ***To add a check-for-updates check box to the SetupComplete dialog:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Set the **ISENABLEDWUSFINISHDIALOG** property to 1.

Registering Your Application with FlexNet Connect

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

FlexNet Connect uses the product code and product version to uniquely identify products. Before you can properly test FlexNet Connect and automatic update notifications, you need to register the product code and product version of your application with FlexNet Connect. If you run FlexNet Connect before registering, your end users receive a “product not registered” message.

Task: ***To register the product code and product version:***

1. In the View List under **Installation Information**, click **Update Notifications**.
2. Set the **Enable FlexNet Connect** property to **Yes** if you have not already done so.
3. Click the **Is Product/Version Registered** property. The help window displays instructions for setting this property. Follow the instructions there to complete the registration process.

To learn more about FlexNet Connect, see the FlexNet Connect Help Library.

Configuring Servers

When you are creating an installation, you may find it necessary to provide server-side support for some technology that will be installed on a target system. InstallShield makes it easy to configure server-side installations or manage COM+ server applications and application proxies. InstallShield provides support for Internet Information Services, SQL, and component services.

Configuring SQL Support

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

InstallShield provides SQL support for Microsoft SQL Server, Microsoft Windows Azure, MySQL, and Oracle. The SQL Scripts view provides a central location for managing and organizing all SQL scripts by server connections and settings within the user interface. SQL support within InstallShield enables you to do the following:

- Connect to SQL servers.
- Import catalog schema and/or data.
- Associate SQL scripts with features.
- Set required SQL server/script properties (server name, database name, authentication method, etc.).
- Set SQL script for execution during installation or uninstallation.
- Edit SQL scripts.
- Require and/or target specific versions of SQL Server, MySQL, or Oracle.
- Define SQL script text replacement.
- Open scripts in Microsoft SQL Server Management Studio or Microsoft SQL Server Query Analyzer.

Note • *The import database functionality applies to the Microsoft SQL Server Database. Oracle users should refer to the Oracle Web page on Oracle Database Utilities for information on utilities that may work in conjunction with InstallShield.*

If you have Microsoft SQL Server Management Studio or Microsoft SQL Server 2000 SQL Query Analyzer installed on your system, you can open a new SQL script that you have added to your project to test, edit, and syntax-check the script. To launch one of those tools and open your script from within InstallShield, right-click the script file in the SQL Scripts view and then click Open Script in Microsoft SQL Server Management Studio. InstallShield searches your system for the following tools in order and launches the first one that it finds:

1. *Microsoft SQL Server 2008 Management Studio (any edition, including Express; `ssms.exe`)*
2. *Microsoft SQL Server 2005 Management Studio (`SqlWb.exe`)*
3. *Microsoft SQL Server 2005 Management Studio Express (`ssmsee.exe`)*
4. *Microsoft SQL Server 2000 Query Analyzer (`isqlw.exe`)*

Using Windows Installer Properties for SQL Login Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

When you use the SQL Scripts view to add a new SQL database connection to your project, InstallShield adds the following Windows Installer properties to the project by default.

Table 4-1 • Default SQL Login Properties

Property	Description
IS_SQLSERVER_AUTHENTICATION	This property identifies the type of authentication that you want to use to connect to the specified catalog. The default property is **IS_SQLSERVER_AUTHENTICATION**. The following numbers are valid property values: • **0**—Windows authentication credential of the current user • **1**—Server authentication This property is the default value for the Authentic Type Property Name setting on the Advanced tab for the selected SQL connection.
IS_SQLSERVER_DATABASE	This property identifies the name of the SQL catalog to which you want to create a connection during the installation. This property is the default value for the Target Catalog Property Name setting on the Advanced tab for the selected SQL connection.
IS_SQLSERVER_PASSWORD	This property identifies the password that should be used for server authentication. This property is the default value for the Server Authentication Password Property Name setting on the Advanced tab for the selected SQL connection.
IS_SQLSERVER_SERVER	This property identifies the name of the target server instance (for Microsoft SQL Server and MySQL) or the connect URL string or local net service name (for Oracle). This property is the default value for the Target Server Property Name setting on the Advanced tab for the selected SQL connection.

Table 4-1 • Default SQL Login Properties (cont.)

Property	Description
IS_SQLSERVER_USERNAME	This property identifies the login ID that should be used for server authentication. This property is the default value for the Server Authentication Login ID Property Name setting on the Advanced tab for the selected SQL connection.

If you want to override one of these Windows Installer property for an existing connection, add a new property in the Property Manager. Then, in the SQL Scripts view, select the connection. On the Advanced tab, select the name of the new property in the appropriate list.

If you want to store the values of any of these properties on the target system for later use by your product, you can do so. Following are examples of ways you can use these properties:

- In the Registry view, create a registry value whose data is `[IS_SQLSERVER_SERVER]`. At run time, when your installation creates the registry value, the data for that registry value is set to the name of the SQL catalog.
- Use the Text File Changes view to configure text string replacements that you want to occur at run time. In this view, add a text file reference that describes a file that is installed with your product, and then specify the search-and-replace criteria. For the search-and-replace criteria, you can enter `[IS_SQLSERVER_DATABASE]` in place of the name of the SQL Server machine. At run time, when your installation edits the text file, the name of the SQL Server machine is written in the text file.

Tip • *For a list of additional Windows Installer properties that you can define in your project to override default SQL run-time behavior, see Overriding the Default SQL Run-Time Behavior.*

Project • *In a Basic MSI installation, the built-in SQLLogin dialog lets end users configure the aforementioned properties. If you change any of the SQL properties on the Advanced tab of a SQL connection in a Basic MSI project, the corresponding properties are not automatically updated in the SQLLogin dialog in the Dialogs view. Therefore, you must manually change the properties in the dialog to match the properties that selected on the Advanced tab of the SQL connection.*

Specifying Whether New SQL Connections Should Share the Same Windows Installer Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

InstallShield lets you specify whether new SQL database connections that you add to your project should share the same Windows Installer properties by default.

For example, if you want connections to share the same default Windows Installer properties, you could add one connection to your project in the SQL Scripts view, and specify a catalog name of **MyConnection**. If you add a second connection to your project, InstallShield uses the same catalog name of **MyConnection** for that second connection. If you change the catalog name of either connection, InstallShield automatically updates the catalog name of the other connection, since both are based on the same Windows Installer property.

Task: ***To specify whether SQL connections should share the same Windows Installer properties:***

1. On the **Tools** menu, click **Options**. The **Options** dialog box opens.
2. Click the **SQL Scripts** tab.
3. Select or clear the **Generate unique Windows Installer properties for new connections** check box:
   - To share Windows Installer properties between any new connections that you add, clear this check box.
   - To use different Windows Installer properties for any new connections that you add, select this check box.

If you select the check box and then add a second connection to your project, InstallShield creates a new set of Windows Installer properties for the second connection.

If you clear the check box and then add a second connection, InstallShield uses the default Windows Installer properties for the second connection. The default Windows Installer properties are the ones that were added for the first connection that you added to your project.

Tip • *If you want to override a Windows Installer property for an existing connection, add a new property in the Property Manager. Then, in the SQL Scripts view, select the connection. On the Advanced tab, select the name of the new property in the appropriate list.*

Project • *For Basic MSI projects, the built-in SQLLogin dialog is designed to work with the default Windows Installer properties for the first SQL connection that was added to the project. If you select the* ***Generate unique Windows Installer property for new connections*** *option, you need to duplicate the dialog for each connection to work with the new Windows Installer properties.*

Using the SQL Run-Time Functions in InstallScript and InstallScript MSI Projects

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The InstallScript language includes many built-in SQL run-time (SQLRT) functions that begin with a prefix of *SQLRT*. Some of the functions are available only in InstallScript projects, some are available only in InstallScript MSI projects, and some are available in both project types.

The SQLRT functions require that you configure SQL information through the SQL Scripts view; the configuration information is written to the `SQLRT.ini` file so that the SQL run-time functions work properly. For InstallScript projects, the SQLRT functions are in the `SQLRT.obl` file, and they call the `SQLRT.dll` file. For InstallScript MSI projects, the SQLRT functions are in the `SQLCONV.obl` file, and they call the `ISSQLSRV.dll` file. These support files are added automatically to your project when you use the SQL Scripts view.

The **SQLRTInitialize2** function initializes the SQL server run time. In InstallScript projects, the **SQLRTInitialize2** function is called automatically during the OnSQLServerInitialize event handler. In InstallScript MSI projects, the **SQLRTInitialize2** function is called automatically during the OnSQLLogin event handler. If you need to call one of the SQLRT functions before the OnSQLServerInitialize or OnSQLLogin events, you must first call the **SQLRTInitialize2** function.

Note • *In earlier versions of InstallShield, the **SQLRTInitialize** function was used to initialize the SQL server run time in InstallScript projects. This function has been superseded by the **SQLRTInitialize2** function.*

Adding a New SQL Connection

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

In the SQL Scripts view, scripts are organized by connection, since no script can run on a server until a connection has been established. Therefore, before you can add any SQL scripts to your project, you must first create a SQL connection.

Task: ***To create a new SQL connection:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Right-click the **SQL Scripts** explorer and click **New SQL Connection**.

InstallShield adds a new connection in the explorer. Use the tabs in the right pane to configure the settings that are associated with this connection.

Note • *The SQLLogin and SQLBrowse dialogs let end users use alias names for connecting and browsing to SQL Server databases.*

Overriding the Default TCP/IP Network Library with a Different Protocol for a SQL Server Database

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

By default, InstallShield installations use the TCP/IP network library when connecting to a SQL Server database. You can override this default behavior as needed if you want to use a different protocol.

Task: ***To override the default TCP/IP network library when connecting to a SQL Server database:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, click the **ISSQLDBMetaData** table.
3. Find the AdoCxnNet1Library field. The default value is:

   `Network Library=DBMSSOCN`

   `DBMSSOCN` refers to the name of the module for the TCP/IP network library, without the file extension.
4. Replace the default DBMSSOCN name as required. For example:
   - To use the Named Pipes network library, specify `DBNMPNTW`.
   - To use SPX/IPX, specify `DBMSSPXN`.
   - To use Banyan Vines, specify `DBMSVINN`.
   - To use Multi-Protocol (Windows RPC), specify `DBMSRPCN`.

At run time, the installation uses the protocol that you specified when connecting to a SQL Server database.

Requirements for Connecting to Instances of SQL Server Express LocalDB

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

If you want your installation to support connections to instances of SQL Server Express LocalDB, the target system must have the SQL Server Native Client 11 ODBC driver. To ensure that it is present on target systems, you can include the Microsoft SQL Server 2012 Native Client prerequisite in your installation. You also must configure your project to use the driver.

Task: ***To include the appropriate SQL Server Native Client prerequisite in your project for connecting to instances of SQL Server Express LocalDB:***

1. For Basic MSI and InstallScript MSI projects: In the View List under **Application Data**, click **Redistributables**.

   For InstallScript projects: In the View List under **Application Data**, click **Prerequisites**.

2. In the list of redistributables, select the appropriate **Microsoft SQL Server 2012 Native Client** check box.

The InstallShield prerequisite is launched only if the conditions that are defined in the InstallShield prerequisite file (.prq) are met. To see the list of conditions, click the SQL Server Native Client prerequisite in the Redistributables view or the Prerequisites view, and then review the details that are listed in the details pane on the right. You can hide or show the details pane by clicking the Show Details button in these views.

Task: ***To configure your InstallShield installation project so that your installation uses the SQL Server Native Client 11 ODBC driver:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, click the **ISSQLDBMetaData** table.
3. In the **ISSQLDBMetaData** column, find the **MSSQLServer** row.
4. Replace the value of the **AdoDriverName** column with the following:

   ```
   sqlncli11
   ```

At run time, the installation uses the SQL Server Native Client 11 ODBC driver when connecting to a SQL Server Express LocalDB database.

Adding a New SQL Script

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Task: ***To add a new SQL script once you have created a new SQL connection:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Right-click the new connection and click **New Script**.

When you add a new script to your project, InstallShield adds a new component for the script. You must associate the script with a feature. If one does not exist, the Create a New Feature dialog box opens when you add the SQL script, prompting you to create a new feature. You can change the script-feature association later by using the **Select Features the SQL Script Belongs to** area on the General tab in the SQL Scripts view for the SQL script.

Tip • *You can also add scripts to your project by importing or inserting them. For more information, see Inserting and Importing SQL Scripts.*

Note • *If you have Microsoft SQL Server Management Studio or Microsoft SQL Server 2000 SQL Query Analyzer installed on your system, you can open a new SQL script that you have added to your project to test, edit, and syntax-check the script. To launch one of those tools and open your script from within InstallShield, right-click the script file in the SQL Scripts view and then click Open Script in Microsoft SQL Server Management Studio. InstallShield searches for one of the following tools and launches the first one that it finds:*

- *Microsoft SQL Server 2008 Management Studio (any edition, including Express; `ssms.exe`)*
- *Microsoft SQL Server 2005 Management Studio (`SqlWb.exe`)*
- *Microsoft SQL Server 2005 Management Studio Express (`ssmsee.exe`)*
- *Microsoft SQL Server 2000 Query Analyzer (`isqlw.exe`)*

Inserting and Importing SQL Scripts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

InstallShield enables you to reuse SQL script files (.sql) in multiple projects. You can insert or import script files into a project through the SQL Scripts view:

- Inserting a script file creates a link to the script file in its current location.
- Importing a script file copies the script file to the folder containing the script files for your project. The script files that you import can be stored somewhere on your system, or they can be stored in a repository.

Inserting SQL Script Files

Task: ***To insert a SQL script file:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, add a SQL connection if you have not already done so.
3. Right-click the SQL connection and then click **Insert Script Files**. The **Open** dialog box opens.
4. Select the SQL script file (.sql) that you want to insert.
5. Click **Open**.

Importing SQL Script Files

Task: ***To import a SQL script file:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, add a SQL connection if you have not already done so.
3. Right-click the SQL connection and then click **Import Script Files**. The Import SQL Script Files Dialog Box opens.
4. Do one of the following:
   - In the **Repository Items** box, click the SQL script file (.sql) that you want to add to your project.
   - If the script file that you want to import is not stored in the repository, click the browse button to select it.
5. Click **OK**.

When you insert or import a new script to your project, InstallShield adds a new component for the script. You must associate the script with a feature. If one does not exist, the Create a New Feature dialog box opens when you add the SQL script, prompting you to create a new feature. You can change the script-feature association later by using the **Select Features the SQL Script Belongs to** area on the General tab in the SQL Scripts view for the SQL script.

Importing a SQL Server Database and Generating a SQL Script File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Task: ***To import an existing Microsoft SQL Server database and then generate a script file from it:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Right-click the **SQL Scripts** explorer and then click **Database Import Wizard**. The **Database Import Wizard** opens.
3. Complete the panels in the Database Import Wizard.

The Database Import Wizard will guide you through the process of importing your database settings and generating a SQL script file based on those settings and other options that you determine.

Note • *The import database functionality applies to the Microsoft SQL Server Database. The script generated by the Database Import Wizard is not compatible with other database types.*

Editing a SQL Script File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Once you have created, inserted, or imported a script file, you can edit it from within InstallShield.

Project • *In an InstallScript project, if you are working on a script that had overridden OnFirstUIBefore before upgrading to InstallShield and it is not calling OnSQLServerInitialize, you should add that code to your script file.*

Task: ***To edit a script file in InstallShield:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the script file that you want to edit.
3. Click the **Script** tab, which displays the contents of your script file.
4. Edit the file as needed.

If you want to re-create your script each time that you build your project, you can select the Regenerate SQL Script at Build check box on the Database Import tab for the script in the SQL Scripts view. A backup of any existing script file is always saved first.

Note • *If you have Microsoft SQL Server Management Studio or Microsoft SQL Server 2000 SQL Query Analyzer installed on your system, you can open a new SQL script that you have added to your project to test, edit, and syntax-check the script. To launch one of those tools and open your script from within InstallShield, right-click the script file in the SQL Scripts view and then click Open Script in Microsoft SQL Server Management Studio. InstallShield searches for one of the following tools and launches the first one that it finds:*

- *Microsoft SQL Server 2008 Management Studio (any edition, including Express; `ssms.exe`)*
- *Microsoft SQL Server 2005 Management Studio (`SqlWb.exe`)*
- *Microsoft SQL Server 2005 Management Studio Express (`ssmsee.exe`)*
- *Microsoft SQL Server 2000 Query Analyzer (`isqlw.exe`)*

Specifying a Version Number for a SQL Script File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

You can assign a schema version number to a SQL script file after you have a created or imported a script file in the SQL Scripts view. Specifying schema version information helps you to trigger the launching of the SQL script only when it is appropriate.

Task: ***To specify the schema version for your SQL script file:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the SQL script that you want to configure.
3. Click the **General** tab.
4. In the **Schema Version (xxxxx.xxxxx.xxxxx.xxxxx)** box, type the schema version number for your SQL script

The installation checks the current schema version that is on the target database. The schema version is stored in the **ISSchema** column of the custom table named **InstallShield**. When you specify a schema version for a SQL script, the installation runs the script only if the script schema version number is greater than the current schema version number. Once the script is executed, the installation updates the current schema version on the target database to reflect the new schema version number.

If you do not specify a schema version number for a SQL script, the script is always launched.

For example, your installation may create a new connection to a database called **TestDB** and then create a script that is called **TestScript** and that has a schema version number of **12345.54321.12345.54321**. The installation creates the custom **InstallShield** table in the **TestDB** database and stores the schema version in the **ISSchema** column of that table. If another installation is run on that system, and this installation also has a SQL script called **TestScript**, the SQL script is executed only if the schema version number of this other script is greater than the version number that is stored in the **ISSchema** column in the **InstallShield** table of the target database. If the script is executed, the installation updates the **ISSchema** column with the new schema version number.

Tip • *When you specify a number for the Schema Version setting and InstallShield adds the custom **InstallShield** table for storing the schema version number on the target database, the data is not automatically removed upon uninstallation. Therefore, if you want the installation to be able to roll back the changes, you need to create a custom script upon uninstallation to drop the **InstallShield** table.*

Specifying the Order for Running Multiple SQL Scripts That Are Associated with a Connection

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

If you add more than one SQL script to a SQL connection in your project, you can specify the order in which the installation runs those SQL scripts on the target machine. The procedure for specifying the order differs for Windows Installer–based and InstallScript-based projects.

Specifying the SQL Script Order in Basic MSI, DIM, and InstallScript MSI Projects

The order in which a connection's SQL scripts are listed in the SQL Scripts view of a Basic MSI, DIM, and InstallScript MSI project is the order in which the installations run the SQL scripts. For example, if you create a connection in the SQL Scripts view and add two SQL scripts to that connection, the script that is listed first under the SQL connection is the one that the installation runs first.

Task: ***To change the order in which a connection's SQL scripts are run:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, right-click the SQL script that you want to move and click **Move Up** or **Move Down**.

The next time that you build and run the installation, the order is updated.

Specifying the SQL Script Order in InstallScript Projects

By default for InstallScript installations, batch mode for SQL scripts is disabled; therefore, the order in which a connection's SQL scripts are run corresponds with the order in which the installation processes the associated components.

If you want to be able to override this default behavior and specify a particular order for running the SQL scripts, you can do so by enabling the batch mode in the SQL Scripts view.

Task: ***To enable or disable batch mode:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Right-click the **SQL Scripts** explorer and click **Batch Mode**.

Batch mode is enabled if the Batch Mode command has a check mark; it is disabled if the command does not have a check mark.

The **SQLRTGetBatchList** function returns the list of components that are associated with SQL scripts that need to be run when batch mode is enabled. For more information, see SQLRTGetBatchList.

Overriding the Default SQL Run-Time Behavior

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

You can define the following Windows Installer properties to override default run-time behavior:

Table 4-2 • Windows Installer Properties for SQL

Property	Description
IS_SQLSERVER_CONNECTIONS_TO_VALIDATE	Overrides the connections that will be tested when clicking the Next button on the SQLLogin dialog. Specify multiple connections by separating each with a semicolon. By default, all the connections in the **ISSQLConnection** table will be validated.

Table 4-2 • Windows Installer Properties for SQL (cont.)

Property	Description
IS_SQLSERVER_CXNS_ABSENT_FROM_INSTALL	Specifies one or more SQL connections that should be skipped during installation or uninstallation. To specify more than one SQL connection, separate each with a semicolon (;). To skip all of the SQL connections, set the value of this property to **ALL**. Using this property is helpful if you cannot uninstall a product because of a SQL scripting error.
IS_SQLSERVER_DO_NOT_USE_REG	Specifies not to use the stored SQL Server login information written in the registry. Since the SQLLogin dialog is not displayed in maintenance and uninstall modes, the installation stores the login information that is specified during installation. If you do not want this behavior, set the **IS_SQLSERVER_DO_NOT_USE_REG** property.
IS_SQLSERVER_LOCAL_ONLY	Specifies to show only the local SQL Server in the SQL Server browse combo box and list box controls.  ***Note*** • *To show only the local SQL Server and either remote SQL Servers or SQL Server aliases, you can set the* ***IS_SQLSERVER_LOCAL_ONLY*** *property, as well as either the* ***IS_SQLSERVER_REMOTE_ONLY*** *property or the* ***IS_SQLSERVER_ALIAS_ONLY*** *property.*
IS_SQLSERVER_REMOTE_ONLY	Specifies to show only the remote SQL Servers in the SQL Server browse combo box and list box controls.  ***Note*** • *To show only the remote SQL Servers and either the local SQL Server or SQL Server aliases, you can set the* ***IS_SQLSERVER_REMOTE_ONLY*** *property, as well as either the* ***IS_SQLSERVER_LOCAL_ONLY*** *property or the* ***IS_SQLSERVER_ALIAS_ONLY*** *property.*
IS_SQLSERVER_ALIAS_ONLY	Specify to show only the SQL Server aliases in the SQL Server browse combo box and list box controls.  ***Note*** • *To show only the SQL Server aliases and either the local SQL Server or remote SQL Servers, you can set the* ***IS_SQLSERVER_ALIAS_ONLY*** *property, as well either the* ***IS_SQLSERVER_LOCAL_ONLY*** *property or the* ***IS_SQLSERVER_REMOTE_ONLY*** *property.*

Project • *For Basic MSI projects, all connections are linked to the SQLLogin dialog. To display multiple SQLLogin dialogs, you can copy the SQL dialogs from the Dialogs view and modify their behavior and events similar to the default SQL dialogs. Remember to create new properties, and set them in the connection's Advanced tab of the SQL Scripts view. You can use those new properties when you modify the copies of the SQL dialogs that you made.*

Handling SQL Run-Time Errors

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Task: ***To set SQL script error-handling properties in the interface:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the SQL script file for which you want to add error handling.
3. Click the **Runtime** tab.
4. In the **Script Error Handling** area, select one of the options listed, or click the **Custom** button to override the script's default error handling. Available options are:
   - On Error, Goto Next Script
   - On Error, Goto Next Statement
   - On Error, Abort Installation

Setting Up a Database Server Type Condition for SQL Scripts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

InstallShield enables you to create a single connection that targets both Microsoft SQL Server and MySQL and that has multiple SQL scripts specific to each database server technology. However, a connection is created based on whichever database type is detected first. Therefore, scripts are run only for the detected database type, and the scripts that are specific to the non-detected database server type fail. For example, if the run time detects a Microsoft SQL Server, then the scripts associated with Microsoft SQL Server run, and the scripts that are specific to MySQL fail.

As a workaround to this behavior, it is recommended that you set a condition in your SQL script so that a SQL scripting error occurs when the installation is running a non-detected database server type script. Then you can set up custom error handling for the scripting error and skip to the next script for the connection. The following instructions discuss how you can set this database server type condition for scripts.

Task: ***To set up a database server type condition for a script that targets Microsoft SQL Server:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the script file for which you are creating the condition.
3. Click the **Script** tab.
4. Add the following statement at the beginning of the script:

   ```
   SELECT @@ROWCOUNT
   ```

5. Click the **Runtime** tab.
6. In the **Script Error Handling** area, click the **Custom** button. The **Custom Error Handling** dialog box opens.
7. Click the **Click here to add a new item** row.
8. In the **Error Number** column, type `1193`. This is the error number that MySQL returns when it does not have the specified system variable that you added at the beginning of the script.
9. In the **Behavior** column, click **On Error, Goto Next Script**.
10. In the **Project Wide** column, click **No**.
11. Click **OK**.

Task: ***To set up a database server type condition for a script that targets MySQL:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the script file for which you are creating the condition.
3. Click the **Script** tab.
4. Add the following statement at the beginning of the script:

   ```
   SELECT @@table_cache
   ```

5. Click the **Runtime** tab.

6. In the **Script Error Handling** area, click the **Custom** button. The **Custom Error Handling** dialog box opens.
7. Click the **Click here to add a new item** row.
8. In the **Error Number** column, type `137`. This is the error number that Microsoft SQL Server returns when it does not have the specified system variable that you added at the beginning of the script.
9. In the **Behavior** column, click **On Error, Goto Next Script**.
10. In the **Project Wide** column, click **No**.
11. Click **OK**.

Conditionally Launching a SQL Script in a Windows Installer-Based Installation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

You may want your installation to launch a SQL script only if certain conditions are met on the target system. For example, your SQL script may require that the end user have administrator rights. If an end user does not have administrator rights, the SQL script is not launched.

Task: ***To create a SQL script condition:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the script file for which you are creating the condition.
3. Click the **Runtime** tab.
4. In the **Script Condition** area, select the **Specify a Conditional Statement** check box.
5. Click the ellipsis button (**...**). The **Condition Builder** dialog box opens.
6. Create one or more conditions.

The SQL scripts are tied to component states. The condition that is set in the SQL Scripts view is the condition for the SQL script's component. If the component conditions are met on the target system, the installation installs the SQL script. If the installation installs a SQL script that you did not expect to be installed on a target system, generating a log file for your installation may help you determine why the SQL script was installed.

Tip • *For information on conditions and on condition syntax, see Building Conditional Statements and Conditional Statement Syntax.*

Conditionally Launching a SQL Script in an InstallScript Installation

Project • *This information applies to InstallScript projects.*

You may want your installation to launch a SQL script only if certain conditions are met on the target system.

InstallShield generates a set of default global event handlers, each of which is a function scripted in the InstallScript language. The following SQL-related events are automatically called by the InstallShield framework:

- OnSQLServerInitialize
- OnSQLComponentInstalled

OnSQLServerInitialize is called by OnFirstUIBefore, and OnSQLComponentInstalled is called during file transfer, for each component installed.

Note • *If you are working on a script that had overridden OnFirstUIBefore before upgrading to InstallShield and it is not calling OnSQLServerInitialize, you should add that code to your script file.*

In your script, you can modify OnSQLServerInitialize and OnSQLComponentInstalled to perform checks for different things. For example, you can check for a user with administrator rights in the sample code below.

```
function OnSQLComponentInstalled(szComponent)
string sMessage;
string sData;
number nResult;
begin

    if( Is( USER_ADMINISTRATOR, sData ) ) then

        nResult = SQLRTComponentInstall( szComponent );

        if( nResult = SQL_ERROR_ABORT ) then

            sMessage = SdLoadString( IDS_IFX_SQL_ERROR_RUN_FAILED );
            MessageBox( sMessage, MB_OK );
            abort;

        endif;
    else
        //User does not have administrator rights, so we do not run scripts
    endif;
end;
```

Note • *You can configure the behavior for script failure in the InstallShield interface when you click a SQL script in the SQL Scripts explorer, and then go to the Runtime tab. The Script Error Handling section lets you select one of the following options:*

- *On Error, Go to Next Script*

- *On Error, Go to Next Statement*
- *On Error, Abort Installation*

Requiring that SQL Scripts Be Run Only Against a Full SQL Server

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Installations that include SQL script support allow end users to run the SQL scripts on Microsoft SQL Server Desktop Engine (MSDE) and on SQL Server Express Edition, by default. If you want end users to be able to run SQL scripts on only a full SQL Server, you can use the SQL Scripts view to configure that for any database connection in your installation.

Task: ***To prevent your SQL script files from running on target systems that have MSDE or SQL Server Express Edition:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, click the SQL connection that you want to configure.
3. On the **Requirements** tab, clear the **Allow Installation to Microsoft SQL Server Desktop Engine/SQL Server Express** check box.

Using Windows Installer Properties to Dynamically Replace Strings in SQL Scripts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

For Basic MSI, DIM, and InstallScript MSI projects, you can specify a replacement for text in a SQL script at run time through the use of Windows Installer properties. This enables you to let end users specify information that is then used in the SQL script that is launched on the target system. Windows Installer uses **MsiFormatRecord** to resolve the properties in the SQL script at run time.

Example

The following procedure demonstrates how to create a database at run time using a custom SQL script that contains information that end users enter on the built-in SQL login dialog: the SQLLogin dialog in a Basic MSI installation or the SQLServerSelectLogin2 dialog in an InstallScript MSI installation. Windows Installer properties are used for the database name and its target location.

Task: ***To create a database using a SQL script that contains information that end users specify at run time:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Right-click the **SQL Scripts** explorer and click **New SQL Connection**. InstallShield adds a new SQL connection.
3. Click the SQL connection, and then click the **General** tab.
4. Clear the **Create Catalog If Absent** check box.
5. In the **SQL Scripts** explorer, right-click the new connection and click **New Script**. InstallShield adds a new SQL script to the SQL connection.
6. Click the SQL script, and then click the **Script** tab.
7. In the script pane, enter the following:

```
if not exists(select name from master.dbo.sysdatabases where name = '%DBNAME%')
begin
CREATE DATABASE %DBNAME%
ON
( NAME = %DBNAME%_dat,
    FILENAME = '%DBPATH%%DBNAME%dat.mdf',
    SIZE = 10,
    MAXSIZE = 50,
    FILEGROWTH = 5 )
LOG ON
( NAME = %DBNAME%_log,
    FILENAME = '%DBPATH%%DBNAME%log.ldf',
    SIZE = 5MB,
    MAXSIZE = 25MB,
    FILEGROWTH = 5MB ) ;
end
GO
```

8. Configure two text replacements for the SQL script:
   a. Click the **Text Replacement** tab, and then click the **Add** button. The **Find and Replace** dialog box opens.
   b. In the **Find What** box, type the following:

      `%DBNAME%`

   c. In the **Replace What** box, type the following:

      `[IS_SQLSERVER_DATABASE]`

d. Click **OK**. The **Find and Replace** dialog box closes.

e. Click the **Add** button. The **Find and Replace** dialog box opens.

f. In the **Find What** box, type the following:

```
%DBPATH%
```

g. In the **Replace What** box, type the following:

```
[INSTALLDIR]
```

h. Click **OK**. The **Find and Replace** dialog box closes.

9. Click the **Runtime** tab.
10. Clear the **Run Script During Install** check box and select the **Run Script During Login** check box.
11. Build your release.

Using InstallScript Text Substitution to Dynamically Replace Strings in SQL Scripts

Project • *This information applies to InstallScript projects.*

For InstallScript projects, you can specify a replacement for text in a SQL script at run time through the use of text substitution string variables. This enables you to let end users specify information that is then used in the SQL script that is launched on the target system. The InstallScript run-time code uses the **TextSubSubstitute** function to replace the string variable with the appropriate value in the SQL script.

Example

The following procedure demonstrates how to create a database at run time using a custom SQL script that contains information that end users enter on the **SQLServerSelectLogin2** dialog. InstallScript text substitution is used for the database name and its target location.

Task: ***To create a database using a SQL script that contains information that end users specify at run time:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Right-click the **SQL Scripts** explorer and click **New SQL Connection**. InstallShield adds a new SQL connection.
3. Click the SQL connection, and then click the **General** tab.
4. Clear the **Create Catalog If Absent** check box.
5. In the **SQL Scripts** explorer, right-click the new connection and click **New Script**. InstallShield adds a new SQL script to the SQL connection.

6. Click the SQL script, and then click the **Script** tab.
7. In the script pane, enter the following:

```
if not exists(select name from master.dbo.sysdatabases where name = '%DBNAME%')
begin
CREATE DATABASE %DBNAME%
ON
( NAME = %DBNAME%_dat,
    FILENAME = '%DBPATH%\%DBNAME%dat.mdf',
    SIZE = 10,
    MAXSIZE = 50,
    FILEGROWTH = 5 )
LOG ON
( NAME = %DBNAME%_log,
    FILENAME = '%DBPATH%\%DBNAME%log.ldf',
    SIZE = 5MB,
    MAXSIZE = 25MB,
    FILEGROWTH = 5MB ) ;
end
GO
```

8. Configure two text replacements for the SQL script:
   a. Click the **Text Replacement** tab, and then click the **Add** button. The **Find and Replace** dialog box opens.
   b. In the **Find What** box, type the following:

      %DBNAME%

   c. In the **Replace What** box, type the following:

      <MYDATABASENAME>

   d. Click **OK**. The **Find and Replace** dialog box closes.
   e. Click the **Add** button. The **Find and Replace** dialog box opens.
   f. In the **Find What** box, type the following:

      %DBPATH%

   g. In the **Replace What** box, type the following:

      <TARGETDIR>

   h. Click **OK**. The **Find and Replace** dialog box closes.
9. Click the **Runtime** tab.
10. Clear the **Run Script During Install** check box and select the **Run Script During Login** check box.
11. In the View List under **Behavior and Logic**, click **InstallScript**.
12. Find the dialog code in the OnSQLServerInitialize event for the dialog that should contain the Database Name control, and add a call to the InstallScript function **TextSubSetValue**. For example, if you want the user name

to be the name that the end user specifies on the SQLServerSelectLogin2 dialog, you would add a **TextSubSetValue** call as shown in the following lines of code:

```
    // Display login dialog (without connection name)
    // UNCOMMENT OUT TO SWAP DIALOGS
    // nResult = SQLServerSelectLogin2( szConnection, szServer, szUser, szPassword,
bWinLogin, szDB, FALSE, TRUE );

    // Display login dialog (with connection name)
    // COMMENT OUT TO SWAP DIALOGS
    nResult = SQLServerSelectLogin2( szConnection, szServer, szUser, szPassword,
bWinLogin, szDB, TRUE, TRUE );
    TextSubSetValue ("<MYDATABASENAME>", szDB, FALSE);
```

13. Build your release.

Requiring a SQL Server-Side Installation for a Windows Installer-Based Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

One way to configure your installation so that it runs only on SQL Server machines is to perform a system search for registry information, store the result in a property, and then use the property in a condition that you set. The following step-by-step instructions show how to do this.

Task: ***To configure a Windows Installer–based installation to run only on SQL Server machines:***

1. In the View List under **Behavior and Logic**, click **System Search**.
2. Right-click the grid and click **Add**. The **System Search Wizard** opens.
3. In the **What do you want to find** panel, click **Registry entry** and click **Next**.
4. In the **How do you want to look for it** panel, do the following:
   a. In the **Registry Root** list, click **HKEY_LOCAL_MACHINE**.
   b. In the **Registry Key** box, type the following text:

      ```
      Software\Microsoft\Microsoft SQL Server
      ```

   c. In the **Registry Value** box, type the following text:

      ```
      InstalledInstances
      ```

   d. Click **Next**.

5. In the **What do you want to do with the value** panel, do the following:
   a. In the **Store the value in this property** box, type the following:

      `SQLSERVERFOUND`

   b. In the **Additional Options** area, select the **Store the value in the property and use the property in an Install Condition** option.
   c. Click **Finish**. The **Condition Builder** opens.
6. Verify the condition, and type a message that you want end users to see if the registry entry is not found on the system. For example, you can type the following message:

   ```
   Microsoft SQL Server was not found on this machine. This installation was designed to
       run only on the server machine.
   ```

7. Click **OK**.

InstallShield adds an entry to the System Search grid.

Requiring a Server-Side Installation for an InstallScript Project

Project • *This information applies to InstallScript projects.*

One way to enforce a server-side installation in an InstallScript project is to set up your installation project so that it searches for a specific registry key and value and only installs the installation project if the value is found. See the sample code below for an example of how you can do this in your InstallScript project.

```
function OnBegin()
    string sKey, sValue, sData;
    string sMsg;
    number nType, nSize, nResult;
begin

    RegDBSetDefaultRoot( HKEY_LOCAL_MACHINE );
    sKey = "Software\\Microsoft\\Microsoft SQL Server";
    sValue = "InstalledInstances";
    nResult = RegDBGetKeyValueEx( sKey, sValue, nType, sData, nSize );

    if( nResult < 0 ) then

        //SQL Server registry key is missing
        sMsg = "Microsoft SQL Server was not found on this machine.\n" +
               "This installation was designed to run only on the server machine.";
        MessageBox( sMsg, SEVERE );
        abort;

    endif;

end;
```

Publishing SQL Script Files to a Repository

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

If you have an existing SQL script file that you would like to reuse in other projects or share with other users, you can publish it to a repository.

Task: ***To publish a SQL script file to a repository:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. In the **SQL Scripts** explorer, right-click the script file that you would like to publish, and then click **Publish Wizard**. The **Publish Wizard** opens.
3. Complete the panels in the Publish Wizard.

After you have imported a script file from a repository into a project, there is no link between the current script file and the existing repository script file. If you make a change to the script file and then republish it to the repository, it does not affect the script file in the project to which it was imported. However, you can reimport the script file from the repository into your project.

Installing the MySQL ODBC Driver

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

If you want to install and launch the MySQL ODBC driver before your installation is run, you can include the InstallShield prerequisite for MySQL Connector 3.51 in your project.

Task: ***To install and launch the MySQL ODBC driver before your installation is run:***

1. For Basic MSI and InstallScript MSI projects: In the View List under **Application Data**, click **Redistributables**.

   For InstallScript projects: In the View List under **Application Data**, click **Prerequisites**.

2. In the list of redistributables, select the **MySQL Connector ODBC 3.51** check box.

Tip • *The MySQL Connector ODBC 3.51 prerequisite is available only if you have downloaded the installer and added the InstallShield prerequisite to your system. For detailed instructions, see Including the MySQL Connector ODBC Prerequisite.*

Deleting a SQL Server Database During Uninstallation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Note • *You cannot delete a database to which you are currently connected.*

If you need to remove a SQL database during uninstallation, you can do so through your SQL script. The following procedure demonstrates how to configure your project and SQL script to delete a Microsoft SQL Server database.

Task: ***To remove a Microsoft SQL Server database during uninstallation:***

1. In the View List under **Server Configuration**, click **SQL Scripts**.
2. Add a SQL connection.
3. On the **General** tab, in the **Catalog Name** box, type `Master`.

   Master is the name of the system database that exists on all Microsoft SQL Server systems; since you cannot delete a database to which you are currently connected, you can connect to the Master database and then delete a different database to which you are not connected.
4. Enter the authentication information for the server.
5. Add a new SQL script file.
6. Add the following to the SQL script file:

   ```
   DROP DATABASE DatabaseName
   GO
   ```

   DatabaseName is the name of the database that you want to delete.

Tip • *As an alternative to the aforementioned procedure, you can perform the same operation completely in SQL script. To do so, enter the following code in your SQL script:*

```
USE Master
DROP DATABASE DatabaseName
GO
```

`DatabaseName` is the name of the database that you want to delete.

Connecting to a Microsoft Windows Azure Database Server and Running SQL Scripts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Target System Requirements for Connecting to a Microsoft Windows Azure SQL Database Server

Connecting to a Microsoft Windows Azure SQL database server requires the SQL Server Native Client 10.0 ODBC driver on target system that are running the installation. To ensure that this driver is available on target systems, you can include the InstallShield prerequisite for Microsoft SQL Server 2008 Native Client 10.00.2531 in your project.

Task: ***To include the Microsoft SQL Server 2008 Native Client 10.00.2531 prerequisite in your project:***

1. For Basic MSI and InstallScript MSI projects: In the View List under **Application Data**, click **Redistributables**.

   For InstallScript projects: In the View List under **Application Data**, click **Prerequisites**.

2. In the list of redistributables, select the appropriate **Microsoft SQL Server 2008 Native Client 10.00.2531** check box or check boxes, depending on whether the architecture of target systems is 32 bit or 64 bit.

The InstallShield prerequisite is launched only if the conditions that are defined in the InstallShield prerequisite file (.prq) are met. To see the list of conditions, click the SQL Server Native Client prerequisite in the Redistributables view or the Prerequisites view, and then review the details that are listed in the details pane on the right. You can hide or show the details pane by clicking the Show Details button in these views.

Specifying the User Name for the Windows Azure SQL Database Connection at Run-Time

If you use the SQLLogin dialog in your installation and your installation is targeting a Windows Azure SQL database, end users should use the following format to enter a string in the Login ID box on the SQLLogin dialog:

DatabaseUserName@ServerName

Following is an example:

MyUserName@wbzdh64drd

Connecting to an Instance of Oracle and Running SQL Scripts

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Note • *If you want your installation to download the Oracle 11g Instant Client whenever it needs to be installed on a target system, check with Oracle to ensure that it is allowed. If it is allowed, you must host the download on your own Web site and add its download path to the InstallShield prerequisite. Flexera Software does not make this installation available for download.*

Connecting to an instance of Oracle requires the following elements on the end-user machine that is running the installation:

- Microsoft ODBC for Oracle
- 32-bit version of the Oracle Instant Client software (even on 64-bit target systems)

The latest Microsoft Data Access Components (MDAC) include support for the Microsoft ODBC for Oracle drivers. However, the Microsoft ODBC for Oracle driver requires Oracle Instant Client software to communicate with Oracle database servers. Therefore, you may want to include the Oracle 11g Instant Client prerequisite to help configure the Oracle Instant Client on target machines upon installation. Oracle does not provide an installation for the files; you can do so easily by using the Oracle Instant Client installation project that is available in the InstallShield Program Files folder. For instructions, see Downloading the Oracle Instant Client and Creating an .msi Package for It.

Note that if your SQL script contains Unicode characters, you may want to use the Oracle ODBC Instant Client, since it has support for running SQL scripts that contain Unicode characters, but Microsoft ODBC for Oracle does not. You may want to include an ODBC Instant Client installation with the Oracle 11g Instant Client prerequisite to help configure the Oracle Instant Client on target machines, and to also set up the ODBC Instant Client. For more information, see Downloading the Oracle Basic Instant Client and the Oracle ODBC Instant Client and Creating an

.msi Package and InstallShield Prerequisite for Both. If you plan on using the ODBC Instant Client instead of Microsoft ODBC for Oracle, ensure that you configure your project accordingly. For more information, see Running SQL Scripts with Unicode Characters on an Oracle Database Server.

Downloading the Oracle Instant Client and Creating an .msi Package for It

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Before you can add Oracle 11g Instant Client support to your Basic MSI, InstallScript, or InstallScript MSI project, you must download the Oracle Instant Client from Oracle's Web site. Oracle does not provide an installation for the files, so you also need to create an .msi package; you can do so easily by using the Oracle Instant Client installation project that is available in the InstallShield Program Files folder.

Once you have created the .msi package, you can add it to the appropriate folder on your machine, and then add the InstallShield prerequisite that uses this Oracle Instant Client .msi package.

Note • *Note that if your SQL script contains Unicode characters, you may want to use the Oracle ODBC Instant Client, since it has support for running SQL scripts that contain Unicode characters, but Microsoft ODBC for Oracle does not. You may want to include an ODBC Instant Client installation with the Oracle 11g Instant Client prerequisite to help configure the Oracle Instant Client on target machines, and to also set up the ODBC Instant Client. For more information, see Downloading the Oracle Basic Instant Client and the Oracle ODBC Instant Client and Creating an .msi Package and InstallShield Prerequisite for Both.*

Task: ***To download the Oracle Instant Client and create an .msi package:***

1. Visit http://www.oracle.com/technetwork/database/features/instant-client/index-097480.html and download the 11.1.0.x version of the Oracle Instant Client (the Basic package for 32-bit Windows platforms). The download file is called `instantclient-basic-win32-11.1.0.7.0.zip`.

   

   Important • *The Oracle support in InstallShield requires that the target system have the 32-bit version of the Oracle Instant Client, regardless of whether the target system is a 32-bit or 64-bit system.*

2. Unzip the files to the root of your C drive. Unzipping the files adds all of the files to the following location:

   `C:\instantclient_11_1`

3. Open the Oracle Instant Client installation project in InstallShield. The path for the project is as follows:

   `InstallShield Program Files Folder``\Support\Oracle Instant Client\instantclient-win32-11_1.ism`

Flexera Software created this project for the 11.1.0.7 version of the Oracle Instant Client; however, you can use this same project for more-recent versions of the Oracle 11g Instant Client, such as 11.2.01, for example.

4. The name that is displayed at run time during the Oracle 11g Instant Client installation is **Oracle11g Instant Client 11.1.0.7**; this name is also used for the .msi file. If you want to change this name to something else to reflect a different version number, such as 11.2.0.1 or 11.2.0.x, you can do so:

   a. In the View List under **Installation Information**, click **General Information**.

   b. In the **Product Name** setting, edit the existing text as needed.

5. If you are using a version that was released after 11.1.0.7 and it requires any dependencies, add the files or merge modules to the project.

6. On the toolbar, click the **Build** button.

InstallShield builds an Oracle 11g Instant Client .msi file and adds it to the following directory so that you can include the Oracle 11g Instant Client in your InstallShield projects:

InstallShield Program Files Folder\SetupPrerequisites\oracle

Tip • *If you are using a version that was released after 11.1.0.7, open the Oracle 11g Instant Client 11.1.0.7 prerequisite in the InstallShield Prerequisite Editor. Rename the prerequisite to reflect the appropriate version number. In addition, update the conditions to reflect the appropriate version number.*

For instructions on how to add the Oracle 11g Instant Client to installations, see Installing the Oracle 11g Instant Client.

Downloading the Oracle Basic Instant Client and the Oracle ODBC Instant Client and Creating an .msi Package and InstallShield Prerequisite for Both

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

Before you can add support for the Oracle 11g Instant Client and the Oracle ODBC Instant Client to your Basic MSI, InstallScript, or InstallScript MSI project, you must download the Oracle Basic Instant Client and the Oracle ODBC Instant Client from Oracle's Web site. Oracle does not provide an installation for the files, so you also need to create an .msi package; you can do so easily by using the Oracle Instant Client installation project that is available in the InstallShield Program Files folder.

Once you have created the .msi package, you can add it to the appropriate folder on your machine, and then add the InstallShield prerequisite that uses this Oracle .msi package.

Task: ***To download the Basic Instant Client and the ODCBC Instant Client and create an .msi package:***

1. Visit http://www.oracle.com/technetwork/database/features/instant-client/index-097480.html and download the 11.1.0.x version of the Oracle Instant Client (the Basic package for 32-bit Windows platforms), as well as the 11.1.0.x version of the Instant Client Package for ODBC. The download files are called `instantclient-basic-win32-11.1.0.7.0.zip` and `instantclient-odbc-win32-11.1.0.7.0.zip`.

   

   Important • *The Oracle support in InstallShield requires that the target system have the 32-bit version of the Basic Instant Client and of the ODBC Instant Client, regardless of whether the target system is a 32-bit or 64-bit system.*

2. Unzip the files to the root of your C drive. Unzipping the files adds all of the files to the following location:

   `C:\instantclient_11_1`

   Ensure that the files are not unzipped to `C:\instantclient11_1\instantclient11_1`.

3. Make a copy of the Oracle Instant Client installation project. The path for the project is as follows:

   `InstallShield Program Files Folder``\Support\Oracle Instant Client\instantclient-win32-11_1.ism`

   Name the copy `instantclient-win32-odbc11_1.ism`, and put it in the same directory as the original .ism file. The path for this new file is:

   `InstallShield Program Files Folder``\Support\Oracle Instant Client\instantclient-win32-odbc11_1.ism`

   Flexera Software created the `instantclient-win32-11_1.ism` project for the 11.1.0.7 version of the Oracle Instant Client; however, you can use this same project for more-recent versions of the Oracle 11g Instant Client and ODBC Instant Client, such as 11.2.01, for example.

4. Open the new project that you created in InstallShield.

5. Update the product code, the upgrade code, and the product name:

   a. In the View List under **Installation Information**, click **General Information**.

   b. In the **Product Code** setting, click the **Generate a new GUID** button (**{..}**).

   c. In the **Upgrade Code** setting, click the **Generate a new GUID** button (**{..}**).

   d. In the **Product Name** setting, change the existing text as needed.

      `Oracle11g Instant Client - ODBC 11.1.0.7`

      The name that you enter is displayed at run time during the Oracle installation. If you want to change this name to something else to reflect a different version number, such as 11.2.0.1 or 11.2.0.x, you can do so.

6. If you are using a version that was released after 11.1.0.7 and it requires any dependencies, add the files or merge modules to the project.

7. Add a custom action that launches the ODBC Instant Client installation:

a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.

b. In the center pane, right-click the **Custom Actions** explorer, point to **New EXE**, and click **Path referencing a directory**. InstallShield adds a new custom action.

c. Configure the custom action's settings in the right pane as follows:

- Working Directory: INSTALLDIR
- Filename & Command Line: [INSTALLDIR]odbc_install.exe
- In-Script Execution: Deferred Execution in System Context
- Install Exec Sequence: After InstallODBC
- Install Exec Condition: Not Installed

8. Add a custom action that uninstalls the ODBC Instant Client when end users uninstall the Instant Client:

a. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.

b. In the center pane, right-click the **Custom Actions** explorer, point to **New EXE**, and click **Path referencing a directory**. InstallShield adds a new custom action.

c. Configure the custom action's settings in the right pane as follows:

- Working Directory: INSTALLDIR
- Filename & Command Line: [INSTALLDIR]odbc_uninstall.exe
- In-Script Execution: Deferred Execution in System Context
- Install Exec Sequence: After RemoveODBC
- Install Exec Condition: REMOVE="ALL"

9. Specify a name for the .msi package file:

a. In the View List under **Media**, click **Releases**.

b. In the center pane, in the **Releases** explorer, click the product configuration called **Product Configuration 1**.

c. In the **MSI Package File Name** setting, enter the following name:

```
Oracle11g Instant Client - ODBC 11.1
```

InstallShield will use the name that you enter for the .msi package that it creates for the Basic Instant Client and ODBC Instant Client. This is the file that will be launched by the InstallShield prerequisite that you create.

10. On the toolbar, click the **Build** button.

InstallShield builds an Oracle .msi file and adds it to the following directory so that you can include the `Oracle11g Instant Client - ODBC 11.1.msi` file in your InstallShield projects:

InstallShield Program Files Folder\SetupPrerequisites\oracle

Task: ***To create an InstallShield prerequisite that launches the .msi package that you created in the aforementioned procedure:***

1. Make a copy of the existing InstallShield prerequisite (.prq) for the Oracle11g Instant Client. The path for the prerequisite is as follows:

   InstallShield Program Files Folder\SetupPrerequisites\Oracle11g Instant Client 11.1.0.7.prq

   Name the copy `Oracle11g Instant Client - ODBC 11.1.0.7.prq`, and put it in the same directory as the original .prq file. The path for this new file is:

   InstallShield Program Files Folder\SetupPrerequisites\Oracle11g Instant Client - ODBC 11.1.0.7.prq

2. On the **Tools** menu, click **Prerequisite Editor**. The **InstallShield Prerequisite Editor** opens.
3. On the **File** menu, click **Open**. The **Open** dialog box opens.
4. Browse to the new `Oracle11g Instant Client - ODBC 11.1.0.7.prq` file, and then click the **Open** button.
5. On the **Properties** tab, in the **Unique identifier for InstallShield prerequisite** setting, enter:

   `Oracle11g Instant Client - ODBC 11.1.0.7`

   If you are using a different version, update the identifier accordingly.

6. Configure the conditions for the InstallShield prerequisite:
   a. Click the **Conditions** tab.
   b. Click each existing condition and then click the **Remove** button.
   c. Click the **Add** button. The **Prerequisite Condition** dialog box opens.
   d. Select the **A registry key does or does not exist** option.
   e. In the **Specify the registry key name to check** setting, enter:

      `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBCINST.INI\Oracle in instantclient11_1`

      If you are using a different version, configure the condition accordingly.

   f. Select the **32-bit** option.
   g. Select the **If the specified registry key DOES NOT EXIST** option, and then click **OK**.
7. Specify the appropriate .msi file to include in your InstallShield prerequisite:
   a. Click the **Files to Include** tab.
   b. Select the existing **Oracle11g Instant Client 11.1.msi** file, and then click the **Modify** button. The **New File** dialog box opens.
   c. Select the `Oracle11g Instant Client - ODBC 11.1.msi` file that you built in the aforementioned procedure, and then click **OK**.
8. Specify the file that the InstallShield prerequisite should launch:

a. Click the **Application to Run** tab.

b. In the **Specify the application you wish to launch** setting, select the .msi file.

9. On the **File** menu, click **Save**.

For instructions on how to add the Oracle 11g Instant Client and the ODBC Instant Client to installations, see Installing the Oracle 11g Instant Client.

If you plan on using the Oracle ODBC Instant Client instead of Microsoft ODBC for Oracle, ensure that you configure your project accordingly. For more information, see Running SQL Scripts with Unicode Characters on an Oracle Database Server.

Installing the Oracle 11g Instant Client

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

If you want to install the Oracle 11g Instant Client when your installation is run, you can include the Oracle 11g Instant Client prerequisite in your project.

Note that before you can include the InstallShield prerequisite, you must download the Oracle Basic Instant Client and create an .msi package. If you also want the Oracle ODBC Instant Client to be installed—for example, if you need to use Unicode support with Oracle—you must download the Basic Instant Client and the ODBC Instant Client, build an .msi package, and create an InstallShield prerequisite; you can use the Oracle 11g Instant Client prerequisite as a template, and modify the settings as needed. For more information, see:

- Downloading the Oracle Instant Client and Creating an .msi Package for It
- Downloading the Oracle Basic Instant Client and the Oracle ODBC Instant Client and Creating an .msi Package and InstallShield Prerequisite for Both

Important • *The Oracle support in InstallShield requires that the target system have the 32-bit version of the Oracle Instant Client, regardless of whether the target system is a 32-bit or 64-bit system.*

Task: ***To include the Oracle 11g Instant Client prerequisite in your project:***

1. For Basic MSI and InstallScript MSI projects: In the View List under **Application Data**, click **Redistributables**.

   For InstallScript projects: In the View List under **Application Data**, click **Prerequisites**.

2. In the list of redistributables, select the **Oracle11g Instant Client 11.1.0.7** check box (or the check box for whatever Oracle prerequisite that you are using).

The InstallShield prerequisite is launched only if the conditions that are defined in the InstallShield prerequisite file (.prq) are met. To see the list of conditions, click the Oracle prerequisite in the Redistributables view or the Prerequisites view, and then review the details that are listed in the details pane on the right. You can hide or show the details pane by clicking the Show Details button in these views.

Note • *If you want your installation to download the Oracle 11g Instant Client whenever it needs to be installed on a target system, check with Oracle to ensure that it is allowed. If it is allowed, you must host the download on your own Web site and add its download path to the InstallShield prerequisite. Flexera Software does not make this installation available for download.*

Running SQL Scripts with Unicode Characters on an Oracle Database Server

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

For installations that use the default SQL script support that is available in the SQL Scripts view of InstallShield, Microsoft ODBC for Oracle is used to connect to an Oracle database server on a target system. In some cases, you may want to override the default behavior, and use the Oracle ODBC Instant Client instead of Microsoft ODBC for Oracle.

For example, if your SQL script contains Unicode characters, you may want to use the Oracle ODBC Instant Client, since it has support for running SQL scripts that contain Unicode characters, but Microsoft ODBC for Oracle does not.

Task: ***To configure your InstallShield project so that your installation uses the Oracle ODBC Instant Client instead of Microsoft ODBC for Oracle:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, click the **ISSQLDBMetaData** table.
3. Perform the following steps for the **Oracle** record:
   a. Change the AdoDriverName field to the following value:

      ```
      {Oracle in instantclient11_1}
      ```

   b. Change the AdoCxnServer field to the following value:

      ```
      DBQ=
      ```

At run time, the installation uses the Oracle ODBC Instant Client for connecting to the Oracle database and running SQL scripts.

Tip • *The Oracle ODBC Instant Client is available on a target system if the ODBC package of the Oracle Instant Client software is installed. To learn how to add it to your installation, see Downloading the Oracle Basic Instant Client and the Oracle ODBC Instant Client and Creating an .msi Package and InstallShield Prerequisite for Both.*

Creating a Sample Installation that Creates a SQL Server Database by Running Customized SQL Script

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The following procedure demonstrates how to create an installation that creates a SQL Server database through customized SQL script.

Task: ***To create an installation that creates a SQL Server database on the target machine by running customized SQL script:***

1. Create a new Basic MSI or InstallScript MSI project.
2. In the View List under **Behavior and Logic**, click **Property Manager**.
3. Create a new property that has the following name:

   IS_SQLSERVER_DATABASE2
4. In the View List under **Server Configuration**, click **SQL Scripts**.
5. Add and configure a new SQL connection:
   a. Right-click the **SQL Scripts** explorer and click **New SQL Connection**. InstallShield adds a new connection with the name **NewConnection1** as the default name.
   b. In the **SQL Scripts** explorer, click the **NewConnection1** item, and then click the **General** tab.
   c. In the **Default Target Server Name (optional)** box, type TESTSQLSERVER.
   d. Clear the **Create Catalog If Absent** check box.
   e. In the **Connect using** area, select the **Server authentication using the Login ID and password below** option.
   f. In the **Login ID** box, type sa. Leave the **Password** box blank.
   g. Click the **Requirements** tab.

h. Ensure that the **Microsoft SQL Server** check box is selected and the **MySQL** and **Oracle** check boxes are cleared.

6. Add and configure a new SQL script for NewConnection1:

   a. In the **SQL Scripts** explorer, right-click **NewConnection1** and click **New Script**.

   b. Change the name of the script to `NewScript1`.

   c. In the **SQL Scripts** explorer, click **NewScript1**, and then click the **Script** tab.

   d. In the script editor pane, add the following script:

```
CREATE DATABASE [TestDB] ON (NAME = N' TestDB', FILENAME = N'C:\Program Files\Microsoft SQL
Server\MSSQL\data\testdb.mdf' , SIZE = 3, FILEGROWTH = 10%) LOG ON (NAME = N' TestDB_log',
FILENAME = N'C:\Program Files\Microsoft SQL Server\MSSQL\data\testdb.ldf' , SIZE = 1,
FILEGROWTH = 10%)
COLLATE SQL_Latin1_General_CP1_CI_AS
```

   e. Click the **Runtime** tab.

   f. In the **Script Execution** area, select the **Run Script During Login** check box and ensure that the **Run Script During Install** and **Run Script During Uninstall** check boxes are cleared.

7. Add and configure a second new SQL connection:

   a. Right-click the **SQL Scripts** explorer and click **New SQL Connection**. InstallShield adds a new connection with the name **NewConnection2** as the default name.

   b. In the **SQL Scripts** explorer, click the **NewConnection2** item, and then click the **Advanced** tab.

   c. In the **Target Catalog Property Name** list, select **IS_SQLSERVER_DATABASE2**.

   d. Click the **General** tab.

   e. In the **Catalog Name** box, type `TestDB`.

   f. Clear the **Create Catalog If Absent** check box.

   g. In the **Default Target Server Name (optional)** box, type `TESTSQLSERVER`.

   h. In the **Connect using** area, select the **Server authentication using the Login ID and password below** option.

   i. In the **Login ID** box, type `sa`. Leave the **Password** box blank.

   j. Click the **Requirements** tab.

   k. Ensure that the **Microsoft SQL Server** check box is selected and the **MySQL** and **Oracle** check boxes are cleared.

8. Add and configure a new SQL script for NewConnection2:

   a. In the **SQL Scripts** explorer, right-click **NewConnection2** and click **New Script**.

   b. Change the name of the script to `NewScript2`.

   c. In the **SQL Scripts** explorer, click **NewScript2**, and then click the **Script** tab.

   d. In the script editor pane, add the following script:

```
CREATE TABLE TestTable (TestColumn1 CHAR NOT NULL PRIMARY KEY)
```

e. Click the **Runtime** tab.

f. In the **Script Execution** area, select the **Run Script During Install** check box and ensure that the **Run Script During Login** and **Run Script During Uninstall** check boxes are cleared.

When you run the installation, it creates the **TestDB** database and adds a table called **TestTable** to that database.

Project • *You can achieve the same outcome when following the above procedure but using a DIM project, and then adding the DIM to an installation project.*

Creating a Sample Installation that Creates an Oracle Schema by Running Customized SQL Script

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The following procedure demonstrates how to create an installation that creates an Oracle schema through customized SQL script.

Task: ***To create an installation that creates an Oracle schema on the target machine by running customized SQL script:***

1. Create a new Basic MSI or InstallScript MSI project.
2. In the View List under **Behavior and Logic**, click **Property Manager**.
3. Create three new properties that have the following names:

   IS_SQLSERVER_DATABASE2

   IS_SQLSERVER_USERNAME2

   IS_SQLSERVER_PASSWORD2
4. In the View List under **Server Configuration**, click **SQL Scripts**.
5. Add and configure a new SQL connection:

   a. Right-click the **SQL Scripts** explorer and click **New SQL Connection**. InstallShield adds a new connection with the name **NewConnection1** as the default name.

   b. In the **SQL Scripts** explorer, click the **NewConnection1** item, and then click the **General** tab.

   c. In the **Default Target Server Name (optional)** box, type the following:

//sch01jsmith.installshield.com:1521/orcl

d. Clear the **Create Catalog If Absent** check box.

e. In the **Connect using** area, select the **Server authentication using the Login ID and password below** option.

f. In the **Login ID** box, type `scott`.

g. In the **Password** box, type `scott`.

h. Click the **Requirements** tab.

i. Ensure that the **Oracle** check box is selected and the **Microsoft SQL Server** and **MySQL** check boxes are cleared.

6. Add and configure a new SQL script for NewConnection1:

a. In the **SQL Scripts** explorer, right-click **NewConnection1** and click **New Script**.

b. Change the name of the script to `NewScript1`.

c. In the **SQL Scripts** explorer, click **NewScript1**, and then click the **Script** tab.

d. In the script editor pane, add the following script:

```
CREATE TABLESPACE TEST_TS LOGGING DATAFILE 'test01.dbf' SIZE 1M AUTOEXTEND ON NEXT 2M MAXSIZE
UNLIMITED
Go
CREATE USER TEST_USER IDENTIFIED BY MYPSWD DEFAULT TABLESPACE TEST_TS QUOTA UNLIMITED on
TEST_TS
Go
GRANT CONNECT TO TEST_USER
Go
GRANT DBA TO TEST_USER
Go
ALTER USER TEST_USER DEFAULT ROLE ALL
Go
```

e. Click the **Runtime** tab.

f. In the **Script Execution** area, select the **Run Script During Login** check box and ensure that the **Run Script During Install** and **Run Script During Uninstall** check boxes are cleared.

7. Add and configure a second new SQL connection:

a. Right-click the **SQL Scripts** explorer and click **New SQL Connection**. InstallShield adds a new connection with the name **NewConnection2** as the default name.

b. In the **SQL Scripts** explorer, click the **NewConnection2** item, and then click the **Advanced** tab.

c. In the **Target Catalog Property Name** list, select **IS_SQLSERVER_DATABASE2**.

d. In the **Server Authentication Login ID Property Name** list, select **IS_SQLSERVER_USERNAME2**.

e. In the **Server Authentication Password Property Name** list, select **IS_SQLSERVER_PASSWORD2**.

f. Click the **General** tab.

g. In the **Catalog Name** box, type `TEST_USER`.

h. Clear the **Create Catalog If Absent** check box.

i. In the **Default Target Server Name (optional)** box, type the following:

```
//sch01jsmith.installshield.com:1521/orcl
```

j. In the **Connect using** area, select the **Server authentication using the Login ID and password below** option.

k. In the **Login ID** box, type `TEST_USER`.

l. In the **Password** box, type `MYPSWD`.

m. Click the **Requirements** tab.

n. Ensure that the **Oracle** check box is selected and the **Microsoft SQL Server** and **MySQL** check boxes are cleared.

8. Add and configure a new SQL script for NewConnection2:

a. In the **SQL Scripts** explorer, right-click **NewConnection2** and click **New Script**.

b. Change the name of the script to `NewScript2`.

c. In the **SQL Scripts** explorer, click **NewScript2**, and then click the **Script** tab.

d. In the script editor pane, add the following script:

```
CREATE TABLE TestTable (TestColumn1 CHAR NOT NULL PRIMARY KEY)
```

e. Click the **Runtime** tab.

f. In the **Script Execution** area, select the **Run Script During Install** check box and ensure that the **Run Script During Login** and **Run Script During Uninstall** check boxes are cleared.

When you run the installation, it creates the **TEST_USER** user and a **TestTable** table on the **TEST_USER** schema.

Project • *You can achieve the same outcome when following the above procedure but using a DIM project, and then adding the DIM to an installation project.*

Managing COM+ Applications and Components

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The Component Services view enables you to manage COM+ applications and components for your installation package. You can manage both COM+ server applications and application proxies. A COM+ application proxy consists of a subset of the attributes of the server application, and it enables remote access from a client machine to the machine where the application resides.

Note the following information regarding component services in InstallShield:

- Only non-system COM+ applications can be added to your project. Therefore, InstallShield displays only non-system COM+ applications under the COM+ Applications explorer in the Component Services view.
- Only the COM+ applications that are installed on the local machine are included in the Component Services view and available for you to add to your projects.
- An application proxy is available for COM+ server applications only, not for library applications.

The look and feel of the Component Services view is similar to that of the Component Services administrative tool in the Control Panel.

Managing COM+ Server Applications

Project *• This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Task: ***To configure the installation settings for a COM+ server application:***

1. In the View List under **Server Configuration**, click **Component Services**.
2. In the **Component Services** explorer, select the COM+ application that you would like to configure if you have not already done so.
3. On the **Installation** tab, select the **Server** check box.

   

   Note *• You must select the* ***Proxy*** *check box, the* ***Server*** *check box, or both check boxes. Once you clear one of these check boxes, the other check box remains selected but it is no longer available; this prevents you from clearing both check boxes.*
4. Select the **Refresh the COM+ settings from the client machine at build** check box if appropriate.
5. If your installation does not include the COM+ application proxy support, clear the **Proxy** check box

When you add a COM+ server application to your project, InstallShield creates a corresponding component for each of the features that are associated with the proxy component. This component has the COM+ application's server .dll files.

Note • *If the selected COM+ application includes both server and proxy installations, you can add installation conditions so that the appropriate COM+ application is installed on the target machine. For more information, see Including a COM+ Application that Targets Servers and Client Machines.*

Managing COM+ Application Proxies

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The COM+ application proxy support configures the system settings that enable remote access from a client machine to the machine where the server application resides. You may also need to add the client application to your installation.

Task: ***To configure the installation settings for a COM+ application proxy:***

1. In the View List under **Server Configuration**, click **Component Services**.
2. In the **Component Services** explorer, select the COM+ application that you would like to configure if you have not already done so.
3. On the **Installation** tab, select the **Proxy** check box.
4. Clear the **Server** check box if your installation does not include the COM+ server application.

   

   Note • *You must select the **Proxy** check box, the **Server** check box, or both check boxes. Once you clear one of these check boxes, the other check box remains selected but it is no longer available; this prevents you from clearing both check boxes.*

5. In the **Remote Server Name** box, specify the name of the remote server computer where the application resides. You can type the exact name or use the default **[REMOTESERVERNAME]** property, which is automatically created when you select the **Proxy** check box for a COM+ application in your installation.

   

   Note • *The default value for the **[REMOTESERVERNAME]** property is the name of the machine used to add the COM+ application to the installation project in InstallShield. To change the value of the **[REMOTESERVERNAME]** property, use the Property Manager view.*

*If you would like the end user to be able to specify the remote server, add a Remote Server edit field control to an end-user dialog in the **Dialogs** view. Set the **Property** value of this control to `REMOTESERVERNAME`.*

6. Select the **Enable distributed COM on the client machine** check box if appropriate. Clear this check box if you know that distributed component object model (DCOM) is already enabled on all client machines and you will not have administrative privileges on them.

   If you select this check box, Y is written at installation time to the EnableDCOM entry of the HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Ole registry key to enable DCOM.

   

   ***Note** • End users can enable or disable DCOM on their machines using the Component Services administrative tool in the Control Panel. However, the application proxy will not work on a client machine if DCOM is disabled on that machine. For this reason, you may want to select the Enable distributed COM on the client machine check box.*

   If an end user uninstalls the application proxy support, the EnableDCOM registry entry is not changed, even if the installation process involved changing this registry entry to Y on the target machine.

When you add a COM+ application proxy to your project, InstallShield creates a corresponding component for each of the features that are associated with the server component. This component has the COM+ application's server .dll files. These server files are installed on the client machine for the type libraries.

***Note** • If the selected COM+ application includes both server and proxy installations, you can add installation conditions so that the appropriate COM+ application is installed on the target machine. For more information, see Including a COM+ Application that Targets Servers and Client Machines.*

Including a COM+ Application that Targets Servers and Client Machines

***Project** • This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

If you want your installation to install the server application on the server as well as the application proxy support on client machines, you can create installation conditions so that the appropriate component is installed on the target machine. The following example procedure illustrates how you can do this.

Task: ***To include a COM+ application in an installation that targets both servers and client machines:***

1. In the **Property Manager** view, create a new property called **COMPLUSTYPE**.
2. In the **Dialogs** view, add a radio button group control to a new or existing end-user dialog, and set the **Property** value of this control to `COMPLUSTYPE`. This radio button group will enable end users to specify which installation they would like to run: server or proxy.
3. Add a radio button for the **Server** option to the radio button group, and set the **Value** property of this control to Server.
4. Add a radio button for the **Proxy** option to the radio button group, and set the **Value** property of this control to Proxy.
5. In the **Component Services** view, select the COM+ application that you would like to configure.
6. On the **Installation** tab, set the parameters for server installations and application proxies.
7. In the **Condition** box under the **Server** check box, type the following:

   ```
   COMPLUSTYPE="Server"
   ```

8. In the **Condition** box under the **Proxy** check box, type the following:

   ```
   COMPLUSTYPE="Proxy"
   ```

Managing Internet Information Services

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Internet Information Services (IIS) is a Web server developed by Microsoft. It provides a secure platform for building and deploying Web-based applications, managing Web sites, and publishing information to the Internet or an intranet.

The Internet Information Services view in InstallShield enables you to create and manage new IIS Web sites, applications, virtual directories, application pools, and Web service extensions.

Version-Specific Information for IIS Support in InstallShield

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Following is information about specific versions of IIS:

- IIS is included with Windows 2000 Server and later and Windows XP and later systems. IIS 6 is available only on Windows Server 2003 systems. IIS 7 is available on Windows Vista and Windows Server 2008 systems. IIS 7.5 is available on Windows 7 and Windows Server 2008 R2 systems. IIS is not installed automatically by default.
- Some of the Web site and virtual directory settings in the Internet Information Services view apply to specific versions of IIS. Version-specific information is noted for these settings in the inline help panes in InstallShield. If you configure a version-specific property but a target system does not have the corresponding version of IIS, IIS ignores the version-specific property.

  For example, IIS 7 and IIS 6 do not support the Application Protection property for applications or virtual directories. In the Internet Information Services view, this property is configured through a setting in the Application Settings area for an application or a virtual directory. When you select this setting in the Internet Information Services view, the help pane that is displayed in the lower-right corner indicates that the setting does not apply to IIS 6 or later. If you configure this setting and an end user installs your product on a target system that has IIS 6 or later, the Application Protection setting is ignored.
- Web service extensions, application pools, and all of the associated properties are available only on machines with IIS 6 or later.

  On systems with IIS 7, Web service extensions require that the IIS Metabase and IIS 6 Configuration Compatibility feature be installed. If it is not installed, the installation's log file may show error -2147467259 to inform you that this feature may be required.

  For information on how to determine whether a Windows Vista or Windows Server 2008 system has the IIS Metabase and IIS 6 Configuration Compatibility feature installed, see Determining If a Target System Has IIS 6 or Earlier or the IIS 6 Metabase Compatibility Feature.
- Windows Vista and later and Windows Server 2008 and later systems store settings for individual Web sites, applications, and virtual directories in configuration files that are located at the physical path that you specify in your installation project—in the Content Source Path (Local or UNC) setting in the Internet Information Services view. Therefore, each Web site, application, or virtual directory should have a unique physical path. Otherwise, you may notice unexpected behavior, especially in testing environments, if you have two different applications or virtual directories with the same physical path.

For example, if you have two virtual directories that have the same physical path, and directory browsing is enabled in one but not the other, the directory browsing setting for the second virtual directory that is created overrides the setting for the first virtual directory.

- On systems that have Windows Server 2003, if IIS 6 is not installed, other IIS directories and sites are still created. IIS 6-specific settings are skipped.
- IIS 5.1 for Windows XP Professional can service only one Web site at a time. This is a limitation of IIS 5.1.
- InstallShield supports version 5 and later of IIS.

Determining Which Version of IIS Is Installed

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

When you add a Web site in the Internet Information Services view, an entry is added to the System Search view to search for the version of IIS that is installed on the target system. The IIS_VERSION property is set by entries in the **RegLocator** and **AppSearch** tables (available in the Direct Editor), which determine the version of IIS that is installed.

The **IIS_VERSION** property contains the IIS version number. If you need to determine the IIS version that is installed, check the value of this property.

Run-Time Requirements for IIS Support

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

IIS support in InstallShield installations works only if IIS is installed on the target machine and the end user has administrative privileges.

During the installation of a package that includes IIS settings, an InstallShield installation checks for the existence of IIS on the target machine. If IIS is not installed, the installation displays a dialog informing the end user that they do not have IIS installed. The dialog gives the end user the option to abort, retry, or ignore:

- If the end user chooses to abort, the installation stops.

- If the end user installs IIS and then chooses to retry, the installation checks for IIS again, and continues with the installation. If the end user does not install IIS but still chooses to retry, the installation checks for IIS again and then displays the dialog again.
- If the end user chooses to ignore, the installation continues, but IIS Web sites, applications, virtual directories, and other IIS elements are not configured.

Note • *InstallShield does not support the creation of Web sites on target machines other than the one on which the installation is running.*

Project • *If you are creating an application pool in an InstallScript project and you want the application pool to be associated with a virtual directory, application, or Web site, you must create the application pool and the virtual directory, application, or Web site within the same component. If you do this, the application pool is created before the virtual directory, application, or Web site is created. This is a requirement of IIS 6 and later, and it is not a limitation for Basic MSI, DIM, InstallScript MSI, or Merge Module projects.*

Specifying Whether a Web Server Should Allow the CMD Command to Be Used for SSI #exec Directives

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Server-side include (SSI) directives instruct a Web server to insert content into a Web page. The #exec type of directive enables the Web server to include the output of a shell command in a Web page.

You can configure an IIS Web server to prevent the CMD command for the #exec directive from being used to execute shell commands, or you can configure it to allow the CMD command to be used to execute this type of command. The SSIEnableCmdDirective registry value for the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters registry key is what determines whether the CMD command is permitted.

InstallShield lets you specify how your installation should configure the SSIEnableCmdDirective registry value on target systems. If you do not want your installation to change the SSIEnableCmdDirective registry value, you can also specify that.

Because of security concerns, the default SSIEnableCmdDirective registry value is FALSE (0); the FALSE (0) value prevents end users from running unauthorized server-side executable files.

Task: ***To specify whether a Web server should allow the CMD command to be used for SSI #exec directives:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the center pane, click the **Web Sites** explorer. InstallShield displays the Web server settings in the right pane.
3. For the **SSIEnableCmdDirective registry value** setting, select the appropriate option:
   - **Ignore**—Do not change the SSIEnableCmdDirective registry value on the target system. This is the default option.
   - **FALSE (0)**—Set the SSIEnableCmdDirective registry value on the target system to 0. This prevents the #exec CMD directive of server-side includes to be used to execute shell commands. Note that if you select this value and an IIS Web server has applications that rely on #exec CMD directives, those applications may stop working properly after your installation project's Web site and virtual directory are installed.
   - **TRUE (1)**—Set the SSIEnableCmdDirective registry value on the target system to 1. This allows the #exec CMD directive of server-side includes to be used to execute shell commands.

If you select the FALSE or TRUE options, InstallShield stores the value—either 0 for FALSE or 1 for TRUE—in the **INSTALLSHIELD_SSI_PROP** property.

If one or more Web sites, virtual directories, application pools, or Web service extensions in your installation are installed on a target system and you selected the FALSE or TRUE options for the **SSIEnableCmdDirective registry value** setting, the SSIEnableCmdDirective registry value is updated on the target system.

Note • *If your product is uninstalled from a target system, the SSIEnableCmdDirective registry value is not changed, even if its value was changed during installation.*

Creating a Web Site and Adding an Application or a Virtual Directory

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

The Internet Information Services view in InstallShield is where you add an IIS Web site to your project. It is also where you can add applications and virtual directories to a Web site. Note that you can add a Web site without any applications or virtual directories if you associate the Web site with a component.

Task: ***To create a Web site on the target system at run time:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. Right-click the **Web Sites** explorer and click **Add Web Site**. InstallShield adds a new Web site.
3. Select the Web site to configure its settings.

Tip • *InstallShield lets you specify the TCP port and site numbers for a Web site in your project. These settings help determine whether a new Web site is created or an existing one is updated at run time. To learn more, see Configuring the TCP Port and Site Numbers.*

Task: ***To create an application on the target system at run time:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, right-click the Web site that should contain the application and click **New Application**. InstallShield adds a new application.
3. Select the application to configure its settings.

Task: ***To create a virtual directory on the target system at run time:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, right-click the Web site that should contain the virtual directory and click **New Virtual Directory**. InstallShield adds a new virtual directory.
3. Select the virtual directory to configure its settings.

Note • *To learn how Web sites, applications, and virtual directories are associated with components and features, see Feature and Component Associations for IIS Support.*

Scanning an IIS Web Site and Importing Its Settings into an InstallShield Project

Edition • *The ability to import IIS data into an InstallShield project is available only in the Premier edition of InstallShield.*

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield includes support for scanning an existing IIS Web site, recording IIS data about the Web site, and importing those settings into the Internet Information Services view of an InstallShield project. Once you have imported the data into a project, you can make changes to the IIS settings as needed, and build an installation that creates or maintains an IIS Web site.

The IIS scanner (`IISscan.exe`) is a command-line tool that scans an IIS Web site and records the values of the settings that you can configure in the Internet Information Services view in InstallShield. `IISscan.exe` creates an XML file that contains all of the values. You can use this XML file to import the values into the Internet Information Services view.

`IISscan.exe` is installed in the following location:

`InstallShield Program Files Folder``\System\iisscan.exe`

Task: ***To scan an existing Web site and record all of the IIS data that can be configured in the Internet Information Services view:***

1. Place the `IISscan.exe` tool on the server that has the IIS Web site that you want to scan.
2. At the command prompt, enter the command-line statement that launches the IIS scanner to scan a specific Web site. Following is a sample statement:

   ```
   iisscan.exe -website "Site Name" -outfile "C:\PathToFile\FileName.xml"
   ```

   For more information about `IISscan.exe`, see IISscan.exe.

The IIS scanner creates an XML file that contains the IIS data for the specified Web site.

Task: ***To import the data from the XML file into an InstallShield project:***

1. Obtain the XML file that the IIS scanner created, and place it in a location that can be accessed from the machine that has InstallShield.
2. In the View List under **Server Configuration**, click **Internet Information Services**.
3. Right-click the **Web Sites** explorer and click **Import Web Site**. The **Open** dialog box opens.
4. Select the XML file that the IIS scanner created, and then click **Open**.

InstallShield imports the Web site and its settings into the Internet Information Services view. All of the Web site's settings, virtual directories, and applications are configured in this view during the import.

Tip • *InstallShield lets you configure filters if you want to prevent certain IIS data—such as Web sites, applications, virtual directories, application pool, or any of their settings—from ever being imported into the Internet Information Services view. To learn more, see Filtering IIS Data When Importing a Web Site and Its Settings into an InstallShield Project.*

Filtering IIS Data When Importing a Web Site and Its Settings into an InstallShield Project

Edition • *The ability to import IIS data into an InstallShield project is available only in the Premier edition of InstallShield.*

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

When you use an XML file that is generated by the IIS scanner to import an IIS Web site and its settings into the Information Services view, you may find that certain IIS settings are imported, even though you do not need them to be configured in your installation. To avoid having these settings configured every time that you use an XML file to import IIS settings, you can edit `Filters.xml`. This file enables you to specify any IIS settings that you want the import to ignore.

`Filters.xml` is in the following location:

`InstallShield Program Files Folder``\Support`

The file must remain in this location after you edit it; otherwise, the IIS import will not work properly.

Tip • *You can also use the `Filters.xml` file to control which registry items should be excluded during COM extraction. For more information, see Filtering Registry Changes for COM Extraction.*

The `Filters.xml` file also lets you control which files should be included or excluded during dependency scanning. For more information, see Filtering Files in Dependency Scanners.

Excluding IIS Data

The <Exclude> element in the `Filters.xml` file is where you add subelements for each of the IIS items (Web sites, applications, virtual directories, and application pools) that you do not want to be imported. You can also add subelements for each of the IIS settings that you do not want to be imported. Any items and settings that are listed here will not be added to the Internet Information Services view of your project.

Examples for Specifying IIS Data in the <Exclude> Element

To prevent an application pool named TestAppPool from being imported into the Internet Information Services view, add the following line within the <Exclude> element.

```
<IisScanItem name="TestAppPool" type="4"/>
```

The type is required. The following table shows the available IIS item types:

Table 4-3 • Recognized Attributes for the type Attribute of the <IisScanItem> Subelement

Attribute Value	Description
1	Web site
2	Application
3	Virtual directory
4	Application pool

To prevent an IIS setting with a specific value from being imported into the Internet Information Services view, add the following line within the <Exclude> element.

```
<IisScanProperty name="PropertyName" value="PropertyValue"/>
```

If this line is within the <Exclude> element, InstallShield blocks a setting named **PropertyName** with a value that equals or contains **PropertyValue**.

Note • *The property names and values are not Windows Installer properties and values. They are abbreviations for the names and values of settings that InstallShield lets you configure in the Internet Information Services view.*

Important • *Ensure that your XML code is well formed; if its not well formed, all of the filters fail. In most cases, you can identify improperly formed XML code by opening the `Filters.xml` file in Internet Explorer. You should be able to expand and contract the <Filters>, <Include>, and <Exclude> elements; if you cannot, check the code for errors.*

If you add subelements to the <Exclude> or <Include> elements, be sure that you do not place them within the commented-out section, since InstallShield ignores that area of the `Filters.xml` file.

The following sample XML code shows the format of the `Filters.xml` file:

```
<Filters>
 <Include>
  <!--Instructions on how to add files to this element.
  -->
  <File name="mfc42.dll" We="needthis"/>
 </Include>
 <Exclude>
  <!--Instructions on how to add files to this element.
  -->
```

```
  <Registry key="HKEY_CLASSES_ROOT\Interface\{00020404-0000-0000-C000-000000000046}"/>
  <File name="12520437.cpx" path="[SystemFolder]" W2kSp4="WPF" WxpSp2="WPF" W2k3Sp1="WPF"
WinMe="WPF"/>
  <File name="12520850.cpx" path="[SystemFolder]" W2kSp4="WPF" WxpSp2="WPF" W2k3Sp1="WPF"
WinMe="WPF"/>
  <IisScanProperty name="AppMappings" value="*;;*;0" />
  <IisScanProperty name="CustomErrors" value="C:\WINDOWS\help\iisHelp\common" />
 </Exclude>
</Filters>
```

Creating a Nested Virtual Directory

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

You can create a virtual subdirectory under an existing virtual directory.

You can also create a virtual subdirectory under a virtual directory that is being installed as part of your installation. The parent virtual directory must be installed before the virtual subdirectory.

Project • *For InstallScript projects, if a parent virtual directory should be installed before its child virtual subdirectory, the component that contains the parent virtual directory must be installed before the component that contains the child virtual subdirectory.*

Task: ***To create a virtual directory under an existing virtual directory:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site that should contain the nested virtual directory.
3. Right-click the new Web site and click **New Virtual Directory**. InstallShield adds a new virtual directory.
4. Click the **General** tab.
5. In the **Name** setting, indicate the name of the existing directory, as well as the name of the nested virtual subdirectory that you want to create. Separate both names with a slash.

   For example, to create a virtual directory called **MySubDirectory** under the existing virtual directory called **VirtualDirectory**, enter the following:

   ```
   VirtualDirectory/MySubDirectory
   ```

Note • *If the parent directory does not already exist on the target system, the target system displays an error when the end user opens the directory in the IIS Manager.*

Configuring the TCP Port and Site Numbers

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield lets you specify the TCP port and site numbers for a Web site in your project. These settings help determine whether a new Web site is created or an existing one is updated at run time. They also affect whether the Web site settings that are configured in the Internet Information Services view are applied to a Web site on the target system.

Task: ***To specify the TCP port and site numbers for a Web site:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site that you want to configure.
3. Click the **Web Site** tab.
4. In the **TCP Port Number** and **Site Number** boxes, enter the appropriate numbers.

Run-Time Behavior

At run time, the installation creates the Web site, applications, and virtual directories according to the following rules:

Table 4-4 • Run-Time Results for Various Sample TCP Port Number and Site Number Setting Values

TCP Port Number Setting in InstallShield	Site Number Setting in InstallShield	Result at Run Time
0	Any non-zero number	Since the TCP Port Number setting is 0 but the Site Number setting is not 0, the installation installs the Web site's applications and virtual directories to the first site number on the system. The specified site number is ignored. For example, if the first site number on the target system is 1, the installation installs the Web site's applications and virtual directories under site number 1, even if a different non-zero number such as 3 is specified for the Site Number setting. The installation does not apply any of the Web site settings that are configured in the Internet Information Services view to the Web site on the target system.
80 (a non-zero number)	0 (the default value)	If the specified TCP port exists on the target system, the installation installs the applications and virtual directories to the Web site that is running on the TCP port—in this example, port 80. The installation does not apply any of the Web site settings that are configured in the Internet Information Services view to the Web site on the target system. If the TCP port does not exist on the target system, a new Web site is created with the Web site settings that are configured in the project. In addition, the installation installs the Web site's applications and virtual directories.

Table 4-4 • Run-Time Results for Various Sample TCP Port Number and Site Number Setting Values (cont.)

TCP Port Number Setting in InstallShield	Site Number Setting in InstallShield	Result at Run Time
81 (a non-zero number)	3 (a non-zero number)	If the specified TCP port and site number exist on the target system, the installation installs the applications and virtual directories under the Web site whose site number matches the specified one—in this example, site number 3. The installation does not apply any of the Web site settings that are configured in the Internet Information Services view to the Web site on the target system. If the TCP port exists on the target system but the site number does not, the installation installs the new Web site, plus its applications and virtual directories, to the existing port with the new site number. In addition, the installation configures the Web site's properties that are set in the Internet Information Services view. If the TCP port does not exist on the target system but the site number does, the installation installs the new Web site, plus its applications and virtual directories, to this TCP port. In addition, the installation configures the Web site's properties that are set in the Internet Information Services view.

Installing an IIS Web Site and Its Applications and Virtual Directories to the Next Available New Site Number

The following procedures demonstrate how to install an IIS Web site and its applications and virtual directories to the next available new site number. Note that the procedure differs, depending on the project type.

Task: ***To install to the next available new site number for a Basic MSI, DIM, InstallScript MSI, or Merge Module project:***

1. Create a new Windows Installer property and set its value to `INSTALLSHIELD_IIS_NEXT_NEW_SITE_NUMBER`:
   a. In the View List under **Behavior and Logic**, click **Property Manager**.
   b. Click the **New Property** button. InstallShield adds a new row at the bottom of the view.
   c. In the **Name** column, type a new property; for example:

      `MYPROPERTY`

   d. In the **Value** column, enter the following value:

      `INSTALLSHIELD_IIS_NEXT_NEW_SITE_NUMBER`

2. Specify the property for the Web site's site number:
    a. In the View List under **Server Configuration**, click **Internet Information Services**.
    b. In the **Web Sites** explorer, select the Web site that you want to configure.
    c. For the **Site Number** setting, enter the property that you created in step 1c. It must be in uppercase letters and enclosed within brackets; for example:

        ```
        [MYPROPERTY]
        ```

At run time, the installation installs the Web site and its applications and virtual directories to the next available new site number.

Task: ***To install to the next available new site number during an InstallScript installation:***

1. Create a new string entry and set its value to **INSTALLSHIELD_IIS_NEXT_NEW_SITE_NUMBER**:
    a. In the View List under **User Interface**, click **String Editor**.
    b. Click the **New String Entry** button. The **String Entry** dialog box opens.
    c. In the **String Identifier** box, enter a new variable name; the variable name must be in uppercase letters; for example:

        ```
        MYPROPERTY
        ```

    d. In the **Value** box, enter the following value:

        ```
        INSTALLSHIELD_IIS_NEXT_NEW_SITE_NUMBER
        ```

2. Specify the variable for the Web site's site number:
    a. In the View List under **Server Configuration**, click **Internet Information Services**.
    b. In the **Web Sites** explorer, select the Web site that you want to configure.
    c. For the **Site Number** setting, enter the variable that you created in step 1c. It must be in uppercase letters.

At run time, the installation installs the Web site and its applications and virtual directories to the next available new site number.

Specifying the IIS Host Header Name for a Web Site

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*

- *InstallScript MSI*
- *Merge Module*

InstallShield lets you specify the host header name to identify an IIS Web site that is installed during your installation. Host headers (also known as domain names) enable you to assign more than one Web site to an IP address on a Web server.

Task: ***To specify a host header name for a Web site:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site whose host header name you want to specify.
3. For the **Host Header Name** setting, type the host header name that you want to use. For example:

   `www.mycompany.com`

Specifying the SSL Certificate for a Web Site

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

A server certificate enables users to authenticate your Web server, check the validity of the Web content, and establish a secure connection. InstallShield lets you include a server certificate for a Web site in your installation so that it can be installed at run time.

Task: ***To specify a SSL certificate that should be installed for a Web site:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site whose SSL certificate you want to specify.
3. For the **SSL Certificate** setting, click the ellipsis button (**...**). The **Open** dialog box opens.
4. Select the security certificate file (.cer or .pfx) that you want to be installed, and then click **Open**.
5. If the certificate requires a password, specify it for the **SSL Certificate Password** setting.

InstallShield stores the .cer file in the **Binary** table. At run time, when the installation installs the Web site and its virtual directories, it also installs the SSL certificate.

Adding Files to an IIS Virtual Directory

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Task: ***To add a file to an IIS virtual directory:***

1. Add an IIS Web site to your project if you have not already done so. InstallShield automatically adds the predefined path **[IISROOTFOLDER]** to the **Files and Folders** view.
2. In the View List under **Application Data**, click **Files and Folders**.
3. In the **Feature** list, select the feature with which you want the file associated.
4. In the **Destination computer's folders** pane, add the file to the **[IISROOTFOLDER]** folder, or a subfolder of the **[IISROOTFOLDER]** folder.
5. In the View List under **Server Configuration**, click **Internet Information Services**.
6. Create a new virtual directory.
7. In the **Web Sites** explorer, click the virtual directory that you created.
8. In the **Content Source Path (Local or UNC)** setting, click the ellipsis button (**...**). The **Browse for Directory** dialog box opens. In a Basic MSI or InstallScript MSI project, this dialog box enables you to select a Windows Installer property (such as [IISROOTFOLDER]) or create a new one. In an InstallScript project, this dialog box enables you to select an InstallScript variable (such as <IISROOTFOLDER>) or create a new one. By default, the files are stored in IISROOTFOLDER.
9. Enter the same target directory as the one that contains the new file that you added in the **Files and Folders** view.
10. Click **OK**.

At installation, files are copied to the target directory folder. In addition, the virtual directory is configured for that folder on the target system if IIS is present.

Removing Applications and Virtual Directories from the Internet Information Services View

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Task: ***To remove an application or a virtual directory from your installation:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, right-click the application or virtual directory and click **Delete**.

Adding Application Pools

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

An application pool is a group of configuration settings that specify how one or more Web applications are routed to one or more worker processes. InstallShield lets you create application pools and associate Web sites, applications, and virtual directories with those application pools.

Project • *If you are creating an application pool in an InstallScript project and you want the application pool to be associated with a virtual directory, application, or Web site, you must create the application pool and the virtual directory, application, or Web site within the same component. If you do this, the application pool is created before the virtual directory, application, or Web site is created. This is a requirement of IIS 6 and later, and it is not a limitation for Basic MSI, DIM, InstallScript MSI, or Merge Module projects.*

Note • *Application pools are available only on machines with IIS 6.0 or later installed.*

Task: ***To add a new application pool in the Internet Information Services view:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. Right-click the **Application Pools** explorer and click **Add Application Pool**. InstallShield adds a new application pool item.

3. Rename the new application pool item, and configure its settings.

Removing Application Pools from the Internet Information Services View

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Project • *To remove an application pool from your installation:*

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Application Pools** explorer, right-click the application pool and click **Delete**.

Adding Web Service Extensions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

A Web service extension is an IIS feature that extends the basic IIS functionality beyond serving static content. Examples of Web service extensions are active server pages (.asp), ASP.NET, and server-side includes (SSI).

InstallShield lets you add Web service extensions to your installation.

Note • *Web service extensions are available only on machines with IIS 6.0 or later installed.*

On systems with IIS 7, Web service extensions require that the IIS Metabase and IIS 6 Configuration Compatibility feature be installed. For more information, see Version-Specific Information for IIS Support in InstallShield.

Task: ***To add a web service extension to your installation:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. Right-click the **Web Service Extensions** explorer and click **Add Web Service Extension**. InstallShield adds a new Web service extension.
3. Rename the new Web service extension item, and configure its settings.

Removing Web Service Extensions from the Internet Information Services View

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Task: ***To remove a Web service extension from your installation:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Service Extension** explorer, right-click the Web service extension and click **Delete**.

Feature and Component Associations for IIS Support

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

There is a one-to-many relationship between components and IIS data (that is, Web sites, applications, virtual directories, application pools, or Web service extensions). Therefore, you can associate more than one IIS element with a single component. If a component is being installed, any Web sites, applications, virtual directories, application pools, and Web service extensions that are associated with the component are created at run time.

Project • *If a Web site is associated with a component in an InstallScript project, any applications or virtual directories that are added to that Web site must be associated with the same component. Therefore, if you try to change the component for a Web site that contains one or more applications or virtual directories, InstallShield displays a message box to inform you that it will also make the same component change for all of that Web site's applications and virtual directories; InstallShield also displays this message box if you try to change the component for any applications or virtual directories in a Web site. In either case, the message box enables you to proceed or cancel the component change.*

Note that for Basic MSI, DIM, InstallScript MSI, and Merge Module projects, keeping a Web site in the same component as all of the Web site's applications and virtual directories is not required, but it is recommended. If you are creating an application pool in an InstallScript project and you want the application pool to be associated with a virtual directory, application, or Web site, you must create the application pool and the virtual directory, application, or Web site within the same component. If you do this, the application pool is created before the virtual directory, application, or Web site is created. This is a requirement of IIS 6 and later, and it is not a limitation for Basic MSI, DIM, InstallScript MSI, or Merge Module projects.

At any time, you can use the Internet Information Services view to change which component contains the Web site, application, virtual directory, application pool, or Web service extension.

Task: ***To associate a Web site, application, virtual directory, application pool, or Web service extension with a different component in your project:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the explorer, click the Web site, application, virtual directory, application pool, or Web service extension that you want to associate with a component.
3. In the **Component** setting, select the name of the existing component that should contain the selected IIS data. You can click the ellipsis button (...) to select an existing component or create a new one for the IIS data.

Tip • *If you delete a component in your project, any Web sites, applications, virtual directories, application pools, and Web service extensions that are associated with the component are simultaneously removed from your project.*

Uninstalling Web Sites, Applications, and Virtual Directories

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

- *Merge Module*

Web sites that are created by an installation are never removed unless both of the following conditions are true:

- The Web site no longer contains applications or virtual directories.
- The value for the **Delete on Uninstall** setting for the Web site in the Internet Information Services view is Yes.

Note • *If a Web site is associated with a component, the **Delete on Uninstall** setting for the Web site corresponds with the Permanent setting for that component in a Basic MSI, DIM, InstallScript MSI, or Merge Module project, or with the Uninstall setting for that component in an InstallScript project. That is, if you select or clear the **Delete on Uninstall** setting for a Web site, InstallShield automatically updates the value of the component's Permanent setting or Uninstall setting, as appropriate.*

If a component is uninstalled, all of its Web sites, applications, and virtual directories are uninstalled. A component is not uninstalled if it is configured to be permanent. For more information, see Specifying Whether a Component's Files and Other Associated Data Are Uninstalled During Uninstallation.

Uninstalling Web Service Extensions and Application Pools

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Note • *Web service extensions, application pools, and associated properties are available only on machines with IIS 6.0 or later installed.*

On systems with IIS 7, Web service extensions require that the IIS Metabase and IIS 6 Configuration Compatibility feature be installed. For more information, see Version-Specific Information for IIS Support in InstallShield.

Any Web service extensions and application pools installed in the IIS Manager that have identical names as the Web service extensions and application pools in an installation will always be uninstalled when the features with which they are associated are uninstalled unless their components are marked as permanent. Even if the Web service extension or application pool was originally created by something other than the installation, it will be removed from the target system upon uninstallation if the names (of the Web service extensions and application pools) match those in the installation. One exception is that the default application pool, named DefaultAppPool, will never be removed by the uninstallation.

Task: ***To configure a Web service extension to be uninstalled during uninstallation:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Service Extensions** explorer, select the Web service extension.
3. For the **Mark Component as Permanent** setting, select **No**.

Task: ***To configure an application pool to be uninstalled during uninstallation:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Application Pool** explorer, select the application pool.
3. For the **Mark Component as Permanent** setting, select **No**.

If Yes is selected for the Mark Component as Permanent setting, the Web service extension or application pool is left on the target system after uninstallation.

Tip • *Changing the value of the Mark Component as Permanent setting affects the value of the Permanent setting (in Basic MSI, DIM, InstallScript MSI, and Merge Module projects) or the Uninstall setting (in InstallScript projects) for the component that contains the Web service extension or the application pool. Therefore, if you select Yes for the Mark Component as Permanent and the component contains other data, such as files, shortcuts, and registry entries, the IIS data, as well as the other data in the component, are not uninstalled during uninstallation.*

Setting the ASP.NET Version for a Web Site or Application

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield lets you set the ASP.NET version for a Web site or application in your installation. If you specify the ASP.NET version, after the Web site or application is created, the installation runs the ASP.NET IIS Registration tool (`Aspnet_regiis.exe`) to map the Web site or application to the version that you specify.

If you specify the ASP.NET version for a Web site, IIS uses that value for the Web site that is created at run time, as well as for any of its applications.

Important • *Microsoft does not recommend using the `Aspnet_regiis.exe` tool on Windows Vista and Windows Server 2008 systems because it has limited capabilities. As a result, you may need to manually define application mappings in the Internet Information Services view. To learn more, see Defining Application Mappings for a Web Site, Application, or Virtual Directory.*

ASP.NET 3.0 does not include the `Aspnet_regiis.exe` tool. Therefore, you cannot set the ASP.NET version to version 3 of ASP.NET.

Task: ***To specify the ASP.NET version for a Web site or application in your project:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site or application whose ASP.NET version you want to specify. The settings for the Web site or application are displayed on the right.
3. For the **ASP.NET Version** setting, enter the complete version number of the .NET Framework that is required by your application, or select it from the list.

   For example, to specify version 2 of ASP.NET, type `2.0.50727`. To specify version 1.1 of ASP.NET, type `1.1.4322`.

Tip • *If the installation may be run on a 64-bit version of Windows with the .NET Framework, you can use the ASP.NET Platform setting for a Web site or application to specify which ASP.NET platform (32 bit or 64 bit) should be used to map the Web site or application to the ASP.NET version. Note that it is not possible to register 32-bit ASP.NET on a 64-bit system unless the Enable32BitAppOnWin64 property is set to true on the system.*

Considerations for Supporting IIS 6 on 64-Bit Platforms

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

If your IIS installation may be run on a 64-bit version of Windows with the .NET Framework, you can use the ASP.NET Platform setting in the Internet Information Services view for a Web site or application. This setting lets you specify which ASP.NET platform should be used to map the Web site or application to the ASP.NET version. By default, this setting is not configured in InstallShield; if you do not change the value of this setting, the installation assumes that 32-bit support is needed.

Depending on the value that you configure for the ASP.NET Platform and ASP.NET Version settings, the following behavior occurs by default at run time:

- If the target system has a 32-bit version of Windows, the 32-bit version of the specified ASP.NET version is used.
- If the target system has a 64-bit version of Windows, and 64 bit was specified for the ASP.NET platform, the Enable32bitAppOnWin64 property on the target system needs to be set to False. Otherwise, using the 64-bit version of ASP.NET on a system that is configured to support the 32-bit version would cause ASP.NET to become corrupted. Thus, the installation is aborted to prevent damage to ASP.NET services.
- If the target system has a 64-bit version of Windows, and 32 bit was specified for the ASP.NET platform, the Enable32bitAppOnWin64 property on the target system needs to be set to True. Otherwise, using the 32-bit version of ASP.NET on a system that is configured to support the 64-bit version would cause ASP.NET to become corrupted. Thus, the installation is aborted to prevent damage to ASP.NET services.

You can set the Enable32bitAppOnWin64 property on a target system that has IIS 7 by configuring the Enable 32-Bit Applications setting for an application pool in the Internet Information Services view. At run time, the installation sets the Enable32bitAppOnWin64 property as appropriate for the application pool that is being installed.

On systems with IIS 6, the Enable32bitAppOnWin64 property is a global property that affects all Web sites and applications on an IIS server. Since changing the value of that property at installation run time might cause other already installed Web sites and applications on that server to fail, installations that are created with InstallShield do not modify the Enable32bitAppOnWin64 property at run time if the target system has IIS 6.

At run time, you can have your installation check the Enable32bitAppOnWin64 property on systems that have IIS 6. Depending on the requirements for your product and the results of that check, you may want the installation to skip a particular component that contains a 32-bit IIS 6 application, or a 64-bit IIS application, for example, and proceed with the rest of the file transfer.

InstallShield includes a sample Windows Installer DLL file that detects how the Enable32bitAppOnWin64 property is set. Release and debug versions of the DLL file, as well as the Visual Studio 2008 C++ project that was used to create the file, are installed to the following location:

InstallShield Program Files Folder\Samples\WindowsInstaller\Detect IIS6 Compatibility

To use the Windows Installer DLL file in your project, you first need to create a custom action that calls the **DetectIIS6AppPool32BitSupport** function in the `DetectIIS6Compat.dll` file.

Task: ***To add a custom action that checks for support for 32-bit applications on systems that have IIS 6:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI or InstallScript MSI projects) or **Custom Actions** (in DIM or Merge Module projects).
2. In the center pane, right-click the **Custom Actions** explorer, point to **New MSI DLL**, and click **Stored in Binary table**. InstallShield adds a new custom action.
3. Change the name of the action to something like **DetectIIS6AppPool32BitSupport**.
4. Configure the custom action's settings in the right pane:
    - In the **DLL Filename** setting, specify the path to the `DetectIIS6Compat.dll` file. The typical path is:

```
<ISProductFolder>\Samples\WindowsInstaller\Detect IIS6 Compatibility\DetectIIS6Compat.dll
```

- In the **Function Name** setting, enter the following name:

  ```
  DetectIIS6AppPool32BitSupport
  ```

- In the **In-Script Execution** setting, select **Immediate Execution**.
- Schedule the custom action as needed by selecting the appropriate option in one or more sequence settings.
- In the condition setting, enter the following condition:

  ```
  VersionNT<600
  ```

  This condition ensures that the custom action is not run on Windows Server 2008 or later or on Windows Vista or later, since these operating systems would have IIS 7 or later.

At run time, the custom action sets the Windows Installer property **ISIIS6APPPOOLSUPPORTS32BIT** under certain conditions:

Table 4-5 • Windows Installer Property for Checking for 32-Bit Application Support on IIS 6 Systems

Target System Environment	Result
32-bit Windows, IIS 6 (The value of Enable32bitAppOnWin64 is not relevant.)	**ISIIS6APPPOOLSUPPORTS32BIT** is set to 1.
64-bit Windows, IIS 6, Enable32bitAppOnWin64=true	**ISIIS6APPPOOLSUPPORTS32BIT** is set to 1.
64-bit Windows, IIS 6, Enable32bitAppOnWin64=false	**ISIIS6APPPOOLSUPPORTS32BIT** is not set.

You can use the **ISIIS6APPPOOLSUPPORTS32BIT** property in conditional statements. For example, if your product cannot be used on an IIS 6 server without 64-bit application support, enter the following conditional statement in the Install Condition setting of the General Information view:

```
Not ISIIS6APPPOOLSUPPORTS32BIT
```

As an alternative, you can create an error custom action. At run time, an error would be displayed if the condition for that custom action is true. Thus, if your product cannot be used on an IIS 6 server without 64-bit application support, use the following condition for an error custom action:

```
ISIIS6APPPOOLSUPPORTS32BIT=1
```

If you have a component that should be installed only on IIS 6 servers that have 32-bit application support enabled, enter the following conditional statement in the Condition setting of the Components view:

```
ISIIS6APPPOOLSUPPORTS32BIT=1
```

Defining Application Mappings for a Web Site, Application, or Virtual Directory

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield lets you define mappings between file name extensions and the applications that process those files.

Task: ***To add, edit, or remove an application mapping:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site, application, or virtual directory that you want to configure.
3. In the **Application Mappings** setting, click the ellipsis button (**...**). The **Application Mappings** dialog box opens.
4. Do one of the following:
   - To add a new mapping, click the **Add** button. The **Application Extension Mapping** dialog box opens. For more information, see Application Extension Mapping Dialog Box.
   - To change an existing mapping, select the one that you want to edit, and then click the **Edit** button.
   - To delete an existing mapping, select it and then click the **Delete** button.

Specifying Timeout Parameters for a Web Site, Application, or Virtual Directory

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

InstallShield lets you specify timeout parameters for a Web site, application, or virtual directory.

Task: ***To specify timeout parameters:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site, application, or virtual directory that you want to configure.
3. In the **Application settings** area, click the **Configuration** button. The **Application Mappings** dialog box opens.
4. In the **Session Timeout (minutes)** and the **ASP Script Timeout (seconds)** settings, specify the appropriate timeout values.

Determining If a Target System Has IIS 6 or Earlier or the IIS 6 Metabase Compatibility Feature

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

At run time, you can have your installation detect if the IIS Metabase and IIS 6 Configuration Compatibility feature is installed on a target system, or if IIS 6 or earlier is installed. Depending on the requirements for your product and the results of that detection, you may want the installation to exit and display an error message.

For example, Web service extensions can be installed on systems that have IIS 6. On systems that have IIS 7, Web service extensions can be installed only if the IIS Metabase and IIS 6 Configuration Compatibility feature is installed. Thus, you might want to configure your installation to verify that IIS 6 is present or the IIS 6 compatibility feature is installed; if either of those conditions are false, the installation would exit and display an error message.

InstallShield includes a sample Windows Installer DLL file that detects if either of the following are true:

- The target system has IIS 7 and the IIS Metabase and IIS 6 Configuration Compatibility feature is installed.
- The target system has IIS 6 or earlier.

Release and debug versions of the DLL file, as well as the Visual Studio 2008 C++ project that was used to create the file, are installed to the following location:

InstallShield Program Files Folder\Samples\WindowsInstaller\Detect IIS6 Compatibility

To use the Windows Installer DLL file in your project, you first need to create a custom action that calls the **DetectIIS6Interfaces** function in the `DetectIIS6Compat.dll` file.

Task: ***To add a custom action that checks for the IIS Metabase and IIS 6 Configuration Compatibility feature and for IIS 6 and earlier:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI or InstallScript MSI projects) or **Custom Actions** (in DIM or Merge Module projects).
2. In the center pane, right-click the **Custom Actions** explorer, point to **New MSI DLL**, and click **Stored in Binary table**. InstallShield adds a new custom action.
3. Change the name of the action to something like **DetectIIS6Interfaces**.
4. Configure the custom action's settings in the right pane:
   - In the **DLL Filename** setting, specify the path to the `DetectIIS6Compat.dll` file. The typical path is:

     `<ISProductFolder>\Samples\WindowsInstaller\Detect IIS6 Compatibility\DetectIIS6Compat.dll`
   - In the **Function Name** setting, enter the following name:

     `DetectIIS6Interfaces`
   - In the **In-Script Execution** setting, select **Immediate Execution**.
   - Schedule the custom action as needed by selecting the appropriate option in one or more sequence settings.

If the IIS Metabase and IIS 6 Configuration Compatibility feature is installed or the target system has IIS 6 or earlier, the Windows Installer property **ISIISMETABASECOMPATPRESENT** is set to a value of 1. If the target system has IIS 7 or later and the compatibility feature is not installed, the property is not set.

You can use the **ISIISMETABASECOMPATPRESENT** property in conditional statements. For example, if your product cannot be used on a system without the IIS Metabase and IIS 6 Configuration Compatibility feature or IIS 6 or earlier, enter the following conditional statement in the Install Condition setting of the General Information view:

```
ISIISMETABASECOMPATPRESENT
```

As an alternative, you can create an error custom action. At run time, an error would be displayed if the condition for that custom action is true. Thus, if your product cannot be used on a system without the IIS Metabase and IIS 6 Configuration Compatibility feature or IIS 6 or earlier, use the following condition for an error custom action:

```
Not ISIISMETABASECOMPATPRESENT
```

If you have a component that should be installed only on systems that have the IIS Metabase and IIS 6 Configuration Compatibility feature or IIS 6 or earlier, enter the following conditional statement in the Condition setting of the Components view:

```
ISIISMETABASECOMPATPRESENT=1
```

Configuring Advanced IIS Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Note • *The advanced IIS settings apply to IIS 6 and earlier. IIS 7 ignores these settings.*

When you select a Web site, application, or a virtual directory in the Web Sites explorer in the Internet Information Services view, the right pane exposes the most common IIS settings. You can use the Advanced area at the bottom of the right pane to configure other IIS settings that are not exposed in the other areas.

Task: ***To configure a setting that is not exposed in the Internet Information Services view:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, select the Web site, application, or virtual directory whose advanced settings you want to configure.
3. In the **Other IIS Properties** setting, click the ellipsis button (**...**). The **Other IIS Properties** dialog box opens.
4. In the property list, select the property whose value you want to change, and then click the **Change Value** button. The **Edit IIS Metabase Value** dialog box opens.
5. In the **Value** box, specify the new value.

If you change the default value for any advanced property, InstallShield adds the property, the value that you specify, and the additional required information to the **ISIISProperty** table. For more information, see ISIISProperty Table.

Configuring Custom Error Messages for a Web Site, Application, or Virtual Directory

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

When an end user tries to connect to a Web site and a hypertext transfer protocol (HTTP) error occurs, the end user's browser displays a default message describing the error. You can have your installation configure IIS so that it uses custom error messages instead of the default error messages by mapping the HTTP error codes to a file or a URL.

Task: ***To configure custom error messages for a Web site, application, or virtual directory:***

1. Create a file that contains your custom error message and add it to your installation.
2. In the View List under **Server Configuration**, click **Internet Information Services**.
3. Select the Web site, application, or virtual directory for which you want to customize HTTP error messages. The settings for the Web site, application, or virtual directory are displayed on the right.
4. In the **Custom Errors** setting, click the ellipsis button (**...**). The **Custom Errors** dialog box opens.
5. Select the HTTP error code that you want to change and then click the **Edit Properties** button. The **Error Mapping Properties** dialog box opens.
6. To map the error code to a file:
   a. In the **Message Type** list, select **File**.
   b. In the **File** box, type the path and file name that points to the custom error message in your installation, or click the browse button to locate the file.

   To map the error code to a URL:
   a. In the **Message Type** list, select URL.
   b. In the **URL** box, type the URL that points to your custom error message.

Using Windows Installer Properties to Dynamically Modify IIS Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For Basic MSI and InstallScript MSI projects, you can configure an IIS setting dynamically at run time through the use of Windows Installer properties. This enables you to let end users specify the name of the virtual directory, the TCP port, the site number, or other IIS settings for the Web sites, applications, virtual directories, application pools, and Web service extensions that they are installing on the target machine.

Windows Installer uses **MsiFormatRecord** to resolve the property at run time. The installation writes the property and its value to the following registry key so that the value is available during uninstallation and repair:

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall\InstallShield Uninstall Information*{ProductCode}*

Therefore, if your Web site is installed to an end user–specified site number, the Web site, its applications, and its virtual directories can be successfully uninstalled from that site number.

Tip • *If you do not want the IIS data to be stored in the registry, set the* ***IS_IIS_DO_NOT_USE_REG*** *property in your project.*

If you use a property for any of the passwords in the Internet Information Services view, the passwords are encrypted when they are stored in the registry.

Example

The following procedure demonstrates how to let end users specify during installation the user name used for anonymous access to the Web site. Note that you can substitute a hard-coded value with a property for any of the IIS settings in the Internet Information Services view that allow you to enter characters. The property that you specify in this view must be enclosed within square brackets, and the property name must be all uppercase; for example, **[MYPROPERTY]**.

Step 5 of the procedure is slightly different, depending on the project type, since Windows Installer controls the user interface of Basic MSI installations, and the InstallScript engine controls the user interface of InstallScript MSI installations.

Task: ***To let end users specify the user name:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, click the Web site whose user name end users should be able to specify for anonymous access.
3. For the **Enable anonymous access** setting, select **Yes**.
4. In the **Anonymous User Name** setting, type the following:

   `[MYPROPERTY]`

5. Use the property in a dialog. This part of the procedure depends on which project type you are using.
   - For Basic MSI projects:
     a. In the View List under **User Interface**, click **Dialogs**.
     b. In the **Dialogs** explorer, expand the **All Dialogs** folder, and click the language under the dialog that should contain the User Name control. As an alternative, you can add a new dialog.
     c. Add an **Edit Field** control to the dialog, and set its **Property** property to the following:

        `MYPROPERTY`

   - For InstallScript MSI projects:
     a. In the View List under **Behavior and Logic**, click **InstallScript**.

b. Find the dialog code in the OnFirstUIBefore event for the dialog that should contain the User Name control, and add a call to the Windows Installer API function **MsiSetProperty**. For example, if you want the user name to be the name that the end user specifies on the CustomerInformation dialog, you would add an **MsiSetProperty** call as shown in the following lines of code:

```
Dlg_SdCustomerInformation:
    nResult = SdCustomerInformation(szTitle, svName, svCompany, nUser);
    MsiSetProperty(ISMSI_HANDLE, "MYPROPERTY", svName);
    if (nResult = BACK) goto Dlg_SdWelcome;
```

6. Build your release.

Using InstallScript Text Substitution to Dynamically Modify IIS Settings

Project • *This information applies to InstallScript projects.*

For InstallScript projects, you can configure an IIS setting dynamically at run time through the use of text substitution string variables. This enables you to let end users specify the name of the virtual directory, the TCP port, the site number, or other IIS settings for the Web sites, applications, virtual directories, application pools, and Web service extensions that they are installing on the target machine. The InstallScript run-time code uses the **TextSubSubstitute** function to replace the string variable with the appropriate value.

Example

The following procedure demonstrates how to let end users specify during installation the user name used for anonymous access to the Web site. Note that you can substitute a hard-coded value with a text substitution string variable for any of the IIS settings in the Internet Information Services view that allow you to enter characters. The string variable that you specify in this view must be enclosed within angle brackets; for example, **<MYPROPERTY>**. The string variable that you specify is case-sensitive.

Task: ***To let end users specify the user name:***

1. In the View List under **Server Configuration**, click **Internet Information Services**.
2. In the **Web Sites** explorer, click the Web site whose user name end users should be able to specify for anonymous access.
3. For the **Enable anonymous access** setting, select **Yes**.
4. In the **Anonymous User Name** setting, type the following:

   `<MYPROPERTY>`

5. In the View List under **Behavior and Logic**, click **InstallScript**.
6. Find the dialog code in the OnFirstUIBefore event for the dialog that should contain the User Name control, and add a call to the InstallScript function **TextSubSetValue**. For example, if you want the user name to be the name that the end user specifies on the CustomerInformation dialog, you would add a **TextSubSetValue** call as shown in the following lines of code:

```
Dlg_SdRegisterUser:
    szMsg = "";
    szTitle = "";
    //{{IS_SCRIPT_TAG(Dlg_SdRegisterUser)
    nResult = SdRegisterUser( szTitle, szMsg, szName, szCompany );
    TextSubSetValue("<MYPROPERTY>", szName, TRUE);
    //}}IS_SCRIPT_TAG(Dlg_SdRegisterUser)
    if (nResult = BACK) goto Dlg_SdLicense2;
```

7. Build your release.

Deploying Web Services on a Target Machine

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*

Deploying a Web service onto a target system requires copying the Web service–specific files to a particular location and assigning a virtual directory name for that folder so that the Web service can be accessed via HTTP.

Tip • *To learn how to add a virtual directory to your project, see Creating a Web Site and Adding an Application or a Virtual Directory.*

Task: ***To deploy a Web service on a target machine:***

1. In the View List under **Application Data**, click **Files and Folders**.
2. Select the folder (target directory) for installing files on the target system. Add your files to this folder.
3. In the View List under **Server Configuration**, click **Internet Information Services**.
4. In the **Web Sites** explorer, select the virtual directory that is associated with the Web service.
5. In the **Content Source Path (Local or UNC)** setting, click the ellipsis button (**...**). The **Browse for Directory** dialog box opens. Enter the same target directory as the one that contains the new files that you added in the **Files and Folders** view.

At installation, files are copied to the target directory folder. In addition, the virtual directory is configured for that folder on the target system if IIS is present.

Adding IISROOTFOLDER Support

IISROOTFOLDER is an InstallShield directory variable that is used to determine the root directory of the Web server on a target system. If you are using IIS functionality in your installation project and you have added a Web site, then IISROOTFOLDER is automatically added.

Note • *All of the files added to the IISROOTFOLDER directory in the Files and Folders view are installed to the Web server's root directory on the target machine. If IIS is not installed, the files are copied to the root folder.*

IIS_WEBSITE_NAME Property

The **IIS_WEBSITE_NAME** property is obsolete. If this property exists from earlier project versions, the upgrader will handle it automatically. The upgrader will create a Web site and set the site number field to [IIS_WEBSITE_NAME]. For new Web sites, you can use any property or hard-coded number.

IIS_PORT_NUMBER Property

The **IIS_PORT_NUMBER** property is obsolete. If this property exists from earlier project versions, the upgrader will handle it automatically. The upgrader will create a Web site and set the port number field to [IIS_PORT_NUMBER]. When you create new Web sites, you can use any property or hard-coded number.

Preparing Installations for Maintenance and Uninstallation

InstallShield lets your users rerun your installation to change program features or reinstall or remove your application. When users select your application in Add or Remove Programs in the Control Panel, the installation displays dialog boxes that let users do any of the following:

- Install individual features that were not previously installed, and uninstall individual features.
- Reinstall your application with the settings selected during the first installation.
- Uninstall your application.

To modify, repair, or uninstall an application, the operating system must have some indication that the application is present. To allow this, an installation registers an application with the operating system so that it can be easily maintained or uninstalled. You enter the necessary information in the General Information view.

In all InstallShield installations, maintenance (that is, modification and repair) is handled automatically by default.

In a Windows Installer–based installation, uninstallation is handled automatically—with the sole exception of custom actions, which must either undo their own effect during uninstallation or have their effect undone by another custom action that runs only during uninstallation.

In an InstallScript or InstallScript MSI installation, many script functions' actions are logged for automatic uninstallation; your uninstallation script must handle those script function actions that are not logged.

Preparing an InstallScript Installation for Uninstallation

Setting up uninstallation functionality is simple, considering the complexity of the operations that result. **CreateInstallationInfo** (or **InstallationInfo**) and **MaintenanceStart** (or **DeinstallStart**) must be called. In an event-based script, **CreateInstallationInfo** and **MaintenanceStart** are called in the default **OnMoveData** event handler code.

There are other functions that play important roles in setting up uninstallation functionality. For example, all keys created using the **RegDBCreateKeyEx** function are recorded for uninstallation, unless logging is disabled. Also, if you call the **Disabl**e function to disable logging, remember to call **Enable** to enable the logging again for subsequent actions that must be recorded for uninstallation.

MaintenanceStart (or **DeinstallStart**) creates the necessary registry key and its necessary values. To create additional registry values under this key, call RegDBSetItem, or for custom values use code like the following:

```
RegDBSetDefaultRoot( HKEY_USER_SELECTABLE );
RegDBSetKeyValueEx( "Software\\Microsoft\\Windows\\Current Version\\Uninstall\\" + INSTANCE_GUID,
"My Custom Value", nType, szValue, nSize);
```

Note • *Uninstallation is available only if the initial installation calls* ***FeatureTransferData*** *or* ***FeatureMoveData****. (In an event-based script, the* ***FeatureTransferData*** *function is called automatically.) If your installation installs files by some other means (for example,* ***XCopyFile****) and you want to make uninstallation available to your end users,*

*deselect all components and call **FeatureTransferData** or **FeatureMoveData**; while this call is executed, you can call **SdShowMsg** to display a message.*

Including Script Code to Be Executed During Uninstallation

***Note** • If you call **DeinstallStart** to enable uninstallation, the installation script is not executed during uninstallation. To execute script code during uninstallation, call **MaintenanceStart** instead. (In an event-based installation, **MaintenanceStart** is called in the default **OnMoveData** event handler code.)*

Event-Based Scripts

If your script is event-based, the following event handler functions are called during uninstallation:

- **OnBegin**
- **OnMaintUIBefore**
- **OnMoving**
- <Feature name>**Uninstalling** (for each installed feature)
- <Feature name>**Uninstalled** (for each installed feature)
- **OnMoved**
- **OnMaintUIAfter**
- **OnEnd**

The code in these event handler functions (whose default code you can override) is executed during the uninstallation. For instructions on executing certain event handler code only during uninstallation, or only during installation, see Executing Script Code Only During Uninstallation or Only During Installation.

Procedural Scripts

If your script is procedural (that is, uses a program block) and calls **MaintenanceStart** rather than **DeinstallStart** to enable uninstallation, the script is executed during uninstallation. For instructions on executing certain script code only during uninstallation, or only during installation, see Executing Script Code Only During Uninstallation or Only During Installation.

Executing Script Code Only During Uninstallation or Only During Installation

The installation script is executed during uninstallation and maintenance installations if **MaintenanceStart** rather than **DeinstallStart** is called to enable uninstallation. (In an event-based script, **MaintenanceStart** is called in the default **OnMoveData** event handler code.) To execute code only during uninstallation or maintenance installations, enclose it in the following if-then statement:

```
if MAINTENANCE then
    /* this code is executed only during
```

```
    uninstallation or maintenance installations */
endif;
```

To execute code only during a first installation, enclose it in the following if-then statement:

```
if !MAINTENANCE then
    /* this code is executed only during
    a first installation */
endif;
```

If code is not enclosed in either if-then statement, it is executed during uninstallation, maintenance installations, and first installations—with the following exceptions in event-based scripts:

- The code in the following event handlers is executed only during uninstallation and maintenance installations:

  OnMaintUIBefore

  OnMaintUIAfter

- The code in the following event handlers is executed only during the first installation:

  OnCCPSearch

  OnAppSearch

  OnFirstUIBefore

  OnFirstUIAfter

InstallScript Functions that Are Logged for Uninstallation

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI —if the InstallScript user interface (UI) style is the traditional style (which uses the InstallScript engine as an external UI handler)*

This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the new style (which uses the InstallScript engine as an embedded UI handler). To learn more, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

In general, if logging is enabled, all of the files, folders, registry entries, .ini file entries, shortcuts, shortcut folders, and services that are created or replaced while logging is enabled are logged for uninstallation. In addition, all of the InstallScript functions that make changes to the target system during InstallScript installations and InstallScript MSI installations are logged for uninstallation. Following are some common examples of functions that an installation logs for uninstallation by default:

- AddFolderIcon
- AddProfString
- CopyFile
- CreateInstallationInfo

- CreateProgramFolder
- FeatureMoveData
- FeatureTransferData
- RegDBSetAppInfo
- RegDBSetItem
- ReplaceProfString
- ServiceAddService
- ServiceStartService
- VerSearchAndUpdateFile
- VerUpdateFile
- WriteProfString
- XCopyFile

You can disable and re-enable logging by calling `Disable (LOGGING);` and `Enable (LOGGING);` in your InstallScript code. For more information, see Disable and Enable.

Maintenance/Uninstallation Feature

The maintenance/uninstallation feature installs the files needed for maintenance setups and uninstallation, including engine files; the files' target location is specified by the value of the system variable *DISK1TARGET*. This feature is automatically placed in your .cab files by the release builder and is not displayed in the InstallShield interface.

At run time the maintenance/uninstallation feature is automatically selected for all setup types. Calling **FeatureUpdate** deselects this feature. The maintenance/uninstallation feature can also be selected or deselected by calling **FeatureSelectItem** and passing the system variable *DISK1COMPONENT* as the function's second argument. For example, the following code deselects the feature:

```
FeatureSelectItem( MEDIA, DISK1COMPONENT, FALSE );
```

Removing Files that Were Created by Your Product

By default, files created by your product after the installation is complete are assumed to be user data, and are not removed when the user uninstalls your application.

Basic MSI Project

Records you create in the RemoveFile table (using Direct Editor) can specify additional files to remove. For example, if your application creates a file called Product.ini inside *INSTALLDIR* and you want the file removed when the component containing your main executable is removed, add a record with the following contents to the RemoveFile table:

Table 4-1 • Additions to Add to the RemoveFile Table

FileKey	remove_file
Component_	ProgramFiles
FileName	Product.ini
DirProperty	INSTALLDIR
InstallMode	2

InstallScript and InstallScript MSI Projects

In your script, you can call the DeleteFile and DeleteDir functions in uninstallation event handler functions to remove any files or directories you want removed.

Removing Registry Data Created by Your Product

By default, your product's uninstallation removes only data that was created by your installation program.

Basic MSI Project

The Registry explorer understands a special uninstallation flag that controls the registry data to be removed during uninstallation. In particular, using the "-" flag ("Uninstall entire key") on a registry key causes the key and all its values and subkeys to be removed during uninstallation.

Note • *The RemoveRegistry table—exposed in the Direct Editor—specifies data to be removed only when your product is installed. For details, see the Windows Installer Help Library.*

InstallScript MSI Project

In your script, you can call the RegDBDeleteValue and RegDBDeleteKey functions in your uninstallation event-handler functions to remove specified registry values and keys.

Configuring Multiple Packages for Installation Using Transaction Processing

Project • *The following project types support multiple-package installations that use transaction processing:*

- *Basic MSI*
- *InstallScript MSI*

Windows Installer 4.5 includes support for installing multiple packages using transaction processing. The packages are chained together and processed as a single transaction. If one or more of the packages in the transaction cannot be installed successfully or if the end user cancels the installation, the Windows Installer initiates rollback for all of the packages to restore the system to its earlier state.

This section of the documentation explains how to specify .msi packages that you want InstallShield to include in your installation as chained packages. This section also explains how to configure settings such as the properties that should be passed to the chained packages.

Note • *Windows Installer 4.5 includes support for installing multiple packages using transaction processing. Earlier versions do not launch any chained .msi packages.*

If you want your installation to install Windows Installer 4.5, see Adding Windows Installer Redistributables to Projects to learn how.

Overview of Multiple-Package Installations that Use Transaction Processing

Project • *The following project types support multiple-package installations that use transaction processing:*

- *Basic MSI*
- *InstallScript MSI*

When you add one or more .msi packages to your installation as chained packages and an end user runs your installation on a system that has Windows Installer 4.5, the Windows Installer can install all of the packages in a single transaction. If one or more of the packages in the transaction cannot be installed successfully or if the end user cancels the installation, the Windows Installer initiates rollback for all packages to restore the system to its earlier state.

When the Windows Installer uses transaction processing, it batches together the various script states from the .msi packages. For example, Windows Installer executes the InstallInitialize action during the Execute sequence; at this point in the sequence Windows Installer executes all of the immediate actions for all of the packages and puts all of the deferred actions in the installation script. Next, Windows Installer executes the deferred actions—but not the

commit or rollback actions—in the installation script for all of the packages. In addition, Windows Installer copies the rollback actions to the rollback script. If the products for each of the packages are successfully installed up until this point, the Windows Installer runs all of the commit actions for each of the packages; otherwise, the Windows Installer executes the rollback script to return the target system to its original state.

For more information about this functionality, see Multiple-Package Installations in the Windows Installer Help Library.

Note • *Windows Installer 4.5 includes support for installing multiple packages using transaction processing. Earlier versions do not launch any chained .msi packages.*

If you want your installation to install Windows Installer 4.5, see Adding Windows Installer Redistributables to Projects to learn how.

Adding a New Chained .msi Package to Your Project

Project • *The following project types support multiple-package installations that use transaction processing:*

- *Basic MSI*
- *InstallScript MSI*

InstallShield enables you to add already built Windows Installer packages (.msi files) to your project as chained .msi packages. Windows Installer 4.5 includes support for installing the multiple packages using transaction processing. The packages are chained together and processed as a single transaction. If one or more of the packages in the transaction cannot be installed successfully or if the end user cancels the installation, the Windows Installer initiates rollback for all packages to restore the system to its earlier state.

The Chained .msi Packages area of the Releases view is where you add to your project one or more .msi packages that you want to be chained to your main installation.

Note • *Windows Installer 4.5 includes support for installing multiple packages using transaction processing. Earlier versions do not launch any chained .msi packages.*

If you want your installation to install Windows Installer 4.5, see Adding Windows Installer Redistributables to Projects to learn how.

Task: ***To add an .msi package as a chained package:***

1. In the View List under **Media**, click **Releases**.
2. Right-click the **Chained .msi Packages** explorer and then click **New Chained Package**. InstallShield adds a new item with a default name.

3. Enter a new name, or right-click it later and click **Rename** to give it a new name.

   The name is not displayed at run time; it is an internal name that is used to differentiate between different chained .msi packages in the main installation.

4. Select the new chained package item. InstallShield displays its settings in the right pane.

5. For the **Installation (run-time path)** setting, click the **Browse** button. The **Browse for File** dialog box opens.

6. Select the Windows Installer package (.msi file) that you would like to add, and then click **Open**. The package that you select must be an .msi package that can be installed through **MsiInstallProduct**. Note that it cannot be an InstallScript MSI package.

InstallShield prompts you to specify whether you want to stream the .msi package—and its uncompressed files, if the .msi package is not compressed—into your product's main .msi package:

- If you specify that you want InstallShield to stream the files, InstallShield adds the name of the .msi package to the **Installation (run-time path)** setting. InstallShield also automatically adds either the file name (if it is a compressed .msi package) or the entry ***.*** (if it is an uncompressed .msi package) to the **Streamed files** box. For the *.* wild-card entry, InstallShield streams in the .msi package as well as all of the files in the same folder as the .msi package.
- If you specify that you do not want InstallShield to stream the files, InstallShield adds the following path to the **Installation (run-time path)** setting:

  ```
  [SourceDir]FileName.msi
  ```

  You can change this path if appropriate. For example, you may want to use a path such as the following one, and also clear the **Delete streamed files after installation** check box:

  ```
  [LocalAppDataFolder]{ProductCodeGUID}\FileName.msi
  ```

  In this example, the .msi package is cached on the local system, and it is available for maintenance.

Tip • *You may not want to stream in the .msi package, since Windows Installer has limitations for the file size of .msi packages.*

7. Configure the chained .msi package settings as needed. To learn more, see Chained .msi Package Settings.

If your main installation includes several chained .msi packages, InstallShield uses the Order column in the **ISChainPackage** table of the main installation to determine the order in which the chained packages should be launched at run time. All uninstallations are processed in reverse order, from highest to lowest order number; all installations are processed in forward order, from lowest to highest order number.

Note • *If you have specified .msi packages in the Chained .msi Packages area in the Releases view, InstallShield does not build the chained packaged when you build releases for your main installation.*

Assigning Release Flags to a Chained .msi Package

Project • *The following project types support multiple-package installations that use transaction processing:*

- *Basic MSI*
- *InstallScript MSI*

You can assign one or more release flags to a chained .msi package that you want to exclude from certain builds. For example, if you have a chained .msi package that should be included only in a special edition of your product that contains a special add-on that requires the chained .msi package, you can flag that chained package and include it only when it is needed.

Task: ***To add a release flag to a chained .msi package that you have added to your installation project:***

1. In the View List under **Media**, click **Releases**.
2. In the **Chained .msi Packages** explorer, select the package that should contain the release flag.
3. For the **Release flags** setting, type a string. The string can be any combination of letters or numbers. To have more than one flag on a chained package, use a comma to separate the flags.

To learn more about filtering chained .msi packages based on release flags, see Release Flags.

Removing a Chained .msi Package from Your Project

Project • *The following project types support multiple-package installations that use transaction processing:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a chained .msi package from your project:***

1. In the View List under **Media**, click **Releases**.
2. In the **Chained .msi Packages** explorer, right-click the chained .msi package that you want to remove from your project, and then click **Remove**.

InstallShield removes the chained .msi package from your project. Note that InstallShield does not delete the .msi package, or any of its files, from your file system.

Building, Testing, and Deploying Installations

Once you have configured the features, components, files, shortcuts, registry entries, end-user dialogs, and other elements of your installation project, you are ready to create and build a release for your installation. InstallShield lets you create multiple releases for a project and configure each release for a different media type and according to different sets of requirements. Building releases packages the content of your installation, creating a disk image that you can copy to your distribution media and distribute or deploy as needed.

Testing is an essential part of creating a reliable installation. InstallShield enables you to selectively test run just the end-user interface portion of a release. You can also run your installation by simply clicking a button in InstallShield; when you run an installation by using this method, your installation executes exactly as it would on an end user's machine. All files are transferred, shortcuts and registry entries are made, and the user interface is displayed.

Before you release your product, you may want to validate your installation project. Validating a Windows Installer project involves applying a set of internal consistency evaluator (ICE) rules to your installation project. These ICEs are designed by Microsoft to help you determine whether your resulting installation package contains a valid database that performs its actions correctly.

With the debugging tools in InstallShield, you can debug your InstallScript script or Windows Installer release to identify the sources of problems. When you debug a script, you execute your script, statement by statement, and trace the flow of control by watching the execution point as it moves through the script. You can also monitor the value of any variable in your script at any point during script execution. When you debug a Windows Installer release, InstallShield runs through each action and dialog box until it reaches your breakpoint, when it halts execution. At this point, you can view and set properties.

Creating and Building Releases

Once you have designed your project in InstallShield, you are ready to create a release that you can configure and build to distribute to end users. The release is built according to the options you set for it in the Release Wizard or in settings that are displayed in the Releases view.

Working with Product Configurations

Project • *The following project types support product configurations:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

Every release that you build is a member of a product configuration. A product configuration provides a means for grouping together releases that share similar properties, such as the product name, product code, and package code.

Product configurations also enable you to keep a history of your builds without having to set up a folder structure outside InstallShield. For example, when your product is in development, you might have many releases of the same version. You do not necessarily want to overwrite each release every time that you rebuild the product. With product configurations, you can maintain your previous build history and incorporate new releases at the same time.

In the past, you may have had to maintain this type of historical record of your builds outside InstallShield. You had to create a directory structure on a drive, label each folder manually, and then copy the release into its directory. With product configurations, all of this is done for you in InstallShield.

Task: ***To create a product configuration:***

1. In the View List under **Media**, click **Releases**.
2. Right-click the **Releases** explorer and then click **New Product Configuration**.

InstallShield adds a new product configuration to the Releases explorer. InstallShield lists the product configuration settings on the General tab.

For descriptions about each of the product configuration settings, see General Tab for a Product Configuration.

Tip • *You can also create product configurations through the Release Wizard. You can specify existing product configurations from the command line (using the -a parameter), but you cannot define the settings of a release through the command line.*

Selecting the Appropriate Type of Architecture Validation for Builds

Project • *The following project types support product configurations:*

- *Basic MSI*
- *Merge Module*

As x64 Windows-based systems that do not have 32-bit Windows-on-Windows (WOW64) support become more common, you may want to perform architecture validation when building a release in InstallShield. Architecture validation enables you to detect potentially problematic cases in which your installation may try to install product files or use run-time binaries that may not match the architecture of a target system.

For example, if end users may run your installation on x64 Windows Server Core systems that do not have WOW64 support, architecture validation can help you identify any x86 product files or x86 custom action files in your installation; x86 binaries cannot be loaded on x64 target systems without WOW64 support.

In addition, if you are mixing x64 and x86 product files (or x64 and x86 custom actions) in a single project and generating separate x86 and x64 .msi packages, you can use architecture validation to identify any x64 product or custom action files in your x86 releases, since these files cannot be loaded on x86 target systems.

Architecture validation also enables you to generate pure x86 .msi packages that contain only x86 versions of the built-in InstallShield custom action DLLs, or pure x64 .msi packages that contain only x64 versions of the built-in InstallShield custom action DLLs. To enable this functionality, InstallShield uses two predefined path variables: ISRedistPlatformDependentFolder and ISRedistPlatformDependentExpressFolder. By default, the values of these path variables are subfolders that contain x86 versions of the InstallShield custom action DLLs; the subfolders are in the following directory: *InstallShield Program Files Folder*\Redist. InstallShield modifies the values of these path variables at build time if necessary to include the x64 versions (instead of the x86 versions) of the InstallShield custom action DLLs in releases; these files are in different subfolders in *InstallShield Program Files Folder*\Redist.

Overview of Architecture Validation

InstallShield offers two different levels of support for build-time architecture validation:

- **Lenient**—This type of validation lets you build x86 and x64 .msi packages (as indicated by the Template Summary property), and mix x86 and x64 product files and custom action files in both of those types of packages.

  At build time, the ISRedistPlatformDependentFolder and ISRedistPlatformDependentExpressFolder path variables point to the x86 locations that contain x86 InstallShield custom action DLLs. InstallShield includes these x86 custom action DLLs in the build if your project includes support that requires these custom actions.

  Lenient validation does not trigger build errors if the architecture that the Template Summary property specifies does not match the architecture for one or more of the custom action files that are being included in the release.

  Lenient validation does not trigger build warnings if the architecture that the Template Summary property specifies does not match the architecture for one or more of the product files that are being included in the release.

  Lenient is the default option.

- **Strict**—With this type of validation, InstallShield attempts to build a pure x86 or pure x64 .msi package, depending on whether the Template Summary property specifies Intel (for x86) or x64.

  If the Template Summary property specifies Intel, the ISRedistPlatformDependentFolder and ISRedistPlatformDependentExpressFolder path variables point to the x86 locations that contain x86 InstallShield custom action DLLs. However, if the Template Summary property specifies x64 and you are using strict validation, these path variables point to the x64 locations that contain x64 InstallShield custom action DLLs. If your project includes support that requires any of these custom actions, InstallShield adds the appropriate x86 or x64 versions of the DLLs to the build.

  Strict validation may trigger build errors if the architecture that the Template Summary property specifies does not match the architecture for one or more of the custom action files that are being included in the release. Thus, during build-time validation of an x86 package, InstallShield generates a build error for each x64 custom action file in the package. During build-time validation of an x64 package, InstallShield generates a build error for each x86 custom action file in the package.

Strict validation may trigger build warnings if the architecture that the Template Summary property specifies does not match the architecture for one or more of the product files that are being included in the release. Thus, during build-time validation of an x86 package, InstallShield generates a build warning for each x64 product file in the package. During build-time validation of an x64 package, InstallShield generates a build warning for each x86 product file in the package.

Tip • *For information on the Template Summary property, see Using the Template Summary Property.*

For additional tips on targeting 64-bit operating systems, see Targeting 64-Bit Operating Systems with Basic MSI and InstallScript MSI Installations.

Selecting the Type of Architecture Validation

InstallShield lets you specify which type of architecture validation you want to use for each product configuration that is defined in the Releases view of your project.

Task: ***To select the type of architecture validation that you want InstallShield to perform at build time:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, select the product configuration that you want to configure.
3. On the **General** tab, in the **Architecture Validation** setting, select the appropriate option. Available options are:
   - Lenient
   - Strict

Troubleshooting Build Errors and Warnings for Strict Architecture Validation

If you are using strict architecture validation to build an .msi package that specifies x64 for the Template Summary property, InstallShield may generate errors and warnings such as the following ones at build time:

```
error -7319: 32-bit Standard DLL Custom Action MyCustomAction must not be included in a strict 64-bit
    package.
```

```
warning -7326: Including 32-bit PE file C:\SourceFiles\x86\Myx86File.exe in a strict 64-bit package.
```

In many cases, an x64 target system can run an x86 file. However, if the x64 system does not have WOW64 support, it may not be able to run an x86 file.

Depending on your requirements, you may want to replace the x86 file or custom action that is referenced in a build error or warning with an x64 file or custom action. In other scenarios, you may want to ignore a build error or warning. For example, if a file's component has a condition that prevents the component from being installed on x64 systems, you may want to ignore its corresponding build warning. In some cases, you may decide to reexamine your requirements—that is, you may want to avoid supporting x64 target systems that do not have WOW64 support.

Similarly, you may encounter build errors and warnings if you are using strict architecture validation to build an x86 .msi package; for example:

```
error -7320: 64-bit Standard DLL Custom Action MyCustomAction must not be included in a strict 32-bit
    package.

warning -7327: Including 64-bit PE file C:\SourceFiles\x64\Myx64File.exe in a strict 32-bit package.
```

An x86 system cannot run any x64 files or custom actions. Depending on your requirements, you may choose to make changes to your project or ignore the build errors and warnings. In some cases, you may decide to reexamine your requirements.

Working with Releases

Project • *For installation projects: Before building your installation project, ensure that you have completed designing and configuring the settings for every element in your project, including the features, components, files, shortcuts, registry entries, and end-user interface.*

For merge module projects: Before building your package, ensure that you have completed designing and configuring the settings for every element in your merge module, including components, files, shortcuts, and registry entries.

Once you have designed your project in InstallShield, you are ready to create a release that you can configure and build to distribute to end users. You can create multiple releases for a project and configure each release for a different media type and according to different sets of requirements. InstallShield offers several methods for creating and building a release:

- Use the Release Wizard. (This method is not available in Advanced UI or Suite/Advanced UI projects.)
- Use the Releases view.
- Build from the command line using `ISCmdBld.exe`.
- Build a release through the automation interface. (This method is not available in Advanced UI or Suite/Advanced UI projects.)

For information on building an InstallShield release from within Visual Studio, see Building Releases in Microsoft Visual Studio.

Tip • *Make sure that Windows Explorer is not pointing to the `Disk1` folder or a subfolder when you build your release. If Windows Explorer is pointing to the `Disk1` folder, the build process fails and generates an error.*

Using the Release Wizard to Create and Build a Release

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*

- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The Release Wizard provides an easy way for you to build a product release and specify the settings for that release.

Task: ***To launch the Release Wizard and build your installation package, do one of the following:***

- Click the **Release Wizard** button on the toolbar.
- On the **Build** menu, click **Release Wizard**.
- In the **Releases** view, right-click a release and click **Release Wizard**.

Follow the instructions in the panels of the Release Wizard. For a list of errors returned by the wizard, see Build Errors and Warnings.

Using the Releases View to Create and Build a Release

The Releases view lets you specify the settings for a release and build it. The procedure for creating and building a release depends on what project type you are using.

Creating and Building a Release in Basic MSI, InstallScript MSI, and Merge Module Projects

Task: ***To create and build a release:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, right-click the product configuration that should contain the new release, and then click **New Release**. For information on how to create a new product configuration, see Working with Product Configurations. InstallShield adds a new release under the product configuration. Its settings are displayed on the tabs.
3. Configure the release's settings as appropriate.
4. Right-click the release and then click **Build**.

Creating and Building a Release in Advanced UI and Suite/Advanced UI Projects

Edition *• The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Task: ***To create and build a release:***

1. In the View List under **Media**, click **Releases**.
2. Right-click the **Releases** explorer, and then click **New Release**. InstallShield adds a new release. Its settings are displayed on the tabs.
3. Configure the release's settings as appropriate.
4. Right-click the release and then click **Build**.

Creating and Building a Release in an InstallScript or InstallScript Object Project

Task: ***To create and build a release:***

1. In the View List under **Media**, click **Releases**.
2. Right-click the **Releases** explorer, point to **New Release**, and click the type of media that you want to create. InstallShield adds a new release to the explorer. Its settings are displayed on the tabs.
3. Configure the release's settings as appropriate.
4. Right-click the release and then click **Build**.

Setting the Release Location

The disk image folders for your installation are built in the release location. All additional files and folders that are necessary for storing uncompressed application files are placed in subfolders of the disk image folders. The release location is a subfolder of your project's location.

To see your release after you have built it, click `Disk Images` under the product name and the release name in the Releases view. If you have not changed the release location, InstallShield places the built installation package into the following folder:

`InstallShield Project Folder``\`*`project name`*`\`*`product configuration`*`\`*`release name`*`\DiskImages\Disk1`

You can set the release location either in the Advanced Settings panel of the Release Wizard or in the Release Location property in the Releases view.

Building a Release from the Command Line

You can build a release from the command line using `ISCmdBld.exe` for Windows Installer–based projects, for InstallScript projects, and for Advanced UI or Suite/Advanced UI projects. If your project includes InstallScript, `ISCmdBld.exe` also compiles it before building the release.

Using `ISCmdBld.exe` to build an installation can be useful if you are trying to build from a batch file. Also, building a release from the command line using `ISCmdBld.exe` will handle the conversion of .ipr and .ipo files (object project files created using InstallShield Professional) to an .ism file, in addition to building the release.

Tip *• An .ism file in either binary or XML format is accepted by the command-line build. The command-line build also works with Advanced UI and Suite/Advanced UI project files (.issuite).*

You can build a release from the command line using `ISCmdBld.exe` *with the Standalone Build. For more information, see Standalone Build.*

Using ISCmdBld.exe to Build a Release from the Command Line

`ISCmdBld.exe` is located by default in the InstallShield folder's System subfolder. Do not move `ISCmdBld.exe` from its installed location.

For the syntax and available command-line parameters for `ISCmdBld.exe`, see ISCmdBld.exe.

Passing Command-Line Build Parameters in an .ini File

Project *• This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

If you want to pass numerous parameters during a command-line build, or if you consistently pass the same parameters, it might be convenient to use an .ini file. The following statement illustrates running `ISCmdBld.exe` to build a release with parameters as specified in the **MySetup.ini** file.

```
ISCmdBld.exe -i "C:\InstallShield 2013 Projects\MySetup.ini"
```

You need to include the same information in the .ini file as you would if you were passing the parameters at the command line. There are four sections for this file:

- **[Project]**—In this section, include entries for the path to the project file (.ism), as well as the name of the product configuration. If you are building a patch, include an entry for the name of the patch configuration that you are building.
- **[Release]**—In this section, include entries for release configuration information such as the compression type (compressed or uncompressed), build flags, `Setup.exe` settings, and the release name.
- **[Mode]**—In this section, include any of the available optional entries, such as the Silent=yes entry if you want to build your release while suppressing any build errors or warning messages. This section also lets you indicate whether a log file should be created.
- **[BuildLocation]**—In this section, you can optionally specify the release output location.

Not all sections are required. As with passing parameters directly from the command line, parameters for requirements such as silent build and build location are optional. In the example .ini file below, these parameters are in the `[Mode]` and `[BuildLocation]` sections. You can omit these entries from your .ini file if you want to accept the defaults. By default, no log file is created, the installation is not run in silent mode, and your release is created in the project location that is specified on the File Locations tab of the Options dialog box.

Sample .ini File

The following tables contain sample entries from each of the four sections in a sample .ini file. The first column of each table shows a sample entry. The other columns provide the corresponding command-line parameter and description.

Entries in the [Project] Section

Table 4-1 • Sample Entries in the [Project] Section of the .ini File

Entry	Corresponding ISCmdBld.exe Command-Line Parameter	Description
Name="C:\InstallShield 2013 Projects\Othello.ism"	-p	Path to the .ism file.
BuildLabel=Label1	-a	Name of the product configuration for the release that you are building. If it does not exist, it is created.
Product=Othello		Name of your product. This entry lets you override the value that is specified in the General Information view.
PatchConfigName="Version 1.2"	-patch_config	Name of the patch configuration in the Patch Design view that you want to build.
CompileScript=no	-n	Ensures that `Setup.rul` is not compiled as part of the build process.  ***Note*** • *`CompileOnly` should not be used with `CompileScript`.*

Entries in the [Release] Section

Table 4-2 • Sample Entries in the [Release] Section of the .ini File

Entry	Corresponding ISCmdBld.exe Command-Line Parameter	Description
BuildFlags=flags	-f	Release flags to be included in the installation, separated by commas.
Configuration=COMP	-c	Compressed vs. uncompressed.
Name=Othello Beta	-r	Release name.
SetupEXE=yes	-e	Creates a `Setup.exe` file.

Entries in the [Mode] Section

Table 4-3 • Sample Entries in the [Mode] Section of the .ini File

Entry	Corresponding ISCmdBld.exe Command-Line Parameter	Description
CubFile="C:\Program Files\InstallShield\2013\Support\Validation\MyValidation.cub"	-m	Validate the installation or merge module package after it is built using the specified .cub file. Include the full path and name to the .cub file. To use multiple .cub files, separate each path with a semicolon (;). Enclose long file names in quotation marks. For example, the following entry indicates that validation should be performed with the InstallShield Validation Suite for Windows 8 (`ISWin8.cub`) and the Full MSI Validation Suite (`darice.cub`): `CubFile="C:\Program Files\InstallShield\2013\Support\Validation\ISWin8.cub;C:\Program Files\InstallShield\2013\Support\Validation\darice.cub"`
Silent=yes	-s	Runs in silent mode.
StopOnFirstError=yes	-x	Aborts the build when the first error is encountered.
CompileOnly=no	-q3	Compiles only `Setup.rul` and streams `Setup.inx` into the **Binary** table of the .msi file, if one was previously built. ***Note*** • *The entries `CompileOnly`, `BuildTablesRefreshFiles`, and `BuildTablesOnly` are mutually exclusive. Only one can be set to **yes**.* *`CompileOnly` should not be used with `CompileScript`.*
BuildTablesRefreshFiles=no	-q2	Builds the Windows Installer tables and refreshes files. ***Note*** • *The entries `CompileOnly`, `BuildTablesRefreshFiles`, and `BuildTablesOnly` are mutually exclusive. Only one can be set to **yes**.*

Table 4-3 • Sample Entries in the [Mode] Section of the .ini File (cont.)

Entry	Corresponding ISCmdBld.exe Command-Line Parameter	Description
BuildTablesOnly=yes	-q1	Builds only the Windows Installer tables for your release.  ***Note*** • *The entries `CompileOnly`, `BuildTablesRefreshFiles`, and `BuildTablesOnly` are mutually exclusive. Only one can be set to **yes**.*
UpgradeOnly=no	-u	Allows you to upgrade—but not build—your release.
Verbose=yes	-v	Generates an engine log file.
WarningAsError=yes	-w	Treats any build warnings as build errors.
MSIVersion=2.0	-g	Version of Windows Installer required on target system.  ***Note*** • *This entry applies to the Standalone Build only.*
DotNetVersion=	-j	Minimum version of Microsoft .NET Framework required on the target system. This parameter is optional and defaults to the latest version of the .NET Framework supported by InstallShield.  ***Note*** • *This entry applies to the Standalone Build only.*
DotNetPath="C:\..."	-t	Path to the Microsoft .NET Framework on the build machine.  ***Note*** • *This entry applies to the Standalone Build only.*
SkipValidators=yes	-h	Enables you to turn off the upgrade validators that normally run at the end of the build.  ***Note*** • *This entry applies to the Standalone Build only.*

Table 4-3 • Sample Entries in the [Mode] Section of the .ini File (cont.)

Entry	Corresponding ISCmdBld.exe Command-Line Parameter	Description
MergeModulePath="C:\..."	-o	Search path for merge modules (.msm files). For more information, see Specifying the Directories that Contain Merge Modules.  ***Note*** • *This entry applies to the Standalone Build only.*
PrerequisitePath="C:\..."	-prqpath	Search path for InstallShield prerequisite files (.prq). For more information, see Specifying the Directories that Contain InstallShield Prerequisites.  ***Note*** • *This entry applies to the Standalone Build only.*

Entries in the [BuildLocation] Section

Table 4-4 • Sample Entries in the [BuildLocation] Section of the .ini File

Entry	Corresponding ISCmdBld.exe Command-Line Parameter	Description
Path="C:\InstallShield 2013 Projects\Othello"	-b	Release output location.

For more information about the .ini file entries, see Building a Release from the Command Line.

Using ISBuild.exe to Build from the Command Line

Project • *This information applies to InstallScript projects.*

`ISBuild.exe`, a command-line tool that is available for legacy InstallScript projects, is a shell that calls into `ISCmdBld.exe`. `ISCmdBld.exe` handles the conversion of .ipr and .ipo (object projects created using InstallShield Professional) files to an .ism file and builds the release.

For a list of command-line parameters for `ISBuild.exe`, see ISBuild.exe.

Building a Self-Extracting Executable File from the Command Line

Project • *This information applies to InstallScript projects.*

You can build a self-extracting executable file from the command line using `ReleasePackager.exe`. This can be useful if you are building from a batch file.

`ReleasePackager.exe` is located by default in the InstallShield folder's `System` subfolder. Do not move `ReleasePackager.exe` from its installed location.

For syntax and available arguments and options for `ReleasePackager.exe`, see ReleasePackager.exe.

Rebuilding Releases

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *Suite/Advanced UI*

You can rebuild a release at any time using the default entries that you already provided in the settings in the Releases view. The release that currently has focus is rebuilt.

Task: ***To rebuild a release, do one of the following:***

- Click the **Build** button.
- On the **Build** menu, click **Build**.
- In the **Releases** view, right-click a release name and then click **Build**.

You can run the Release Wizard again to rebuild a release. Because the wizard stores the release settings in your InstallShield project file, the wizard displays all of the options that you set when you last built the release, even if you deleted the release.

To see your new installation package, click Disk Image(s) for the appropriate release in the Releases view. InstallShield places the built installation package into the following folder if you have not changed the default release location:

`C:\InstallShield 2013 Projects\`*`project name`*`\`*`product configuration`*`\`*`release name`*`\DiskImages\Disk1`

Note • *Make sure that Windows Explorer is not pointing to the `Disk1` folder or a subfolder when you build your release. If it is pointing to the `Disk1` folder, the build process can continue indefinitely. If Windows Explorer is accessing a subfolder, the build generates an error.*

Performing Quick Builds

When you are testing your installation, you might not want to continually build all of your installation files if no files have been changed. InstallShield provides you with two quick build options: Build Tables Only and Build Tables & Refresh Files.

Build Tables Only

As the name of this option implies, only the Windows Installer tables are built. If you have not built this installation already, a new .msi file is created, but no files are added to your installation. If you have built your installation already, the .msi file is updated when all the tables are built, but no files are transferred. You can use this option to test the installation's user interface.

Task: ***To build only your installation's Windows Installer tables, do one of the following:***

- On the **Build** menu, click **Build Tables Only**.
- In the **Releases** view, right-click the release that you would like to build and click **Build Tables Only**.

Build Tables & Refresh Files

If you would like a near-complete build without having to transfer all of the installation's files to a new location, you can perform a build that rebuilds your .msi file and updates the **Files** table, thereby including any new or changed files in your installation. Changed files are updated only if the size or time stamp differs from the copy already included in the build. References to deleted files are removed from the installation, but the file remains in the build location. This type of build works only when the media is an uncompressed network image.

Task: ***To build your Windows Installer tables and refresh the installation's files, do one of the following:***

- On the **Build** menu, click **Build Tables & Refresh Files**.
- In the **Releases** view, right-click the release that you would like to build and click **Build Tables & Refresh Files**.

Performing Batch Builds

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

You might need to build multiple releases with different configurations simultaneously. This functionality is known as a batch build.

Task: ***To perform a batch build through InstallShield:***

1. In the View List under **Media**, click **Releases**.
2. In a Basic MSI, InstallScript MSI, or Merge Module project: Right-click a product configuration and click **Batch Build**.

   In an InstallScript or InstallScript Object project: Right-click the **Releases** explorer and click **Batch Build**.

The Batch Build dialog box opens to prompt you to select the product configurations and releases that you would like to build.

Specifying Commands that Run Before, During, and After Builds

Edition • *This functionality is available in the Premier edition of InstallShield.*

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *Merge Module*
- *Suite/Advanced UI*

Some project-specific differences are noted where applicable.

InstallShield lets you specify commands that you want to be run at various stages of the build process. For example, if you are developing a Basic MSI project, you may want to modify the .msi package that InstallShield creates at build time before InstallShield digitally signs it and streams it into the `Setup.exe` file. You can specify a command that runs a script that makes the required changes to the .msi package at the appropriate time during the build.

When you are entering a command, you can use any path variables and environment variables that are defined in your project, instead of using a hard-coded path. You can also use the following variables that are defined specifically for build event commands.

Table 4-5 • Build Event Variables

Variable	Project Types	Description
<ISReleaseName>	Basic MSI, InstallScript, InstallScript MSI, Merge Module, Suite/Advanced UI	This variable indicates the name of the release that InstallShield is building.
<ISProductConfigName>	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This variable indicates the name of the product configuration that contains the release that InstallShield is building. (Note that this is always *Media* for InstallScript projects.)
<ISReleasePath>	Basic MSI, InstallScript, InstallScript MSI, Merge Module, Suite/Advanced UI	This variable indicates the build location of the release that InstallShield is building. It is set through the Release Location setting on the Build tab for a release in the Releases view.
<ISReleaseUsesShallowFolderPaths>	Basic MSI, InstallScript MSI	This variable is set to true or false to indicate whether InstallShield uses a shallow folder directory structure when building your release.

At build time, InstallShield sets temporary `<ISReleaseName>`, `<ISProductConfigName>`, `<ISReleasePath>`, and `<ISReleaseUsesShallowFolderPaths>` environment variables; InstallShield also sets temporary environment variables for all of the defined path variables in your project. You can refer to the value of one of these environment variables in a batch file by surrounding the variable name with percent signs (%); for example:

```
set PATH = %<ISReleaseName>%;%PATH%
```

When the build is complete, InstallShield deletes the temporary environment variables that it set.

Task: ***To specify one or more commands that run before, during, or after a build:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you would like to configure.
3. Click the **Events** tab.
4. In one or more of the following settings, enter the commands that you want InstallShield to run:

- Prebuild Event
- Precompression Event (This event is not available in Suite/Advanced UI projects.)
- Postbuild Event

Enter each command as it would be launched from the command prompt. Thus, for example, if you specify a path that includes spaces, enclose the path within quotation marks.

For details about each setting, see Events Tab for a Release.

To specify more than one command for any of those settings, click the ellipsis button (**...**) in the setting. A dialog box opens, enabling you to enter one or more commands. Enter each command on a separate line.

If you enter more than one command for an event settings, InstallShield runs each command at build time in the order that they are listed for that setting. The build waits until a command finishes before proceeding to the next one.

Tip *• A verbose build log shows each of the build events that are run at build time. To troubleshoot build events, generate a verbose log file and search for strings such as "Launching prebuild events", "Launching precompression build events", and "Launching postbuild events". These areas of the log list details about the commands that are run at build time.*

To generate a verbose build log, pass the `-v` *parameter when launching* `IsCmdBld.exe` *from the command line.*

Resolving Build Errors and Warnings

When you build a release, the Output window opens across the bottom of the InstallShield user interface. The Tasks tab of this window lists any build errors and warnings that occur during the build process.

Task: ***To learn how to resolve a build error or warning that you encounter, do one of the following:***

- On the **Tasks** tab of the **Output** window, click an error code to launch your Internet browser and see Knowledge Base articles and HelpNet topics for the selected build error or warning.
- See Build Errors and Warnings, which provides tips on how to resolve build errors and warnings.

Changing Project Settings from the Command Line

The InstallShield automation interface enables you to query and modify many project settings from an unattended build process, using, for example, a VBScript script or Visual Basic application.

The framework of any script that uses the automation interface to access a project appears as follows (you can copy this script into a text file called `Framework.vbs` and then double-click the file icon):

```
Set oProject = CreateObject("IswiAuto20.ISWiProject")
oProject.OpenProject "C:\MySetups\MyProject.ism"

' perform queries and changes here
```

```
oProject.SaveProject ' necessary only if modifying the project
oProject.CloseProject
```

Canceling Builds

Task: ***To cancel a build after it has started:***

Click the **Stop Build** button on the toolbar.

Standalone Build

InstallShield provides a Standalone Build module that enables you to install only the part of InstallShield that compiles the installations, plus any redistributables that you want to include. For instructions on installing the Standalone Build and any redistributables on a build machine, see Installing the Standalone Build on a Build Machine.

The InstallShield 2013 Standalone Build can coexist with other major versions of the Standalone Build on the same machine (in different folders).

Upgrading Projects

The Standalone Build automatically upgrades projects that were created with InstallShield Developer 7.0 or later. However, it does not upgrade projects that were created with InstallShield for Windows Installer.

Using the Command-Line Build

You can run the Standalone Build from the command line. For more information, see Standalone Command-Line Build.

Using the Standalone Automation Interface

The Standalone Build includes a standalone version of the automation interface—the Standalone Automation Interface.

Installing the Standalone Build on a Build Machine

Edition • *Support for multilanguage installations is available with InstallShield Premier Edition only.*

Installing the Standalone Build

The installation for the Standalone Build consists of a single, compressed executable file. It includes all of the files that are required for building multilanguage installations.

Task: ***To install the Standalone Build on a build machine:***

1. Locate the executable file for the Standalone Build installation:
   - If you have the InstallShield DVD, the file is on the DVD and you can find it using the DVD Browser.
   - If you downloaded InstallShield, the Standalone Build installation file is available for download as documented in the Standalone Build licensing instructions (http://www.installshield.com/instructions/sab.asp).
2. Double-click the executable file and run the installation. For detailed information on configuring licensing for the Standalone Build, see the Standalone Build licensing instructions (http://www.installshield.com/instructions/sab.asp).

During the installation, the Custom Setup dialog shows two Standalone Build features that are disabled by default. Enable these features if you want to be able to use them.

- **Automation Interface**—This feature installs and registers the files that you need to use the automation interface with the Standalone Build.
- **InstallScript Objects Support**—This feature installs and registers the InstallScript Object support files that enable you to build InstallScript projects that contain InstallScript Objects.

Files that Are Registered During the Standalone Build Installation

When you install the Standalone Build, the installation installs and registers each of the following merge modules if they are not present:

- ATL 3.0 (`ATL.msm`)
- Microsoft C Runtime Library (`MSVCRT.msm`)
- Microsoft C Runtime Library 7.1 (`VC_User_CRT71_RTL_X86_---.msm`)
- MSXML3 (`msxml3_wim32.msm`)
- MSXML4 (`msxml4sxs32.msm` or `msxml4sys32.msm`)
- Visual C++ 8.0 ATL (x86) WinSXS MSM (`Microsoft_VC80_ATL_x86.msm`)
- Visual C++ 8.0 ATL.Policy (x86) WinSXS MSM (`policy_8_0_Microsoft_VC80_ATL_x86.msm`)
- Visual C++ 8.0 CRT (x86) WinSXS MSM (`Microsoft_VC80_CRT_x86.msm`)
- Visual C++ 8.0 CRT.Policy (x86) WinSXS MSM (`policy_8_0_Microsoft_VC80_CRT_x86.msm`)

The Standalone Build installation also installs and registers the Microsoft Scripting Runtime Library (`scrrun.dll`) if it is not present. It is installed to the [SystemFolder].

If you copy the Standalone Build files from one machine to another instead of running the installation on that second machine, you must manually install the technologies that are included in these merge modules and the `scrrun.dll` file if they are not already present. You can obtain the installation packages for the merge module technologies from the Microsoft Web site (http://www.microsoft.com).

Files that Are Registered During the Installation of the Optional Automation Support Feature

The Automation Interface feature in the Standalone Build installation installs and registers the files that you need in order to use the automation interface with the Standalone Build. Following is the list of files that need to be registered:

- *Program Files Folder*\Common Files\InstallShield\Shared\IsmAuto.tlb
- *Program Files Folder*\Common Files\InstallShield\Shared\Ismmupdater.tlb
- *Program Files Folder*\Common Files\InstallShield\Shared\ISWIBuild.tlb
- *Program Files Folder*\Common Files\InstallShield\Shared\IsAppServices.tlb
- *Program Files Folder*\Common Files\InstallShield\Shared\IsUpgrade.tlb
- *Standalone Build Program Files Folder*\System\ISWiAutomation20.dll

If you copy the Standalone Build files from one machine to another instead of running the installation on that second machine, and if you want to be able to use the automation interface with the Standalone Build, you must manually register these files.

Files that Are Registered During the Installation of the Optional InstallScript Objects Support Feature

The InstallScript Objects Support feature installs and registers the InstallScript Object support files that enable you to build InstallScript projects that contain InstallScript Objects. Following is the list of files that need to be registered:

- *Standalone Build Program Files Folder*\System\DObj20.dll
- *Standalone Build Program Files Folder*\System\ISBE.dll
- *Standalone Build Program Files Folder*\System\ISMK20.dll
- *Standalone Build Program Files Folder*\System\StockWiz.dll

If you copy the Standalone Build files from one machine to another instead of running the installation on that second machine, and if you want to be able to build InstallScript projects that contain InstallScript Objects, you must manually register these files.

Manually Registering Files for the Standalone Build

To manually register one of the aforementioned DLL files for the Standalone Build, use `Regsvr32.exe`, which is installed in the System32 folder.

To manually register one of the .tlb files, use the following file:

Standalone Build Program Files Folder\System\RegTypLib.exe

Adding Redistributables to the Build Machine for the Standalone Build

Most of the redistributables—including merge modules, objects, and InstallShield prerequisites—are not installed automatically with the Standalone Build because they would require significantly more hard disk space. This allows you to install on the build machine only the redistributables that are required by your InstallShield projects. The only one that is included is the .NET Framework 2.0 redistributable.

Tip • *The Standalone Build uses the same basic directory structure that InstallShield uses for its program files. Therefore, if you need to copy a redistributable or some other file from a machine that has InstallShield to a machine that has the Standalone Build, use the same relative path. For example, if a file is in the `InstallShield Program Files Folder\Modules\i386` directory on the machine that has InstallShield, copy that file to the `Standalone Build Program Files Folder\Modules\i386` directory on the machine that has the Standalone Build.*

Task: ***To add a .NET redistributable to your build machine:***

1. Locate the required redistributables on the machine that has the full version of InstallShield. The file is typically located in `InstallShield Program Files Folder\Redist` or a subfolder of the Redist folder. If an InstallShield redistributable is not available on your machine, you must download it first. For more information, see Redistributable Downloader Wizard.
2. Copy the redistributable from the machine that has InstallShield to the Standalone Build Program Files Folder on the build machine.

Task: ***To add a redistributable for Basic MSI or InstallScript MSI projects to your build machine:***

1. Locate the required redistributables on the machine that has the full version of InstallShield. If an InstallShield redistributable is not available on your machine, you must download it first. For more information, see Downloading Redistributables to Your Computer.
   - The two default locations for InstallShield merge modules are:

     `InstallShield Program Files Folder``\Modules\i386`

     `Common Files\Merge Modules`
   - The default location for the InstallShield objects is:

     `InstallShield Program Files Folder``\Objects`
   - All InstallShield prerequisites are stored in the following location:

     `InstallShield Program Files Folder``\SetupPrerequisites`
   - If you built your own merge modules in InstallShield, you would find them in any of the locations that are listed on the Merge Modules tab of the Options dialog box.
2. Copy the redistributable from the machine that has InstallShield to appropriate location on the build machine.
   - Add merge modules to the following folder:

Standalone Build Program Files Folder\Modules\i386

- Add objects to the following folder:

  Standalone Build Program Files Folder\Objects

- Add InstallShield prerequisites to the following folder:

  Standalone Build Program Files Folder\SetupPrerequisites

Task: ***To add an InstallShield prerequisite for InstallScript projects to your build machine:***

1. Locate the required InstallShield prerequisite on the machine that has the full version of InstallShield. If an InstallShield redistributable is not available on your machine, you must download it first. For more information, see Downloading Redistributables to Your Computer.

   All InstallShield prerequisites are stored in the following location:

   InstallShield Program Files Folder\SetupPrerequisites

2. Copy the InstallShield prerequisite from the machine that has InstallShield to appropriate location on the build machine:

   Standalone Build Program Files Folder\SetupPrerequisites

Task: ***To add to your build machine one of the other InstallShield redistributables for InstallScript projects:***

1. Download the installation for the redistributable. The installations are available through FlexNet Connect. For more information, see Obtaining Updates for InstallShield.
2. Run the redistributable installation on the build machine. When the InstallShield Wizard displays the Choose Destination Location dialog, browse to the following location:

   Standalone Build Program Files Folder\ObjectsPro

   If the ObjectsPro folder has not been created yet, you will need to add that folder.

The InstallScript object installations install and register the required object files.

Task: ***To add to your build machine one of your own InstallScript redistributables or a third-party redistributable:***

1. Locate the redistributable.
2. Place it in the following location on the build machine:

   Standalone Build Program Files Folder\ObjectsPro

   If the ObjectsPro folder has not been created yet, you will need to add that folder.

Standalone Command-Line Build

The Standalone Build lets you use `ISCmdBld.exe` to build releases from the command line. For instructions, see Building a Release from the Command Line.

For a list of command-line parameters that `ISCmdBld.exe` supports, see ISCmdBld.exe.

Standalone Automation Interface

The Standalone Build includes a standalone version of the automation interface—the InstallShield Standalone Automation Interface. This interface uses the same `ISWiAutomation20.dll` file that is installed with InstallShield, but it is installed to a different location.

Note • *If you install the Standalone Build on the same machine as InstallShield, the first `ISWiAutomation20.dll` file that is installed is the one that is registered. To learn more, see Installing the Standalone Build and InstallShield on the Same Machine.*

Future versions of the Standalone Build will have new ProgIDs and new GUIDs. This enables you to install multiple versions of the Standalone Automation Interface side by side on the same build machine.

Registering ISWiAutomation20.dll

The Standalone Automation Interface is contained in the file `ISWiAutomation20.dll`. If you installed the Standalone Build by running the installation for the Standalone Build, this file is already registered. If you copied the files for the Standalone Build instead of running the installation, you need to register this file manually using `Regsvr32.exe`, which is installed in the System32 folder. The `ISWiAutomation20.dll` file is installed in the System subfolder of the Standalone Build Program Files folder.

Installing the Standalone Build and InstallShield on the Same Machine

In most cases, the Standalone Build is not installed on the same machine where InstallShield is installed. If you do install both on the same machine, you need to be aware that the Standalone Automation Interface uses the same `ISWiAutomation20.dll` file that InstallShield uses, but it is installed to a different location. In addition, both the Standalone Automation Interface and InstallShield use the same ProgID: `IswiAuto20.ISWiProject`. This enables you to use the same automation script with both the Standalone Automation Interface and InstallShield, without requiring you to change your code to reflect the appropriate ProgID.

When you first install either InstallShield or the Standalone Build, the installation registers `ISWiAutomation20.dll`. If you next install the other tool, that second installation detects that `ISWiAutomation20.dll` is already registered, so it does not re-register it. As long as one instance of `ISWiAutomation20.dll` is registered, you can use both the Standalone Build and InstallShield with the automation interface.

If you uninstall the first instance that you originally installed, the installation unregisters `ISWiAutomation20.dll`. Therefore, you must manually register `ISWiAutomation20.dll` so that you can use the automation interface with the product that still remains. For example, if you install InstallShield, install the Standalone Build, and then uninstall InstallShield, you must next manually register the `ISWiAutomation20.dll` file for the Standalone Build; otherwise, you cannot use the Standalone Automation Interface.

To manually register `ISWiAutomation20.dll`, use `Regsvr32.exe`, which is installed in the System32 folder. The `ISWiAutomation20.dll` file is installed in the System subfolder of the InstallShield and Standalone Build Program Files folders.

Microsoft Build Engine (MSBuild)

InstallShield supports the Microsoft Build engine (MSBuild) included with the .NET Framework. MSBuild support enables you to build Visual Studio solutions with InstallShield projects in build lab environments where Visual Studio is not installed.

Overview

MSBuild is an extensible build framework designed to remove the build dependence on Visual Studio. The .NET Framework functions in a role similar to the InstallShield Standalone Build, providing the capability to build projects or solutions from the command line or any other host of MSBuild. For more information on MSBuild, see the MSDN Library.

MSBuild Tasks

The flexibility and extensibility of MSBuild is controlled through atomic groupings of internal build steps referred to as *tasks*. One example of a task that ships with MSBuild is Csc, which can compile code from a Visual C# project. InstallShield installs an MSBuild task called InstallShield, which builds an InstallShield project, and a targets file that provides default build steps for the project. This customized task, along with the targets file, enables MSBuild to perform all required actions to build the InstallShield project as part of a Visual Studio solution.

This table describes the parameters of the InstallShield task. The Project Type column lists the applicable project types

Table 4-6 • MSBuild InstallShield Task

Parameter	Type	Project Type	Description
InstallShieldPath	String	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies the path to folder containing the InstallShield application.
Project	String	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies the location of the project file (.ism).
ProductConfiguration	String	Basic MSI, InstallScript MSI, Merge Module	This parameter specifies the product configuration for the release.

Table 4-6 • MSBuild InstallShield Task

Parameter	Type	Project Type	Description
ReleaseConfiguration	String	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies the release name.  ***Note*** • *You must specify the ReleaseConfiguration or the PatchConfiguration. If you do not specify one of these, or if you specify both of these, a build error occurs.*
PatchConfiguration	String	Basic MSI, InstallScript MSI	This parameter specifies the name of the patch configuration in the Patch Design view that is being built.  ***Note*** • *You must specify the ReleaseConfiguration or the PatchConfiguration. If you do not specify one of these, or if you specify both of these, a build error occurs.*
OutDir	String	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies the fully qualified path to the folder where you want the output folders and files to be placed.
MergeModulePath	String[ ]	Basic MSI, InstallScript, InstallScript MSI	This parameter specifies one or more folders that contain the merge modules (.msm files) that are referenced by your project. InstallShield provides additional ways for specifying the folders that contain merge modules. For more information, see Specifying the Directories that Contain Merge Modules.
PrerequisitePath	String[ ]	Basic MSI, InstallScript, InstallScript MSI	This parameter specifies one or more semicolon-delimited folders that contain the InstallShield prerequisite files (.prq files) that are referenced by your project. InstallShield provides additional ways for specifying the folders that contain InstallShield prerequisite files. For more information, see Specifying the Directories that Contain InstallShield Prerequisites.

Table 4-6 • MSBuild InstallShield Task

Parameter	Type	Project Type	Description
ReleaseFlags	String[ ]	Basic MSI, InstallScript MSI	This parameter enables you to specify any release flags that you want to include in your release. Separate multiple flags with commas.
PathVariables	ITaskItem[ ]	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter enables you to override the path variables for the project. Using this parameter, you can specify the path to the path variable and also define a value for the name of the path variable using the PathVariable subelement. For more information on MSBuild ITaskItem[ ] properties, see the MSDN Library.
PreprocessorDefines	ITaskItem[ ]	Basic MSI, InstallScript, InstallScript MSI	This parameter enables you to add or override the preprocessor defines for the project. Using this parameter, you can specify the definition of the preprocessor define and also define a value for the name of the preprocessor define using the Token subelement. For more information on MSBuild ITaskItem[ ] properties, see the MSDN Library.
OutputGroups	ITaskItem[ ]	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies the project output groups from the Visual Studio solution. Using this parameter, you can specify the path to the source location of the project output group and also define these additional values using these subelements as listed: • **Name**—Name of the project • **OutputGroup**—Name of the project output group • **TargetPath**—Target path of the project output group (different from its source location) For more information on MSBuild ITaskItem[ ] properties, see the MSDN Library.

Table 4-6 • MSBuild InstallShield Task

Parameter	Type	Project Type	Description
Build	String	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies what type of build to perform. You can choose from these types of builds: • **Complete**—This option builds the entire release. • **Compile**—This option compiles the `Setup.rul` script file. In Basic MSI and Merge Module projects, this option also streams `ISSetup.dll` into the **Binary** table of the .msi package. • **Tables**—This option builds only the Windows Installer tables for the database. If you have not built this installation already, a new .msi file is created, but no files are added to your installation. If you have built your installation already, the .msi file is updated when all the tables are built, but, again no files are transferred. Ideally, this option is to be used to test the user interface of your installation. This option is applicable to Basic MSI, InstallScript MSI, Merge Module projects. • **TablesAndFiles**—For Basic MSI, InstallScript MSI, and Merge Module projects, this option builds the Windows Installer tables and refreshes the files. This type of build can be run only after a complete build has been performed, and it works only when the media is an uncompressed network image. For InstallScript projects, this option rebuilds only those portions of the release that have changed since the last build. If this parameter is not used, the entire file media library is rebuilt. • **UpgradeOnly**—This option enables you to upgrade—but not build—a Basic MSI project that was created in an earlier version of InstallShield.

Table 4-6 • MSBuild InstallShield Task

Parameter	Type	Project Type	Description
BuildCompressed	Boolean	Basic MSI, InstallScript MSI, Merge Module	This parameter specifies whether your release is compressed into one file or remains uncompressed in multiple files.
BuildSetupExe	Boolean	Basic MSI, InstallScript MSI, Merge Module	For Basic MSI and InstallScript MSI projects, this parameter specifies whether you want to create a `Setup.exe` file along with your installation. For merge module projects, this option specifies whether you want to build the merge module and also copy it to the merge modules folder, or just build the .merge module without copying it.
ProductVersion	String	Basic MSI, InstallScript MSI, Merge Module	This parameter specifies the product version. This is especially helpful if you want to increment the build version (the third field) of the product version. For information on valid product version numbers, see Specifying the Product Version.
PropertyOverrides	ITaskItem[ ]	Basic MSI, InstallScript MSI, Merge Module	This parameter enables you to override the value of a Windows Installer property or create the property if it does not exist. To use this parameter, include a property list of items whose value is the new property value, and whose metadata `Property` is the name of the property. This parameter is exposed as the InstallShieldPropertyOverrides ItemGroup passthrough to the PropertyOverrides property on the InstallShield task.
RunMsiValidator	ITaskItem[ ]	Basic MSI, InstallScript MSI, Merge Module	This parameter enables you to specify one or more .cub files to use for validating the installation package or merge module after it is built. To learn more about validation, see Validating Projects.
RunUpgradeValidation	Boolean	Basic MSI, InstallScript MSI	This parameter specifies whether or not to run upgrade validation.

Table 4-6 • MSBuild InstallShield Task

Parameter	Type	Project Type	Description
StopOnFirstError	Boolean	Basic MSI, InstallScript MSI, Merge Module	This parameter specifies whether or not to stop the build after an initial error.
MsiVersion	String	Basic MSI, InstallScript MSI, Merge Module	This parameter specifies the minimum version of Windows Installer that the installation can accept on the target machine.
DotNetFrameworkVersion	String	Basic MSI, InstallScript MSI	This parameter specifies the minimum version of the .NET Framework that the installation can accept on the target machine.
DotNetUtilPath	String	Basic MSI, InstallScript MSI	`Regasm.exe` and `InstallUtilLib.dll` are utilities that are included with each version of the .NET Framework. This parameter specifies the path for the directory that contains the 32-bit version of these files that you want to use at build time for releases that include .NET installer classes and COM interop. This is not the path to .NET Framework redistributable files. ***Note*** • *If you are using InstallShield on a 64-bit system, `ISCmdBld.exe` determines the location of the corresponding 64-bit version of the .NET Framework based on the path that you specify for this parameter, and `ISCmdBld.exe` uses the 64-bit location of `Regasm.exe` and `InstallUtilLib.dll` when appropriate.*
Disk1Folder	Output String	Basic MSI, InstallScript, InstallScript MSI, Merge Module	This parameter specifies the location of the output folder.

MSBuild Scripts

MSBuild natively understands one file format: its XML build script, which is used as the project file format for Visual C# and Visual Basic .NET projects (.csproj and .vbproj). MSBuild also has internal hooks to handle solution files and the Visual C++ project file format (.sln and .vcproj).

The InstallShield integration with Visual Studio uses an MSBuild-compatible XML format project file (.isproj), which enables MSBuild to seamlessly build Visual Studio solutions that include InstallShield projects. To build solutions in a standalone environment, install the InstallShield Standalone Build on the build machine.

Customizing the .isproj File

To incorporate changes for your InstallShield project into your .isproj file, add a PropertyGroup element or an ItemGroup element near the top of your .isproj file, or update an existing PropertyGroup or ItemGroup element. Then add InstallShield-related parameters as needed.

The following sample code from an .isproj file demonstrates how to do the following:

- Set the product version.
- Set the product name.
- Set a custom public property called **MY_PROPERTY** to the value *My Value*.
- Override a path variable called **MyPathVariableName** with a new value of *C:\MyPath*.
- Specify the following search paths for InstallShield prerequisites: `<ISProductFolder>\SetupPrerequisites` and `<ISProjectFolder>\MyCustomPrerequisites`.

```
<PropertyGroup>
   <InstallShieldProductVersion>1.2.3</InstallShieldProductVersion>
</PropertyGroup>
<ItemGroup>
   <InstallShieldPropertyOverrides Include="My New Product">
       <Property>ProductName</Property>
   </InstallShieldPropertyOverrides>
   <InstallShieldPropertyOverrides Include="My Value">
       <Property>MY_PROPERTY</Property>
   </InstallShieldPropertyOverrides>
   <InstallShieldPathVariableOverrides Include="C:\MyPath">
      <PathVariable>MyPathVariableName</PathVariable>
   </InstallShieldPathVariableOverrides>
   <InstallShieldPrerequisitePath Include="&lt;ISProductFolder&gt;\SetupPrerequisites"/>
   <InstallShieldPrerequisitePath Include="&lt;ISProjectFolder&gt;\MyCustomPrerequisites"/>
</ItemGroup>
```

Using MSBuild to Build a Release from the Command Line

Note • *If you use MSBuild to build Visual Studio solutions with InstallShield projects, MSBuild requires .NET Framework 3.5 or later.*

MSBuild provides an easy way to build a release from the command line on a machine on which Visual Studio is not installed. The only components you must have installed on the machine are the .NET Framework and the InstallShield Standalone Build. Place a copy of your Visual Studio solution on the machine, and run MSBuild.

Task: ***To use MSBuild from the command line:***

1. Open the Command Prompt window.
2. Change the directory to the one that contains `MSBuild.exe`:

   `C:\Windows\Microsoft.NET\Framework\`*`Version Folder`*`\`
3. Type the command-line statement to build the release build of the Visual Studio integration project. For example:

   ```
   MSBuild.exe C:\Folder Containing My Visual Studio Solution\My Solution.sln /
       property:Configuration=Release
   ```

Configuring Release Settings

When you create a release, it has default settings. You can edit all of the release settings in the Releases view. When you use the Release Wizard, you can also edit the settings of a release.

Task: ***To edit the settings of a release:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, select the release whose settings you would like to configure. The settings are displayed on tabs in the right pane.
3. Select a setting on one of the tabs to modify its value. Information about the setting is displayed in the help pane or when you press F1 from within the **Releases** view.

Creating a Single Executable File for Distribution

Project • *This information applies to InstallScript projects.*

To package a build as a single executable file, use the **Create a single file executable** option in the General Options panel of the Release Wizard, or the Singe Exe File Name setting in the Releases view, as described in the following procedures.

Note • *The single executable file that you create accepts any command-line parameter that `Setup.exe` accepts.*

Task: ***To package a build as a single executable file by using the Release Wizard:***

1. Launch the Release Wizard.
2. Navigate to the **General Options** panel.
3. Select the **Create a single file executable** check box.
4. By default, the file name **<project name>.exe** is entered in the **File Name** box. If you want the self-extracting executable file to have a different name, type a new file name in the box or select a path variable whose value defines the file name.
5. In the **Icon** box, you can specify the fully qualified name of the file that contains the icon that InstallShield should use when it creates the `Setup.exe` file at build time.

   To specify a file, type an explicit path or path variable, or click the browse button to open the **Change Icon** dialog box, in which you can click the **Browse** button to select a file.

   By default, the icon with index 0 is used; to specify a different icon, either select an icon in the **Change Icon** dialog box or append the icon's index or resource ID (preceded by a minus sign) to the file name. For example, **C:\Temp\MyLibrary.dll,2** indicates the icon with an index of 2, and **C:\Temp\MyLibrary.dll,-100** indicates the icon with a resource ID of 100.
6. If you want the executable file to extract the installation files to the target machine and not run the installation, enter `-extract_all:<path>` in the **Setup Command Line** box, where *<path>* is the desired target folder; for example:

   ```
   -extract_all:"C:/ProductName Setup Files"
   ```
7. Complete the **Release Wizard**; in the **Summary** panel, select the **Build the Release** check box and then click the **Finish** button.

Task: ***To package a build as a single executable file by using the settings in the Releases view:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, select the release that you want to package as a single executable file.
3. Select the **Setup.exe** tab.
4. For the **Single .exe File Name** setting, type a file name or a path variable (enclosed in angle brackets—for example, **<MY EXE FILE NAME>**) whose value defines the file name.
5. In the **Setup.exe Icon File** setting, specify the fully qualified name of the file that contains the icon that InstallShield should use when it creates the `Setup.exe` file at build time.

   To specify a file, type an explicit path or path variable, or click the ellipsis button (**...**) to open the **Change Icon** dialog box, in which you can click the **Browse** button to select a file.

By default, the icon with index 0 is used; to specify a different icon, either select an icon in the **Change Icon** dialog box or append the icon's index or resource ID (preceded by a minus sign) to the file name. For example, **C:\Temp\MyLibrary.dll,2** indicates the icon with an index of 2, and **C:\Temp\MyLibrary.dll,-100** indicates the icon with a resource ID of 100.

6. If you want the executable file to extract the installation files to the target machine and not run the installation, enter the following for the **Setup Command Line** setting:

   ```
   -extract_all:<path>
   ```

   where *<path>* is the desired target folder; for example:

   ```
   -extract_all:"C:/ProductName Setup Files"
   ```

7. Build the release.

To learn how to digitally signing your executable file, see Digital Signing and Security. For information about requiring end users to enter a password in order to launch the self-extracting executable file, see Password-Protecting Installations.

Leaving Files Uncompressed in a Disk Image

Project • *This information applies to InstallScript projects.*

Task: ***To place some or all features' files uncompressed in the disk image, use the Media Layout panel in the Release Wizard:***

1. Launch the **Release Wizard** and navigate to the **Media Layout** panel.
2. Do either of the following:
   - To place all features' files uncompressed in the disk image: Select the **CDROM Folder(s)** option. All features' files are placed in the disk image in the folders specified by the features' **CD-ROM Folder** properties. If no folder is specified for a feature, that feature's files are placed in the root of the disk image.
   - To place some features' files uncompressed in the disk image:
     a. Select the **Custom** option, and then click **Next**. The **Custom Media Layout** panel opens.
     b. In the **Features in cabinets** box, select or clear the check boxes next to the features. If a feature's files are stored in cabinet files, clear the check box. If a feature's files should be placed in the disk image in the folder specified by the feature's **CD-ROM Folder** property, select the check box. If no folder is specified, that feature's files are placed in the root of the disk image.

Tip • *If you want most of your features stored in cabinet files, click* ***Clear All*** *and then select the features to be placed uncompressed in the disk image. Conversely, if you want most of your features placed uncompressed in the disk image, click* ***Select All*** *and then clear the check boxes for the features to be stored in cabinet files.*

3. Complete the **Release Wizard**.

Note • *Regardless of whether you selected Yes or No for the Compressed setting of a feature's component, by selecting the uncompressed (CD-ROM folder) option for the feature, its files will be uncompressed on the distribution media.*

Specifying the Required Execution Level for Your Setup Launcher on Windows Vista and Later Platforms

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *Suite/Advanced UI*

InstallShield lets you specify the minimum execution level required by your installation's `Setup.exe` file for running the installation (the setup launcher, any InstallShield prerequisites, the .msi file, and any Advanced UI or Suite/Advanced UI packages) on Windows Vista and later platforms. You can configure this for each individual release in your project.

Task: ***To specify the required execution level for a release:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you would like to configure.
3. Click the **Setup.exe** tab.
4. For the **Required Execution Level** setting, select the appropriate option.

The available options are:

- **Administrator**—`Setup.exe` requires administrative privileges to run. Administrators must provide consent, and non-administrators must provide credentials.
- **Highest available**—`Setup.exe` prefers administrative privileges. Administrators must provide consent to run it; non-administrators run it without administrative privileges. This is the default option for InstallScript and InstallScript MSI projects.
- **Invoker**—`Setup.exe` does not require administrative privileges, and all users can run it without administrative privileges. `Setup.exe` does not display any UAC messages prompting for credentials or for consent. This is the default option for Advanced UI, Basic MSI, and Suite/Advanced UI projects.

For Advanced UI, InstallScript, InstallScript MSI, and Suite/Advanced UI projects, and for Basic MSI projects if the Setup Launcher setting is set to Yes, InstallShield embeds a Windows application manifest in the `Setup.exe` launcher as a resource. This manifest specifies the selected execution level. Operating systems earlier than Windows Vista ignore the required execution level. The execution level is defined in the manifest as follows:

```
<requestedExecutionLevel
  level="asInvoker"
  uiAccess="false"/>
```

Other valid values for the level attribute are **highestAvailable** and **requireAdministrator**.

If the Setup Launcher setting is set to No for a Basic MSI project, InstallShield does not embed the Windows application manifest in the `Setup.exe` launcher.

The benefit of elevating the required execution level in Basic MSI projects is that privileges can be elevated only once if necessary to run `Setup.exe`, and that these privileges can be carried over to all of the installation's InstallShield prerequisites and the Execute sequence of the .msi package without requiring multiple prompts for approval. Thus, if two of your InstallShield prerequisites require administrative privileges, for example, you can change this setting to Administrator, and then end users are prompted only once during the installation, before Windows Installer runs the `Setup.exe` file.

A similar benefit exists for Advanced UI and Suite/Advanced UI projects, where privileges can be elevated only once if necessary to run `Setup.exe`, and that these privileges can be carried over to all of the installation's Advanced UI or Suite/Advanced UI packages without requiring multiple prompts for approval.

Note, however, that if you elevate the privileges and also launch the application at the end of the installation, the elevated privileges are carried over to the application. In most cases, running an application with elevated privileges on Windows Vista and later platforms is discouraged.

Important • *InstallShield runs with elevated privileges. If you launch your installation from within InstallShield, those elevated privileges are carried over to your installation; thus, your installation automatically has elevated privileges. That may not reflect the behavior that end users will see if they are using Windows Vista or later. Therefore, if you are using Windows Vista or later on your development system, consider opening the release folder and launching the installation directly (instead of from within InstallShield).*

To quickly access your release folder so that you can launch your release directly, click the Open Release Folder on the Standard toolbar, or on the Tools menu, click Open Release Folder.

Note that an end user's installation experience is more secure when installations are run with only the permissions that they need. Unless an application is designed to be run only by system administrators, it should be run with the least privilege.

Specifying Whether a Product Should Be Advertised If Its InstallShield Prerequisites Are Run with Elevated Privileges

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript MSI*

Depending on how it is configured, an installation that includes InstallShield prerequisites may display a User Account Control (UAC) prompt for elevated privileges on Windows Vista and later systems at several different points during the installation:

1. When the end user launches the `Setup.exe` file
2. When the `Setup.exe` file launches a setup prerequisite that requires elevated privileges
3. When the `Setup.exe` file launches a feature prerequisite that requires elevated privileges
4. When the Windows Installer begins the Execute sequence of the .msi package

If you select Administrator for your installation's Required Execution Level setting in the Releases view, Windows Vista and later typically display only one UAC prompt; it is displayed when the end user launches the `Setup.exe` file. However, if you select Invoker for this setting, Windows Vista and later may display more than one UAC prompt during the installation. For example, Windows Vista and later may display a UAC prompt for a setup prerequisite that requires elevated privileges and another UAC prompt for the Execute sequence of the .msi package. If this scenario applies to your installation, you may want to specify that your installation should advertise and then run your .msi package to help end users avoid the UAC prompt for the .msi package. If this scenario does not apply to you, it is recommended that you avoid advertising the .msi package because it would not avoid a UAC prompt.

Tip • *The Require Administrative Privileges setting in the General Information view is where you specify whether the .msi package requires administrative privileges. The Behavior tab in the InstallShield Prerequisite Editor is where you specify whether a prerequisite requires administrative privileges. For more information about other InstallShield settings that may affect whether Windows Vista and later displays UAC prompts, see Minimizing the Number of User Account Control Prompts During Installation.*

Task: ***To specify whether your .msi package should be advertised:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you would like to configure.
3. Click the **Setup.exe** tab.
4. For the **Advertise If Prerequisites Are Elevated** setting, select the appropriate option.

The available options are:

- **Advertise: Silent**—Indicates that if setup prerequisites in the installation are successfully installed with elevated privileges, the .msi package should be advertised and run silently (without a user interface). Then the Execute sequence of the main installation does not require an additional UAC prompt for consent or credentials.
- **Advertise: Full UI**—Indicates that if setup prerequisites in the installation are successfully installed with elevated privileges, the .msi package should be advertised and run with a full user interface. Then the Execute sequence of the main installation does not require an additional UAC prompt.

- **No**—Indicates that the .msi package should not be advertised. When end users run the installation, one or more UAC prompts may be displayed to install the setup prerequisites. If the Execute sequence of the .msi package also requires elevation, an additional UAC prompt may be displayed before the Windows Installer begins the Execute sequence.

Important *• The package must support advertisement in order for either of the advertise options to work. Advertisement is not instantaneous, and it adds extra delays to the installation. In addition, unexpected behavior may occur if the end user clicks Cancel after advertisement but before the main part of the installation has finished. For example, advertised shortcuts for your product may appear on the desktop before the main installation begins, and a confused user canceling the main installation may leave your package advertised but not fully installed. Therefore, in some cases, it may be better to leave this setting as No to allow the extra UAC prompt and avoid product advertisement.*

A common goal is for an installation to display only one UAC prompt. The advertise options for the Advertise If Prerequisites Are Elevated setting facilitate this but do not guarantee it in all situations. For example, any time that an installation causes a restart, the installation process returns to limited privileges after the restart. The subsequent privilege elevation may display an additional UAC prompt, whether the elevation is required for a setup prerequisite, for a feature prerequisite, or for the .msi package. When the restart comes between the last prerequisite and the .msi package, the .msi package is not advertised. Following are some examples of different outcomes that may occur when you select one of the advertise options for this setting:

- The prerequisites require elevation and install successfully on the target machine. The product is advertised and installed. The product installation does not display a UAC prompt.
- One of the prerequisites in the installation may require a restart. After the restart for the prerequisite occurs, either no additional prerequisites are installed or none of the other prerequisites that are installed require elevation. Since the last prerequisite that is installed in this scenario is not a simple success of an elevated prerequisite, advertisement of the .msi package does not occur.
- None of the prerequisites in the installation need to be installed because they are already present on the target machine; therefore, advertisement of the .msi package does not occur.
- None of the prerequisites in the installation require elevation; therefore, advertisement of the .msi package does not occur.
- Elevated prerequisites are successfully installed. However, for this situation, the package is a minor upgrade for a product that is already installed. That is, the product code in the package matches the product code of the product that is already present on the target machine. Advertisement of the .msi package does not occur. UAC prompts may or may not be displayed; it depends on whether a suitable digital certificate is included in the earlier installation and in the patch.

Password-Protecting Installations

For added security, you can password-protect your installation package. When you password-protect your installation, any end user who wants to install your package must enter a case-sensitive password to open your installation.

You can activate password protection in the Password & Copyright panel of the Release Wizard.

Preparing a Trialware Release of Your Product

If you have added a trialware file to your project in the Trialware view, you can build a trialware version of your product. InstallShield will wrap a trialware shell around the executable file (.exe, .dll, .ocx, or .scr file) specified in the Trialware view. The executable file can be unwrapped and used only according to the license settings that you configure, such as the trial limit (a specified number of days or a specified number of uses).

Task: ***To prepare a trialware release of your product:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you want to build.
3. Click the **Build** tab.
4. For the **Disable Trialware Build** setting, select **No**. This is the default setting.
5. Build the release.

At build time, a folder called `TestTools` is created and placed in the same folder as the `DiskImages` folder for the selected release.

Caution • *Do not release the files in the `TestTools` folder with your product or make them available to your customers. Doing so would enable end users to continually restart a trial each time that it expires. Note that the `TestTools` files are specific to a particular product and license and cannot be used to delete licenses for other products.*

For each file being wrapped, the `TestTools` folder contains the following files:

- SCResetLicense*<WrappedBaseFileName>*.exe
- IsSvcInstSCResetLicense*<WrappedBaseFileName>*.dll

For example, if a file called `Calc.exe` is wrapped, the files in the `TestTools` folder are **SCResetLicenseCalc.exe** and **IsSvcInstSCResetLicenseCalc.dll**.

You can use the `TestTools` files to remove the license for your product from a machine, resetting the trialware state. This enables you to restart the trial for your protected product and retest it. For more information, see Testing a Trialware Release of Your Product.

Excluding Trialware Protection from a Release

If you have added a trialware file to your project in the Trialware view, you might need to build a release of your product that does not have the trialware protection. You can use this release if you want to test the installation of your product but you do not want to test the trialware run time.

You also may want to build a release without trialware protection if you distribute the Try and Die type of trialware to prospective customers. You can give them the unprotected release when they have finished evaluating your product and they purchase it from you.

Task: ***To prepare a release of your product that does not have the trialware protection:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you want to build.
3. Click the **Build** tab.
4. For the **Disable Trialware Build** setting, select **Yes**.
5. Build the release.

If you have not added a trialware file to your project in the Trialware view, the Disable Trialware Build property has no effect on the release build.

Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

InstallShield lets you specify the run-time location of the InstallShield prerequisites that are included with your installation.

Task: ***To specify where all of the InstallShield prerequisites should be located for a release, do one of the following:***

- Use the **InstallShield Prerequisites** panel of the **Release Wizard**.
- In the **Releases** view, select the release. Then on the **Setup.exe** tab, for the **InstallShield Prerequisites Location** setting, select the appropriate option.

Task: ***To specify different locations for each InstallShield prerequisite:***

1. In the **Redistributables** view (in Basic MSI and InstallScript MSI projects) or the **Prerequisites** view (in InstallScript projects), specify the appropriate location for each InstallShield prerequisite. For more information, see Specifying a Run-Time Location for a Specific InstallShield Prerequisite.
2. In the View List under **Media**, click **Releases**.
3. Select the release that you want to build.
4. Click the **Setup.exe** tab.

5. For the **InstallShield Prerequisites Location** setting, select **Follow Individual Selections**.

Tip • *As an alternative, you can select the Follow Individual Selections option in the InstallShield Prerequisites panel of the Release Wizard.*

Note that if an InstallShield prerequisite is added to a project as a dependency of another prerequisite, the location for the prerequisite dependency follows the location setting of the prerequisite that requires it.

If you build a release that includes InstallShield prerequisites and both of the following are true, one or more build errors may be generated:

- You specify for the InstallShield prerequisites location that the prerequisites should be extracted from `Setup.exe` or copied from the source media (instead of being downloaded from the Web to the end user's computer).
- The prerequisite files are not on your computer.

To eliminate the build errors, remove the InstallShield prerequisite from your project, download the InstallShield prerequisite from the Internet to your computer, or change the InstallShield prerequisites location for the release to the download option; then rebuild the release.

Specifying the Run-Time Location for Advanced UI or Suite/Advanced UI Packages at the Release Level

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you specify the run-time location of the packages that are included with your Advanced UI or Suite/Advanced UI installation.

Tip • *If you are configuring an Advanced UI or Suite/Advanced UI project for an update setup launcher, the run-time location of the packages must be either extracted from the setup launcher or downloaded from the Web. The update setup launcher cannot rely on packages that are stored on the source media.*

For more information, see Adding Support for Automatic Updates to an Advanced UI or Suite/Advanced UI Installation.

Task: ***To specify where all of the packages should be located for a release:***

1. In the View List under **Media**, click **Releases**.
2. Select the release that you want to build.
3. Click the **Setup.exe** tab.
4. In the **Package Location** setting, select the appropriate option.

Task: ***To specify different locations for each package:***

1. In the View List under **Organization**, click **Packages**.
2. Specify the appropriate location for each InstallShield prerequisite. For more information, see Specifying a Run-Time Location for a Specific Package in an Advanced UI or Suite/Advanced UI Project.
3. In the View List under **Media**, click **Releases**.
4. Select the release that you want to build.
5. Click the **Setup.exe** tab.
6. In the **Package Location** setting, select **Follow Individual Selections**.

Note that if a package is added to a project as a dependency of another package, the location for the package dependency follows the location setting of the package that requires it.

If you build a release that includes package and both of the following are true, one or more build errors may be generated:

- You specify for the package location that the packages should be extracted from `Setup.exe` or copied from the source media (instead of being downloaded from the Web to the end user's computer).
- The package files are not on your computer.

To eliminate the build errors, remove the package from your project, add the package to your computer, or change the package location for the release to the download option; then rebuild the release.

Digital Signing and Security

You can digitally sign your installation and your application to assure end users that neither your installation nor the code within your application has been tampered with or altered since publication. When you digitally sign your application, end users are presented with a digital certificate when they run your installation.

The Signing tab is where you specify the digital signature information—including the digital signature files granted to you by a certification authority—that InstallShield should use to sign your files.

The Signing tab is also where you specify which files in your installation should be digitally signed by InstallShield at build time. InstallShield enables you to sign any and all of the following files in a release, depending on what type of project you are using:

- Windows Installer package (.msi file) for Basic MSI and InstallScript MSI projects
- Merge module package (.msm file) for Merge Module projects
- `Setup.exe` file for Basic MSI, InstallScript, and InstallScript MSI projects
- Media header file for InstallScript projects
- Any files in your release, including your application files

Windows Logo • *All executable files (including .exe, .dll, .ocx, .sys, .cpl, .drv, and .scr files) in an installation must be digitally signed for the Windows logo program.*

To learn more about the various settings on the Signing tab, see Signing Tab for a Release.

Certification Authorities

A certification authority is an organization such as VeriSign that issues and manages digital certificates (also known as digital IDs). The certification authority validates the requester's identity according to prescribed criteria and issues a digital certificate. Obtaining a digital certificate requires providing the certificate authority with specific information about your company and your product.

For a list of certification authorities, see Microsoft Root Certificate Program Members on the MSDN Web site.

Digital Certificate Files

When you sign your installation and your application, you must use one or more digital certificate files. These files are used to generate the digital signature. Two options are available:

Option 1—.spc and .pvk Files

When a certification authority issues you a digital certificate, they provide two files:

- Private key file (.pvk)
- Software publishing credentials file (.spc)

The .pvk file is typically associated with a password.

InstallShield uses `Signcode.exe` to digitally sign your files with your .pvk and .spc files according to the settings that you configure on the Signing tab in the Releases view. The `Signcode.exe` file is a Microsoft tool that is installed with InstallShield in the following directory:

`InstallShield Program Files Folder``\System`

To learn more about `Signcode.exe`, including its command-line parameters, see the Microsoft Web site.

Option 2—.pfx File

As an alternative to using the .pvk and .spc files to digitally sign your installation and your application, you can use a personal information exchange file (.pfx). The following tools enable you to create a .pfx file from a .pvk file and .spc file:

- `PVK2PFX.exe`—This is part of the Windows Platform SDK, and it is also included with Microsoft Visual Studio 2005.
- `pvkimprt.exe`—You can download this PVK Digital Certificate Files Importer tool from the downloads area on the Microsoft Web site (http://www.microsoft.com/downloads/details.aspx?FamilyID=F9992C94-B129-46BC-B240-414BDFF679A7&displaylang=EN).

The .pfx file is typically associated with a password.

InstallShield uses `SignTool.exe` to digitally sign your files with your .pfx file according to the settings that you configure on the Signing tab in the Releases view. The `SignTool.exe` file is a Microsoft tool that is installed with InstallShield in the following directory:

`InstallShield Program Files Folder``\System`

Tip *• Using a .pfx file is often the preferred method for digitally signing files, since it is more likely to work in many different environments (such as locked build machines). Since the `SignTool.exe` utility accepts the password as a command-line parameter, it can be automatically provided even in scenarios where `Signcode.exe` cannot accept the password. Therefore, if you specify the digital signature password in InstallShield, you will never see a password prompt if you are using a .pfx file.*

Important *• InstallShield does not support using .pfx files to sign media header files (.hdr files), which are used for the One-Click Install type of installation for InstallScript projects. For this type of installation, consider one of the following alternatives:*

- *Use .spc and .pvk files instead of a .pfx file for your digital signature.*
- *Build a compressed installation, which would enable you to sign with a .pfx file.*

To learn more about `SignTool.exe`, including its command-line parameters, see the Microsoft Web site.

Contact a certification authority for more details about digital certificate files.

Digital Certificates

A digital certificate identifies you, your company, or both to end users and assures them the data they are about to receive has not been altered during its transfer over the Web. Certification authorities issue and manage digital certificates.

When end users download your application, a digital certificate is displayed. The digital certificate is a panel that informs end users when your application was signed and asks if they want to download and run your application. End users click OK to accept your application package.

Below is an example of a digital certificate. The appearance of digital certificates may vary among browsers and browser versions.

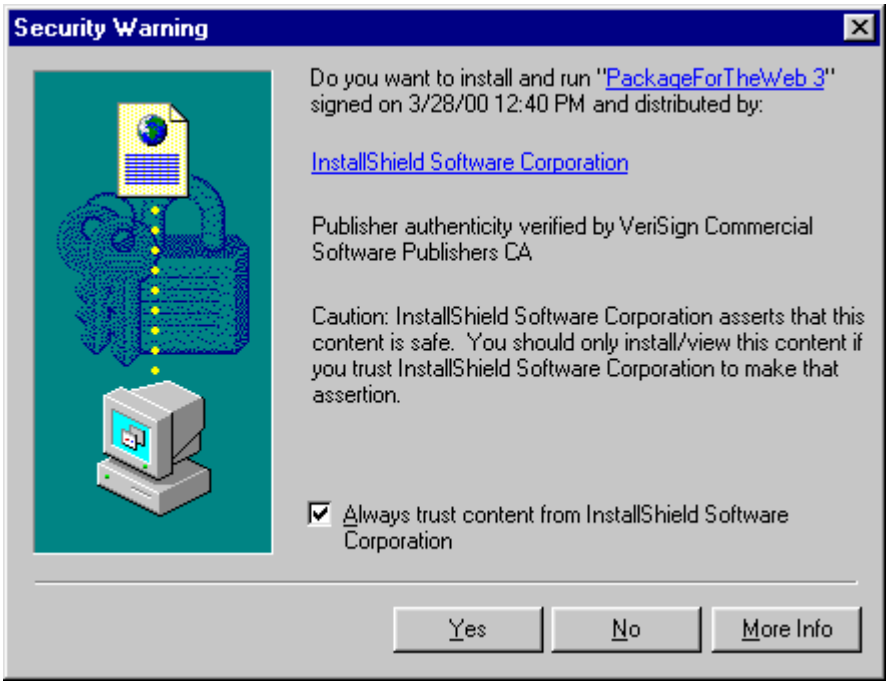

Figure 4-1: Sample Digital Certificate

Digitally Signing a Release and Its Files at Build Time

InstallShield lets you configure digital signing settings for a release. At build time, InstallShield uses the settings that you have configured to sign your installation package, your `Setup.exe` file, and any other files in your release that meet the criteria that you have defined.

Task: ***To configure digital signing for your release and its files:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you want to sign.
3. Click the **Signing** tab.
4. Configure the following settings as appropriate:
   - **Certificate URL**
   - **Digital Certificate File**
   - **Private Key File**—Note that if you specify a .pfx file, you do not also need to specify a .pvk file.
   - **Certificate Password**
5. In the **Sign Output Files** setting, specify which files (`Setup.exe`, the .msi package, both of those files, or neither of those files) you want to be signed.

6. In the **Sign Files in Package** setting, specify whether you want to sign additional files in your installation.

   If you select **Yes**, use the other settings under the **Sign Files in Package** setting to indicate which files and file patterns should be signed and which should not be signed.

   Note that the files and file patterns that should not be signed override any files and file patterns that should be signed. For example, if you specify `*.exe` in an **Include** setting and in an **Exclude** setting, InstallShield does not sign any .exe files.

Tip • *For detailed information about any of the settings on the Signing tab, see Signing Tab for a Release.*

At build time, InstallShield signs the files as specified on the Signing tab. If the release is for an installation that includes merge modules, note that the files are signed before the merge module is merged.

Digitally Signing a Release After It Has Been Built From the Command Line

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

As an alternative to having InstallShield sign your application at build time, you can use the iSign application (`iSign.exe`) to digitally sign a release of an InstallScript project from the command line after you have built the release from the command line.

The iSign application is located in the following directory:

`InstallShield Program Files Folder``\System`

This application uses Microsoft Authenticode technology to create digital signatures for your installation. In order to use this program, you need a digital ID from VeriSign.

When you use the iSign application, you can specify options that are not available in the release build, such as the cryptographic service provider.

The iSign syntax is as follows:

`iSign [options]` *`Filename`*

`Filename` is the fully qualified file name of your built release's `Data1.hdr` file.

Following is a list of the options that you can use with iSign. Note that, unlike other command-line applications, the switch and the argument for the switch should be separated by a space; for example:

```
iSign.exe -spc "C:\Temp\MyFile.spc" -v "C:\Temp\MyFile.pvk" -p "Test" -cp "Microsoft Base
    Cryptographic Provider v1.0"
```

Table 4-7 • Options for iSign.exe

Option	Description
-spc	Fully qualified file name of the software publishing credentials (.spc) file.
-v	Fully qualified file name of the private key (.pvk) file.
-p	Password for private key file.
-cp	Cryptographic service provider name, for example, **"Microsoft Enhanced Cryptographic Provider v1.0"**. If the `-cp` option is not used, iSign tries each of the following service providers to find one that works with the specified private key file: • "*Microsoft Base Cryptographic Provider v1.0*" • "*Microsoft Enhanced Cryptographic Provider v1.0*" • "*Microsoft Strong Cryptographic Provider*" For a list of cryptographic service providers, see Cryptographic Provider Names in the Platform SDK documentation or at the MSDN Web site. "Microsoft Base Cryptographic Provider v1.0" (MS_DEF_PROV) is appropriate for older certificates; if you are using a recent certificate and iSign fails, try using the other two. Note that the "v1.0" portion is required, even though some SDK documentation does not list it.

If `iSign.exe` is unable to determine the file to sign, the .spc file, or the .pvk file from the specified command line, the application displays the options (help) screen.

Release Flags

Project • *The following project types include support for release flags:*

- *Basic MSI*
- *InstallScript MSI*

When you build your release, you can include and exclude features, InstallShield prerequisites, and chained .msi packages depending on the type of release. For example, if you are creating a trial version of your product and do not want to include all the features in the build, you can flag features and then specify those flagged features under the product configuration or the release.

Task: ***To filter features, InstallShield prerequisites, and chained .msi packages based on release flags:***

1. Assign release flags to the features, InstallShield prerequisites, and chained .msi packages.

   For detailed information on how, see Assigning Release Flags to Features, Assigning Release Flags to InstallShield Prerequisites, or Assigning Release Flags to a Chained .msi Package.

2. Specify which flags to include in the release if appropriate.

The scenario of a trial version versus a full version is a good example of why you might use release flags. The table below gives an example of four different features that may be available in a product, depending on which version the end user receives.

In this example, the full version comes with the application's executable file, help files, a spellchecker, and an add-on pack that is included as a chained .msi package. The trial version does not include the add-on pack, but it does include an upgrade pack. Rather than having to create two separate installation projects for what is essentially one product, you can flag those features that are specific to certain versions. For example, the add-on feature is flagged as **Full** and the upgrade feature as **Trial**.

Table 4-8 • Sample Release Flags

Feature, InstallShield Prerequisite, or Chained .msi Package	Version	Release Flag
Windows Installer 4.5 Redistributable (InstallShield prerequisite)	All Versions	Not applicable
Program_Executable (feature)	All Versions	Not applicable
Help_Files (feature)	All Versions	Not applicable
Spellchecker (feature)	Full Version	Full
Add_Ons (chained .msi package)	Full Version	Full
Upgrade_Pack (feature)	Trial Version	Trial

If you build your release through the Release Wizard, you are given the option of including any flagged features, flagged InstallShield prerequisites, and flagged chained .msi packages into your release. By default, the release contains all features, InstallShield prerequisites, and chained .msi packages. If you specify the release flag **Full** in the Filtering Settings panel of the Release Wizard, only the **Spellchecker** feature and the **Add_Ons** chained .msi package—along with all features and InstallShield prerequisites without release flags—are built into your release. The upgrade pack is not included in the installation.

Tip • *By default, all features, InstallShield prerequisites, and chained .msi packages are included in a release. When you specify a release flag in either the Releases view or the Release Wizard, only the unflagged features, the unflagged InstallShield prerequisites, the unflagged chained .msi packages, the features that contain the specified*

flag, the InstallShield prerequisites that contain the specified flag, and the chained .msi packages that contain the specified flag are included in your installation. InstallShield does not include in the release any features, InstallShield prerequisites, or chained .msi packages that have a release flag that you did not include in the Releases view or Release Wizard.

Product Configuration Flags vs. Release Flags

Project • *The following project types include support for product configuration flags and release flags:*

- *Basic MSI*
- *InstallScript MSI*

You can specify which flags to include in your installation both on the release, known as *release flags*, and on the product configuration, known as *product configuration flags*. Although release flags are exposed both as a setting of the release and in the Release Wizard's Filtering Settings panel, you can edit the product configuration flags only on the General tab of the product configuration in the Releases view.

Product configuration flags complement release flags. That is, any feature flags that you specify for the product are combined with the flags on the individual release that you are building, and all of the features, InstallShield prerequisites, and chained .msi packages with the specified flags are built into the release. Be careful when specifying flags in the Release Wizard, because you cannot see which flags are included at the product configuration level.

To demonstrate how product configuration and release flags interact, consider a project with the following features, InstallShield prerequisites, and chained .msi packages.

Table 4-9 • Sample Features, InstallShield Prerequisites, and Chained .msi Packages

Feature, InstallShield Prerequisite, or Chained .msi Package	Version	Release Flag
Windows Installer 4.5 Redistributable (InstallShield prerequisite)	All Versions	Not applicable
Program_Executable (feature)	All Versions	Not applicable
Help_Files (feature)	All Versions	Not applicable
Spellchecker (feature)	Full Version	Full
Add_Ons (chained .msi package)	Full Version	Full
Upgrade_Pack (feature)	Trial Version	Trial

The following table explains which features, InstallShield prerequisites, and chained .msi packages are included in your installation based on the combination of product configuration flags and release flags:

Table 4-10 • Combining Product Configuration Flags and Release Flags

Product Configuration Flags	Release Flags	Features, InstallShield Prerequisites, and Chained .msi Packages in Installation
<None>	<None>	Windows Installer 4.5 Redistributable, Program_Executable, Help_Files, Spellchecker, Add_Ons, Upgrade_Pack
<None>	Full	Windows Installer 4.5 Redistributable, Program_Executable, Help_Files, Spellchecker, Add_Ons
Trial	<None>	Windows Installer 4.5 Redistributable, Program_Executable, Help_Files, Upgrade_Pack
Full	Trial	Windows Installer 4.5 Redistributable, Program_Executable, Help_Files, Spellchecker, Add_Ons, Upgrade_Pack

Filtering Based on Release Flags

Project • *The following project types include support for product configuration flags and release flags:*

- *Basic MSI*
- *InstallScript MSI*

Once you have assigned release flags to your features and InstallShield prerequisites, you can create a release that includes the ones that are based on those flags. By default, all features, InstallShield prerequisites, and chained .msi packages are included in a release. Once you specify a flag in either the Releases view or the Release Wizard, only the unflagged features, the unflagged InstallShield prerequisites, the unflagged chained .msi packages, the features that contain the specified flag, the InstallShield prerequisites that contain the specified flag, and the chained .msi packages that contain the specified flag are included in your installation. To include only unflagged features, unflagged InstallShield prerequisites, and unflagged chained .msi packages, specify a flag that does not exist. For example, you might use **NoFlags**. This way, only unflagged features, unflagged InstallShield prerequisites, and unflagged chained .msi packages are built into a release.

It is possible to include a subfeature but not its parent feature. In such a case, the subfeature is built into the release as a top-level feature, and its parent is excluded from the release.

You can filter features, InstallShield prerequisites, and chained .msi packages in the Release Wizard or in the Releases view. Both methods are described below.

Filtering in the Release Wizard

The easiest way to create a release is to use the Release Wizard. The Filtering Settings panel of this wizard enables you to specify which flags you want to include in your release.

Filtering in the Releases View

You can also use the Releases view to specify flags to include. You can include flags both at the product configuration level and on the release itself. For more information, see Product Configuration Flags vs. Release Flags.

Task: ***To specify product configuration flags:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the product configuration that you want to modify. Its settings are displayed on the **General** tab in the right pane.
3. For the **Product Configuration Flags** setting, enter the flags that you would like to include. To include more than one flag, separate each with a comma.

Task: ***To specify release flags:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you want to modify. Its settings are displayed on tabs in the right pane.
3. For the **Release Flags** setting, enter the flags that you would like to include in this release. To include more than one flag, separate each with a comma.

Using One Project to Create Installations for Multiple Product Configurations

Project • *This information applies to InstallScript projects.*

You may want to release your product with more than one configuration—for example, an evaluation release and a full release. Within a single project, you can build releases containing different subsets of the project's features; with a single installation script using preprocessor directives, you can build releases with different run-time behaviors.

Task: ***To determine a release's included features at build time:***

1. Launch the **Release Wizard** and navigate to the **Features** panel.
2. Select the **Specify the features to be included below** option.
3. In the **Features** explorer, select the check boxes of the features that you want to include in the product configuration, and clear the check boxes of the features that you do not want to include.
4. Complete the other panels in the **Release Wizard**.

Task: ***To determine a release's run-time behavior using preprocessor directives:***

1. In your script, use preprocessor directives to execute different code for different product configurations; for example:

```
#ifdef EVAL_RELEASE
    /* Evaluation-specific code */
#elif FULL_RELEASE
    /* Full release-specific code */
#endif
```

2. In the **Compiler Preprocessor Defines** box (on the **General Options** panel of the **Release Wizard**) or the **Compiler Preprocessor Defines** setting (on the **Build** tab in the **Releases** view), specify the preprocessor constant that corresponds to the code that you want the release to execute.
3. Build the release.

Typical Web Installation vs. One-Click Install

When downloading an application from the Internet, many end users experience a long and confusing series of instructions explaining how to download and run the application properly. The typical download can take as many as 10 steps. It can be a frustrating and time-consuming process that is not always successful. End users who fail to download the application properly must rely on product support to assist them, or they give up completely and never gain access to the application. This results in time lost for both the consumer and the development team.

With a One-Click Install setup, however, the end user can download an application with minimum effort and can begin using the application immediately. Compare the installation processes for both typical and One-Click Install setups below.

Typical Internet Installation Process

A typical Internet installation might happen like this:

1. The end user navigates to the Web page and clicks the link to download the application.
2. A dialog opens. The dialog prompts the end user to agree to a software licensing agreement.
3. The end user is given the opportunity to save the installation's executable file to disk. The end user must remember this location to access the installation's executable file later.

4. The file transfer begins.
5. The end user must search for the installation executable file and then launch it.
6. The installation executable file unpacks and executes.
7. If any other resources are necessary for the proper execution of the application, the end user must download them at this time.
8. The installation executes and begins to walk the end user through the installation process.
9. The end user makes several choices, such as the disk location of the application executable file.
10. The application file transfer begins.
11. The end user locates the application executable file on disk and launches the application.

One-Click Install Installation Process

With a One-Click Install setup, installations are easier and faster for the end user. A One-Click Install setup can happen like this:

1. The end user navigates to the Web page and clicks the download button.
2. A dialog opens. The dialog shows the progress of the file transfer. Once the installation has been downloaded, the installation runs.
3. The end user begins using the application.

One-Click Install setups keep the end user on your Web page, instead of searching for an executable file to run. One-Click Install setups make it possible for the end user to concentrate on using the application, not struggling to download it.

One-Click Install Installations in InstallScript Projects

Project • *This information applies to InstallScript projects.*

A One-Click Install installation includes a setup player (`Setup.ocx`) that downloads and then launches the `Setup.exe` file with the appropriate command line. This enables end users who are using Windows Vista and later with limited privileges to run the installation; if elevated privileges are required because of the required execution level specified in the installation's manifest, the appropriate User Account Control (UAC) prompt is displayed when the `Setup.exe` file is launched. If end users have an earlier version of Windows on their systems, the manifest is ignored, but the other behavior is the same.

The `Setup.exe` file for One-Click Install installations does not include any COM information.

Like any other installation, an Internet installation can use features such as updating, maintenance mode, multi-instance installation, silent installation—in short, any feature that is available for any InstallShield installation.

The following InstallScript functions are Internet-enabled:

Table 4-11 • Internet-Enabled InstallScript Functions

Function	Description
CopyFile	Copies a file that is specified by a valid URL, or transmits a CGI or ASP request.
ExistsDir	Checks the existence of a folder that is specified by a valid URL.
GetFileInfo	Gets information about a file that is specified by a valid URL.
GetLine	Reads lines from a file that is specified by a valid URL.
Is	Checks the following: • Whether the installation is being run from the Internet • The existence of a file or folder that is specified by a valid URL • Whether a given string is a URL • The validity of a URL
OpenFile	Opens a file that is specified by a valid URL.
ParseUrl	Retrieves the parts of the specified URL.
ReadBytes	Reads bytes from a file that is specified by a valid URL.
SeekBytes	Repositions the file pointer within a file that is specified by a valid URL.

One-Click Install Objects

Project • *This information applies to InstallScript projects.*

The objects within One-Click Install's setup player are Player and Ether. The Player object is the highest level of the object model, followed by Ether.

Player Object

Before you can use the setup player, you must create an instance of it. For more information, see Using the Setup Player.

The Player has one method and one property.

- Open (<URL>)—Specifies the location of the data .cab files and returns a reference to an Ether object. The argument consists of a URL representing the path to a web server, a UNC path, or the path to the location of the files on your local drive.

- LastError—Integer value representing an error code thrown by a method, usually Open().

Examples

```
Player.Open("http://www.mydomain.com/myproduct");
Player.Open("file://\\server\myproduct");
Player.Open("file://c:/my installations/myproduct/media/default");
```

LastError Method

***Project** • This information applies to InstallScript projects.*

This is the LastError method of the Player object. This is an integer value containing the error code for an error thrown by a method of the Player, usually Open().

Syntax

```
var nError = player.LastError;
```

Example

```
var ether = Player.Open("http://www.installshield.com")
```

Parameters

None.

Return Values

Table 4-12 • Return Values for the LastError Method

Return Code	Description
-2147186688	No permissions were granted. Clicking Deny on the Java Security dialog throws this error.
-2147186686	Failed to update or install the Setup Player ActiveX control. Verify your ability to download from the URL specified in the Codebase attribute of the APPLET tag.
-2147186685	Failed to instantiate ISPlayer or initialization of the ISPlayer failed.
-2147186684	Failed to call player.Open.
-2147186683	Player.Open call timed out waiting for applet initialization.
-2147166892	Requested URL not found. Verify that your installation files are available at the URL specified during the player.Open call.
-2147166895	Unable to access protected resource. This error is returned when attempting to access an installation that requires authentication and the end user does not enter the correct information.
-2147012889	The server name could not be resolved. Verify that the URL used in your player.Open call. Misspelling the domain name the URL is a common cause of this error.

Note • *For the first six errors listed, the end user can check the Java console for detailed error information.*

Open Method

Project • *This information applies to InstallScript projects.*

The Open method of the Player object accepts one string argument that specifies the URL of the installation's cabinet files.

Syntax

```
var ether = Player.Open("<URL string>")
```

Example

```
var ether = Player.Open("http://www.installshield.com")
```

Parameters

Table 4-13 • Valid Parameter for the Open Method

Parameter	Description
<URL string>	Specifies the URL of the installation's cabinet files.

Return Values

The Open method returns a reference to an Ether object.

Ether Object

The Ether object supports the following methods:

Table 4-14 • Methods Supported by the Ether Object

Method	Description
GetLastError	Returns a numeric value indicating the result of the installation.
IsPlaying	Returns a Boolean value indicating if the installation is running.
Play	Starts the installation.
SetProperty	Sets a property to a certain value.

GetLastError Method

After calling the Ether object's Play method, call the GetLastError method to find out the result of the installation. GetLastError tells you if an error occurred, if the installation finished successfully, or if the installation was canceled.

Syntax

```
ether.GetLastError( );
```

Example

It is best to poll GetLastError as in the following example:

```
var intervalID = 0;

function startInstall() {
    if (ether)
    {
```

```
        ether.Play();
        if (intervalID == 0)
            intervalID = window.setInterval("IsSetupFinished()", 3000);
    }
}

function IsSetupFinished()
{
    var nResult = ether.GetLastError();
    if (nResult != 0)
    {
        if (nResult == SETUP_FINISHED) // setup has completed successfully
            /* to do */ ;
        if (nResult == SETUP_ERR_CANCELLED) // setup was cancelled
            /* to do */ ;

        clearInterval(intervalID);
        intervalID = 0;
    }
}
```

Parameters

None.

Return Values

A complete list of GetLastError return values is in `Disk1\_graphics\Utilities.js` under the release's `Disk Images` folder, and is given below.

- SETUP_RUNNING
- SETUP_FINISHED
- SETUP_ERR_GENERAL
- SETUP_ERR_LOADMEDIA
- SETUP_ERR_INSTALLKERNEL
- SETUP_ERR_STARTKERNEL
- SETUP_ERR_OPENCAB
- SETUP_ERR_INSTALLSUPPORT
- SETUP_ERR_SETTEXTSUB
- SETUP_ERR_INITINFO
- SETUP_ERR_GETSETUPDRIVER
- SETUP_ERR_INITPROPERTIES
- SETUP_ERR_RUNINSTALL
- SETUP_ERR_UNINSTALLSUPPORT

- SETUP_ERR_EXTRACTBOOT
- SETUP_ERR_DOWNLOADFILE
- SETUP_ERR_CANCELLED

IsPlaying Method

The IsPlaying method of the Ether object returns a Boolean value indicating whether the installation is running.

Syntax

```
var <variable> = ether.IsPlaying();
```

Example

```
var bPlaying = ether.IsPlaying();
```

Parameters

None.

Return Values

Table 4-15 • Return Values for the IsPlaying Method

Return Value	Description
true	Indicates that the installation is running.
false	Indicates that the installation is not running.

Play Method

The Play method of the Ether object starts the installation.

To see an example of the use of this method, build a release using the Create a default Web page option in the Release Wizard's Internet Options panel or the Release property grid's Create Default Web Page property, then examine the code in the generated Web page (`Setup.htm`).

Syntax

```
ether.Play();
```

Parameters

None.

Return Values

None.

SetProperty Method

The SetProperty method of the Ether object accepts two arguments. The first, a string, represents the name of the property is::CmdLine. The second is a string specifying `Setup.exe` command-line parameters.

Syntax

```
ether.SetProperty("is::CmdLine","Setup.exe command-line options");
```

Example

```
ether.SetProperty("is::CmdLine","-l0x0407");
```

Parameters

The following table contains the parameters for the SetProperty method.

Table 4-16 • Parameters for the SetProperty Method

Property Name	Property Value
is::CmdLine	A string specifying `Setup.exe` command-line parameters. For a list of supported parameters, see Setup.exe and Update.exe Command-Line Parameters.

Return Values

None.

Digital Signatures for One-Click Install Installations

When an end user runs a One-Click Install installation, the setup player (`Setup.ocx`) needs to verify the digital signatures for following files:

- `Setup.ocx`
- `Setup.exe`
- `Data1.hdr`
- `ISSetup.dll`

If any of those files are unsigned or the signature is corrupted, the setup player displays a single prompt to inform the end user that the signature could not be verified. If all files are properly signed and your certificate is not yet always trusted, the setup player displays a prompt to ask the end user to authorize it (similar to the one that is displayed when you run an executable file that you downloaded).

InstallShield signs the `Setup.ocx` file for you. The certificate that is used to sign the `Setup.exe`, the `Data1.hdr`, and `ISSetup.dll` files must match. This happens automatically if you select the options for signing the `Setup.exe` file and the media header.

Replacing Obsolete Properties and Methods

InstallShield's simplified model for Internet installations eliminates several methods and properties that the Ether object and its subobjects had in InstallShield Professional 6.x. The following is a list of those methods and properties, and how to replace them if you are converting an InstallShield Professional 6.x installation Web page to work with an InstallShield installation.

AskDestPath

To display the equivalent dialog during the installation, call the InstallScript function **AskDestPath** in your installation script. To pass a destination path to the installation from the Web page, set a script-defined property.

CommandLine

Replace a line like the following:

```
ether.CommandLine = "<string value>";
```

with a line like the following:

```
ether.SetProperty("is::CmdLine","<string value>");Features, SetState
```

To offer the equivalent functionality during the installation, call the InstallScript function **SdFeatureTree** in your installation script. To pass a feature selection to the installation from the Web page, set a script-defined property; in addition, in the installation script, use its value to conditionally call **FeatureSelectItem**.

Features, GetState

To get a feature's selection state during the installation, call the InstallScript function **FeatureIsItemSelected** in your installation script. A Web page cannot get a feature's selection state.

FileToOpen

To open a file during the installation, call the InstallScript function **LaunchApplication** in your installation script. To pass a file name to the installation from the Web page, set a script-defined property.

GetDownloadSize, FileLevelCosting

To get the required disk space during the installation, call the InstallScript function **FeatureGetTotalCost** in your installation script. (Feature dialogs such as **SdFeatureTree** display the required disk space.) A Web page cannot get the required disk space.

Language

Replace a line like the following:

```
ether.Language = "<language code>";
```

with a line like the following:

```
ether.SetProperty("is::CmdLine","-l<language code>");LegacyMode
```

By default, Internet installations run in *legacy mode*—that is, with the installation's user-interface events generated as appropriate. There are two ways to duplicate the effect of setting ether.LegacyMode=false; on your Web page:

- Run the installation silently with the following line:

  ```
  ether.SetProperty("is::CmdLine","-s");
  ```

- Set a script-defined property or check the return value of Is(WEB_BASED_SETUP), and conditionally call the installation's user-interface event handler functions in the OnShowUI handler.

ProductName

A Web page cannot get this information.

GetTargetDir

A Web page cannot get this information.

GetTextSub

A Web page cannot get this information.

IsInstalled

A Web page cannot get this information.

SetSetupType

To specify a setup type during the installation, call the InstallScript function **FeatureSetupTypeSet** in your installation script. To display a setup type selection dialog during the installation, call **SdSetupType** in your installation script. To pass a setup type to the installation from the Web page, set a script-defined property.

SetTargetDir

To specify a target directory during the installation, assign a value to the system variable TARGETDIR in your installation script. To pass the target directory to the installation from the Web page, set a script-defined property.

SetTextSub

To specify a text substitution during the installation, assign a value to the TextSub object's Value property in your installation script. To pass a text substitution to the installation from the Web page, set a script-defined property.

Default Web Page (Setup.htm)

Project • *This information applies to InstallScript projects.*

A default Web page called `Setup.htm` is created in your disk image folder when you build your One-Click Install installation using one of the following methods:

- Select the **Create a default Web page for the setup** check box on the Internet Options panel in the Release Wizard.
- Select Yes for the Create Default Web Page setting on the Internet tab in the Releases view.

You can use this page as it is, customize it however you want, or refer to it as an example of using the Setup Player.

Note that the aforementioned Web page creation settings are disabled if the Generate One-Click Install setting in the Releases view is set to No.

System Requirements for One-Click Install Installations

Project • *This information applies to InstallScript projects.*

You must have a Web server that supports HTTP 1.1 on the hosting system. Note that FTP does not support One-Click Install installations.

Alternate Ways to Call the Setup Player

Project • *This information applies to InstallScript projects.*

It is not necessary to call the Setup Player from a Web page. It is possible to call the Player from other sources such as a login script or a Visual Basic or Visual C/C++ application. Any programming tool that supports ActiveX controls can call the Player.

Sample Visual Basic Script for Calling the Player

```
Dim player, ether
Set player = CreateObject("Setup.Player.20")
Set ether = player.open("http://www.mydomain.com/mysetup")

If ether.IsPlaying() Then
    MsgBox "Setup is running."
Else
    MsgBox "Setup is not running."
End If

Set player = Nothing
Set ether = Nothing
```

HTTPS and One-Click Install Installations

Project • *This information applies to InstallScript projects.*

Your One-Click Install installation can be run under the secure hypertext transfer protocol (HTTPS)—that is, HTTP using the Secure Sockets Layer (SLL). The only modification that your installation requires in order to run with HTTPS is to change http:// to https:// in URLs that are passed to Internet-enabled functions.

Creating One-Click Install Installations

You can create a One-Click Install installation using the Release Wizard.

Task: ***To create a One-Click Install installation for an InstallScript project:***

1. Launch the **Release Wizard**.
2. Navigate to the **Internet Options** panel.
3. Select the **Generate One-Click Install** option.
4. Select the **Create a default Web page for the setup** check box or specify the location of a custom Web page in the **Enter the URL to launch** box.
5. Specify other options as desired.
6. Complete the rest of the Release Wizard panels.
7. Build your release.

Task: ***To create a One-Click Install installation for a Basic MSI or InstallScript MSI project:***

1. Launch the **Release Wizard**.
2. Navigate to the **Media Type** panel.
3. In the **Media Type** list, click **Web**.
4. Navigate to the **One Click Install** panel, and select the **Generate One-Click Install** option.
5. Specify the file name for your .htm or .cab file.
6. Indicate the browsers that you want your One-Click Install installation to support.
7. Complete the rest of the Release Wizard panels.
8. Build your release.

Using the Setup Player

Project • *This information applies to InstallScript projects.*

The Setup Player is a `Setup.ocx` file that downloads and then launches the `Setup.exe` file with the appropriate command line. The `Setup.ocx` file also supports launching a setup executable file with a name other than `Setup.exe`; for this to work correctly, the [Startup] section of the `Setup.ini` file should contain the following key:

`LauncherName=`*`SetupLauncher`*

where *`SetupLauncher`* is the file name of the alternate setup launcher.

For an example of using the Setup Player in a Web page, build a release using the Create a default Web page option in the Release Wizard's Internet Options panel or the Create Default Web Page setting on the Internet tab in the Releases view. Then examine the code in the generated Web page (`Setup.htm`).

Once an instance of the Player has been created, you may use the methods and properties associated with each of the objects within the Player to customize your installation.

Passing Data to the Launched One-Click Install Installation

To pass data to a launched One-Click Install installation, use the is::CmdLine parameter and the CMDLINE script variable.

Running an Internet Installation Silently

To run an Internet installation silently, pass it the desired Setup.exe command-line options by calling the Ether object's SetProperty method, as in the following examples:

```
ether.SetProperty("is::CmdLine","-s -f1\"C:\\My Folder\\Mydir.iss\"");
```

```
ether.SetProperty("is::CmdLine","-s -f1\"C:\\My Folder\\Mydir.iss\" -
    f2\"C:\\My Folder\\Mydir.log\"");
```

Note the following:

- When running a silent Internet installation, you must specify the `-f1` option; there is no valid default location for the response file in Internet installations.
- When recording or running a silent Internet installation, you must specify a fully qualified absolute path if using the `-f1` or `-f2` option; these options do not accept URLs.
- The second argument to **SetProperty** must use the escape sequences (\\ and \") to specify backslashes and quotation marks, as in the preceding examples.

Setting the Run-Time Language

Project • *This information applies to InstallScript projects.*

Edition • *Multilingual support is available in InstallShield Premier Edition.*

When you specify a language by using the following method, the One-Click Install installation runs in this language regardless of the default language specified in InstallShield or the default language of the target system. If you do not use this method, the One-Click Install installation determines the run-time language in the same way as any other installation.

Task: ***Add set the run-time language:***

1. Add support for the language to your project:
   a. On the **Project** menu, click **Settings**. The **Project Settings** dialog box opens.
   b. Click the **Languages** tab.
   c. Select the check box for that language that your installation should target.
2. Add that language to the release:
   a. On the **Build** menu, click **Release Wizard**.
   b. In the **Setup Languages** panel, select the appropriate language.
3. On your Web page, before you call the Play method, call the SetProperty method to specify the appropriate language identifier.

   For example, the language ID for English is 0009. To set English as the runtime language use the following code:

```
ether.SetProperty("is::CmdLine","-l0009");
```

Running a One-Click Install Installation in Debug Mode

Project • *This information applies to InstallScript projects.*

To run your One-Click Install installation in debug mode, enter the following code before invoking ether.Play:

```
ether.SetProperty( "is::CmdLine", "/d")
```

Authenticating a User from InstallScript

Project • *This information applies to InstallScript projects.*

If your One-Click Install installation requires authentication after it is started, you can authenticate the user on the fly using InstallScript. When authentication is required, the Web server returns HTTP error code 401 to your installation, which generates an InternetError event. Respond to that event by prompting the user for a user name and password in the OnInternetError event handler.

The easiest way to do so is to use the **InternetErrorDlg** API in `WinInet.dll` and return the value IDRETRY from OnInternetError. This causes the installation to issue the HTTP request for the file again. If users enter incorrect information, they will be prompted to enter it again.

Setup.ini

Project • *This information applies to InstallScript projects.*

`Setup.ini` is an initialization file that is created during the build process of InstallScript-based projects to control certain elements of the installation. The build process fills in only certain key names and values in `Setup.ini`. After the build process creates `Setup.ini`, it is placed in the `Disk1` folder in `<project folder>\Media\<media name>\Disk Images`.

If you want to customize `Setup.ini` further, modify it with a text editor. You can automate this process by using the Postbuild Options panel of the Release Wizard or the Execute Batch File property in the Releases view to launch a batch file or executable file that performs the desired modifications. Do not simply overwrite `Setup.ini` with a modified copy from a previous media build; doing so could cause your installation to work improperly.

`Setup.ini` contains two predefined sections:

- [Startup]
- [Mif]

You can add additional sections to `Setup.ini` to pass information to your setup script. You can then call the **GetProfString** and **GetProfInt** functions to transfer the information from the `Setup.ini` file to your installation.

Here is an example `Setup.ini` file:

```
[Startup]
EnableLangDlg=Y
Product=My Application
ProductGUID=23EAFFCA-361D-11D3-8B0F-00105A9846E9
CompanyName=My Company Name
Skin=Setup.skin
SmallProgress=N
SplashTime=5
CheckMD5=N
CmdLine=/f1Test1.iss
LauncherName=MyInstall.exe

[Mif]
Type=SMS
Filename=Ishield
```

```
SerialNo=IS50-32XYZ-12345
Locale=DEU
```

Note • *If you need to access the file later (after `Disk1` has been removed), you should copy `Setup.ini` to the support folder (SUPPORTDIR) at the beginning of the installation.*

The [Startup] Section

You can use the following keynames in the `[Startup]` section of `Setup.ini`:

- EnableLangDlg
- Product
- ProductGUID
- CompanyName
- Skin
- SmallProgress
- SplashTime
- CheckMD5
- CmdLine
- LauncherName

EnableLangDlg

The EnableLangDlg keyname tells the installation whether to display the Language dialog during installation initialization. The Language dialog lets your end user decide which available language the installation should run in. You can set this value in the **Setup Languages** panel of the **Release Wizard** or through the **Languages Dialog** property in the **Releases** view.

For more information about the Language dialog, see How an Installation Determines Which Language to Use for the User Interface.

Product

The Product keyname identifies an application or product name to be displayed at the beginning of the text string in the startup message dialog box.

ProductGUID

The ProductGUID keyname specifies the installation's GUID so that `Setup.exe` has access to this data during initialization. The media builder automatically enters the correct value in `Setup.ini`; do not change the value.

CompanyName

The CompanyName keyname specifies the name of the company name.

Skin

The Skin keyname specifies the name of the skin file that the installation uses to display end-user dialogs. If this keyname is not in `Setup.ini`, no skin is used. You can specify a skin in the User Interface panel of the Release Wizard or through the Specify Skin property in the Releases view.

SmallProgress

The SmallProgress keyname specifies whether the installation initialization dialog is the small box that was shown by installations created with InstallShield Professional version 6.31 and earlier, or if it is larger and is consistent with the rest of the end-user dialogs. Set the value to Y to display the small dialog or N to display the larger dialog. (If the installation displays a security, Save and/or Run Setup, Choose Setup Language, or Qualifying Product(s) Detected dialog, the installation initialization dialog is larger and is consistent with the rest of the end-user dialogs, regardless of the value of this key.) You can set this value in the User Interface panel of the Release Wizard or through the Small initialization dialog property in the Releases view.

If SmallProgress is set to N, the installation initialization dialog (and the Choose Setup Language dialog, if any) are not displayed until the startup graphic closes. To specify the length of time for which the startup graphic displays, set the SplashTime value.

SplashTime

The SplashTime keyname specifies the length of time (in seconds) for which the startup graphic is displayed.

CheckMD5

The CheckMD5 keyname tells the installation whether to compare each file's MD5 hash value to the value stored in the installation header file during file extraction. You can set this value with the Verify MD5 signature check box in the General Options - Advanced dialog box.

Tip • *MD5 checking can detect corrupted files, which is useful during Internet installations; not doing MD5 checking can make file transfer proceed faster.*

CmdLine

The CmdLine keyname identifies command-line parameters that are to be passed to `Setup.exe` if none are passed from the command line.

Note • *If you use the `/v` parameter at the command prompt when launching `Setup.exe`, any parameters that are specified for the CmdLine keyname are ignored.*

For more information about available command-line parameters, see Setup.exe and Update.exe Command-Line Parameters.

LauncherName

If you rename `Setup.exe`, the LauncherName keyname specifies the file's new name. This keyname is required if another installation will launch this installation using the **DoInstall** function.

The [Mif] Section

If the `[Mif]` section is present, the installation will automatically create a installation .mif file in the `Temp` folder. You can also create an .mif file by using the `-m` command-line option for `Setup.exe` and optionally its `-m1` and `-m2` options.

These are the keynames under the `[Mif]` section of `Setup.ini`:

- Type
- Filename
- SerialNo
- Locale

Type

Set this key to SMS.

Filename

The Filename key is optional. It provides the alternate name for the .mif file to be created. If this key is not included, the installation tries to use the AppName key under the `[Startup]` section of `Setup.ini` as the .mif file name. If the AppName key is also not present, the installation creates a file with the default name `Status.mif`.

The file name should not include an extension, since .mif files must have the .mif extension. The file name should not include a path—it is placed in the `Temp` folder by default.

SerialNo

The SerialNo key is also optional. If provided, the information from this key is placed in the Serial Number section in the .mif file. If this key is not present, the installation instead places quotation marks ("").

Locale

The Locale key tells the installation to place the indicated locale in the .mif file. English (ENU) is the default; refer to Microsoft documentation for a complete listing of locale strings.

The following is an example of a `Setup.ini` file for an installation that will automatically create an .mif file.

```
[Startup]
AppName=InstallShield

[Mif]
Type=SMS
```

```
Filename=IShield
SerialNo=IS50-32XYZ-12345
Locale=DEU
```

Cloning Releases

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

InstallShield enables you to clone or copy a release in the Releases view. This allows you to create a release with all of its properties populated as they were in the cloned release. This way, if you want to create more than one release with only a few differences between them, you can clone a release and change only the settings that you need to change.

Task: ***To copy or clone a release:***

1. On the View List under **Media**, click **Releases**.
2. Right-click the release that you want to copy and click **Clone**.

A release named *Copy of Release x* is created. The release copy has all of the same properties as the original release. Rename the release and modify the release settings that you want to change.

Testing and Running Installations

Before distributing your installation, you should test run it to ensure that you discover any issues rather than your customers. InstallShield enables you to test the end-user dialogs (without copying any files to the target system), run the entire installation including transferring files.

Test Running Installations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

You can test run an installation to review the end-user dialogs. The test run displays the full user interface, but it does not copy any files over to the target system or update the registry.

Task: ***To test run a project, do one of the following:***

- In the **Releases** view, right-click a release and click **Test Setup**.
- Click the **Test** button on the toolbar.

Testing a Trialware Release of Your Product

If you have added a trialware file to your project in the Trialware view and you have built a trialware version of your product, you can test your protected product to determine whether it behaves as planned. Check all of the hyperlinks in the trialware run-time dialogs to make sure that they point to the desired locations.

If you test a Try and Die product by running the protected trial version, it will expire at the end of the trial; you will not be able to test your product further on the same test machine without removing the license, as described in the procedure below.

Task: ***To remove a license from a test machine:***

1. Copy the files that are added to the TestTools folder at build time to the test machine that contains the license that you want to delete. For each file being wrapped, the TestTools folder contains the following files:
   - SCResetLicense*<WrappedBaseFileName>*.exe
   - IsSvcInstSCResetLicense*<WrappedBaseFileName>*.dll

   For example, if a file called **Calc.exe** is wrapped, the files in the TestTools folder are **SCResetLicenseCalc.exe** and **IsSvcInstSCResetLicenseCalc.dll**.
2. On the test machine, run the SCResetLicense*<WrappedBaseFileName>*.exe file.

The license for your protected product is removed, and the trial state is reset. The next time you restart your protected product on the same test machine, the trial starts over, enabling you to retest it.

Caution • *Do not release the files in the TestTools folder with your product or make them available to your customers. Doing so would enable end users to continually restart a trial each time that it expires. Note that the TestTools files are specific to a particular product and license and cannot be used to delete licenses for other products.*

Running Installations from the InstallShield Interface

After you run the Release Wizard and build a release of your installation, you can run it from within InstallShield.

Task: ***To run any of your built installation packages, do one of the following:***

- Click the **Run** button on the toolbar.
- In the **Releases** view, right-click a release and click **Run Setup**.
- On the **Build** menu, click **Run ReleaseName**, where *ReleaseName* is the name of the release that currently has focus in the **Releases** view.

InstallShield runs the release that currently has focus in the Releases view.

If you selected the Uninstall before installing check box in the **Options** dialog box, the previously run release (if any) is uninstalled before the current release is run. This option is available on the Preferences tab in the Options dialog box.

You cannot specify any command-line parameters when launching your installation from the InstallShield interface. You must launch your installation from the command line to pass parameters to the Windows Installer. For more information, see MsiExec.exe Command-Line Parameters.

Running Installations in Silent Mode

Silent installations are installations that run without an end-user interface. If you want your installation to run silently, InstallShield allows you to create silent installations for Basic MSI, InstallScript MSI, and InstallScript project types.

Basic MSI Silent Installations

To run a Basic MSI installation silently, type the following at the command line:

```
msiexec /i Product.msi /qn
```

If your release settings include `Setup.exe`, you can run the following command:

```
Setup.exe /s /v"/qn"
```

Basic MSI installations do not create or read response files. To set installation properties for a Basic MSI project, run a command line such as:

```
msiexec /i Product.msi /qn INSTALLDIR=D:\ProductFolder USERNAME="Valued Customer"
```

InstallScript MSI and InstallScript Silent Installations

For InstallScript MSI and InstallScript projects, you need to record a response file that records the end-user interaction. This response file is passed to `Setup.exe` so that the installation can be run. The traditional silent installation works almost exactly the same as regular installations. It follows the same script logic as the regular installation.

If you need to install an InstallScript MSI installation without using `Setup.exe`, you can use the MSI silent mode.

InstallScript MSI and InstallScript Silent Installations

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

InstallShield Silent allows automated electronic software distribution, also known as silent installation. With InstallShield Silent, there is no need for end users to monitor the installation and provide input through dialogs. An InstallShield Silent installation runs on its own, without any end-user intervention.

If there are multiple instances of your application on a machine, and if a silent update installation for your application runs on that machine, it applies the update to the first instance that it finds, and it does not display the Qualifying Product(s) Detected dialog.

To launch InstallShield Silent, use the `Setup.exe -s` command line parameter.

Windows Logo • *To comply with Windows logo requirements, a silent installation must create a response file in which the default installation options are selected.*

You can run your installation with the `Setup.exe -r` parameter to select installation options and automatically record the InstallShield Silent response file, or you can create your own. To view a real-world example of a response file, refer to the `Setup.iss` file located on InstallShield installation's `Disk1`. For a description of the response file format, see Creating the Response File.

If you need to install an InstallScript MSI installation without using `Setup.exe`, you can use the MSI silent mode.

Task: ***To create a silent installation:***

1. Create the installation.
2. Create the response file.
3. Run the silent installation.
4. Check for errors.

Creating a Silent Installation

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

If you want to create an installation that will be run in silent mode, create your installation in a typical manner, and test the script in the normal (non-silent) manner.

You can easily modify your installation script logic to include flow control based on whether your installation is being run in silent mode. InstallShield provides a system variable called *MODE*. The *MODE* variable contains one of the following constants to identify the installation's current mode:

- **NORMALMODE**—Indicates that the installation is running in normal mode.
- **RECORDMODE**—Indicates that the `Setup.exe` file is automatically generating a silent installation file (.iss file), which is a record of the installation input, in the Windows folder.
- **SILENTMODE**—Indicates that the installation is running in silent mode.

For more information, see MODE.

Tip • *All InstallShield built-in and Sd dialogs automatically handle the values stored in the InstallShield Silent response file (.iss file). If you are creating custom dialogs, you will need to call* ***SilentReadData*** *to handle the dialog's return values in silent mode.*

After you have created or modified the installation, the next step in creating a silent installation is to create the response file.

Creating the Response File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

A normal (non-silent) installation receives the necessary input from end users in the form of responses to dialogs. However, a silent installation does not prompt the end user for input. A silent installation must get its end-user input from a different source. That source is the InstallShield Silent response file (.iss file).

A response file contains information similar to that which an end user would enter as responses to dialogs when running a normal installation. InstallShield Silent reads the necessary input from the response file at run time.

The format of response files resembles that of an .ini file, but response files have .iss extensions. A response file is a plain text file consisting of sections containing data entries.

There are two ways in which you can create an InstallShield Silent response file: you can run the installation and have InstallShield record and create the response file for you, or you can write the response file directly.

Recording a Response File

You have the option of letting InstallShield create the response file for you. Simply run your installation with the `Setup.exe -r` command-line parameter. InstallShield will record all your installation choices in `Setup.iss` and place the file in the Windows folder.

All InstallShield built-in and Sd dialog functions are designed to write values into the `Setup.iss` file when InstallShield runs in record mode (Setup -r). If you are creating custom dialogs, you will need to call **SdMakeName** and **SilentWriteData** to add sections and dialog data to the response file when the installation runs in record mode. Refer to the Sd dialogs' source code in the `<InstallShield location>\Include` folder for examples of using these functions to write to `Setup.iss`. Read the following section for more information about what data to add to `Setup.iss` when calling **SdMakeName** and **SilentWriteData**.

Manually Creating a Response File

You can also create the response file completely by hand. As mentioned, the `Setup.iss` file is similar to an .ini file. The sections of an InstallShield response file must be in the following order:

1. Silent Header Section
2. Application Header Section
3. Dialog Sequence Section
4. Dialog Data Sections (one per dialog)

Section names are contained in square brackets, as in **[InstallShield Silent]**.

Data entries follow their section names and consist of <name=value> pairs, as in the following example:

```
Dlg0={23EAFFCA-361D-11D3-8B0F-00105A9846E9}-Welcome-0
```

Task: ***To create the response file:***

1. Create a text file named `Setup.iss` using any text editor.
2. Enter the silent header into `Setup.iss`.
3. Enter the application header into `Setup.iss`.
4. Enter the dialog sequence into `Setup.iss`.
5. Enter the dialog data into `Setup.iss`.
6. Save and close `Setup.iss`.

A sample response file is included to help familiarize you with the format.

Response File Silent Header

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

All response files begin with a response file silent header. The response file silent header enables InstallShield to identify the file as a legitimate InstallShield response file. It also helps to verify that the response file corresponds to an installation created with the proper version of InstallShield.

The format of the silent header is shown below. Enter the following lines at the beginning of your `Setup.iss` file:

```
[InstallShield Silent]
Version=v7.00
File=Response File
```

The Version=v7.00 line indicates the version of the InstallShield Silent response file, not the version of InstallShield. Use `v7.00` in all response files.

When you are creating response files, be sure to use the same version of InstallShield to create the response file that will be used to run the silent installation.

Response File Application Header

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The response file application header is the second block of information in the response file, immediately following the response file silent header. The response file application header enables you to identify response files visually. It is not used by the installation script or by `Setup.exe`. You can use the application header to identify exactly which installation the response file is for, since it is often difficult to determine this by looking at the dialog data.

The format of the application header is shown below. The values assigned to Name, Version, and Company are derived from the values written to the registry in the call to the **CreateInstallationInfo** function in your installation script. (In an event-based script, **CreateInstallationInfo** is called in the default OnMoveData event handler code.) Enter the following lines into your `Setup.iss` file below the silent header:

```
[Application]
Name=<ProductKey from CreateInstallationInfo>
Version=<VersionKey from CreateInstallationInfo>
Company=<CompanyKey from CreateInstallationInfo>
```

Response File Dialog Sequence

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The third block of information in the response file, after the silent header and the application header, is the response file dialog sequence. The dialog sequence section lists all dialogs that you would need to use in a normal installation (including custom dialogs), in the order in which they would appear. The dialogs are listed under the section heading [<PRODUCT_GUID>-DlgOrder].

The dialog numbering sequence begins at 0. There is no limit to the number of dialogs that you can list.

The order and the number of dialogs is significant. When InstallShield Silent runs, if either the number or the order of the dialogs does not match the order or the number of the dialogs in the non-silent installation, the silent installation fails and the log file records the failure. Make one entry for each occurrence of a dialog. A given dialog may be listed more than once if it appears more than once in the installation.

The format for a dialog sequence entry is as follows:

```
Dlg<#>=<PRODUCT_GUID>-<DialogIdentifier>
```

The Dlg*<#>* part consists of the letters Dlg and a sequence number. The first dialog in the installation is Dlg0. Each dialog after that increments the value of *<#>* by one.

<DialogIdentifier> is in the form *functionname*-*<#>*, where *functionname* is the name of the function that created the dialog, and *<#>* represents the sequential order of that particular dialog in the installation.

For custom dialogs, you can use any unique alphanumeric name for the *functionname* portion of <DialogIdentifier>. For example, you could refer to a custom dialog as MyDialog. If the tenth dialog in the installation were the second occurrence of the custom dialog MyDialog, there would be an entry in the dialog sequence section such as the following:

```
Dlg9=<PRODUCT_GUID>-MyDialog-1
```

The <DialogIdentifier> expression is used to identify the dialog data section for the dialog.

Always end the dialog sequence section with a statement that has the following form:

```
Count=<number of dialogs>
```

The statement specifies the exact number of dialogs listed in the dialog sequence section. Count every entry. Since dialog numbering begins with 0, the value of Count will always be 1 greater than the highest *<#>* value for a dialog sequence.

The example below lists two dialogs, the Welcome dialog and the **AskOptions** dialog. Enter your dialog sequence list into `Setup.iss` as shown in the example below.

```
[{23EAFFCA-361D-11D3-8B0F-00105A9846E9}-DlgOrder]
Dlg0={23EAFFCA-361D-11D3-8B0F-00105A9846E9}-Welcome-0
Dlg1={23EAFFCA-361D-11D3-8B0F-00105A9846E9}-AskOptions-0
Count=2
```

Response File Dialog Data

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The last block of information in a response file is the response file dialog data. The response file dialog data is a collection of sections containing the values returned by each dialog identified in the dialog sequence section. Each dialog has its own section. The values listed are the same values that the dialog returns in a normal end-user input-driven installation. You can also create dialog data sections for custom dialogs.

The format for a dialog data section is shown below:

```
[<PRODUCT_GUID>-<DialogIdentifier>]
Result=value
Keyname1=value
Keyname2=value
```

The [<PRODUCT_GUID>-<DialogIdentifier>] section header identifies the specific dialog and is followed by the dialog data entry list. <DialogIdentifier> is the same expression used to list the dialog in the dialog sequence section.

Data entry items are in the format keyname=value. The keyname is a name for a value returned by a dialog and recorded in the response file. All dialogs, including custom dialogs, return a value for the keyname Result, reflecting the button that was clicked to end or exit the dialog. Many dialogs will also set or return a value in a variable.

For example, in a non-silent installation, the **AskDestPath** dialog returns the destination location in the `svDir` parameter. The line in the script might look like the following:

```
nResult = AskDestPath( szTitle, szMsg, svDir, 0 );
```

The corresponding dialog data entry in the `Setup.iss` file for a silent installation might look like the following:

```
[{23EAFFCA-361D-11D3-8B0F-00105A9846E9}-AskDestPath-0]
Result=1
szPath=C:\Program Files\InstallShield\2013
```

In the above example, **Result=1** is equivalent to clicking the Next button in the dialog, and **szPath=C:\Program Files\InstallShield\2013** is the value returned in the `svDir` parameter of **AskDestPath**.

The name of the variable used in the script is meaningless relative to the `Setup.iss` file. However, in the `Setup.iss` dialog data sections, each built-in and Sd dialog has its own set of keynames that map to its parameters. The keynames are important and must be exactly as defined for each dialog. Refer to Dialog Data Keynames List, below.

When you use custom dialogs, you must create a dialog data entry for the Result keyname for each dialog, plus entries for any other values set or returned by the custom dialogs. Use the Dialog Data Keynames List, below, as an indicator of how to create keyname=value expressions for your custom dialogs. Call **GetProfString** or **GetProfInt** to read the dialog data information for the custom dialog. **GetProfString** and **GetProfInt** allow you to specify the .iss file, the section, and the keyname, and they return the value assigned to that keyname.

Standard Values for the Result Keyname

All dialogs, including custom dialogs, return a keyname value called Result, indicating which button was clicked to end the dialog. Unless otherwise indicated, the Result standard values are:

- 12 for the Back button
- 1 for the Next or OK button

Recording Component and Subcomponent Selections

Some dialog functions allow the end user to select components and subcomponents. There are three kinds of dialog data keyname entries used to record component and subcomponent selections in response files: type, count, and <#> (described below).

Every set of component selections and every set of subcomponent selections has one type keyname entry, one count keyname entry, and as many <#> keyname entries as are required to document each individual component or subcomponent selection.

When you are creating keynames to record component selections, precede the type, count, and <#> keyname entries with the word Component, thus:

```
Component-typeComponent-countComponent-0
```

When you are creating keynames to record subcomponent selections, precede the type, count, and <#> keyname entries with the name of the component to which the subcomponents belong, thus:

```
Program Files-typeProgram Files-countProgram Files-0Program Files-1
```

To create complete value entries, use the equal sign to attach the values to the keynames. (The types of values assigned to each kind of keyname are described below.) The following example shows complete value entries for two components, **Program Files** and **Binary Files**, and two subcomponents of **Program Files**, **Executables** and **Support Elements**:

```
Component-type=string
Component-count=2
Component-0=Program Files
Component-1=Binary Files
Program Files-type=string
Program Files-count=2
Program Files-0=Executables
Program Files-1=Support Elements
```

The type keyname indicates the data type of the components or subcomponents list. Since InstallShield dialogs currently use only string lists for components and subcomponents lists, type is always equal to `string`, as in Component-type=string. Future versions may use number lists, in which case type could equal `number`.

Count Keyname Entry

Count is equal to the number of selections for a given component or subcomponent entry. For example, if two components were selected for installation in the **ComponentDialog** dialog, the count dialog data entry would be `Component-count=2`. If two subcomponents of the **Program Files** component were selected, there would be a `Program Files-count=2` entry.

<#> Keyname Entry

The number portion of the <#> keyname entry is simply a sequential (one-up) number, beginning with 0, that numbers each recorded component or subcomponent selection. Since numbering begins with 0, the greatest number value will always be one less than the value of count.

The value assigned to a <#> keyname entry is the selected component's or subcomponent's visible name (the string passed as the second parameter to **ComponentAddItem** when the components or subcomponents list was built).

For example, assume the **ComponentDialog** dialog offers end users a component selection of **Program Files**, **Help Files**, **Sample Files**, and **Utilities**. If the end user selects **Program Files** and **Help Files**, then the dialog data section for that instance of the **ComponentDialog** dialog will have two list item entries and will look something like this:

```
[{23EAFFCA-361D-11D3-8B0F-00105A9846E9}-ComponentDialog-0]
szDir=C:\MYAPP\FILES
Component-type=string
Component-count=2
Component-0=Program Files
Component-1=Help Files
Result=
```

The following example shows how subcomponent list selections are recorded. The example is for an instance of the **SdComponentMult** dialog. The example shows that two components—**Program Files** and **Help Files**—were selected. It also shows that four subcomponents were chosen: **Main Files**, **Aux. Files**, **Main Help**, and **Tutorial Files**. **Main Files** and **Aux. Files** are subcomponents of **Program Files**, and **Main Help** and **Tutorial Files** subcomponents of **Help Files**.

```
[{23EAFFCA-361D-11D3-8B0F-00105A9846E9}-SdComponentMult-0]
Component-type=string
Component-count=2
Component-0=Program Files
Component-1=Help Files
Program Files-type=string
Program Files-count=2
Program Files-0=Main Files
Program Files-1=Aux. Files
Help Files-type=string
Help Files-count=2
Help Files-0=Main Help
Help Files-1=Tutorial Files
Result=1
```

Dialog Data Keynames List

The dialog data keynames for the InstallShield dialogs are listed in the table below. The first column contains the dialog names. The second column lists the keynames applicable to each dialog. The third column contains descriptions of the values associated with the keynames.

Table 4-17 • Dialog Data Keynames

Dialog	Keyname	Description
AskDestPath-<#>	Result	Standard values
AskDestPath-<#>	szPath	The path that is set in the edit field

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
AskOptions-<#>	Result	Standard values AskOptions is special because the number of return values can change based on the script call. You can use a sequence of keynames of the form Sel-<#>, where <#> is the number of the selection variable. Numbering begins with 0. The number of Sel-<#> entries should match the number of variables (check boxes/radio buttons) in the particular call to **AskOptions**. Refer to the following examples: • **Sel-0**—Maps to first selection variable in **AskOptions**. • **Sel-1**—Maps to second selection variable in **AskOptions**. • **Sel-2**—Maps to third selection variable in **AskOptions**.
AskPath-<#>	Result	Standard values
AskPath-<#>	szPath	The path entered in the Destination Directory edit field
AskText-<#>	Result	Standard values
AskText-<#>	szText	The text from the edit field
AskYesNo-<#>	Result	1 = End user clicked the Yes button 0 = End user clicked the No button
ComponentDialog-<#>	Result	Standard values
ComponentDialog-<#>	szDir	The path entered in the Destination Directory field
ComponentDialog-<#>	Component-type	String (the only value currently allowed)
ComponentDialog-<#>	Component-count	The total number of component selections
ComponentDialog-<#>	Component-<#>	The selected item's number in the list (numbering begins with 0)
MessageBox-<#>	Result	1 = End user clicked the OK button
RebootDialog-<#>	Result	0 (Result is always 0.)

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
RebootDialog-<#>	Choice	Indicates the final reboot selection made before restarting the machine. Maps to the radio buttons and has these possible values: • 602 = "Yes, I want to restart my computer now." • 0 = "No, I will restart my computer later."
SdAskDestPath-<#>	Result	Standard values
SdAskDestPath-<#>	szDir	The path entered in the Destination Directory field
SdAskOptions-<#>	Result	Standard values
SdAskOptions-<#>	Component-type	String (the only value currently allowed)
SdAskOptions-<#>	Component-count	The total number of component selections
SdAskOptions-<#>	Component-<#>	The selected item's number in the list (numbering begins with 0)
SdAskOptionsList-<#>	Result	Standard values
SdAskOptionsList-<#>	Component-type	String (the only value currently allowed)
SdAskOptionsList-<#>	Component-count	The total number of component selections
SdAskOptionsList-<#>	Component-<#>	The selected item's number in the list (numbering begins with 0)
SdBitmap-<#>	Result	Standard values
SdComponentDialog-<#>	Result	Standard values
SdComponentDialog-<#>	szDir	The path entered in the Destination Directory field
SdComponentDialog-<#>	Component-type	String (the only value currently allowed)
SdComponentDialog-<#>	Component-count	The total number of component selections

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
SdComponentDialog-<#>	Component-<#>	The selected item's number in the list (numbering begins with 0)
SdComponentDialog2-<#>	Result	Standard values
SdComponentDialog2-<#>	Component-type, <subcomponent>-type	String (the only value currently allowed)
SdComponentDialog2-<#>	Component-count, <subcomponent>-count	The total number of component or subcomponent selections
SdComponentDialog2-<#>	Component-<#>, <subcomponent>-<#>	The selected item's number in the list (numbering begins with 0)
SdComponentDialogAdv-<#>	Result	Standard values
SdComponentDialogAdv-<#>	szDir	The path entered in the Destination Directory field
SdComponentDialogAdv-<#>	Component-type	String (the only value currently allowed)
SdComponentDialogAdv-<#>	Component-count	The total number of component selections
SdComponentDialogAdv-<#>	Component-<#>	The selected item's number in the list (numbering begins with 0)
SdComponentMult-<#>	Result	Standard values
SdComponentMult-<#>	Component-type, <subcomponent>-type	String (the only value currently allowed)

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
SdComponentMult-<#>	Component-count, <subcomponent>-count	The total number of component or subcomponent selections
SdComponentMult-<#>	Component-number, <subcomponent>-<#>	The selected item's number in the list (numbering begins with 0)
SdComponentTree-<#>	Result	Standard values
SdConfirmNewDir-<#>	Result	1 = End user clicked the Yes button 0 = End user clicked the No button
SdConfirmRegistration-<#>	Result	1 = End user clicked the Yes button 0 = End user clicked the No button
SdDisplayTopics-<#>	Result	Standard values
SdFinish-<#>	Result	1 = Finish
SdFinish-<#>	bOpt1	1 = "Yes, I want to view the README file." is selected 0 = "Yes, I want to view the README file." is not selected
SdFinish-<#>	bOpt2	1 = "Yes, I want to launch [app name]" is selected 0 = "Yes, I want to launch [app name]" is not selected
SdFinishEx		Requires special handling.
SdFinishReboot-<#>	Result	1 = Finish
SdFinishReboot-<#>	BootOption	0 = Do not restart Windows or the machine 2 = Restart Windows 3 = Reboot the machine
SdLicense-<#>	Result	12 = End user clicked the Back button 1 = End user clicked the Yes button

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
SdOptionsButtons-<#>	Result	12 = End user clicked the Back button Or, when the Next button is clicked: 101 = Option button one (top) is selected 102 = Option button two is selected 103 = Option button three is selected 104 = Option button four is selected
SdRegisterUser-<#>	Result	Standard values
SdRegisterUser-<#>	szName	The text entered in the Name field
SdRegisterUser-<#>	szCompany	The text entered in the Company field
SdRegisterUserEx-<#>	Result	Standard values
SdRegisterUserEx-<#>	szName	The text entered in the Name field
SdRegisterUserEx-<#>	szCompany	The text entered in the Company field
SdRegisterUserEx-<#>	szSerial	The text entered in the Serial (number) field
SdSelectFolder-<#>	Result	Standard values
SdSelectFolder-<#>	szFolder	The folder name entered in the Program Folder field
SdSetupType-<#>	Result	12 = End user clicked the Back button Or, when the Next button is clicked: 301 = Typical radio button is currently selected 302 = Compact radio button is currently selected 303 = Custom radio button is currently selected
SdSetupType-<#>	szDir	The path entered in the Destination Directory edit field
SdShowDlgEdit1-<#>	Result	Standard values
SdShowDlgEdit1-<#>	szEdit1	The text entered in the svEdit1 field
SdShowDlgEdit2-<#>	Result	Standard values
SdShowDlgEdit2-<#>	szEdit1	The text entered in the svEdit1 field

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
SdShowDlgEdit2-<#>	szEdit2	The text entered in the svEdit2 field
SdShowDlgEdit3-<#>	Result	Standard values
SdShowDlgEdit3-<#>	szEdit1	The text entered in the svEdit1 field
SdShowDlgEdit3-<#>	szEdit2	The text entered in the svEdit2 field
SdShowDlgEdit3-<#>	szEdit3	The text entered in the svEdit3 field
SdShowFileMods-<#>	Result	Standard values
SdShowFileMods-<#>	nSelection	The “Choose what you want Setup to do” radio button selection: 101 = Let Setup modify the AUTOEXEC.BAT file. 102 = Save the required changes to AUTOEXEC.NEW file. 103 = Do not make any changes.
SdShowInfoList-<#>	Result	Standard values
SdStartCopy-<#>	Result	Standard values
SdWelcome-<#>	Result	Standard values
SdWelcomeMaint-<#>	Result	301 = Indicates that the Modify button was selected when the Next button was clicked. 302 = Indicates that the Repair button was selected when the Next button was clicked. 303 = Indicates that the Remove button was selected when the Next button was clicked.
SelectDir-<#>	Result	Standard values
SelectDir-<#>	szDir	The path selected by this dialog
SelectDirEx-<#>	Result	Standard values
SelectDirEx-<#>	szDir	The path selected by this dialog
SelectFolder-<#>	Result	Standard values

Table 4-17 • Dialog Data Keynames (cont.)

Dialog	Keyname	Description
SelectFolder-<#>	szResultFolder	The folder selected by this dialog
SetupType-<#>	Result	12 = End user clicked the Back button Or, when the Next button is clicked: 301 = Typical radio button is currently selected 302 = Compact radio button is currently selected 303 = Custom radio button is currently selected
SprintfBox-<#>	Result	1 = End user clicked the OK button
Welcome-<#>	Result	Standard values

Special Handling for SdFinishEx

SdFinishEx calls either **SdFinish** or **SdFinishReboot**, depending on the value of the system variable *BATCH_INSTALL*. For this reason, *SdFinishEx* cannot be handled by a response file. To create a silent installation for a script that calls *SdFinishEx*, use script code such as the following:

```
if (MODE = NORMALMODE) then
    SdFinishEx (szTitle, szMsg1, szMsg2, szOpt1, szOpt2, bvOpt1, bvOpt2);
else
    if !BATCH_INSTALL then
        /* Set bvOpt1 and bvOpt2 to the values you want them
        to have during a silent installation that does not require
        rebooting; for example: */
        bvOpt1 = FALSE;
        bvOpt2 = TRUE;
    else
        /* When the silent installation requires rebooting,
        if you want to reboot immediately call
        the System function as follows: */
        System (SYS_BOOTMACHINE);
    endif;
endif;
```

Sample Response File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The following response file is the .iss file for a silent InstallShield installation.

```
[InstallShield Silent]

Running the Silent Installation

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

After you have created the installation and the response file, do the following:

1. Add the response file (which is located in your Windows folder by default) to the Disk1 folder under Advanced Files in the Support Files/Billboards view.
2. Build your release. If you are creating a self-extracting executable file for your installation, enter `-s` for the Setup Command Line property in the General Options panel of the Release Wizard or for the Setup Command Line property in the Releases view.

Now you are ready to run the installation in silent mode using InstallShield Silent. When running an installation in silent mode, be aware that no messages are displayed. Instead, a log file named `Setup.log` captures installation information, including whether the installation was successful. You can review the log file and determine the result of the installation. (Note that for certain installation initialization errors, the log file may instead be named `Setupexe.log` and be created in SUPPORTDIR if the installation is run from the Internet or in SRCDIR otherwise.)

To launch InstallShield Silent, run `Setup.exe` with the `-s` option. If you created a self-extracting executable file, simply launch it; you included the `-s` option in step 2 above.

InstallShield also provides the `-f1` and `-f2` switches so that you can specify the name and location of the response file and the location of the log file. For more information, see Setup.exe and Update.exe Command-Line Parameters.

To verify if a silent installation succeeded, look at the ResultCode value in the [ResponseResult] section of `Setup.log`. InstallShield writes an appropriate return value after the ResultCode keyname.

Checking for Errors Using the Setup.log File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

`Setup.log` is the default name for the silent installation log file—generated when the end user runs `Setup.exe` with the `/s` argument—and it is by default created in the directory containing the response file Setup.iss. You can specify a different name and location for `Setup.log` using the `/f1` and `/f2` switches to `Setup.exe`.

The `Setup.log` file contains three sections. The first section, [InstallShield Silent], identifies the version of InstallShield Silent used in the silent installation. It also identifies the file as a log file.

The second section, [Application], identifies the installed application's name and version, and the company name.

The third section, [ResponseResult], contains the result code indicating whether the silent installation succeeded. An integer value is assigned to the ResultCode keyname in the [ResponseResult] section. The installation places one of the following return values in the ResultCode key.

Project • *Note that in an InstallScript MSI installation, there is no initialization process for reading or writing response files. As a result, the only errors that may occur for InstallScript MSI installation are -3 for silent installations and -6 for recording installations. Thus, the following table shows applicable project types where appropriate.*

Table 4-18 • Return Values for the Setup.log File

Result Code	Project Type	Description
0	InstallScript, InstallScript MSI	Success.
-1	InstallScript	General error.
-2	InstallScript	Invalid mode.
-3	InstallScript, InstallScript MSI	Required data not found in the Setup.iss file.
-4	InstallScript	Not enough memory available.
-5	InstallScript	File does not exist.
-6	InstallScript, InstallScript MSI	Cannot write to the response file.
-7	InstallScript	Unable to write to the log file.
-8	InstallScript	Invalid path to the InstallShield Silent response (.iss) file.
-9	InstallScript	Not a valid list type (string or number).
-10	InstallScript	Data type is invalid.
-11	InstallScript	Unknown error during setup.
-12	InstallScript	Dialog boxes are out of order.
-51	InstallScript	Cannot create the specified folder.
-52	InstallScript	Cannot access the specified file or folder.
-53	InstallScript	Invalid option selected.

The `Setup.log` file for a successful silent installation appears as follows:

```
[Application]
Name=Sample App 3000
Version=1.00.0000
Company=Sample Software Corporation
Lang=0409

[ResponseResult]
ResultCode=0
```

MSI Silent Mode Installations for InstallScript MSI Projects

Project • *This information applies to InstallScript MSI projects.*

If you need to silently install an InstallScript MSI project without using `Setup.exe`, you can use the MSI silent mode.

Launching MSI Silent Installations for InstallScript MSI Projects

The MSI silent installation is launched in the following cases:

- The installation is launched at the command line by typing the following:

  ```
  msiexec product.msi /qn
  ```

- The installation is activated from an advertised shortcut.
- The installation is activated from install-on-demand.
- When the product is removed when an update package is running.

Unlike the traditional silent mode, the MSI silent mode does not follow the regular logic provided through script. It simply runs through the InstallExecuteSequence table. (To see this table, navigate to the Direct Editor.) As a result, some events are not called, including the following:

- All UI installation events—OnFirstUIBefore and OnFirstUIAfter
- All Feature events

The OnMsiSilentInstall Event

What the Event Does

In an InstallScript MSI–based installation, InstallShield runs the OnMsiSilentInstall event handler if the product is not already installed on the target system. This happens if the installation is activated from an advertised shortcut or if the installation is launched through the following command line:

```
msiexec product.msi /qn
```

You need to override the OnMsiSilentInstall event if you want to support the MSI silent installation mode. This allows you to perform tasks that are normally performed in the OnFirstUIBefore, OnFirstUIAfter, and feature event handlers.

Overriding the Event

By default, **OnMsiSilentInstall** displays a message and then aborts the installation. You can override this event handler by writing your own implementation of the function. The prototype of this function is as follows:

```
external prototype OnMsiSilentInstall(HWND hInstall);
```

where `hInstall` is the handle to the installation.

The simplest thing that you can do is to implement an empty body of this event so that the installation will not abort. For example:

```
function OnMsiSilentInstall(hInstall)
begin
  //Do nothing and allow installation to continue.
end;
```

Again, **OnMsiSilentInstall** will be called on MSI silent installation and on activation of an advertised shortcut. It will not be called on Install-On-Demand, auto-repair, and uninstall mode.

Detecting the Mode in which a Silent Installation is Running

To detect whether a traditional silent installation is running from InstallShield script, use the following:

```
if (MODE = SILENTMODE)
```

To detect whether an MSI silent mode installation (including `/q`, advertise, auto-repair, uninstall, or install-on-demand) is running from InstallShield script, check the Windows Installer property **ISSETUP_UISEQUENCE_PROCESSED** using the **MsiGetProperty** Windows Installer API function. If this property is not set, then it is a silent install. (It indicates that the InstallUISequence is not executed.)

Silent Uninstallations from the Command Line (InstallScript MSI Only)

Project • *This information applies to InstallScript MSI projects.*

To initiate a silent uninstallation for a product that was installed through an InstallScript MSI installation, use a response file.

Task: ***To run an uninstallation using a response file:***

1. Prepare a response file for the uninstallation (.iss) by running `Setup.exe` with the `/r` argument:

   ```
   Setup.exe /r
   ```

2. Type the following at the command line (items in Italics represent data that is specific to your product's uninstallation):

   ```
   Setup.exe /s /f1"FullPath\YourResponseFile.iss"
   ```

Validating Projects

Validating a project involves applying a set of internal consistency evaluator (ICE) rules to your installation or merge module package. The ICEs are designed to help you determine whether the package contains a valid database that performs its actions correctly. If a package fails one or more ICEs, InstallShield reports the specific ICE rules that were violated and offers additional information to help you troubleshoot the problem.

Microsoft created many of the ICEs that are available in InstallShield; Flexera Software created the custom InstallShield ICEs (ISICEs) that are available for the some of the InstallShield installation and merge module validation suites. The ISICEs help you validate your package against best practices for Windows-based installations.

Windows Logo • *Validating your project may help you identify whether your installation meets installation requirements for Microsoft's Windows logo program. Therefore, if you are interested in being able to use the Windows logo, it is recommended that you use the InstallShield Validation Suite for Windows 8 and the Full MSI Validation Suite to validate your installation package. If you create a merge module in InstallShield, use the InstallShield Merge Module Validation Suite for Windows 8 and the Merge Module Validation Suite for Windows 8 to validate your merge module. For more details, see Requirements for the Windows Logo Program.*

To learn more about the Windows logo program, visit MSDN.

Edition • *The Virtualization Pack includes several sets of validation suites for helping you to determine how ready your products are for virtualization. The InstallShield virtualization internal consistency evaluators (ISVICEs) that are included in these suites let you check suitability for Microsoft App-V 4.x, Microsoft App-V 5.x, Microsoft Server App-V, VMware ThinApp, and Citrix XenApp. The validation suites can enable you to make more informed decisions about how you would build your product if you are considering offering your customers a virtualized version.*

The InstallShield Premier Edition includes a set of validators called the InstallShield Best Practice Suite. The InstallShield Best Practice (ISBP) validators in this suite alert you if your installation violates best-practice guidelines.

InstallShield also provides an engine for upgrade and patching validation. You can access this through the Upgrade Validation Wizard.

Validating an Installation Package or Merge Module

There are two ways to validate an installation package or a merge module from within InstallShield:

- You can configure InstallShield to validate the installation package or merge module every time that you build a release. This is disabled by default. For more information, see Specifying Whether Validation Should Be Performed at Build Time.

  If you perform validation at build time, you can specify multiple validation suites.

- You can run validation on demand for a built release. To learn how, see Validating an Installation Package or Merge Module on Demand.

If you perform validation on demand, you can specify only one validation suite at a time.

Tip • *As an alternative, you can validate the installation package or merge module after you build it from the command line by using `ISCmdBld.exe`. For more information, see ISCmdBld.exe.*

Project • *The only way to validate a package for an MSI Database project or an MSM Database project is to perform validation on demand.*

Note • *If you want to see validation warnings that apply to your installation or merge module, you must perform validation on demand; this type of validation message is not available if you perform validation at build time. InstallShield reports the other types of validation messages—errors and failures—during both validation methods. To learn more about the different types of validation messages, see Viewing Validation Results.*

Specifying Whether Validation Should Be Performed at Build Time

InstallShield enables you to specify whether installation packages and merge modules should be validated each time that a release is successfully built. InstallShield also lets you specify one or more validation suites that should be used for validation.

Task: ***To configure validation settings:***

1. On the **Tools** menu, click **Options**. The **Options** dialog box opens.
2. Click the **Validation** tab.
3. Select the check boxes for the types of validation that you would like InstallShield to perform at build time. If you prefer to validate on demand, and not at build time, clear the check boxes.
4. If you select the **Perform validation using** check box or the **Perform Merge Module validation using** check box, select one or more types of validation that should be performed.

   To add a new or custom validator (.cub file), click the **Browse** button and select it.

Note • *If you want to see validation warnings that apply to your installation or merge module, you must perform validation on demand; this type of validation message is not available if you perform validation at build time. InstallShield reports the other types of validation messages—errors and failures—during both validation methods.*

Specifying Which ICEs, ISICEs, ISVICEs and ISBPs Should Be Run During Validation

InstallShield lets you customize the list of ICEs, ISICEs, and ISBPs that should be used for installation package validation and merge module validation.

Task: ***To specify which ICEs, ISICEs, ISVICEs, and ISBPs should be run during validation:***

1. On the **Tools** menu, click **Options**. The **Options** dialog box opens.
2. Click the **Validation** tab.
3. Click the **Customize** button. The **Customize Validation Settings** dialog box opens.
4. In the **Select CUB file to customize** list, click the suite that you want to customize.
5. In the list of ICEs, select the check box for each of the validators that should be used to evaluate the installation package or merge module. Clear the check box for each of the validators that should not be used for the validation.

   To configure multiple consecutive validators, select the first file, press and hold SHIFT, and select the last file. Then either select or clear the check box of one of the selected validators.
6. Click **OK**.

If you customize the list of ICEs, ISICEs, and ISBPs for a validation suite, anytime that validation is performed—whether it occurs at build time or on demand—only the selected ICEs, ISICEs, or ISBPs are used.

Validating an Installation Package or Merge Module on Demand

InstallShield enables you to validate an installation package or merge module separately from the build process. Doing so is especially helpful if you configured InstallShield so that validation is not performed as part of every successful build, but you do need to run it at some point to test your product for Windows logo compliance or for best-practice compliance.

Task: ***To validate your release on demand:***

1. Complete a successful build of a release.
2. On the **Build** menu, point to **Validate**, and then click the validation type that you want to run.

Viewing Validation Results

InstallShield displays the results of the validation scan on the Validations tab of the Output window. In addition, InstallShield saves the results to a text (.txt) file in a `ValidationFiles` folder within the release folder. You can view this file either by navigating to your build directory, or by navigating to the Releases view and selecting the Validations folder under your release.

Validation Messages

Validation messages are broken down into three categories:

- **Errors**—Describe problems with your database, such as having duplicate component GUIDs.
- **Warnings**—Describe problems in your database that may occur in certain circumstances.
- **Failures**—Occur when your database has severe enough problems that the validation tool might not be able to run.

If the scan results for your project include validation messages, the messages and associated codes are also listed on the Tasks tab of the Output window.

Note *• If you want to see validation warnings that apply to your installation or merge module, you must perform validation on demand; this type of validation message is not available if you perform validation at build time. InstallShield reports the other types of validation messages—errors and failures—during both validation methods. To learn more about these two validation methods, see Validating an Installation Package or Merge Module.*

Tip *• You can click a validation code on the Tasks tab of the Output window to see the corresponding Knowledge Base article or HelpNet topic.*

In addition, you can click a validation message on the Tasks tab to jump to the area of the Direct Editor that corresponds to the validation message. This functionality is available for ICEs, ISICEs, ISVICEs, and ISBPs.

ICEs

The validation tool checks your project for compliance with each of the internal consistency evaluators, or ICEs. These ICEs are those used by `Msival2.exe` (part of the Microsoft Windows Installer Platform SDK) to validate installation and merge module packages for Windows logo compliance.

If your installation project or merge module project fails one or more of these ICEs, InstallShield reports the specific ICE rules that were violated and offers additional information to help you troubleshoot the problem.

To learn about specific ICEs, see ICE Reference in the Windows Installer Help Library.

ISICEs

The InstallShield validation suites consist of a number of InstallShield ICEs (ISICEs) that help you check your project for compliance with installation requirements of the Windows logo program.

The following table lists the ISICEs that are available in InstallShield.

Table 4-19 • ISICEs

ISICE	Project Type	Description
ISICE01	Basic MSI, InstallScript MSI, MSI Database	Validates that the application is installed to ProgramFiles or the user's AppData folder by default.
ISICE02	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that all executable files included with the installation or merge module are digitally signed.
ISICE03	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that there are no nested-installation custom actions (type 7, 23, and 39).
ISICE04	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that there are no custom columns added to standard .msi tables.
ISICE05	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that there are no properties or custom tables that begin with MSI (case-insensitive).
ISICE06	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that the installation does not include any files protected by Windows Resource Protection.
ISICE07	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that MSI components are authored for proper installation and uninstallation.
ISICE08	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that deferred custom actions do not have the impersonate bit set.
ISICE09	Basic MSI, InstallScript MSI, MSI Database	Validates that the installation includes an MsiPatchCertificate table entry.

Table 4-19 • ISICEs (cont.)

ISICE	Project Type	Description
ISICE10	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that each custom action has a path specified for the Help File Path setting in the Custom Actions view.
ISICE11	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that .exe files have embedded manifests with required information.
ISICE12	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that no protected registry keys are modified.
ISICE13	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that no .hlp files or WinHelp run-time files are included in the installation. This ICE is now ISBP17.
ISICE14	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that no obsolete APIs are imported. This ICE is now ISBP18.
ISICE15	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that no deprecated APIs are imported. This ICE is now ISBP19.
ISICE16	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that no 16-bit components are distributed in an installation that targets 64-bit systems.
ISICE17	Basic MSI, InstallScript MSI, Merge Module, MSI Database	Validates that the installation or merge module does not force a reboot.
ISICE18	Basic MSI, MSI Database	Validates that the MsiRMFilesInUse dialog is included.

Table 4-19 • ISICEs (cont.)

ISICE	Project Type	Description
ISICE19	Basic MSI, InstallScript MSI, MSI Database	Validates properties related to upgrades, that the Upgrade table is present, and that the installation prevents downgrades.
ISICE20	Basic MSI, InstallScript MSI, MSI Database	Validates that no machine-wide settings are installed by a non-privileged installation.
ISICE21	Basic MSI, InstallScript MSI, MSI Database	Validates that the app does not depend on the VB6 runtime.
ISICE22	Basic MSI, InstallScript MSI, MSI Database	Validates that the app does not start automatically on system startup.
ISICE23	Basic MSI, InstallScript MSI, MSI Database	Validates that the app sets strong and appropriate ACLs.
ISICE24	Basic MSI, InstallScript MSI, MSI Database	Validates that the installation does not install 16-bit components.
ISICE25	Basic MSI, InstallScript MSI, MSI Database	Validates that the installation does not install any files to the Windows directory or its subdirectories.
ISICE26	Basic MSI, InstallScript MSI, MSI Database	Validates that applications support Windows security features by controlling permissions appropriately.

Tip • *In some cases, the following validation error message may be displayed for an ISICE:*

`File [1] in Component [2] could not be found. All tests against this file's contents may be invalid.`

This error occurs if the specified file is missing, and the associated ISICE could not be verified for the file. For example, if an executable file is missing, ISICE11 cannot verify whether the file has an embedded manifest.

If the aforementioned validation error message is displayed, resolve the missing file issue, and then rerun validation for your project.

ISICE01

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
The application should be installed to either ProgramFiles or AppData folder by default. The current
    default location is [1].
```

[1] is the default installation location for the product.

Description

Users should be able to install products where they need them, and they should have a consistent experience with where files are stored by default.

ISICE01 verifies that the default destination location for your product is the Program Files folder or the Application Data folder. If a different location is used, this error message is displayed during validation.

Corrective Action

Change the default location. For more information, see Setting the Default Product Destination Folder (INSTALLDIR).

ISICE02

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
File [1] in Component [2] is not digitally signed. All [3] files distributed to Windows Vista and
    later are required to be signed.
```

[1] is the name of an executable file, [2] is the name of the component that contains that file, and [3] is the type of file that must be signed.

Description

ISICE02 verifies that all executable files in your installation have been digitally signed. This includes files with the following extensions: exe, dll, ocx, sys, cpl, drv, and scr. If an executable file in your installation has not been digitally signed, this error message is displayed during validation.

Corrective Action

Ensure that all executable files in your installation have been digitally signed. For more information, see Digital Signing and Security.

ISICE03

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
Nested custom action [1] of type [2] is not allowed.
```

[1] is the name of a custom action in your project, and [2] is the Windows Installer type number of custom action.

Description

ISICE03 verifies that your installation does not include any nested-installation custom actions. Nested installations is a deprecated feature of the Windows Installer. Applications installed with nested installations sometimes fail because they are difficult for end users to service correctly. Microsoft Corporation recommends that you avoid using nested installations and nested-installation custom actions to install products that are intended to be released to the public. To learn more, see Concurrent Installations on the MSDN Web site.

Corrective Action

To resolve this error, remove the nested-installation custom action from your project. The MSI Type Number value in the Custom Actions and Sequences view (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or the Custom Actions view (in Merge Module and MSM Database projects) for nested-installation custom actions is 7, 23, or 39.

As an alternative to using a nested installation, you may want to create a create an InstallShield prerequisite, and then add that InstallShield prerequisite to your installation project. For more information, see Defining InstallShield Prerequisites.

ISICE04

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
The standard MSI table [1] does not match the MSI schema defined in schema.msi.
```

[1] is the name of a table in your project.

Description

ISICE04 verifies that your installation does not add custom table columns to standard tables. Adding columns to standard tables is reserved for future versions of Windows Installer.

Corrective Action

To resolve this error, remove any custom table columns that were added to the table that is mentioned in the error message. You can do this by exporting the table from the Direct Editor, editing the table in a text editor, and importing the revised table.

ISICE05

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Messages

Message 1 (Error)

```
MSI property [1] begins with reserved characters. MSI property names cannot start with "MSI" (case-
    insensitive).
```

[1] is the name of a property in your project.

Message 2 (Error)

```
Table [1] begins with reserved characters. Custom table names cannot start with "MSI" (case-
    insensitive).
```

[1] is the name of a table in your project.

Description

ISICE05 verifies that your installation does not include any custom properties or custom tables whose names begin with **MSI** in any combination of uppercase and lowercase letters. The **MSI** prefix is reserved for future use in new standard properties and tables.

Corrective Action

To resolve the property-related error, use the Property Manager to rename the custom property that is mentioned in the error message.

To resolve the table-related error, use the Direct Editor to export the table, use a text editor to edit the table name in the exported .idt file, and use the Direct Editor to import the newly renamed table into the Direct Editor. Then delete the original custom table.

ISICE06

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message 1 (Error)

```
File [1] in Component [2] is a Windows Protected File. Protected files may not be distributed to
    Windows Vista and later.
```

[1] is the name of a file in your project, and [2] is the name of the component that contains that file.

Message 2 (Warning)

```
File [1] in Component [2] has the same file name as a Windows Protected File, but appears to be
    distributed to a different path.
```

[1] is the name of a file in your project, and [2] is the name of the component that contains that file.

Description

ISICE06 verifies that your installation does not install files that are protected by Windows Resource Protection (WRP). WRP is designed to ensure that protected system resources are updated on Windows Vista and later machines only through Microsoft-approved installation or update mechanisms.

If your installation installs a file that has the same name as a Windows Protected File, but the file is not installed to the same location as the Windows Protected File, warning message 2 is displayed.

Corrective Action

To resolve the validation error, remove the file that is mentioned in the error message from your project.

If you encounter the validation warning, determine if the file that is mentioned in the message is a protected file:

- If the file is not a protected file but it has the same name as a protected file, you can ignore this warning.
- If the file is a protected file, remove it from your project to resolve this warning.

If your product requires newer versions of system components, the components must be updated on target machines by using a Microsoft service pack or a Microsoft-approved installation package that contains the system component. System components should not be repackaged.

ISICE07

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Messages

Message 1 (Error)

```
Component.ComponentId for Component [1] is null. All components must have a valid ComponentId for
    proper installation and uninstallation. If this is left null, justification must be documented.
```

[1] is the name of a component in your project that does not have a GUID specified in the Component Code setting in the Components view.

Message 2 (Error)

```
Component [1] contains COM data, but it has more than 1 file. Each COM component should contain only
    1 COM file.
```

[1] is the name of a component in your project that contains more than one COM server.

Message 3 (Error)

```
Component [1] has more than one file as the target of a Desktop or Start Menu shortcut.
```

[1] is the name of a component in your project that has more than one file specified as the target of a shortcut.

Message 4 (Error)

```
Component [1] is associated with multiple features and is referenced in the following tables: [2].
    These references require the component to be associated with exactly 1 feature.
```

[1] is the name of a component in your project that is associated with more than one feature and that has references in any of the following tables: **Class**, **Extension**, **MsiAssembly**, **PublishComponent**, **TypeLib**. [2] is a comma-delimited list of tables that contain references to the component.

Description

ISICE07 verifies that the components in your installation adhere to component rules, which help to ensure that the installation or uninstallation of one product does not harm any other product on a target system. These rules also help to ensure that Windows Installer correctly removes all resources that are connected with a product that is being uninstalled.

Corrective Action

To resolve error 1, open the Components view, select the component that is mentioned in the error message, and click the Component Code setting. In the help pane that is displayed in the lower-right pane, click Generate GUID. If you have a valid reason for leaving the Component Code setting blank, you can document it in the application that you submit for the Windows logo program.

To resolve error 2, move any COM servers to separate components so that each COM server is the key path of its component.

To resolve error 3, use the Shortcuts view to delete all but one of the shortcuts that are associated with the component mentioned in the error message.

To resolve error 4, use the Setup Design view or the Features view to remove the component from all but one feature.

ISICE08

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
Custom Action [1] uses impersonation. Impersonation should not be used when running setups on Windows
    Vista or later.
```

[1] is the name of a custom action in your project.

Description

ISICE08 verifies that your installation does not contain any custom actions that use impersonation. If you select one of the Terminal Server Aware options for the type of in-script execution setting (in the Custom Actions and Sequences view, in the Custom Actions view, or on the Respond Options panel of the Custom Action Wizard), the custom action impersonates the end user during per-machine installations on terminal server machines.

Corrective Action

To resolve this validation error, open the Custom Actions and Sequences view (or the Custom Actions view) and click the custom action that is mentioned in the error message. Change the value of the In-Script Execution setting to one of the options that does not include Terminal Server Aware.

ISICE09

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
An MsiPatchCertificate table entry is required for User Account Control (UAC) patching.
```

Description

ISICE09 verifies that your installation includes an **MsiPatchCertificate** table entry. In a base installation, this table provides the signer certificate that will be used to verify the digital signature of subsequent patches when they are applied by a non-administrator or an administrator who is not using elevated privileges.

Corrective Action

To resolve this validation error, add the **MsiPatchCertificate** table to your project. To learn how, see Preparing Installations for Non-Administrator Patches.

ISICE10

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
Custom action [1] of type [2] is not documented in table [3].
```

[1] is the name of a custom action in your project, and [2] is its Windows Installer type number. [3] is the name of the table that is missing an entry for the custom action that is listed.

Description

The intended behavior of each custom action must be documented for the Windows logo program. This is especially helpful if system administrators deploy your product to enterprise environments; they sometimes need to know what the custom actions do.

ISICE10 verifies that each custom action in your installation is documented by validating that each entry in the **CustomAction** table has a corresponding **ISCustomActionReference** table entry.

Corrective Action

To resolve this validation error, open the Custom Actions and Sequences view (or the Custom Actions view), select the custom action that is mentioned in the error message, and use the Help File Path setting to specify a path to the document that describes the behavior of the custom action. When you specify a value in the Help File Path setting, InstallShield adds a row for that custom action in the **ISCustomActionReference** table if one has not already been created.

In addition, configure the product configuration for the release so that InstallShield streams the contents of each of the custom action help files into the .msi file at build time. For more information, see the description of the Include Custom Action Help setting on the General tab for a product configuration in the Releases view.

Note that if the custom action is a merge module that is consumed in your installation project, specify the path in the Custom Actions view of the merge module project and then rebuild the merge module.

ISICE11

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Messages

Message 1 (Error)

```
Exe [1] in component [2] lacks a manifest.
```

[1] is the name of an executable file in your project that does not have a manifest, and [2] is the name of the component that contains the executable file.

Message 2 (Error)

```
Exe [1] in component [2] lacks a requestedExecutionLevel level setting in its manifest.
```

[1] is the name of an executable file in your project that has a manifest that was possibly created for Windows XP but that was not updated for Windows Vista and later. The manifest does not define the execution level for the executable file. [2] is the name of the component that contains the executable file.

Message 3 (Error)

```
Exe [1] in component [2] lacks a requestedExecutionLevel uiAccess setting in its manifest.
```

[1] is the name of an executable file in your project that has a manifest that was possibly created for Windows XP but that was not updated for Windows Vista and later. The manifest does not define the UI accessibility value for the executable file. [2] is the name of the component that contains the executable file.

Message 4 (Warning)

```
Exe [1] in component [2] is marked to require elevated privileges (highestAvailable) which requires
    a waiver from Microsoft.
```

[1] is the name of an executable file in your project that has a manifest that specifies that elevated privileges are required, and [2] is the name of the component that contains the executable file.

Message 5 (Warning)

```
Exe [1] in component [2] is marked to require elevated privileges (requireAdministrator) which
    requires a waiver from Microsoft.
```

[1] is the name of an executable file in your project that has a manifest that specifies that elevated privileges are required, and [2] is the name of the component that contains the executable file.

Message 6 (Warning)

```
Exe [1] in component [2] is marked to require uiAccess which requires a waiver from Microsoft.
```

[1] is the name of an executable file in your project that has a manifest that specifies that the executable file is allowed to bypass UI protection levels in order to use higher privileges to pass information to other windows on the desktop; that is, the value of uiAccess is set to true. [2] is the name of the component that contains the executable file.

Description

ISICE11 verifies that every .exe file in your installation has an embedded manifest that defines its execution level. The execution level is defined in the manifest as follows:

```
<requestedExecutionLevel
  level="asInvoker"
  uiAccess="false"/>
```

Other valid values for the level attribute are highestAvailable and requireAdministrator. Note that if you set the level value to highestAvailable or requireAdministrator, you must apply for a waiver from Microsoft to obtain Windows logo certification.

The uiAccess attribute indicates whether the executable file is allowed to bypass UI protection levels in order to use higher privileges for passing information to other windows on the desktop, such as on-screen keyboards. This attribute should be set to true only for UI accessibility applications. Note that if you set the UI accessibility value to true, you must apply for a waiver from Microsoft to obtain Windows logo certification.

Corrective Action

To resolve the validation errors (messages 1 through 3), replace the executable file in your installation with one that has an embedded manifest whose level and uiAccess values are set appropriately.

The validation warnings (messages 4 through 6) are displayed to inform you that if you want to have your product qualify for the Windows logo program but you keep the requestedExecutionLevel element as it is currently defined in the executable file's manifest, you may need to obtain a waiver from Microsoft.

ISICE12

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
Registry key [1] in Component [2] is a protected registry key. Protected registry keys may not be
    modified on Windows Vista and later.
```

[1] is a registry key that only the Trusted Installer group can modify on Windows Vista or later systems, and [2] is the name of the component that contains that registry key.

Description

ISICE12 verifies that the installation does not attempt to modify registry keys that are protected by Windows Resource Protection (WRP) on Windows Vista and later systems. Registry keys that can be modified by only the Trusted Installer group are protected by WRP.

Corrective Action

To resolve this validation error, use the Registry view to remove the protected registry key from your project, or move it to a part of the registry that is not protected by WRP.

ISICE16

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Message (Error)

```
File [1] in Component [2] is a 16-bit file. Installations that target 64-bit systems may not include
    16-bit files.
```

[1] is the name of a 16-bit file in your project, and [2] is the name of the component that contains the file.

Description

If your installation targets 64-bit platforms, ISICE16 verifies that it does not contain any 16-bit files, since 64-bit platforms do not support 16-bit files.

Corrective Action

To resolve this validation error, replace the 16-bit file with a 64-bit or 32-bit file.

ISICE17

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*

Messages

Message 1 (Error)

```
Sequence [1] includes the [2] action. Use of the [2] action requires a waiver from Microsoft.
```

[2] is the name of an action in your project, and [1] is the name of the sequence that contains that action.

Message 2 (Error)

```
Control [1] on Dialog [2] runs the [3] action. Use of the [3] action requires a waiver from
    Microsoft.
```

[3] is the name of an action in your project. [2] is the name of the control that includes an event that launches that action. [2] is the name of the dialog that has the control.

Description

ISICE17 verifies that the installation does not use an action to force a reboot. Currently, the only action that is validated is ForceReboot.

Corrective Action

The errors are displayed to inform you that if you want to have your product qualify for the Windows logo program but you keep the specified action in your installation, you may need to obtain a waiver from Microsoft.

To resolve these validation errors, remove the action from sequence or dialog that is mentioned in the message.

Ensure that your project includes the MsiRMFilesInUse dialog to minimize system reboots, and that your application has been properly instrumented to use the Restart Manager API. For more information, see Minimizing Reboots on Windows Vista and Later Systems.

ISICE18

Project • *This information applies to the following project types:*

- *MSI Database*

Messages

Message 1 (Error)

```
Dialog [1] is not present in the Dialog table.
```

[1] is the name of a dialog that should be in your project.

Message 2 (Error)

```
The Title of Dialog [1] does not include '[2]' or '[ProductName]'.
```

[1] is the name of a dialog in your project, and [2] is the value of the [ProductName] variable.

Description

ISICE18 verifies that the installation includes the MsiRMFilesInUse dialog, and that the dialog's title bar contains the name of the product.

Corrective Action

To resolve error 1, ensure that the MsiRMFilesInUse dialog is in your project. All Basic MSI projects include this dialog by default. For more information about this dialog, see Minimizing Reboots on Windows Vista and Later Systems.

To add the dialog back to a Basic MSI project, you can open another Basic MSI project that contains this dialog, or create a new Basic MSI project. Then export the dialog to the project that needs it. For more information, see Exporting Dialogs to Other Projects.

To resolve error 2, add the product name or the [ProductName] property to the Caption property for the MsiRMFilesInUse dialog.

ISICE19

Project • *This information applies to the following project types:*

- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
The table [1] is not present in the installation package.
```

[1] is the name of a table that must be in the package.

Message 2 (Error)

```
UpgradeCode [1] does not detect and prevent downgrades with a properly scheduled Type 19 Custom
    Action; the package must prevent downgrades.
```

[1] is the value of the UpgradeCode property.

Message 3 (Error)

```
The property [1] is not listed in SecureCustomProperties; this can prevent it from being used
    correctly for downgrade prevention.
```

[1] is the name of a property.

Message 4 (Error)

```
The property [1] must be a valid GUID; '[2]' is not a valid GUID.
```

[1] is the name of a property whose value should be a valid GUID. [2] is the invalid value that is currently used for that property.

Message 5 (Error)

```
Column [1] of table Upgrade must hold a valid GUID; '[2]' is not a valid GUID.
```

[1] is the name of a column in the **Upgrade** table, and [2] is the value of an entry in the specified column.

Message 6 (Error)

```
The property [1] must hold a valid numeric version in the format Major.Minor.Build; '[2]' is not a
    version in this format.
```

[1] is the name of a property whose value should be a version number in the Major.Minor.Build format. [2] is the invalid value that is currently used for that property.

Message 7 (Error)

```
Column [1] of table Upgrade must hold a valid numeric version in the format Major.Minor.Build; '[2]'
    is not a version in this format.
```

[1] is the name of a column in the **Upgrade** table, and [2] is the value of an entry in the specified column.

Message 8 (Error)

```
The property [1] must not be null or empty.
```

[1] is the name of a property that is null or empty.

Message 9 (Error)

```
Column [1] of table Upgrade must not be null or empty.
```

[1] is the name of a column in the **Upgrade** table.

Message 10 (Error)

```
The property [1] must be provided; '[2]' is the default value.
```

[1] is the name of a property in your project that has not been customized. [2] is the default value that InstallShield uses for that property.

Message 11 (Error)

```
The property [1] must hold a valid numeric LANGID; '[2]' is not a numeric LANGID.
```

[1] is the name of a property whose value should be a valid language identifier. [2] is the invalid value that is currently used for that property.

Description

ISICE19 validates properties related to upgrades and that the **Upgrade** table is present. ISICE19 also helps you determine whether the installation prevents an earlier package from installing over a new package.

Corrective Action

To resolve errors 1 and 2, ensure that the Upgrades view contains a major upgrade item, that the major upgrade item is properly configured to prevent the current version of your product from being installed over a future version, and that your project includes a properly configured and scheduled type 19 custom action. For detailed instructions, see Preventing the Current Installation from Overwriting a Future Major Version of the Same Product. For more information, see Preventing an Old Package from Installing Over a Newer Version in the Windows Installer Help Library.

To resolve error 3, add the specified property to the value of the **SecureCustomProperties** property. You can use the Property Manager view to set a value for a property. To add multiple values, separate each with a semicolon. For more information, see SecureCustomProperties Property in the Windows Installer Help Library.

To resolve errors 4 and 5, replace the existing value with a valid GUID. To change the value, open the General Information view. Then click the setting that is listed in the error message. Enter a valid GUID. Note that if you want to use a new, unique GUID, you can click the **Generate a new GUID** button in the setting. For more information, see GUIDs.

To resolve errors 6 and 7, replace the specified value with a valid version number; you can click the error message in the Output window to move to the location in the Direct Editor that has the invalid value. The version number must contain only numbers, and it must be in the format **aaa.bbb.ccccc**, where *aaa* represents the major version number, *bbb* represents the minor version number, and *ccccc* represents the build number. The maximum value for the *aaa* and *bbb* portions is 255. The maximum value for *ccccc* is 65,535. For more information, see Specifying the Product Version.

To resolve error 8, enter a value for the specified property. You can use the Property Manager view to set a value for a property.

To resolve error 9, enter a value for the specified column. You can use the Direct Editor view to set the value; you can click the error message in the Output window to move to the location in the Direct Editor that needs to be revised. To learn more about any of the Windows Installer tables, see Database Tables in the Windows Installer Help Library.

To resolve error 10, replace the default value of the specified property with the appropriate value. You can use the Property Manager view to change the value.

To resolve error 11, replace the existing value of the specified property with a valid language identifier.

- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
Row [1] of Table [2]: installing, modifying, or deleting a registry key in root [3] requires elevated
    privileges, but this package does not request elevated privileges.
```

[1] is the name of the row that contains information about a registry change in your project. [2] is the name of the table that contains that registry-related data. [3] is the predefined root key for the registry data, as listed in the Root column for the specified row.

Message 2 (Error)

```
Row [1] of Table [2]: installing, modifying, or deleting a file in directory [3] requires elevated
    privileges, but this package does not request elevated privileges.
```

[1] is the name of a row that contains information about a directory that end users cannot access without elevated privileges. [2] is the name of the table that contains that directory data. [3] is the name of the directory.

Message 3 (Error)

```
Environment variable [1] is a system environment variable, but this package does not request elevated
    privileges.
```

[1] is the name of a system environment variable that is included in your project.

Description

If the Require Administrative Privileges setting in the General Information view is set to No for your project, ISICE20 verifies that your installation does not attempt to perform tasks that require administrative privileges, such as writing to system registry or folder locations.

Corrective Action

To resolve ISICE20 errors, do one of the following:

- Select Yes for the Require Administrative Privileges setting in the General Information view. For more information, see Entering Summary Information Stream Data.
- Change your project so that it does not install, modify, or delete data in system locations. For example, if your project adds a registry key to HKEY_LOCAL_MACHINE, use the Registry view to move that registry key to HKEY_CURRENT_USER. If your project adds or modifies a system environment variable, use the Environment Variables view to change the Type setting of that environment variable from System to User.

ISICE21

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
File '[1]' in Component '[2]' depends on the VB6 runtime.
```

[1] is the name of a file that requires the Visual Basic 6 runtime. [2] is the name of the component that contains that file.

Description

ISICE21 verifies that your product does not depend on the Visual Basic 6 runtime.

Corrective Action

To resolve this validation error, consider the following options:

- If the file is in a component that your product no longer uses, remove the file and its component from your project. Consider using a newer language such as Visual Basic .NET for the creation of your file.
- Remove the file and its component from your project and replace them with new versions that do not rely on the Visual Basic 6 runtime.

If neither of those options are feasible for your product, your installation will not qualify for the Windows logo program.

ISICE22

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
Shortcut '[1]' in Component '[2]' targets the startup folder.
```

[1] is the name of a shortcut in your project, and [2] is the name of the component that contains that shortcut.

Message 2 (Error)

```
Registry key '[1]' in Component '[2]' sets a Run key.
```

[1] is a registry key in your project, and [2] is the name of the component that contains that shortcut.

Description

ISICE22 verifies that your product does not start automatically when the target system starts.

Error message 1 occurs if your installation creates a shortcut in the Startup folder on the Start Menu.

Error message 2 occurs if your installation sets a Run key in locations of the registry such as the following ones:

- HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion
- HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion
- HKEY_LOCAL_MACHINE\Software\Wow6432Node\Microsoft\Windows\CurrentVersion
- HKEY_CURRENT_USER\Software\Wow6432Node\Microsoft\Windows\CurrentVersion

Corrective Action

To resolve this validation error, remove the shortcut or registry key and—if appropriate—the component that contains it from your project.

ISICE23

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
LockObject '[1]' in Component '[2]' sets insecure permissions.
```

[1] is the name of a file, directory, or registry key for which permissions are configured. [2] is the name of the component that contains that file, directory, or registry key.

Description

ISICE23 verifies that your installation does not expose a target system to security risks through the configuration of inappropriate permissions for files, directories, and registry keys.

For example, if your installation assigns write permission to the Everyone user for a particular folder that your installation installs, ISICE23 triggers an error to alert you to the security vulnerability to which your installation exposes target systems.

Corrective Action

To resolve this validation error, use strong and appropriate permissions for the file, directory, or registry key that is mentioned in the error. For more information, see:

- Configuring Permissions for Files and Folders
- Configuring Permissions for Registry Keys

ISICE24

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
File '[1]' in Component '[2]' is a 16-bit file. Installations that target Windows 8 systems may not
    include 16-bit files.
```

[1] is the name of a 16-bit file in the installation. [2] is the name of the component that contains that file.

Description

ISICE24 verifies that the installation does not contain any 16-bit files; 64-bit versions of Windows do not support 16-bit files.

Corrective Action

To resolve this validation error, replace the 16-bit file with a 64-bit or 32-bit file.

ISICE25

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
The destination of Component '[1]' is the Windows folder or one of its subfolders.
```

[1] is the name of a component.

Description

ISICE25 verifies that the installation does not write directly to the Windows folder or any of its subfolders.

Corrective Action

To resolve this validation error, do one of the following:

- Change the destination of the component.
- If the component is installing a font, ensure that the font file is included in the project according to best practices. To learn how, see Installing Fonts.
- If the component is installing a device driver, ensure that the driver is included in the project according to best practices. To learn how, see Configuring Device Driver Settings.

ISICE26

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
File '[1]' in Component '[2]' does not have the Option Header bit [3] set.
```

[1] is the name of a file, and [2]is the name of the component that contains the file. [3] is the parameter (SafeSEH, NXCOMPAT, or DYNAMICBASE) that was not used when compiling the file.

Description

ISICE26 verifies that the installation supports Windows security features. It checks the PE header of the executable files that the installation installs to verify that they were compiled using the following command-line parameters:

- /SafeSEH—to ensure safe exceptions handling
- /NXCOMPAT—to prevent data execution
- /DYNAMICBASE—for address space layout randomization (ASLR)

A single file can trigger multiple ISICE26 errors, one for each of the aforementioned parameters.

Corrective Action

To resolve this validation error, review build the options for your product's source code, and edit them as needed. In Visual Studio, these are configured on the Advanced property page for Linker settings.

ISVICEs

The InstallShield application virtualization suitability validation suites consist of a number of InstallShield virtualization ICEs (ISVICEs) that help you check your project's suitability for various virtualization technologies.

The following table lists the ISVICEs that are available in InstallShield.

Table 4-20 • ISVICEs

ISICE	Project Type	Technology	Description
ISVICE01	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of files that may normally be part of the Windows operating system.

Table 4-20 • ISVICEs (cont.)

ISICE	Project Type	Technology	Description
ISVICE02	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of device driver files.
ISVICE03	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of ClickOnce deployment files.
ISVICE04	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks for the presence of files that are part of ASP.NET/IIS applications.
ISVICE05	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks for the presence of files that are part of WMI providers.
ISVICE06	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of files that are part of J2EE application servers.
ISVICE07	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of files that are part of applications that may not work when virtualized.
ISVICE08	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of files that are part of applications that are known to fail when virtualized.
ISVICE09	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks for the presence of InstallShield IIS support indicating that an ASP.NET/IIS application is installed.

Table 4-20 • ISVICEs (cont.)

ISICE	Project Type	Technology	Description
ISVICE10	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of drivers installed through the **MsiDriverPackages** table.
ISVICE11	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks the package to ensure that it contains at least one shortcut.
ISVICE12	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, Server App-V, ThinApp, XenApp	Checks for the presence of shell extensions.
ISVICE13	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, Server App-V, ThinApp, XenApp	Checks for the presence of URL protocol handlers.
ISVICE14	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, Server App-V, ThinApp, XenApp	Checks for the presence of support for the Default Programs list.
ISVICE15	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks for the presence of boot start services.
ISVICE16	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, Server App-V, XenApp	Checks to ensure that the total installed file size is less than 4 GB.
ISVICE17	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks for the usage of the Windows Installer COM+ tables.

Table 4-20 • ISVICEs (cont.)

ISICE	Project Type	Technology	Description
ISVICE18	Basic MSI, InstallScript MSI, MSI Database	App-V 4.x, App-V 5.x, ThinApp, XenApp	Checks for the presence of COM DLL surrogate files.
ISVICE19	Basic MSI, InstallScript MSI, MSI Database	ThinApp, XenApp	Checks to see if this is a 64-bit package. ThinApp and XenApp do not support 64-bit applications.

ISVICE01

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE01 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be a file that is closely integrated with the OS. The files that make up
    applications like Internet Explorer or Windows Media Player, or frameworks like the .NET
    Framework, do not make good candidates for virtualization. These files should instead be
    installed locally on the machine.
```

[1] is the name of a file in the project.

Description

ISVICE01 checks for the presence of files that may normally be part of the Windows operating system. If the release contains one or more of those type of files, this error message is displayed during validation.

Corrective Action

If your end users may be interested in a virtualized version of your product, and if your InstallShield project contains the .NET Framework or other items that are closely integrated with Windows, you may want to remove those items from your project. You could document the technologies that are required for your product and instruct your end users to install them locally on their machines before using a virtualized version of your product.

ISVICE02

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE02 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be a device driver. System-level drivers such as print drivers or USB
    device drivers do not work from a virtualized environment. It may be possible to extract this
    driver such that it can be installed locally on the machine and allow the rest of the package to
    be virtualized.
```

[1] is the name of a file in the project.

Description

ISVICE02 checks for the presence of device driver files. System-level drives such as print drivers or USB device drivers do not work from a virtualized environment.

Corrective Action

If your end users may be interested in a virtualized version of your product, and if your InstallShield project contains a device driver, consider removing the device driver component from your project, and creating a separate installation for the driver. End users can then install the driver locally to their machines before using a virtualized version of your product.

ISVICE03

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE03 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be a ClickOnce deployment file. ClickOnce is a per-user installation format
    that is often incompatible with the per-machine nature of virtual packages. A ClickOnce
    application also may try to automatically update itself, which can result in invalid versioning
    in virtual application management systems.
```

[1] is the name of a file in the project.

Description

ISVICE03 checks for the presence of ClickOnce deployment files. If your project includes ClickOnce deployment files, ISVICE03 occurs.

Corrective Action

Evaluate how important the ClickOnce deployment files are to the application so that you can determine if it matters whether the ClickOnce installation behaves as intended. If the ClickOnce deployment files are unimportant, it is probably safe to deploy a virtualized version of the product with slightly reduced functionality. If the ClickOnce deployment files are important, a virtualized version of the product may not function well.

ISVICE04

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE04 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be a part of an ASP.NET/IIS application. This is not supported by desktop
    application virtualization.
```

[1] is the name of a file in the project.

Description

ISVICE04 checks for the presence of files that are part of ASP.NET or IIS applications.

Corrective Action

If the ASP.NET or IIS application is not an important part of the product, or if it can be separately installed locally on target systems, you can ignore this validation error.

ISVICE05

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE05 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be a WMI provider. This is not supported by desktop application
    virtualization. If the provider is not a critical piece of the package, it may be possible to use
    the rest of the package as a virtual application.
```

[1] is the name of a file in the project.

Description

ISVICE05 checks for the presence of files that are part of Windows Management Instrumentation (WMI) providers.

Corrective Action

If the WMI provider is not an important part of the product, or if it can be separately installed locally on target systems, you can ignore this validation error.

ISVICE06

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE06 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be part of a J2EE application server. This is not supported by desktop
    application virtualization.
```

[1] is the name of a file in the project.

Description

ISVICE06 checks for the presence of files that are part of J2EE application servers.

Corrective Action

If the J2EE application is not an important part of the product, or if it can be separately installed locally on target systems, you can ignore this validation error.

ISVICE07

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE07 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Warning)

```
The file '[1]' appears to be a part of an application that is known to not be a good candidate for
    virtualization; however, it may be possible to virtualize the rest of the package and install the
    unsuitable piece physically.
```

[1] is the name of a file in the project.

Description

ISVICE07 checks for the presence of files that are part of applications that may not work when virtualized. This includes files that are from applications such as SQL Server.

Corrective Action

If the unsupported application is not an important part of the product, or if it can be separately installed locally on target systems, you can ignore this validation error.

ISVICE08

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE08 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error)

```
The file '[1]' appears to be a part of an application that is known to not be a good candidate for
    virtualization.
```

[1] is the name of a file in the project.

Description

ISVICE08 checks for the presence of files that are part of applications that may not work when virtualized. This includes files that are from applications such as antivirus software or server software such as Exchange Server.

Corrective Action

If the unsupported application is not an important part of the product, or if it can be separately installed locally on target systems, you can ignore this validation error.

ISVICE09

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE09 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Error)

```
IIS [1] item '[2]' is included in the package. This is not supported by desktop application
    virtualization.
```

[1] is the name of a type of IIS item in the project, and [2] is the name of that item.

Description

ISVICE09 checks for the presence of InstallShield IIS support indicating that an ASP.NET or IIS application is installed.

Corrective Action

If the unsupported ASP.NET or IIS application is not an important part of the product, or if it can be separately installed locally on target systems, you can ignore this validation error.

ISVICE10

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE10 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error)

```
Component '[1]' contains a device driver installed through the MsiDriverPackages (DIFxApp) table.
    System-level drivers such as print drivers or USB device drivers do not work from a virtualized
    environment. It may be possible to extract this driver such that it can be installed locally on
    the machine and allow the rest of the package to be virtualized.
```

[1] is the name of a device driver that is included in the project.

Description

ISVICE10 checks for the presence of drivers that are configured to be installed through the **MsiDriverPackages** table.

Corrective Action

If your end users may be interested in a virtualized version of your product, and if your InstallShield project contains a driver, consider removing the driver from your project, and creating a separate installation for the driver. End users can then install the driver locally to their machines before using a virtualized version of your product.

ISVICE11

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE11 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Warning for App-V 4.x and App-V 5.x; Error for ThinApp and XenApp)

```
This package contains no shortcuts. Shortcuts are usually necessary to define the entry point into
    the virtual application.
```

Description

ISVICE11 checks the package to ensure that it contains at least one shortcut. Shortcuts provide the most visible entry points for launching applications in a virtual package. Most virtual packages should have at least one shortcut.

Corrective Action

If the package is intended to be used as a dependency by a different virtual package, you can ignore this ISVICE.

If the package is intended to be used as a plug-in, it may be necessary to create a shortcut to the application for which this is a plug-in.

If end users need to be able to launch the virtual application independently, consider adding a shortcut for the main executable file.

ISVICE12

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE12 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- Server App-V
- ThinApp
- XenApp

Message (Error for App-V 4.x, App-V 5.x, ThinApp, and XenApp; Warning for Server App-V)

```
This package contains a shell extension (key '[1]'). Shell extensions extend Windows Explorer and
    cannot be loaded from a virtual package. This extension may be critical to the use of this
    application, and if so this application will not function when virtualized. However, if this
    extension is non-critical, the application can still be used.
```

[1] is the key of a shell extension that is included in the project.

Description

ISVICE12 checks for the presence of shell extensions.

Corrective Action

Evaluate how important the shell extension is to the product so that you can determine if it matters whether the shell extension behaves as intended. If the shell extension is unimportant, it is probably safe to deploy a virtualized version of the product with slightly reduced functionality. If the shell extension is important, a virtualized version of the product may not function well.

ISVICE13

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE13 is available for the following virtualization technologies:

- App-V 4.x
- Server App-V
- ThinApp
- XenApp

Message (Warning)

```
This package registers a URL protocol (friendly name '[1]').
```

[1] is the friendly name of a URL protocol.

Description

ISVICE13 checks for the presence of URL protocol handlers.

Corrective Action

Evaluate how important the registration of the URL protocol is to the product so that you can determine if it matters whether the product behaves as intended. If the registration of the URL protocol is unimportant, it is probably safe to deploy a virtualized version of the product with slightly reduced functionality. If the registration of the URL protocol is important, a virtualized version of the product may not function well.

Consider performing validation to see if App-V 5.x is a suitable virtualization technology for your product, since it has support for URL protocol handlers.

ISVICE14

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE14 is available for the following virtualization technologies:

- App-V 4.x
- Server App-V
- ThinApp
- XenApp

Message (Warning)

`This package registers its capabilities in the Default Programs list (key '%1').`

[1] is the name of the key that corresponds with registration information for an item in the Default Programs list.

Description

ISVICE14 checks for the presence of support for the Default Programs list.

Corrective Action

If the Default Programs list registration is not an important part of the product, you can ignore this validation error.

Consider performing validation to see if App-V 5.x is a suitable virtualization technology for your product, since it has support for registering items in the Default Programs list.

ISVICE15

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE15 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Error)

```
This package contains a service (name '[1]'), which starts at boot time. Virtualized services are
    limited to the lifetime of the virtual application so services that must start at boot time do
    not make good candidates for virtualization. It may be possible to extract this service such that
    it can be installed locally on the machine and allow the rest of the package to be virtualized.
```

[1] is the name of a service in the project.

Description

ISVICE15 checks for the presence of boot start services.

Corrective Action

Evaluate how important the service is to the product so that you can determine if it matters whether the product behaves as intended. If the service is unimportant, it is probably safe to deploy a virtualized version of the product with slightly reduced functionality.

If the service is important but you can separate it from the rest of the project, remove it from the project, and create a separate installation for the service. End users can then install the service locally to their machines before using a virtualized version of your product.

If the service is important but you cannot separate it from the rest of the project, a virtualized version of the product may not function well.

ISVICE16

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE16 is available for the following virtualization technologies:

- App-V 4.x
- Server App-V
- XenApp

Message (Error)

```
This package contains more than 4 GB of files. Since the target virtualization technology has a 4 GB
    size limit, this application cannot be successfully virtualized.
```

Description

ISVICE16 checks to ensure that the total installed file size is less than 4 GB. App-V 4.x, Server App-V, and XenApp do not support packages that contain more than 4 GB of files.

Corrective Action

Consider performing validation to see if App-V 5.x or ThinApp are suitable virtualization technologies for your product, since they support sizes larger than 4 GB.

ISVICE17

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE17 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Error)

```
This package contains COM+ data (component '[1]'), which is not supported, so the application may not
    work correctly if virtualized.
```

[1] is the name of a component in the project; the component contains COM+ data.

Description

ISVICE17 checks for use of the Windows Installer COM+ tables.

Corrective Action

Evaluate how important the COM+ application is to the product so that you can determine if it matters whether the product behaves as intended. If the COM+ application is unimportant, it is probably safe to deploy a virtualized version of the product with slightly reduced functionality. If the COM+ application is important, a virtualized version of the product may not function well.

ISVICE18

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE18 is available for the following virtualization technologies:

- App-V 4.x
- App-V 5.x
- ThinApp
- XenApp

Message (Error)

```
This package contains a COM DLL surrogate (registry key '[1]'), which is not supported, so the
    application may not work correctly if virtualized.
```

[1] is the name of a registry key in the project.

Description

ISVICE18 checks for the presence of COM DLL surrogate files.

Corrective Action

Evaluate how important the COM DLL surrogate is to the product so that you can determine if it matters whether the product behaves as intended. If the DLL surrogate is unimportant, it is probably safe to deploy a virtualized version of the product with slightly reduced functionality. If the DLL surrogate is important, a virtualized version of the product may not function well.

ISVICE19

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

ISVICE19 is available for the following virtualization technologies:

- ThinApp
- XenApp

Message (Error)

```
The package is 64-bit. ThinApp and XenApp do not support 64-bit applications.
```

Description

ISVICE19 checks to see if you are building a 64-bit package. ThinApp and XenApp do not support 64-bit applications.

Corrective Action

Consider performing validation to see if App-V or Server App-V is a suitable virtualization technology for your product, since it has 64-bit support.

InstallShield Best Practice Suite

Edition • *The InstallShield Best Practice Suite is available in the Premier edition of InstallShield.*

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Note that some of the ISBPs apply to only Basic MSI and MSI Database projects.

InstallShield includes a set of validators called the InstallShield Best Practice Suite. The InstallShield Best Practice (ISBP) validators in this suite alert you if your installation violates best-practice guidelines.

The following table lists the ISBPs that are available in InstallShield.

Table 4-21 • ISBPs

ISICE	Project	Description
ISBP01	Basic MSI, InstallScript MSI, MSI Database	Verifies that no feature is named “ALL”.
ISBP02	Basic MSI, InstallScript MSI, MSI Database	Verifies that no directory is named “DATABASE”.
ISBP03	Basic MSI, MSI Database	Verifies that no ComboBox is shorter than 50 units.
ISBP04	Basic MSI, MSI Database	Verifies that properties used on dialogs are secure or restricted public properties.
ISBP05	Basic MSI, MSI Database	Verifies that no ControlEvent condition is NULL.
ISBP06	Basic MSI, InstallScript MSI, MSI Database	Verifies that InstallUISequence custom actions are also sequenced in the InstallExecuteSequence.

Table 4-21 • ISBPs (cont.)

ISICE	Project	Description
ISBP07	Basic MSI, InstallScript MSI, MSI Database	Verifies that all features have associated components and all components are associated with features.
ISBP08	Basic MSI, InstallScript MSI, MSI Database	Verifies that ARPINSTALLLOCATION is set after CostFinalize in the InstallExecuteSequence.
ISBP09	Basic MSI, InstallScript MSI, MSI Database	Verifies that LIMITUI is not set without ARPNOMODIFY.
ISBP10	Basic MSI, InstallScript MSI, MSI Database	Verifies that AppSearch properties are secure or restricted public properties.
ISBP11	Basic MSI, InstallScript MSI, MSI Database	Verifies that no precompiled .NET assemblies are being distributed.
ISBP12	Basic MSI, InstallScript MSI, MSI Database	Verifies that no file is self-registered.
ISBP13	Basic MSI, MSI Database	Verifies that properties set by dialog controls and used in the installation have a default value.
ISBP14	Basic MSI, InstallScript MSI, MSI Database	Verifies that each file has the correct version information or an MsiFileHash entry.
ISBP15	Basic MSI, MSI Database	Verifies that no RadioButtonGroup has Text defined.
ISBP16	Basic MSI, InstallScript MSI, MSI Database	Verifies that each component with a 64-bit destination is marked as a 64-bit component.
ISBP17	Basic MSI, InstallScript MSI, MSI Database	Verifies that no .hlp files or WinHelp run-time files are included in the installation.

Table 4-21 • ISBPs (cont.)

ISICE	Project	Description
ISBP18	Basic MSI, InstallScript MSI, MSI Database	Verifies that no obsolete APIs are imported.
ISBP19	Basic MSI, InstallScript MSI, MSI Database	Verifies that no deprecated APIs are imported.
ISBP20	Basic MSI, InstallScript MSI, MSI Database	Verifies that no registry entries contained in the Registry table attempt to remove root-level registry keys (such as HKLM\Software) or other keys that would cause adverse issues on target machines.

ISBP01

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
Feature ALL conflicts with the installation meta-feature ALL.
```

Description

ISBP01 verifies that your installation does not have a feature called **ALL** in uppercase, lowercase, or mixed case letters. In the context of features, Windows Installer reserves the word **ALL** for use as a valid value for feature-state properties such as **ADVERTISE**, **REINSTALL**, and **ADDLOCAL**, which can contain the names of specific features, as well as the word **ALL** to indicate all features. Therefore, none of the individual features in a project should be called **ALL**.

Corrective Action

To resolve this error, change the name of the feature to something other than ALL. For more information, see Creating Features.

You can also resolve this error by clicking the ISBP01 error message in the Output window. InstallShield displays the **Feature** table in Direct Editor view, and highlights the row that contains the feature named **ALL**. To rename the feature, select the current name and then type a new one.

ISBP02

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
Directory DATABASE conflicts with Windows Installer's undocumented directory DATABASE.
```

Description

ISBP02 verifies that your installation does not have a directory called **DATABASE** in uppercase, lowercase, or mixed case letters. Windows Installer reserves this directory name.

Corrective Action

To resolve this error, click the ISBP02 error message in the Output window. InstallShield displays the **Directory** table in Direct Editor view, and highlights the row that contains the directory named **DATABASE**. To rename the directory, select the current name and then type a new one.

ISBP03

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*

Message (Warning)

```
ComboBox [1] on Dialog [2] has a height less than 50. This results in a ComboBox too short to view
    multiple items at once.
```

[1] is the name of a combo box control, and [2] is the name of the dialog that has that control.

Description

If a combo box control has a height of less than 50 installer units, end users may be able to see only one item in the box at a time. To improve the usability, consider changing the height to 50 or higher.

Corrective Action

To resolve this warning, click the ISBP03 warning message in the Output window. InstallShield displays the **Control** table in Direct Editor view, and highlights the row that contains the combo box control. Then change the value in the Height column for that control to 50 or higher.

ISBP04

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*

Messages

Message 1 (Warning)

```
Dialog [1] Control [2] uses private property [3]. Its value will be unavailable to the execute
    sequence.
```

[1] is the name of a dialog in your project, [2] is the name of a control on that dialog, and [3] is the name of a private property that is being set or used by the control.

Message 2 (Warning)

```
Dialog [1] Control [2] uses insecure custom property [3]. Its value may be unavailable to the execute
    sequence.
```

[1] is the name of a dialog in your project, [2] is the name of a control on that dialog, and [3] is the name of a property that is used by that control.

Description

You cannot set a private property in the user interface sequence of the installation and then pass the value of that private property to the execute sequence. Therefore, ISBP04 verifies that your installation does not have any dialog controls that use private properties. If a dialog control does use a private property, warning 1 occurs to alert you that you may need to take steps to allow a property's value to be passed to the execute sequence.

In addition, if you set a public property in the user interface sequence of an installation that requests elevated privileges for the execute sequence, and you want to pass the property's value to the execute sequence, the property must be listed as a value for the **SecureCustomProperties** property, or it must be a restricted public property. Therefore, ISBP04 also verifies that if your installation has dialog controls that use custom public properties, the custom public properties are listed as values for the **SecureCustomProperties** property. If the custom public properties are not listed in the **SecureCustomProperties** property, warning 2 occurs to alert you that you may need to take steps to allow a property's value to be passed to the execute sequence.

Corrective Action

If you do not need to use the property in the execute sequence, you can disregard the warning message. However, if you do need to use the property in this sequence, you need to resolve the warning.

If you need to resolve warning 1, change the private property to a public property. To do so, find the dialog control in the Dialogs view; for the Property property of that control, use all uppercase letters, since public properties must be in all uppercase. Also update all other instances of that property name in your project so that it matches.

If you need to resolve warning 2, open the Property Manager view. For the Value column of the **SecureCustomProperties** property, add the name of the property that is mentioned in the warning message. If this property contains more than one property, separate each one with a semicolon (;).

ISBP05

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*

Message (Warning)

```
Dialog [1] Control [2] has a NULL condition. To ensure the control event always runs, use a condition
    of 1.
```

[1] is the name of a dialog in your project, and [2] is the name of a control on that dialog.

Description

ISBP05 verifies that each event's condition for each dialog control is not null. This helps to ensure that Windows Installer triggers the control's events under the proper circumstances.

Corrective Action

If Windows Installer should trigger the event that has a null condition only if no other event for that control is triggered, you can disregard the warning message.

If you do need to resolve this warning, locate the dialog in the Dialogs view. Click the Behavior item under the dialog. In the list of controls, click the one that is mentioned in the warning message. Ensure that in the lower-right pane, the Events tab is displayed. Then, in the grid in the upper-right pane, enter a condition for the event. To ensure that Windows Installer triggers the event, enter 1 as the condition.

ISBP06

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Warning)

```
Custom Action [1] is scheduled in the InstallUISequence but not the InstallExecuteSequence. It will
    not run during a silent or reduced UI installation.
```

[1] is the name of a custom action in your project.

Description

Actions that are scheduled for the Execute sequence during the Installation sequence do not run during silent, basic UI, or reduced UI installations.

Corrective Action

If Windows Installer should launch the custom action during silent, basic UI, and reduced UI installations, consider scheduling the custom action for the installation execute sequence—in addition to or instead of the installation UI sequence.

To reschedule the action, open the Custom Actions and Sequences view, and find the action mentioned in the warning message. Then drag it from the Installation sequence's User Interface sequence to the Installation sequence's Execute sequence.

To schedule the action in both sequences, copy the action in the Installation sequence's User Interface sequence to the Installation sequence's Execute sequence. You can do this in the Custom Actions and Sequences view by pressing and holding CTRL while dragging the action from the former sequence to the latter sequence.

If Windows Installer should not launch the custom action during silent, basic UI, and reduced UI installations, you can ignore this warning.

ISBP07

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Warning)

```
Feature [1] has no components.
```

[1] is the name of a feature in your project.

Message 2 (Warning)

```
Component [1] is not associated with any features.
```

[1] is the name of a component in your project.

Description

ISBP07 verifies that every component in your project belongs to at least one feature. If you do not associate a component with at least one feature, Windows Installer cannot install the component.

ISBP07 also verifies that every feature in your project contains at least one component. Components contain the installation elements, such as files, shortcuts, and registry entries; if a feature does not contain a component, it does not contain anything to install.

Corrective Action

To resolve either of these warnings, use the Setup Design view to associate components with features. To learn more, see Associating Existing Components with Features.

ISBP08

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Warning)

```
There does not appear to be a Type 51 action setting ARPINSTALLLOCATION after CostFinalize in the
    InstallExecuteSequence.
```

Description

The **ARPINSTALLLOCATION** property specifies the fully qualified path to the primary destination folder of a product. Windows Installer writes this value to the Uninstall registry key.

The **ARPINSTALLLOCATION** property is typically set by a set-a-property type of custom action (type 51).

The SetARPINSTALLLOCATION custom action is a built-in InstallShield custom action that is added automatically to Basic MSI and InstallScript MSI projects. If you delete this custom action from your project, you may encounter the ISBP08 warning.

Corrective Action

To resolve this warning, add to your project a custom action with the following settings:

- Property Name: ARPINSTALLLOCATION
- Property Value: [INSTALLDIR]
- Execution Scheduling: Always execute
- Install Exec Sequence: After CostFinalize

  

  Note • *As a best practice, any actions after CostFinalize should be sequenced after MigrateFeatureStates when feature migration is selected on a major upgrade item.*

- Install Exec Condition: Not Installed

Leave the default values for all of the other settings.

For more information, see Creating Custom Actions in the Custom Actions and Sequences View (or the Custom Actions View).

ISBP09

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
The property LIMITUI has been set, but ARPNOMODIFY has not. This can lead to undesirable behavior
    with Add or Remove Programs.
```

Description

If you set the **LIMITUI** property in an installation, you should also set the **ARPNOMODIFY** property.

The **LIMITUI** property sets the user interface level to basic. An installation run with a basic UI typically displays only progress messages to end users. It does not allow end users to select features or provide other feedback.

The **ARPNOMODIFY** property prevents end users from modifying the product through Add or Remove Programs.

Corrective Action

To resolve this error, add the **ARPNOMODIFY** property to your project through the Property Manager view, and set its value to 1. For more information, see Creating Properties.

ISBP10

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Warning)

```
AppSearch [1] uses insecure custom property [2]. Its value may be unavailable to the execute
    sequence.
```

[1] is the name of a system search in your project, and [2] is the name of a property that is used by that system search.

Description

If you set a public property in the user interface sequence of an installation that requests elevated privileges for the execute sequence, and you want to pass the property's value to the execute sequence, the property must be listed as values for the **SecureCustomProperties** property, or it must be a restricted public property. Therefore, ISBP10 verifies that if the AppSearch table in your project contains custom public properties, the custom public properties are listed as values for the **SecureCustomProperties** property. If the custom public properties are not listed in the **SecureCustomProperties** property, the warning occurs to alert you that you may need to take steps to allow a property's value to be passed to the execute sequence.

Corrective Action

If you do not need to use the property in the execute sequence, you can disregard the warning message. However, if you do need to use the property in this sequence, you need to resolve the warning.

To resolve this warning, open the Property Manager view. For the Value column of the **SecureCustomProperties** property, add the name of the property that is mentioned in the warning message. If this property contains more than one property, separate each one with a semicolon (;).

ISBP11

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Warning)

```
File [1] appears to be a precompiled native image of a .NET assembly. This may decrease the
    efficiency compared to precompiling on the target machine.
```

[1] is the name of a precompiled native image (.ni) of a .NET assembly.

Description

ISBP11 verifies that your project does not include a precompiled native image of a .NET assembly.

Corrective Action

To resolve this warning, replace the native image file mentioned in the message with the appropriate .NET assembly file.

If you want the assembly to be compiled to machine code during the installation, select Yes for the .NET Precompile Assembly setting of the file's component.

Precompilation, or just-in-time compilation, takes into account the fact that some code might never be called during execution. It converts the assembly as it is needed during execution and stores the resulting native code so it is accessible for subsequent calls. Precompiling on the target machine allows the process to take advantage of the exact architecture of the machine on which it will be running.

ISBP12

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
Custom Action '[1]' appears to invoke self-registration via RegSvr32. Best practices encourage
    authoring COM and Registry table data into the installer package.
```

[1] is the name of a custom action in your project that may be registering a file through `RegSvr32.exe` at installation time.

Message 2 (Error)

```
File '[1]' is self-registered. Best practices encourage authoring COM and Registry table data into
    the installer package.
```

[1] is the name of a file that is marked as self-registering.

Description

Although InstallShield lets you designate that a COM server is self-registering, the preferred method of registering a COM server is to extract the COM information from the file at build time or design time; with this method, InstallShield writes the COM class information to the **Class**, **ProgID**, and **Registry** tables of the .msi database. Self-registration has several limitations; for details, see Self-Registering COM Servers.

Corrective Action

To resolve error 1, remove the custom action that is referenced in the error message, and configure COM extraction for the file as appropriate.

To resolve error 2, configure COM extraction for the file as appropriate.

To learn more, see Extracting COM Information from a COM Server.

ISBP13

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*

Message (Error)

```
Property '[1]' has no default, is set by a dialog control, and is used in table [2]. This may not be
    populated in a silent or reduced UI installation.
```

[1] is the name of a property in your project, and [2] is the name of the table that uses that property.

Description

In most cases, each property in the **Property** table should have a default value. The default value is used if end users run the installation in silent, reduced UI, or basic UI mode.

Corrective Action

If you do not need to add a default value for the property, you can disregard the error message.

To resolve this error, open the Property Manager view. Enter a value in the Value column for the property that is specified in the error message.

ISBP14

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
File '[1]' has neither a file version nor an MsiFileHash record. This may require the source package
    when installing a patch.
```

[1] is the name of file in your project.

Message 2 (Error)

```
File '[1]' is recorded as version '[2]' but is actually version '[3]'. This may require the source
    package when installing a patch.
```

[1] is the name of file in your project. [2] is the version number that is configured for the file, but [3] is the actual version number.

Description

ISBP14 verifies that each file in the project has the correct version information or an MsiFileHash entry. Using the correct version information in versioned files and MsiFileHash entries for unversioned files helps Windows Installer to detect and eliminate unnecessary file copying. It also helps ensure that the source package is not required to apply a patch to an earlier version of a product.

Corrective Action

To resolve error 1, consider adding the file version number to the file. If the file is an unversioned file, configure the file so that a file hash is used.

InstallShield enables you to override a file's version information. Error 2 may occur if the file's properties were overridden. To resolve this error, consider removing the version override.

To configure the settings for a file, open the Files and Folders view. In the **Destination computer's files** pane, locate the file, right-click it, and click Properties. The Properties dialog box opens, enabling you to configure version information and specifying whether file hashing should be used.

ISBP15

Project • *This information applies to the following project types:*

- *Basic MSI*
- *MSI Database*

Message (Error)

```
Control [2] on the Dialog [1] is a borderless RadioButtonGroup with overlapping controls and data in
    the Text column. This may cause repaint issues on some systems.
```

Description

ISBP15 verifies that if you have a borderless radio button group control on a dialog and one or more other controls overlap the radio button group, the radio button group does not have anything specified for its Text attribute. If it does, it may cause repaint issues for some versions of Windows Installer.

Corrective Action

To resolve this error, click the ISBP15 error message in the Output window. InstallShield displays the **Control** table in Direct Editor view, and highlights the row that contains the radio button control that is mentioned in the error message. Delete the string in the Text column for that radio button control.

As an alternative, you can change the radio button group control so that it uses a border. To do this, open the Dialogs view and find the dialog mentioned in the error message. Click the radio button control, and change its Has Border property to True.

ISBP16

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
Component [1] installed to 64-bit location [2] is not marked with the 64-bit component attribute.
    This may allow files to be installed to an incorrect location.
```

[1] is the name of a component, and [2] is the destination folder for the component's files.

Description

If a component is not configured to be 64 bit, Windows Installer may not install the component's files to the appropriate 64-bit location.

Corrective Action

To specify that a component is 64 bit, select Yes for the component's 64-Bit Component setting.

For more information about the 64-Bit Component setting, as well as additional component settings, see Component Settings.

ISBP17

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
File [1] in Component [2] is a WinHelp file and may not be distributed to Windows Vista or later.
```

[1] is the name of an .hlp file in your project, and [2] is the name of the component that contains the .hlp file.

Message 2 (Error)

```
File [1] in Component [2] is a WinHelp run-time file and may not be distributed to Windows Vista or
    later.
```

[1] is the name of a Windows Help application file in your project, and [2] is the name of the component that contains that file.

Description

ISBP17 verifies that .hlp files are not included in your project because Windows Vista and later do not support this type of file.

In addition, ISBP17 verifies that `WinHlp32.exe` and `WinHelp.exe` are not included in the project because these applications should not be redistributed.

Corrective Action

To resolve this validation error, remove the help file from your project. Consider converting your help system to a different file format such as .chm, .htm, or .xml. Note that you would need to change your calls from the WinHelp API to the new help system.

ISBP18

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
File [1] in Component [2] imports obsolete API [3].
```

[1] is the name of a file in your project, and [2] is the name of the component that contains the file. [3] is the name of the obsolete API that the file uses.

Description

ISBP18 verifies that none of the .dll or .exe files in your project use obsolete kernel APIs.

Corrective Action

To resolve this validation error, replace the file with an updated version that does not use the obsolete API. Note that to create the updated version, you may need to rewrite and rebuild the .exe or .dll file. If the .exe or .dll file is from a third-party vendor, contact the vendor to request an updated version.

ISBP19

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Message (Error)

```
File [1] in Component [2] imports deprecated API [3].
```

[1] is the name of a file in your project, and [2] is the name of the component that contains the file. [3] is the name of the deprecated API that the file uses.

Description

ISBP19 verifies that none of the .dll or .exe files in your project use deprecated kernel APIs.

Corrective Action

To resolve this validation error, replace the file with an updated version that does not use the deprecated API. Note that to create the updated version, you may need to rewrite and rebuild the .exe or .dll file. If the .exe or .dll file is from a third-party vendor, contact the vendor to request an updated version.

ISBP20

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*

Messages

Message 1 (Error)

```
Registry entry [1] contains an asterisk in the Name column. This will cause Windows Installer to
    attempt to remove a root registry key [2].
```

[1] is the name in the **Registry** table's Registry column for the registry entry row that has the asterisk (*). [2] is the name of the registry key that would be removed during uninstallation.

Message 2 (Warning)

```
Registry entry [1] installs to a key that is not recommended for installation with software
    applications. Installing this entry could have an adverse effect on target machines ([2]).
```

[1] is the name in the **Registry** table's Registry column for the registry entry row that may cause issues on the target system. [2] is the name of the registry key.

Description

ISBP20 verifies that your project does not include any registry entries that would remove root-level registry keys such as HKEY_LOCAL_MACHINE\SOFTWARE if your product is removed from a target machine. The following table shows an example of some registry data that would cause issues during uninstallation; in this example, the entire HKEY_LOCAL_MACHINE\SOFTWARE, and all of its subkeys and values, would be removed.

Table 4-22 • Example of Registry Data that Triggers an ISBP20 Error

Registry	Root	Key	Name	Value	Component
Registry2	2	SOFTWARE	*		MyComponent

ISBP20 also verifies that your project does not include other registry entries that would cause adverse issues on target machines.

Corrective Action

To resolve the validation error or warning, click the ISBP20 message in the Output window. InstallShield displays the **Registry** table in Direct Editor view, and highlights the row that contains the potentially problematic registry entry. To delete the registry entry, right-click the row and then click Drop Row(s).

Understanding When an Installation or Uninstallation Restarts the Target System

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI—if the InstallScript user interface (UI) style is the traditional style (which uses the InstallScript engine as an external UI handler)*

This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the new style (which uses the InstallScript engine as an embedded UI handler). To learn more, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

The BATCH_INSTALL system variable is set to a non-zero value to indicate that one or more operations need to be performed after the target system restarts. For example, BATCH_INSTALL can be set to a non-zero value if the installation determines that a file cannot be installed because the file already exists on the target system and it is locked.

When a file in an installation cannot be installed because it is locked, the installation automatically notifies the operating system that the file needs to be updated the next time that the system restarts. Because the file may need to be updated before additional Windows files are loaded, it is updated when Windows is loaded; it is not updated by the InstallScript installation.

BATCH_INSTALL can be set during an uninstallation in order to remove locked files after the system restarts. However, after the reboot, the cached installation files are no longer present. Therefore, the only reboot-related operations that can occur are those that the operating system can perform.

If BATCH_INSTALL is set to a non-zero value when the file transfer finishes, the following occurs:

- The installation does not attempt to self-register any files. This is because it may be necessary for all of the installation's files to be completely installed and updated before the files can be self-registered successfully. Note that this is true regardless of whether the files that could not be installed are self-registering, since the installation assumes that these files could be dependencies of other self-registering files. In this case, the installation records the files that need to be self-registered so that after the restart, the installation can self-register those files.
- The framework automatically calls **SdFinishReboot** (in the OnFirstUIAfter or OnMaintUIAfter events) to give the end user the option of automatically restarting the system after the installation completes.
- When the installation finishes, it creates an appropriate RunOnce registry value so that the installation runs after the restart; after the restart, the installation is run with the `/reboot` parameter.

  If the ALLUSERS script variable is set to 1, the RunOnce entry is created under HKEY_LOCAL_MACHINE; otherwise, the entry is created under HKEY_CURRENT_USER. Windows supports RunOnce entries under both of these locations.

  The RunOnce registry value's name is **InstallShield Setup %n**, where **%n** is the lowest integer available to make a unique key name. The registry value's data is the complete command line for the installation to run after restart; the command line includes the path and file name of `Setup.exe`.

  After restart, the installation is run from the installed Disk1 location—DISK1TARGET. Thus, for the installation to run after restart, the Disk1 files for the installation must be currently installed.

  Note that this does not apply to an uninstallation, since after the restart, the cached installation files are no longer present.

When the installation runs after the restart (that is, when it runs with the `/reboot` parameter), the following occurs:

- Any self-registering files that were noted by the installation as needing to be registered are registered.
- The **OnRebooted** event handler is called.

Note that for an uninstallation, the installation does not run after the restart; therefore none of these operations can occur.

Debugging Windows Installer–Based Installations

You can debug a Windows Installer–based release using the MSI Debugger. The MSI Debugger enables you to view and set Windows Installer properties as you step through the package's User Interface and Execute sequences.

The MSI Debugger runs through each action and dialog until it reaches your breakpoint, at which point it halts execution. Now, you can view and set properties in the Watch window and the Variable window. Finally, you can step through each of the remaining actions, or you can stop the debugger.

Note • *Do not confuse the MSI Debugger with the InstallScript Debugger, since they have completely separate purposes. You cannot debug an installation package with the InstallScript Debugger, and you cannot debug an InstallScript custom action with the MSI Debugger.*

Starting the MSI Debugger

Before starting the MSI Debugger, you must have built a release and opened the MSI Debugger view in InstallShield. In addition, you should always set a breakpoint so that you can view the state of the installation at a particular action or dialog.

When you open the MSI Debugger and begin debugging, it acts on the release that currently has focus in the Releases view. If you have not yet built the release or if the release is compressed into `Setup.exe`, the debugger is blank and its toolbar and menu items are disabled. Switch to a built release or rebuild with the required options to debug the package.

Task: ***To start debugging, do one of the following:***

- Click the **MSI Debugging** button on the MSI Debugger toolbar.
- Click the **Step Over** button on the MSI Debugger toolbar.
- On the **Build** menu, point to **MSI Debugger** and click **Start MSI Debugging**.
- On the **Build** menu, point to **MSI Debugger** and click **Step Over**.
- Press F5.
- Press F11.

The debugger runs the installation, returns focus to itself, and stops the execution of the installation when it reaches the breakpoint. Back in the debugger, you can do any of the following:

- View and set Windows Installer properties.
- Step through the rest of the installation.
- Exit the debugger and/or the installation.

Setting Breakpoints in the MSI Debugger

Task: ***To set a breakpoint in the MSI Debugger:***

1. In the **Releases** view, select the release you want to debug.
2. Open the **MSI Debugger** view. The debugger displays two lists: first every standard and custom action in the User Interface sequence, and then every dialog in the installation.

3. Place the cursor on the line that contains the action or dialog on which you want the debugger to break.
4. Do one of the following to set the breakpoint on that line:
   - Click the **Toggle Breakpoint** button on the MSI Debugger toolbar.
   - On the **Build** menu, point to **MSI Debugger** and click **Toggle Breakpoint**.
   - Press F9.

You can set the breakpoint before you start debugging or while a debugging session is open.

When the debugger reaches the breakpoint, you can view and set properties or continue debugging.

Tip • *Notice that the debugger lists the condition, if any, after each action. Set breakpoints carefully on conditional actions, because if the condition does not evaluate to true, the action is not executed and the debugger will not step in at that point.*

Removing Breakpoints

Task: ***To remove a breakpoint:***

1. In the View List under **Additional Tools**, click **MSI Debugger**.
2. Place the cursor in a line with a breakpoint and click the **Toggle Breakpoint** button or press F9 to remove it.

Task: ***To clear all breakpoints set in the debugger, do one of the following:***

- Click the **Remove All Breakpoints** button.
- Press SHIFT+F9.

Viewing and Setting Properties in the MSI Debugger

When the debugger stops at a breakpoint or at an action or dialog because you are stepping through the installation, you can view Windows Installer properties and change their values at run time in the Watch window or the Variable window.

The Variable Window

The Variable window displays every property in the database's **Property** table—exposed in InstallShield through Property Manager View—and its current value.

To change a property's value as the installation is running, edit the **Property Value** column.

If you do not see the Variable window, click Variable on the View menu.

The Watch Window

You can enter the name of any property in the Watch window to check its value at any point in the installation. For example, enter `TARGETDIR` in the name column to see what TARGETDIR resolves to at run time.

To change the property's value as the installation is running, edit the **Property Value** column.

If you do not see the Watch window, click Watch on the View menu.

Step Into Actions in the MSI Debugger

You can debug your code when you step into the custom action in the MSI Debugger. You can launch your registered debugger when you step into one of the following types of custom actions:

- Windows Installer .dll file custom action
- Standard .dll file custom action
- Visual Basic Script or JavaScript custom action
- InstallScript custom action

Task: ***To step into the current action in the MSI Debugger, do any of the following:***

- Click the **Step Into** button on the MSI Debugger toolbar.
- On the **Build** menu, point to **MSI Debugger** and click **Step Into**.
- Press F11.

A dialog box opens and asks if you want to launch your registered debugger. Select Yes to launch the deubugger. Select No to step over to the next custom action.

Note • *Because InstallShield does not provide the source code for the entry point, you will see some machine code once the registered debugger is launched. You need to click the Step Into button twice to see your code.*

Step Through Actions in the MSI Debugger

Task: ***To step over the current action or dialog and continue the execution in the MSI Debugger, do any of the following:***

- Click the **Step Over** button on the MSI Debugger toolbar.
- On the **Build** menu, point to **MSI Debugger** and click **Step Over**.
- Press F10.

Once the debugger reaches a breakpoint on a standard or custom action, it halts the execution of the installation and receives focus. You can then watch and set installer properties.

To continue stepping through each successive action, keep pressing F10. You may need to click Next on each dialog in the Setup wizard to progress through the sequence. To view the return value of an action, place the cursor over the action after it has executed. The return value is displayed as a tooltip. If the action executed successfully, the tool tip reads ERROR_SUCCESS.

Although setting a breakpoint on an action causes the debugger to break at each subsequent action, setting a breakpoint on a dialog takes you just to that dialog and then the debugger does not step in again until the next breakpoint.

Stopping the MSI Debugger

Task: ***To discontinue debugging a release, do one of the following:***

- Click the **Stop Debugger** button on the MSI Debugger toolbar.
- On the **Build** menu, point to **MSI Debugger** and click **Stop MSI Debugging**.
- Press SHIFT+F5.

If the debugger is stopped at a break point on a dialog when you try to end the debugging session, InstallShield displays a message box with this message: “Please close all the dialogs to stop the debugging session.” To close any open dialogs, first press F11 to step over the current breakpoint. Then, close any open dialogs.

Canceling out of the installation also stops the debugger.

Spanning Installations over Multiple Disks or CDs

As programs become larger, the need for disk spanning increases. Years ago, this meant shipping your product on multiple floppy disks. The standard is now to use CD-ROMs or DVDs. Although the storage space on a CD or on a DVD is significantly more than what is available on a floppy disk, many products require even more space. Multimedia tutorials, vast help libraries, and graphic-rich programs can result in a product that is larger than 650 MB—the size of a standard CD.

If your installation requires more than one CD, DVD, or custom-sized media disk, you need to span it across multiple disks.

Using the Release Wizard

The only way to define how your installation spans across multiple disks is to use the Release Wizard. The wizard’s panels walk you through the process of creating your release for any size media that you choose, and it lets you specify how your files will span across multiple disks. You can also specify the compression to apply to these files.

The wizard offers you the choice of having InstallShield automatically span your installation across disks, if necessary, or you can customize how you want your installation files to be split. If you plan on customizing the way your installation spans across multiple disks, refer to Disk Spanning Rules to reduce problems with your installation.

Limitations

Due to limitations of the Windows Installer service, you cannot run multi-disk installations on a non-removable drive. For example, if your installation spans two CDs, you need to physically burn the CDs in order to test your installation. If you try to run it from a fixed drive, the installation will fail.

Compressing Multi-Disk Installations

Because neither `Setup.exe` nor your .msi file can be spanned across multiple disks, your source files need to be kept separate from these files. If you create a network installation, which has unlimited size, and specify that all the files should be compressed, these files are placed inside the .msi file or inside `Setup.exe` if you elected to create one. All other media types put `Setup.exe`, your .msi file, and the .cab files that contain all of your source files separately on the media.

For example, you might have an installation that contains three features—each containing a 1.5 MB file, `Setup.exe`, and the installation files for Windows NT—and you want to create a custom media type that is 2 MB in size. The build will span multiple disks. Disk one will contain `Setup.exe`, `InstMsiW.exe` (which contains the logic to install the Windows Installer service on Windows NT machines), `Setup.ini` (which is required for installations that include `Setup.exe`), and your .msi file. The remaining disks will contain .cab files that store compressed copies of all your source files.

Disk Spanning Rules

You can elect to have the Release Wizard automatically span your installation across as many disks as required. The wizard adheres to the following rules, which all multi-disk installations must follow. If you plan to customize how your installation spans across multiple disks, follow these rules:

- **Setup.exe must be on disk one.** This rule is applicable if you want to ship your installation on floppy disks and you need to ship `Setup.exe`. The size of `Setup.exe`—depending on whether you choose one for Windows 9x, Windows NT, or both—can be 1.31 MB to 2.58 MB in size. The installation file for the Windows Installer service is included in the build as well. This file—called `InstMsiW.exe` or `InstMsiA.exe`, depending on the platform you choose—must also reside on disk one.
- **The second file that must be included on disk one is the .msi file that you are building.** The total combined size of the .msi file, `Setup.exe`, and the Windows Installer installation files exceeds the maximum capacity of a standard 1.4 MB floppy disk. You have two options if you plan to distribute your setup on floppy disks:
  - You can distribute your installation without `Setup.exe`. This option is not available if you are creating an InstallScript MSI project.
  - The second and most feasible option is to use a distribution medium other than floppy disks.

- **Any transforms included in your installation must reside on the first disk.** For example, if you create an installation with multiple run-time languages, an .mst file is created for each of those languages. This file is applied to the installation database, and it provides the language selected in the Language Selection dialog.
- **Redistributables (including merge modules) included in your installation must be stored on the first disk.** Redistributables are streamed into the installation database while the script is built. This process cannot be completed if the redistributables are located on another disk.

Custom Disk Spanning

In the Release Wizard, you will come across a panel that asks you how you would like to handle disk spanning. You can choose to let the wizard automatically span your installation across disks if necessary, or you can manually define the disk spanning. Although you cannot indicate where every file is placed, you can define the disk on which each feature resides. Components and files are automatically placed on the same disk as their feature. There are other guidelines that InstallShield automatically follows, whether you choose to define the layout or let the wizard do it for you.

In addition to defining the features that reside on each disk, you can customize the volume label for each disk, create your own disk prompts, and choose to have the wizard enforce the size of your disks. The step-by-step instructions for customizing your disk layout are outlined in the Release Wizard documentation.

Disk Prompts

Disk prompts are displayed to end users when they need to place another disk in the drive to continue with the installation. Although a standard disk prompt is provided, you can provide a prompt that is specific to your product.

The string that is displayed actually comes from a number of sources throughout your project, as described below:

1. The complete prompt originates in the **Error** table (exposed in the Direct Editor) as error 1302.
2. This value comes from the project's list of string entries, and the default value for English is "Please insert the disk: *[2]*."
3. Windows Installer resolves *[2]* with the value of the property **DiskPrompt**, which is set to *[1]* in the Property Manager.
4. Finally, Windows Installer evaluates *[1]* to the string you enter into the Disk Prompt field.

In most cases, you will want to enter the same name as the disk volume. For example, assuming the defaults are unchanged, a Disk Prompt entry of **Disk8** would cause the user to be prompted with "Please enter the disk: Disk8."

You can use a question mark where the disk number will be displayed. This question mark automatically evaluates to the correct disk number. If you want to prompt your users with, "Please insert the disk: DISK4," you would enter `DISK?` for the fourth disk's name. You need to specify the disk prompt for each disk in your installation.

Volume Labels

The volume label is the name of the disk on which your installation resides. When the installation calls for a new disk, the Windows Installer engine verifies that the volume label of the disk matches the volume label that is stored in the installation database. If the labels do not match, the service assumes that the wrong disk has been inserted in the drive. You can change the volume label when you customize your disk spanning options. The default volume

label is DISK1, DISK2, DISK3, and so on. When you build your installation, you will see these directories created in your output location. The disks on which you put your setup need to have the volume labels set to the same names as given by the wizard.

Caution • *You cannot change a volume label after the installation has been built. If you do not specify the correct volume label, the Windows Installer service will not recognize the disk and the installation will fail.*

You can use a question mark to define the number of the disk. For example, if you want to set the volume label for your disks to **InstallShield Disk 1**, **InstallShield Disk 2**, and so on, you would rename every disk so that they read `InstallShield Disk ?`. At build time, this question mark evaluates to the disk number.

Enforce Disk Size

The Enforce Disk Size option helps you to ensure that your current layout fits on the disks that you have specified. If this option is not selected, and any disk that you want to create goes over the size of the media that you selected, the wizard automatically creates another disk and splits your features accordingly. If you select this option and the disk size exceeds the media size, the build will fail and you will receive build error 1531. You can then go back and trim down your feature size or try a different layout strategy.

Additional Information

If you add features to your installation after you have defined how you want your installation to span across multiple disks, those features are automatically added to the last disk of your installation. You can add new disks to your installation at any time by using the Release Wizard.

Creating a Setup Launcher

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Note that InstallScript installations always include a setup launcher.

Advanced UI and Suite/Advanced UI installations also always creates a setup launcher; they run .msi, .msp, InstallScript, and .exe packages. To learn more, see Creating Advanced UI and Suite/Advanced UI Installations.

InstallShield lets you specify whether you want your installation to include a `Setup.exe` setup launcher. A `Setup.exe` setup launcher is required in the following cases:

- You want to automatically update or install the Windows Installer engine on a target system, when necessary.
- You are building a multilanguage installation project and you want the language selection dialog to be displayed.
- Your project includes InstallShield prerequisites.
- Your project includes the .NET Framework.

- You are building a release for an InstallScript MSI project and it uses the traditional style for the user interface.
- You are building a release whose product configuration includes support for installing multiple instances of a product and you want the instance selection dialog to be displayed when appropriate.
- You are building a release for a Basic MSI project that includes billboards.

The `Setup.exe` setup launcher is a bootstrap application that manages the aforementioned scenarios.

The Setup.exe tab for a release in the Releases view is where you specify information such as whether you want to use a `Setup.exe` launcher. To learn more, see Setup.exe Tab for a Release.

Tip • *You can also specify setup launcher requirements in the Setup Launcher panel of the Release Wizard.*

Windows Installer and Setup.exe

If it is possible that Windows Installer is not present on a target system, or if your installation depends on certain functionality that is available in only a certain version of Windows Installer, InstallShield gives you the option of including with your installation a redistributable that installs Windows Installer. If you select this option, InstallShield creates a `Setup.exe` launcher that checks for the presence of Windows Installer on the target system. If Windows Installer is not installed, or a more recent version needs to be installed, `Setup.exe` launches the Windows Installer installation and then launches your installation package.

For more information, see Adding Windows Installer Redistributables to Projects.

Multilanguage Support and Setup.exe

Depending on your selections in the language-related settings on the Build tab for a release in the Releases view, `Setup.exe` also gives end users a choice of the language in which to run the installation.

If you plan to distribute your installation in more than one language, `Setup.exe` is required whenever you want to provide end users the option of selecting which language version of the installation they would like to run. To learn more about multilanguage support, see Creating Multilingual Installations.

InstallShield Prerequisites and Setup.exe

Projects that include InstallShield prerequisites require `Setup.exe` because `Setup.exe` checks to see if the target system meets the InstallShield prerequisite conditions. If the conditions are met, `Setup.exe` installs the InstallShield prerequisites. For more details, see Working with InstallShield Prerequisites that Are Included in Installation Projects.

.NET Framework and Setup.exe

Projects that include the .NET Framework require `Setup.exe` because `Setup.exe` checks the target system for the presence of the .NET Framework; if the appropriate version of the .NET Framework is not present, `Setup.exe` installs it.

To learn more about including the .NET Framework, see Adding .NET Framework Redistributables to Projects.

InstallScript MSI Projects and Setup.exe

The traditional-style InstallScript MSI installations require `Setup.exe` because `Setup.exe` initiates the InstallScript engine to display the user interface. For this traditional style, the InstallScript engine serves as an external UI handler.

Note that if you use the new style of UI for an InstallScript MSI installation, InstallShield embeds the InstallScript engine within the .msi package, and a setup launcher is not required.

For detailed information about these two styles, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

Multiple-Instance Support and Setup.exe

If you are configuring your product to allow end users to install your product multiple times in each context on a target system, the `Setup.exe` setup launcher must be used if you want the instance selection dialog to be displayed when appropriate. The `Setup.exe` file displays the instance selection dialog.

To learn more about multiple-instance support, see Installing Multiple Instances of Products.

Billboards and Setup.exe

Basic MSI projects that include billboards require `Setup.exe` because `Setup.exe` displays the billboards at run time.

For more information about billboards, see Displaying Billboards in Basic MSI Installations.

Customizing File Properties for the Setup Launcher

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *Suite/Advanced UI*

Note that project-specific differences are noted where applicable.

InstallShield lets you use custom information for the version resources of the `Setup.exe` setup launcher. The information is displayed on the Properties dialog box for the setup launcher; this Properties dialog box opens when end users right-click the `Setup.exe` file and then click Properties.

Settings in InstallShield that Let You Configure Setup.exe Properties

The following table lists various properties that Windows includes on the Properties dialog box, along with the corresponding settings in InstallShield that you can use to configure them.

Note • *The Properties dialog box is different on different versions of Windows. For example, on Windows 7 systems, the version resource information is displayed on the Details tab of the Properties dialog box. However, on Windows XP systems, the version resource information is displayed on the Version tab of that dialog box.*

Also note that some versions of Windows do not show some settings on the Properties dialog box.

Table 4-23 • Source of Information for Setup.exe Properties

Setup.exe Property	InstallShield Setting that Configures the Setup.exe Property
Company Name	The setting that contains the value for this field varies, depending on the project type that you are using. • In Basic MSI and InstallScript MSI projects: Publisher setting in the General Information view. • In InstallScript projects: Company Name setting in the General Information view. • In Advanced UI and Suite/Advanced UI projects: InstallShield uses either a custom value that you provide, or a default InstallShield-specific name. If you want InstallShield to use your own custom value for the company field in an Advanced UI or Suite/Advanced UI project: 1. In the **Releases** view, select the release that you want to configure. 2. On the **Setup.exe** tab, in the **Use Custom Version Properties** setting, select **Yes**. 3. In the **Company** setting, enter the text that you want to use for the company field in the properties of your `Setup.exe` file. If you select No for the Use Custom Version Properties setting or you leave the Company setting blank, InstallShield uses the Publisher setting in the General Information view. If that setting is blank, InstallShield uses the default InstallShield-specific name.
Product Name	The setting that contains the value for this field varies, depending on the project type that you are using. • In Basic MSI and InstallScript MSI projects: Product Name setting for the product configuration in the Releases view. If that setting is blank, InstallShield uses the Product Name setting in the General Information view. • In Advanced UI, InstallScript, and Suite/Advanced UI projects: Product Name setting in the General Information view.

Table 4-23 • Source of Information for Setup.exe Properties (cont.)

Setup.exe Property	InstallShield Setting that Configures the Setup.exe Property
Product Version and File Version	The setting that contains the value for these fields varies, depending on the project type that you are using. • In Basic MSI and InstallScript MSI projects: Product Version setting for the product configuration in the Releases view. If that setting is blank, InstallShield uses the Product Version setting in the General Information view. • In InstallScript projects: Product Version setting in the General Information view. • In Advanced UI and Suite/Advanced UI projects: Product Version setting in the General Information view. You can use the Releases view to override this value. Note that the file version always contains four fields. If you specify fewer than four fields for your product version, the remaining fields are filled with zeros. For example, if you specify a product version of **1.1**, the file version that is used in the version resources of `Setup.exe` is **1.1.0.0**. If you want to override the value in the General Information view in an Advanced UI or Suite/Advanced UI project: 1. In the **Releases** view, select the release that you want to configure. 2. On the **Setup.exe** tab, in the **Use Custom Version Properties** setting, select **Yes**. 3. In the **Version** setting, enter the value that you want to use for the version fields in the properties of your `Setup.exe` file. If you select No for the Use Custom Version Properties setting or you leave the Version setting blank, InstallShield uses the Version setting in the General Information view. If that setting is blank, InstallShield uses the default InstallShield-specific values.

Table 4-23 • Source of Information for Setup.exe Properties (cont.)

Setup.exe Property	InstallShield Setting that Configures the Setup.exe Property
Copyright	InstallShield uses either a custom value that you provide, or the default InstallShield copyright notice. If you want InstallShield to use your own custom value for the copyright field: 1. In the **Releases** view, select the release that you want to configure. 2. On the **Setup.exe** tab, in the **Use Custom Version Properties** setting, select **Yes**. 3. In the **Launcher Copyright** setting, enter the text that you want to use for the copyright field in the properties of your `Setup.exe` file. If you select No for the Use Custom Version Properties setting or you leave the Launcher Copyright setting blank, InstallShield uses the default InstallShield copyright notice.
File Description	InstallShield uses either a custom value that you provide, or the default InstallShield `Setup.exe` description. If you want InstallShield to use your own custom value for the description field: 1. In the **Releases** view, select the release that you want to configure. 2. On the **Setup.exe** tab, in the **Use Custom Version Properties** setting, select **Yes**. 3. In the **File Description** setting, enter the text that you want to use for the description field in the properties of your `Setup.exe` file.  ***Project*** • *In an Advanced UI, InstallScript, or Suite/Advanced UI project—If you select No for the Use Custom Version Properties setting or you leave the File Description setting blank, InstallShield uses the default InstallShield `Setup.exe` description.* *In a Basic MSI or InstallScript MSI project—If you select No for the Use Custom Version Properties setting, InstallShield uses the default InstallShield `Setup.exe` description. If you select Yes but leave the File Description setting blank, InstallShield uses the value for the Comments setting of the product configuration in the Releases view. If that setting is blank, InstallShield uses the Summary Information Stream Comments setting in the General Information view. If that setting is blank, InstallShield uses the default InstallShield `Setup.exe` description.*
Language	For this field, InstallShield uses the language that is specified in the Default Language setting for the release in the Releases view that you are building.

Sample Setup.exe Properties Dialog Boxes

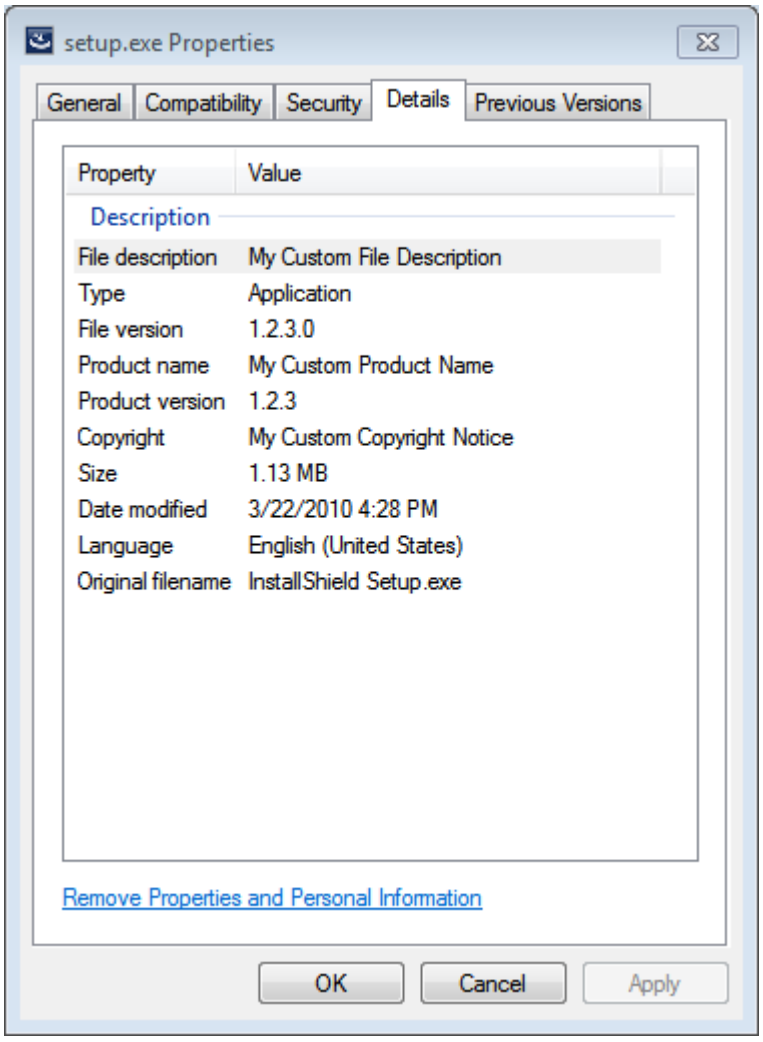

Figure 4-2: Sample Properties for Setup.exe on a Windows 7 Machine

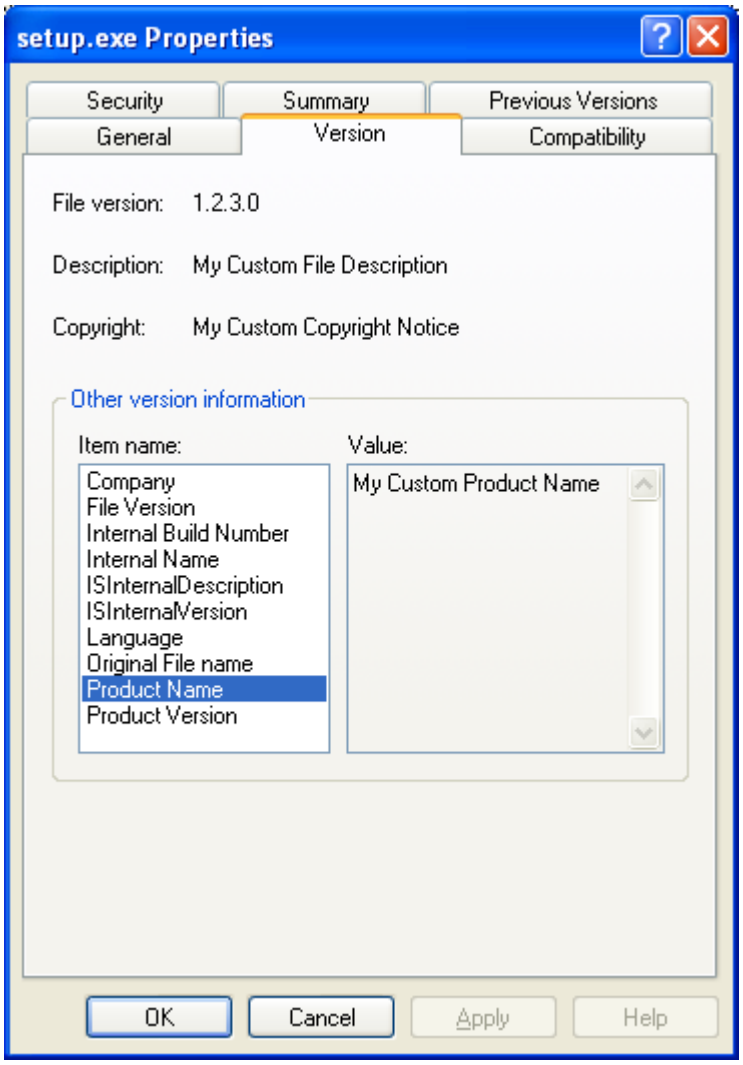

Figure 4-3: Sample Properties for Setup.exe on a Windows XP Machine

Specifying the Icon for the Setup Launcher

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *Suite/Advanced UI*

InstallShield lets you specify the icon that should be used for your `Setup.exe` setup launcher. The icon can be in an .exe, .dll, or .ico file.

End users can see this icon when they view your `Setup.exe` file in Windows Explorer. The icon is also displayed on the Properties dialog box for `Setup.exe`; this Properties dialog box opens when end users right-click the `Setup.exe` file and then click Properties.

If you do not specify an icon, InstallShield uses a default icon for your `Setup.exe` file.

Task: ***To specify the icon for your Setup.exe file:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, select the release that you want to configure.
3. Click the **Setup.exe** tab.
4. In the **Setup.exe Icon File** setting, specify the fully qualified name of the file that contains the icon that InstallShield should use when it creates the `Setup.exe` file at build time.

   To specify a file, type an explicit path or path variable, or click the ellipsis button (**...**) to open the **Change Icon** dialog box, in which you can click the **Browse** button to select a file.

   By default, the icon with index 0 is used; to specify a different icon, either select an icon in the **Change Icon** dialog box or append the icon's index or resource ID (preceded by a minus sign) to the file name. For example, **C:\Temp\MyLibrary.dll,2** indicates the icon with an index of 2, and **C:\Temp\MyLibrary.dll,-100** indicates the icon with a resource ID of 100.

The next time that you build the release, InstallShield uses the icon that you specified for your `Setup.exe` file.

Distributing Installations

Once you have created your installation, you may need to distribute it to a specified location. This location can be a network drive, a CD, a different location on a local drive, or an FTP site. When you distribute your installation, the disk image created when you built your installation is copied to the location that you specify.

Distributing Releases to a Folder or FTP Site Automatically

When your release is built and tested, the only remaining task is to distribute it to the appropriate location. You can manually copy your release to the appropriate location, or you can use the Events tab in the Releases view to configure the release so that InstallShield automatically copies the release to the appropriate location—a local or network location, or an FTP site.

Task: ***To configure InstallShield to automatically distribute your release to a particular location:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, select the release that you want to configure.

3. Click the **Events** tab.
4. Configure the settings as appropriate. To learn more about the settings on the **Events** tab, see Events Tab for a Release.

Note *• If your installation consists of only one disk, the contents of the Disk1 folder are copied to the release location, but not the folder itself. If your installation spans across multiple disks, the folders and their contents are copied to the release location.*

Project *• For InstallScript and InstallScript Object projects, InstallShield automatically copies the release to the location that you specify on the Events tab every time that you build the release.*

For any of the following project types, InstallShield copies all of the relevant files for your release to the specified location whenever you right-click the release in the Releases view and then click Distribute:

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

If you specify a folder and an FTP site on the Events tab, InstallShield copies the files to only the FTP location.

If you want the build engine to copy your release to the specified location after every build in a Basic MSI, InstallScript MSI, or Merge Module project, select Yes for the Distribute After Build setting.

Preparing Installations for Internet Distribution

The way in which consumers receive software is rapidly changing. Before the advances in Internet technology and the introduction of high-speed connections, all software was shipped on some type of removable medium, such as floppy disks or CD-ROMs. Today, many people download their software directly from the Internet. In order to take advantage of this time- and money-saving software distribution process, you must package your installation in an easily downloadable and installable manner.

There are several criteria that your Web-ready installation may need to meet:

Compressed Size

Although many people now connect to the Internet through high-speed cable modems or DSL lines, others still use lower-speed modems. Package size is very important to people with slower connections due to the increased amount of online time required to download an application.

Self-Extracting

Many file compression utilities require a special client-side application to decompress the application files. This need for another utility complicates the download and installation process for end users. To simplify the installation process, the compression utility that you use should be self-extracting so that no other application is required.

Digitally Signed

To make your customers feel more secure about downloading and installing your software, you can digitally sign your application package. The digital signature identifies you or your company to end users and assures them that the application code has not been altered or tampered with since publication. To learn how to digitally sign your application, see Digital Signing and Security.

To learn more about digital signatures, visit www.verisign.com.

Easy to Use

Perhaps the most important aspect of packaging your installation for Internet distribution is making it easy to use. Your end users may not want to specify a location where the installation files should be saved and then search their computer to locate those files. Instead, the installation should be seamlessly integrated into the compression package, requiring only one step to begin the installation.

Proxy Server Support

You may want to configure your installation to download certain files only if they are needed on the target system. For example, the Windows Installer engine, the .NET Framework, and some InstallShield prerequisites may already be present on some or most target systems. Instead of embedding these files in your installation (which would increase your overall installation size), you can configure your project so that only the ones that are needed are downloaded at run time.

If your end users access the Internet through a proxy server and your installation is configured to download files, the installation uses the system proxy settings that are manually configured in Internet Explorer during the download. This occurs even if another browser on the target system is the default browser.

Note that InstallShield does not include support for the Automatically Detect Settings functionality in Internet Explorer. (If end users have the Automatically Detect Settings check box selected in Internet Explorer for their LAN connection and the installation needs to download files, the installation fails because the files cannot be downloaded. If it is possible that your end users may have the Automatically Detect Settings check box selected in Internet Explorer for their LAN connections, you may want to embed all of the files in your installation rather than configure them to be downloaded; if the files are embedded, the failures can be avoided.) However, InstallShield does support the Automatic Configuration Script functionality that is set up for LAN connections in Internet Explorer.

Redistributable Files that Are Distributed with an InstallScript Installation

Project • *This information applies to InstallScript projects.*

The following files are automatically created by InstallShield and can be redistributed with your software distribution, as discussed in your End-User License Agreement.The media build automatically includes them as needed in your disk image folders.

Main Media Files

- data<2, 3, 4, …>.cab

- data1.cab
- data1.hdr
- ISSetup.dll
- layout.bin
- setup.exe
- setup.ini
- setup.inx

Optional Files

- setup.isn—Skin File
- setup.htm—One Click Install .htm page

Creating Trialware

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

Offering prospective customers a free trial version of your product can be a highly effective sales tool, but it carries the risk that some will abuse the privilege and continue to use the product without paying for it. InstallShield enables you to create a protected trialware version of your product without requiring you to modify the source code.

With the Trialware view, you can configure trialware settings for one or more of your product's executable files to protect your product from piracy. Using InstallShield to protect your product lets you do the following:

- Invest minimal time and expense to turn your product into trialware.
- Set firm expiration dates using sophisticated, flexible technology that blocks unauthorized extensions of trials.
- Specify hyperlinks that should be displayed in the trialware run-time dialogs, which are launched whenever end users launch a protected application. The hyperlinks direct users to Web pages that inform them, for example, how to purchase your product.

Types of Trialware

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

InstallShield offers one type of trialware to help you control unauthorized use of your product: Try and Die. InstallShield also enables you to build an unprotected release (that is, the product's installation is built without applying trialware protection).

Try and Die

Try and Die trialware lets you offer prospective customers a fully functional trial version of your product. After the predetermined trial limit has been reached on an end user's machine, the trial version expires, and it no longer runs on that machine.

Try and Die trialware is often used for distribution at trade shows. It is also sometimes used to protect beta versions of a product. If prospective customers want to buy the product and continue using it after the trial limit has been reached, they need to uninstall the Try and Die version and then install an unprotected version.

Unprotected Product

You can configure the trialware settings in your installation project and then later easily build a release of your product that does not have the trialware protection. You can use this non-trialware release if you want to test the installation of your product but you do not want to test the trialware run time. You can also distribute this release to customers who have finished evaluating your product and have decided to purchase it. For more information, see Excluding Trialware Protection from a Release.

How InstallShield Protects Trialware

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

The following sections explain the structure of applications and how they are protected when trialware protection is applied.

Unprotected Product

If an application is not protected with the trialware functionality available in InstallShield, the end user launches the main application file when starting the product. This main application may call subordinate applications and use data contained in data files.

The structure of a typical unprotected application is illustrated in the following diagram:

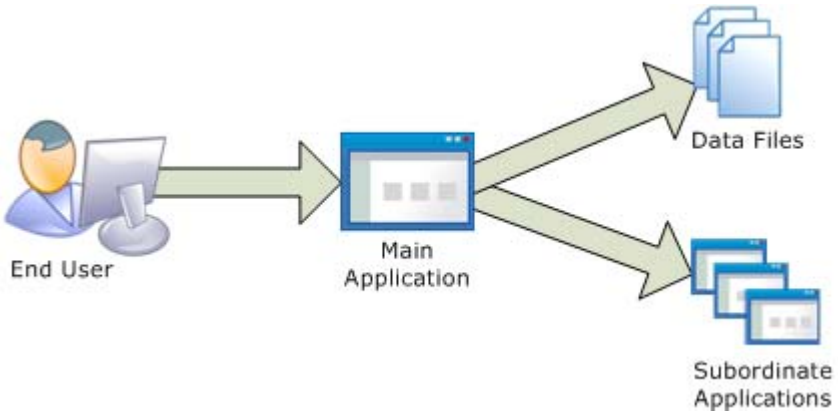

Figure 4-1: Unprotected product

Application Protected with Try and Die

If the installation for an application is built with the Try and Die functionality, the main application file (.exe, .dll, .ocx, or .scr) is protected by a Try and Die shell. This protection includes changes to the application code that prevent the application from being run directly. The application must be run by the shell in order to execute successfully. Subordinate applications can be either protected in the same way as the main application file or left unprotected. Shells can be used in this way to protect main application files and subordinate application files. The shell will run the product file (or product files, if more than one is protected) only if the trial limit has not been reached.

The Try and Die trialware protection is implemented as illustrated in the following diagram:

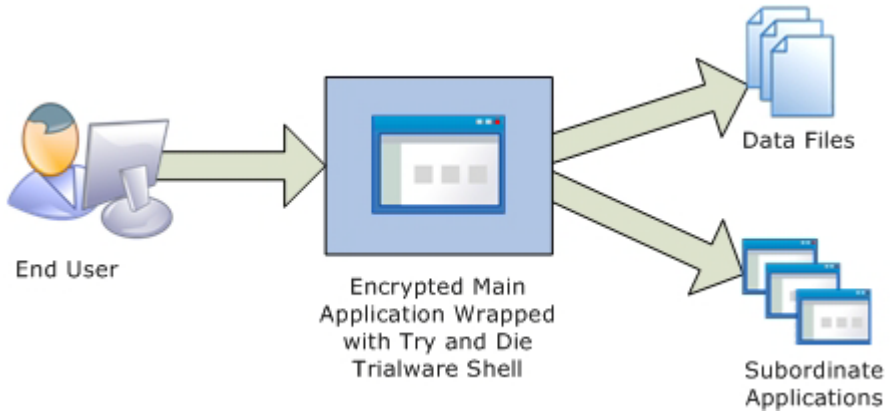

Figure 4-2: Product protected with a Try and Die shell

The addition of the Try and Die shell to the main application file does not change the file's version number or the file's last-modified date. However, it does increase the size of that file.

Trialware Technology

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

With the Trialware view, you can configure a license for trialware. InstallShield uses the license to wrap a trialware shell around your product's executable file (.exe, .dll, .ocx, or .scr file). The file can be unwrapped and used only according to the license settings that you configure, such as the trial limit (a specified number of days or a specified number of uses).

The trialware technology available in InstallShield should not be confused with freeware or shareware. Often freeware and shareware have limited functionality. For example, end users sometimes cannot print anything from shareware or freeware, or a watermark might be added to every page. Such limitations are established to encourage prospective customers to purchase a fully functional version of a product; however, building such limitations into your product can be costly and waste valuable development time.

With trialware, the only limitation is the time limit or the limited number of uses. You enable a prospective customer to use the latest version of your product—with all of its features fully available—on a trial basis. No dongle is used to limit or lock software access. After a predetermined trial limit has been reached, the trialware expires.

Licenses

Trialware technology actually involves two types of licenses: a license that wraps the protected executable file and a license that identifies a protected trialware product on the end user's machine. Both types of license are associated with each other by a license number, and the term *license* is used to refer to both types of licenses.

When you create trialware with InstallShield, you acquire a unique license for your product. The license is downloaded from the license server to your machine, and it is stored in your InstallShield project file.

InstallShield uses the license to wrap a trialware shell around your product's application file. The application file can be unwrapped and used only according to the license settings that you configure.

When an end user runs your trialware for the first time on their machine, the trialware stores a license in both a license file and an anchor. Both must be present on a system to allow licensing to work. The anchor is stored in an operating system–specific location to hinder end users from trying to reset the license state by simply deleting the license file. This approach allows license data to remain safe even if the trialware product or the operating system requires reinstallation.

If an end user reformats a hard drive that has trialware, it will not affect license data stored on that machine. However, repartitioning the hard drive will. End users can use ghosting utilities to back up a disk or partition to an image and restore the trialware later.

InstallShield Licensing Service

The InstallShield Licensing Service is required for all trialware products. During the installation of a trialware product, the installation checks to see if the service is already on the machine:

- If the InstallShield Licensing Service is not already on the machine, the installation automatically installs it as a service. The reference count for the service is set to one.
- If it is already on the machine, the reference count is increased by one.

During the uninstallation of a trialware product, the uninstallation decreases the reference count by one:

- If the updated reference count is zero, the service is automatically uninstalled because no other products on the machine need the service.
- If the updated reference count is not zero, the service is not uninstalled.

The reference count helps prevent the service from being removed if remaining trialware products need the service.

Files Installed with a Trialware Product

When you build a trialware version of a product, InstallShield automatically adds a file called IsSvcInst*<FileName>*.dll to your installation, where *<FileName>* is the name of your wrapped file without the dot or file extension. This IsSvcInst*<FileName>*.dll file is installed with the executable file that you are protecting, and the trialware technology uses it if an end user manually removes the InstallShield Licensing Service.

End-User Privacy

Try and Die trialware is completely anonymous. It does not allow or involve product activation. No information is sent to any sort of server for activation when an end user runs Try and Die trialware.

Workarounds for Trialware Issues with .NET, Java, PowerBuilder, or Other Interpretive Languages

InstallShield cannot wrap .NET or Java files for the Try and Die type of trialware. In addition, InstallShield cannot wrap files that were created with applications such as PowerBuilder, which uses interpretive languages.

With .NET and Java-based applications, build errors may occur in InstallShield when users attempt to build the installation. With PowerBuilder-created applications, end users can install the application, but the application cannot be launched when end users click Finish in the trialware run-time dialog.

If your application is a .NET or Java-based application or you used a tool such as PowerBuilder to create your application, create a traditional Windows-based .dll file:

- The .dll file should contain a function that is called by your product's executable file.
- Wrap the .dll file with the trialware protection in InstallShield.
- Obfuscate the function call to make it difficult for unscrupulous users to create their own versions of the unwrapped .dll file in an attempt to work around the trialware protection and use your application without having to activate it.

With this workaround, when an end user tries to launch the executable file, the executable file calls the protected .dll file, which triggers the trialware technology.

Adding a Trialware File

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

When you add a trialware file to your project and then configure its settings, you are preparing a fully functional, protected trial version of your product.

Task: ***To add a trialware file:***

1. Open the **Trialware** view.
2. Right-click the **Trialware Files** explorer and then click **New File Configured for Trial Usage**. InstallShield adds the item to the explorer.
3. Rename the item if necessary. The name is for internal use only and is not displayed to end users.
4. On the **General** tab, select the application file (.exe, .dll, .ocx, or .scr) in your project that you want to protect.

Once you have added the file in the Trialware view, you need to select the appropriate type of trialware and acquire a license.

Note • *InstallShield displays a warning icon (*  *) for the item that you added to the Trialware Files explorer. In order to protect a file, you must specify the corresponding .exe, .dll, .ocx, or .scr file; the type of trialware; and the license.*

Once you have specified these settings, InstallShield changes the warning icon to a protected trialware icon ( *).*

Specifying the Type of Trialware

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

InstallShield enables you to prepare one type of trialware: Try and Die. This type lets end users try your product for a specified number of days or a specified number of uses. You can allow end users to extend the trial for an additional limited number of days or uses. Once the trial limit or extension limit has been reached, they can no longer run the product.

Acquiring a License

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

A license identifies a protected trial product. It is recommended that you acquire a unique license for each version of your product. Otherwise, if end users try version 1.0 of your Try and Die product, the trial expires when the predetermined trial limit has been reached. Thus, the same end users would not be able to also try version 2.0 if you use the same license to wrap version 2.0.

Task: ***To acquire a license:***

1. Open the **Trialware** view.
2. Add a trialware file if you have not already done so, and select the executable file (.exe, .dll, .ocx, or .scr file) that you want to protect.
3. In the **License(s)** area of the **General** tab, click **Acquire**. The **Acquire New License Wizard** opens.
4. Complete the panels in the Acquire New License Wizard. The license server downloads the license to your machine and stores it in the project file.
5. In the **License(s)** list, select the license that you just obtained.

Once you have specified the license and the executable file on the General tab, the icon in the Trialware Files explorer changes from a warning icon ( ) to a protected trialware icon ( ). InstallShield cannot protect a file unless you configure these settings. If you build your project when the warning icon is displayed, a build error occurs (unless you have chosen to Excluding Trialware Protection from a Release).

Trial Limits and Extensions

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

When you create a trial version of your product using InstallShield, you set the trial limit—either a specific number of days or a specific number of uses. Note the following details about the trial limit:

- If you set the trial limit to a specific number of days, the trial period starts on the day that the end user launches your trialware product for the first time. The trial period starts on that first day even if the end user clicks the Cancel button on one of the trialware run-time dialogs and does not start using the product.
- If you set the trial limit to a specific number of uses, the countdown for the number of trial uses starts with the first time that the end user launches your product. If an end user clicks the Cancel button on one of the trialware run-time dialogs and does not start using the product, the number of uses does not change.

  Note that for per-user installations of trialware, the trialware usage count is per machine—not per user on the same machine.

In addition to specifying the trial limit, you can specify whether end users are allowed to extend the trial limit. If you allow trial extensions, you must specify the number of days or the number of uses that the trial can be extended. You also must specify the extension serial number that all end users should use to extend the trial.

If you want to prevent end users from evaluating or activating your trialware after a specific date, you can specify the expiration date. To learn more, see Expiration Dates for Trialware.

Trial Limit and Extension Example for Try and Die

To illustrate how the trial limit and a trial extension affect the Try and Die type of trialware, consider the following properties and the corresponding values that are specified on the Advanced tab of the Trialware view:

- Type of Trial Limit = Days
- Trial Limit Quantity = 20
- Allow Trial Extension = Yes
- Extension Limit Quantity = 10
- Expiration Date = (Does not expire)

The following table shows what happens in this example if an end user starts using your trialware product on January 1:

Table 4-1 • Trial Limit and Extension Example for Try and Die

Date	Description
January 1	An end user launches the trialware for the first time on this day. Therefore, the trial period begins on this day, regardless of what day the trialware was actually installed on the target machine.

Table 4-1 • Trial Limit and Extension Example for Try and Die (cont.)

Date	Description
January 1 through January 20	Whenever the end user launches the product, a trialware run-time dialog is displayed before the product starts, informing the end user how many days remain in the trial period. For example, on January 18, there are 3 days left in the trial period. If the Product Purchase URL property contains a URL, the run-time dialog displays a hyperlink that the end user can click to visit a Web page for information on purchasing the product. When the end user clicks Next, the trialware run-time dialog closes and the product starts.
January 21 through January 30	If the end user launches the product during this period, the trialware run-time dialog is displayed to inform the end user that the trial period has expired. If the Product Purchase URL property contains a URL, the run-time dialog displays a hyperlink that the end user can click to visit a Web page for information on purchasing the product. If the end user clicks the icon in the upper-left corner of the dialog and then clicks Sales Support, the run-time dialog prompts the end user for the extension serial number: • If the end user enters the correct extension serial number, the trial period is extended through January 30 (even if the end user waits until January 30 to extend the trial). When the end user clicks Next, the trialware run-time dialog closes and the product starts. • If the end user does not enter the correct extension serial number, the trialware run-time dialog does not permit the end user to start the product. The end user can try to re-enter the extension serial number. Note that the countdown for the number of days in the trial extension period starts the day after the initial trial period ends. This occurs even if the end user does not immediately extend the trial, but instead waits several days after the trial period is over to extend it.
January 31 or anytime afterward	If the end user tries to use the product, the product cannot be started. A trialware run-time dialog is displayed to inform the end user that the trial period has ended. If the Product Purchase URL property contains a URL, the run-time dialog displays a hyperlink that the end user can click to visit a Web page for information on purchasing the product. Note that the end user can no longer extend the trial.

Expiration Dates for Trialware

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

If you want to prevent end users from evaluating or activating your trialware after a specific date, you can specify the expiration date. The trial expires when either of the following conditions is met:

- The current date is on or after the date specified in the Expiration Date property on the Advanced tab of the Trialware view.
- The end user has used the product for the maximum number of times or uses as specified in the Type of Trial Limit and Trial Limit Quantity properties on the Advanced tab of the Trialware view.

Expiration Date Example with the Days Type of Trial Limit

The following table shows what happens under certain conditions when an expiration date is used. In each scenario, the Type of Trial Limit property is set to Days.

Table 4-2 • The Effect of an Expiration Date on Trialware with the Days Type of Trial Limit

Scenario	Result
The end user starts and finishes the trial period and the trial extension period before the expiration date.	The expiration date does not affect the trialware.
The end user starts the trial period before the expiration date; however, the trial period is set to end after the expiration date.	When the number of days remaining is displayed in the trialware run-time dialogs, it will take into account the expiration date. For example, if the trial limit is set to 30 days, but the end user first launches the trialware 10 days before the expiration date, the trialware run-time dialog states that 10 days remain in the trial. Note that even if trial extensions are allowed, the end user will not be able to extend the trial because it would occur after the expiration date.
The end user tries to start the trial period after the expiration date.	The end user cannot run the trialware. The trialware run-time dialog states that the trial period has ended.

Table 4-2 • The Effect of an Expiration Date on Trialware with the Days Type of Trial Limit (cont.)

Scenario	Result
The end user starts and finishes the trial period before the expiration date. Next, the end user tries to extend the trial.	The expiration date does not affect the initial trial period. If the end user tries to extend the trial period after the expiration date, the end user will not be able to do so. The trialware run-time dialog will state that the trial period has ended. If the end user extends the trial period before the expiration date, the end user can continue evaluating the product, as long as the end user is extending the trial before the trial extension period is over. (Note that the countdown for the number of days in the trial extension period starts the day after the initial trial period ends. This occurs even if the end user does not immediately extend the trial, but instead waits several days after the trial period is over to extend it.) When the system calculates the number of days remaining in the trial period, it takes into account the expiration date. If the trial extension is scheduled to end after the expiration date, the number of days remaining is decreased accordingly.

Expiration Date Example with the Uses Type of Trial Limit

The following table shows what happens under certain conditions when an expiration date is used. In each scenario, the Type of Trial Limit property is set to Uses.

Table 4-3 • The Effect of an Expiration Date on Trialware with the Uses Type of Trial Limit

Scenario	Result
Before the expiration date, the end user launches the trialware the maximum number of times that are allowed for the initial trial limit and the trial extension.	The expiration date does not affect the trialware.
The end user starts using the product before the expiration date; however, the end user does not (before the expiration date) launch the trialware the maximum number of times that are allowed.	The end user can continue using the trialware until either of the following occurs: • The end user launches the trialware the maximum number of times that are allowed. • The current date is the expiration date (or after the expiration date). As soon as either of those conditions becomes true, end user cannot run the trialware. The trialware run-time dialog states that the trial period has ended.

Table 4-3 • The Effect of an Expiration Date on Trialware with the Uses Type of Trial Limit (cont.)

Scenario	Result
Before the expiration date, the end user launches the trialware the maximum number of times that are allowed. Next, the end user tries to extend the trial.	The expiration date does not affect the number of initial trial uses in this scenario. If the end user tries to extend the trial after the expiration date, the end user will not be able to do so. The trialware run-time dialog will state that the trial period has ended. If the end user extends the trial before the expiration date, the end user can continue evaluating the product until they no longer have any remaining uses or until the expiration date is reached—whichever occurs first.

Setting the Trial Limit

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

Task: ***To set the trial limits:***

1. Open the **Trialware** view.
2. In the **Trialware Files** explorer, click the file whose trial limits you want to set.
3. Click the **Advanced** tab.
4. Set the trial limit–related properties as appropriate for your trialware.

The trial limit–related properties that you should set are:

- **Type of Trial Limit**
- **Trial Limit Quantity**
- **Allow Trial Extension**—If you set this property to Yes, also set the values of the **Extension Limit Quantity** and **Extension Serial Number** properties.

For details about setting the trial limits and allowing a trial extension, see Trial Limits and Extensions.

Setting or Changing a Trialware Expiration Date

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

You can set an expiration date to prevent evaluations and activations of your product after a certain date. Expiration dates are often used for beta versions of a product. For example, you may want to set the expiration date to the last day of the beta trial period. When the beta trial period is over, end users can no longer use the trialware version of your product, even if they have additional days or uses remaining in their trial.

Task: ***To set or change the expiration date for your trialware:***

1. Open the **Trialware** view.
2. In the **Trialware Files** explorer, click the file whose expiration date you want to set.
3. Click the **Advanced** tab.
4. Double-click the **Expiration Date** property. The **Expiration Date** dialog box opens.
5. Select the **I want my trial to expire on this date** option.
6. Specify the last day on which any end users should be able to evaluate or activate your product. You can either type the date in the box or click the arrow to select the date from a calendar.
7. Click **OK**.

InstallShield sets the value of the Expiration Date property to the date that you specified.

End users will not be able to evaluate your product after the expiration date.

Removing a Trialware Expiration Date

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

If you previously set an expiration date for your trialware and you later decide that it should not have one, you can remove it.

Task: ***To remove the expiration date for your trialware:***

1. Open the **Trialware** view.
2. In the **Trialware Files** explorer, click the file whose expiration date you want to set.
3. Click the **Advanced** tab.
4. Double-click the **Expiration Date** property. The **Expiration Date** dialog box opens.
5. Select the **I do not want my trial to have an expiration date** option.
6. Click **OK**.

InstallShield sets the value of the Expiration Date property to (Does not expire).

Setting the Hyperlinks for the Trialware Run-Time Dialogs

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

The default values for the hyperlink properties are for pages on the InstallShield Web site. You must change these default values or delete them before releasing your trialware. Otherwise, hyperlinks to the InstallShield Web site will be included in your trialware run-time dialogs.

Task: ***To set the hyperlinks for the trialware run-time dialogs:***

1. Open the **Trialware** view.
2. In the **Trialware Files** explorer, click the file whose run-time hyperlinks you want to configure.
3. Click the **Advanced** tab.
4. Set the URL-related properties as appropriate for your trialware.

Trialware Run-Time Dialogs

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

Whenever an end user launches a protected Try and Die product, a trialware run-time dialog or message box opens before the application starts.

The following topics describe the end-user experience with Try and Die trialware and provide sample run-time dialogs:

- Try and Die Dialog (Trial Has Not Expired)
- Try and Die Dialog (Trial Has Expired)
- Try and Die Dialog (Serial Number Required to Extend Trial)
- Try and Die Dialog (Trial Is Extended)

If an end user resets the machine's date or time and then tries to run trialware, a message box opens. For more information, see Trialware Message Box (System Clock Change).

Hyperlinks in the Trialware Run-Time Dialogs

The trialware run-time dialogs contain a number of hyperlinks that you can set or exclude as appropriate. If you do not specify a uniform resource locator (URL) for some of the hyperlinks, the hyperlinks that do have specific URLs are automatically rearranged to eliminate gaps between missing hyperlinked text.

The Help, Privacy Policy, and Feedback hyperlinks, for example, are arranged flush right near the lower-right corner of the run-time dialogs. If you do not specify a URL for the Privacy Policy link, the Help link is moved closer to the Feedback link automatically.

In most cases, you may want to specify a page on your Web site as the URL. However, you do have the ability to set a URL property with a mailto URL. If an end user clicks a mailto URL hyperlink in one of the trialware run-time dialogs, a new email message is opened in the end user's email application, and the destination address is populated in the To field.

For example, if you set the Feedback URL property to the following string, an email message will open with **feedback@mycompany.com** in the To field whenever the end user clicks the Feedback link.

```
mailto:feedback@mycompany.com
```

You can also specify the text for the Subject line with the following code, using `%20` in place of spaces:

```
mailto:feedback@mycompany.com?Subject=My%20Subject
```

Try and Die Dialog (Trial Has Not Expired)

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

Whenever an end user launches the Try and Die version of a product, a trialware run-time dialog opens before the application starts.

If the trial has not expired, the trialware run-time dialog displays a message stating how many days or uses remain in the trial, as shown in the sample dialog below for a product called Try and Die. The end user can click the Finish button to begin using the application.

This same dialog is also displayed if the end user has extended the trial and then launched the product anytime before the trial extension expires.

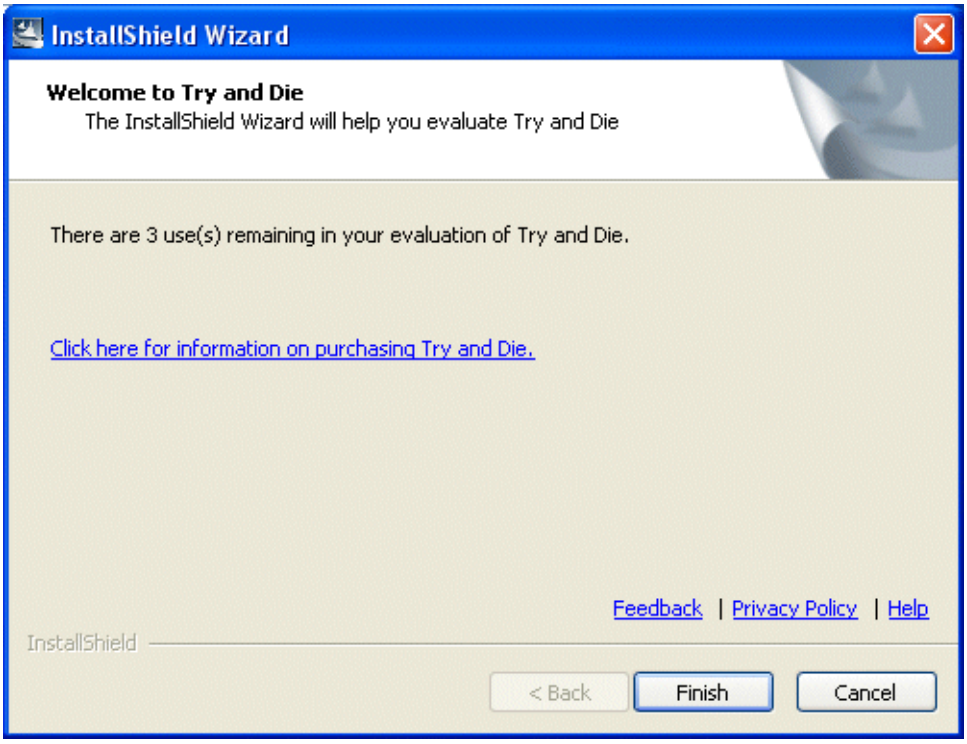

Figure 4-3: Sample Try and Die dialog (Trial has not expired.)

Try and Die Dialog (Trial Has Expired)

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

Whenever an end user launches the Try and Die version of a product, a trialware run-time dialog opens before the application starts.

If the trial has expired, the trialware cannot be started. The trialware run-time dialog displays a message informing the end user that the trial has ended, as shown in the first sample dialog below for a product called Try and Die.

When the end user clicks Finish, the trialware run-time dialog closes and the product does not start.

If the trialware has been configured to allow an extension of the trial, InstallShield adds a Sales Support menu command to this trialware run-time dialog. This command is hidden on a menu in the dialog to encourage your prospective customers to purchase the product rather than try to extend the trial.

If end users click the icon in the upper-left corner of the dialog, as shown in the second dialog below, they can select this Sales Support command. Then the next run-time dialog prompts the end user for the extension serial number.

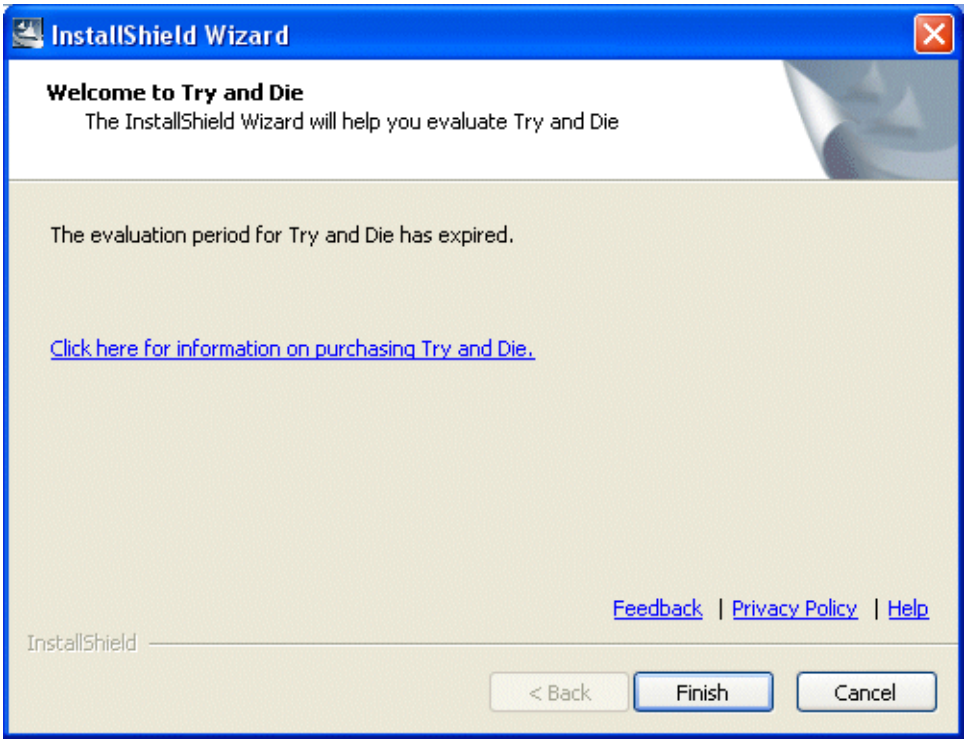

Figure 4-4: Sample Try and Die dialog (Trial has expired.)

Figure 4-5: Sample Try and Die dialog (Trial extension is allowed.)

Try and Die Dialog (Serial Number Required to Extend Trial)

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

If the end user clicks Sales Support, as shown in the previous trialware run-time dialog, the dialog shown below opens to enable the end user to enter the extension serial number:

- If the end user does not enter the correct extension serial number, the trialware run-time dialog does not permit the end user to start the product. The end user can try to re-enter the extension serial number.

- If the end user enters the correct extension serial number and then clicks Next, the trial is extended for the predetermined number of extension days or uses. When the end user clicks Next, the next trialware run-time dialog opens.

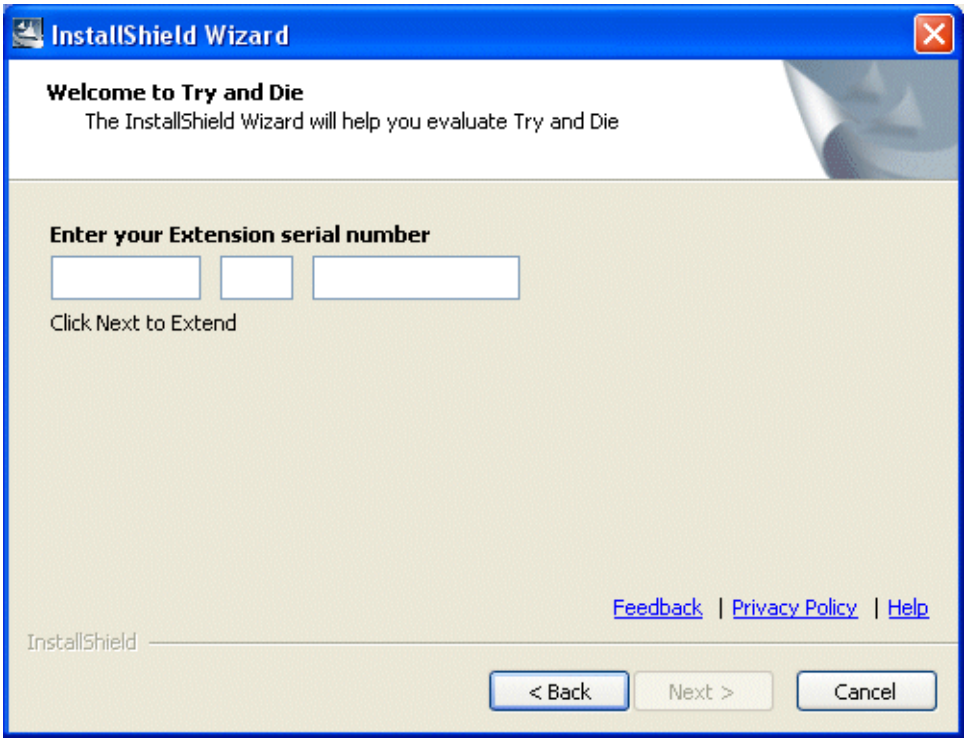

Figure 4-6: Sample Try and Die dialog (Serial number required to extend trial.)

Try and Die Dialog (Trial Is Extended)

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

If the end user enters the correct extension serial number to extend the trial, the trialware run-time dialog shows how many days or uses remain in the trial, as shown in the sample dialog below. The end user can click the Finish button to begin using the application.

Subsequent launches of an extended trial will show the Trial Is Extended dialog, as long as the trial extension has not expired.

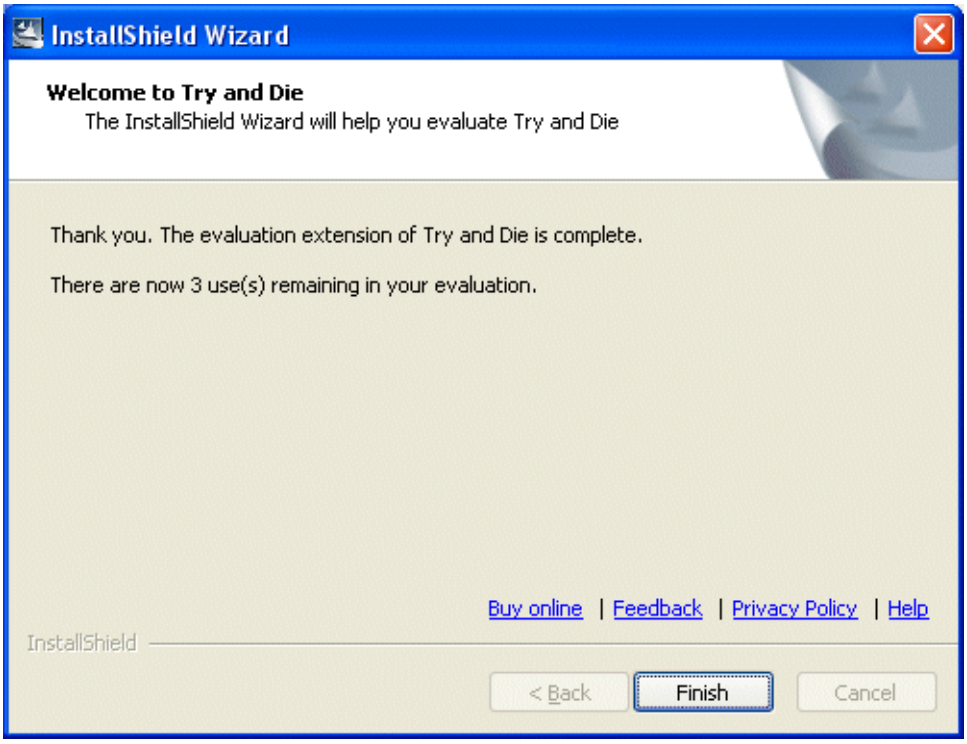

Figure 4-7: Sample Try and Die dialog (Trial is extended.)

Trialware Message Box (System Clock Change)

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

If an end user attempts to abuse the trial limit by setting back the system clock and then running Try and Die trialware (either before or after the trial has expired), the message box shown below opens.

- If the end user clicks Yes, the message box closes, enabling the end user to restore the date and time.
- If the end user clicks No, the trial ends, and the trialware cannot be started.

This is done to prevent end users from trying to gain more time for their trial by setting their computer's date back to an earlier date.

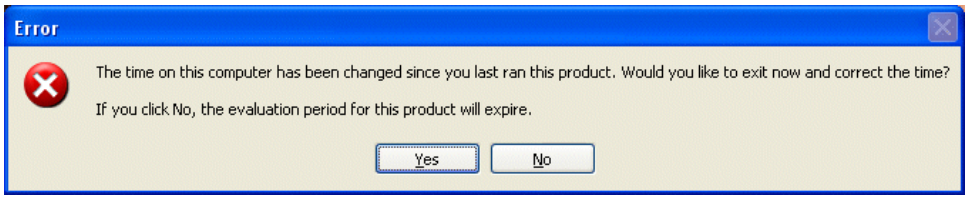

Figure 4-8: Trialware message box (System clock change)

Resetting the License During Development and Testing

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

Note that if you test a Try and Die product by running the protected trial version, it will expire at the end of the trial; you will not be able to test your product further on the same test machine without removing the license.

When you build a trialware release and the Disable Trialware Build property in the Releases view is set to the default setting of No, a folder called TestTools is created and placed in the same folder as the DiskImages folder for the selected release.

Caution • *Do not release the files in the TestTools folder with your product or make them available to your customers. Doing so would enable end users to continually restart a trial each time that it expires. Note that the TestTools files are specific to a particular product and license and cannot be used to delete licenses for other products.*

For each file being wrapped, the `TestTools` folder contains the following files:

- SCResetLicense*<WrappedBaseFileName>*.exe
- IsSvcInstSCResetLicense*<WrappedBaseFileName>*.dll

For example, if a file called **Calc.exe** is wrapped, the files in the `TestTools` folder are `SCResetLicenseCalc.exe` and `IsSvcInstSCResetLicenseCalc.dll`.

You can use the `TestTools` files to remove the license for your product from a machine, resetting the trialware state. This enables you to restart the trial for your protected product and retest it. For more information, see Testing a Trialware Release of Your Product.

Informing End Users How to Extend a Trial

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

You can configure your trialware so that it allows end users to extend a trial. Note that if you allow trial extensions, end users can extend the trial only once. They cannot continually extend the trial.

If you allow trial extensions for your trialware and then end users ask for an extension, you need to provide them with the extension serial number.

The instructions below explain how end users would extend a Try and Die trial if it has expired.

Task: ***If end users want to extend a Try and Die trial, they need to:***

1. Start the trialware product. The trialware run-time dialog displays a message that states that the trial has ended.
2. Click the icon in the upper-left corner of the dialog, and then click **Sales Support**.

Figure 4-9: Sample Try and Die dialog (Trial extension is allowed.)

3. Enter the extension serial number that you have provided to them, and then click **Next**.

Removing a Trialware File

Edition • *Trialware functionality is available with the Premier edition of InstallShield.*

If you no longer want to include a particular trialware file in your project, you can remove it.

Task: ***To remove a trialware file:***

1. Open the **Trialware** view.
2. In the **Trialware Files** explorer, click the trialware file that you want to remove from your project.
3. Press **Delete**.

The trialware file is removed from your project.

If you need to build a release of your product that does not have the trialware protection, refer to Excluding Trialware Protection from a Release.

Creating Transforms

Project • *This information applies to Transform projects.*

A transform (.mst file) is a simplified Windows Installer database that contains the differences between two .msi databases. Transforms enable an administrator to apply modified settings to a database when deploying an installation package.

Customizing Installations

For example, a user may need to customize an installation in different ways for different departments in their company. The traditional office suite comes with a spreadsheet program, a word processor, and a presentation tool. The accounting department may need only the spreadsheet and the presentation programs, while the writing department may need the word processor and the spreadsheet. A third department may need the entire suite of applications.

Rather than manually setting up every person in the company, a user can take the original installation of the entire suite, customize it to the needs of each department, and then create a transform between the two packages. A transform needs to be created for each separate product configuration.

Creating Transforms

InstallShield makes the task of creating multiple configurations of your product as easy as stepping through a wizard. You can create a transform by using either of the two methods described below.

Creating a Transform by Comparing Two .msi Packages

In one method of creating a transform, a base .msi package serves as the starting point for all of your customization, and the target package contains all of the changes that you would like to be reflected in the installation. Once you have prepared the base .msi package and the target .msi package, you can use the Transform Wizard to create a transform. When you finish this wizard, InstallShield compares the two packages and creates a transform (.mst file) that contains the differences between the two packages.

Creating a Transform Based on a Single .msi Package

Another way to create a transform is to create a new transform project. When you create a new transform project, the Open Transform Wizard launches. Use the Open Transform Wizard to open an existing .msi package in Direct MST mode and edit the project as needed. InstallShield evaluates the differences between the base .msi package and the changes you make in Direct MST mode and creates a transform project (.mst file) that contains the differences.

This method of creating a transform enables you to specify additional transforms that should be incorporated into your transform project. It also lets you specify default user-interface responses for end users.

Applying Transforms

Once a transform has been created, it can be applied at run time, depending on whose machine the application is being installed. For example, you can check if the target machine is in the accounting department. If it is, the accounting transform is applied to the original installation, and only the spreadsheet and presentation programs are installed.

Creating a Transform by Comparing Two .msi Packages

Project • *This information applies to Transform projects.*

Note • *If a transform project includes new files (files not found in the original .msi file), these files will not be found when running the installation. To avoid this issue, you can either put the transform project in the same location as the base .msi package, or manually copy the source files to the location of the base .msi package.*

Task: ***To create a transform by comparing two .msi packages:***

1. Open the base .msi package in InstallShield.
2. Save the project with a new name. This new project is your target project. For more information, see Saving a Project with a New Name and Location.
3. Make all of the changes that you would like to be reflected in the installation and then build a release.
4. On the **Tools** menu, click **Create/Apply Transform**. The Transform Wizard opens.
5. Complete the panels in the **Transform Wizard** to create the transform.

Creating a Transform Based on a Single .msi Package

Project • *This information applies to Transform projects.*

Note • *If a transform project includes new files (files not found in the original .msi file), these files will not be found when running the installation. To avoid this issue, you can either put the transform project in the same location as the base .msi package, or manually copy the source files to the location of the base .msi package.*

Task: ***To create a transform based on a single .msi package:***

1. On the **File** menu, click **New**. The **New Project** dialog box opens.
2. On the **Windows Installer** tab, click **Transform**.
3. In the **Project Name** box, type a name for your transform project.
4. In the **Location** box, type the path where your transform project should be stored or click **Browse** to find the location.
5. Click **OK**. The **Open Transform Wizard** opens.
6. Complete the panels in the **Open Transform Wizard** to create the transform.

Applying Transforms

Project • *This information applies to Transform projects.*

When you apply a transform, you are modifying a base .msi package to incorporate changes that you included in the transform (an .mst file).

The two methods of applying a transform are described below.

Applying a Transform from the Command Line

One way to apply a transform is to pass a command line to Msiexec.exe or Setup.exe. When you apply a transform from the command line, you are changing the database of your .msi package at run time. To apply a transform at run time, your command-line statement should look something like this, specifying the desired transform with the TRANSFORMS property:

```
msiexec /i "ProductName.msi" TRANSFORMS="YourTransform.mst"
```

Use semicolons to separate multiple transforms.

Caution • *Do not use semicolons in the name of your transform because the Windows Installer service interprets semicolons as file name separators.*

When you specify more than one transform at the command line, the transforms are applied in the order specified. For example, you could have a base package that has only one feature, and one transform that adds a second feature, and another transform that changes the second feature in some way. The transform that adds the feature must be specified before the transform that changes the second feature; otherwise, the change will not be made properly.

Using the Transform Wizard to Apply a Transform

When you use the Transform Wizard to apply a transform, you create an installation package (.msi package) that reflects all of the changes contained in the transform file. This can be useful for network administrators who are customizing applications for all of their users.

Task: ***To launch the Transform Wizard:***

On the **Tools** menu, click **Create/Apply**.

Editing Transforms

Project • *This information applies to Transform projects.*

InstallShield enables you to edit .msi packages without having to convert them to an InstallShield (.ism) project. You can save the changes made as a transform (.mst) file.

Opening Existing Transforms for Editing

In InstallShield, you can browse for an existing .mst file. Before InstallShield can open the .mst file, it needs the base .msi to which this file should be applied. Also, it requires the names of any additional .mst files that should be applied to the base .msi file before opening the .mst file for editing.

The first time that you open an .mst file in InstallShield, the Open Transform Wizard launches. This wizard enables you to specify the .mst file, the base .msi file, and any additional transforms to apply before editing. The last panel of this wizard—the Create a Response Transform panel—lets you specify whether or not your transform should be a response transform. A response transform includes default responses for the user interface portion of the installation. If you specify that you want to create a response transform, the user interface elements of the installation are executed, enabling you to customize the options available in each panel of the installation wizard.

When the Open Transform Wizard is finished, the transforms are applied and the .mst file opens in InstallShield in Direct MST mode (which is similar to Direct Edit mode). The data specified in the wizard is saved so that the next time that you open the .mst file, the transform project opens directly in InstallShield.

Task: ***To open an existing transform:***

1. On the **File** menu, click **Open**. The **Open** dialog opens.
2. Select the .mst file that you would like to open.
3. Click **Open**. The **Open Transform Wizard** opens.

Saving .msi Files as Transforms

When you are editing an .msi file in Direct Edit mode, you can save the file as an .mst file.

Task: ***To save an .msi file as an .mst file:***

1. On the **File** menu, click **Save As**. The **Save As** dialog box opens.
2. In the **Save as type** box, select **Windows Installer Transforms (*.mst)**.

All the changes made since the last save are saved to the .mst file specified.

Saving Transforms as .msi Files

You can save an .mst file as an .msi file.

Task: ***To save a transform as an .msi file:***

1. Open the transform project in InstallShield if you have not already done so.
2. On the **File** menu, click **Save As**. The **Save As** dialog box opens.
3. In the **Save as type** box, select **Windows Installer Packages (*.msi)**.

An .msi file is created. It contains all of the data from the base .msi file, the .mst file that you were editing, and any additional .mst files applied. The project is treated as a Direct Mode MSI project. For more information, see Editing .msi and .msm Databases in Direct Edit Mode.

Response Transforms

Project • *This information applies to Transform projects.*

A response transform is a type of transform that enables administrators to set up default values for an installation by simply running the user interface sequence and entering the desired values. For example, you might want to create a response transform that contains default values for which features are installed, for the installation location of the application, and for the company name. The default values that you specify are used as a starting point for your transform.

To create a response transform, use the Open Transform Wizard.

Creating a Response Transform

Project • *This information applies to Transform projects.*

Task: ***To create a response transform:***

1. Open the Open Transform Wizard.
2. Complete each panel of the wizard as needed. On the Create Response Transform panel, select **Create response transform**.
3. In the **Command line properties (optional)** box, specify command-line properties (in property name/value pairs separated by semicolons) that you would like to be passed to the response transform.
4. Click **Finish**. The user interface elements of the installation are executed.
5. Complete the simulated installation, customizing the options available in each panel of the installation wizard as needed. No file transfer takes place, and no changes to your machine occur.
6. When you reach the end of the installation sequence, click **Install**.

The simulated installation exits, and InstallShield saves all of the changes that you made during the simulated installation as values in the Property table of your transform project. These values are used as default values in the your installation.

Modifying a Response Transform

Project • *This information applies to Transform projects.*

Task: ***To modify an individual response in an existing transform project:***

1. On the **File** menu, click **Open**. The **Open** dialog box opens.
2. Select the transform project (.mst file) whose responses you would like to modify.
3. Click **Open**. InstallShield opens your transform project in Direct MST mode.
4. In the **Direct Editor**, click the **Property** table.
5. Modify the values of any response properties as needed. Examples of properties that you may want to modify include **COMPANYNAME** and **USERNAME**.

As an alternative, you can also follow the same steps described for Creating Transforms; these steps enable you to launch the user interface of the installation and select the appropriate responses.

Testing a Response Transform

Project • *This information applies to Transform projects.*

To see the changes you made to the responses, you can test the user interface part of your transform by doing any of the following:

- On the **Build** menu, click **Test**.
- Click the **Test** button.
- Press CTRL+T.

Configuring Server Locations

Project • *This information applies to Transform projects.*

If end users install a product from a network server or Web site, and they install features to run from the server or Web site, the product may need access to the .msi package and related files on the server or Web site sometime after the initial installation. The product may also require access if a file is deleted or becomes corrupted; the installation can copy the problematic file or files automatically from the server or Web site.

InstallShield enables you to specify in your transform a list of network or URL source paths to your product's installation package. The paths in this list are stored in the **SOURCELIST** property. Windows Installer appends this list to the end of an end user's existing source list for the product at run time.

Adding Server Locations

Project • *This information applies to Transform projects.*

Task: ***To add a network server path or a Web site URL for a server location:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Server Locations** setting, click the ellipsis button (**...**). The **Server Locations** dialog box opens.
3. Specify server locations as needed.
4. Click **OK**.

InstallShield updates the value in the Server Locations setting with the locations that you specified.

Modifying Server Locations

Project • *This information applies to Transform projects.*

Task: ***To modify a location in the server list:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Server Locations** setting, click the ellipsis button (**...**). The **Server Locations** dialog box opens.
3. Modify server locations as needed.
4. Click **OK**.

InstallShield updates the value in the Server Locations setting as required.

Removing Server Locations

Project • *This information applies to Transform projects.*

Task: ***To remove a path for a server location:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Server Locations** setting, click the ellipsis button (**...**). The **Server Locations** dialog box opens.
3. In the **Source Paths** list, select the path that you want to remove.
4. Click the **Delete** button.
5. Click **OK**.

Changing the Order of Server Locations

If an installation needs access to the source files that are stored on a network server or a Web site, it uses the first accessible path in the list of server locations. InstallShield lets you change the order of paths if necessary.

Project • *This information applies to Transform projects.*

Task: ***To change the order of the server locations:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Server Locations** setting, click the ellipsis button (**...**). The **Server Locations** dialog box opens.
3. In the **Source Paths** list, select the path that you want to move.
4. Click the **Move Up** and **Move Down** buttons as needed to change the order.
5. Click **OK**.

5

Creating Advanced UI and Suite/ Advanced UI Installations

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Advanced UI and Suite/Advanced UI installations are bootstrap applications that package together installations and InstallShield prerequisites as a single installation while providing a unified, fully customizable user interface. They use a setup launcher (`Setup.exe`) to conditionally launch packages on target systems as needed.

The following diagram shows the various parts of a Suite/Advanced UI installation, which has support for running multiple primary packages (including .exe packages, sideloading app packages (.appx), and Windows Installer transactions) and multiple InstallShield prerequisite packages. Note that the parts of an Advanced UI installation are similar, except that an Advanced UI installation can run only one primary package, but multiple InstallShield prerequisite packages.

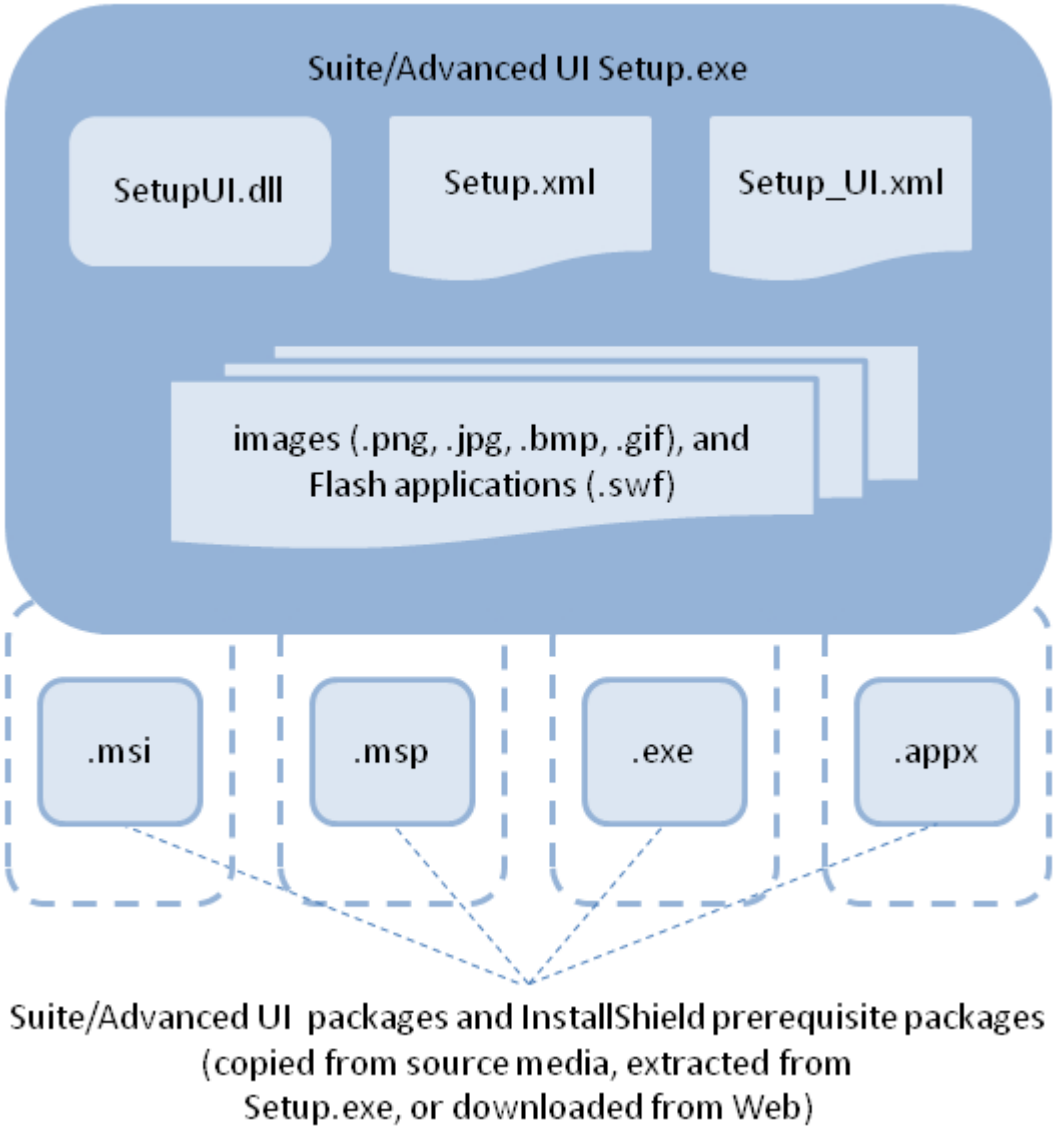

Figure 5-1: Parts of a Suite/Advanced UI Installation

At build time, InstallShield uses the various sections of the .issuite file—the Advanced UI project's or Suite/Advanced UI project's XML project file—to create `Setup.xml` and `Setup_UI.xml`, and bundle these together with the Advanced UI's or Suite/Advanced UI's packages and other files that are required to run the Advanced UI or Suite/Advanced UI installation. The resulting Advanced UI or Suite/Advanced UI installation includes the following files:

- `Setup.exe`, which contains the Advanced UI or Suite/Advanced UI engine
- `Setup.xml`, which describes the packages that are in the Advanced UI or Suite/Advanced UI installation, the conditions under which they are launched, and the string entries that are used in the wizard user interface of the Advanced UI or Suite/Advanced UI installation
- `Setup_UI.xml`, which defines style settings, layout information, and other UI parameters for the wizard user interface

- `SetupUI.dll`, which consists of the Advanced UI and Suite/Advanced UI library that is used to render the UI of Advanced UI and Suite/Advanced UI installations

InstallShield also gathers the packages in the Advanced UI or Suite/Advanced UI project and sets up the folder structure, if applicable, for the packages and their associated uncompressed files. In addition, InstallShield incorporates the support files of the Advanced UI or Suite/Advanced UI installation; these support files are resources such as EULAs and image files that are shown on wizard pages.

When an end user launches the Advanced UI or Suite/Advanced UI installation, the Advanced UI or Suite/Advanced UI engine reads the `Setup.xml` file, loads the `SetupUI.dll` file, evaluates the conditions that are defined for the installation and each of its packages, follows the instructions in the `Setup.xml` file, (if applicable) downloads packages and files that are needed on the target system, runs the packages that need to be run, and cleans up resources.

Note that Advanced UI and Suite/Advanced UI installations require that Windows Installer 3.1 or later be present on target systems. They also require Windows XP or later or Windows Server 2003 or later.

For more information on the Advanced UI and Suite/Advanced UI types of projects, refer to this section of the documentation.

Advanced UI Projects vs. Suite/Advanced UI Projects

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield.*

Advanced UI and Suite/Advanced UI projects enable you to develop bootstrap applications for installations and create a unified, fully customizable user interface. The following table compares various capabilities and traits of these two types of projects.

Table 5-1 • Summary of Differences Between Advanced UI Projects and Suite/Advanced UI Projects

Comparison Category	Advanced UI Projects	Suite/Advanced UI Projects
Edition of InstallShield For more details on the differences between the Premier and Professional editions, see Upgrading from Other InstallShield Editions.	InstallShield Professional	InstallShield Premier
Project file extension	.issuite	.issuite
Supported file format for primary packages For information on selecting the appropriate package file format, see Guidelines for Adding Packages to an Advanced UI or Suite/Advanced UI Project.	.msi package, .msp patch, InstallScript package	.appx package .msi package, .msp patch, InstallScript package, .exe package, Windows Installer transaction Note that the ability to create and build a Suite/Advanced UI installation that includes a sideloading app package (.appx) requires Windows Vista or later or Windows Server 2008 or later on the machine that has InstallShield or the Standalone Build.
Number of primary packages that you can include in the project For more detailed, see Primary Packages vs. Dependency Packages in Advanced UI and Suite/Advanced UI Projects.	1 This capability enables you to create a contemporary, customizable user interface for a single .msi package, .msp package, or InstallScript package.	1 or more This capability enables you to create a contemporary, customizable user interface for one or more .msi packages, .msp packages, InstallScript packages, and .exe packages. This capability also lets you package together multiple separate installations as a single installation while providing a unified user interface.

Table 5-1 • Summary of Differences Between Advanced UI Projects and Suite/Advanced UI Projects (cont.)

Comparison Category	Advanced UI Projects	Suite/Advanced UI Projects
Support for including InstallShield prerequisites in the project To learn more, see Including InstallShield Prerequisites (.prq) in an Advanced UI or Suite/Advanced UI Project.	Include as many InstallShield prerequisites as needed as .msi packages, .msp packages, and .exe packages, depending on the type of file that is configured to run for the prerequisite.	Include as many InstallShield prerequisites as needed as .msi packages, .msp packages, and .exe packages, depending on the type of file that is configured to run for the prerequisite.
Support for indicating which packages are primary packages and which are secondary packages To learn more, see Primary Packages vs. Dependency Packages in Advanced UI and Suite/Advanced UI Projects.	Limited flexibility. You can add one .msi, .msp, or InstallScript package as a primary package to your project. Any InstallShield prerequisites that you include in your project are added as dependency packages. This cannot be changed.	Full flexibility. You can add .msi, .msp, InstallScript, .exe and transaction packages to your project and easily specify whether they are primary or dependency packages. Any InstallShield prerequisites that you include in your project are added as dependency packages, but you can override this and mark them as primary packages.
Support for creating actions and scheduling them to run during the appropriate run-time events To find out more, see Using Actions to Extend the Behavior of a Suite/Advanced UI Installation.	Not available.	A Suite/Advanced UI project includes an Events view that lets you define actions that you want to occur at run time on target systems. You can schedule an action to occur during a particular event in the Events view, or you can assign to a package in the Packages view.
Support for build events For more information, see Specifying Commands that Run Before, During, and After Builds.	Not available.	A Suite/Advanced UI project includes release settings that let you schedule commands that run before InstallShield starts building the release, as well as after InstallShield has built and signed the release.

Table 5-1 • Summary of Differences Between Advanced UI Projects and Suite/Advanced UI Projects (cont.)

Comparison Category	Advanced UI Projects	Suite/Advanced UI Projects
Run-time language support For more information, see Run-Time Language Support in InstallShield.	The end-user interface of an Advanced UI installation is limited to a single language that you determine when installing InstallShield.	Create a single installation that displays end-user text in multiple languages. Change wizard pages and messages to any one of 34 additional languages using pre-translated strings.

Organizing Features, Packages, Prerequisites, and Files in an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

An Advanced UI or Suite/Advanced UI installation is a bootstrap application whose primary purpose is typically to conditionally launch packages on target systems as needed. An Advanced UI or Suite/Advanced UI installation may also need to run InstallShield prerequisites to install third-party or custom redistributables to ensure that the product can function properly.

A feature is the smallest installable part of an Advanced UI or Suite/Advanced UI installation from the end user's perspective. Each package and InstallShield prerequisite that is included in an Advanced UI or Suite/Advanced UI installation should be associated with a feature in the project.

For information on adding and configuring packages and InstallShield prerequisites in an Advanced UI or Suite/Advanced UI project, review this section of the documentation.

Guidelines for Adding Packages to an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

File Format Recommendations

The recommended file format for a package in an Advanced UI or Suite/Advanced UI project is one that does not include a bootstrap application or setup launcher (`Setup.exe`). The following file formats are recommended for Advanced UI and Suite/Advanced UI projects:

- .msi package
- .msp patch
- InstallScript package—The package must be an uncompressed InstallScript installation that is built in InstallShield 2012 Spring or later.

To learn more about use of these types of packages in an Advanced UI or Suite/Advanced UI project, see Adding an .msi Package, an .msp Patch, or a Transaction to an Advanced UI or Suite/Advanced UI Project and Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project.

InstallShield also enables you to add executable packages (.exe) to a Suite/Advanced UI project. Examples include:

- Setup launcher executable file that was built in InstallShield for a Windows Installer–based installation
- Setup launcher executable file that was built in InstallShield for a Windows Installer–based patch
- Setup launcher file for an InstallScript installation (This includes InstallScript installations that were built in InstallShield 2012 or earlier, as well as compressed InstallScript installations.)
- Setup launcher executable file that was built in a tool other than InstallShield

The .msi, .msp, and InstallScript packages are preferred to the setup launcher executable file formats for various reasons:

- The wizard interface of the Advanced UI and Suite/Advanced UI setup launcher can show the incremental progress of the recommended file formats as they are being run on target systems, but not of the executable packages.

- When you add one of the recommended file formats as a package to an Advanced UI or Suite/Advanced UI project, InstallShield automatically adds an appropriate eligibility condition that prevents the Advanced UI or Suite/Advanced UI installation from allowing an earlier version of a package to install over a later version. If you add an executable package to your Suite/Advanced UI project, you must manually define an eligibility condition that prevents such downgrades.
- If you add one of the recommended file formats as a package to an Advanced UI or Suite/Advanced UI project, you are not required to define for that package a detection condition that evaluates whether the package is already installed on target systems, since the Advanced UI or Suite/Advanced UI installation blocks this scenario from occurring. If you add an executable package to your Suite/Advanced UI project, you must manually define that sort of detection condition for the package.
- The Advanced UI or Suite/Advanced UI setup launcher automatically suppresses the user interface of the recommended file formats, in favor of the wizard interface of the Advanced UI or Suite/Advanced UI installation. If your project includes an executable package, you must manually suppress its user interface and have the Advanced UI or Suite/Advanced UI installation launch it silently. Otherwise, at run time, the installation shows the Advanced UI or Suite/Advanced UI user interface and the separate user interface of the .exe package, presenting two disparate user interfaces.

For more information, see Adding an Executable Package (.exe) to a Suite/Advanced UI Project.

In addition, InstallShield includes support for adding sideloading app packages (.appx) to Suite/Advanced UI projects. Sideloading an app is the process of installing an app without obtaining it through the Windows Store. For more information, see Adding a Sideloading App Package (.appx) to a Suite/Advanced UI Project. Because .appx packages are supported in limited scenarios, these packages are typically used in concert with a more common installation format, such as an .msi package.

Media Type Requirements

An Advanced UI or Suite/Advanced UI installation cannot install a package that spans multiple disks (for example, CDs or DVDs). It also cannot install a multiple-disk package from a fixed disk such as a network. Therefore, any package (.msi package, .msp package, InstallScript package, .exe package, or .appx package) that you include in an Advanced UI or Suite/Advanced UI project must be a single-disk removable media type, a network image media type, or a Web media type.

Adding an .msi Package, an .msp Patch, or a Transaction to an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Project-specific differences are noted where appropriate.

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you add the following types of Windows Installer–based installations to Advanced UI and Suite/Advanced UI projects:

- Windows Installer packages (.msi packages)
- Windows Installer patches (.msp packages)

InstallShield also lets you add Windows Installer transactions to Suite/Advanced UI projects (but not to Advanced UI projects).

A transaction consists of Windows Installer packages (.msi) and Windows Installer patches (.msp) that you want to be run on target systems using transaction processing, a feature of Windows Installer 4.5 and later. The packages are chained together and processed as a single transaction. Each Suite/Advanced UI installation can have multiple separate transactions. If one or more of the packages in a transaction cannot be installed successfully or if the end user cancels the installation, Windows Installer initiates rollback for all of the chained packages within the current transaction to restore the system to its earlier state.

Adding an .msi or .msp Package That Runs Without Transaction Processing

Task: ***To add an .msi or .msp package that is run without transaction processing to your Advanced UI or Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. Right-click the **Packages** explorer and then click the appropriate command: **New Windows Installer Package (.msi)** or **New Patch Package (.msp)**. The **Select the installation file for this package** dialog box opens.
3. Select the package file that you want to add to your Advanced UI or Suite/Advanced UI project, and then click **Open**. The **Add Files for This Package** dialog box opens.
4. Specify whether you want to include additional folders and files with your package file, and if so, whether you want to include dynamically linked files.

InstallShield adds the package, plus any additional folders and files, in the Packages explorer.

Adding a Package That Runs With Transaction Processing

Task: ***To add a package that is run with transaction processing to your Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. Right-click the **Packages** explorer, and then click **New Transaction**. InstallShield adds a **Transaction** folder to the **Packages** explorer.

3. In the **Packages** explorer, right-click the **Transaction** folder and then click the appropriate command: **New Windows Installer Package (.msi)** or **New Patch Package (.msp)**. The **Select the installation file for this package** dialog box opens.
4. Select the package file that you want to add to your Suite/Advanced UI project, and then click **Open**. The **Add Files for This Package** dialog box opens.
5. Specify whether you want to include additional folders and files with your package file, and if so, whether you want to include dynamically linked files.

InstallShield adds the package, plus any additional folders and files, in the Packages explorer.

Important • *Running a package in a transaction from a Suite/Advanced UI installation requires Windows Installer 4.5 or earlier. If a package in a transaction is launched by a Suite/Advanced UI installation on a target system that has an earlier version of Windows Installer, the Suite/Advanced UI installation fails. Therefore, if you are using transaction processing for packages in your Suite/Advanced UI installation, it is recommended that you consider performing one or more of the following tasks:*

- *Include the Windows Installer 4.5 redistributable as a package in the Suite/Advanced UI project for target systems that have an earlier version, and schedule it before the packages that use transaction processing.*
- *Create an exit condition that prevents the entire Suite/Advanced UI installation from running on systems that do not have Windows Installer 4.5 or later. To learn more, see Defining Exit Conditions for an Advanced UI or Suite/Advanced UI Installation.*
- *Create an eligibility condition for each package in the transaction that checks for Windows Installer 4.5 or later and does not launch those packages in the transaction. For more information, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.*

Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between the Suite/Advanced UI and Advanced UI project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Requirements for Adding an InstallScript Installation as an InstallScript Package (Instead of as an Executable Package) to an Advanced UI or Suite/Advanced UI Project

InstallShield lets you add an InstallScript package to an Advanced UI or Suite/Advanced UI project if the InstallScript package meets the following requirements:

- The InstallScript package is uncompressed.
- InstallShield 2012 Spring or later is used to build the InstallScript package and the Advanced UI or Suite/Advanced UI installation.
- The InstallScript package uses an event-based script; it should not use the program...endprogram style script. For information on converting a script that uses a program...endprogram block to an event-based script, see OnShowUI.

If either of these conditions cannot be met, you can include the InstallScript installation as an executable file package (.exe) in your Suite/Advanced UI project, instead of as an InstallScript package. However, including the InstallScript installation as an InstallScript package instead of as an executable package (.exe) is preferred. For more information, see Guidelines for Adding Packages to an Advanced UI or Suite/Advanced UI Project.

Note • *If you include an InstallShield 2012 or earlier InstallScript installation as a package in an Advanced UI or Suite/Advanced UI installation, the Advanced UI or Suite/Advanced UI installation encounters a run-time error when it attempts to launch the InstallScript package.*

Instructions for Adding an InstallScript Package to an Advanced UI or Suite/Advanced UI Project

Task: ***To add an InstallScript package to your Advanced UI or Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. Right-click the **Packages** explorer and then click **InstallScript Package (.hdr)**. The **Select the installation file for this package** dialog box opens.
3. Select the `data1.hdr` file of the InstallScript installation, and then click **Open**. The `data1.hdr` file must be in the same folder as the remaining files of the uncompressed InstallScript installation that you want to include as a package in your Advanced UI or Suite/Advanced UI project.

Tip • *When you select the `data1.hdr` file for the InstallScript installation, InstallShield automatically includes the necessary .cab files, InstallScript files (.rul), and other files that the Advanced UI or Suite/Advanced UI installation needs to launch the InstallScript package in an Advanced UI or Suite/Advanced UI installation.*

InstallShield adds the package, plus any additional folders and files, in the Packages explorer.

Special Considerations for InstallScript Packages in Advanced UI and Suite/Advanced UI Projects

Run-Time User Interface, Events, and Functions

When an Advanced UI or Suite/Advanced UI installation launches an InstallScript package, the Advanced UI or Suite/Advanced UI installation displays its own user interface (UI) while automatically suppressing the UI of the InstallScript package. The Advanced UI or Suite/Advanced UI installation also displays progress information for the InstallScript package. To make these changes possible, the Advanced UI or Suite/Advanced UI installation uses several Advanced UI– and Suite/Advanced UI–specific InstallScript events and functions by default, and ignores some of the standard InstallScript events and functions. The Advanced UI– and Suite/Advanced UI–specific InstallScript events also augment how file transfer starts.

In a standard InstallScript installation that is launched via the InstallScript `Setup.exe` file (that is, not launched from an Suite/Advanced UI installation), most events are called directly from the OnShowUI event. In an Advanced UI or Suite/Advanced UI installation that launches an InstallScript package, OnShowUI is replaced with OnSuiteShowUI. For more information, including the Advanced UI– and Suite/Advanced UI–specific events that are launched by default through OnSuiteShowUI, see OnSuiteShowUI.

The InstallScript language includes some Advanced UI– and Suite/Advanced UI–specific functions that enable interaction between an InstallScript package and the Advanced UI or Suite/Advanced UI installation that is running it. For more information, see Advanced UI and Suite/Advanced UI Interaction Functions.

Note the following guidelines:

- Because an Advanced UI or Suite/Advanced UI installation suppresses the standard InstallScript UI of an InstallScript package, any script dialog calls (for example, **DefineDialog**, **EzDefineDialog**) return an error. Therefore, no dialog calls should be made in the Advanced UI– or Suite/Advanced UI–specific events or in feature transfer events.
- Advanced UI and Suite/Advanced UI installations route all script-provided message box functionality (for example, **MessageBox**, **SprintfBox**) through the SuiteErrorReport function. Calls to these functions should not be made as a way of requesting user input except in error cases. All user input should be obtained through the Advanced UI or Suite/Advanced UI wizard pages, which you can configure in the Wizard Interface view of an Advanced UI or Suite/Advanced UI project. This enables you to provide a consistent UI experience for all of the packages in an Advanced UI or Suite/Advanced UI installation.
- Non-InstallScript UI (such as custom UI implemented through DLLs or other means) should not be called from Advanced UI– or Suite/Advanced UI–specific InstallScript events or feature transfer events. All user input should be obtained through the Advanced UI installation's or Suite/Advanced UI installation's UI.

Passing Data from an Advanced UI or Suite/Advanced UI Installation to an InstallScript Package in the Advanced UI or Suite/Advanced UI Installation

To pass data from an Advanced UI or Suite/Advanced UI installation to an InstallScript package through the command line, use the CMDLINE variable. For more information, see CMDLINE.

To pass Advanced UI or Suite/Advanced UI property values to an InstallScript package, use the InstallScript functions SuiteGetProperty or SuiteFormatString.

Run-Time Detection for Launching Through an Advanced UI or Suite/Advanced UI Installation

To determine whether the InstallScript installation is running as an InstallScript package in an Advanced UI or Suite/Advanced UI installation, use the SUITE_HOSTED variable in your InstallScript code. For more information, see SUITE_HOSTED.

Adding an Executable Package (.exe) to a Suite/Advanced UI Project

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you add executable packages (.exe) to a Suite/Advanced UI project. This format of Suite/Advanced UI package is recommended only if one of the preferred format types is not available. For more information, see Guidelines for Adding Packages to an Advanced UI or Suite/Advanced UI Project.

Task: ***To add an .exe package to your Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. Right-click the **Packages** explorer and then click **New Executable Package (.exe)**. The **Select the installation file for this package** dialog box opens.
3. Select the .exe file that you want to add to your Suite/Advanced UI project, and then click **Open**. The **Add Files for This Package** dialog box opens.
4. Specify whether you want to include additional folders and files with your package file, and if so, whether you want to include dynamically linked files.

InstallShield adds the package, plus any additional folders and files, in the Packages explorer.

Special Considerations for Configuring Executable Packages in a Suite/Advanced UI Project

The following tasks are recommended when you are configuring an executable package in a Suite/Advanced UI project:

- Define appropriate conditions that direct the Suite/Advanced UI installation how to behave under various scenarios—for example, evaluating whether the package is already installed and checking for requirements and dependencies. For more information, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.

- Suppress the user interface of the executable package and have the Suite/Advanced UI installation launch it silently. Otherwise, at run time, the installation shows the Suite/Advanced UI user interface and the separate user interface of the .exe package, presenting two disparate user interfaces. For more information, see Passing Command-Line Parameters to a Package in an Advanced UI or Suite/Advanced UI Installation.

Adding a Sideloading App Package (.appx) to a Suite/Advanced UI Project

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Note • *The ability to create and build a Suite/Advanced UI installation that includes a sideloading app package (.appx) requires Windows Vista or later or Windows Server 2008 or later on the machine that has InstallShield or the Standalone Build.*

InstallShield lets you add sideloading app packages (.appx) to a Suite/Advanced UI project.

Sideloading an app is the process of installing an app without obtaining it through the Windows Store. This type of app is sometimes distributed to enterprise environments. Following are requirements for sideloading apps:

- The target system must have Windows 8 or later or Windows Server 2012 or later.
- The **Allow all trusted applications to install** group policy setting must be enabled on the target system.

For additional requirements for sideloading and running these types of apps, see the Windows 8 documentation on the MSDN Web site.

Note that InstallShield does not have support for including .appx packages that target the ARM processor architecture in a Suite/Advanced project.

Task: ***To add an .appx package to your Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. Right-click the **Packages** explorer and then click **New Sideloading App Package (.appx)**. The **Select the installation file for this package** dialog box opens.
3. Select the .appx file that you want to add to your Suite/Advanced UI project, and then click **Open**. The **Add Files for This Package** dialog box opens.

4. Specify whether you want to include additional folders and files with your package file, and if so, whether you want to include dynamically linked files. Typically an .appx package is self-contained, and it requires only the .appx file and possibly the certificate file (.cer).

InstallShield adds the package, plus any additional folders and files, in the Packages explorer.

Note that when you add a sideloading app package to a Suite/Advanced UI project, InstallShield automatically adds an eligibility condition for that package to check for the presence of Windows 8 or later or Windows Server 2012 or later. This eligibility condition ensures that the Suite/Advanced UI installation does not attempt to add the package to systems that have earlier versions of Windows.

Static vs. Dynamic Files for Packages in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are adding or configuring an .msi, .msp, or .exe package in an Advanced UI or Suite/Advanced UI project, you can indicate whether the package requires additional files that are located near the package file. For example, if a package that you are adding is an uncompressed .msi package, you may need to include other files—such as .cab files and uncompressed data files in nearby subfolders—along with the package file.

InstallShield supports several ways of including the additional files for a package in your project:

- **Use static links for all of the additional files**—This method is useful if the package has been finalized, and no other changes will be made. This method may also be useful if the names of all of the additional files are not likely to change while you are designing the Advanced UI or Suite/Advanced UI installation. At build time, InstallShield copies all of the package's static files that are listed in the Packages view into your Advanced UI or Suite/Advanced UI installation.
- **Use dynamic links for all of the additional files**—With this method, you specify the source location for the additional files. At build time, InstallShield copies all of the files that are present in the source location into your Advanced UI or Suite/Advanced UI installation.

  This method is useful if you are authoring both the package and the Advanced UI or Suite/Advanced UI installation, and the list of additional files that the package requires is likely to change between builds.
- **Use a combination of static and dynamic file links for the additional files**—With this method, you can use static links for all critical additional files whose names are known at design time, and use dynamic links for any other additional files. At build time, InstallShield copies all of the package's static files that are listed in the

Packages view into your Advanced UI or Suite/Advanced UI installation. In addition, InstallShield also copies all of the dynamic files as needed.

Note • *InstallShield always includes a static link for the package file (.msi, .msp, InstallScript package, or .exe). Therefore, the name of the package file should be consistent from one build to another.*

Important • *Dynamic file linking should be used with caution. If you inadvertently delete a dynamically linked file from the source folder that your dynamic link references, that file is not included in your release the next time you build it, and InstallShield does not display any build warning or error. Your product may install without any issues, but it may not work as expected, since the dynamically linked file that was inadvertently deleted is no longer being installed.*

Distinguishing Static Source Locations from Dynamic Source Locations in InstallShield

When a statically linked folder is displayed within the Packages view, the folder's icon is a plain yellow folder.

When a dynamically linked folder is displayed within the Packages view, the folder's icon includes an image that indicates that it is dynamically linked:

InstallShield adds an arrow to the folder image—in addition to the dynamic file image—on the icon of a folder that contains one or more dynamically linked subfolders.

You can click either of those special folder icons to configure settings such as the source location for the content. You can also set up filters that you want InstallShield to use at build time to include or exclude certain files in the build.

Creating a Dynamic Link in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

You can use the Packages view to create a dynamic link for the additional files that a package in the project requires.

You can include dynamic file links when you add your package to the project. You can also add them to your project later. The following sections provide instructions for both procedures.

Creating a Dynamic File Link When Adding a Package

When you add a package to your project in the Packages view, InstallShield displays the Add Files for This Package dialog box. This dialog box lets you specify whether the package file that you are adding requires other files and folders that are near the package that you are adding. For example, if you are adding an uncompressed .msi package to your project, you may need to include other files as well as folders that contain files that the .msi package installs on target systems. These folders and other files are typically in the same folder that contains the .msi package.

Do one of the following when InstallShield displays the Add Files for This Package dialog box:

- If you want to include only static files, clear the **Add files dynamically found during build** check box on this dialog box.
- If you want to include any dynamic files, with or without static files, select the **Add files dynamically found during build** check box on this dialog box.

Then select the option that describes where the source files are in relation to the package file. For more information about the various options, see Add Files for This Package Dialog Box.

Creating a Dynamic File Link After a Package Has Been Added

Task: ***To add a dynamic file link for additional files after the package has been added to the project:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, find the package that requires the additional files, and click its corresponding folder that should contain the dynamic link. The **Files** pane shows the list of current files and dynamic folders.
3. Right-click in the **Files** pane and then click **Add Dynamic Link**. The **Browse for Folder** dialog box opens.
4. Browse to the folder that contains the files that you want to include dynamically, and then click **OK**.

Configuring a Dynamic File Link

Once you have added a dynamic file link to your project, you can configure its settings, which includes filter criteria for including files in and excluding files from the dynamic link. To learn more, see Defining Filters for a Dynamically Linked Folder in an Advanced UI or Suite/Advanced UI Project

Defining Filters for a Dynamically Linked Folder in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Once you have added a dynamic link to your project, you can specify filter criteria for including files in and excluding files from the dynamic link.

Task: ***To specifying filter criteria for a dynamic file link:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, select the dynamically linked folder.
3. In the **Files** pane, click the folder for which you want to configure filter criteria.
4. In the **Dynamic Link** pane, review the subsettings under the **Filter** setting.
5. Do one of the following:
   - To add a filter:
     a. In the **Filter** setting, click the **New filter** button, and then select **Include File**, **Exclude File**, **Include Folder**, or **Exclude Folder**, depending on the type of filter you want to add. InstallShield adds a new row that you can use to define the filter.
     b. In the new row, specify the name or the pattern for the file or folder.

        To indicate a wild-card character, use an asterisk (*). For example, to include all .htm files, you could enter `*.htm` in an **Include File** setting. To include all files, you could enter `*.*`.

        To refer to the root folder (the one that contains the package file) in a path, use a dot and a backslash:

        ```
        .\
        ```

        For example, to refer to a **ReadMe.txt** file in a subfolder called **MyDirectory**, where **MyDirectory** is a subfolder of the folder that contains the package, you could use the following filter:

        ```
        .\MyDirectory\ReadMe.txt
        ```

   - To modify a filter: In the setting for the filter that you want to modify, enter the appropriate name or pattern for your filter.

- To change the order of the filter criteria: In the setting for the filter that you want to move, click the **Move Filter** button, and then click **Move Up** or **Move Down**.
- To remove a filter: In the setting for the filter that you want to remove, click **Delete this Filter** button.

How an Advanced UI or Suite/Advanced UI Installation Evaluates the Filter Criteria at Build Time

At build time, InstallShield uses the filters that are set up for a dynamically linked folder to determine which folders and files to include in the release for a particular package, and which ones to exclude.

When InstallShield checks the dynamic link's source folder (the folder that contains the package), it reviews the filters in the order that they are listed under the Filter setting, from top to bottom. The first file filter that matches a file is the one that determines whether the file is included in the build. Similarly, the first folder filter that matches a folder is the one that determines whether the folder's files are included in the build.

For example, if the first filter in the list is as follows, InstallShield includes all files that are in the source folder, including a file called **ReadMe.txt**:

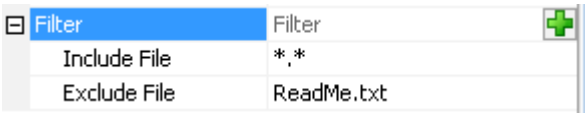

Figure 5-2: The *.* Include File filter overrides the ReadMe.txt Exclude File filter since the *.* filter is listed above the ReadMe.Txt filter.

If you move the **ReadMe.txt** filter exclusion above the *.* inclusion filter, the build includes all files except any that are named **ReadMe.txt**.

If a dynamically linked folder does not contain any filters, InstallShield includes all of the files that are in the source folder but none of the files in its subfolders.

Including InstallShield Prerequisites (.prq) in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

An InstallShield prerequisite is an installation for a product or technology framework that is required by your product. You can add any of the existing InstallShield prerequisites (.prq files) to your Advanced UI and Suite/Advanced UI projects. You can also create your own InstallShield prerequisites, and add them to your Advanced UI and Suite/Advanced UI projects.

Task: ***To include an InstallShield prerequisite (.prq file) in an Advanced UI or Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. Right-click the **Packages** explorer, and then click **Import Prerequisite (.prq)**.

InstallShield adds the InstallShield prerequisite to the Packages explorer as an .msi package, an .msp package, or an .exe package, depending on the type of file that is configured to run for the prerequisite.

If the InstallShield prerequisite has dependencies (that is, if one or more other .prq files are specified as dependencies in the InstallShield prerequisite that you are adding to the Advanced UI or Suite/Advanced UI project), InstallShield automatically adds the dependency prerequisites as separate packages in the Packages explorer.

Tip • *When you add InstallShield prerequisites to an Advanced UI or Suite/Advanced UI project, InstallShield automatically configures default values for the prerequisite package's settings. You can change these settings as needed, just as you can change the settings for packages in your Advanced UI or Suite/Advanced UI project. For more information, see Configuring Settings for a Package in an Advanced UI or Suite/Advanced UI Project.*

Reviewing the Detection and Evaluation Conditions of an InstallShield Prerequisite That Is Included as a Package in an Advanced UI or Suite/Advanced UI Project

Once you have imported an InstallShield prerequisite into an Advanced UI or Suite/Advanced UI project, review the detection and evaluation conditions of the package, and make changes as needed.

For example, if you import an InstallShield prerequisite that targets version 5.0 and all later versions of the Windows operating system, you may want to change the conditions that InstallShield configures by default when you include the prerequisite in your project; you could replace the multiple platform conditions with a single platform condition in which the OS Version condition subsetting is **5.0-** (to indicate version 5.0 and later).

Note that Advanced UI and Suite/Advanced UI projects do not have support for the following conditions that InstallShield prerequisites support:

- If you use the condition **A file does or does not exist** or **A file with a certain date exists** in a prerequisite and if you reference a registry key as a property for part of the path to the file, a Basic MSI, InstallScript, or InstallScript MSI installation resolves the registry key with the registry value. However, an Advanced UI or Suite/Advanced UI installation cannot properly resolve the path; therefore, this type of condition always evaluates as false. Thus, if you import an InstallShield prerequisite with that type of condition, ensure that you review the detection and eligibility conditions, and make any required changes.
- If you use the condition **A file does or does not exist** or **A file with a certain date exists** in a prerequisite and if you omit the path to the file, a Basic MSI, InstallScript, or InstallScript MSI installation searches for the specified file in all directories that are defined for the PATH environment variable on the target system.

However, an Advanced UI or Suite/Advanced UI installation cannot properly resolve the path; therefore, this type of condition always evaluates as false. Thus, if you import an InstallShield prerequisite with that type of condition, ensure that you review the detection and eligibility conditions, and make any required changes.

Primary Packages vs. Dependency Packages in Advanced UI and Suite/Advanced UI Projects

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Project-specific differences are noted where appropriate.

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Each package in Advanced UI and Suite/Advanced UI projects needs to be identified as either a primary package or a dependency package. The package type identifies whether the presence of that package on a target system should influence whether the Advanced UI or Suite/Advanced UI installation runs in first-time installation mode or maintenance mode:

- **Primary package**—A primary package is a main part of the Advanced UI or Suite/Advanced UI installation.

  At run time, if all of the primary packages in the installation are absent from the target system, the installation runs as a first-time installation. If any of the primary packages are present on the target system, the installation runs in maintenance mode.

- **Dependency package**—The presence or absence of a dependency package on the target system does not influence which mode is used to run the installation.

The Package Type setting that is available when you select a package in the Packages view indicates whether the package is a primary package or a dependency package.

In Suite/Advanced UI projects, you can change the value of the Package Type setting as needed for any packages in your project. However, in Advanced UI projects, this setting is read-only, since an Advanced UI project has support for only one primary package.

Note that when you import an InstallShield prerequisite into an Advanced UI project or a Suite/Advanced UI project, InstallShield adds the InstallShield prerequisite to the project as a dependency package. In a Suite/Advanced UI project, you can use the Package Type setting to override this default value, and specify that the package is a primary package if appropriate. However, an InstallShield prerequisite in an Advanced UI project is always identified as a dependency package, and this default behavior cannot be overridden in the Professional edition of InstallShield.

Specifying the Installation Order of Packages and Transactions in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Project-specific differences are noted where appropriate.

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

If your Suite/Advanced UI project includes more than one package, transaction, or InstallShield prerequisite, the Packages view is where you specify the order in which the packages should be installed and the transactions should be launched at run time on target systems.

Similarly, if your Advanced UI project includes a package and one or more InstallShield prerequisites, the Packages view is where you specify the order in which the packages should be installed at run time on target systems.

This Packages view lists the packages, InstallShield prerequisite packages, and (if supported) transactions in the same order in which the Advanced UI or Suite/Advanced UI installation launches them at run time.

Task: ***To modify the order in which the packages should be installed on target systems:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, right-click the package or transaction that you want to move and click **Move Up** or **Move Down**.

Configuring Settings for a Package in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you add a package to an Advanced UI or Suite/Advanced UI project, you can configure its settings to specify details such as the display name and the conditions under which the Advanced UI or Suite/Advanced UI installation should launch the package.

Task: ***To configure a package in your Advanced UI or Suite/Advanced UI project:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, click the package that you want to configure.
3. Use the settings on the **Common** tab to define conditions for the package and configure other settings.

For information on any of the package settings, see Common Tab.

At run time, the `Setup.exe` file launches each package based on the conditions that you have defined and the order in which you listed the packages in the Packages view.

Tip • *If you add an .msi package to your project, InstallShield automatically creates an MSI Package eligibility condition for the package, and uses an asterisk (*) in the condition's Product Code and Product Version settings as placeholders for the package's own product code and product version. InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from launching the package if a package with a matching product code but a later product version is already installed. You can override this built-in condition if necessary.*

You can use an asterisk as a placeholder for the current package's product code and product version when you are defining eligibility and detection MSI package conditions, as long as the package that you are configuring is an .msi package.
You can also use an asterisk as a placeholder for the current' package's upgrade code and either the minimum or maximum version number when you are defining eligibility and detection MSI upgrade conditions, as long as the package that you are configuring is an .msi package.

Associating a Package in an Advanced UI or Suite/Advanced UI Project with a Feature

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Each package that is included in an Advanced UI or Suite/Advanced UI project should be associated with a feature in the project.

Task: ***To associate a package in your Advanced UI or Suite/Advanced UI project that requires the target system to be restarted:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, select the package that you want to configure.
3. Click the **Features** tab.
4. Select the check box of each feature that you want to contain the package.

Specifying a Run-Time Location for a Specific Package in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield enables you to specify a different run-time location for each package in your project. For example, you can have a package and its files stored on the source media, or downloadable if required from the Web. Or, you can have a package compressed into the Advanced UI or Suite/Advanced UI `Setup.exe` file and extracted at run time if necessary.

Task: ***To specify a different run-time location for each package in your project:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, select the package that you want to configure.

3. In the **Location** list, select the appropriate option.

Note that the location that you specify can be overridden at the release level. To avoid overriding the value that you selected for an individual package, the Package Location setting at the release level must be set to Follow Individual Selections. For more information, see Specifying the Run-Time Location for Advanced UI or Suite/Advanced UI Packages at the Release Level.

Tip • *If you are configuring an Advanced UI or Suite/Advanced UI project for an update setup launcher, the run-time location of the packages must be either extracted from the setup launcher or downloaded from the Web. The update setup launcher cannot rely on packages that are stored on the source media.*

For more information, see Adding Support for Automatic Updates to an Advanced UI or Suite/Advanced UI Installation.

Configuring Package Operations for an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Advanced UI projects include support for .exe packages only if they are included in the project from an InstallShield prerequisite.

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

An Advanced UI or Suite/Advanced UI operation is the state in which a package in the Advanced UI or Suite/Advanced UI installation is running. The different types of operations are install, remove, repair, modify, and maintenance.

When you add a package to an Advanced UI or Suite/Advanced UI project, you can configure various operation settings for the package. The settings let you specify whether each of the operations are applicable to the package. The settings also let you enter command lines that you want the Advanced UI or Suite/Advanced UI installation to use when launching the package in each mode. You can specify separate command lines: one for when the Advanced UI or Suite/Advanced UI installation is running with a user interface, and one when it is running silently (without a user interface).

Install Operation

An Advanced UI or Suite/Advanced UI installation runs an install operation to install the package onto a target system. This occurs during either a first-time installation, or when a feature is selected to be installed during maintenance. All packages typically have an install operation.

When an Advanced UI or Suite/Advanced UI installation runs an install operation for an .msi, .msp, or InstallScript package, the Advanced UI or Suite/Advanced UI installation automatically launches the package silently. However, when an Advanced UI or Suite/Advanced UI installation runs an install operation for an .exe package, the Advanced UI or Suite/Advanced UI installation cannot automatically launch the package silently, since different types of .exe packages may use different ways of running without a user interface. If you want the Advanced UI or Suite/Advanced UI installation to run an .exe package silently, ensure that you enter the appropriate command line for the package's install operation subsettings.

If any of your Advanced UI or Suite/Advanced UI packages should be configurable by end users, create wizard pages that let end users configure properties, and pass the associated properties to the packages through the command lines.

Remove Operation

An Advanced UI or Suite/Advanced UI installation runs a remove operation to uninstall the package from a target system. Packages that are marked as a primary package typically have a remove operation; packages that are marked as a dependency package often do not have a remove operation, since they are typically left on target systems. A package that installs the .NET Framework is an example of a package that would be marked as a dependency package. The Package Type setting for the package identifies whether the package is a primary package or a dependency package.

An Advanced UI or Suite/Advanced UI installation runs a remove operation when an Advanced UI or Suite/Advanced UI feature is turned off during maintenance, or when the Advanced UI or Suite/Advanced UI product is uninstalled. Like during installation, an .exe package's command lines should run the package silently.

Note that the remove operation does not apply to .msp packages; removing an .msp package requires removing the base .msi package.

Repair Operation

An Advanced UI or Suite/Advanced UI installation runs a repair operation to invoke the repair functionality that some packages support. If you are configuring an Advanced UI or Suite/Advanced UI package that supports repair, configure the package's repair operation setting to allow repairs. The Advanced UI or Suite/Advanced UI installation runs the repair operation only when the Advanced UI or Suite/Advanced UI installation is being repaired as part of maintenance, and only if the package is already installed.

If you are configuring a repair operation for an .msi package, you do not need specify any special command lines to trigger a silent repair, since the Advanced UI or Suite/Advanced UI installation can trigger the repair automatically if appropriate. However, if you are configuring a repair operation for an .exe package, you must enter the appropriate command line to trigger the repair. For example, for a Basic MSI `Setup.exe` package, you could enter the following command line in the EXE Command Line and the EXE Silent Command Line subsettings under the Repair operation setting:

```
[SystemFolder]msiexec.exe /f {8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC} /qn
```

The GUID in braces is the product code of the Windows Installer package.

Note that the repair operation does not apply to .msp packages.

Modify Operation

An Advanced UI or Suite/Advanced UI installation runs a modify operation to perform feature selection. If you are configuring an Advanced UI or Suite/Advanced UI package that offers feature selection, configure the package's modify operation setting to allow modifications. The Advanced UI or Suite/Advanced UI installation runs the modify operation when Advanced UI or Suite/Advanced UI feature selection changes indicate that a package's features should be added or removed.

Note that the modify operation does not apply to .msp packages.

Maintenance Operation

An Advanced UI or Suite/Advanced UI installation runs a maintenance operation in scenarios such as the following ones:

- An end user chooses to modify the product through its entry in Add or Remove Programs.
- An end user reruns the Advanced UI or Suite/Advanced UI installation.

The maintenance operation differs from the other types of operations because it is not controlled through an operation setting.

Using Custom Folder Names for Packages in Advanced UI and Suite/Advanced UI Installations

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you build an Advanced UI or Suite/Advanced UI installation, InstallShield creates a folder for each package that is included in the installation; these folders are created in the same folder that contains the Advanced UI or Suite/Advanced UI setup launcher. By default, the name of each folder is a GUID that InstallShield generates.

The Packages view in InstallShield now lets you override the GUID name with a user-friendly name for each package folder.

Task: ***To specify your own text for the name of a package folder:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, expand the node for the package whose folder name you want to customize.
3. Right-click the **Package Files** folder, and then click **Rename**.

   

   Note • *If you leave the default name (**Package Files**), InstallShield uses a GUID for the name of the package folder.*
4. Enter a new name for the folder. If you customize more than one package folder name, ensure that each folder name is different.

At build time, InstallShield uses the text that you entered instead of a GUID for the name of the package folder when creating the release.

Customizing the Behavior of a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

An important aspect of creating a Suite/Advanced UI installation is customizing it for your product's requirements and your end users' needs. InstallShield lets you extend the functionality of your Suite/Advanced UI installation to perform various run-time tasks that are outside the scope of the packages that you are including in the installation. For more information, see:

- Enabling Windows Roles and Features During a Suite/Advanced UI Installation
- Using Actions to Extend the Behavior of a Suite/Advanced UI Installation

Enabling Windows Roles and Features During a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Some Windows functionality is disabled by default on target systems. In addition, some end users, or perhaps IT administrators, may choose to disable some Windows functionality. To manually enable or disable such Windows roles and features, they can use the **Turn Windows features on or off** link in the Programs and Features Control Panel.

If a particular package in your Suite/Advanced UI installation requires that one or more Windows roles or features be enabled on target systems, you can specify the required roles and features when you are configuring the package in your Suite/Advanced UI project. At run time, if an eligible package that is being installed requires one or more Windows roles or features that are disabled, the Suite/Advanced UI installation enables them before launching the package.

For example, your Suite/Advanced UI project may have a package that installs an IIS Web site that requires that the Internet Information Services feature in Windows be turned on. Another package in the same project may require that the PowerShell feature be turned on. When you are configuring the settings of those packages in your project, you can specify the Windows features that are required; at run time, if a package is eligible to be installed on a target system but any of its required Windows features are disabled, the Suite/Advanced UI installation enables those disabled Windows features before launching it. If the package is not eligible, its required Windows features are not enabled.

Note that during uninstallation, any Windows roles and features that the Suite/Advanced UI installation had enabled during installation are not removed; this helps avoid breakage of other products on the target system that require those roles and features.

InstallShield has built-in support for enabling several Windows features:

- Internet Information Services
- PowerShell
- .NET Framework 3.x

InstallShield also lets you specify additional Windows roles and features that a package requires.

Task: ***To specify a Windows role or feature that you want to be enabled if a particular package is eligible for installation:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, click the package that you want to configure.
3. On the **Common** tab, in the **Windows Features** setting, click the **Add New Windows Feature** button, and then click one of the available feature options:
   - **Internet Information Services**
   - **PowerShell**
   - **Microsoft .NET Framework 3.x**
   - **Custom**—This option lets you specify any Windows feature that is not listed as an option in this setting.

   InstallShield adds a new **Windows Feature** row under the **Windows Features** setting, and configures it as needed for any of the built-in feature options (Internet Information Services, PowerShell, or Microsoft .NET Framework 3.x). For the **Custom** option, the **Windows Feature** row contains a placeholder string for the name of a feature.
4. If you selected one of the built-in options, leave the value that InstallShield adds to the **Windows Feature** setting as is.

   If you selected the **Custom** option: In the **Windows Feature** setting, enter the name of the Windows role or feature that you want to be enabled. The name that you enter for any custom option should be the string that tools such as Deployment Image Servicing and Management (`DISM.exe`) and Package Manager (`Pkgmgr.exe`) use to identify the role or feature on a particular version of Windows.

   For a list of available Windows roles and features on each version of Windows for which you are supporting, see Microsoft TechNet.

Special Considerations for Enabling Windows Roles and Features

Availability of Windows Roles and Features on Various Versions of Windows

The support for enabling Windows roles and features is available for target systems that have Windows Vista or later or Windows Server 2008 or later. The list of Windows roles and features that can be enabled on a given target system varies, depending on the version of Windows that is present. In addition, different versions of Windows may use different strings for the same role or feature.

If a Suite/Advanced UI installation attempts to enable a Windows role or feature that is not available on a target system, the Suite/Advanced UI installation fails and writes error 0x800f080c in the log file.

Thus, in some scenarios in which you are specifying required Windows roles and features, you may want to use a package's Eligibility Condition setting to identify the appropriate operating system versions that correspond with the required Windows role or feature that you are selecting for the package. To target multiple versions of Windows, each with a different string for the name of the Windows role or feature that you are enabling, consider

adding the package to your project multiple times. For each instance of the package, use the package's Windows Features and Eligibility Condition settings to specify the appropriate string for the corresponding target operating systems.

Note that some roles and features may not only be disabled on some versions of Windows; they also may not be installed. If a Suite/Advanced UI installation is configured to enable a Windows role or feature that is not installed on a target system, the Suite/Advanced UI installation attempts to install the role or feature. If the role or feature cannot be installed, the Suite/Advanced UI installation fails. An example of a Windows feature to which this scenario may apply is the .NET Framework 3.x feature, which may not be installed by default on Windows 8 systems. The payload for this feature is available only through Windows Update. If an Internet connection is not available, or if the system is configured to obtain updates through Windows Server Update Services instead of Windows Update, the Suite/Advanced UI installation cannot install and enable the .NET Framework 3.x feature.

Identifying Dependencies for a Required Windows Role or Feature

Some Windows roles and features depend on other Windows roles or features. One way to determine whether a disabled role or feature has any dependencies is to run the following command from an elevated Command Prompt window (which you can launch by right-clicking a shortcut for `cmd.exe` and then clicking **Run as admin**):

```
dism /online /enable-feature FEAT-NAME
```

In this example, FEAT_NAME is the name of the disabled feature that you are checking. If the aforementioned command works, the feature has no dependencies. If it fails, the error lists the dependencies.

If the role or feature that you are enabling for a package requires one or more roles or features that may be disabled on target systems, ensure that you also specify the dependency features in the package's Windows Features setting.

Run-Time Behavior for Enabling a Windows Role or Feature

If a Suite/Advanced UI installation enables a Windows role or feature on some target systems, the InstallationProgress wizard page of the Suite/Advanced UI installation can show the progress of the role or feature being enabled. This progress information is available on target systems that have Windows 8 or later or Windows Server 2012 or later. On these target systems, a Suite/Advanced UI installation uses DISM APIs to enable roles and features, and these APIs have support for reporting the progress information.

On Windows Vista, Windows Server 2008, Windows 7, and Windows Server 2008 R2 target systems, a Suite/Advanced UI installation uses `Pkgmgr.exe` to enable roles and features. `Pkgmgr.exe` does not have support for reporting progress information; therefore, on these systems, the progress bar cannot updated as roles and features are being enabled.

Although `DISM.exe` is available on Windows 7 and Windows Server 2008 R2 systems, the API support is not shipped on these versions of Windows. In addition, the API DLL dependencies are not available for redistributing to target systems.

Using Actions to Extend the Behavior of a Suite/ Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

You may require your Suite/Advanced UI installation to perform various run-time tasks that are outside the scope of the packages that you are including in the installation. For example, you may need the Suite/Advanced UI installation to do one or more of the following:

- Install an application before the user interface of the Suite/Advanced UI installation is displayed.

  One sample scenario in which this may be necessary is when one of the packages in your Suite/Advanced UI installation runs SQL scripts to install an Oracle database. Before this package is run, you may want the Suite/Advanced UI interface to display a wizard page that lets end users select the appropriate server from a list of servers that are available on the network. This type of UI support requires that ODBC drivers be installed on the target system.

- Search the target system for the presence or absence of a particular product, technology, folder, file, registry entry, or other item.

  Support for searching the target system enables you to trigger behavior based on whether certain conditions are met. For example, if a particular file is missing on a target system, you can set a Suite/Advanced UI property accordingly, and then use that property to set a property in one or more of the packages in the Suite/Advanced UI installation.

- Configure the target system before or after running a package in the Suite/Advanced UI installation.

  In some scenarios—for example, if your Suite/Advanced UI installation installs an IIS application on servers—you may want to enable IIS-related Windows roles and features on target systems. In other scenarios, you may want to edit configuration files, registry data, or other items on the target system based on which packages in the Suite/Advanced UI installation are selected to be run by end users.

To extend the capabilities of a Suite/Advanced UI installation and make it possible to perform those sorts of tasks and more, you can use the Events view in your Suite/Advanced UI project to create actions that run executable files, call DLL functions, run PowerShell scripts, or set a Suite/Advanced UI property at run time.

Task: ***To author an action and add it to your Suite/Advanced UI project:***

1. Create your own .exe file (if appropriate), DLL file, or PowerShell script that performs the functionality that your installation requires.
2. In the Events view, create an action that runs your .exe file, calls a function in your DLL, or runs your PowerShell script. For more information, see Adding an Action to a Suite/Advanced UI Project.
3. Decide when your action should run, and schedule it: add it to an event, or assign it to an event in a specific package in your project.

Working with an .exe File for an Action in a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

You can use an .exe action in a Suite/Advanced UI installation to launch an executable file that is included in your installation (as a temporary support file or installed with the product) or that already exists on the target system.

Following are examples of scenarios in which you may want to add an .exe action to your Suite/Advanced UI installation:

- You can add an .exe action that launches a `Setup.exe` installation that you or a third party created.
- You can add an .exe action that sets permissions on existing directories.
- You can add an .exe action that opens a ReadMe file in its associated application—perhaps Notepad or Adobe Reader.
- You can add an .exe action that opens a data file in your product.

The first step in adding an .exe action to a Suite/Advanced UI project is to create or acquire the .exe file, if applicable, or to create the document or other file that the executable file will launch.

Note that .exe actions do not have access to the running installation session. Thus, you cannot pass Suite/Advanced UI properties to the .exe file (except as command-line arguments) or back from the .exe file (except through external storage, such as the registry or a file).

Task: ***To add an action that runs an executable file in a Suite/Advanced UI installation:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. Right-click the **Actions** explorer and then click **New EXE**. InstallShield adds an executable-file action to the **Actions** explorer.
3. Enter a new name, or right-click it later and click **Rename** to assign it a new name. Use a name that helps you distinguish this action from other actions in your project.
4. Configure the action's settings as needed.

Once you have added the action to your project, schedule it as needed. For more information, see Scheduling a Suite/Advanced UI Action.

Note • *If you are launching an interactive application from an .exe action, you may want to add a condition to the action to prevent it from launching when the Suite/Advanced UI installation is running silently (without a user interface). You can use the* ***ISSilentInstall*** *property in this type of condition; if the Advanced UI or Suite/Advanced UI installation is running silently (without a user interface), this property is set to True.*

As an alternative, you may want to launch interactive applications from the user interface of your installation. Thus, instead of using an .exe action to launch a PDF file, you may want to add the ability to open the PDF file from one of the wizard pages in your installation's user interface.

Working with a DLL File for an Action in a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Creating a DLL File for a DLL Action

The first step in adding a DLL action to a Suite/Advanced UI project is to create the DLL. You can create the DLL with any recent version of Visual C++ or any tool or language that supports COM and DLL exports.

The Suite/Advanced UI engine requires one entry point per action. To specify the entry point, enter it in the Function Name setting for the action in the Events view. The function should be defined as follows:

```
HRESULT __stdcall MyFunction(IDispatch *pAction);
```

To be able to call this function from the Suite/Advanced UI installation, you must include a definition file (.def) when you build the DLL to export the function properly. The following is the contents of a sample .def file. The name after LIBRARY should be the name that you are using for the DLL.

```
LIBRARY "MyActionLibrary"
EXPORTS
    MyAction
```

The Suite/Advanced UI installation calls the function entry point when an action for an event or a package in the installation is scheduled to run. Your entry-point function should return ERROR_SUCCESS to indicate that the action finished successfully. If the action fails, it should return a non-zero value. The values are the same ones that Windows Installer custom actions return.

Note that although the Suite/Advanced UI installation allows any action to be performed, actions are run with the privileges that they are configured to have. Some actions may require administrator privileges (such as reading IIS 7.x configuration data). In such cases, in order for the action to access the required data successfully, the action would need to be configured to require administrator privileges; that is, Yes would need to be selected for the Requires Administrative Privileges setting for the action in the Events view. As an alternative, the Suite/Advanced UI installation's `Setup.exe` file could be run with administrator privileges, or it would need to include an administrator manifest. However, privileges should be elevated for as short of a duration as possible.

The IDispatch interface that is passed to the action's entry point implements the ISuiteExtension2 interface (which includes all of the ISuiteExtension methods and properties). To obtain a pointer to ISuiteExtension2, call the QueryInterface method on the IDispatch interface. The ISuiteExtension2 interface allows the action function to access the attribute parameter that is defined for the action in the Suite/Advanced UI project. Note that each action in the project receives a different interface pointer that is specific to each action instance. Therefore, the interface pointer that is passed to the entry point function should always be used and should not be saved across calls to the action DLL.

The interface is defined as follows:

```
interface ISuiteExtension2 : IDispatch {
  [propget, id(1), helpstring("Attribute")]
    HRESULT Attribute([in]BSTR bstrName, [out, retval]BSTR *bstrValue);

  [id(2), helpstring("method LogInfo")]
    HRESULT LogInfo([in]BSTR bstr);

  [propget, id(3), helpstring("Property")]
    HRESULT Property([in]BSTR bstrName, [out, retval]BSTR *bstrValue);

  [propput, id(3), helpstring("Property")]
    HRESULT Property([in]BSTR bstrName, [in]BSTR bstrValue);

  [id(4), helpstring("FormatProperty")]
    HRESULT FormatProperty([in]BSTR bstrValue, [out, retval]BSTR *bstrReturnValue);

  [id(5), helpstring("ResolveString")]
    HRESULT ResolveString([in]BSTR bstrStringId, [out, retval]BSTR *bstrReturnValue);

  [id(6), helpstring("ProgressMessage")]
    HRESULT SendProgressMessage([in]BSTR bstrMsg, [in]INT iCurrent, [in]INT iMax,
                                [in]EnumProgressFlags eFlags);
};
```

Suite/Advanced UI projects use the function prototype to pass the ISuiteExtension2 COM interface pointer to an action, which enables you to access the following functions:

- **LogInfo**

  ```
  HRESULT LogInfo([in]BSTR bstr);
  ```

  This method writes any information that is needed to the Suite/Advanced UI debug log, making it available for debugging or other informational purposes. The bstr parameter contains the string to be written to the log.

- **get_Property**

  ```
  HRESULT get_Property([in]BSTR bstrName, [out, retval]BSTR *bstrValue);
  ```

  This method retrieves the value of any property that is currently defined in the running Suite/Advanced UI installation. Properties that are not defined return an empty value. The bstrName parameter specifies the name of the property whose value is being obtained. The value for the property is returned in the bstrValue parameter.

- **put_Property**

  ```
  HRESULT put_Property([in]BSTR bstrName, [in]BSTR bstrValue);
  ```

  This method sets the value of a new property or changes the value of an existing property in the currently running Suite/Advanced UI installation. Passing an empty value effectively deletes the property. The bstrName parameter specifies the name of the property to set. The bstrValue parameter specifies the value to set for the specified property.

- **FormatProperty**

  ```
  HRESULT FormatProperty([in]BSTR bstrValue, [out, retval]BSTR *bstrReturnValue);
  ```

  This method formats a string that contains embedded property references (in the form '[PROPERTYNAME]') in the string that is provided in the bstrValue parameter. The formatted value is returned in the bstrReturnValue parameter.

  Note that only one level of property references is formatted. If one property's formatted value contains another property reference, this method does not format the second property.

- **ResolveString**

  ```
  HRESULT ResolveString([in]BSTR bstrStringId, [out, retval]BSTR *bstrReturnValue);
  ```

- **SendProgressMessage**

  ```
  HRESULT SendProgressMessage([in]BSTR bstrMsg, [in]INT iCurrent, [in]INT iMax,
                              [in]EnumProgressFlags eFlags);
  ```

  This method updates the status message and the progress bar on the InstallationProgress wizard page of the Suite/Advanced UI installation. To update the progress bar, specify epfProgressValid for the eFlags parameter; to update the status message, specify epfMessageValid. To update both the status message and the progress bar, use the bitwise OR operator (|) with both flags.

Note that the get_Attribute method is not available for DLL actions in a Suite/Advanced UI installation, and it should not be called.

To access the ISuiteExtension2 interface from your DLL, you can use `#import` to incorporate the type library information from the `SetupSuite.exe` file that is installed with InstallShield. The path is:

InstallShield Program Files Folder\Redist\Language Independent\i386\SetupSuite.exe"

For example, to import the type library in a VC++ project (such as in `stdafx.h`), use the following statement:

```
#import "C:\Program Files\InstallShield\2013\Redist\Language Independent\i386\SetupSuite.exe"
no_namespace raw_interfaces_only named_guids
```

Note that if InstallShield is installed to a different location, adjust the path in the #import statement accordingly.

Adding a DLL Action

Task: ***To add an action that calls a function in a DLL file during a Suite/Advanced UI installation:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. Right-click the **Actions** explorer and then click **New DLL**. InstallShield adds a DLL action to the **Actions** explorer.
3. Enter a new name, or right-click it later and click **Rename** to assign it a new name. Use a name that helps you distinguish this action from other actions in your project.
4. Configure the action's settings as needed.

Once you have added the action to your project, schedule it as needed. For more information, see Scheduling a Suite/Advanced UI Action.

Working with a PowerShell Script for an Action in a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Windows PowerShell is a .NET Framework–based command-line shell and script language that enables system administrators to automate system configuration tasks. InstallShield lets you include in Suite/Advanced UI installations actions that run PowerShell scripts (.ps1). You may want to add this type of action to a project to perform system configuration tasks at installation run time. Note that PowerShell actions require PowerShell 2.0 or later on target systems.

Adding a PowerShell Action

Task: ***To add an action that runs a PowerShell script in a Suite/Advanced UI installation:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. Right-click the **Actions** explorer and then click **New PowerShell**. InstallShield adds a PowerShell action to the **Actions** explorer.
3. Enter a new name, or right-click it later and click **Rename** to assign it a new name. Use a name that helps you distinguish this action from other actions in your project.
4. Configure the action's settings as needed.

If you select a PowerShell action in the Actions explorer or the Events explorer, InstallShield displays a PowerShell Script tab on the right; you can use this tab to edit your script.

Once you have added the action to your project, schedule it as needed. For more information, see Scheduling a Suite/Advanced UI Action.

Interacting with the Running Suite/Advanced UI Installation

Several cmdlets that let you interact with the running Suite/Advanced UI installation are available:

Table 5-2 • Cmdlets that Interact with a Running Suite/Advanced UI Installation

Cmdlet	Description
get-suiteproperty -name [Property Name]	This cmdlet gets the value of a Suite/Advanced UI property. The following sample code gets the value of the property called **MYPROPERTY**: `$Value = get-suiteproperty -name MYPROPERTY`
set-suiteproperty -name [Property Name] -value [value]	This cmdlet sets the value of a Suite/Advanced UI property. The following sample code uses the value of the **MYPROPERTY** property to set the value of a second property called **NEWPROPERTY**: `$Value = get-suiteproperty -name MYPROPERTY` `set-suiteproperty -name NEWPROPERTY -value $Value`

Table 5-2 • Cmdlets that Interact with a Running Suite/Advanced UI Installation (cont.)

Cmdlet	Description
format-suiteproperties -Value [format string]	This cmdlet formats a string that contains one or more property references (a Suite/Advanced UI property name surrounded by square brackets). Note that only one level of property references is formatted. If one property's formatted value contains another property reference, the cmdlet does not format the second property. The following sample code formats a string that contains a Suite/Advanced UI property called **NEWPROPERTY**. The property name and its surrounding square brackets are replaced by the value of the property at run time. `$myFormat = format-suiteproperties -Value "This is a text string with '[NEWPROPERTY]' embedded."`
resolve-suitestring -StringId [string ID]	This cmdlet resolves a Suite/Advanced UI string identifier with its corresponding string value in the currently selected UI language. If no such string identifier exists, the returned string is empty. The following sample code resolves a string identifier called **IDS_MY_MESSAGE**: `$StringValue = resolve-suitestring -StringId IDS_MY_MESSAGE`
trace-suiteinfo -LogMessage [log string]	This cmdlet writes any information that is needed to the Suite/Advanced UI debug log, making it available for debugging or other information purposes. The following sample code resolves a string identifier called **IDS_MY_MESSAGE** and then writes its value to the Suite/Advanced UI debug log. `$StringValue = resolve-suitestring -StringId IDS_MY_MESSAGE` `trace-suiteinfo -LogMessage $StringValue`

To indicate that your script has succeeded, ensure that it returns 0. For example, you may want to end your script with the following:

```
exit(0)
```

Once you have added a PowerShell action in the Events view of your project, you can select it in the Actions explorer or the Events explorer, and use the PowerShell Script tab that InstallShield displays on the right to edit your script.

Working with an Action that Sets a Property in a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you add to your Suite/Advanced UI project an action that sets a Suite/Advanced UI property at run time.

Task: ***To add an action that sets a property in a Suite/Advanced UI installation:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. Right-click the **Actions** explorer and then click **New Set Property**. InstallShield adds a property action to the **Actions** explorer.
3. Enter a new name, or right-click it later and click **Rename** to assign it a new name. Use a name that helps you distinguish this action from other actions in your project.
4. Configure the action's settings as needed.

Once you have added the action to your project, schedule it as needed. For more information, see Scheduling a Suite/Advanced UI Action.

Adding an Action to a Suite/Advanced UI Project

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Task: ***To add an action to a Suite/Advanced UI project:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. Right-click the **Actions** explorer and then click the type of action that you want to add.

If you are creating a PowerShell action, the **Open** dialog box opens and enables you select the PowerShell script file (.ps1) that you want to use.

3. Optionally rename the new action by selecting it, pressing the F2 key, and typing the new name.
4. Configure the action's settings.

Note that if the action cannot be launched or loaded at run time, the installation is aborted.

Configuring a Suite/Advanced UI Action's Settings

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Task: ***To configure an action in a Suite/Advanced UI project:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. In the **Actions** explorer, click the type of action that you want to configure.
3. Configure the settings in the grid on the right.

Note that if the action cannot be launched or loaded at run time, the installation is aborted.

Scheduling a Suite/Advanced UI Action

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Once you have added an action to your project, you can schedule when at run time you want it be launched. You can also define one or more conditions that the Suite/Advanced UI engine should evaluate before launching the action.

InstallShield has support for scheduling actions in two different types of places:

- You can schedule an action to run during one or more of the built-in events that the Suite/Advanced UI manages. For example, shortly after a Suite/Advanced UI installation is loaded, the Suite/Advanced UI engine triggers the execution of an event called OnBegin. This event specifies the instructions that need to be carried out when the OnBegin event occurs.
- You can schedule an action to run before or after the Suite/Advanced UI engine installs, removes, modifies, or repairs a package.

For more detailed information, see Types of Events in a Suite/Advanced UI Installation.

Scheduling an Action During an Event

The events and actions that are listed under the Events explorer in the Events view are organized by chronological order, according to when they are launched at run time. When you add an action to an event, you specify when the action should be launched by adding it to the appropriate event.

Task: ***To schedule an action during an event:***

1. In the View List under **Behavior and Logic**, click **Events**.
2. In the **Events** explorer, right-click the event or action that you want your action to follow, point to **Add Existing Action**, and then click the name of the action that you are scheduling. InstallShield adds the action to the **Events** explorer.
3. Configure the settings in the grid on the right. One of the settings lets you build conditional statements that control whether the action is launched. For details on how to define conditions, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.

   To indicate that an action should run only during certain modes, use the Suite/Advanced UI property **ISInstallMode** in a Property Comparison condition. For more information on this and other built-in properties, see Advanced UI and Suite/Advanced UI Property Reference.

Tip • *The Events view supports drag-and-drop editing:*

- *To sequence a new action, you can drag it from the Actions explorer to the appropriate event under the Events explorer. When you drop it, drop it onto the item that should be directly before it in the sequence.*
- *To move an action to a different point in an event (or from one event to another), drag it from the old location and drop it onto the item that should be directly before it in the sequence.*
- *To copy an action from one event to another, press and hold CTRL while dragging the action from one event to another event, and drop it onto the action or event that should be directly before it.*

Scheduling an Action Before or After the Suite/Advanced UI Engine Installs, Removes, Modifies, or Repairs a Package

Task: ***To schedule an action before or after a package is installed, removed, modified, or repaired:***

1. In the View List under **Organization**, click **Packages**.
2. In the **Packages** explorer, click the package that you want to be associated with the action.
3. On the **Common** tab, expand the **Events** area if it is not already expanded.
4. Do one of the following:
   - To schedule an action before the package is installed, removed, modified, or repaired: In the **Package Configuring** setting, point to the **New Action** button, and then click the name of the action that you are scheduling. InstallShield adds an **Action** subsetting and sets its value to the name of the action that you selected.
   - To schedule an action after the package is installed, removed, modified, or repaired: In the **Package Configured** setting, point to the **New Action** button, and then click the name of the action that you are scheduling. InstallShield adds an **Action** subsetting and sets its value to the name of the action that you selected.
5. Optionally, to build a conditional statement so that you can further control when the action is launched, click the **Add a condition** button. For details on how to define conditions, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.

   To indicate that an action should be run only if a specific package in the installation is running in a particular state, create a Package Operation condition.

   To indicate that an action should run only during certain modes, use the Suite/Advanced UI property **ISInstallMode** in a Property Comparison condition. For more information on this and other built-in properties, see Advanced UI and Suite/Advanced UI Property Reference.

Types of Events in a Suite/Advanced UI Installation

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Suite/Advanced UI installations are driven by the Suite/Advanced UI installation, which manages a series of events in a specific order. These events run actions that you have added to your project.

The following table describes each of the events that are listed in the Events view of a Suite/Advanced UI installation:

Table 5-3 • Events That Are Listed in the Events View

Event Name	Description
OnBegin	The OnBegin event is the first event in a Suite/Advanced UI installation. Actions that are scheduled for this event are executed during all modes (install, maintenance, repair, etc.) unless the conditional statement that is defined for the action evaluates as false. To indicate that an action should run only during certain modes, use the Suite/Advanced UI property **ISInstallMode** in a Property Comparison condition. For more information on this and other built-in properties, see Advanced UI and Suite/Advanced UI Property Reference. Actions that are scheduled during OnBegin run before the Suite/Advanced UI installation displays the wizard interface. A long-running action during this event could result in a long delay between the moment when an end user launches the installation and the point at which the wizard interface is first shown. This could lead the end user to think that the installation was not launched properly. Thus, you may want to avoid scheduling long-running actions during OnBegin. Note that you also may want to avoid using an action that displays its own user interface when launched. The wizard interface of the Suite/Advanced UI installation can appear behind other open windows in this scenario, possibly confusing an end user.
OnResuming	The OnResuming event launches its actions when a Suite/Advanced UI installation is resuming after the target machine has been restarted.
OnStaging	The OnStaging event launches its actions immediately before the Suite/Advanced UI installation is staged; that is, before the Suite/Advanced UI installation downloads its package (if applicable), extracts its packages from the `Setup.exe` file (if applicable), and copies its packages to a directory that the end user specifies on the BrowseStageFolder wizard page or by setting the **ISRootStagePath** property through the command line.
OnStaged	The OnStaged event launches its actions after the Suite/Advanced UI installation has downloaded its packages (if applicable), extracted them from the `Setup.exe` file, and copied them to the staging directory.
OnPackagesConfiguring	The PackagesConfiguring event launches its actions immediately before the packages in the Suite/Advanced UI installation are being installed, modified, repaired, or removed.
OnPackagesConfigured	The OnPackagesConfigured event launches its actions when the packages in the Suite/Advanced UI installation have been installed, modified, repaired, or removed.

Table 5-3 • Events That Are Listed in the Events View (cont.)

Event Name	Description
OnRebooting	The OnRebooting event launches its actions immediately before the Suite/Advanced UI installation triggers a restart of the machine. Note that actions that are scheduled during OnRebooting should run for a brief period of time. Otherwise, the actions may fail to complete if a reboot is initiated by some prior action and Windows shuts down the Suite/Advanced UI process before the reboot events complete.
OnEnd	The OnEnd event launches its actions immediately before the end of a successful Suite/Advanced UI installation. If the end user cancels the Suite/Advanced UI installation or the installation encounters an error, the OnEnd event does not run.

Note that the Suite/Advanced UI engine does not maintain states to track which events have run or not run. Therefore, you may need to define Property Comparison conditions for actions to prevent the actions from being rerun after the Suite/Advanced UI installation resumes because of a reboot. You can use the ISOnRebooted property in these conditions; if the Suite/Advanced UI installation is resuming after a reboot, this property is set to True.

If you define a Feature Operation condition or a Package Operation condition for an action, the earliest event for which you can schedule the action is OnStaging.

Defining Exit Conditions for an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you specify one or more exit error messages that you want the Advanced UI or Suite/Advanced UI installation to display under various conditions before ending the installation. For example, if your Advanced UI or Suite/Advanced UI installation requires Windows Vista or later, you could set up an exit message to inform end users about the requirement. You would also define a condition for that exit message to evaluate whether target

systems have earlier versions of Windows. If the condition that you define is true when an end user launches the Advanced UI or Suite/Advanced UI installation, the Advanced UI or Suite/Advanced UI installation displays the error message. When end users dismiss the error message, the Advanced UI or Suite/Advanced UI installation ends.

Task: ***To define an exit condition and message for your Advanced UI or Suite/Advanced UI installation:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Exit Conditions** setting, click the **New Condition** button. InstallShield adds exit message subsettings under the **Exit Conditions** setting.
3. In the **Exit Message** setting, enter the error message that you want the Advanced UI or Suite/Advanced UI installation to display at run time if the condition that you are configuring is true.
4. Expand the **Exit Message** setting, and use its subsetting to define the conditional statement that you want the Advanced UI or Suite/Advanced UI installation to evaluate at run time.
    - In the first subsetting, use the list to select the option that you want to use for the condition or group of conditions that you are configuring. Available options are:
        - **Any**—An Any condition group operates like a logical OR operation. If any of the conditions that are in the Any group evaluate to true, the entire condition group evaluates to true. If none of the conditions that are in the Any group evaluate to true, the entire condition group evaluates to false.
        - **All**—An All condition group operates like a logical AND operation. All of the conditions that are in the All group must evaluate to true in order for the condition group to evaluate to true.
        - **None**—A None condition group operates like a logical NOR operation. If none of the conditions that are in the None group evaluate to true, the entire condition group evaluates to true. If any of the conditions that are in the None condition group evaluate to true, the entire condition group evaluates to false. Note that if the None condition group consists of only one conditional statement, it operates like a logical NOT operation.
    - To add a subcondition group, click the **New Condition** button in this setting and then select **Any**, **All**, or **None**, as needed. InstallShield adds a new row that you can use to define the condition.
    - To add a condition, click the **New Condition** button in this setting and then select one of the available condition types. InstallShield adds a new row that you can use to define the condition.

For more details on configuring conditions, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.

For descriptions of each of the condition settings, see Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects.

Triggering Install Mode or Maintenance Mode of an Advanced UI or Suite/Advanced UI Installation

Project *• This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition *• The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

An Advanced UI or Suite/Advanced UI installation runs in one of the following modes:

- Install mode, in which the installation behaves as a first-time installation
- Maintenance mode, in which the installation displays a wizard page that lets end users select whether they want to remove, repair, or modify the product

InstallShield creates install and maintenance mode conditions automatically in Advanced UI and Suite/Advanced UI projects. The mode conditions are not available for edit within InstallShield; they are shown only in the project file (.issuite). These mode conditions determine whether an Advanced UI or Suite/Advanced UI installation runs in first-time installation mode or in maintenance mode.

Install Mode Condition

The install mode condition is based on the following factors:

- **Detection conditions**—Part of the install mode condition consists of the detection conditions of all of the primary packages in the Suite/Advanced UI project (or, in an Advanced UI project, the one primary package). If none of the primary packages' detection conditions evaluate as true (that is, if none of the primary packages are already installed), the detection condition part of the install mode condition is true. If one or more of the primary packages' detection conditions evaluate as true (that is, at least one of the primary packages is already installed), the detection condition part of the install mode condition is false.
- **Suite Installed condition**—The other part of the install mode condition consists of a Suite Installed condition, which may trigger the installation to run in first-time installation mode if the same version of the Advanced UI or Suite/Advanced UI installation is absent from the target system. The Suite Installed part of the install mode condition compares the Suite GUID and the version of the Advanced UI or Suite/Advanced UI installation with, if applicable, those of the Advanced UI or Suite/Advanced UI installation that is installed on the target system. If these values are different, the Suite Installed part of the install mode condition suggests that the Advanced UI or Suite/Advanced UI installation is absent, so a first-time installation may result. For more details about the Suite Installed type of condition check, see Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed.

If all of the primary packages' detection conditions evaluate as false, or if the Suite Installed condition indicates that the Advanced UI or Suite/Advanced UI installation is not already installed, the install mode condition is true, and the installation runs as a first-time installation.

Maintenance Mode Condition

The maintenance mode condition is based on the detection conditions of all of the primary packages in the Suite/Advanced UI project (or, in an Advanced UI project, the one primary package). If any of the primary packages' detection conditions evaluate as true (that is, if one or more of the primary packages are already installed), the mode condition is true, and the installation runs in maintenance mode.

Add or Remove Program Entries for an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Advanced UI and Suite/Advanced UI projects let you specify whether you want to have an entry in Add or Remove Programs for your Advanced UI or Suite/Advanced UI installation. This entry lets end users perform maintenance for your Advanced UI or Suite/Advanced UI installation, modifying or removing if needed. The General Information view in an Advanced UI or Suite/Advanced UI project has a Show Add or Remove Programs Entry setting that lets you indicate the appropriate behavior.

If you want to show only a single entry for the entire Advanced UI or Suite/Advanced UI installation, ensure that you hide the entries from the packages that you include in the Advanced UI or Suite/Advanced UI project.

For an .msi package, for example, you could set the value of the Windows Installer property **ARPSYSTEMCOMPONENT** to 1 through the command-line settings for the package in the Packages view.

Note that the Show Add or Remove Programs Entry setting is not the only factor that determines whether the Advanced UI or Suite/Advanced UI engine creates an Add or Remove Programs entry for your Advanced UI or Suite/Advanced UI product. The maintenance mode condition also determines whether this occurs. The maintenance mode condition is a combination of all of the detection conditions for all of the primary packages in the installation. If the detection conditions for all of the primary packages in an Advanced UI or Suite/Advanced UI installation evaluate to false after a first-time installation, the Advanced UI or Suite/Advanced UI engine does not add an Add or Remove Program entry for the Advanced UI or Suite/Advanced UI product. If the detection

conditions for all of the primary packages in an Advanced UI or Suite/Advanced UI installation evaluate to true after the Advanced UI or Suite/Advanced UI product is removed, the Advanced UI or Suite/Advanced UI engine leaves any existing Add or Remove Program entry for the Advanced UI or Suite/Advanced UI product.

Passing Command-Line Parameters to a Package in an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are configuring a package in the Packages view of an Advanced UI or Suite/Advanced UI project, you can use the command line and silent command line settings to specify the command lines that you want the Advanced UI or Suite/Advanced UI installation to use when launching the package. These settings are available as subsettings in the Operation area of the grid in the Packages view.

If the Advanced UI or Suite/Advanced UI installation is run with a user interface, the Advanced UI or Suite/Advanced UI `Setup.exe` file uses the command line that you enter in the MSI Command Line setting, the MSP Command Line setting, the Command Line setting, or the EXE Command Line setting (depending on the package type) to launch the package. If the installation is run silently (without a user interface), the Advanced UI or Suite/Advanced UI `Setup.exe` file uses the command line that you enter in the MSI Silent Command Line setting, the MSP Silent Command Line setting, the Silent Command Line setting, or the EXE Silent Command Line setting to launch the package.

When you are entering values in these settings, refer to the following background information, depending on which type of package you are configuring.

.msi Package

If you are configuring the Install and Remove operations for an .msi package, the only type of command-line parameters that you should enter are Windows Installer properties. An Advanced UI or Suite/Advanced UI installation uses MsiInstallProduct to launch an .msi package in install or remove mode, and this function accepts only Windows Installer properties as command lines.

If you are configuring the Repair and Modify operations for this type of package, the only type of command-line parameters that you should enter are Windows Installer feature properties:

- **ADDDEFAULT**

- **ADDLOCAL**
- **ADDSOURCE**
- **ADVERTISE**
- **COMPADDDEFAULT**
- **COMPADDLOCAL**
- **COMPADDSOURCE**
- **FILEADDDEFAULT**
- **FILEADDLOCAL**
- **FILEADDSOURCE**
- **MSIDISABLELUAPATCHING**
- **MsiPatchRemovalList**
- **MSIRESTARTMANAGERCONTROL**
- **MSIDISABLERMRESTART**
- **MSIRMSHUTDOWN**
- **MSIPATCHREMOVE**
- **PATCH**
- **REINSTALL**
- **REINSTALLMODE**
- **REMOVE**

An Advanced UI or Suite/Advanced UI installation uses MsiConfigureProductEx to launch an .msi package in repair or modify mode, and this function accepts only Windows Installer feature properties.

If you are using a Windows Installer property for a package's MSI Command Line settings and the MSI Silent Command Line settings, use the following format:

```
MYPROPERTYNAME=MyPropertyValue
```

The /l command-line option cannot be passed to the package to generate a log file. If you want to log the installation, consider enabling logging for the package in the Packages view. For more information, see Supporting the Creation of Package Log Files for Command-Line Launching of an Advanced UI or Suite/Advanced UI Installation. As an alternative, you can use either the logging system policy, or the MsiLogging property to log the installation.

Note that an Advanced UI or Suite/Advanced UI installation always launches .msi packages silently. Therefore, it is not necessary to pass a command-line parameter that hides the user interface of the .msi package.

.msp Package

If you are configuring the Install operation for an .msp package, the only type of command-line parameters that you should enter are Windows Installer properties. An Advanced UI or Suite/Advanced UI installation uses MsiApplyPatch to apply an .msp package to a target system, and this function accepts only Windows Installer properties as command lines.

To update all of the features through an .msp package, you would enter command-line properties such as the following:

```
REINSTALLMODE=vomus REINSTALL=ALL
```

To update only certain features that are included in the .msp package, you would set **REINSTALL** to a comma-separated list of features that you want to be updated:

```
REINSTALLMODE=vomus REINSTALL=Feature1,Feature3,Feature5
```

Note that an Advanced UI or Suite/Advanced UI installation always launches .msp packages silently. Therefore, it is not necessary to pass a command-line parameter that hides the user interface of the .msp package.

InstallScript Package

If you are configuring the Install and Modify operations for an InstallScript package, you can use the Advanced UI and Suite/Advanced UI properties **ISFeatureInstall** and **ISFeatureRemove** in your command line. The InstallScript function FeatureConfigureFeaturesFromSuite uses these properties to set feature states for the InstallScript package.

You can set these properties to a comma-delimited list of feature names as follows in the Command Line setting and the Silent Command Line setting:

```
ISFeatureInstall=Feature1,Feature2 ISFeatureRemove=Feature3
```

In the above example, **Feature1** and **Feature2** are selected to be installed; **Feature3** is selected to be removed, if it is present.

If any features are used in the values of both properties, the features that are set for the **ISFeatureRemove** property supersede the **ISFeatureInstall** property.

Note that Advanced UI and Suite/Advanced UI installations launch InstallScript packages silently by default. Therefore, it is not necessary to pass a command-line parameter that hides the user interface of the InstallScript package, and it is not necessary to use a silent response file.

.exe Package

If you are configuring the Install, Remove, Repair, and Modify operations for an .exe package, you can enter any command-line parameters that are supported by the .exe file.

If all of the customization can be done without end-user intervention, consider including the command-line parameter for running the .exe package silently.

Silently Running the Setup.exe File that Was Built in InstallShield for a Windows Installer–Based Installation

To have the Advanced UI or Suite/Advanced UI installation launch a Windows Installer–based `Setup.exe` installation silently, use the following syntax in the EXE Command Line settings and the EXE Silent Command Line settings:

```
Setup.exe /s /v"/qn"
```

Silently Running the Update.exe File that Was Built in InstallShield for a Windows Installer–Based Patch

To have the Advanced UI or Suite/Advanced UI installation launch a Windows Installer–based `Update.exe` patch silently, enter the following in the EXE Command Line settings and the EXE Silent Command Line settings:

```
Update.exe /s /v"/qn"
```

Silently Running the Setup Launcher File for an InstallScript Installation

To have the Advanced UI or Suite/Advanced UI installation launch an InstallScript `Setup.exe` installation silently, create a silent response file, and add it as a support file in the Support Files view of your Advanced UI or Suite/Advanced UI project. In the EXE Command Line setting and the EXE Silent Command Line setting of the Install operation, use the following syntax:

```
Setup.exe /s /f1"[SETUPSUPPORTDIR]\Setup.iss"
```

Instead of launching the original `Setup.exe` file for uninstallation silently, you can create a silent response file for the uninstallation, and add it as a support file in the Support Files view of your Advanced UI or Suite/Advanced UI project. In the EXE Command Line setting and the EXE Silent Command Line setting of the Remove operation, use the following syntax:

```
"[ProgramFilesFolder]InstallShield Installation Information\{PRODUCT-GUID-HERE}\Setup.exe" /s /
f1"[SETUPSUPPORTDIR]\Uninstall.iss" -remove_only -runfromtemp
```

Using Advanced UI and Suite/Advanced UI Properties to Dynamically Configure Command Lines

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield lets you use Advanced UI and Suite/Advanced UI properties to dynamically configure the command lines that the Advanced UI or Suite/Advanced UI installation uses to launch the Advanced UI or Suite/Advanced UI packages. In some scenarios, you can use a single Advanced UI or Suite/Advanced UI property to configure most or all of your packages; in other scenarios, each package requires a different Advanced UI or Suite/Advanced UI property.

Using an Advanced UI or Suite/Advanced UI Property to Pass the Same Value to Packages in the Advanced UI or Suite/Advanced UI Installation

When you are creating an Advanced UI or Suite/Advanced UI installation, you may need to use an Advanced UI or Suite/Advanced UI property to set a Windows Installer property to change how each .msi package is installed. For example, if you are creating a multilanguage installation, you may need to select a language transform that controls which language is installed. In this particular example, the language (and hence, the property value) would probably be the same for each package in your Advanced UI or Suite/Advanced UI project.

In an Advanced UI project, the Advanced UI or Suite/Advanced UI property **ISSelectedLanguage** property identifies the language that is used for the Advanced UI or Suite/Advanced UI installation. If you configure your release to allow end users to select the language, the InstallationLanguage wizard page prompts end users for the language; the installation sets the **ISSelectedLanguage** property to a string that contains the decimal language identifier of the language that they selected.

In order to run the .msi packages in the Advanced UI or Suite/Advanced UI project in the appropriate language, include the following in the value that you enter for the command line settings for each .msi package:

```
TRANSFORMS="[ISPREREQDIR]\[ISSelectedLanguage].mst"
```

The .mst file should be in the same folder as the .msi package.

Use the following syntax for your command line settings of Basic MSI .exe packages:

```
/L[ISSelectedLanguage]
```

Using an Advanced UI or Suite/Advanced UI Property to Pass Different Values to Packages in the Advanced UI or Suite/Advanced UI Installation

You may want to use an Advanced UI or Suite/Advanced UI property to pass different property values to each or some packages in your Advanced UI or Suite/Advanced UI installation. For example, you may want to allow end users to override **INSTALLDIR** to different locations, one for each package. In this example, the value of **INSTALLDIR** could be different for each package.

When you add the predefined BrowseFolder wizard page to your project for one of the packages in your Advanced UI or Suite/Advanced UI project, InstallShield automatically adds the following to the package's command line settings for the install operation in the Packages view:

```
INSTALLDIR="[ISInstallDir_PackageDisplayName]"
```

You can override that command line if appropriate. If the package is an .msi package, that command line sets the package's INSTALLDIR value to the path that the end user selected on the BrowseFolder wizard page for that package.

If the package is a Basic MSI or InstallScript MSI .exe package, change the default command lines to use this syntax:

```
/v"INSTALLDIR=\"[ISInstallDir_PackageDisplayName]\""
```

Defining the End-User Interface of an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

The elements of the wizard interface of an Advanced UI or Suite/Advanced UI installation consist of wizard pages and secondary windows (also known as pop-up windows). Advanced UI and Suite/Advanced UI projects contain a number of standard predefined wizard pages and secondary windows. You can add or delete pages and windows, as well as customize the layout and behavior of them.

Note that the Advanced UI or Suite/Advanced UI setup launcher automatically suppresses the user interface of .msi, .msp, and InstallScript package formats, in favor of the wizard interface of the Advanced UI or Suite/Advanced UI installation. If an Advanced UI or Suite/Advanced UI project contains an .exe package, you must manually suppress its user interface and have the Advanced UI or Suite/Advanced UI installation launch it silently. Otherwise, at run time, the installation shows the Advanced UI or Suite/Advanced UI wizard pages and the separate user interface of the .exe package, presenting two disparate user interfaces. For more information, see Passing Command-Line Parameters to a Package in an Advanced UI or Suite/Advanced UI Installation.

To learn more about defining the end-user interface of an Advanced UI or Suite/Advanced UI installation, see Working with the Wizard Interface.

Referring to Feature States and Other Feature Data in the UI of an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition *• The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

At run time during an Advanced UI or Suite/Advanced installation, you may need to trigger specific UI behavior that depends on feature-related information. Following are examples of how you may want to use this information:

- If a particular feature is not selected for installation, you can skip a special corresponding wizard page.
- If a specific feature is already installed, you can disable a check box on one of the wizard pages.
- You can create an extension condition DLL to define a custom condition for a feature-related check that you want the installation to perform at run time.
- You can configure the installation to display a custom feature tree wizard page that shows how much space on the target system each feature requires.

Following are various feature-related pseudo properties that you can check at run time during an Advanced UI or Suite/Advanced UI installation. In each case, the *name* portion should be replaced with the name of the feature.

Table 5-4 • Feature-Related Pseudo Properties for the UI of an Advanced UI or Suite/Advanced UI Installation

Pseudo Property	Type	Description
FEATURE[*name*].actionState	Read-write	This indicates the upcoming action for the specified feature. Available values are: • **install**—This state indicates that the feature is set to be installed. This state is valid only when the feature is not already installed. • **remove**—This state indicates that the feature is set to be removed. This state is valid only when the feature is already installed. • **null (empty string)**—An empty string state requests no action. It is always valid.
FEATURE[*name*].installState	Read-only	This indicates the current state of the specified feature. Available values are: • **0**—The feature is currently absent from the target system. • **1**—The feature is partially available on the target system; that is, only some of the packages in this feature are present. • **2**—Only some of the feature's child features are present on the target system. • **3**—The feature is currently present on the target system.

Table 5-4 • Feature-Related Pseudo Properties for the UI of an Advanced UI or Suite/Advanced UI Installation

Pseudo Property	Type	Description
FEATURE[*name*].displayName	Read-only	This indicates the name that is displayed for the specified feature on the appropriate wizard page at run time.
FEATURE[*name*].description	Read-only	This indicates the description of the specified feature that is displayed on a wizard page at run time.
FEATURE[*name*].cost	Read-only	This indicates how much space the specified feature requires on the target system.

You can set the read-write pseudo property FEATURE[name].actionState through an extension condition, for example, or through the Action setting for a control in the wizard interface.

You can read any of those pseudo properties through an extension condition or through in binding conditions for the Visible or Enabled settings for a control in the wizard interface.

Minimizing the Number of User Account Control Prompts During Advanced UI and Suite/Advanced UI Installations

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Some of the specific details apply to only the Suite/Advanced UI project type. These differences are noted where appropriate.

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

One of the goals of Windows Vista and later, as well as User Account Control (UAC), is to allow users to run as standard users all of the time. Elevation should rarely be required; if it does occur, it should occur for as short of a duration as possible.

Settings in several different areas of InstallShield affect whether an Advanced UI or Suite/Advanced UI installation triggers UAC consent or credential prompts for elevated privileges. In addition, settings in the packages that are included in an Advanced UI or Suite/Advanced UI installation also affect whether end users see a UAC prompt for

elevated privileges. Understanding these different settings will help you create the appropriate UAC experience for your installation when end users run it on Windows Vista and later systems and on Windows Server 2008 and later systems.

UAC-Related Settings in an Advanced UI or Suite/Advanced UI Project

The following settings in an Advanced UI or Suite/Advanced UI project help determine whether UAC prompts are displayed:

- **Required Execution Level**—Use this setting on the Setup.exe tab in the Releases view to specify the minimum execution level required by your installation's `Setup.exe` file. InstallShield uses the value that you select (Administrator, Highest Available, or Invoker) in the application manifest that it embeds in the `Setup.exe` launcher. For more information, see Specifying the Required Execution Level for Your Setup Launcher on Windows Vista and Later Platforms.
- **Require Elevated Privileges**—Use this setting for a package in the Packages view to specify whether the package requires elevated system privileges.
- **Requires Administrative Privileges**—Use this setting for an action that you have added to your project in the Events view to specify whether the action requires administrative privileges.

Project *• Suite/Advanced UI projects include the Events view, as well as support for assigning actions to events.*

UAC-Related Settings in a Package That Is Included in an Advanced UI or Suite/Advanced UI Project

The packages that you include in an Advanced UI or Suite/Advanced UI project have various ways of triggering a UAC prompt for elevated privileges. To learn more, see Minimizing the Number of User Account Control Prompts During Installation.

UAC-Related Run-Time Behavior for an Advanced UI or Suite/Advanced UI Installation

Note the following UAC-related behavior on Windows Vista and later and on Windows Server 2008 and later:

- If Required Execution Level is set to Invoker, none of the actions in the project require administrative privileges, and none of the packages in the installation require administrative privileges, end users should see no UAC prompts during installation. The entire installation (displaying the UI, launching the actions, and running the packages) is run in a nonelevated process.
- If Required Execution Level is set to Invoker, if none of the actions in the project require administrative privileges, and if one or more of the packages in the installation require administrative privileges, end users should see one UAC prompt—plus up to one additional UAC prompt for each reboot—during installation. The UAC prompt is displayed after the end user clicks the button in the UI to install. The packages that have a Require Elevated Privileges value of Yes are launched with elevated privileges in a new separate process. The remaining portions of the UI, the actions, and the packages that have a Require Elevated Privileges value of No are launched in the original nonelevated process.

- If the Required Execution Level is set to Invoker and if one or more of the actions in the project require administrative privileges, end users should see one UAC prompt—plus up to one additional UAC prompt for each reboot—during installation. The timing of the UAC prompt depends on when elevation is first required.

  For example, if the earliest scheduled action that requires administrative privileges is configured to occur during the OnBegin event (which is well before any packages are run), the UAC prompt may be displayed shortly after end users launch the `Setup.exe` file. After end users provide consent or credentials, the installation launches a new elevated process for this action, as well as any subsequent actions and packages that require elevation. Any subsequent actions and packages that do not require elevation are launched in the original nonelevated process, along with the remaining portions of the UI.

  However, if the earliest scheduled action that requires administrative privileges is configured to occur after a package that requires elevated privileges, the UAC prompt is displayed after the end user clicks the button in the UI to install. After end users provide consent or credentials, the installation launches a new elevated process for the package, as well as any subsequent actions and packages that require elevation. Any subsequent actions and packages that do not require elevation are launched in the original nonelevated process, along with the remaining portions of the UI.

Restarting a Target System for an Advanced UI or Suite/Advanced UI Package

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

InstallShield uses several methods to determine if a target system should be restarted after running a package in an Advanced UI or Suite/Advanced UI installation.

Registry Key Changes for .exe Packages

The target system may need to be restarted if any of the following registry keys have been modified after an .exe package in the Advanced UI or Suite/Advanced UI has been run:

- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnce
- HKEY_CURRENT_USER\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnce
- (64-bit) HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce
- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx

- (64-bit) HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx
- HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Session Manager, value of PendingRenameOperations

The registry keys are counted before and after the package is run. If these numbers are not the same, it is assumed that the file is trying to restart the system and exit the installation.

Return Code Specified for a Package in the Advanced UI or Suite/Advanced UI Installation

If the exit code of the package in an Advanced UI or Suite/Advanced UI installation matches the return code that is specified for applicable operation type (install, remove, repair, or modify) for the package in the Reboot Codes setting of the Packages view of the Advanced UI or Suite/Advanced UI project, the target system may need to be restarted.

Return Codes 1641 and 3010

The target system may need to be restarted if a reboot state is returned for an .msi package that is run for a package in an Advanced UI or Suite/Advanced UI installation. The standard Windows Installer reboot return codes are:

- ERROR_SUCCESS_REBOOT_INITIATED (1641)
- ERROR_SUCCESS_REBOOT_REQUIRED (3010)

Behavior Specified for the Package

The Reboot Request setting for a package in the Packages view of the Advanced UI or Suite/Advanced UI project enables you to specify what should happen if any of the aforementioned conditions are or are not applicable to a particular package in the Advanced UI or Suite/Advanced UI project. You can specify different behaviors for each operation type: install, remove, repair, and modify.

For more information, see Specifying the Behavior for an Advanced UI or Suite/Advanced UI Package that Requires a Restart.

Specifying the Behavior for an Advanced UI or Suite/Advanced UI Package that Requires a Restart

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are configuring a new package in an Advanced UI or Suite/Advanced UI project or modifying the settings of an existing one, you can specify how the Advanced UI or Suite/Advanced UI installation should proceed if it appears that the target system needs to be restarted. For example, in some cases, you may want the installation to first prompt the end user before restarting the target system; in other cases, you may want to skip the restart. The Packages view of the Advanced UI or Suite/Advanced UI project provides the flexibility needed to carry out the response that is appropriate for each type of operation (install, remove, repair, or modify) and for each package in the Advanced UI or Suite/Advanced UI project.

Task: ***To specify the behavior for an Advanced UI or Suite/Advanced UI package that requires the target system to be restarted:***

1. Open the Advanced UI or Suite/Advanced UI project that contains the package whose restart behavior you want to configure.
2. In the View List under **Organization**, click **Packages**.
3. In the **Packages** explorer, select the package that you want to configure.
4. Under the appropriate operation (**Install**, **Remove**, **Repair**, or **Modify**), in the **Reboot Request** setting, select the appropriate option.

The following table explains appropriate options for various restart-related behaviors that a package in an Advanced UI or Suite/Advanced UI installation may perform.

Table 5-5 • Restart Behavior for Advanced UI or Suite/Advanced UI Packages

Behavior of the Package in the Advanced UI or Suite/Advanced UI Installation	Guidelines for the Reboot Request Setting
Prompts the end user and, based on the end user's response, may restart the target system	Consider selecting one of the following options for the Reboot Request setting: • **Allow the machine to reboot**—This option is appropriate for most scenarios. • **Always reboot the machine**—Note that this option may conflict with the end user's response to the package's prompt if the end user chooses the option to avoid restarting the target system. If this scenario is possible and you always want to restart the system, consider suppressing the package's prompt, and selecting the appropriate option for the package's Reboot Request setting.

Table 5-5 • Restart Behavior for Advanced UI or Suite/Advanced UI Packages (cont.)

Behavior of the Package in the Advanced UI or Suite/Advanced UI Installation	Guidelines for the Reboot Request Setting
Always triggers a restart; may or may not prompt the end user	Consider selecting one of the following options for the Reboot Request setting: • **Allow the machine to reboot**—This option is appropriate for most scenarios. • **Always reboot the machine**—Note that this option may conflict with the end user's response to the package's prompt if the end user chooses the option to avoid restarting the target system. If this scenario is possible and you always want to restart the system, consider suppressing the package's prompt, and selecting the appropriate option for the package's Reboot Request setting.
Uses a return code or the registry to indicate the need to restart; does not prompt the end user	Consider selecting one of the following options for the Reboot Request setting: • **Prompt, then exit or reboot the machine**—If the target system must be restarted for a subsequent package, you may want to select this option. • **Always prompt, then exit or reboot the machine**—If the target system must be restarted immediately, you may want to select this option. • **Ignore the reboot request**—If the package's restart request is unnecessary, you may want to select this ignore option. • **Delay the prompt, then exit or reboot the machine**—If the restart is not required for a subsequent package, consider selecting this option. If more than one package in the Advanced UI or Suite/Advanced UI installation requires a restart, this option may help minimize the number of restarts. Note that if a restart must occur before a subsequent package runs, and if a restart is not guaranteed to occur before that subsequent package runs, avoid selecting this delay option.
Requires a restart but does not prompt the end user or indicate the need to restart	Consider selecting the following option for the Reboot Request setting: • **Always prompt, then exit or reboot the machine**—If the restart is required, you may want to select this option.

Adding Support for Automatic Updates to an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Advanced UI and Suite/Advanced UI installations have the ability to automatically check for an updated Advanced UI or Suite/Advanced UI `Setup.exe` file that you host on your Web site, and download and launch it if it is available. The updated Advanced UI or Suite/Advanced UI `Setup.exe` file can be used to deploy upgrades and patches for your latest Advanced UI and Suite/Advanced UI packages.

Requirements and Recommendations for Supporting Automatic Updates

If you want to include support for automatic updates in your Advanced UI or Suite/Advanced UI installations, the following guidelines are recommended when you are preparing your base setup launchers and your update setup launchers for your Advanced UI or Suite/Advanced UI projects.

- Decide the URL that you will use for hosting the Advanced UI or Suite/Advanced UI update setup launcher. The URL should contain the absolute path to the update setup launcher, including the file name.

  You will need to specify the update URL in your base Advanced UI or Suite/Advanced UI project.

- At a minimum, the update setup launcher must be digitally signed. For the best end-user experience, the same digital signature should be used to sign the update setup launcher and the base setup launcher.

- When you are configuring the Advanced UI or Suite/Advanced UI project for the update setup launcher, the run-time location of the packages must be either extracted from the setup launcher or downloaded from the Web. The update setup launcher cannot rely on packages that are stored on the source media.

  Note that your base setup launcher can use packages that are stored on the source media.

  For instructions on how to specify the run-time location for specific packages in an Advanced UI or Suite/Advanced UI project, see Specifying a Run-Time Location for a Specific Package in an Advanced UI or Suite/Advanced UI Project.

  Note that you can override the run-time location for all packages in an Advanced UI or Suite/Advanced UI project. To learn more, see Specifying the Run-Time Location for Advanced UI or Suite/Advanced UI Packages at the Release Level.

Adding Automatic Update Support

Task: ***To add automatic update support to a base Advanced UI or Suite/Advanced UI project:***

1. Open the Advanced UI or Suite/Advanced UI project that contains the package for which you want to enable automatic update support.
2. In the View List under **Media**, click **Releases**.
3. In the **Releases** explorer, select the release that you want to configure.
4. On the **Setup.exe** tab, in the **Update URL** setting, enter the absolute path URL (starting with either `http://` or `https://`) that you want to use for the future path to the update setup launcher that you will make available for download to target systems.
5. On the **Signing** tab, it is recommended that you enter digital signature information and configure the release to sign the `Setup.exe` launcher.

Task: ***To prepare the update setup launcher for an Advanced UI or Suite/Advanced UI project:***

1. Open the Advanced UI or Suite/Advanced UI project that you want to update, and update it as necessary.
2. In the View List under **Media**, click **Releases**.
3. In the **Releases** explorer, select the release that you want to configure.
4. On the **Signing** tab, enter digital signature information and configure the release to sign the `Setup.exe` launcher. It is recommended that you use the same digital signature that was used to sign the base `Setup.exe` launcher.

Run-Time Behavior for Automatic Updates

If the base Advanced UI or Suite/Advanced UI setup launcher runs a non-maintenance operation such as an install operation at run time, the Advanced UI or Suite/Advanced UI setup launcher checks the update URL for a download. If a download is not available in the update URL that was specified in the base project, the base setup launcher runs.

If a download is available, the base Advanced UI or Suite/Advanced UI setup launcher downloads it and then verifies its digital signature.

If the digital signature in the update setup launcher matches that in the base setup launcher, the update setup launcher runs automatically.

If the digital signature does not match, or if the base setup launcher is not digitally signed, a security warning is displayed, allowing the end user to choose whether to proceed with the update setup launcher.

If the update setup launcher is not digitally signed, the installation fails, and the debug log reports the digital signature problem.

Troubleshooting Issues with an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

The following information provides background information to help you resolve issues with Advanced UI and Suite/Advanced UI installations.

Reasons Why an Advanced UI or Suite/Advanced UI Installation May Run in Maintenance Mode

An Advanced UI or Suite/Advanced UI installation may run in maintenance mode in the following scenarios:

- An end user chooses to modify the product through the product's Add or Remove Programs entry.
- An end user reruns the Advanced UI or Suite/Advanced UI installation.
- The detection conditions for one or more of the primary packages in the Advanced UI or Suite/Advanced UI installation are not configured properly. For information on configuring conditions for an Advanced UI or Suite/Advanced UI package, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.
- A package in the Advanced UI or Suite/Advanced UI installation is configured erroneously to be a primary package instead of a dependency package, and the package is already installed on the target system.

  InstallShield creates maintenance mode conditions automatically, based on the detection conditions of all of the primary packages in the Advanced UI or Suite/Advanced UI project. The Advanced UI or Suite/Advanced UI engine uses these conditions to determine whether the Advanced UI or Suite/Advanced UI installation runs in maintenance mode. If any of the primary packages' detection conditions evaluate as true (that is, if one or more of the primary packages seem to be installed already), the maintenance mode condition is true, and the Advanced UI or Suite/Advanced UI installation runs in maintenance mode.

  Use the Package Type setting in the Packages view to indicate whether a package is a primary package or a dependency package.

  To learn more about mode conditions, see Triggering Install Mode or Maintenance Mode of an Advanced UI or Suite/Advanced UI Installation.

Logging an Advanced UI or Suite/Advanced UI Installation to Troubleshoot Issues

If you are troubleshooting issues with an Advanced UI or Suite/Advanced UI installation, start with a debug log file. Debug log files provide some insight into the operations that an Advanced UI or Suite/Advanced UI installation performs at run time. To create a debug log file, run the Advanced UI or Suite/Advanced UI installation from the command line with `/debuglog` parameter. To generate a log file named `InstallShield.log` in the same directory as the `Setup.exe` file, pass just the command-line parameter. Note that this does not work if the `Setup.exe` file is in a read-only location. For example:

```
Setup.exe /debuglog
```

To specify the name and location of the log file, pass the path and name, as in the following example:

```
Setup.exe /debuglog"C:\PathToLog\setupexe.log"
```

Advanced UI and Suite/Advanced UI debug log files contain the following information:

- Initialization information from the Advanced UI or Suite/Advanced UI engine
- Property values and property value changes
- Information about the actions and installed states of features
- Information about the detected state and eligibility of packages
- Package command lines and launch result information
- For an InstallScript package—Information that is logged by the InstallScript function SuiteLogInfo

The default Advanced UI or Suite/Advanced UI user interface in Advanced UI and Suite/Advanced UI projects also logs information to the debug log file; however, in general, this information can be ignored. (UI information is typically prefixed with `UI DLL:` in the log.)

Note that when the Advanced UI or Suite/Advanced UI engine writes feature, package state, and Advanced UI or Suite/Advanced UI mode information to the log file, it writes only numeric values for the states. The following tables map the numeric values to state representations.

Table 5-6 • Feature Action States

Log Value	State
0	No action will be taken for the feature.
1	The feature will be installed.
2	The feature will be removed.

Table 5-7 • Feature Installed States

Log Value	State
0	The feature is not currently installed.
3	The feature is installed.

Table 5-8 • Package States

Log Value	Installed State	Action State
0	The package is not installed.	—
1	The package is currently installed.	The package will run its install operation.
2	—	The package will run its modify operation.
3	—	The package will run its repair operation.
4	—	The package will run its remove operation.
5	—	No action will be performed for the package.

Table 5-9 • Advanced UI and Suite/Advanced UI Installation Modes

Log Value	Install Mode
0	First-time installation
1	Maintenance/UI maintenance mode selection
2	Maintenance/modify
3	Maintenance/remove
4	Maintenance/repair
5	Stage only (The installation is run in stage-only mode, in which the Advanced UI or Suite/Advanced UI installation is staged—or uncompressed and copied to a specified location. Note that none of the packages in the installation are run in this mode.)

Example Debugging Walkthrough

Debug log files can be useful in any number of scenarios where an Advanced UI or Suite/Advanced UI installation is not behaving in an expected manner. For example, suppose a Suite/Advanced UI project contains two packages: one .exe file and one .msi file, each associated with their own feature in the Suite/Advanced UI installation. At run time on some machines, even though both features appear to be selected, only the .exe package is installing. To begin troubleshooting this behavior, generate a debug log file on one of the machines that is encountering this behavior. Once the log file is available, verify that both features were in fact selected to be installed. The Suite/Advanced UI records logs information such as the following about each feature:

```
9-21-2011[03:07:04 PM]: Engine: determining suite feature states

9-21-2011[03:07:04 PM]: Initializing state for feature 'NewFeature'

9-21-2011[03:07:04 PM]: Default action state 1 for mode 0

9-21-2011[03:07:04 PM]: Initial feature state: 1

9-21-2011[03:07:04 PM]: Final feature state: 1

…

9-21-2011[03:07:04 PM]: Initializing state for feature 'NewFeature1'

9-21-2011[03:07:04 PM]: Default action state 1 for mode 0

9-21-2011[03:07:04 PM]: Initial feature state: 1

9-21-2011[03:07:04 PM]: Final feature state: 1
```

The above information indicates the initial states of features NewFeature and NewFeature1. Both have been initialized to a state of 1, indicating they are selected for installation. So the features in this Suite/Advanced UI installation do not appear to be an issue. Continuing on in the log, the following information is provided:

```
9-21-2011[03:07:10 PM]: Engine: setting parcel states as determined by feature selections

9-21-2011[03:07:10 PM]: Feature NewFeature setting parcel states, parent override: no, override
    state: 0

9-21-2011[03:07:10 PM]: Requesting action state 1 for parcel '{BA3EAE7A-0701-4CE0-9224-
    4F5C0F135792}'

9-21-2011[03:07:10 PM]: Containing feature is request state change to parcel {BA3EAE7A-0701-4CE0-
    9224-4F5C0F135792}, feature request: 1
```

At this point in the Suite/Advanced UI installation, the UI DLL has completed the UI selection phase and gathered all necessary data for the installation to start. The Suite/Advanced UI engine now determines what packages (referred to as parcels in the log file) will be installed based on the features with which they are associated. This information indicates package {BA3EAE7A-0701-4CE0-9224-4F5C0F135792} (this GUID comes from the Package GUID setting that is set in each package in an Advanced UI or Suite/Advanced UI project) is being requested to install (action state 1) from feature NewFeature (whose action state is selected to install). Looking forward a couple lines in the log provides the following information:

```
9-21-2011[03:07:10 PM]: Parcel is ineligible or the current parcel state and install mode to not
    allow parcel configuration
```

That line indicates that the package (the .msi package that is not installing as expected) has become ineligible. Looking for this package with the given package ID in the Packages view in the Suite/Advanced UI project shows that the package contains an eligibility condition. The condition indicates that the package is eligible if either (a) a package with a particular .msi product code and package code are already installed, or (b) an .msi package with a specific product code is installed, and the product version is not greater than the .msi package's product version. The purpose of this condition is to prevent the package from installing if a newer version of this product is already installed.

Investigating further on the machine that produced this behavior shows that a newer version of the product is already present on the machine, causing the .msi package in the Suite/Advanced UI installation to become ineligible.

Supporting the Creation of Package Log Files for Command-Line Launching of an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are configuring the settings for a package in an Advanced UI or Suite/Advanced UI project, you can specify whether you want the package to generate a log file if the Advanced UI or Suite/Advanced UI installation is launched from the command line with the `/l*log` command-line parameter. Depending on the type of package, you can also configure one or two other settings to specify information such as which log options you want the Advanced UI or Suite/Advanced UI installation to pass to the package when the log file is being created.

Note that if a package does not have support for logging, it is recommended that you leave logging support disabled for that package.

Enabling Package Logging Support

Task: ***To enable logging support for a package in an Advanced UI or Suite/Advanced UI installation:***

1. Open the Advanced UI or Suite/Advanced UI project that contains the package for which you want to enable logging.
2. In the View List under **Organization**, click **Packages**.
3. In the **Packages** explorer, select the package that you want to configure.
4. On the **Common** tab, in the **Enable Logging Support** setting, select **Yes**.
5. For an .msi or .msp package, configure the following optional subsettings as needed:
   - **Log File**—Specify a name for the log file. Do not include a path for the file; the Advanced UI or Suite/Advanced UI `/l*log` command-line parameter lets end users specify the directory for the package log files.

     If you leave this setting blank, the name of the log file that the installation creates is *PackageGUID*`.log`, where *PackageGUID* is the GUID that is assigned to the package in the Package GUID setting in the Packages view.

- **Log Options**—Specify the Windows Installer log `/L` flags that you want the package to use when generating the log file. For example, to generate a log file that logs everything verbosely, enter the following in this setting:

  *v

  For additional valid flags, see the /L description.

  If you leave this setting blank, the asterisk (*) and v flags are used to generate the log file.

For an .exe package, configure the following subsetting:

- **Logging Command Line**—Specify the command line that the Advanced UI or Suite/Advanced UI installation should pass to the .exe package to enable the logging. Include any appropriate supported flags. If the .exe package that you are configuring supports it, include a path that references the Advanced UI or Suite/Advanced UI property **ISLogDir**, enclosed within square brackets, in place of the path to the directory where the log file should be created.

  For example, to generate a log file that logs everything verbosely for an .msi package that is run by a `Setup.exe` file that InstallShield built, enter the following command line:

  ```
  /v"/l*v \"[ISLogDir]FileName.log\""
  ```

  The Advanced UI or Suite/Advanced UI installation replaces **[ISLogDir]** with the path to the folder that will contain the log file. The Advanced UI or Suite/Advanced UI `/log` command-line parameter lets end users specify the path to the directory for the package log files.

Generating Package Log Files While Running an Advanced UI or Suite/Advanced UI Installation

To create a package log file, run the Advanced UI or Suite/Advanced UI installation from the command line with the `/log` parameter. The `/log` parameter lets you generate a log file for each package in the Advanced UI or Suite/Advanced UI installation for which logging is enabled.

To generate package log files in a particular folder, pass the folder path with the `/log` parameter to the Advanced UI or Suite/Advanced UI `Setup.exe` file. You can optionally separate the `/log` parameter and the path with a colon. For example, both of the following command lines generate a log file in the `PathToLogFiles` folder:

```
Setup.exe /log"C:\PathToLogFiles"
```

```
Setup.exe /log:"C:\PathToLogFiles"
```

Note that the path to the log file location must already exist.

To generate package log files in the *%TEMP%* directory, leave out the path. For example:

```
Setup.exe /log
```

The Advanced UI or Suite/Advanced UI property **ISLogDir** stores the path to the directory that contains the package log files.

Tip *• You can also use the logging system policy or the MsiLogging property to generate log files for Windows Installer–based packages in an Advanced UI or Suite/Advanced UI installation.*

6

Designing InstallShield Prerequisites and Other Redistributables

InstallShield provides many third-party redistributables that you can incorporate into projects as InstallShield prerequisites, merge modules, and InstallScript objects. You can also create your own redistributables and distribute them to other installation developers. The following sections describe each of these types of redistributables.

InstallShield Prerequisites

Project • *The following project types include support for InstallShield prerequisites:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

InstallShield also includes support for including InstallShield prerequisites as packages in Advanced UI and Suite/Advanced UI projects. For more information, see Including InstallShield Prerequisites (.prq) in an Advanced UI or Suite/Advanced UI Project.

An InstallShield prerequisite is an installation for a product or technology framework that is required by your product. Some examples of InstallShield prerequisites that are included with InstallShield are Java Runtime Environment (JRE) and SQL Server Express Edition. You can add any of the existing InstallShield prerequisites to your installation projects and configure many of their settings. You can also create your own InstallShield prerequisites, and add them to your projects.

Project • *In Windows Installer–based installations, including InstallShield prerequisites in your project enables you to chain multiple installations together, bypassing the Windows Installer limitation that permits only one Execute sequence to be run at a time. The* `Setup.exe` *setup launcher serves as a bootstrap application that manages the chaining.*

Note • *Unlike Windows Installer 4.5 chaining, the InstallShield prerequisite installations are not processed as a single transaction; that is, successful installations are not rolled back after failures in later prerequisites. To learn more about Windows Installer 4.5 chaining support, see Configuring Multiple Packages for Installation Using Transaction Processing.*

For information on configuring the settings for the InstallShield prerequisites that are available in InstallShield, as well as details on how to create your own InstallShield prerequisites, see Defining InstallShield Prerequisites.

Types of InstallShield Prerequisites

When you add an InstallShield prerequisite to a Basic MSI, InstallScript, or InstallScript MSI project, it is considered to be the *setup prerequisite* type of InstallShield prerequisite by default. That is, it is treated as a base application or component that must be installed on the target machine before your product can be installed. The installation for a setup prerequisite runs before the main installation runs if the prerequisite is not already installed on the system.

Basic MSI projects enable you to associate InstallShield prerequisites with features in your main installation. When an InstallShield prerequisite is associated with one or more features, it is called a *feature prerequisite*; it is installed if one or more features that contain the prerequisite are installed at run time and if the prerequisite is not already installed on the system. Thus, if a feature has a condition that is not met on the target system, or if the end user chooses not to install the feature, the feature is not installed. As a result, none of its associated feature prerequisites are installed, unless the feature prerequisites are also associated with other features that are installed.

To learn more about these two types of InstallShield prerequisites, see Setup Prerequisites vs. Feature Prerequisites.

Merge Modules

InstallShield enables you to create your own merge modules that can be used in any of your installation projects or distributed for use by other installation developers.

To learn more, see Designing Merge Modules.

Note • *Many of the merge modules included in the Redistributables view are authored by Microsoft or another third party. InstallShield distributes these modules as a courtesy to assist you in creating your installation project. However, InstallShield cannot modify or fix any problems that may exist within third party-authored modules. You are encouraged to contact the vendor regarding issues with specific third party-authored modules.*

InstallScript Objects

InstallShield enables you to create your own InstallScript objects that can be used in any of your installation projects or distributed for use by other installation developers.

To learn more, see Creating InstallScript Objects.

Defining InstallShield Prerequisites

Project • *The following project types include support for InstallShield prerequisites:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

All of these project types include support for the setup prerequisite type of InstallShield prerequisite. Basic MSI projects include support for the feature prerequisite type.

InstallShield also includes support for including InstallShield prerequisites as packages in Advanced UI and Suite/Advanced UI projects. For more information, see Including InstallShield Prerequisites (.prq) in an Advanced UI or Suite/Advanced UI Project.

Use the InstallShield Prerequisite Editor in InstallShield to modify the settings for any of the prerequisites that are included with InstallShield. You can also create custom prerequisites using this tool and then add them to your projects.

Specifying your own InstallShield prerequisites and modifying existing ones enables you to set options such as the following:

- The URL from where the prerequisite files should be downloaded to the target machine
- Conditions under which the prerequisite should be installed
- Other prerequisites on which a particular prerequisite is dependent
- The command line for the prerequisite
- The command line to be used if the installation is running in silent mode
- Whether the target machine should be restarted after installation of a prerequisite
- Whether the administrative privileges are required to install the prerequisite
- Whether the installation should display a message box that enables end users to choose whether to install the prerequisite

Creating an InstallShield Prerequisite

Task: ***To create a new InstallShield prerequisite:***

1. On the **Tools** menu, click **Prerequisite Editor**. The **InstallShield Prerequisite Editor** opens.
2. Configure the settings on each of the tabs as needed.
3. On the **File** menu, click **Save**.

Modifying an Existing InstallShield Prerequisite

Task: ***To modify an existing InstallShield prerequisite:***

1. On the **Tools** menu, click **Prerequisite Editor**. The **InstallShield Prerequisite Editor** opens.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the InstallShield prerequisite file (.prq) by browsing, and then click **Open**.
4. Make changes as needed.
5. On the **File** menu, click **Save**.

Setting Properties for an InstallShield Prerequisite

The Properties tab of the InstallShield Prerequisite Editor is where you specify a description and a unique identifier for an InstallShield prerequisite.

Task: ***To set properties for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Properties** tab.
3. In the **Unique identifier for InstallShield prerequisite** box, type a unique file identifier for the prerequisite or leave the default value as is. This could be the name of the prerequisite application or component, or a GUID.

   Note • *Every time you open the InstallShield Prerequisite Editor to create a new prerequisite, a new GUID is generated and listed in the* ***Unique identifier for InstallShield prerequisite*** *box.*
4. In the **Description** box, type an overview of the InstallShield prerequisite. This description is displayed under the **Overview** heading when you select an InstallShield prerequisite in the **Redistributables** view.

Specifying an Alternate URL for a .prq File

You may want to specify an alternate URL for your .prq file if both of the following conditions are true:

- You have specified that one or more InstallShield prerequisites in your installation should be downloaded from the Web instead of being included in the `Setup.exe` file or on the source media. For more information, see Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level.
- It is possible that later you might want to redirect your end users to a different URL to download an InstallShield prerequisite's application files.

In this scenario, the .prq file that you include with your `Setup.exe` installation has an alternate URL specified. When an end user runs the installation, the target machine visits the alternate URL specified in the `Setup.exe` .prq file, downloads that .prq file, and uses the file URLs specified in the alternate .prq file to download the necessary files for the prerequisite application.

Task: ***To specify an alternate URL for a .prq file:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Properties** tab.
3. In the **Alternate location to download .prq from if prerequisite files are being downloaded** box, type the alternate URL for your .prq file. For example:

   ```
   http://www.mywebsite.com/MyPrq.prq
   ```

Note • *InstallShield prerequisites do not have support for FTP URLs.*

Setting Installation Conditions for an InstallShield Prerequisite

You need to specify installation conditions that determine whether an InstallShield prerequisite is already installed on the target machine. Failure to do so causes problems because the target system behaves as if the prerequisite was not properly installed. You can also create installation conditions that specify operating system, registry, or file requirements. The Conditions tab of the InstallShield Prerequisite Editor is where you set installation conditions.

If the InstallShield prerequisite should be installed on some—but not all—operating systems, you can create multiple operating system conditions for the prerequisite. If a target machine meets any one individual operating system condition, it meets the operating system requirements for that prerequisite.

If a condition evaluates as true at run time, that condition is met. The InstallShield prerequisite is installed on the target machine if the following are true:

- The target machine meets any of the operating system conditions and all of the other conditions that are listed on the Conditions tab.
- For feature prerequisites only (that is, an InstallShield prerequisite that is associated with one or more features in the main installation)—The feature that contains the feature prerequisite must be installed. Thus, if the feature has a condition that is not met on the target system, or if the end user chooses not to install the feature, the feature is not installed. As a result, none of its associated feature prerequisites are installed, unless the feature prerequisites are also associated with other features that are installed.

Note • *Because installation of prerequisites such as Windows service packs is not supported, the operating system version information is not expected to change. Therefore, the operating system conditions are not considered in verifying whether a prerequisite was installed correctly.*

Adding a New Installation Condition for an InstallShield Prerequisite

Task: ***To add a new installation condition for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Conditions** tab.
3. Click **Add**. The **Prerequisite Condition** dialog box opens.
4. Select the appropriate option for the type of condition and then set the properties for the condition as needed.

The InstallShield Prerequisite Editor adds the condition to the Conditions tab.

If a condition evaluates as true at run time, that condition is met. The InstallShield prerequisite is installed on the target machine if the following are true:

- The target machine meets any of the operating system conditions and all of the other conditions that are listed on the Conditions tab.
- For feature prerequisites only (that is, an InstallShield prerequisite that is associated with one or more features in the main installation)—The feature that contains the feature prerequisite must be installed. Thus, if the feature has a condition that is not met on the target system, or if the end user chooses not to install the feature, the feature is not installed. As a result, none of its associated feature prerequisites are installed, unless the feature prerequisites are also associated with other features that are installed.

For example, you might have an InstallShield prerequisite that has several different conditions:

- A specific file is not present on the target machine. In this example, if this file is missing, it indicates that an application that your product requires must be installed; otherwise, your product should not be installed.
- The target machine has Windows XP.
- The target machine has Windows Vista.

In this example, if the target machine is running Windows XP or Windows Vista and the InstallShield prerequisite is not associated with a feature, the prerequisite is installed, but only if the specified file is not present. The same is true if the InstallShield prerequisite is associated with a feature that the installation installs at run time.

Note • *Because installation of prerequisites such as Windows service packs is not supported, the operating system version information is not expected to change. Therefore, the operating system conditions are not considered in verifying whether a prerequisite was installed correctly.*

Adding an Operating System Condition for an InstallShield Prerequisite

If the InstallShield prerequisite should be installed on some—but not all—operating systems, you can create multiple operating system conditions for the prerequisite. If a target machine meets any one individual operating system condition, it meets the operating system requirements for that prerequisite.

Task: ***To add a new operating system requirement for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Conditions** tab.
3. Click the **Add** button. The **Prerequisite Condition** dialog box opens.
4. Select the Setup is running on a specified platform option.
5. Do one of the following:
   - In the **Select which platform the prerequisite should be run on** box, select the operating system that is required on the target system for the prerequisite.
   - In the **Select which platform the prerequisite should be run on** box, select **Custom**. Then configure the operating system settings as appropriate.

Tip • *You can also use the values from an existing predefined operating system condition as the basis for a new custom condition. To do so: In the* ***Select which platform the prerequisite should be run on*** *box, select the appropriate predefined operating system, and then change the setting to* ***Custom****. Then you can further configure the operating system condition by specifying additional values in the* ***Custom*** *area.*

6. To specify a range of service pack numbers for which this prerequisite condition is true, use the **Service Packs** boxes. For example, if target system must have service pack 2, 3, or 4, enter 2 in the first box and 4 in the second box. To target all future service packs, leave the second box blank. To target only service pack 3, enter 3 in both boxes.
7. Click **OK**.

The InstallShield Prerequisite Editor adds the operating system condition to the Conditions tab.

Note • *Instead of storing in the .prq file the value that you selected in the* ***Select which platform the prerequisite should be run on*** *box, the InstallShield Prerequisite Editor stores the underlying operating system settings that are associated with the value that you selected. Therefore, if you select the Custom option but do not change or configure any settings in the Custom area, the InstallShield Prerequisite Editor does not set the value of this box to Custom the next time that you reopen the Prerequisite Condition dialog box for the selected condition. Instead, it sets the value of the box to the predefined operating system option.*

Modifying an Installation Condition for an InstallShield Prerequisite

Task: ***To modify an existing condition:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Conditions** tab.
3. Select the condition that you would like to modify.
4. Click the **Modify** button. The **Prerequisite Condition** dialog box opens.
5. Modify the condition as needed.

The InstallShield Prerequisite Editor updates the modified condition on the Conditions tab.

Removing an Installation Condition from an InstallShield Prerequisite

Task: ***Remove a condition from an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Conditions** tab.
3. Select the condition that you would like to remove.
4. Click **Remove**.

Specifying Files for an InstallShield Prerequisite

When you are creating a new InstallShield prerequisite, you must specify the installation files that should be included with the prerequisite. You can also modify the list of files for an existing InstallShield prerequisite. The Files to Include tab of the InstallShield Prerequisite Editor is where you specify the files.

Task: ***To add one file for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Files to Include** tab.
3. Click **Add**. The **New File** dialog box opens.
4. In the **File** box, type the path and name of the file. To find the file by browsing, click the ellipsis (**...**) button.
5. If end users should be able to download the file from the Web, specify the URL in the **URL to file** box. This URL is the same one that InstallShield uses when installation authors use the **Redistributables** view to download an InstallShield prerequisite from the Internet to their local machines.

For example, if the URL for the file is **http://www.mywebsite.com/Folder1/Notepad.exe**, enter the following in this box:

```
http://www.mywebsite.com/Folder1
```

Note • *InstallShield prerequisites do not have support for FTP URLs.*

Task: ***To add more than one file at a time for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, click the **Files to Include** tab.
2. Click **Add Multiple Files**. The **Open** dialog box opens.
3. Select the files that you would like to add. To select multiple consecutive files, select the first file, press and hold SHIFT, and select the last file. To select multiple nonconsecutive files, select the first file, press and hold CTRL, and select each additional file.
4. Click **Open**.

Note • *Adding files by using this method does not also set the URL where those files can be downloaded. To set the URL for multiple files, see Specifying URLs for Downloading InstallShield Prerequisites.*

Task: ***To modify the settings for an existing file:***

1. In the **InstallShield Prerequisite Editor**, click the **Files to Include** tab.
2. Select the file whose name, path, or URL you would like to modify.
3. Click **Modify**. The **New File** dialog box opens.
4. Modify the settings as needed.

Task: ***Remove a file from an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, click the **Files to Include** tab.
2. Select the file that you would like to remove.
3. Click **Remove**.

Specifying URLs for Downloading InstallShield Prerequisites

If end users should be able to download the files for an InstallShield prerequisite in your installation, you must specify the URL on the Files to Include tab of the InstallShield Prerequisite Editor.

Note • *InstallShield prerequisites do not have support for FTP URLs.*

Task: ***To specify the URL of one or more files for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Files to Include** tab.
3. Select one or more files for which you would like to specify the URL. To select multiple consecutive files, select the first file, press and hold SHIFT, and select the last file. To select multiple nonconsecutive files, select the first file, press and hold CTRL, and select each additional file.
4. Click **Set File(s) URL**. The **Set File(s) URL** dialog box opens.
5. In the **URL to File's Parent Folder** box, type the URL for the parent directory of the selected file or files. This URL is the same one that InstallShield uses when installation authors use the **Redistributables** view to download an InstallShield prerequisite from the Internet to their local machines.

   For example, if you selected files called **Notepad.exe** and **Paint.exe**, and the URLs for these files are **http://www.mywebsite.com/Folder1/Notepad.exe** and **http://www.mywebsite.com/Folder1/Paint.exe**, enter the following in this box:

   ```
   http://www.mywebsite.com/Folder1
   ```

6. Click **OK**.

Tip • *As an alternative to the above steps, you can also specify the URL for an individual file when you add it to the list of prerequisite files on the Files to Include tab. For more information, see Specifying Files for an InstallShield Prerequisite.*

Specifying Parameters for Installing an InstallShield Prerequisite

The Application to Run tab of the InstallShield Prerequisite Editor is where you specify how a prerequisite should be installed on the target machine.

Task: ***To specify parameters for installing an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Application to Run** tab.
3. In the **Specify the application you wish to launch** list, select the file—typically a `Setup.exe` setup launcher or an .msi file—that should be launched on the target machine if the InstallShield prerequisite is installed. Only files that have been specified on the **Files to Include** tab are included in this list.

   If the main installation is a Basic MSI or InstallScript MSI installation, and if you specify an .msi file and you indicate on the Behavior tab that the progress should be shown, the `Setup.exe` setup launcher captures progress messages and uses Windows Installer APIs instead of `MsiExec.exe` to launch the .msi package at run time.

   If you specify any other file type, or if you specify an .msi file for which progress should not be shown, the `Setup.exe` setup launcher runs the file with either the open verb (for .msi and .exe files) or the default verb (for all other file types) at run time.

   

   Project • *If you specify an .msi file and you indicate on the Behavior tab that the progress should be shown, the `Setup.exe` setup launcher captures progress messages and uses Windows Installer APIs instead of `MsiExec.exe` to launch the .msi package at run time.*

   If you specify any other file type, if you specify an .msi file for which progress should not be shown, or if the main installation is an InstallScript installation, the `Setup.exe` setup launcher runs the file with either the open verb (for .msi and .exe files) or the default verb (for all other file types) at run time.
4. If the Windows Installer engine, the .NET Framework, or both must be installed before this InstallShield prerequisite is installed, select the **Requires Windows Installer engine and/or .NET Framework to be installed first** check box.

   

   Note • *Selecting this check box does not add the Windows Installer engine or the .NET Framework to your installation. It only specifies that if they are included in the installation, they should be installed before this InstallShield prerequisite is installed. To include the Windows Installer engine or the .NET Framework with your installation, you must add them to your project. To learn how, see Adding Windows Installer Redistributables to Projects or Adding .NET Framework Redistributables to Projects.*
5. If applicable, in the **Specify the command line for the application** box, type the command line for the file selected in the **Specify the application you wish to launch** list. Do not include the name of the file in this box.

   For more details, see Specifying Command-Line Parameters for an InstallShield Prerequisite.
6. If applicable, in the **Specify the command line for the application when the setup is running in silent mode** box, type the appropriate command line. Do not include the name of the file in this box.

   For more details, see Specifying Command-Line Parameters for an InstallShield Prerequisite.

7. If the selected InstallShield prerequisite application requires that the target machine be restarted after the application is installed, type the return code in the **Specify the return code (in decimal) the application returns if a reboot is required** box.

Tip • *If multiple return codes exist, list each one separated by a comma.*

- *If you do not know the return codes for the file that you are launching as the InstallShield prerequisite, contact the author of the file.*
- *For more information on InstallShield prerequisites that require a restart, see Restarting a Target Machine for InstallShield Prerequisite Installations.*

Specifying Command-Line Parameters for an InstallShield Prerequisite

The Application to Run tab of the InstallShield Prerequisite Editor lets you specify command-line parameters that you want to be used when the InstallShield prerequisite is launched on the target system.

Task: ***To specify command-line parameters that you want to be used when an InstallShield prerequisite installation is launched:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Application to Run** tab.
3. In the **Specify the command line for the application** box, type any valid command-line parameters for the file that is selected in the **Specify the application you wish to launch** list. Do not include the name of the file in this box.
4. If you want to specify the command line that should be used for the InstallShield prerequisite if the main installation is running in silent mode, type any valid command-line parameters in the **Specify the command line for the application when the setup is running in silent mode** box. Do not include the name of the file in this box.

   The command-line parameters that you enter in this setting are also used if the prerequisite is configured to be hidden—that is, if the **The prerequisite should be hidden from the installation list** check box on the Behavior tab is selected.

Note • *Using the `/s` command-line parameter to launch an installation that includes an InstallShield prerequisite does not automatically run the prerequisite installation silently. You may also need to specify a valid silent command-line parameter for the InstallShield prerequisite in the **Specify the command line for the application when the setup is running in silent mode** setting on the Application to Run tab.*

*Also note that no command-line parameters are passed to the InstallShield prerequisite if you leave the **Specify the command line for the application when the setup is running in silent mode** box blank and one or both of the following conditions are also true:*

- *The main installation is run silently.*
- *The **The prerequisite should be hidden from the installation list** check box on the Behavior tab is selected for the prerequisite.*

Therefore, if you specify standard command-line parameters, it is recommended that you also specify silent command-line parameters.

How the Setup Launcher Passes the Command-Line Parameters to the InstallShield Prerequisite

If the InstallShield prerequisite installation is an .msi package and you indicate on the Behavior tab that the progress should be shown, the setup launcher uses Windows Installer APIs—instead of MsiExec.exe—to launch the .msi package with the command-line parameters that you specify on the Application to Run tab. Under these circumstances, you can enter any of the following types of parameters for the command line:

- Windows Installer property names and values in the following format:

  `PROPERTY=VALUE`

- `/L` (as well as any variants such as `/L*v`)
- `/log`
- `/q` (as well as any variants such as `/qb+!`)
- `/quiet`

Note that if you specify that the progress should be shown, the user interface of the prerequisite's .msi package is not displayed by default. If you want to override this behavior, you can specify `/qf` as a command-line parameter.

If the InstallShield prerequisite installation is any other file type, or it is an .msi package for which progress should not be shown, the setup launcher runs the file with either the open verb (for .msi and .exe files) or the default verb (for all other file types) at run time. Therefore, in the case of an .msi package for which progress should not be shown, you can use any of the command-line parameters that `MsiExec.exe` accepts. For a list of the supported command-line parameters, see Command-Line Options and Standard Installer Command-Line Options in the Windows Installer Help Library.

If your InstallShield prerequisite installation is a `Setup.exe` file that was created with InstallShield, the formatting that is done for that prerequisite command-line parameters that you specify on the Application to Run tab differs depending on whether you associated the InstallShield prerequisite with a feature in your project. If the InstallShield prerequisite is not associated with a feature, it is called a *setup prerequisite*. If the InstallShield prerequisite is associated with one or more features, it is called a *feature prerequisite*.

***Note** • To learn more about the differences between setup prerequisites and feature prerequisites, see Setup Prerequisites vs. Feature Prerequisites.*

In the setup prerequisite case, the setup launcher supports property substitution through the command-line parameters for the following properties:

- **SETUPEXEDIR**—This property identifies the path to the setup launcher file. For example, if the path to the setup launcher is `C:\MySetups\MyApp\Setup.exe`, the value of **[SETUPEXEDIR]** is `C:\MySetups\MyApp`.

- **SETUPEXENAME**—This property identifies the name of the setup launcher file that was created when the project was built. The installation updates the value of this property at run time if the setup launcher file was renamed. The following path identifies the full path to this file:

  `[SETUPEXEDIR]\[SETUPEXENAME]`

- **ISPREREQDIR**—This property identifies the path to the running InstallShield prerequisite. The path includes the final slash. You can use this property to refer to files within the InstallShield prerequisite—for example, **[ISPREREQDIR]MyConfigFile.ini**.

- **ProductLanguage**—This property identifies the language that the installation should use for any strings in the user interface that are not authored into the database.

For a feature prerequisite, the command-line parameters that you specify on the Application to Launch tab are formatted at run time like a formatted text field. Therefore, you can use the aforementioned properties at the command line, as well as any of the standard command-line parameters that `Setup.exe` supports. For a list of supported command-line parameters, see Setup.exe and Update.exe Command-Line Parameters.

Restarting a Target Machine for InstallShield Prerequisite Installations

InstallShield uses several methods to determine if a target machine should be restarted after running the InstallShield prerequisite.

Registry Key Changes

The target machine may need to be restarted if any of the following registry keys have been modified after the InstallShield prerequisite has been run:

- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnce
- HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx
- HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Session Manager\FileRenameOperations

The registry keys are counted before and after the InstallShield prerequisite is run. If these numbers are not the same, it is assumed that the file is trying to restart the system and exit the installation.

Return Code Specified in the .prq File

If the exit code of the .exe file matches the return code specified in the InstallShield prerequisite file (.prq), the target machine may need to be restarted. The return code of the .prq file is entered in the **Specify the return code the application returns if a reboot is required** box of the InstallShield Prerequisite Editor. For more information, see Specifying Parameters for Installing an InstallShield Prerequisite.

Return Codes 1641 and 3010

The target machine may need to be restarted if a reboot state is returned for an .msi package that is run for an InstallShield prerequisite. The standard Windows Installer reboot return codes are:

- ERROR_SUCCESS_REBOOT_INITIATED (1641)

- ERROR_SUCCESS_REBOOT_REQUIRED (3010)

Behavior Specified in the .prq File

One of the fields on the Behavior tab in the InstallShield Prerequisite Editor enables you to specify what should happen if any of the aforementioned conditions are or are not applicable to a particular InstallShield prerequisite. For more information, see Specifying the Behavior for an InstallShield Prerequisite that Requires a Restart.

Specifying Installation Behavior for an InstallShield Prerequisite

When you are creating a new InstallShield prerequisite or modifying an existing one, you can specify whether end users may skip the InstallShield prerequisite installation. You can also specify how the prerequisite installation should proceed if it appears that the target machine does or does not need to be restarted. The Behavior tab of the InstallShield Prerequisite Editor is where you specify these types of InstallShield prerequisite installation behavior.

Specifying that an InstallShield Prerequisite Requires Administrative Privileges

In the Windows Vista and later environment, end users typically run as standard users without administrative privileges. If an InstallShield prerequisite requires administrative privileges, Windows displays a User Account Control (UAC) prompt that requires end users to provide consent or credentials.

If your InstallShield prerequisite does require administrative privileges or if you want the InstallShield prerequisite to be installed per machine, you can specify that on the Behavior tab of the InstallShield Prerequisite Editor.

Task: ***To specify that an InstallShield prerequisite installation requires administrative privileges:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Behavior** tab.
3. Select the **The prerequisite requires administrative privileges** check box.

Note • *This setting applies to installations that are run on Windows Vista and later systems. Earlier versions of Windows ignore this setting.*

Allowing End Users to Choose Whether to Install an InstallShield Prerequisite

You may want your InstallShield prerequisite's installation to display a message box that permits end users to choose whether they want to install the InstallShield prerequisite. You can indicate this on the Behavior tab of the InstallShield Prerequisite Editor.

Task: ***To allow end users to choose whether to install an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Behavior** tab.
3. Select the **The prerequisite may be optionally skipped by the user** check box.

Specifying Whether to Include the Name of a Prerequisite in the List of Setup Prerequisites to Be Installed on the Target System

If a target system needs one or more setup prerequisites to be installed, the setup prerequisite dialog is typically displayed at run time before the main installation runs. When an end user clicks the Install button on this dialog, the setup prerequisites are installed.

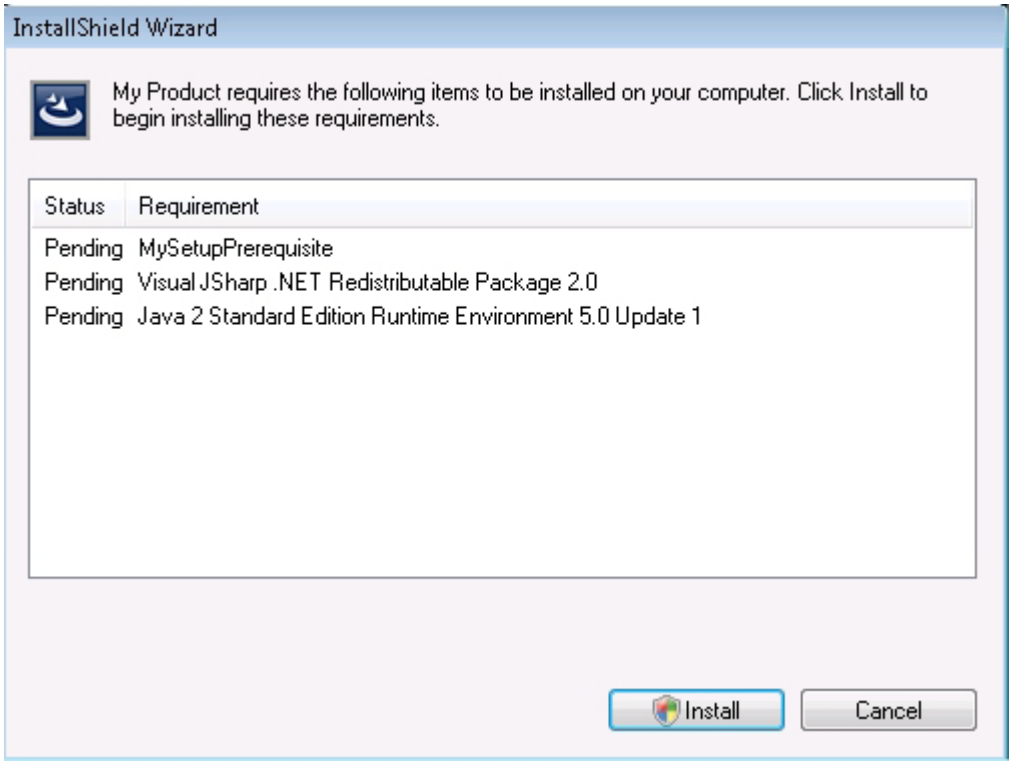

Figure 6-1: Sample Setup Prerequisite Dialog that Shows the List of Setup Prerequisites that Need to Be Installed

The Behavior tab of the InstallShield Prerequisite Editor lets you specify whether you want a setup prerequisite to be hidden from the list in the prerequisite dialog. If a prerequisite is hidden, it is installed when the conditions require it, even though it is not listed as one of the prerequisites that needs to be installed.

If all of the setup prerequisites in an installation are hidden, the installation does not display the setup prerequisite dialog at run time.

Task: ***To specify whether to list a setup prerequisite in the setup prerequisite dialog at run time:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Behavior** tab.
3. Do one of the following:
   - To hide the setup prerequisite, select the **The prerequisite should be hidden from the installation list** check box.

     Note that if the setup prerequisite is hidden, it is launched with its silent command-line parameters—not its standard command-line parameters. To learn more, see Specifying Command-Line Parameters for an InstallShield Prerequisite.
   - To include the setup prerequisite in the list, clear the **The prerequisite should be hidden from the installation list** check box.

Note • *Note that feature prerequisites are never listed in the setup prerequisite dialog at run time, regardless of whether the* ***The prerequisite should be hidden from the installation list*** *check box is selected or cleared. That is, if you add an InstallShield prerequisite to your project and associate it with a feature, that feature prerequisite is not listed in the setup prerequisite dialog that is displayed at run time before the main installation runs. For more information about feature prerequisites, see Setup Prerequisites vs. Feature Prerequisites.*

Specifying Whether to Show the Progress of an InstallShield Prerequisite Installation at Run Time

The Behavior tab of the InstallShield Prerequisite Editor lets you specify whether you want the InstallShield prerequisite installation to show the status bar that shows the actual progress of the prerequisite installation, along with installation progress messages from Windows Installer, at run time. This functionality is available only if the prerequisite launches an .msi file; it is not possible if the prerequisite launches a `Setup.exe` file. In addition, the installation that contains the InstallShield prerequisite must be a Basic MSI or InstallScript MSI installation.

If the progress is not shown—or if the installation that contains the InstallShield prerequisite is an InstallScript installation, the prerequisite installation displays an **Installing [PrerequisiteName]** message on the run-time dialog, and the status bar loops continuously until the prerequisite installation has completed.

Task: ***To specify whether to show the progress messages and the status bar for an InstallShield prerequisite installation:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Behavior** tab.
3. Do one of the following:

- To show the progress, select the **Progress should be shown in the prerequisites window (raw MSI files only)** check box.
- To avoid showing the progress, clear the **Progress should be shown in the prerequisites window (raw MSI files only)** check box.

Note *• If you specify that the progress should be shown, only some command-line parameters are supported. Command-line parameters are specified on the Application to Run tab of the InstallShield Prerequisite Editor. For more information, see Specifying Command-Line Parameters for an InstallShield Prerequisite.*

Also note that if you specify that the progress should be shown for a prerequisite that is an .msi package, the user interface of the prerequisite's .msi package is not displayed by default. If you want to override this behavior, you can specify `/qf` as a command-line parameter on the Application to Run tab of the InstallShield Prerequisite Editor.

Planning for Issues that Could Occur with an InstallShield Prerequisite Installation

Sometimes after an InstallShield prerequisite installation has been run, the conditions still indicate that the InstallShield prerequisite needs to be installed. If that occurs, either of the following may be true:

- The InstallShield prerequisite was not successfully installed.
- The conditions that were specified for the InstallShield prerequisite were not accurate.

For example, a condition may indicate that the InstallShield prerequisite needs to be installed if a particular file does not exist on the target machine. If the file is still missing even after the InstallShield prerequisite is installed, it is possible that the condition should not have been created. The Behavior tab of the InstallShield Prerequisite Editor lets you indicate how the installation should proceed under these types of circumstances.

Task: ***To plan for potential issues related to an InstallShield prerequisite's installation:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Behavior** tab.
3. In the **If, after installing the prerequisite, the conditions still indicate it is required** list, click the appropriate item.

Specifying the Behavior for an InstallShield Prerequisite that Requires a Restart

When you are creating a new InstallShield prerequisite or modifying an existing one, you can specify how the InstallShield prerequisite installation should proceed if it appears that the target machine does or does not need to be restarted. For example, in some cases, you may want the installation to first prompt the end user before

restarting the machine; in other cases, you may want to skip the restart. The Behavior tab of the InstallShield Prerequisite Editor provides the flexibility needed to carry out the response that is appropriate for each InstallShield prerequisite.

Task: ***To specify the behavior for an InstallShield prerequisite that requires the target machine to be restarted:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Behavior** tab.
3. In the **If the prerequisite requires a reboot** list, click the appropriate item.

To learn about the available options, see Behavior Tab.

Specifying Dependencies for an InstallShield Prerequisite

When you are creating a new InstallShield prerequisite or modifying an existing one, you can specify other InstallShield prerequisites (.prq files) on which this InstallShield prerequisite depends. The Dependencies tab of the InstallShield Prerequisite Editor is where you specify the dependencies.

Adding a Dependency for an InstallShield Prerequisite

Task: ***To add a dependency for an InstallShield prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Dependencies** tab.
3. Click the **Add** button. The **New Dependency** dialog box opens.
4. In the **File** box, type the path and name of the .prq file that is required for the current InstallShield prerequisite. To find the .prq file by browsing, click the ellipsis (**...**) button. InstallShield prerequisite files are stored in the following location:

   InstallShield Program Files Folder\SetupPrerequisites
5. Click **OK**.

Modifying a Dependency for an InstallShield Prerequisite

Task: ***To modify an existing dependency setting:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Dependencies** tab.
3. Select the dependency that you would like to modify.
4. Click **Modify**. The **New Dependency** dialog box opens.
5. Modify the setting as needed.

Removing a Dependency from an InstallShield Prerequisite

Task: ***Remove a dependency from a prerequisite:***

1. In the **InstallShield Prerequisite Editor**, open the prerequisite that you want to modify.
2. Click the **Dependencies** tab.
3. Select the dependency that you would like to remove.
4. Click **Remove**.

Saving an InstallShield Prerequisite

Once you have created a new InstallShield prerequisite or modified an existing one using the InstallShield Prerequisite Editor in InstallShield, you must save the InstallShield prerequisite file (.prq).

Task: ***To save an InstallShield prerequisite that is open in the InstallShield Prerequisite Editor:***

1. On the **File** menu, click **Save As**. The **Save As** dialog box opens.
1. Specify the file name and .prq extension for the InstallShield prerequisite file. InstallShield prerequisite files are stored in the following location:

   InstallShield Program Files Folder\SetupPrerequisites
2. Click the **Save** button.

InstallShield prerequisites that are stored in the SetupPrerequisites directory are listed in the Redistributables view.

Designing Merge Modules

Merge modules enable several development teams to work on separate components independently. Each team can populate its installation database without immediately considering how their work will affect other components. When the components are fully developed, each component in the merge module database can be merged into the main product installation database.

InstallShield enables you to create your own merge modules that can be used in any of your installation projects or distributed for use by other installation developers.

The most important step in creating your merge module lies in its design. To have a well-designed merge module, you need to break up your files into components, which constitute the developer's perspective of the project. Unlike creating a complete installation with features, components, and files, a merge module contains only components, which, in turn, contain files.

The major aspects involved in creating a merge module are listed below.

Table 6-1 • Major Aspects of Merge Module Creation

Merge Module Element	Description
Components	Enable you to group your application data together. They constitute the developer's view of a project—containing data such as files, registry entries, and shortcuts. The Components view is where you design the components for your merge module.
Files, registry data, and shortcuts	Elements that are added to a component to complete the hierarchy, as described above.
Advanced settings	Enable you to publish your component, register COM servers, file extension servers, and MIME types. You can also use the component's advanced settings to create an application paths entry in the registry.

Creating a Merge Module Project

A merge module (or .msm file) contains all of the logic and files needed to install distinct pieces of functionality. For example, many applications require Visual Basic run-time DLLs. Instead of having to include the file in a component and figure out its installation requirements, you can simply attach the Visual Basic Virtual Machine merge module to one of your project's features.

Merge module properties include the following:

- Product Name
- Product Version
- Language
- INSTALLDIR

You can specify any merge module dependencies and exclusions in the Module Dependencies and Module Exclusions settings in the General Information view.

To create a merge module, start by creating a Merge Module project.

Task: ***To create a Merge Module project:***

1. On the **File** menu, click **New**.
2. Click the **Windows Installer** tab.
3. In the box of project types, click **Merge Module Project**.
4. In the **Project Name** box, enter a name for your project.

   Important • *When you create a new Merge Module project, the name that you specify in the New Project dialog box should have 35 characters or fewer. This is because the name that you enter is used with the GUID in the ModuleID field of the* ***ModuleSignature*** *table of your merge module file, and the limit for the object name portion of the ModuleID field is a maximum of 35 characters.*
5. In the **Location** box, specify the location where you want to save the project, or click the **Browse** button to navigate to the location.
6. Click **OK**.

Specifying the Default Destination Folder for a Merge Module

The value that you enter for the INSTALLDIR setting in the General Information view serves as the default folder for all of your merge module's files. That is, its value is assigned to the Windows Installer folder property **INSTALLDIR**, which is the default component destination folder.

If you would like to let the users of your merge module override the default destination directory, enter `[TARGETDIR]` in the INSTALLDIR setting. To learn more, see Overriding a Merge Module's Destination.

Other Destination Folder Considerations

Note that each component in your Merge Module project also has a Destination setting. The component's Destination setting overrides the INSTALLDIR setting in the General Information view. Therefore, if you want all of your merge module's files to be installed by default to the merge module's destination folder, enter [INSTALLDIR] for all of your components' Destination settings.

Selecting the Merge Module Language

The Language setting in the General Information view lets you to select the language for which your module is designed. For example, if your module installs a user interface, specify the language for which that user interface was designed. If the module is run on a machine that does not match your module language setting, it is not installed.

Tip • *Select Language Independent to allow your module to run on all languages.*

Adding Dependencies to Merge Modules

While some merge modules are self-contained, some require other merge modules in order to function properly. For example, your merge module may require the Visual Basic run-time libraries. If this is the case, you need to add that merge module as a dependency to your new merge module.

When adding a file to a merge module, you may encounter a Setup Best Practices violation if the file is contained in another merge module that is stored on your system. If this happens, you should add that merge module as a dependency.

Caution • *When you are creating a typical Basic MSI or InstallScript MSI project, merge modules are automatically added to your project when you add a file that is available within a merge module. When you are creating a merge module and you add a file that is available within another merge module, you will receive a Setup Best Practices alert telling you to set that merge module as a dependency. InstallShield does not create the dependency for your Merge Module project.*

Dependency information entered in the General Information view is written to your project's **ModuleDependency** table, which you can view using the Direct Editor.

Adding Dependencies from the Redistributables Gallery

A merge module is in your redistributables gallery if it is located in one of the paths that are specified on the Merge Modules tab of the Options dialog box.

Task: ***To add one or more dependencies from the redistributables gallery:***

1. In the View List under **Installation Information**, click **General Information**.
2. In **Module Dependencies** setting, click the ellipsis button (**...**). The **Module Dependencies** dialog box opens.
3. Select the check boxes of the merge modules that are required for the merge module that you are creating.
4. Click **OK**.

InstallShield adds the dependency to the grid in the General Information view. You can change the settings for the dependency if necessary.

Adding Dependencies that Are Not in the Redistributables Gallery

Task: ***To add a dependency that is not present on your machine:***

1. In the View List under **Installation Information**, click **General Information**.
2. In **Module Dependencies** setting, click the **Add a new module dependency** button.

InstallShield adds the dependency to the grid in the General Information view. Configure each of its settings as needed.

Note • *Be careful when entering the value for the Module ID setting, since InstallShield does not check to ensure that it is correct. You will not know if it fails until you try to run the installed program.*

Adding Exclusions to Merge Modules

Occasionally you may need to exclude certain merge modules from being associated with the module that you are creating. This may occur because an older version of a module might not be compatible with your new module. As a result, you need to exclude that module from any setup that your new module will be associated with.

Adding Exclusions from the Redistributables Gallery

A merge module is in your redistributables gallery if it is located in one of the paths that are specified on the Merge Modules tab of the Options dialog box.

Task: ***To add an exclusion from the redistributables gallery:***

1. In the View List under **Installation Information**, click **General Information**.
2. In **Module Exclusions** setting, click the ellipsis button (**...**). The **Module Exclusions** dialog box opens.
3. Select the check boxes of the merge modules that are not compatible with the merge module that you are creating.
4. Click **OK**.

InstallShield adds the exclusion to the grid in the General Information view. You can change the settings for the exclusion if necessary.

Adding New Exclusions that Are Not in the Redistributables Gallery

Task: ***To add an exclusion that is not present on your machine:***

1. In the View List under **Installation Information**, click **General Information**.
2. In **Module Exclusions** setting, click the **Add a new module exclusion** button.

InstallShield adds the exclusion to the grid in the General Information view. Configure each of its settings as needed.

Note • *Be careful when entering the value for the Module ID setting, since InstallShield does not check to ensure that it is correct. You will not know if it fails until you try to run the installed program.*

Publishing a Merge Module to a Repository from Within a Merge Module Project

If you are designing a merge module that you would like to reuse in Windows Installer–based installations or share with other users, you can publish it to a repository. InstallShield enables you to configure a release for the merge module so that the merge module is published to a repository whenever the release is built.

Task: ***To configure the settings for publishing a merge module to a repository from within the merge module project:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you would like to configure.
3. Click the **Events** tab.
4. In the **Publish Merge Module** setting, select the **Publish to repository** option.
5. In the **Repository Name** setting, select the appropriate repository. All of the repositories to which you have access are listed in this setting.
6. In the **Display Name** setting, specify a name for the merge module that you are publishing to the repository. This name is displayed for the merge module in the Redistributables view.
7. In the **Publisher** setting, type your name.
8. In the **Description** setting, type a description of the merge module.

Whenever you build the selected release, InstallShield publishes the merge module to the specified repository.

Merge modules are built into an installation at build time. If you make a change to a repository merge module and then republish it to the repository, any project that has the old version of the repository merge module will be updated the next time that a release of the project's installation is rebuilt.

Creating InstallScript Objects

Project • *This information applies to InstallScript Object projects.*

InstallShield enables you to create your own InstallShield objects that can be used in any of your installation projects or distributed for use by other installation developers. Objects replace the templates found in earlier versions of InstallShield.

Note • *Objects that you create can be used only with InstallShield X or later, InstallShield DevStudio, or InstallShield Professional 6.1 or later.*

Creating an object is little different from creating a standard installation project. One difference is the importance of scope. When you create an object, you need to ensure that the object's scope is optimal for its intended use. The scope of an object affects its usability. If the scope is too narrow, the object may be insufficient for your needs. If the scope is too large, the object may to be too cumbersome to be practical.

The following sections describe the steps in the object creation process.

Creating an Object

Currently, there are two ways to create an object. You can create a new InstallScript Object project from the New Project dialog box or convert an existing InstallScript project into an InstallScript object.

Task: ***To convert an existing InstallScript project into an InstallScript object:***

1. On the **File** menu, click **Save Project As**. A **Save As** dialog box opens.
2. Select a folder in which to create a copy of the project. Note that you cannot save the new object project in the same folder as the original project.
3. In the **File name** box, type a name for the new project.
4. In the **Save as type** list, select **InstallScript Object Project (*.ism)**.
5. Click **Save**.

An object project file (.ism file) with the name that you specified, and all project subfolders, are created in the location that you specified. That project opens in InstallShield.

Object Design

The purpose of an object is to install a discrete piece of functionality. For example, you may need to install the latest version of DirectX in order for your application to run. Rather than including all the necessary files separately in your installation project, you can include the DirectX object that comes with InstallShield. Imagine if this same object contained, for example, Visual Basic run-time .dll files and MDAC support. The object would be too large for

your needs. It would install files that are not needed and would increase the time required for the installation process. Therefore, it is a good idea to streamline your object as much as possible. Do not try to include four different technologies in one object. Instead, create four separate objects.

Objects follow the same structure as traditional installations, with one major difference—objects do not support setup types. The highest level of organization in an object is the feature. Under features fall components. Additionally, objects do not support shell objects. If you would like to create shell objects from an object, you will need to do so via script.

For more information, see Designing Objects.

Building an Object

Building an object is very similar to building an installation project. The easiest way to complete this task is to use the Release Wizard. The main difference between building an object and building an installation project is the fact that you do not need to specify a media type for an object. The wizard enables you to create media in the CD-ROM format only.

For more information, see Building an Object from the User Interface.

Testing Objects

As with any other software endeavor, it is a good idea to test before you release to the public. Testing an object is easy—just create a standard installation project, add your object to it, build it, and run it. If it works as planned, you are ready to include your object in projects. If not, you will need to debug. See Testing and Debugging an Object. (Note that if you have the object project and its associated installation project open in separate instances of InstallShield and you modify and rebuild your object, you must close and reopen the associated installation project to incorporate those modifications.)

Distributing Objects

As used here, *distributing an object* does not mean including that object in an installation and installing the files from that object on a target machine. Instead, *distributing an object* refers to creating an installation that will make that object available on other users' machines for use in their installation projects. Because you do not want to install the logic contained within an object, you cannot just add it to a component as you normally would. To help you register your objects, you can use the InstallShield Object Installer object. When you associate this object with a feature, you will be prompted to select the object from your local gallery that you would like to distribute.

For more information, see Distributing an Object.

Designing Objects

The design of your object—how components and file groups are arranged—accompanied by the actual content of the object, is the single biggest hurdle you need to clear in order to have a stable, usable object.

Several key areas are involved in designing an object. Each is described below.

Object Project Settings

Another difference between standard installation projects and objects lies in the project settings. Tabs for object creation are available on the Project Settings dialog box. On these tabs, you can define the language the object was developed in, the display name of the object, and the icon and help topic associated with the object. You can also can choose the kind of wizard interface, if any, that you would like to provide with your object.

For more information, see Designing an Object's Wizard.

Managing Components

It is important that you take the time to properly divide your project into features. When designing your features, you need to plan for scenarios such as localization and conditional selection of features. For more information, see Designing Features for Objects.

Properties and Methods

Properties and Methods allow your users to interact with your object both during design time and run time. For more information, see Creating a Property and Creating a Method.

Creating a Design-Time Wizard

If you include any properties in your object, it is a good idea to provide a graphical interface so that users of your object can easily set those properties according to their needs. For more information, see Designing an Object's Wizard.

Creating the Runtime User Interface

Your object can display dialogs to the end users of installations that include the object. For information on creating a run-time user interface for your object and calling that interface from an installation that includes the object, see Creating the Object's Run-Time User Interface.

Localizing Your Object's Design Environment

The InstallShield interface is localized into English and Japanese. If you would like your object to be localized to these languages, see Localizing an Object's Design-Time Environment for more information.

Internationalizing Your Object's Run-Time Experience

If your application is designed to run in multiple languages, you will need to prepare an internationalized object. Installing language-specific files with an object differs slightly from standard installations. For more information, see Preparing an Object for Internationalization.

Making Your Object Compatible with Installations During Run Time

Your object should support all the operating systems and languages that are supported by any installation that includes the object. For more information, see Making Your Object Compatible with Installations During Run Time.

Designing Features for Objects

It is very important that you design your features well. A haphazard design of features may make it difficult for you to internationalize your object, selectively build files into the object, or conditionally install files. The following sections discuss a few guidelines that will help you accurately and efficiently design the feature layout of your object.

Selectively Installing an Object's Features

More often than not, you will want to place conditions on the selection of your object's features. For example, if you are creating an object that installs DCOM, you will want to check if the target system already has DCOM installed. If DCOM is present, reinstalling it would be a waste of time and may cause complications. To allow your object's features to be conditionally selected without unwanted effects on the project that includes the object, you must design your object according to the following guidelines.

Your object should never select its own features but only deselect them as needed. (An object's features are selected by default.) If your object selects one or more of its own features, that will cause the feature that includes the object to be selected—even if that feature had previously been deselected by the end user or the project's internal logic.

However, an object's deselecting its own features can also potentially cause a problem. The following paragraphs describe the problem and its solution.

Suppose a project has two main features, A and B; B has no subfeatures but contains an object that, in turn, contains a feature, C. The InstallScript engine automatically deselects a feature when all its child features are deselected; so if feature C is not selected, the DCOM object will not be selected. If the DCOM object is not selected, feature B will not be selected. This behavior can cause problems if you have components associated with the main feature, in this case feature B. Because the feature that contains the components is not selected, the components directly associated with it will not be installed.

If you want your component to be selected regardless of whether DCOM is selected, create a "dummy" feature within your object. If feature C is not selected, the dummy feature will still be selected. Since the dummy feature is selected, feature B will also be selected, and its component will be installed.

Installing Language Dependent Files

When developing an installation that targets multiple languages, you often have different language versions of the same file. If these files have a common name, you may encounter problems when InstallShield builds your installation and copies all of the installation files to the release. When the Release Wizard runs, it takes all of the files within a feature and stores them in the same directory on the release. If you have two files with the same name, but in separate components, one of those files will be overwritten if the two components belong to the same feature. To overcome this problem, you will need to create a separate feature for each language that you are targeting. For more information, see Preparing an Object for Internationalization.

Managing Object Files

When you build an object, all of its files are sent to the release in an uncompressed fashion. As a result, objects that contain multiple files with the same name can run into problems. If those files with the same name reside in the same feature, only one of them will end up in the release. The rest of the identically named files will be overwritten by the last one sent to the release.

The main reason you would have files with the same name is for multiple language support. If that is the case, it is recommended that you create a separate feature for each language that you are supporting. For more information, see Preparing an Object for Internationalization.

An additional layer of assurance can be added by defining a CD-ROM folder for every feature. By defining a CD-ROM folder, you are specifying where on the media the files for each feature will be sent. To define a CD-ROM folder, simply navigate to the Features view and enter a name for your folder in the CD-ROM Folder property.

You must define a CD-ROM folder for every feature that contains a file with the same name as any file that the build places uncompressed in the Disk1 image folder (for example, the compiled script file `Setup.inx`, or any file that you placed in the Support Files/Billboards views' Advanced Files node's Disk1 subnode).

Designing an Object's Wizard

When you include properties in your object, it is a good idea to provide an interface for the users of your object to modify those properties. InstallShield can create a stock wizard for you based on the properties that you created, or you can create your own wizard using Visual Basic or Visual C++.

The InstallShield Stock Wizard

The InstallShield stock wizard is well-suited for in-house use of your object. The stock wizard displays all of your read-only properties and provides an edit field for your read/write properties.

There are a few limitations of the stock wizard that can be overcome by using a custom wizard. For example, the stock wizard cannot be customized to fit your needs. You cannot pick and choose which properties you would like to display, nor can you customize the way the wizard looks. If you would like to create a customized interface for your wizard, you will need to create your own wizard in Visual C++ or Visual Basic. Another drawback of the stock wizard is that it does not provide support for array properties. Although the stock wizard has a few limitations, it is simple to implement and use.

Custom Wizards

If you need to provide a more professional look to your wizard, greater functionality, or customized display, you should create your own wizard using Visual C++ or Visual Basic. If you had these applications installed before you ran the InstallShield installation, the functionality to create an InstallShield object wizard will have been added. If you installed either of these programs after you installed InstallShield, you will need to run the InstallShield installation in maintenance mode in order to add the wizard functionality to your Visual Studio application. To create an InstallShield object wizard in Visual C++, click New on the File menu. Then, select InstallShield Object Wizard from the list of project types. In Visual Basic, select InstallShield Object Wizard from the New Project dialog box.

When you create an InstallShield Object Wizard project in Visual C++, a new ATL-MFC based VC wizard framework project will be displayed. In Visual Basic, a template project will be created. Commented code within the each project type shows how to retrieve and save the object properties. For more information, see Custom Object Wizards.

When you are finished creating your wizard, compile it.

Note • *When you are distributing an object that has a custom wizard, make sure to include any dependencies for the wizard .dll file in the distribution installation project. Include the required files in a feature that you place above the InstallShield Object Installer feature in the Setup Design or Features view. You can avoid having dependencies by creating a static wizard .dll file.*

Specifying Whether to Use the InstallShield Stock Wizard or a Custom Wizard

Task: ***To specify whether you want to use the InstallShield stock wizard or a custom wizard that you have created:***

1. In the View List under **Installation Information**, click **General Information**.
2. Do one of the following:
   - If you want to use the stock wizard: In the **Object Wizard** setting, select **Use InstallShield Object Stock Wizard**.
   - If you want to use your own custom wizard: In the **Object Wizard** setting, click the ellipsis button (**...**). The **Browse for My Custom Object Wizard** dialog box opens. Select the wizard file that you created for your object.

When you build a release for your project, the object will include the wizard that you specified.

Custom Object Wizards

To use your own wizard for your object, rather than InstallShield's predefined stock wizard, you must supply an in-process COM server. This server must implement an IDevWizard interface. This interface is called by InstallShield when the object is first included in a project, and when Modify is selected from the context menu of an already included object in the Objects view's Features pane. This interface is useful for displaying values of object properties and allowing those values to be changed.

This interface must offer a Display method with two arguments:

- An IDispatch pointer that provides access to the object's properties.
- A Boolean return value that indicates whether changes should be made to an existing object's properties or, if there is no existing object, whether a new object should be created.

In C++, this interface is defined as follows:

```
interface IDevWizard : IDispatch
{
```

```
HRESULT Display([in] IDispatch *pObject,
                [out, retval] VARIANT_BOOL* Confirmed);
};
```

The server can also implement an ISetupDesignObjectBuild interface. The InstallShield release builder calls this interface to determine which of the object's features should be excluded from the build of a project containing the object. (If this interface is not implemented, all of the object's features are included in the build.)

This interface is useful for excluding from the built project those object features that will never be installed because of selections that the installation author made in the object's wizard. For example, if your object offers optional support for various drivers, and the project author chooses not to include some of those drivers, the features containing those drivers can be excluded from the built project.

This interface, if implemented, must offer an IsIncluded method with three arguments:

- An IDispatch pointer that provides access to the object's properties.
- A string value specifying the feature, for example, **Feature 1\Subfeature 1A**.
- A Boolean return value that indicates whether the component should be included in the build.

In C++, this interface is defined as follows:

```
interface ISetupDesignObjectBuild : IDispatch
{
HRESULT IsIncluded([in] IDispatch *pObject,
                   [in] BSTR FeaturePath,
                   [out, retval] VARIANT_BOOL* Included);
};
```

***Note** • When you are distributing an object that has a custom wizard, make sure to include any dependencies for the wizard .dll file in the distribution installation project. Include the required files in a feature that you place above the InstallShield Object Installer feature in the Setup Design or Features view. You can avoid having dependencies by creating a static wizard .dll file.*

Localizing an Object's Design-Time Environment

For each of the languages in which the InstallShield interface is localized, you can specify a different display name, short name, .htm file, and icon for your object. You perform this localization on the Project Settings dialog box's Language-Specific Object Properties tab.

The first option on the Language-Specific Object Properties tab is the IDE Language list box. Select the first language you would like to support and, if it is not English, uncheck the Use Default box. Then, fill in the rest of the Language-Specific Object Properties Tab.

If you are only supporting one language, you can close this dialog box. However, if you plan on supporting additional languages, you can select the next language from the list and provide the necessary information for that language.

Note • *If you create your own wizard, you will need to provide run-time strings in the wizard's executable file for each language that you are supporting.*

Preparing an Object for Internationalization

Designing an object that installs different files based on the target machine's language is similar to designing an installation with the same functionality. One vital difference between objects and standard installation projects makes internationalizing your object slightly more complex than installations. This difference—the fact that the release builder places an object project's files uncompressed in the disk image—requires you to handle your internationalized files at the feature level. The following sections discuss the steps and strategies required to prepare your object for internationalization.

Adding Languages to Your Object

If you have the Premier edition of InstallShield, you can associate any of the supported languages with your object through the Language tab of the Project Settings dialog box.

Designing Language-Specific File Groups

The most important step in creating an internationalized object is separating your language-specific data into components. This process is best illustrated with an example. If you are supporting three languages, English, French, and German, and you would like English to be the default language, you should have a minimum of four components. The first component will be for English-only files. The Language property for this component should be set to English and all the languages that you are not directly supporting. By doing this, you are enabling your object to be installed on any language, not just the three you support. If the target machine is running in a language other than one of your three supported languages, the English files will be installed.

For the French and German components, simply add the French and German files to their respective components. Set the language of the French component to French and set the language of the German component to German.

Finally, add your language-independent files to another component. Mark this component as language independent. The table below should help to illustrate the layout of your four file groups.

Table 6-1 • Sample File Group Layout

Language of files	Component language
All English-specific files	English + all unsupported languages
All French-specific files	French
All German-specific files	German
All language-independent files	Language independent

Designing Language-Specific Features

If you would like to include language-specific data in your object, you need to create a feature for each of the languages that you are targeting. This step may seem superfluous, since you cannot actually define a feature's language. However, due to the way files are stored in the disk image, you cannot add components from multiple languages to one feature. When the Release Wizard runs, it takes all the files within a feature and stores them in the same directory on the release. If you have two files with the same name, but in separate components, one of those files will be overwritten if the two components belong to the same feature. To overcome this problem, you will have to make a separate feature for each language that you are targeting. Then, simply add the corresponding components.

Making Your Object Compatible with Installations During Run Time

Your object should support all of the operating systems and languages that are supported by any installation that includes the object. Operating system mismatches could cause the installation to not perform correctly; language mismatches can confuse the installation's end users. To help avoid such mismatches, do one of the following:

- Add support to your object for all operating systems and languages that are supported by InstallShield. To add operating system support to your object project, go to the General Information view and configure the Platform Filtering setting. To add language support to your object project, see Preparing an Object for Internationalization.
- Include, with the object, documentation that informs installation authors which operating systems and languages are supported. To do this, create an .htm file that contains the necessary information, then on the Project menu, click Settings. Click the Language-Specific Object Properties tab, and specify the .htm file in the HTML Help field.

Properties and Methods

By definition, properties are used to describe attributes associated with a data structure, and methods are procedures that are executed when an object receives a message.

Throughout InstallShield, you can add, create, and set properties associated with different aspects of your installation. Properties can be useful in object scripts .

Methods, like properties, allow your object to interact with the installation that contains it. Methods, for all practical purposes, are functions. As a matter of fact, the only difference between a method and a function is the fact that a method is declared with the method keyword. Methods allow you to expose your object's functions to other objects and installations.

Creating a Property

Properties can be useful in object scripts. In an object script, properties enable your object's users to change certain settings of your object during either design time through the use of an InstallShield Object Wizard or during run time by passing parameters through script. Common properties include passing error messages from the object to the installation, getting the user name, or any information that your object needs during either run time or design time. For examples of how properties are used, see the inline help for any of the InstallShield objects included in your Objects view.

Note the following details about properties:

- If a Boolean property's value is set to TRUE, either by the object script or the script of the installation that includes the object, subsequent checks of the property's value will show the value to be –1 rather than 1.
- You cannot pass a LIST variable between an object and an installation script; you can, however, pass a string array.

Creating a Property

Task: ***To create a property:***

1. Open the **InstallScript** view.
2. In the **InstallScript** explorer, right-click **Properties** and click **Add New Property**. The **Add New Property** dialog box opens.
3. Define your property's settings.
4. Click **OK**.

The Add New Property dialog box adds the following to your script:

- A property declaration with the following syntax:

  ```
  property(<procedures>) <property data type> <property name> ( );
  ```

  <procedures> is **get** for a read-only property, **put** for a write-only property, and **get,put** for a read/write property. For example:

  ```
  property(get,put) STRING MyProperty ( );
  ```

  You can specify arguments for your property by adding the arguments' data types inside the parentheses after the property name. For example:

  ```
  property(get,put) STRING MyProperty ( NUMBER );
  ```

  If you add argument data types to the property declaration, you must add corresponding argument variables to the definitions of the property's procedure functions.

- A declaration of a variable to store the property's value within the script. For example:

  ```
  STRING m_strMyProperty;
  ```

  If you specify an array property in the Add New Property dialog box (by selecting the Array check box), two variables are declared: a variable of type VARIANT that stores the property's value and an unsized array variable that is used in the **InitProperties** function block to initialize the property's value. For example:

  ```
  STRING arrayMyArrayProperty();
  VARIANT m_arrayMyArrayProperty;
  ```

- A statement, in the **InitProperties** function block, that initializes the variable that stores the property's value. For example:

  ```
  m_strMyProperty = "My Default Value";
  ```

If you specify an array property in the Add New Property dialog box (by selecting the Array check box), the variable that stores the property's value is assigned the value of an array variable. For example:

```
m_arrayMyArrayProperty = arrayMyArrayProperty;
```

To initialize elements of the array property to non-null or nonzero values, add assignment statements for the array variable's elements before the statement above. For example:

```
/* Resize the array variable, which is declared with no size. */
Resize ( arrayMyArrayProperty , 3 );

/* Assign values to the array variable's elements. */
arrayMyArrayProperty(0) = "zero";
arrayMyArrayProperty(1) = "one";
arrayMyArrayProperty(2) = "two";

m_arrayMyArrayProperty = arrayMyArrayProperty;
```

- A function call, in the **ReadProperties** function block, to retrieve the property values stored in the property bag object. This call has the following syntax:

  ```
  <Read xxxx Property> ( PropertyBag, "<property name>", <property value variable> );
  ```

  <Read*xxxx*Property> is the Read*xxxx*Property function that is appropriate to the data type of the property's value. For example:

  ```
  ReadStringProperty( PropertyBag, "MyProperty", m_strMyProperty );
  ```

- A function call, in the **WriteProperties** function block, to save the property values to the property bag object. This call has the following syntax:

  ```
  <Write xxxx Property> ( PropertyBag, "<property name>", <property value variable> );
  ```

  <Write*xxxx*Property> is the Write*xxxx*Property function that is appropriate to the data type of the property's value. For example:

  ```
  WriteStringProperty( PropertyBag, "MyProperty", m_strMyProperty );
  ```

- A function block or blocks defining the property's procedures—that is, defining the actions that are executed when the property's value is read or written to by a project containing the object or the object's design-time wizard (if any)

  A **get_<property name>** function is defined for a read-only or read/write property; a **put_<property name>** function is defined for a write-only or read/write property. For example:

  ```
  function STRING get_MyProperty()
  begin
      return m_strMyProperty;
  end;

  function void put_MyProperty(newVal)
  begin
      m_strMyProperty = newVal;
  end;
  ```

If you specify arguments for your property (by adding the arguments' data types to the property declaration, inside the parentheses after the property name), you must add corresponding argument variables to the definitions of the property's procedure functions. For example:

```
function STRING get_MyProperty( szAddedArgument )
function void put_MyProperty( szAddedArgument, newVal )
```

When you are adding arguments to the put_ function, place them before the newVal argument. The newVal argument takes the value that is written to the property by an assignment statement in the calling project or by the object's design-time wizard (if any).

Note • *The get_ and put_ functions must not be renamed; if they are renamed, your script will not function properly.*

Creating a Structure-Valued Property

To create a property whose value is a data structure, add the following to your object script:

- A global declaration of the data structure; for example:

  ```
  typedef STRUCT
  begin
      NUMBER Mem1;
      NUMBER Mem2;
  end;
  ```

- A declaration of a read-only property whose data type is OBJECT. (To write values to the property, you will define a method.) For example:

  ```
  property(get) OBJECT StructProp();
  ```

  Place this declaration in the Properties Section block of the object script.

- A declaration of a variable to store the property's value within the object script. For example:

  ```
  STRUCT m_structStructProp;
  ```

  Place this declaration in the Local Variables Section block of the object script.

- A declaration of a method with an argument of the appropriate data type corresponding to each member of the data structure. For the STRUCT structure defined above, the following is an example of an appropriate method declaration:

  ```
  method NUMBER SetStructProp(NUMBER, NUMBER);
  ```

  Place this declaration in the Methods Section block of the object script.

- Statements, in the **InitProperties** function block, that initialize the members of the variable that stores the property's value. For example:

  ```
  m_structStructProp.Mem1 = 3;
  m_structStructProp.Mem2 = 5;
  ```

- Function calls and statements, in the **ReadProperties** function block, to retrieve the property member values stored in the property bag object. The function calls have the following syntax:

```
<Read xxxx Property> ( PropertyBag, "<storage name for member value>", <member value variable> );
```

<Read*xxxx*Property> is the Read*xxxx*Property function that is appropriate to the data type of the property member's value. For example:

```
ReadNumberProperty(PropertyBag, "StructProp_Mem1", nStructPropMem1);
```

For each such function call, add below it a statement that sets a member of the property variable equal to the value that the function retrieved. For example:

```
m_structStructProp.Mem1 = nStructPropMem1;
```

- Function calls, in the **WriteProperties** function block, to save the property member values to the property bag object. The function calls have the following syntax:

```
<Write xxxx Property> ( PropertyBag, "<storage name for member value>", <property variable member>
);
```

<Write*xxxx*Property> is the Write*xxxx*Property function that is appropriate to the data type of the property member's value. For example:

```
WriteNumberProperty(PropertyBag, "StructProp_Mem1", m_structStructProp.Mem1);
```

- A get_<property name> function block defining the property's get procedure—that is, defining the actions that are executed when the property's value is read by a project containing the object or by the object's design-time wizard (if any). For example:

```
function OBJECT get_StructProp()
begin
    return m_structStructProp;
end;
```

- A function block defining the method that you declared; this method sets the members of the property variable equal to the arguments passed to the method. For example:

```
function NUMBER SetStructProp( nMem1, nMem2 )
begin
    m_structStructProp.Mem1 = nMem1;
    m_structStructProp.Mem2 = nMem2;
end;
```

Passing a String Array Between an Object and an Installation

To pass a string array between an object and an installation:

- Add the following to the object script:
  - A declaration of a read-write property whose data type is variant. For example:

    ```
    property(get,put) variant Test();
    ```

    Place this declaration in the Properties Section block of the object script.
  - Declarations of the necessary variables, including a variable to store the property's value within the object script:

    ```
    STRING arrayTest();
    ```

```
variant m_arrayTest;
```

Place these declarations in the Local Variables Section block of the object script.

- Statements, in the InitProperties function block, that initialize the members of the variable that stores the property's value. For example:

```
m_arrayTest = arrayTest;
```

- A function call, in the ReadProperties function block, to retrieve the value stored in the property bag object. For example:

```
ReadArrayProperty(PropertyBag, "Test", m_arrayTest);
```

- A function call, in the WriteProperties function block, to save the value to the property bag object. For example:

```
WriteArrayProperty(PropertyBag, "Test", m_arrayTest);
```

- A function block defining the property's get procedure—that is, defining the actions that are executed when the property's value is read by a project containing the object or by the object's design-time wizard (if any). For example:

```
function variant get_Test()
begin
   return m_arrayTest;
end;
```

- A function block defining the property's put procedure—that is, defining the actions that are executed when the property's value is written to by a project containing the object or by the object's design-time wizard (if any). For example:

```
function void put_Test(newVal)
begin
   m_arrayTest = newVal;
end;
```

- Add the following to the installation script:
  - In each function block in which you will read a string array from or write it to the object, declarations of an object variable and a string array. For example:

```
OBJECT oObject;
string szTest(3);
```

  - A call to GetObject to get a reference to the object. For example:

```
set oObject = GetObject("Object");
if (!IsObject(oObject)) then
    MessageBox( "Failed to get object reference.", INFORMATION );
    abort;
endif;
```

  - To set the value of the object's string array property, use code like the following:

```
oObject.Test = szTest;
```

To retrieve the value of the object's string array property, use code like the following:

```
szTest = oObject.Test;
```

Accessing an Object's Properties

There are two different points in time when your properties can be changed, after you have compiled your object. The first is when your object is added to an installation project. If you provide a wizard interface for your object, its read/write properties can be changed during an installation's design time. The second way to change a property is during run time through script. In order to allow the users of your object to access its properties during run time, you need to document those properties in the object's help topic. With that documentation, your users should be able to change those properties as needed.

Accessing a Property from the InstallShield Interface

When you access an object's properties from within your installation project, you are actually running portions of that object's script right in the InstallShield interface. For example, when you associate an object with your installation project, the object's properties are read with the **get_PropertyName** function that is built into every object containing properties. Alternatively, when you change an object's properties through the object's wizard, the **put_***PropertyName* function is called, where *PropertyName* is the name of the property that you are changing.

Accessing a Property Through Script

To access an object's properties, you must first get a reference to that object. Then, you need to specify which of the object's properties you would like to access. The following code illustrates how to return an object's status property:

```
function OnBegin()
   /* Declare an object variable to hold a reference to the object. */
   OBJECT oObject;
begin
   /* Get a reference to a custom object named "My Custom Object".*/
     set oObject = GetObject("My Custom Object");

   /* Check the Status.Number property. */
   if oObject.Status.Number != OBJ_STATUS_SUCCESS then
      /* Respond to the error as appropriate for your setup.
      For example, you can display the Status.Description
      text and abort the setup. */
      MessageBox ( oObject.Status.Description, SEVERE );
      abort;
   endif;
end;
```

When you change a property at run time, that information is not stored for future uses of the installation. For example, if the installation is later run in maintenance mode, that property will not retain the value it was given during the initial installation.

If a Boolean property's value is set to TRUE, either by the object script or the script of the installation that includes the object, subsequent checks of the property's value will show the value to be –1 rather than 1.

Tip • *If you simply want to retrieve the current status of an object (that is, the current value of Status.Number) in the InstallScript Object, you can use the* ***GetStatus*** *function. For more information, see GetStatus.*

Creating a Method

Methods, like properties, allow your object to interact with the installation containing it. Methods, for all practical purposes, are functions. As a matter of fact, the only difference between a method and a function is the fact that a method is declared with the method keyword. Methods allow you to expose your object's functions to other objects and setups.

Creating a Method

Task: ***To create a method:***

1. Open the **InstallScript** view.
2. In the **InstallScript** explorer, right-click **Methods** and click **Add New Methods**. The **Add New Methods** dialog box opens.
3. Define your method's settings.
4. Click **OK**.

The Add New Method dialog box adds the following to your object script:

- A method declaration with the following syntax:

  ```
  method <method data type> <method name> (<argument data types>);
  ```

  For example:

  ```
  method STRING MyMethod( NUMBER, BOOL );
  ```

- A function block defining the method. For example:

  ```
  function STRING MyMethod( /*NUMBER*/ arg1, /*BOOL*/ arg2 )
  begin
  end;
  ```

Using Methods

An object's methods can be accessed only at run time. You can call an object's methods from within your installation project or from another object. To gain access to an object's methods, you first need to get a reference to that object. The following code displays the current status description for the object:

```
Set oObj = GetObject("ATL 3.0")
MessageBox(oObj.Status.Description, INFORMATION);
```

Object Status Properties

Every InstallScript object—whether predefined or user-defined—has the following read-only properties:

- **Status**
- **StatusBase**
- **StatusStruct**

StatusBase and **StatusStruct** are intended only for advanced users. See the following sections for information on these properties.

Status

The **Status** property is a structure with the following properties as members:

Table 6-2 • Members of the Status Property

Property	Description
Status.Number	The numeric object status.
Status.Description	A string describing the object's status.
Status.szSource	For an error, the source of the error; typically the name of the object as read from one of the object's string entries.
Status.szScriptFile	For an error, the name of the script file that was executing when the error occurred.
Status.nScriptLine	For an error, the line of script that was executing when the error occurred.
Status.nScriptError	For an error, the error return code.

In an object script, you can set these values by calling **SetStatusEx**. When you query the status of an object, by default it first queries the status of its subobjects (if any); if one or more of an object's subobjects report an error (that is, have a **Status.Number** property that is less than OBJ_STATUS_SUCCESS), the value of the first failing object's status property is returned as the value of the parent object's status. A user-defined object's script can override this default behavior by explicitly defining a get_Status function (with no arguments).

You can check the value of an object's **Status.Number** property to determine whether the object can be successfully installed—and, if not, what the cause is—and display the value of **Status.Description** to your end user. You can perform this check at any point in a setup; it is recommended that you at least check for success or failure in the **OnBegin** event handler, as in the following example:

```
function OnBegin()
    /* Declare an object variable to hold a reference to the object. */
    OBJECT oObject;
begin
```

```
    /* Get a reference to a custom object named "My Custom Object". */
    set oObject = GetObject("My Custom Object");

    /* Check the Status.Number property. */
    if oObject.Status.Number != OBJ_STATUS_SUCCESS then
        /* Respond to the error as appropriate for your setup.
        For example, you can display the Status.Description
        text and abort the setup. */
        MessageBox ( oObject.Status.Description, SEVERE );
        abort;
    endif;
end;
```

The following table lists those possible values of **Status.Number** and **Status.Description** that are common to all objects. Some objects also have possible values of these properties that are unique to that object. For lists of those possible values, see the individual object's help page (by selecting the object in the **Objects** view, or in the **Setup Design** or **Features** view under its associated feature).

Table 6-3 • Possible Values of Status.Number and Status.Description that Are Common to All Objects

oObject.Status.Number	oObject.Status.Description
OBJ_STATUS_SUCCESS	The operation was successful.
OBJ_STATUS_OSINVALID	Incorrect target operating system.
OBJ_STATUS_DISKSPACE	Not enough disk space.
OBJ_STATUS_LANGUAGESUPPORT	Language not Supported.
OBJ_STATUS_NOTADMINISTRATOR	Administrator rights required.
OBJ_STATUS_SETKEY	Unable to set registry key.
OBJ_STATUS_GETKEY	Unable to get registry key.
OBJ_STATUS_SETVALUE	Unable to set registry value.
OBJ_STATUS_GETVALUE	Unable to get registry value.
OBJ_STATUS_SETTARGET	Unable to set script-defined folder value.
OBJ_STATUS_LOADDLL	Unable to load DLL.
OBJ_STATUS_FILELOCKED	A required file was locked.
OBJ_STATUS_FILENOTFOUND	File not found.
OBJ_STATUS_FILECOPY	File copy failed.

Table 6-3 • Possible Values of Status.Number and Status.Description that Are Common to All Objects (cont.)

oObject.Status.Number	oObject.Status.Description
OBJ_STATUS_FILELAUNCH	Failed to launch file.
OBJ_STATUS_SETLOGDATA	Unable to set data in setup log.
OBJ_STATUS_GETLOGDATA	Unable to get data from setup log.
OBJ_STATUS_INITVARS	Unable to initialize variables.

StatusBase

The **StatusBase** property is a structure with the same members as the **Status** property. This property is typically used only by objects that have a customized get_Status method; except for special cases a setup should not query this property directly, as it could bypass any custom status handling that the object provides.

The **StatusBase** property enables you to use an object's default status handling, including checking the statuses of the object's subobjects. If you have created a custom get_Status function for your object, you can use the **StatusBase** property within the get_Status function to use the default object status handling, as in the following example:

```
function object get_Status()
    object oThis;
begin
    // Do some custom handling here.

    // Get a reference to this object.
    set oThis = GetObject( "" );

    // Fail if this is not an object.
    if( !IsObject( oThis ) ) then
        return NULL;
    endif;

    // Return the standard status information.
    return oThis.StatusBase;
end;
```

StatusStruct

The **StatusStruct** property is a structure with the same members as the **Status** property. This property is typically used only by objects that have a customized get_Status method; except for special cases, an installation should not query this property directly because it could bypass any custom status handling that the object provides.

The **StatusStruct** property allows you to bypass the default object status handling. You can use this property if you want your object to ignore subobject status values, as in the following example:

```
function object get_Status()
    object oThis;
begin
    // Get a reference to this object.
    set oThis = GetObject( "" );
```

```
    // Fail if this is not an object.
    if( !IsObject( oThis ) ) then
        return NULL;
    endif;

    // Return the status information directly.
    return oThis.StatusProp;
end;
```

Creating the Object's Run-Time User Interface

Your object can display a dialog sequence to end users of an installation that includes the object. To define this dialog sequence, use the object script's UI event handlers—OnFirstUIBefore, OnFirstUIAfter, OnMaintUIBefore, and OnMaintUIAfter. (By default, these handlers do not display any dialogs in an object project.)

In a project containing objects with dialog sequences, you have two alternatives for displaying the objects' dialogs:

- Show all object dialog sequences at one point in the project by calling the **ShowObjWizardPages** function.
- Show each object's dialog sequence whenever you choose by calling any or all of the object's Show*xxxxx*UI*yyyyy* methods (that is, ShowFirstUIBefore, ShowFirstUIAfter, ShowMaintUIBefore, and ShowMaintUIAfter).

The ShowObjWizardPages Function

The **ShowObjWizardPages** function is called by default in each UI event handler of an InstallScript installation project created with InstallShield X, InstallShield DevStudio, or InstallShield Professional 6.1 or later; you can study the use of this function in the default event handlers as a guideline. Calling **ShowObjWizardPages** in a project's UI event handler displays each included object's corresponding UI code. For example, calling **ShowObjWizardPages** in a project's OnFirstUIBefore event handler displays each included object's OnFirstUIBefore code. The included objects' UI event handlers are executed in the order in which the objects appear in the project's Components view.

The end user should be able to advance through the installation's entire dialog sequence by using the Next and Back buttons. To allow this, do what is done in the default UI event handler code: assign each dialog function's return value (NEXT or BACK) to the variable nResult, and call **ShowObjWizardPages** as follows:

```
nResult = ShowObjWizardPages(nResult);
```

The ShowxxxxxUIyyyyy Methods

All user-created objects internally support the methods ShowFirstUIBefore, ShowFirstUIAfter, ShowMaintUIBefore, and ShowMaintUIAfter. When you call an object's Show*xxxxx*UI*yyyyy* method, the object's corresponding UI code is executed. For example, the following call executes the object's OnFirstUIBefore code:

```
nResult = oObject.ShowFirstUIBefore(nResult);
```

As with the **ShowObjWizardPages** function, enable end-user navigation by assigning each dialog function's return value to nResult, and calling Show*xxxxx*UI*yyyyy* methods as in the preceding example.

Object UI Event Handler Code

Create object UI event handler code by modifying the default code. This default code, although it does not display any dialogs, contains the code structure that is necessary to enable end-user navigation.

- To display a single dialog, place the dialog function call immediately after either the FIRST_DIALOG or the LAST_DIALOG label.
- To display two dialogs, place the first dialog function call immediately after the FIRST_DIALOG label and the last dialog function call immediately after the LAST_DIALOG label.
- To display more than two dialogs, place the first dialog function call immediately after the FIRST_DIALOG label and the last dialog function call immediately after the LAST_DIALOG label. For each intermediate dialog, place the dialog function call in a code block structured like the FIRST_DIALOG and LAST_DIALOG blocks.

In each of the above cases, assign the return value from the dialog function call to the variable *nDirection*.

Unsupported Features in Objects

Due to both the purpose and implementation of objects, certain features are not supported when you are creating your object in the InstallShield interface. The following list outlines these unsupported features. For more information on the different design philosophies between objects and installation projects, see Designing Objects.

Table 6-4 • Features that Are Not Supported in Objects

Unsupported Feature	Description
Setup Types	Setup types are not supported in objects. If you are creating an object out of an existing installation project, your setup types will be disregarded.
Media Types	When creating an object, you do not have any choices as to the type of media that you would like to build. All objects will be built uncompressed with the CD-ROM option.
Shortcuts and Folders	The Shortcuts view is not supported in objects. In order to create a shortcut or folder within an object, you need to do so from the script with the **AddFolderIcon**, **CreateProgramFolder**, or **CreateDir** function.
Support Files	Where standard installations allow you to specify splash screens; billboards; and language-dependent, language-independent, and advanced files in the Support Files view, objects allow only language-dependent and language-independent files.

Table 6-4 • Features that Are Not Supported in Objects (cont.)

Unsupported Feature	Description
Product Registry Keys	 ***Windows Logo*** *• When any installation created with InstallShield is run, product registry keys are automatically created on the target machine. The product registry keys, which are created at HKLM\SOFTWARE\<Company name>\<Product name>\<Version> are required for Microsoft Logo compliance. Therefore, if you would like to have these registry keys created, you need to add them yourself.*

Building an Object

Building an object is essentially the same as building a standard installation. To build your object from the InstallShield user interface, you will need to use the Release Wizard, which prompts you for all the information necessary to build your object.

Building an Object from the User Interface

Note *• An object must be compiled using the library files* `Ifxobject.obl` *and* `Isrt.obl`*. These files are automatically referenced by your object project if you created your project by using the New Project dialog box's InstallScript Object project type or the Save As command on the File menu. If you created your object project in some other way, click Settings on the Build menu. Then check the Libraries (.obl) box on the Compile-Link tab to make sure that* `Ifxobject.obl` *and* `Isrt.obl` *are listed there.*

Building an object is essentially the same as building a standard installation. To build your object, you will need to use the Release Wizard, which prompts you for all the information needed to build your object. The Release Wizard displays the following panels for object projects:

Table 6-5 • Object-Specific Panels in the Release Wizard

Release Wizard Panel	Description
Specify a Release Panel	Enables you to create a new release or select an existing release.
General Options Panel	Lets you specify preprocessor variable definitions and advanced release properties.
Modify Property Dialog Box/Release Wizard—Platforms Panel	Lets you select the operating systems that your object supports.

Table 6-5 • Object-Specific Panels in the Release Wizard (cont.)

Release Wizard Panel	Description
Setup Languages Panel	Displayed if more than one language is selected in the Project Settings property sheet's Language page. Lets you select the languages that your object will support, a default object language, and whether to let end users select the language in which the object runs.
Digital Signature Panel	Lets you digitally sign your object. Digitally signing your object assures end users that the code within your object has not been modified or corrupted since publication.
Postbuild Options Panel	Lets you copy disk image folders to a folder or FTP site, or execute a batch file, after the next time you build the release.
Release Settings Summary Panel	Displays a summary of release information. ***Note*** • *When you build an object, that object is automatically added to the Objects view and can be used in any installation that you create from that point on. If a previous version of that object already exists in the gallery, it will be overwritten with the newly built object. If you build more than one media, the latest media will be copied to your Objects view.*

Compiling and Building an Object from the Command Line

Compiling and building an object from the command line is handled in an identical fashion to compiling and building an installation from the command line. To learn how to compile and build your object from the command line, see Using ISCmdBld.exe to Build a Release from the Command Line.

Testing and Debugging an Object

Testing your object is similar to testing a standard installation. The main difference lies in the fact that you must include your object in a standard installation in order to test it. This means you must first build your object, include it in an installation project, and then build and run the installation project. The following methods of debugging are available to you when developing your object.

Note • *If you have the object project and its associated installation project open in separate instances of InstallShield and you modify and rebuild your object, you must close and reopen the associated installation project to incorporate those modifications.*

Script Debugger

The Script Debugger enables you to step through the code of your installation as it runs. To debug an object with the Script Debugger, you must include that object in a standard installation project, compile, and debug. Alternatively, you could design your object as a standard installation, test and debug it, and then convert it to an object through the following procedure.

Task: ***To convert an object:***

1. On the **File** menu, click **Save As**. The **Save As** dialog box opens.
2. Select a folder in which to create a copy of the project. Note that you cannot save the new object project in the same folder as the original project.
3. In the **File name** box, type a name for the new project.
4. In the **Save as type** list, select **InstallScript Object Project (*.ism)**.
5. Click **Save**.

An object project file (.ism file) with the name that you specified, and all project subfolders, are created in the location that you specified. That project opens in InstallShield.

For additional information, see InstallScript Debugger.

Note • *When you are designing your object as a standard installation with the intent to later convert it to an object, be aware of the following restrictions:*

- *An object cannot contain setup types; any setup types that you define or setup type functions that you call in the project are ignored when it is converted to an object project.*
- *There are a number of functions and events that are not supported in objects.*
- *All information on built media will be lost when the project is converted; you will need to rebuild the project.*

Debugging an Object on Another Machine

Generate inline debugging information is an option on the Build Settings dialog box's Compile/Link tab. It enables you to debug your object on a machine other than the machine on which the object was created. If you do not use this option, debugging information is placed in a file named `Setup.dbg`, and its location is stored in the header of `Setup.inx`. This scheme works fine if you debug the script on the same machine on which you did the compilation. However, on a different machine, the .dbg file may not be stored in the same location. The **Generate inline debugging information** option was designed to alleviate this problem. If you use this option, all debugging information is stored in `Setup.inx`. This way, the installation never needs to search for the debugging information.

It is recommended, for two reasons, that you clear the **Generate inline debugging information** option before compiling the `Setup.inx` file that you ship with your final product. First, the debugging information increases the size of `Setup.inx` and may cause the installation to run more slowly. Second, inline debugging information will make it easier for others to reverse engineer your code.

Using the InstallShield Cabinet and Log File Viewer

Use the InstallShield Cabinet and Log File Viewer to do the following:

- View an InstallScript cabinet file (.cab) or InstallScript header file (.hdr), as well as their compressed files, registry entries, components, features, and other data. This tool also lets you extract files from the .cab file.
- View InstallScript log files (.ilg) that are created by InstallScript installations. This tool enables you to see what your installation has recorded in the log file, which contains important uninstallation information in a binary format.

To learn more, see InstallShield Cabinet and Log File Viewer.

Debugging a Custom Design-Time Wizard

If you have created a custom design-time wizard for your object, you may need to debug that wizard.

Task: ***To debug the wizard, do the following:***

1. From within your development environment, launch a debug version of the wizard, setting breakpoints as desired.
2. In the InstallShield interface, insert the object in a feature of another project to launch the object's wizard.
3. If your development environment is Microsoft Visual Basic, you must also do the following:
   a. Minimize the interface. A **Server Busy** message box opens. (You may need to click the title bar's minimize button a few times before the message box opens.)
   b. In the **Server Busy** message box, click the **Switch To** button or press ENTER.

Distributing an Object

The major advantage of objects is the fact that anyone creating an InstallShield installation can include your object in their installation with a minimal amount of work, as long as your object is installed and registered on their machine. The easiest way to register an object is to use the InstallShield Object Installer. This object enables you to package the object that you would like to distribute, and it will register that object on the target machine, if InstallShield X or later, InstallShield DevStudio, or InstallShield Professional 6.1 or later is present.

Task: ***To add the InstallShield Object Installer to your installation:***

1. Open the **Objects** view. The **InstallShield Objects/Merge Modules** pane lists all of the available objects.
2. In the **Features** pane, select the feature to which you want to add the InstallShield Object Installer.
3. Right-click **InstallShield Object Installer** and click **Add to selected feature**.

An associated wizard appears to guide you through the customization process.

Note • *The object that you would like to distribute must be present in your InstallShield Object Gallery. If it is not present, you need to register that object. To learn how, see Registering Objects in InstallScript Projects.*

Object Scripts

InstallShield enables you to extend object support by defining additional functions and constants that are not supported in object projects by adding scripts in the InstallScript view. Essentially, you can write scripts that enhance the functionality supported by the InstallShield interface.

Functions Not Supported in Object Projects

The following is a list of InstallScript functions that are not supported in object projects.

- OnFileReadOnly
- OnRemovingSharedFile
- OnFileLocked
- OnNextDisk
- OnMD5Error
- OnFileError
- OnComponentError
- SdSetupType
- SdSetupTypeEx
- SetupType
- ComponentSetupTypeSet
- ComponentSetupTypeEnum
- ComponentSetupTypeGetData

Constants Not Supported in Object Projects

The following is a list of InstallScript constants that are not supported in object projects.

- IFX_ONNEXTDISK
- IFX_ONNEXTDISK_MSG
- IFX_MAINTUI_MSG
- IFX_ONMAINTUI_CAPTION

- IFX_SDFINISH_MSG1
- IFX_SDFINISH_MAINT_MSG1
- IFX_SDFINISH_MAINT_TITLE

Functions Supported Only in Object Projects

The following is a list of InstallScript functions supported only in object projects.

- SetStatus
- WizardDirection

Adding a ScriptDefinedVar Property to Your Object

Several of the objects included in InstallShield have a ScriptDefinedVar property. This property enables you to set at run time the value of a script-defined variable that you used to define a path (for example, **<MYSERVICEFOLDER>\MyService.exe**) at design time. For example, main script code like the following lets the end user specify the value of *<MYSERVICEFOLDER>*:

```
/* Get a reference to the object that is named
"New Custom Object 1" in the Components pane. */
set oObj = GetObject("New Custom Object 1");

/* Get folder selection from end user. */
svDir = TARGETDIR;
AskDestPath ( "" , "Specify folder for service files:" ,
    svDir , 0 );

/* Tell the object the desired value of <MYSERVICEFOLDER>. */
oObj.ScriptDefinedVar("<MYSERVICEFOLDER>") = svDir;
```

Task: ***To include the ScriptDefinedVar property in your object script:***

1. Open the **InstallScript** view.
2. In the **InstallScript** explorer, right-click **Properties** and click **Add New Property**. The **Add New Property** dialog box opens.
3. Make the following entries:
    c. In the **Property Name** box, type the following:

    ```
    ScriptDefinedVar
    ```

    d. In the **Data Type** list, select **String** (since you will be writing string data to the property).
    e. In the **Access Method** list, select **Read/Write**. (You can select **Write Only** instead if you are certain users of the object will never want to check the current value of the property from their main script.)
4. Click **OK** to close the dialog box and automatically add all the necessary code to your object script.

5. Make the following changes to the property script code that was automatically added:

   a. Open the **InstallScript** view.

   b. In the **InstallScript** explorer, under **Properties**, double-click **ScriptDefinedVar** to move the script editor pane's insertion point to the ScriptDefinedVar declaration. Add a string parameter to the declaration—that is, change the declaration from this:

   ```
   property(get,put) STRING ScriptDefinedVar();
   ```

   to this:

   ```
   property(get,put) STRING ScriptDefinedVar( STRING );
   ```

   c. In the **InstallScript** explorer, under **Functions**, double-click get_ScriptDefinedVar to move the script editor pane's insertion point to the **get_ScriptDefinedVar** function block. Find the following function block:

   ```
   function STRING get_ScriptDefinedVar()
   begin
       return m_strScriptDefinedVar;
   end;
   ```

   Change it to this:

   ```
   function STRING get_ScriptDefinedVar( szScriptVar ) /* Add string argument. */
   begin
       return TextSub.Value( szScriptVar ); /* Get value associated with szScriptVar. */
   end;
   ```

   d. In the **InstallScript** explorer, under **Functions**, double-click **put_ScriptDefinedVar** to move the script editor pane's insertion point to the **put_ScriptDefinedVar** function block. Find the following function block:

   ```
   function void put_ScriptDefinedVar(newVal)
   begin
       m_strScriptDefinedVar = newVal;
   end;
   ```

   Change it to this:

   ```
   function void put_ScriptDefinedVar( szScriptVar, newVal ) /* Add string argument. */
   begin
       TextSub.Value( szScriptVar ) = newVal; /* Associate newVal with szScriptVar. */
   end;
   ```

Using System Variables in Objects

System variables are predefined variables that contain information such as the source path, the target path, the Windows folder, and the Windows system folder. You cannot declare these variables in your script. InstallShield automatically initializes system variables when the installation process begins.

Although you can change and initialize system variables within objects, it is not recommended. When you change a system variable in an object, that change will affect the entire installation. For example, if your object initializes **TARGETDIR** to a specific value, that value will override what was previously set in the installation project. Therefore, the entire installation will be installed to the directory specified in the object, and not the directory specified by the installation developer.

Setting Your Object's Destination Through the Script

You may decide to define of one of your object's components' Destination properties in terms of a script-defined variable. If you do, users of your object will need to ensure that the value of the script-defined variable is set before they call **ComponentCompareSizeRequired** in their script; otherwise, the function will report insufficient disk space. You can provide the ability to set the value of the script-defined variable in one or both of the following ways:

- A write-only or read/write object property whose put_ function calls **ComponentSetTarget**, for example:

```
function VOID put_SetTargetDest ( szScriptVar , szValue )
begin
   ComponentSetTarget ( MEDIA , szScriptVar , szValue );
end;
```

- An end-user dialog displayed by the object's OnFirstUIBefore event handler.

7

Modularizing Installation Projects to Distribute Development Work and Enable Reuse

The developer installation manifest (DIM) support in InstallShield is targeted toward engineering teams who want to foster collaboration, enable distributed installation development, and maximize efficiency in their organizations. A DIM is a feature-sized collection of related items such as product files, shortcuts, registry entries, text file changes, IIS Web sites, and other elements that together make up a discrete, logically separated portion of a product installation. Some benefits of using DIMs are as follows:

- Working with DIMs enables multiple team members to contribute to the development of the installation simultaneously. Each software developer or other team member can work on a separate DIM that the release engineer can reference in one or more installation projects.
- Release engineers can reuse DIMs in multiple installation projects, enabling efficiency.
- DIMs include support for virtually the same functionality that is available in Basic MSI projects. This gives authors of DIMs all of the flexibility that they need to develop their portions of an installation.

This section of the documentation explains how to work with a DIM project in InstallShield.

Specifying Installation Information for a DIM

Project • *This information applies to DIM projects.*

InstallShield stores your project settings in a single project file (.dim). This file contains all of the information about your DIM project. In the General Information view, you can edit basic information about your DIM—including the author's name, internal notes about the project, and any instructions that you want to include for release engineers to consider when they are including the DIM in installation projects.

Saving a DIM Project File in XML or Binary Format

Project • *This information applies to DIM projects.*

InstallShield lets you save your DIM project file (.dim) in XML or binary format.

Task: ***To specify the format of your project file:***

1. In the View List under **Installation Information**, click **General Information**.
2. In **Project File Format** setting, select the appropriate option. Available options are:
   - **Binary**—To save the project file as a database file, select this option. This format is best for the speed of opening and saving the project file.
   - **XML**—To save the project file as a hierarchical text-based format, select this option. This project file format is best for use with source code control systems.

Note • *Your DIM project file (.dim) retains the .ism file extension when you save it in XML or binary format.*

Specifying the Default Destination Folder for a DIM

Project • *This information applies to DIM projects.*

The value that you enter for the INSTALLDIR setting in the General Information view serves as the default folder for all of your DIM's files. That is, its value is assigned to the Windows Installer folder property **INSTALLDIR**, which is the default destination folder. In an installation project, this typically evaluates as follows:

`[ProgramFilesFolder]My Company Name\My Product Name`

If you would like to let the users of your DIM override the default destination, enter `[TARGETDIR]` in the INSTALLDIR setting. To learn more, see Overriding the Destination for a DIM Reference.

Using Path Variables in a DIM

Project • *This information applies to DIM projects.*

When you add product files to a DIM project, InstallShield creates a path variable to use as the source of the product files by default. A path variable is a variable that InstallShield uses to represent a directory that contains a project's source files. Note that InstallShield uses path variables at design time and build time; path variables are not available or used at run time when the installation is running on end users' machines.

A general advantage of using path variables instead of hard-coded paths is that if the source files are moved to a different directory on the development system, you need to change only the value of the path variable. That is, you do not need to update each hard-coded path to all of your source files.

Using path variables in DIM projects can help to simplify source file management, especially if the DIM project is located on a different machine than the Basic MSI projects that will include the DIM project.

Path variables can also be helpful if you use source code control to store all of your code and InstallShield project files, and if you have build machines that obtain the appropriate files from source code control, compile the code, and build the installations. In this type of scenario, different release engineers and developers may use different local working directories for obtaining the latest files from source control. Using path variables to define the locations helps to minimize the issues that occur with different source locations.

Predefined Path Variables in DIM Projects

Following is a list of predefined path variables, as well as their typical values, in a DIM project.

Table 7-1 • Predefined Path Variables in a DIM Project

Predefined Path Variable	Typical Value
CommonFilesFolder	C:\Program Files\Common Files\
ISProductFolder	C:\Program Files\InstallShield\2013\
ISProjectDataFolder.DIM_GUID	<ISProjectFolder>\ProjectName\
ISProjectFolder.DIM_GUID	C:\InstallShield 2013 Projects\
ISRedistPlatformDependentExpressFolder	C:\Program Files\InstallShield\2013\Redist\Language Independent\i386 Express
ISRedistPlatformDependentFolder	C:\Program Files\InstallShield\2013\Redist\Language Independent\i386
ProgramFilesFolder	C:\Program Files\
SystemFolder	C:\Windows\System32\
WindowsFolder	C:\Windows\

In both cases where the path variable name contains *DIM_GUID*, *DIM_GUID* is the identifier that is defined in the DIM GUID setting of the General Information view of the DIM project. Following are sample path variables in a DIM project:

- **ISProjectDataFolder.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC**
- **ISProjectFolder.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC**
- **MyNewPathVariable.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC**

The GUIDs help to identify the applicable path variables as originating in the DIM project. They also help to minimize or eliminate conflicts that would occur if the same path variable is used in a DIM project and also in a Basic MSI project that contains that DIM, and if different values are assigned to those two path variables.

The path variable names that do not include GUIDs—such as *SystemFolder* and *WindowsFolder*—are not specific to the project that is open in InstallShield, and they are available on all machines. The values of these types of path variables may vary depending on the operating system. For example, on a 32-bit machine, the value of **ProgramFilesFolder** may be `C:\Program Files\`. On a 64-bit machine, it may be `C:\Program Files (x86)\`.

Syntax for Referencing Path Variables

When a path variable is used in InstallShield, the path variable is enclosed in angle brackets—for example:

<ISProjectDataFolder.8356F8B7_8DE5_4E04_A77A_6FA722CBE1CC>

In some cases, you may want to define a path variable so that it is relative to a different path variable. For example, you may create a standard path variable called **MySourceFiles**. You may also want to use a different path variable called **BinFiles** to define a path to a **Bin** folder inside that **MySourceFiles** directory. When you enter the relative path variable in the Defined Value column for **BinFiles** variable, you must surround the base path variable name with angle brackets. Thus, the Defined Value column for the **BinFiles** variable would be:

<MySourceFiles>\Bin

If the value of **MySourceFiles** is `C:\CheckoutRoot\`, the value of BinFiles is `C:\CheckoutRoot\Bin\`.

Sample Path Variable Scenarios

If you work in an environment where you create and edit InstallShield projects on one or more machines but you build your installations on other machines, you may need to plan how you want to use path variables in your projects. Otherwise, when you build your installations in InstallShield, you may encounter build errors because of missing files, or the wrong files may be included in your builds.

The following examples illustrate different ways of using path variables in InstallShield projects. The method that is described in example 3 is the easiest one to use.

Example 1: Overriding the Values of DIM Path Variables in the Basic MSI Projects that Contain the DIMs

The following table shows examples of how one predefined path variable and several standard path variables are used in a DIM project.

Table 7-2 • Example 1 Path Variables in a DIM Project

Name	Defined Value	Current Value
ISProjectFolder.4E846FD3_5307_4CF5_9FF1_C476E5505666	(This is a predefined path variable for the folder that contains the InstallShield project file. Its value cannot be manually defined.)	C:\Source\Units\Utility\
CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666	C:\Source	C:\Source
PATH_TO_RELEASE_FILES.4E846FD3_5307_4CF5_9FF1_C476E5505666	<CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666>\SpellLib\Bin\Release	C:\Source\SpellLib\Bin\Release
PATH_TO_DICTIONARIES.4E846FD3_5307_4CF5_9FF1_C476E5505666	<CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666>\Dictionaries	C:\Source\Dictionaries

In this example, the author of the DIM project assigned the path variable **CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666** to his source root folder—the working directory on his machine where he checks out files from source control—**C:\Source**. Path variables for other folders that contain source files are defined relative to the source root path variable.

If the release engineer uses a different working directory location on a build machine, it may be necessary to override the value of this path variable when building a Basic MSI installation for a project that includes the DIM. Therefore, the release engineer can set a new value for the source root path variable by passing the `-l` parameter to `ISCmdBld.exe` when building the installation from the command line. Since the other path variable values are defined by using the source root path variable, the values of those other path variables are updated accordingly.

Note that using this method may be tedious and error prone, especially if you are building an installation for a Basic MSI project that includes several DIM projects, each with their own path variables that need to be overridden.

Example 2: Changing the Values of the DIM Path Variables According to the Build Environment

If the source root paths on the DIM development machine do not match the corresponding paths on the Basic MSI build machine, you can open the DIM directly and update the values of the path variables as needed. To learn how to open the DIM project from within the open Basic MSI project, see Opening a Referenced DIM Project from Within an Installation Project.

This method may not be optimal if you are trying to deliver daily builds to your testing team and you are still making changes to the DIM projects.

Example 3: Using Path Variables that Are Relative to a Predefined Path Variable Such as ISProjectFolder.DIM_GUID

The easiest way to manage path variables in DIM projects is to always store source files in a path that is relative to a predefined path variable such as **ISProjectFolder. DIM_GUID**. The following table illustrates how you can do this.

Table 7-3 • Example 3 Path Variables in a DIM Project

Name	Defined Value	Current Value
ISProjectFolder.4E846FD3_5307_4CF5_9FF1_C476E5505666	(This is a predefined path variable for the folder that contains the InstallShield project file. Its value cannot be manually defined.)	On a development machine, the current value may be: `C:\Source\Units\Utility\` On the build machine, the current value may be: `C:\BuildWorkspace\Source\Units\Utility\`
CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666	<ISProjectFolder.4E846FD3_5307_4CF5_9FF1_C476E5505666>\..\..  ***Note*** • *Using the predefined project folder path variable for the value of this path variable, and then using the checkout root path variable for the other path variable values, makes the InstallShield project and all of its source files portable from one machine to another.*	On a development machine, the current value may be: `C:\Source` On the build machine, the current value may be: `C:\BuildWorkspace\Source`
PATH_TO_RELEASE_FILES.4E846FD3_5307_4CF5_9FF1_C476E5505666	<CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666>\SpellLib\Bin\Release	On a development machine, the current value may be: `C:\Source\SpellLib\Bin\Release` On the build machine, the current value may be: `C:\BuildWorkspace\Source\SpellLib\Bin\Release`

Table 7-3 • Example 3 Path Variables in a DIM Project (cont.)

Name	Defined Value	Current Value
PATH_TO_DICTIONARIES.4E846FD3_5307_4CF5_9FF1_C476E5505666	<CHECKOUT_ROOT.4E846FD3_5307_4CF5_9FF1_C476E5505666>\Dictionaries	On a development machine, the current value may be: `C:\Source\Dictionaries` On the build machine, the current value may be: `C:\BuildWorkspace\Source\Dictionaries`

Using the predefined project folder path variable for the value of the checkout root path variable, and then using the checkout root path variable for the other path variable values, makes the InstallShield project and all of its source files portable from one machine to another.

Organizing Files for a DIM

Project • *This information applies to DIM projects.*

In a DIM project, files are organized in a hierarchy. You add the files for your portion of the installation to components. When you include a DIM in a Basic MSI project, you are adding the DIM's components to one or more features in that Basic MSI project. When end users run your Basic MSI installation, they can select which features they want to install, if you allow them to selectively include and exclude features.

When you are adding files to components in DIM projects, you should be aware of Setup Best Practices. By default, the Setup Best Practices Wizard monitors your DIM design and alerts you if you have violated Best Practices.

To learn more about organizing your files, see the following areas of the documentation:

- Including Files and Folders
- Using Components
- Setup Best Practices

Configuring the Target System for a DIM

Project • *This information applies to DIM projects.*

Every installation changes the target system in some way. The simplest installations might only copy files. More in-depth installations make registry changes, edit .ini files, create shortcuts, configure ODBC resources, use environment variables, modify XML files, and modify text files. For more information on how to include these sorts of configuration changes in a DIM project, see the following areas of the documentation:

- Creating Shortcuts and Program Folders
- Editing the Registry
- Changing .ini File Data
- Configuring ODBC Resources
- Using Environment Variables
- Modifying XML Files
- Modifying Text Files

Customizing Installation Behavior for a DIM

Project • *This information applies to DIM projects.*

An important aspect of creating an installation is customizing it for your end users' needs. For example, you may find it useful to create custom actions to add support for something not directly supported by Windows Installer. In addition, you may want to search for installed data on the target system; depending on the results of the search, the installation can proceed as appropriate. Windows Installer properties allow you to set project-wide values for use in your project. For more information on how to customize the installation behavior for a DIM project, see the following areas of the documentation:

- Using Custom Actions
- Searching for Installed Data
- Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties

Configuring Servers for a DIM

Project • *This information applies to DIM projects.*

When you are creating a DIM project, you may find it necessary to provide server-side support for some technology that will be installed on a target system. InstallShield provides support for creating and managing Internet Information Services (IIS) Web sites, managing and organizing SQL scripts by server connections and settings, and managing COM+ applications and components. For more information on how to configure servers for a DIM project, see the following areas of the documentation:

- Configuring SQL Support

- Managing COM+ Applications and Components
- Managing Internet Information Services

8

Updating Applications

Installing upgrades for applications is a much more common operation than installing the original release of an application. This makes creating effective, reliable upgrades a very important task.

“Updating Applications” provides solid background information on the different types of upgrades and also clears up common misconceptions about patching. It helps you determine the best upgrade solution for your product and guides you through the steps of creating upgrades, patches, QuickPatch projects, differential releases, and full releases. In addition, this section explains how you can use FlexNet Connect to notify end users that a new version of your product is ready for release.

Upgrades Overview

The cost of maintaining software applications is often more expensive than the cost of original development. This makes creating effective, reliable upgrades an important task. Being able to distribute robust upgrades for an application depends on how the original installation package was structured and distributed. This help topic will provide a basic foundation for creating robust upgrade packages.

Upgrade Methods for Basic MSI and InstallScript MSI Projects

Windows Installer provides different methods for implementing three different upgrade types: small update, minor upgrade, and major upgrade. Upgrades can be packaged as either a full installation or a patch. A patch is simply another mechanism for implementing a type of upgrade. With a patch, however, you deliver to your customers only the bits required to change an installed file into a new file, unlike a full release.

Upgrade Methods for InstallScript Projects

When working with InstallScript installations, you can update an application with either a full release package or differential release. Various considerations such as file size and the presence of files from any previous release must be considered in determining the best upgrade method.

Note • *If you used a version of InstallShield Professional earlier than 6.0 to create media for an InstallScript project, the media cannot be updated.*

Major Upgrades

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

In a major upgrade, the product changes are large enough to merit changes to both the product version number and the product code, as well as the package code. An example is updating version 1.2 of a product to 2.0. A major upgrade acts like a first-time installation if an earlier version is not present. If an earlier version is present, a major upgrade typically uninstalls the earlier version and then installs the new version. It is also possible to have a major upgrade first install over the earlier version and then remove any unused files. This method is more efficient, but strict component-authoring rules must be followed.

How Major Upgrades Work

As the Windows Installer help implies, you must change the product code for the latest version of your installation in order to perform a major upgrade.

Note • *You can set the product code for your installation in the General Information view. It does not matter what the new product code is, as long as it is unique.*

By virtue of having a unique product code, your latest installation will have its own independent registration with the Windows Installer service on end users' machines. This means that unless some other step is taken, the Windows Installer installs the latest version of your product independently of any of the previous versions. This may be okay if the two versions of your product can coexist on the same machine, but then that would not be an upgrade. Therefore, for the sake of this discussion, it is assumed that two versions should not coexist on the same machine.

Once you update the product code for your latest installation, you need to use the Upgrades view to specify information for any previous version or versions that you want to upgrade.

For more information about what is involved in creating a major upgrade, see Creating Major Upgrades.

Major Upgrades at Run Time

When an earlier version of the product is not available on the target machine and the end user runs a major upgrade, the installation behaves as a first-time installation.

If an earlier version of the product does exist on the target machine and the end user runs a major upgrade, they encounter almost the exact same installation experience as if they were to install the latest application on a clean target machine. The difference is that before installing its new resources, the installation typically uninstalls the

earlier version from the target machine. This removal is reflected in the progress bar of the Setup Progress dialog, which gives end users the ability to see the progress of the uninstallation. After the removal of the previous installation has completed, the resources from the latest installation are then installed onto the target machine.

This type of upgrade is a complete uninstallation and then reinstallation of all of the resources associated with your application. Therefore, any data for your application that has been configured by the end user may be completely deleted from the end user's machine. If you need to retain some of the end-user data, create a custom action that backs up this data and then replaces it after the installation of new data has completed.

Minor Upgrades

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

A minor upgrade is a change to the product database and files large enough to merit a change to the **ProductVersion** property but not to the **ProductCode** property. In other words, both the package code and the product version number are different than those in the earlier installation package, but the product code of the minor upgrade does not change. An example is updating version 1.1 of a product to version 1.2. Minor upgrades usually do not have significant changes to the installation organization between versions. A minor upgrade packaged as a full installation acts like a first-time installation if an earlier version is not present, or it installs over an existing installation of a product. Essentially for an upgrade of an existing installation, a minor upgrade installs the differences between your version 1.2 and 1.1 application.

Tip • *You can modify the product version for your upgrade in the General Information view.*

Small Updates

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

In essence, a small update is a type of upgrade used to modify a few files for an installed application; it typically delivers small bug fixes. A small update consists of product changes (such as hotfixes) so small that no change to the product version is necessary or desired. A package code change is required for a small update.

A drawback to small updates installed with versions of Windows Installer earlier than 3.0 is that external programs, including installers for later versions of your product, cannot distinguish between the original version and the updated version. In addition, Windows Installer versions earlier than 3.0 cannot enforce the correct order in which small updates should be applied.

Patching

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Patching is a streamlined mechanism for updating earlier versions of a Windows Installer installation package, thereby updating the application. With a patch, you deliver to your customers only the bits required to change an installed file into a new file. One benefit of a patch is that the size of the upgrade package can be significantly smaller than the full-installation package required to deliver the same upgrade. Keeping an upgrade package as small as possible allows you to more easily deliver your upgrades over the Internet.

However, you should note that a patch may not always present the best solution. For example, if you want to change your installation from compressed to uncompressed, or vice versa, you should package your upgrade as a full installation, but not as a patch. To learn more about determining the best packaging option for your upgrade, see Packaging Options for Upgrades.

A patch is delivered in the form of a patch package (.msp) file, which your end user can apply to an installed product. A patch package is capable of updating as many earlier versions of an installation package as required. A patch package contains separate transforms and instructions for updating each previous version that you specify.

An important aspect of patch creation is generating a patch creation properties (.pcp) file, which defines the parameters on which the patch package is to be created. The .pcp file is a database that has a specific schema, but you can open it and edit it directly with InstallShield or Orca.

The Patch Design view provides an easy-to-use interface to simplify the patch creation process. This view groups together all the logical considerations you will need to make in patch creation.

QuickPatch Projects

Project • *You can create a QuickPatch to update an earlier version of your product only if the earlier version was installed using Windows Installer. The installation for the earlier version of your product must have been created with one of the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

A QuickPatch project is a specific type of project recommended for installation authors who want to ship small, single updates to their users. Changes that are more extensive such as adding custom actions and changing .ini data typically require a standard patch.

QuickPatch authoring provides a simple alternative to creating a patch configuration in the Patch Design view, even though it provides less customization. Fundamentally, both patch creation methods produce the same deliverable types: .msp and .exe files.

With a QuickPatch, you can do any of the following:

- Add new files to the original installation or an earlier QuickPatch.
- Delete files in the original installation.
- Delete files that were added with an earlier QuickPatch.
- Perform the same set of above operations on registry entries.
- Remove custom actions that were included with the original installation but that do not apply to the current QuickPatch project.

The creation of a QuickPatch project always begins with the Create New QuickPatch Wizard. After you have completed the wizard, you can configure project settings once the QuickPatch project opens in InstallShield.

Differential Releases

Project • *This information applies to InstallScript projects.*

In an InstallScript project, you can define and build a differential release—that is, a release that contains the files that are absent from—and/or have a different date, time, size, or attribute than the version in—one or more of a specified set of existing releases. A differential release is used to update the versions of your product that were installed by those existing releases. This type of upgrade also includes all of the maintenance/uninstallation feature's files. The new versions of `Data1.hdr`, `Data1.cab`, and `Layout.bin` do not overwrite the existing versions but are placed in a new folder.

Note • *Since a differential release consists of only the changed files between the specified existing media and the new media, installing a differential release on a system that does not have a specified earlier version of the product would most likely not produce a valid application. To update a system that does not have an earlier version of the product, create a full release.*

Files Included in a Differential Release

When you define a differential release, you specify one or more existing releases to which the current project should be compared when new differential release is created. You specify these existing releases in the Update panel of the Release Wizard. A file in the current project is included in the differential release if any of the following are true:

- The file is absent from—or has a different date, time, size, or attribute than the copy in—at least one of the specified comparison releases.
- The file is in a component whose Difference property is set to Include Always.

- The file is in a component that is absent from at least one of the specified comparison releases.
- The file is in a component whose name is different in at least one of the specified comparison releases.
- The file is in a component whose Destination, Languages, or Operating Systems properties are different in at least one of the specified comparison releases.
- The file is in a component that is associated with a feature whose name or path within the feature hierarchy is different in at least one of the specified comparison releases.

Installing a Differential Release

When an installation initializes and the ADDREMOVE system variable is nonzero, the installation automatically attempts to initialize any differential releases that have been installed with the same product code. The installation enumerates all subfolders of the `DISK1TARGET` folder and searches these subfolders for differential releases; a differential release is found and loaded if all of the following conditions are met:

- The subfolder contains a `Data1.hdr` file that is a valid InstallShield X or later, InstallShield DevStudio 9, or InstallShield Professional 6 or later `Data1.hdr` file for a differential release.
- The product code stored in the header file matches the product code of the installation.
- The product version of the differential release is newer than the product version of the installation.

Full Releases

Project • *This information applies to InstallScript projects.*

With an InstallScript project, you can define and build a full release for an upgrade. A full release includes all of the files linked into the installation project. By default, this type of release behaves as a first-time installation if an earlier version of the product is not already present on the target system. It also is capable of installing over an earlier version and replacing that version completely.

When you create a full release to update one or more earlier versions of a product, you must specify whether the release is version specific or non-version specific:

- **Non-version specific—**This is the default option. A non-version-specific full release can be installed on a system that does not have an earlier version of the product. It can also update any earlier version of the product.
- **Version specific—**A version-specific full release updates only the versions that you specify should be updated. If you set your full release to be version specific but you do not also specify version numbers, the update can be applied to any earlier version of your product.

Determining the Best Upgrade Solution

The methods used to create an upgrade for a product depend on how the original installation package was developed. If the original installation was created with a Windows Installer–based project, you will essentially create a major upgrade, a minor upgrade, or a small update to update your product. If the original installation was created with an InstallScript project, you will create a differential or full release to update your product. Both types of projects are discussed below.

Basic MSI and InstallScript MSI Projects

The first step in creating an installation for any type of upgrade is identifying whether you want to address target systems that do not have any earlier version of your product. Then you can determine what type of method you should use to package the upgrade. The following table presents a general overview to help you decide which method you should use. For a more in-depth discussion of the techniques for packaging the upgrade, see Packaging Options for Upgrades.

Table 8-1 • Possible Upgrade Solutions for Windows Installer–Based Projects

Status of the Target Systems	Type of Installation Needed	Technique for Packaging the Update
Some of the target systems have an earlier version of the product, and some do not have any version of the product.	If file size is not an issue, you can create one installation that does both of the following: • Behaves as a first-time installation if an earlier version of the product is not already present on the target system • Updates an existing product if it is already installed on the target system	Create a major or minor upgrade and package it as a full installation.

Table 8-1 • Possible Upgrade Solutions for Windows Installer–Based Projects (cont.)

Status of the Target Systems	Type of Installation Needed	Technique for Packaging the Update
Some of the target systems have an earlier version of the product, and some do not have any version of the product.	If you want a small installation for end users who need to update an earlier version of the product, you can create two separate installations: • A full installation that behaves as a first-time installation. • A smaller installation that updates one or more earlier versions of an already installed product. Since this installation consists of only the changed data between the versions to be updated, it usually enables you to deploy your upgrade using much less bandwidth than that required to deploy a full-installation package.	For the first-time installation, create a major or minor upgrade and package it as a full installation. For end users who have an earlier version of your product, create a major or minor upgrade and package it as a patch.  ***Tip*** • *In some cases, a patch is not appropriate. For more guidelines on determining whether a patch is appropriate for your upgrade, see Packaging Options for Upgrades.*  ***Note*** • *A patch package is not a type of upgrade; it is simply a mechanism for distributing an upgrade with a small footprint.*
All of the target systems have an earlier version of the product.	You can create a small installation that updates one or more earlier versions of an already installed product. Since this installation consists of only the changed data between the versions to be updated, it usually enables you to deploy your upgrade using much less bandwidth than that required to deploy a full-installation package.	Do either of the following: • Create a major or minor upgrade and package it as a standard patch. • Create a QuickPatch project. The QuickPatch technology in InstallShield enables you to create simple patches for previously installed products. Although customization is somewhat limited when you create a patch by using a QuickPatch project, the creation of a QuickPatch project is a simpler alternative to creating a standard patch. For more details, see Patch vs. QuickPatch Project.  ***Note*** • *Like a standard patch, a QuickPatch is a mechanism for distributing an upgrade with a small footprint.*

InstallScript Projects

If the original installation was created with an InstallScript project, you can create one of two types of update releases:

- **Differential release—**This type of release contains the files that are absent from—and/or have a different date, time, size, or attribute than the version in—one or more of a specified set of existing releases. A differential release is used to update the versions of your product that were installed by those existing releases.
- **Full (non-differential) release—**This type of release behaves as a first-time installation if an earlier version of the product is not already present on the target system. It also is capable of installing over an earlier version and replacing that version completely.

Since a differential release consists of only the changed files between the versions to be updated, it usually enables you to deploy your update using much less bandwidth than that required to deploy the full release. However, only a full release can be installed on a system on which no version of your product is currently installed. For more details, see Differential Releases and Full Releases.

Major Upgrade vs. Minor Upgrade vs. Small Update

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Windows Installer supports three types of product upgrades: major upgrades, minor upgrades, and small updates. The following table serves as a guide to help you determine which type of upgrade best suits your needs. If any one of the requirements for your upgrade is not appropriate for a minor upgrade or a small update, you should create a major upgrade. If you are not sure which type of upgrade you should use for your Windows Installer–based project or if you do not have a preference, you can create an automatic upgrade.

Table 8-2 • Major Upgrade vs. Minor Upgrade vs. Small Update

Requirement for the Upgrade	Use a Major Upgrade?	Use a Minor Upgrade?	Use a Small Update?	Note
Change the name of the .msi package	Yes	No	No	The default file name is taken from the Product Name property, provided the .msi file is not compressed in a `Setup.exe` installation launcher.

Table 8-2 • Major Upgrade vs. Minor Upgrade vs. Small Update (cont.)

Requirement for the Upgrade	Use a Major Upgrade?	Use a Minor Upgrade?	Use a Small Update?	Note
Enable end users to install earlier versions and the latest version on the same machine	Yes	No	No	
Add a new subfeature	Yes	In some cases	In some cases	If the new subfeature consists of new components only, you can use a small update, a minor upgrade, or a major upgrade. If the new subfeature consists of existing components, you must use a major upgrade.
Move or delete a feature in the product tree	Yes	No	No	
Add a new component to a new feature	Yes	Yes	Yes	
Add a new component to an existing feature	Yes	Yes, if the version of Windows Installer is 2.0 or later	Yes, if the version of Windows Installer is 2.0 or later	Windows Installer 1.x requires new components in an upgrade package to be placed in new features for minor upgrades and small updates; it also requires special command-line handling.
Move or delete a component in the product tree	Yes	No	No	
Change the component code of an existing component	Yes	No	No	
Change the key file of a component	Yes	No	No	

Table 8-2 • Major Upgrade vs. Minor Upgrade vs. Small Update (cont.)

Requirement for the Upgrade	Use a Major Upgrade?	Use a Minor Upgrade?	Use a Small Update?	Note
Add, remove, or modify any of the following: files, registry keys, or shortcuts	Yes	Yes	Yes	If the file, registry key, or shortcut is in more than one component and the component is shared by two or more features, a major upgrade must be used.

Codes Associated with the Different Types of Upgrades

Several Windows Installer codes help identify a product:

- **Package Code**—Part of the Summary Information Stream, the package code identifies a particular database. The package code is not a Windows Installer property. Any two .msi databases with identical package codes must have identical contents. Therefore, you should change the package code for each build.
- **ProductVersion**—This is a Windows Installer property that contains the product version. Note that Windows Installer uses only the first three fields of the **ProductVersion** property for version comparisons. For example, for a product version of 1.2.3.4, the 4 is ignored. (Note that this is true for comparisons of **ProductVersion** values, and not for file versions.)
- **ProductCode**—This is a Windows Installer property that contains the GUID of a product. Windows Installer treats two products with different **ProductCode** GUIDs as unrelated, even if the values for the **ProductName** property are the same.
- **UpgradeCode**—This is a Windows Installer property that contains a GUID representing the product family. The **UpgradeCode** should be consistent across different versions and languages of a family of related products for patching purposes. You can set the **UpgradeCode** for an upgrade in the Upgrades view.

For any type of upgrade, you must change various combinations of the package code, product version, and product code to identify the product being installed. The following table identifies when each code should be changed for different types of upgrades.

Table 8-3 • Codes that Need to Be Changed for the Different Types of Upgrades

	Package Code	Product Version	Product Code	Upgrade Code
Small Update	X			
Minor Upgrade	X	X		
Major Upgrade	X	X	X	

Automatic Upgrades

Project • *This information applies to InstallScript projects.*

To simplify the upgrade creation process, InstallShield offers you the ability to create automatic upgrades. An automatic upgrade is a special type of upgrade that you can create if you do not know which type of upgrade you should use or if you do not have a preference. With automatic upgrades, InstallShield determines which type of upgrade—major upgrade or minor upgrade—would be optimal based on comparisons between the earlier and later packages that you specify.

Patch vs. QuickPatch Project

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

To update a product without distributing a complete, updated installation package, you can create a Windows Installer patch package (.msp). InstallShield provides two different patch creation alternatives serving different scenarios: one method uses the Patch Design view, and the other uses the QuickPatch project type. Find the appropriate solution for your product by reading about both alternatives below.

Note • *Major upgrades are typically not packaged as patches. Therefore, the table below assumes that the patch created through the Patch Design view is for a minor upgrade or a small update. QuickPatch projects produce QuickPatch packages that serve as minor upgrades.*

Table 8-4 • Patch vs. QuickPatch Project

Requirement for the Patch	Use a Patch?	Use a QuickPatch?	Note
Ability to apply many cumulative patches that update a base package	Yes	Yes, if you are using QuickPatch streamlining	If you are not using QuickPatch streamlining, you cannot patch more than 15 times. For more details, see Specifying Whether to Streamline the QuickPatch Package.
Add a new subfeature	Yes	No	

Table 8-4 • Patch vs. QuickPatch Project (cont.)

Requirement for the Patch	Use a Patch?	Use a QuickPatch?	Note
Add a new component to a new subfeature	Yes	No	
Add a new component to an existing feature	Yes, if the version of Windows Installer is 2.0 or later	No	Windows Installer 1.x requires new components in an upgrade package to be placed in new features for minor upgrades and small updates; it also requires special command-line handling.
Add, modify, or remove a file	Yes	Yes	A new target destination cannot be used for a new file in a QuickPatch; only destinations that were previously defined in the original installation can be used for new files. This limitation does not exist for patches that are created through the Patch Design view.
Add, modify, or delete registry data	Yes	Yes	All new registry data being added with a QuickPatch must be associated with a feature that already exists in the original installation.
Add, modify, or delete a shortcut	Yes	No	
Add, modify, or delete custom actions	Yes	Can only delete custom actions that were included in the original base installation.	
Add or remove a redistributable	Yes	No	

Table 8-4 • Patch vs. QuickPatch Project (cont.)

Requirement for the Patch	Use a Patch?	Use a QuickPatch?	Note
Add, modify, or remove ODBC resources	Yes	No	
Edit an .ini file	Yes	No	
Edit an .xml file	Yes	No	
Configure server settings such as IIS Web sites, component services, and SQL scripts	Yes	No	
Digitally sign files (such as your application's executable files) in the patch package	Yes	Not automatically	For QuickPatch projects, you must manually sign the individual files and then add them to your project.

Using the Patch Design View

The Patch Design view provides an integrated, visual method for creating patches and selecting the proper settings associated with each patch configuration you create. You can create multiple patch configurations in the Patch Design view. Each patch configuration contains the settings and data required to build a patch.

In most cases, you will begin patch creation in the Patch Design view. If you are looking for a simple patching solution, you can create a QuickPatch project.

Using the QuickPatch Project

The Create New QuickPatch Wizard, which is launched when you create a QuickPatch project, is targeted at installation authors who want to ship small updates to their users. It provides a simpler alternative to patch creation in the Patch Design view.

Although customization is limited when you create a patch by using a QuickPatch project, it produces the same deliverable types as the Patch Design view: .msp and .exe files.

Packaging Options for Upgrades

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

When you want to prepare an installation that updates a version of your product installed on an end user's machine, you can consider two different methods for packaging your major upgrade, minor upgrade, or small update:

- You can package your upgrade as a full installation that updates an existing product if an earlier version is installed, or behaves as a first-time installation if no earlier version is present.
- You can package your upgrade as a patch that contains only the changed data (.msi data and byte-level file differences) between the versions to be updated.

Full-Installation Packages

Both a minor upgrade and a small update act like first-time installations if an earlier version is not present, or they install over an existing installation of a product. A major upgrade also acts like a first-time installation if an earlier version is not present; however, a major upgrade typically uninstalls any earlier version and then installs the new version.

Patch Packages

Patches enable you to distribute just the bits and portions of the database necessary to update your application's files to a specific version, possibly resulting in a much smaller package than an upgrade packaged as a full installation. This enables you to deploy your upgrades using much less bandwidth than that required to deploy a full-installation package.

Note *• A patch is not a type of upgrade. Patching is simply a mechanism for distributing a major upgrade, a minor upgrade, or a small update with a small footprint. In fact, creating a patch involves first designing the upgrade and then packaging it as a patch. Before you create a patch, it is recommended that you test the upgrade as a full-installation package.*

Determining the Best Packaging Option for Your Upgrade

The topic Determining the Best Upgrade Solution includes a table that you can review to determine what type of packing option you should use to update an earlier version of your product. In some cases, a standard patch or a QuickPatch may be seem to be the ideal mechanism for packaging your upgrade. However, under certain conditions, you should package your upgrade as a full installation instead of a patch. For example:

- If the target image was created with Windows Installer 1.2 or earlier, and the upgraded image is created with Windows Installer 2.0 or later, you should package your upgrade as a full installation, but not as a patch. Creating patches for packages that span this schema inflection point can be problematic. For more information, see Val0011, which describes the associated validator for upgrading and patching validation.
- If you want your upgrade to move one or more files on the target system from one location to another, you should package your upgrade as a full installation, but not as a patch. If your end users install a patch for an upgrade that moves files on the target system, problems may occur. For example, the patch may not work, a repair to the target system may not work, a subsequent patch may not work, or end users may not be able to

uninstall the product. As a workaround, you can create your patch so that it deletes the files in the old location and adds the files to the new location.

- If you want to change your installation from compressed to uncompressed, or vice versa, you should package your upgrade as a full installation, but not as a patch. If you use a patch in this scenario, a repair to the target system may not work, a subsequent patch may not work, or the end user may not be able to uninstall the product.
- If you need to move files from one .cab file to another, or if you need to change the order of files in a .cab file, you should package your upgrade as a full installation, but not as a patch.
- If your original installation had more than 32,767 files but your latest installation has fewer than 32,767 files, a patch will fail. Similarly, if your original installation had fewer than 32,767 files but your latest installation has more than 32,767 files, a patch will fail. In either case, you should package your upgrade as a full installation.

  Note that if both the original installation and the latest installation have more than 32,767 (or both have fewer than 32,767 files), you can package your upgrade as a patch.
- Patches cannot be created for major upgrades of InstallScript MSI projects. Therefore, if you need to distribute a major upgrade for an InstallScript MSI project, you should package it as a full installation.

Differential vs. Full Releases

Project • *This information applies to InstallScript projects.*

If the original installation for your product was created with an InstallScript project, you need to create a differential release or a full release to update your product.

If some of the target systems have an earlier version of the product, and some do not have any version of the product, you can package your upgrade as a full release. This type of release behaves as a first-time installation if an earlier version of the product is not already present on the target system. It also is capable of installing over an earlier version and replacing that version completely.

If all of the target systems have an earlier version of the product, you can package your upgrade as a differential release. This type of release contains the files that are absent from—and/or have a different date, time, size, or attribute than the version in—one or more of a specified set of existing releases. A differential release is used to update the versions of your product that were installed by those existing releases.

Note • *If you used a version of InstallShield Professional earlier than 6.0 to create media for an InstallScript project, the media cannot be updated.*

Working with Upgrades, Patches, and QuickPatch Projects

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

If you are going to package your upgrade as a full installation or as a standard patch, you begin by opening the latest version of your project and making the necessary changes, such as adding files and registry entries, as needed.

If you would like to package your upgrade as a QuickPatch, you begin by creating a new project—a QuickPatch project. With a QuickPatch project, you identify which earlier releases should be patched by your QuickPatch.

Refer to the topics in this section to learn how to create major upgrades, minor upgrades, small updates, automatic upgrades, patches, and QuickPatch projects. This section also explains how you can validate your upgrade or patch to determine whether your resulting package will perform its actions correctly.

Understanding File Overwrite Rules

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The Windows Installer service uses several file overwrite rules, by default, to determine whether a file included in an upgrade should overwrite a file that already exists on the target system. The rules apply when the **REINSTALLMODE** property uses the o setting to install over older files on the target system. To change this behavior, you can replace the o option with one of the following values:

- p—Reinstall only if there is no equivalent file on the target system.
- e—Reinstall if the file is missing or if it is an earlier or equal version.
- d—Reinstall if file is missing or different.
- a—Reinstall all files, regardless of version.

Note that the setting for **REINSTALLMODE** applies to all of the features being installed; it cannot be set for an individual feature. In addition, setting **REINSTALLMODE** to include a will likely cause prompts for the original installation source during the application of a patch.

Upgrade Considerations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Following are some guidelines for creating upgrades.

Updating the Package Code, the Product Version, and the Product Code

For any type of upgrade, you must change various combinations of the package code, product version, and product code to identify the product being installed. For more information, see Major Upgrade vs. Minor Upgrade vs. Small Update.

Upgrade and Patch Optimization

When you are configuring a minor upgrade or a small update, use the patch optimization functionality in your build settings.

Using patch optimization helps you synchronize component names, component GUIDs, **File** table keys, and **Directory** table keys in the upgraded image with those in the target images. This helps to make the smallest possible patches. If you do not use patch optimization, the patch may be the same size as the target .msi package, or it may break Windows Installer component rules.

The patch-creation process uses the **File** table keys to determine if two files are the same file. (The actual file names cannot be used reliably, since a package might contain more than one file with the same name, installed under different conditions.) If you specify the previous package for patch optimization, InstallShield uses identical **File** table keys for identical files.

Tip • *If your package uses dynamic file linking, it is recommended that you use patch optimization when building your upgrade. This keeps the key files consistent across the releases.*

To use the patch optimization functionality, specify the previous Windows Installer package on the Advanced Settings panel in the Release Wizard. You can also specify the previous Windows Installer package through the Previous Package setting on the Build tab for the release in the Releases view.

Adding a Subfeature with a Minor Upgrade

In general, a minor upgrade should not include a new top-level feature. However, new subfeatures of existing features are allowed. If you are adding a new subfeature for a minor upgrade, set two of the subfeature's properties as follows so that they are installed correctly during a minor upgrade:

- **Remote Installation**—Set this property to **Favor Parent**.
- **Required**—Set this property to **Yes**.

The user interface of a minor upgrade does not usually show the feature tree; however, maintenance mode for the updated installation typically does expose the feature tree. If you want the new subfeature to be excluded from the feature tree so that end users cannot deselect it, set the subfeature's Display property to Not Visible.

Removing Installed Data

If your minor upgrade removes data such as files, registry settings, or .ini files, simply removing the data that existed in the earlier product version from your project will not cause the file to be removed when the upgrade is applied. To learn how to remove such data, see Configuring Minor Upgrades to Remove Installed Data.

Configuring InstallShield to Automatically Determine the Upgrade Type

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

If you do not know which type of upgrade you should use for your Windows Installer–based project or if you do not have a preference, you can create an automatic upgrade. With automatic upgrades, InstallShield determines which type of upgrade—major upgrade or minor upgrade—would be optimal based on comparisons between the earlier and later packages that you specify. The topics in this section explain how to create and work with an automatic upgrade.

Adding an Automatic Upgrade Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add an automatic upgrade item:***

1. Open the **Upgrades** view.
2. In the **Prepare Setup For Upgrade Scenarios** explorer, right-click **Upgrade Windows Installer Setup** and click **Add Automatic Upgrade Item**. InstallShield adds the automatic upgrade item to the explorer.
3. Rename the item so that it reflects the latest version of your installation.

Configuring Automatic Upgrade Item Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

When you add an automatic upgrade item to your project, you must configure its automatic upgrade item properties. You can configure these properties when you click your new automatic upgrade item in the Prepare Setup For Upgrade Scenarios explorer of the Upgrades view.

In addition, you need to configure general upgrade properties that InstallShield will use to create your upgrade, depending on whether InstallShield determines that a major or a minor upgrade is necessary for your automatic upgrade item. You can configure these general properties on the tabs that are displayed when you click Upgrade Windows Installer Setup in the Prepare Setup For Upgrade Scenarios explorer of the Upgrades view:

- Common tab
- Advanced tab

Converting Automatic Upgrades to Major or Minor Upgrades

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To convert an automatic upgrade item to a major upgrade or a minor upgrade:***

1. Open the **Upgrades** view.
2. Right-click the automatic upgrade item that you would like to convert and then click **Convert to Minor Upgrade Item** or **Convert to Major Upgrade Item**.

Removing Automatic Upgrade Items

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove an automatic upgrade item:***

1. Open the **Upgrades** view.
2. Right-click the automatic upgrade item that you would like to delete and then click **Delete**.

Creating Major Upgrades

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Once you have determined that a major upgrade is the best upgrade solution for you, you can begin to create a major upgrade in the Upgrades view. Note that a major upgrade signifies significant change in functionality and warrants a change in the **ProductCode** property; you can update this property in the General Information view.

Note • *When you change the product code, Windows Installer treats your latest and previous product versions as unrelated, even though the* ***ProductName*** *values are likely the same. If you want both versions of your product to be installable on the same system, you can simply change the product code and the main installation directory (often INSTALLDIR).*

Essentially, a major upgrade is two operations rolled into one installation package. The major upgrade either installs the new version of the product and then silently uninstalls the older version or silently uninstalls the older version and then installs the newer version. The sequence of these two separate operations depends on how you configure the installation package of the newer version of the product.

For more information on creating a major upgrade using InstallShield, refer to this section of the InstallShield Help Library.

Adding a Major Upgrade Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add a major upgrade item:***

1. Open the **Upgrades** view.
2. In the **Prepare Setup For Upgrade Scenarios** explorer, right-click **Upgrade Windows Installer Setup** and click **Add Major Upgrade Item**.

InstallShield adds a new major upgrade item.

Configuring Major Upgrade Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

When you add a major upgrade item in the Upgrades view, a general setting that you can modify is the scheduling of the RemoveExistingProducts action. You can modify this setting in the Upgrades view by selecting Upgrade Windows Installer Setup and clicking the Common tab.

The configurable properties for your major upgrade item are presented in a more user-friendly format on the Common and Advanced tabs than in the **Upgrade** table in the Direct Editor.

On the Common tab for a major upgrade item, you specify the Upgrade Code value of the products that you want to update as well as the versions of products that you want to update. On the Advanced tab, InstallShield by default includes an ISSetAllUsers custom action; this action sets **ALLUSERS** correctly during a major upgrade. (In addition, ISSetAllUsers sets the custom property **IS_MAJOR_UPGRADE** if a major upgrade is taking place.) To specify whether to include the ISSetAllUsers action, use the General tab of the Options dialog box. You can access this dialog box by selecting Options from the Tools menu. On that tab, you can clear or select the **Automatically create ISSetAllUsers action** check box.

Removing Major Upgrade Items

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a major upgrade item from the Upgrades view:***

1. Open the **Upgrades** view.
2. In the **Prepare Setup For Upgrade Scenarios** explorer, right-click the major upgrade item and click **Delete**.

Creating Minor Upgrades

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Once you have determined that a minor upgrade is the best upgrade solution for you, you can start by adding a minor upgrade item in the Upgrades view. After you build an installation with a minor upgrade item, the build engine performs a series of tests to determine whether that your latest installation can successfully upgrade the previous version of your installation. However, adding a minor upgrade item is not necessarily required for a minor upgrade to function properly. See the Running a Minor Upgrade with Setup.exe section below for more details.

Any new features that you add to the latest version of your installation must be added as subfeatures of existing features. These new features must have the Remote Installation property set to Favor Parent and the Required attribute set to Yes in the Features view.

Minor Upgrades at Run Time

At run time, the end user will first see a message box announcing that an upgrade will occur. This message specifies the name of the previous product, alerting the end user as to which existing application will be updated. At this point, the end user can stop the installation process if desired. This prompt is followed by a Welcome dialog, and when the end user clicks Next on the Welcome dialog, the setup will install its new resources. While installing its resources, the installation will update the progress bar in the Setup Progress dialog so that users will be able to track the upgrade process.

Tip • *In the Upgrades view, you can disable the initial upgrade prompt when you click Upgrade Windows Installer Setup in the explorer and configure the Common tab properties for small updates and minor upgrades.*

Note • *At run time during a minor upgrade, Windows Installer does not reinstall a component if its key file would be downgraded in the process. Therefore, the key file in the upgrade needs to have a version number that is equal to or greater than that of the key file in the old package. The exception is when the end user sets the* ***REINSTALLMODE*** *property to* ***a****, which forces the installation of all files, regardless of version. For more information about file overwrite rules, see Overwriting Files and Components on the Target System.*

A minor upgrade installs its new resources over the application that currently exists on the target machine. If you want to completely uninstall and then reinstall your application, you should consider a major upgrade.

Running a Minor Upgrade with Setup.exe

If you build a release that includes `Setup.exe`, your latest installation will be minor upgrade enabled. `Setup.exe` can detect when a previous version of your application exists on a target machine. When `Setup.exe` detects a previous version, it will run the rest of your installation in minor upgrade mode.

Running a Minor Upgrade Without Using Setup.exe

If you intend to distribute your installation without wrapping it in `Setup.exe`, there is a manual process that your end users must follow to start the installation. For this reason, you should consider using `Setup.exe`; however, you can achieve similar results without it.

The Installer properties **REINSTALL** and **REINSTALLMODE** must be set from the command line to start an installation in upgrade mode. In all but the most advanced scenarios, the property **REINSTALLMODE** should be set to `vomus` and the property **REINSTALL** should be set to `ALL`. A typical command line can look like the following:

```
msiexec.exe /i \product.msi REINSTALLMODE=vomus REINSTALL=ALL
```

If the update contains features that you do not want to update, you should set **REINSTALL** to a comma-separated list of the features that you want to update, as in the following command:

```
msiexec /i \product.msi REINSTALLMODE=vomus REINSTALL=F1,F3,F5
```

The feature names you use in the **REINSTALL** property are case-sensitive.

Note • *Do not set **REINSTALL** equal to `ALL` for a first-time installation.*

A critical point to note is that you do not want to set these properties on the command line unless a previous version of your installation already exists on the target machine. If you do, the installation will appear to run in minor upgrade mode, and your application files may not be installed. Be sure that your end users will be able to discern when command line should and should not be used.

Note • *The **REINSTALLMODE** attribute v is very important if you are performing a minor upgrade. This parameter tells the installer to refresh its internal setup cache for your product with the new installation package. Without this parameter, your installation will have no knowledge of any of the changes that you have made to the latest installation package.*

Adding a Minor Upgrade Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add a minor upgrade item in the Upgrades view:***

1. Open the **Upgrades** view.
2. In the **Prepare Setup For Upgrade Scenarios** explorer, right-click **Upgrade Windows Installer Setup** and click **Add Minor Upgrade Item**.

InstallShield adds a new major upgrade item.

Tip • *If you are creating an upgrade that can update more than one previous version, you can add additional minor upgrade items.*

Configuring Minor Upgrade Properties

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

When you add a minor upgrade item in the Upgrades view, a general setting you can modify is how a setup launcher (if your build configuration includes a setup launcher) should behave if an earlier product version is present. You can modify this setting in the Upgrades view by selecting Upgrade Windows Installer Setup and clicking the Common tab.

Once you have added a minor upgrade item in the Upgrades view and made sure that it is selected, you can browse for the .msi database for the earlier product version that you want to update in the Setup to Upgrade field of the properties page for that minor upgrade item.

On the same properties page, you can also set release flags in the Release Flags field to exclude the minor upgrade item from the build.

Configuring Minor Upgrades to Remove Installed Data

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

InstallShield includes support for different methods for configuring a minor upgrade to remove installed data. Two methods are discussed in the following sections.

Method 1

To configure a minor upgrade to remove data that was installed during an earlier release, open your InstallShield project in which you are configuring the upgrade, and in the Files and Folders view, delete the file. Then you can create a record in the corresponding Remove tables within the Direct Editor. The Remove tables in the Direct Editor include the **RemoveFile**, **RemoveIniFile**, and **RemoveRegistry** tables.

To remove registry data from a component in a minor upgrade, you should create a record in the **RemoveRegistry** table. Records in the **RemoveRegistry** table describe the registry key and value to remove when the associated component is installed. Unlike the **RemoveFile** table, the **RemoveRegistry** table does not

accept an option to remove the specified registry data when the associated component is uninstalled. Instead, you can author a registry value with the **Uninstall entire key** flag. If your component contains a registry value with a hyphen in the Name field and an empty Value field, the specified registry key and all its contents will be removed when the component is removed.

For other types of data, there is usually either an uninstallation flag available in the Windows Installer table or a corresponding uninstallation table. To remove .ini data, for example, there is a **RemoveIniFile** table. For environment variable data, there is a corresponding uninstallation flag.

Note • *If a component is shared with other products, you should change the component code when removing resources. Furthermore, changing an existing component's component code requires a major upgrade. For major upgrades, you do not need to populate the Remove tables since a major upgrade requires a complete uninstallation.*

Method 2

Mark a component as transitive, and set a condition on the component that will evaluate to false when a minor upgrade is applied.

Removing Minor Upgrade Items

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a minor upgrade item from the Upgrades view:***

1. Open the **Upgrades** view.
2. In the **Prepare Setup For Upgrade Scenarios** explorer, right-click the minor upgrade item and click **Delete**.

Creating Small Updates

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The steps for creating a small update are the same as the steps for creating a minor upgrade with one key exception: the product version should be changed for a minor upgrade, but not for a small update.

If you need to create your upgrades so that they can be applied to your product using versions of Windows Installer earlier than 3.0, it is recommended that you avoid creating small updates. Since small updates do not change the product version, external programs—including installers for later versions of your product—cannot distinguish a product with the small update applied from one without the small update.

Small updates are typically packaged as a patch, not as a full installation. If you are sure that the upgrades that you create will be applied to your product with version 3.0 or later of Windows Installer, you can take advantage of patch sequencing support and use small-update patches to update earlier versions of your product.

Patching Considerations

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Following are some guidelines for creating patches and QuickPatch projects.

Testing the Upgrade Before Creating the Patch

It is recommended that you test your upgrade as a full-installation package before creating the patch. If the full-installation package successfully updates the earlier version of the application, then you can create the patch.

Creating an Update Launcher (Update.exe)

InstallShield lets you specify whether you want your update to include an `Update.exe` update launcher. An `Update.exe` update launcher is required in the following cases:

- You want to automatically update or install the Windows Installer engine on a target system, when necessary.
- You are building a patch for an InstallScript MSI project.
- You want to automatically install the .NET Framework on a target system, when necessary.
- You are building a patch whose product configuration includes support for installing multiple instances of a product and you want the instance selection dialog to be displayed when appropriate.

  To learn more about multiple-instance support, see Installing Multiple Instances of Products and Creating Patches for Multiple Instances of a Product.

The `Update.exe` update launcher is a bootstrap application that manages the aforementioned scenarios.

If you configure InstallShield so that it does not create an `Update.exe` update launcher, it creates an .msp file.

For more information, see:

- Specifying Whether to Build an Update.exe Update Launcher for a Patch
- Specifying Whether to Build an Update.exe Update Launcher for a QuickPatch Package

Optimizing Patches for Large Files

Selecting the **Optimize Patch for Large Files** check box in the Patch Design view results in smaller bit-level patches for application files that are larger than 4 MB.

For QuickPatch projects, each QuickPatch that is built is automatically optimized for large files.

Patches for Compressed Installations

The patch creation process requires an uncompressed release of the previous installations and the latest installation. If the installations are compressed installations, you can use an administrative image of the releases.

InstallShield automatically creates an administrative image for you if you specify an installation that is compressed for a patch configuration in the Patch Design view. InstallShield also automatically creates an administrative image for you if you specify an uncompressed image in a QuickPatch project.

Patches and the REINSTALL Property

If you discover while testing your patch that you are prompted to locate the original installation source, you can sometimes avoid such problems by setting the **REINSTALL** property explicitly to the features that you have modified. This property is set to `ALL` by default.

Self-Registration of COM Servers in a Patch or QuickPatch Package

InstallShield uses InstallShield self-registration (which uses the **ISSelfReg** table) for new COM servers that are marked to be self-registered in a QuickPatch project if all of the following conditions are true:

- The **ISSelfReg** table exists in the upgraded .msi file that is used to create the QuickPatch.
- The ISSelfRegisterFiles custom action is present in the Execute sequence.
- The ISSelfReg option is selected on the Preferences tab of the Options dialog box in InstallShield.

If any of the aforementioned conditions are false, InstallShield uses Windows Installer self-registration (the **SelfReg** table).

To use InstallShield self-registration in a patch if any of the aforementioned conditions are false, use the Patch Design view instead of a QuickPatch project.

Windows Installer 3.0 (and Later) and Patches

Windows Installer 3.0 and later includes many patch-related enhancements. If your patch or QuickPatch will be applied to target machines with Windows Installer 3.0 or later, you can take advantage of those enhancements. For more information, see the following:

- Patch Sequencing
- Patch Uninstallation
- Non-Administrator Patches

Note that Windows Installer 3.0 and later supports major-upgrade patches that do not have any sequencing data. However, the installer does not support major-upgrade patches that have sequencing data, which would be stored in the **MsiPatchSequence** table.

Windows Installer 1.2 and Patches

To create a patch that targets the Windows Installer 1.2 engine, select the appropriate patch configuration in the Patch Design view. Then on the Advanced tab, set the Minimum Windows Installer Version property to `120`.

Support for Patching Multiple Instances of a Product

If you create a patch for a Basic MSI project that includes support for installing multiple instances of a product in the same context on the same machine, InstallShield configures the patch so that end users can apply it to one instance or all of the instances. To learn more, see Creating Patches for Multiple Instances of a Product.

Customizing File Properties for the Update Launcher

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

InstallShield lets you use custom information for the version resources of the `Update.exe` update launcher. The information is displayed on the Properties dialog box for the update launcher; this Properties dialog box opens when end users right-click the `Update.exe` file and then click Properties.

Note • *The Properties dialog box is different on different versions of Windows. For example, on Windows 7 systems, the version resource information is displayed on the Details tab of the Properties dialog box. However, on Windows XP systems, the version resource information is displayed on the Version tab of that dialog box.*

Also note that some versions of Windows do not show some settings on the Properties dialog box.
To see screen shots of the Properties dialog box for a `Setup.exe` file (which looks the same as the Properties dialog box for an `Update.exe` file), see Customizing File Properties for the Setup Launcher.

Task: ***To override the default InstallShield values for the Update.exe settings with your own custom values:***

1. The procedure depends on whether you are creating a standard patch or a QuickPatch package.

   If you are creating a standard patch in a Basic MSI or InstallScript MSI project:

   a. In the View List under **Media**, click **Patch Design**.

   b. In the **Patch Design** explorer, select the patch configuration that you want to configure.

   If you are creating a QuickPatch package:

   a. In the View List under **Patch Settings**, click **General Information**.

   b. In the **General Information** explorer, click **Build Settings**.

2. Click the **Advanced** tab, and then find the **Update Launcher Settings** area.
3. In the following settings, enter the values that you want to use for the properties of your `Update.exe` file.
   - Company Name
   - Product Name
   - Product Version
   - Description
   - Copyright

Tip • *The Product Version setting updates the file version and the product version for `Update.exe`. Note that the file version always contains four fields. If you specify fewer than four fields, the remaining fields are filled with zeros. For example, if you specify a product version of **1.1**, the file version that is used in the version resources of `Update.exe` is **1.1.0.0**.*

If you leave the update launcher settings blank, InstallShield uses the default InstallShield values.

Specifying the Icon for the Update Launcher

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

InstallShield lets you specify the icon that should be used for your `Update.exe` update launcher. The icon can be in an .exe, .dll, or .ico file.

End users can see this icon when they view your `Update.exe` file in Windows Explorer. The icon is also displayed on the Properties dialog box for `Update.exe`; this Properties dialog box opens when end users right-click the `Update.exe` file and then click Properties.

If you do not specify an icon, InstallShield uses a default icon for your `Update.exe` file.

Task: ***To specify the icon for your Update.exe file:***

1. The procedure depends on whether you are creating a standard patch or a QuickPatch package.

   If you are creating a standard patch in a Basic MSI or InstallScript MSI project:

   a. In the View List under **Media**, click **Patch Design**.

   b. In the **Patch Design** explorer, select the patch configuration that you want to configure.

If you are creating a QuickPatch package:

a. In the View List under **Patch Settings**, click **General Information**.

b. In the **General Information** explorer, click **Build Settings**.

2. Click the **Advanced** tab, and then find the **Update Launcher Settings** area.

3. In the **Icon** setting, specify the fully qualified name of the file that contains the icon that InstallShield should use when it creates the `Update.exe` file at build time.

   To specify a file, type an explicit path or path variable, or click the ellipsis button (**...**) to open the **Change Icon** dialog box, in which you can click the **Browse** button to select a file.

   By default, the icon with index 0 is used; to specify a different icon, either select an icon in the **Change Icon** dialog box or append the icon's index or resource ID (preceded by a minus sign) to the file name. For example, **C:\Temp\MyLibrary.dll,2** indicates the icon with an index of 2, and **C:\Temp\MyLibrary.dll,-100** indicates the icon with a resource ID of 100.

The next time that you build the release, InstallShield uses the icon that you specified for your `Update.exe` file.

Patch Sequencing

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

InstallShield enables you to specify the order that Windows Installer version 3.0 or later should apply small-update patches to an installed product, regardless of the order in which they are provided to the target machine. With patch sequencing data, you can ensure that Windows Installer knows the intended relationships among the upgrades packaged within a family of patches. Consequently, applying patch 1 of a product after patch 2 has already been applied will register patch 1 without overwriting patch 2 files. For versions of Windows Installer earlier than version 3.0, the patch sequence is ignored, and any small-update patches are applied to the product in the order that they are provided to the target machine.

The patch sequencing functionality available with Windows Installer 3.0 and later simplifies the patch creation process. The following sections show how.

Creating Patches to Be Applied with Versions of Windows Installer Earlier than 3.0

If you need to create your patches so that they can be applied to your product via versions of Windows Installer earlier than 3.0, it is recommended that you avoid creating small updates. Small updates do not change the product version; therefore, external programs, including installers for later versions of your product, cannot distinguish a product with the small update applied from one without the small update. For scenarios limited to

versions of Windows Installer earlier than 3.0, you need to plan around such limitations of the installer, thus targeting an increasing number of possible earlier product states. The sample application lifecycle presented in the following table illustrates the resulting complexity.

Table 8-5 • Sample Application Lifecycle for Patches Applied with Versions of Windows Installer Earlier than 3.0

Application Package	Product Version	Previous Setups Targeted by Package
1. Base installation	1.0	—
2. Minor upgrade	1.1	1.0
3. Minor upgrade	1.2	1.0, 1.1
4. Minor upgrade	1.3	1.0, 1.1, 1.2
5. Minor upgrade	1.4	1.0, 1.1, 1.2, 1.3
6. Major upgrade	2.0	1.0, 1.1, 1.2, 1.3, 1.4

Creating Patches to Be Applied with Windows Installer 3.0

With the patch sequencing functionality available with Windows Installer 3.0 and later, you can safely use a small-update patch to deliver a discrete upgrade for several different versions of a product, even though small updates do not change the product version. Unlike a small update, a minor upgrade changes the product version. Minor upgrades also form the framework for the sequencing of small-updates patches. If a small update for version 1.1 of a product is applied to version 1.2, the installer registers the small update on the target system and applies it as if it were encountered before the 1.2 minor upgrade was applied.

Small-update patches also enable Windows Installer 3.0 and later to maintain a valid product state as other patches are applied and removed individually from the product. In addition, patch sequencing lets you generate upgrade packages from a smaller set of earlier product states without requiring you to consider every possible combination of patches that could exist on the target machine. The sample application lifecycle presented in the following table illustrates this advantage.

Table 8-6 • Sample Application Lifecycle for Patches Applied with Windows Installer 3.0

Application Package	Patch Sequence Number	Product Version	Previous Setups Targeted by Package
1. Base installation	—	1.0	—
2. Small update	1	1.0	1.0
3. Small update	2	1.0	1.0
4. Small update	3	1.0	1.0

Table 8-6 • Sample Application Lifecycle for Patches Applied with Windows Installer 3.0 (cont.)

Application Package	Patch Sequence Number	Product Version	Previous Setups Targeted by Package
5. Small update	4	1.0	1.0
6. Minor upgrade	—	1.1	1.0

All of the small updates in the table above belong to the same patch family. Windows Installer 3.0 and later uses the patch family to compare a small-update patch with all of the other patches within the same family and determine the order in which each of the patches should be applied to the target machine. Patch sequences are added to the **MsiPatchSequence** table of the patch package database. This table defines the relationships between patches that target the same family of patches.

Creating Patches to Be Applied with Windows Installer 3.1

The patch sequencing functionality available with Windows Installer 3.1 enables you to further simplify the patch creation process with respect to minor upgrades. The **Minor Update to Target RTM Version (MSI 3.1 Required)** property on the Advanced tab of the Patch Design view lets you specify whether you want a minor-upgrade patch to target the release to manufacturing (RTM) version of the product (or the most recent major upgrade of the product, if one has been installed). You have two options for this property:

- If you want your minor-upgrade patch to essentially remove all of the patches up to the RTM version of the product (or the most recent major upgrade of the product, if one has been installed) before applying the current minor-upgrade patch, select Yes for this property. With this option, all patches (with or without sequencing data) are removed. You do not need to target additional baseline versions and thus increase the patch payload. All end users can successfully apply the patch without applying any intermediate patches.
- If you do not want your minor-upgrade patch to remove all of those earlier patches, select No. If you select this option, it may be necessary for your patch to contain the information needed to target each of the earlier minor upgrades that were created after the RTM (or the most recent major upgrade of the product, if one was created).

  For example, if you are creating a minor-upgrade patch for service pack 2 and you select No for this property, your patch needs to target the minor-upgrade patch for service pack 1. You could also optionally target other baselines (such as RTM); doing so would increase the patch payload. Note that if you do not target the RTM version, any end user who has the RTM version but not the service pack 1 minor-upgrade patch would need to install service pack 1 before service pack 2.

Creating Patches to Be Applied with Windows Installer 4.5

If a superseded patch installs a component for the product but later a superseding patch removes that component, the component's feature state may be changed to advertised, and it may not reinstalled. In addition, none of the remaining components associated with that feature can be maintained. This can be a problem on target systems that have Windows Installer 4.0 or earlier. The patch sequencing functionality available with Windows Installer 4.5 offers enhanced supersedence robustness to avoid this issue.

You can specify that a component in the current patch should be flagged for uninstallation in order to avoid leaving this component orphaned on the target system after a future superseding patch is applied. If a subsequent patch is installed and it is flagged to supersede the first patch, Windows Installer 4.5 can unregister and uninstall this component if appropriate.

Windows Installer 4.5 supports two methods for flagging superfluous components for uninstallation if they are superseded:

- Select Yes for the Uninstall Superseded Component setting for an individual component to indicate that you want it to be uninstalled if appropriate. If you select Yes, InstallShield adds the **msidbComponentAttributesUninstallOnSupersedence** attribute to the component in the **Component** table.

  To access the Uninstall Superseded Component setting, open the Components view and then select the component that you want to configure. The setting is displayed in the grid on the right. The default value of this setting is No.

- To indicate that you want all superfluous components in a superseded patch to be uninstalled, set the value of the Windows Installer property **MSIUNINSTALLSUPERSEDEDCOMPONENTS** to 1. You can set the value of the property from the command line or by adding this property to your project through the Property Manager view.

Windows Installer 4.0 and earlier ignore the **msidbComponentAttributesUninstallOnSupersedence** attribute and the **MSIUNINSTALLSUPERSEDEDCOMPONENTS** property.

Patch Uninstallation

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI—if the InstallScript user interface (UI) style is the new style (which uses the InstallScript engine as an embedded UI handler)*
- *QuickPatch*

This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the traditional style (which uses the InstallScript engine as an external UI handler). To learn more, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

Windows Installer 3.0 or later supports the uninstallation of patches for small updates and minor upgrades; the patches to be uninstalled must have been installed with Windows Installer 3.0 or later. When a patch is uninstalled, the product is returned to the state it was in before the patch was uninstalled. With earlier versions of Windows Installer, an end user who wants to remove a patch needs to uninstall the patched product and then reinstall the product without applying the patch. In this case, any patches that should not be removed must be reapplied.

End users can uninstall patches through Add or Remove Programs on systems running Windows XP SP2 and later. For systems running Windows Installer 3.0 or later with earlier versions of Windows, patches must be uninstalled from the command line. For more information, see Uninstalling Patches in the Windows Installer Help Library.

The uninstallation of patches is not enabled by default because not all patches can be uninstalled. Following are examples of scenarios in which a patch cannot be uninstalled, or when certain functionality does not work during patch uninstallation:

- A major upgrade packaged as a patch cannot be uninstalled.
- If a patch adds a row to certain Windows Installer tables, the patch cannot be uninstalled. If your patch adds a row to any of these tables, one of the patch validators (Val0015) warns you that the patch will not be uninstallable. For a list of the applicable tables, see Val0015.
- It is possible that an end user may not be able to remove a patch that adds content to the **RemoveFile** or **RemoveRegistry** tables. If the patch is designed to remove a file or registry entry that was not included in the original installation package, uninstalling the patch will not restore that file or registry entry.
- If you create an uninstallable patch that contains SQL script support that was added through the SQL Scripts view, the SQL script will not run during the patch uninstallation.

It is recommended that you thoroughly test the uninstallation of your patch before deploying it to your end users. To learn more about patches that are not uninstallable, see Uninstallable Patches in the Windows Installer Help Library.

Non-Administrator Patches

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Windows Installer 3.0 and later enables you to create patches that can be installed by non-administrators. Non-administrator patches can be used if all of the following criteria are met:

- The target machine must be running Windows Installer 3.0 or later on the Microsoft Windows XP or later client platform. Server platforms are not supported.
- The application was installed from a removable media such as a CD-ROM or DVD.
- The application was installed in a per-machine context.

Note • *If the ALLUSERS property is overwritten at the command line, non-administrator patches will fail.*

- The base installation must include the certificate that will be used to sign all subsequent patches.
- The base installation must include the **MsiPatchCertificate** table. This table provides the signer certificate that will be used to verify the digital signature of subsequent patches when they are applied by a non-administrator. If necessary, this table can contain multiple certificates, and subsequent patches would need to be able to verify at least one of the certificates. For more information, see Preparing Installations for Non-Administrator Patches.

- The non-administrator patch must contain the **MsiDigitalCertificate** table. This table contains the signing certificates for the signed patches. For more information, see Signing a Patch Package or Signing a QuickPatch Package.

If any of the above criteria are not met, end users cannot install the digitally signed patch in a locked-down environment.

A typical scenario in which non-administrator patches are used is the computer game industry. Some computer game users are children who might not have access to areas of the system other than folders in their own user profile and registry keys under HKEY_CURRENT_USER. Their parents would have administrative access to the machines so that they can control what is installed and what their children can access. Parents would install any and all applications. If patches are available for the installed software, children would be able to download and install non-administrator patches without help from their parents, as long as all of the above criteria have been met.

Creating and Applying Patches

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

This section of the help discusses how to create and apply patches to an installation. It also covers how to enable the uninstallation of a patch, use patch sequencing, and sign a patch package.

Adding a New Patch Configuration Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add a new patch configuration item:***

1. In the View List under **Media**, click **Patch Design**.
2. Right-click **Patch Design** and click **Add New Patch Configuration**.

InstallShield adds a new patch configuration item.

Adding a New Latest Setup Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add a new latest setup item:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click the appropriate patch configuration item and click **Add New Latest Setup**.

InstallShield adds a new latest setup item.

Adding a New Previous Setup Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add a new previous setup item:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click an existing previous setup item and click **Add New Previous Setup**.

InstallShield adds a new previous setup item.

Adding an External File

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To add an external file:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click **Additional External Files** and click **Add New External File**.

InstallShield adds a new external file item. You can configure this file in the pane on the right.

Configuring Patch Settings

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The best way to create and configure a patch is to use the Patch Design view. Before you work in the Patch Design view, you should have already built the projects for your earlier and later product versions.

Each patch designed in the Patch Design view begins as a patch configuration. A patch configuration consists of one latest setup item and one or more previous setup items. At the patch configuration level, you can configure properties on the following property tabs:

- Common
- Identification
- Digital Signature
- Sequence
- Advanced

After you have set the patch configuration properties, drill down the hierarchy in the explorer, and configure the latest and previous setup items.

Specifying Identification Information for a Patch

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Windows Installer 3.0 and later adds an Add or Remove Programs entry for each patch that is applied to a target system, even if the patch is not uninstallable.

Tip • *Every time that you change the latest setup for a patch configuration in the Patch Design view, InstallShield uses the Add or Remove Programs information from the latest setup as the values for the Identification tab settings. You can override the values on the Identification tab as needed.*

Task: ***To specify identification information for a patch:***

1. In the View List under **Media**, click **Patch Design**.
2. Create a patch configuration if you have not already done so.
3. In the **Patch Design** explorer, click the patch configuration.
4. Click the **Identification** tab.
5. Configure each of the settings.

Enabling the Uninstallation of a Patch

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI—if the InstallScript user interface (UI) style is the new style (which uses the InstallScript engine as an embedded UI handler)*

This information does not apply to InstallScript MSI projects in which the InstallScript UI style is the traditional style (which uses the InstallScript engine as an external UI handler). To learn more, see Using the InstallScript Engine as an External vs. Embedded UI Handler for InstallScript MSI Installations.

Windows Installer 3.0 and later supports the uninstallation of patches for small updates and minor upgrades. However, not all patches can be uninstalled. For details about the uninstallation of patches, including the associated limitations, see Patch Uninstallation.

Task: ***To enable the uninstallation of a patch:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, click the patch configuration that you want to configure.
3. Click the **Common** tab.
4. Select the **Allow Patch to be Uninstalled (Requires Windows Installer 3.0)** check box.

Sequencing Patches

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Before you define a sequence for patches, you should create the necessary upgrade items in the Upgrades view. Then you should add a patch configuration item in the Patch Design view. Once you have completed those tasks, you can specify the sequence for the patches.

Task: ***To define a patch sequence:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, click the patch configuration that you want to configure.
3. Click the **Sequence** tab.
4. Do one of the following:
   - To use default patch sequencing that InstallShield generates, select the Use Default Patch Sequencing check box.
   - To use no patch sequencing, clear the Use Default Patch Sequencing check box.
   - To specify your own custom sequencing:
     a. Clear the **Use Default Patch Sequencing** check box.
     b. Click **Add**. The **Patch Sequence** dialog box opens.
     c. Define the sequence information as needed.

Signing a Patch Package

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Windows Installer 3.0 and later enables you to create patches that can be installed by non-administrators. Non-administrator patches can be used if strict criteria are met. For example, the base installation that the patch will update must include the certificate that will be used to sign the patch package. To learn about the other criteria that must be met, see Non-Administrator Patches.

Note • *If you want to digitally sign the files—such as your application's executable fils—in your patch, you can specify which files should be signed through the Signing tab in the Releases view.*

Task: ***To sign a patch package:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, click the patch configuration that you want to configure.
3. Click the **Digital Signature** tab.
4. Select the **Sign the patch package** check box.
5. Configure the digital signature settings.

Password-Protecting a Patch Package

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For added security, you can password-protect your patch. When you password-protect your patch, any end user who wants to apply your patch must enter a case-sensitive password to launch your update.

Task: ***To password-protect a patch package:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, click the patch configuration that you want to configure.
3. Click the **Advanced** tab.
4. For the **Password Protect Launcher** setting, select **Yes**.
5. For the **Launcher Password** setting, specify the password that you want your patch to use.

Note • *The password is case-sensitive.*

Specifying Whether to Build an Update.exe Update Launcher for a Patch

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

InstallShield lets you specify whether you want InstallShield to create an `Update.exe` update launcher for your patch package.

An `Update.exe` update launcher is required if you want to automatically update or install the Windows Installer engine on a target system if necessary. For more information on when an `Update.exe` launcher is required, see Patching Considerations.

If you configure InstallShield so that it does not create an `Update.exe` update launcher, it creates an .msp file.

Task: ***To specify whether to include an Update.exe update launcher for a patch:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, click the patch configuration that you want to configure.
3. Click the **Common** tab.
4. To include `Update.exe`, select the **Create Update.exe** check box.

   To avoid including `Update.exe`, clear the **Create Update.exe** check box.

Tip • *You can also use the Advanced tab to specify whether you want to include `Update.exe`.*

Copying a Latest Setup Item to Another Patch Configuration

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

If you have added more than one patch configuration item to the Patch Design view, you can copy the latest setup item within one patch configuration to another patch configuration.

Task: ***To copy a latest setup item from one patch configuration to another:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, drag the latest setup item that you want to copy to the patch configuration item that does not have it.

InstallShield adds the latest setup item, including all of its previous setup items and additional external files, to the patch configuration.

Removing Patch Configuration Items

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a patch configuration item:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click the patch configuration that you want to delete and then click **Delete**.

Removing Latest Setup Items

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a latest setup item:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click the latest setup item that you want to delete and then click **Delete**.

Removing a Previous Setup Item

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Task: ***To remove a previous setup item:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click the previous setup item that you want to delete and then click **Delete**.

Building a Patch

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Once you have configured the settings for a patch configuration in the Patch Design view and created a new release for the patch in the Releases view, you are ready to build a patch for your upgrade.

Task: ***To build a patch:***

1. In the View List under **Media**, click **Patch Design**.
2. In the **Patch Design** explorer, right-click the patch configuration item for which you want to build a patch, and then click **Build Patch**.

InstallShield builds the patch according to the settings you specified for the patch configuration item. The patch is built in the location that you specified on the Common tab for the patch configuration; InstallShield appends the following subdirectories to the output location that you specified:

`\PatchConfigName\Patch`

By default, InstallShield also performs upgrade and patch validation every time that you build a patch. For more information, see Validating Upgrades, Patches, and QuickPatch Packages.

The build will return an error and exit if your latest setup version was built compressed.

Applying Patches

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

A patch package (.msp) file contains the transforms and instructions necessary for upgrading one or more installed versions of a product.

Before you can apply a patch package, Windows Installer version 1.1 or later must be present on the system. In addition, the package that you want to update must be installed locally or as an administrative image. A further requirement is that the existing installation package be installed with the same privileges and for the same users as the patch package. For example, if the product was installed for all users, the update should be installed for all users, as well.

The easiest way to apply a patch is to double-click the .msp file in Windows Explorer or right-click the file and then click Open. When you apply a patch for a minor upgrade, a PatchWelcome dialog is the first dialog that opens. When you apply a patch for a major upgrade, the full dialog sequence appears, as when you run an installation standalone.

From the command line, you can apply a patch with the MsiExec.exe `/p` option. Type the following statement to apply a patch package located at `X:\Product Updates\Build 36\PatchForV1.msp`:

```
msiexec /p "X:\Product Updates\Build 36\PatchForV1.msp"Update.exe
```

If you selected the Create Update.exe check box for your patch configuration in the Patch Design view, InstallShield wraps your .msp file in an executable file. `Update.exe` launches your patch package with the following command-line expression:

```
msiexec /p <path to .msp file> REINSTALL=ALL REINSTALLMODE=omus
```

Applying Patches in Silent Mode

There are two ways you can apply a patch in silent mode: either launch MsiExec.exe with the `/qn` command-line parameter, or pass `/s` to `Update.exe`.

There is an important consideration to bear in mind when applying a patch in silent mode. In order to operate correctly, the Windows Installer property REINSTALL must be set to `ALL` and REINSTALLMODE to `omus` whenever you apply a patch. Since `Update.exe` always sets these properties at the command line, you do not have to do anything extra if your patch package is applied with `Update.exe`.

When a patch package is applied with a full user interface, one of your installation's default dialogs, PatchWelcome, is displayed. It includes control events to set **REINSTALL** and **REINSTALLMODE** with the correct options. However, since this dialog is not displayed when the end-user interface is suppressed, you must set the properties at the command line, as demonstrated below:

```
msiexec /p <path to .msp file> /qn REINSTALL=ALL REINSTALLMODE=omus
```

Because a patch does not modify the existing cached .msi database, including the `v` setting for **REINSTALLMODE** is unnecessary.

Creating a QuickPatch Project

Project *• You can create a QuickPatch to update an earlier version of your product only if the earlier version was installed using Windows Installer. The installation for the earlier version of your product must have been created with one of the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

A QuickPatch project is recommended for installation authors who want to ship small, single upgrades to their users. QuickPatch authoring provides a simple alternative to creating a patch in the Patch Design view, even though it provides less customization. Fundamentally, both patch creation methods produce the same deliverable types: .msp and .exe files.

To create a QuickPatch project for an existing .msi file or an already existing QuickPatch, use the Create New QuickPatch Wizard.

Creating a QuickPatch Project for an Existing QuickPatch

Project *• This information applies to QuickPatch projects.*

You can create a new QuickPatch project based on an existing QuickPatch project. This creates a patch that you can deliver to any end users who need to apply a patch for the original application or specific patched versions of the application.

Caution *• If you open and modify any of the releases listed in the History area of the General Information view, your latest project will not work, since intermediate data shared across the releases in the History may have been lost or altered. Therefore, whenever you create a QuickPatch project for an existing QuickPatch project, InstallShield changes the existing QuickPatch project (.ism file) to read-only mode.*

Task: ***To create a QuickPatch project for an existing QuickPatch project:***

1. In InstallShield, open the QuickPatch project (.ism file) that you would like to patch.
2. Open the **General Information** view.
3. In the **General Information** explorer, click **History**.
4. Click **Create Next Version**.

Your new QuickPatch project opens in InstallShield.

You can also use the Create New QuickPatch Wizard to create a QuickPatch for an existing QuickPatch.

Specifying Whether to Streamline the QuickPatch Package

Project • *This information applies to QuickPatch projects.*

When you are configuring a QuickPatch project, you have the ability to specify whether you want InstallShield to streamline the creation of your QuickPatch package to build as simple a package as possible. The goal of QuickPatch streamlining is to generate a QuickPatch package that has fewer new subfeatures and custom actions than a non-streamlined QuickPatch package.

For example, if your QuickPatch project includes a new file or registry entry and InstallShield does not use QuickPatch streamlining, InstallShield creates a new subfeature for that file or registry entry. InstallShield also adds one or more prebuilt InstallShield custom actions to work around certain Windows Installer patch requirements. However, if InstallShield does use QuickPatch streamlining, the file or registry entry is added to an existing feature, and no special prebuilt InstallShield custom actions are required.

Note • *InstallShield cannot streamline the creation of a QuickPatch package in the following scenarios:*

- *The QuickPatch package removes an installed file.*
- *The QuickPatch package removes or renames a registry key.*
- *The QuickPatch package targets a non-streamlined QuickPatch image. That is, you cannot use QuickPatch streamlining if you select the check box in the History area of the General Information view for a QuickPatch that did not use QuickPatch streamlining. If you try to build a streamlined QuickPatch that targets one or more non-streamlined QuickPatch images, InstallShield displays a build warning, and it does not use streamlining.*

Also note that you can apply no more than 15 cumulative, non-streamlined QuickPatch packages to a base .msi package or major upgrade package. If you exceed the limit, error 2701 occurs while you are applying the patch. The exact limit is determined by the depth of the package's feature tree and the subfeature that each non-streamlined QuickPatch adds to that tree. Windows Installer limits the depth of the feature tree to 16 levels.

A streamlined QuickPatch package does not contain any new subfeatures, so it does not have this limitation.

Task: ***To specify whether to streamline the QuickPatch package:***

1. In the View List under **Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Advanced** tab.
4. In the **Streamline QuickPatch** setting, select the appropriate option:
   - To streamline the QuickPatch package, select **Yes**. This is the default value for new QuickPatch projects.
   - To avoid streamlining the QuickPatch package, select **No**.

Specifying Target Releases for Patching

Project • *This information applies to QuickPatch projects.*

Task: ***To specify which releases should be patched by your QuickPatch project:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **History**.
3. Select or clear the check boxes next to the intermediate releases—the releases in between the Base QuickPatch Image and the current QuickPatch image—to specify whether or not you want them to be patched by the current project.

Note • *You cannot clear the check box for the Base QuickPatch Image or the current project. If you clear the check box of an intermediate QuickPatch project, your current QuickPatch project cannot be used to upgrade a machine that has that intermediate image as the latest image of your application.*

For example, suppose you distributed version 1.0 as an installation and later released a patch that upgrades the original installation to version 1.1. If you create a version 1.2 QuickPatch and the check box for the 1.1 QuickPatch is not selected in the History, your 1.2 QuickPatch can be used to upgrade the 1.0 release but not the 1.1 release.

Specifying Custom Actions for the QuickPatch to Execute

Project • *This information applies to QuickPatch projects.*

Task: ***To specify which custom actions should be run when your QuickPatch is applied:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Custom Action**.
3. Select or clear the check boxes next to the custom actions to specify whether or not you want them to be run during the installation of your QuickPatch.

Adding Files to a QuickPatch

Project • *This information applies to QuickPatch projects.*

Task: ***To add a file to your QuickPatch:***

Note • *QuickPatch projects do not have support for defining a new target destination for new files that you are adding. Therefore, when you add a new file in a QuickPatch project, the destination location must be a folder that was defined in the original installation.*

1. In the View List under **Define Patch Settings**, click **Files**.
2. Right-click the **Files To Patch** explorer and then click **Insert New File**. The **Open** dialog box opens.
3. Click the file that you want to add, and then click **Open**. InstallShield adds the file to the **Files To Patch** explorer.
4. Click the new file and then configure its settings.

Specifying Identification Information for a QuickPatch

Project • *This information applies to QuickPatch projects.*

Windows Installer 3.0 and later adds an Add or Remove Programs entry for each QuickPatch package that is applied to a target system, even if the QuickPatch is not uninstallable.

Task: ***To specify identification information for a QuickPatch:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Identification** tab.
4. Configure each of the settings.

Enabling the Uninstallation of a QuickPatch

Project • *This information applies to QuickPatch projects.*

Windows Installer 3.0 and later supports the uninstallation of QuickPatch packages for small updates and minor upgrades. However, not all QuickPatch packages can be uninstalled. For details about the uninstallation of standard patches and QuickPatch packages, including the associated limitations, see Patch Uninstallation.

Task: ***To enable the uninstallation of a QuickPatch package:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Common** tab.
4. Select the **Allow Patch to be Uninstalled (Requires Windows Installer 3.0)** check box.

Sequencing QuickPatch Packages

Project • *This information applies to QuickPatch projects.*

Task: ***To define a sequence for a QuickPatch package:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Advanced** tab.
4. Do one of the following:
   - To use default patch sequencing that InstallShield generates, set the **Create patch sequencing entry** property to **Yes**.
   - To use no patch sequencing, set this property to **No**.

Signing a QuickPatch Package

Project • *This information applies to QuickPatch projects.*

Windows Installer 3.0 and later enables you to create patches that can be installed by non-administrators. Non-administrator QuickPatch packages can be used if strict criteria are met. For example, the base installation that the patch will update must include the certificate that will be used to sign the patch package. To learn about the other criteria that must be met, see Non-Administrator Patches.

Note • *With QuickPatch projects, you can digitally sign the patch package and the* `Update.exe` *file. If you want to digitally sign individual files—such as your application's executable files—in your QuickPatch package, you must manually sign them and then add them to your project. You can use* `Signcode.exe` *or* `SignTool.exe` *to manually sign your files. For more information, see Digital Signing and Security.*

Task: ***To sign a patch package:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Digital Signature** tab.
4. Select the **Sign the patch package** check box.
5. Configure the digital signature settings.

Password-Protecting a QuickPatch Package

Project • *This information applies to QuickPatch projects.*

For added security, you can password-protect your QuickPatch package. When you password-protect your QuickPatch package, any end user who wants to apply your QuickPatch must enter a case-sensitive password to launch your update.

Task: ***To password-protect a QuickPatch package:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Advanced** tab.
4. In the **Password Protect Launcher** setting, select **Yes**.
5. In the **Launcher Password** setting, specify the password that you want your patch to use.

Note • *The password is case-sensitive.*

Specifying Whether to Build an Update.exe Update Launcher for a QuickPatch Package

Project • *This information applies to QuickPatch projects.*

InstallShield lets you specify whether you want InstallShield to create an `Update.exe` update launcher for your QuickPatch package.

An `Update.exe` update launcher is required if you want to automatically update or install the Windows Installer engine on a target system if necessary. For more information on when an `Update.exe` launcher is required, see Patching Considerations.

If you configure InstallShield so that it does not create an `Update.exe` update launcher, it creates an .msp file.

Task: ***To specify whether to include an Update.exe update launcher for a QuickPatch:***

1. In the View List under **Define Patch Settings**, click **General Information**.
2. In the **General Information** explorer, click **Build Settings**.
3. Click the **Common** tab.
4. To include `Update.exe`, select the **Create Update.exe** check box.

   To avoid including `Update.exe`, clear the **Create Update.exe** check box.

Tip • *You can also use the Advanced tab in the Build Settings area to specify whether you want to include `Update.exe`.*

Deleting Files from the Files To Patch Explorer

Project • *This information applies to QuickPatch projects.*

Task: ***To delete a file from the Files To Patch explorer:***

1. In the View List under **Define Patch Settings**, click **Files**.
2. Right-click the file that you want to delete and then click **Delete**.

Modifying and Removing Installed Files with a QuickPatch

Project • *This information applies to QuickPatch projects.*

Task: ***To modify or remove an installed file with your QuickPatch:***

1. In the View List under **Define Patch Settings**, click **Files**.
2. Right-click the **Files To Patch** explorer and then click **Patch Existing File**. The **Select File** dialog box opens.

3. Click the file that you would like to modify or delete. InstallShield adds the file to the **Files To Patch** explorer.
4. Click the file that you just added to the **Files To Patch** explorer and then configure its settings.

Tip • *As an alternative to steps 3 and 4 above, you can drag and drop files or folders from the* ***Original Setup Files*** *explorer to the* ***Files To Patch*** *explorer.*

Adding, Modifying, and Deleting Registry Data with a QuickPatch

Project • *This information applies to QuickPatch projects.*

When you add, modify, or delete registry data with a QuickPatch project, the procedures are basically the same as the ones that you perform for the original installation. The one difference is that before you can add registry data for a QuickPatch project, you must select an existing feature in the View Filter list at the top of the Registry view. All registry data must be associated with a feature that already exists in the original product because you cannot add new features or components with a QuickPatch.

Tip • *To change any registry settings that you modified for the QuickPatch project, you can right-click the item and then click Revert.*

Validating Upgrades, Patches, and QuickPatch Packages

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Validation helps identify some common problems that may be encountered when attempting to upgrade an existing Windows Installer–based installation.

Note • *You can perform upgrading and patching validation on uncompressed releases only.*

The validation engine for upgrading and patching currently consists of different validators that are designed to test for a specific condition and report failure as necessary. Upgrading and patching validation was designed to facilitate the detection of upgrade scenario issues and is distinct from Windows Installer validation, which is better suited for validating first-time installation issues.

Validators

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

The following table contains a list of validators for upgrading and patching validation.

Table 8-7 • Upgrade and Patch Validators

Validator Number	Description
Val0001	This validator verifies that when the upgrade is applied, the files that have been removed from the latest version of the installation will be uninstalled from the target machine.
Val0002	This validator detects cases where **RemoveFile** table entries are scheduled to run during installation only.
Val0003	This validator verifies that the proper settings exist so that an upgrade can start successfully.
Val0004	This validator verifies that when the upgrade is applied, all files that have changed in the latest installation will be installed properly on the target system.
Val0005	This validator verifies that feature InstallLevel values are configured so that no feature will be ignored in an upgrade.
Val0006	This validator detects when a minor upgrade is being attempted, even though a major upgrade should be performed.
Val0007	This validator verifies that the name of the .msi package has not changed.
Val0008	This validator verifies the integrity of the ActionProperty and Version elements of all records in the **Upgrade** table.
Val0009	This validator verifies that when the installation is run as an upgrade, registry entries that have been deleted from an installation will be removed.
Val0011	This validator detects when schema incompatibility exists. Schema incompatibility will prevent the creation of a patch.
Val0012	This validator verifies that new features are properly added to the latest installation so that they will be installed when the upgrade is run.

Table 8-7 • Upgrade and Patch Validators (cont.)

Validator Number	Description
Val0013	This validator verifies that the end user is informed of the intended functionality of the Remove attribute for a major upgrade item.
Val0014	This validator warns you that because of a specific entry in the **Upgrade** table, part of the existing product will be left on the target machine when the major upgrade is applied.
Val0015	This validator warns you that if you want to package your upgrade as a patch in certain scenarios, end users will not be able to uninstall your patch. This validator applies to small updates and minor upgrades.

Val0001

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message (Error)

```
The file [1] with a target of [2] appears to have been removed from the setup, but does not appear in
    the RemoveFile table. This file will not be removed from the target machine when an upgrade is
    run unless the RemoveFile table has been authored.
```

[1] is the name of the file that has been removed, while [2] is the target path of this file.

Description

When a small update or minor upgrade is applied, any file or files that have been removed from the latest setup will not automatically be uninstalled from the target machine because a minor upgrade will recache the local .msi database. This recached copy no longer contains any reference to the file, since it has been removed from the setup.

To remove this file when the upgrade is run, you must add entries to the **RemoveFile** table. When the upgrade is run, these **RemoveFile** table entries will be executed, and the file will be deleted.

Note • *This validator does not apply to major upgrades because the uninstall-and-then-reinstall nature of major upgrades does not lend itself to this type of consideration.*

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

Using the file name and file destination from the previous version setup package, create an entry in the **RemoveFile** table using the Direct Editor. The file name can contain wildcard characters.

Note • *When authoring the **RemoveFile** table, you must specify a component. This component's install state is used to determine if a file matching the RemoveFile signature should be removed or not. Be sure to specify a component that you are certain will reinstall when the upgrade is applied.*

Val0002

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message (Note)

```
The RemoveFile table entry [1] has an InstallMode of 1. In an upgrade scenario, if the component [2]
    does not have to reinstall, the files attributed to this table entry will not be removed. You can
    change the InstallMode value to 3 so that the files will at least get removed on uninstall, or
    make sure that this RemoveFile table entry is associated with a component that will get
    reinstalled.
```

[1] is the name of the entry in the first column of the **RemoveFile** table that is causing this message. [2] is the name of the component with which this **RemoveFile** table entry is associated.

Description

When you author an entry in the **RemoveFile** table, you must specify a value in the InstallMode column. If this value is set to 1, this tells the installer that the specified file should only be removed upon installation of the associated component. In an upgrade scenario, if the associated component does not need to be reinstalled, then the **RemoveFile** table entry will not be executed, and the file will not be removed from the target machine.

In a subsequent uninstallation, you will need to manually remove this file and the directory that contains it since the file still exists on the target machine.

Note • *This validator does not apply to major upgrades because the uninstall-and-then-reinstall nature of major upgrades does not lend itself to this type of consideration.*

To perform this validation test, the validation engine will need to compare the latest setup to a previous version of that setup.

Corrective Action

This validator is only a note. It is designed to make you aware of a potential issue with your setup when you are creating an upgrade. If you do not intend on performing an upgrade or you are certain that the component associated with this RemoveFile entry will be reinstalled in an upgrade, you can choose to disregard this note.

You can also choose to change the InstallMode value to 3. In this case, a file will not be removed during installation, but it will always be removed during an uninstallation.

Val0003

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Note)

```
This setup will perform a SMALL upgrade of the referenced previous setup.
```

Message 2(Note)

```
This setup will perform a MINIOR upgrade of the referenced previous setup.
```

Message 3(Note)

```
This setup will perform a MAJOR upgrade of the referenced previous setup.
```

Message 4(Error)

```
The package code for the latest setup does not differ from that of the previous version. In order to
    perform an upgrade, the package code MUST change.
```

Message 5(Note)

```
The product version [1] differs from the product version [2] but only past the third element. The
    Windows Installer does not detect version differences past the third version element.
```

[1] is the version number of the previous installation. [2] is the version number of the latest installation.

Message 6(Error)

```
The setup needs to perform a Major Upgrade of the previous setup specified. However, the Upgrade Code
    for the previous setup [1] is not in the upgrade table. An upgrade will not occur.
```

[1] is the upgrade code of the previous installation.

Message 7(Error)

```
The setup needs to perform a Major Upgrade of the previous setup specified. While upgrade table
    entries exist for the Upgrade Code, there is no upgrade table entry that matches the Product
    Version [1] or Product Language [2].
```

[1] is the version number, and [2] is the language ID of the installation.

Message 8(Error)

```
A previous package does not contain an UpgradeCode property. A major upgrade will fail to uninstall
    any previous versions that do not have an UpgradeCode.
```

Description

This validator determines the type of upgrade that is necessary to update an earlier installation. For example, if you are creating a minor upgrade but this validator states that your installation is configured to perform a major upgrade, consider changing your minor upgrade to a major upgrade.

This validator also checks if the package code has changed. This check is performed for all upgrade types. Changing the package code is a requirement any time that you decide to release an installation, whether or not you intend to upgrade it. If the package code has not changed, you will see the error described in message 4.

If the product version has changed but only past the third version item, the validator displays the note described in message 5. This note is designed to alert you that changes to the fourth item in a version resource will not appear as unique versions to the installer at run time.

Additionally, if a major upgrade is required, this validator will check if the appropriate entries exist in the latest installation to remove the previous installation from the target machine. If these entries do not exist, you will see message 6 or 7. Message 6 is displayed when there are no settings related to the earlier product. Message 7 is displayed when there is a setting related to the earlier product, but the signature of that setting does not patch the signature of the previous setup. Error 8 is displayed if there is a setting related to the earlier product, but the upgrade code was not found in the earlier installation.

Corrective Action

If you receive message 4, you must generate a new package code for the latest version of your installation. A good option is to set the Generate Package Code property for the product configuration to Yes.

If you receive message 5, you can choose to disregard it since it is for informational purposes. However, note that having indistinguishable versions can create difficulties if you attempt to apply a major upgrade at a later date.

If you receive message 6, you need to add a major upgrade item.

There are several possible reasons why you might receive message 7. The first possibility is that the product version does not fall within the range of versions specified as potential target installations. If the version of the previous installation is either the upper bound or the lower bound of the acceptable range of product versions to upgrade, you may want to check the minimum and maximum inclusive settings for your major upgrade item. Additionally, the product language may not be listed in the list of supported languages for upgrading. You will also get error message 7 if you have defined a major upgrade item for the previous setup but have marked that item to **Detect Only**.

If you encounter error 8, remove the earlier package that does not have an upgrade code.

Val0004

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message (Error)

```
The key file '[1]' in component '[2]' is versioned in the previous package and has a lower version or
    is unversioned in the upgraded package (old file version '[3]', new file version '[4]'). This
    will prevent the component from reinstalling in an upgrade scenario.
```

[1] is the name of the key file , [2] is the name of the component that contains the key file, [3] is the version number of the file in the earlier package, and [4] is the version number of the file in the upgrade.

Description

This validator verifies that when the upgrade is applied, all files that have changed in the upgrade will be updated properly on the target system.

At run time during a minor upgrade or small update, Windows Installer does not reinstall a component if its key file would be downgraded in the process. Therefore, the key file in the upgrade needs to have a version number that is equal to or greater than that of the key file in the old package.

The exception is when the end user sets the **REINSTALLMODE** property to **a**, which forces the installation of all files, regardless of version.

Note • *This validator does not apply to major upgrades because the uninstall-and-then-reinstall nature of major upgrades does not lend itself to this type of consideration.*

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

To resolve the error, ensure that the version number of the key file in the upgrade has a version number that is equal to or greater than that of the key file in the old package. As an alternative, you can create a major upgrade.

Val0005

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript MSI*
- *QuickPatch*

Message 1(Warning)

```
The default InstallLevel for feature [1] is zero. If this feature gets enabled on install, you must
    author similar logic to ensure that it is also enabled in maintenance mode, otherwise in an
    upgrade the feature will be ignored.
```

[1] is the name of the feature whose **InstallLevel** is the cause of concern.

Message 2(Warning)

```
A condition for feature [1] may possibly set the InstallLevel for this feature to zero at runtime. If
    this feature gets enabled on install, you must author similar logic to ensure that it is also
    enabled in maintenance mode, otherwise in an upgrade the feature will be ignored.
```

[1] is the name of the feature whose **InstallLevel** is the cause of concern.

Description

The significance of setting a feature **InstallLevel** to zero is that it will cause the feature to appear as disabled at run time, and the user will not be able to enable it. It is tempting to set this feature to zero by default and then enable it as needed through a feature condition.

In an upgrade, if this feature condition does not get evaluated so that it can set the install level to a value other than zero, the **InstallLevel** for the feature will remain at zero. Therefore, no changes made to the components in that feature will be installed.

Another variation of this issue is that the feature **InstallLevel** defaults to something other than zero, but there exists a feature condition that sets this feature **InstallLevel** to zero at run time. This issue raises problems for major upgrades, since the previous installation is already in the field.

Val0005 applies to all upgrade types: major, minor, and small.

To perform this validation test, the validation engine will need to examine only the latest version of your setup.

Corrective Action

Ensure that any processing that can effect the evaluation of these feature conditions is also performed when an upgrade is run. Remember that in an upgrade, the user interface being displayed to the end user may be different from the user interface displayed the first time the installation is run.

Making sure that your feature **InstallLevel** values do not default to zero is important so that a major upgrade will be able to safely install and uninstall files.

Val0006

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript MSI*
- *QuickPatch*

Message 1(Error)

```
The Component [1] identified by ComponentID [2] is missing from the newest version of your setup. You
    cannot delete components and still do a minor/small upgrade. You must perform a major upgrade.
```

[1] is the name of the component that has been removed. [2] is the ComponentID associated with the component that was deleted.

Message 2(Error)

```
The Feature [1] is missing from the newest version of your setup. You cannot delete features and
    still do a minor/small upgrade. You must perform a major upgrade.
```

[1] is the name of the feature that has been removed.

Description

If any components or features have been deleted from the latest version of the installation, you must perform a major upgrade to avoid potential problems associated with leaving resources and registrations on a machine.

Note • *If you move a feature or component to another location in the installation, you have effectively deleted it from its original location.*

This validator does not apply to major upgrades. It identifies when a minor upgrade or small update should be a major upgrade.

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

If you need to make major architecture changes to your installation, you should apply a major upgrade.

You can also use the RemoveFile, RemoveRegistry, and RemoveIniFile tables to clean up some resources that may be orphaned. However, this will not clean up the Windows Installer registration information for those components and features. Leaving that registration information behind can cause unpredictable results in a future upgrade installation or uninstallation of your product.

Val0007

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Error)

```
The MSI package name for the most recent setup [1] differs from the MSI package name of the previous
    setup [2]. Small/Minor upgrades require that the package name remain the same.
```

[1] is the name of the new .msi package that has changed. [2] is the name of the original .msi package.

Description

When you perform a minor upgrade or a small update, the previous and latest versions of your installation must have the same .msi package name. Attempting to perform a minor upgrade or a small update when the .msi file name has changed can lead to Windows Installer run-time error 1316.

This validator does not apply to major upgrades.

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

This is a limitation of the Windows Installer service. The only recourse here is to give your .msi packages the same name. To configure the name of the .msi package, you can use the MSI Package File Name setting on the General tab for a product configuration in the Releases view.

Val0008

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Warning)

```
In the Upgrade table, the Action Property [1] is not listed as a member of SecureCustomProperties.
    The defined upgrade may not function properly.
```

[1] is the name of one of the action properties specified in the **Upgrade** table.

Message 2(Error)

```
In the Upgrade table, the Action Property [1] is not public. The defined upgrade will not function
    properly.
```

[1] is the name of one of the action properties specified in the **Upgrade** table.

Message 3(Error)

```
In the Upgrade table, the Action Property [1] is already defined in the property table. The defined
    upgrade will not function properly.
```

[1] is the name of one of the action properties specified in the **Upgrade** table.

Message 4(Error)

```
In the Upgrade table, the Action Property [1] is used more than once. This may cause undesirable
    results at runtime.
```

[1] is the name of one of the action properties specified in the **Upgrade** table.

Message 5(Error)

```
In the Upgrade table, there exists a record where the MaxVersion [1] is less than the MinVersion [2].
    This will cause unpredictable results a runtime.
```

[1] and [2] are version numbers specified in the **Upgrade** table.

Description

For all records in the **Upgrade** table:

- Ensure that the **ActionProperty** is public.
- Ensure that the **ActionProperty** is unique.
- Ensure that the **ActionProperty** is not predefined in the **Property** table.
- Ensure that the **ActionProperty** is in the **SecureCustomProperties** list.
- Ensure that **MinVersion** is less than or equal to **MaxVersion**.

This validator applies only to major upgrades.

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

To find where the value of the Action property is entered, open the Upgrades view. Select the major upgrade item, and then click the Advanced tab. The Detect Property value is used for the Action property.

Note *• Note the following:*

- *The property is public if it is in all uppercase letters.*
- *The property is unique if it is not shared with any other major upgrade items.*
- *If the property is defined in the **Property** table, go to the Property Manager and delete it.*
- *If the property is not on the SecureCustomProperties list, you can add this to the **SecureCustomProperties** property in the Property Manager. Multiple properties are delimited by semicolons.*
- *Find the major upgrade item in the Upgrades view where the minimum version is higher than the maximum version and correct it.*

Val0009

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Warning)

```
A registry entry has been removed from the component [1]. There exists a corresponding entry in the
    RemoveRegistry table, however, that entry is not associated with this component. This may result
    in the registry entry not being removed when an upgrade is run.
```

[1] is the name of the component from which a registry entry has been removed in the latest version of the setup.

Message 2(Error)

```
A registry entry has been removed from the component [1]. This key must be added to the
    RemoveRegistry table, otherwise it will be orphaned by an upgrade. [2].
```

[1] is the name of the component from which a registry entry has been removed in the latest version of the setup.
[2] is the missing registry entry in the form <Root>|<Key>|<Value>.

Description

When a small update or minor upgrade is performed, any registry entries that have been removed from the latest installation will not automatically be uninstalled from the target machine. The reason is that a minor upgrade will recache the local .msi database. This recached copy no longer contains any reference to these registry entries, since it has been removed from the installation.

To remove this registry entry, add entries to the **RemoveRegsitry** table so that it will be removed when the upgrade is applied. When the upgrade is run, these **RemoveRegistry** table entries will be executed, and the registry entry will be deleted.

Note • *This validator does not apply to major upgrades because the uninstall-and-then-reinstall nature of major upgrades does not lend itself to this type of consideration.*

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

Using the root, key, and value of a registry entry from the previous version of the installation package, create an entry in the **RemoveRegistry** table through the Direct Editor. The Value field can be authored with the minus character (–). This will result in the removal of the entire registry key with all of its values and subkeys.

Note • *When you add an entry to the* ***RemoveRegistry*** *table, you are required to specify a component. This component's install state is used to determine if a registry entry matching this* ***RemoveRegistry*** *signature should be removed. Ensure that you specify a component that you know will be reinstalled when the upgrade is applied.*

Val0011

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Error)

```
The data types for the Version column of the TypeLib table differs from that of the Upgraded image.
    This will cause a failure to create the patch package.
```

Message 2(Warning)

```
The target image was created with Windows Installer 1.2 or previous, and the Upgraded Image was
    created with Windows Installer 2.0 or later. Although validation did not detect any data type
    conflicts, creating patches for packages that span this schema inflection point can be
    problematic.
```

Description

With the release of Windows Installer 2.0, the schema of the .msi installation package changed. The data type of the **Version** column in the **TypeLib** table changed from I2 to I4. It is not possible to patch .msi installations using the old schema with .msi packages using the new schema.

Note • *This validator does not apply to major upgrades because the uninstall-and-then-reinstall nature of major upgrades does not lend itself to this type of consideration.*

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

You can still distribute your upgrade as a minor upgrade, however, you will not be able to distribute your upgrade as a patch.

Val0012

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Error)

```
The new feature [1] is defined as a root level feature. New features MUST be defined as sub-features
    of features that already exist in the original setup.
```

[1] is name of the feature causing the validation message.

Message 2(Error)

```
The validation engine has detected the new feature [1]. This feature must have the 'FavorParent' and
    'Required' attributes set to Yes in order to install in an upgrade scenario.
```

[1] is name of the feature causing the validation message.

Description

If you intend to distribute the latest version of your installation as a small update or a minor upgrade, you must follow certain rules if you decide to add features to the installation. The first rule is that the feature must be added as a child to an existing feature. The second rule is that the feature must have its Remote Installation property set to FavorParent and its Required property set to Yes.

If these two rules are not followed, the contents of the new feature will not be installed when the upgrade is applied. Instead, the end user will need to run the installation in maintenance mode and manually select the feature to be installed locally.

This validator does not apply to major upgrades.

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

Add the new feature as a child of an existing feature, and set its Remote Installation property set to FavorParent and its Required property set to Yes.

Val0013

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript MSI*
- *QuickPatch*

Message 1(Warning)

```
Validation has detected that you are using the Remove column in the Upgrade table for the entry [1].
    Doing this will result in the incomplete uninstallation of the referenced setup. For the most
    common upgrade scenarios, you should not author the Remove column of the upgrade table.
```

[1] is the Upgrade code being referenced in the **Upgrade** table.

Description

When the remove attribute of a major upgrade item is left empty, it will remove all of the features from the target product, effectively uninstalling the entire product.

If you place one feature name in the remove attribute of a major upgrade item, only that feature will be removed, and all of the other features of the existing product will be left on the target machine along with the target product itself. This means that you will be left with two products on the target machine with two entries in Add or Remove Programs.

This feature is intended for users who want to leave the target product on end users' machine while removing only some of its features.

This validator applies only to major upgrades.

To perform this validation test, the validation engine needs to examine the latest installation only.

Corrective Action

This is a warning. If the behavior described above is what you desire, you can disregard this warning. Otherwise, do not use the Remove attribute of a major upgrade item.

Val0014

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Error)

```
The component identified by ID [1] has been removed from the latest version of the setup. On a Major
    Upgrade the resources contained within these components will get uninstalled, possibly deleting
    resources necessary for your application to run.
```

[1] is the component code that identifies a component in the earlier installation.

Description

This validator performs this check only if the major upgrade is configured to install new files, then remove unneeded files. The issue this validator is designed to protect you against does not exist if the major upgrade is configured to uninstall the product first, then reinstall it.

When the target upgrade mode is selected, the installer achieves this functionality by relying on reference count components on the target machine. The reference count for a required component is incremented when the latest application is installed, and it is decremented when the earlier application is removed. However, since the reference count never reaches zero, the persistent components remain on the target machine.

The problem exists when you delete a component from the installation, and then add the resources from that component to a different component. Instead, you should perform the following:

1. Install a new component with new resources.
2. Uninstall the old component with old resources.

When the old component is uninstalled in step 2, it may remove registry entries, .ini file changes, environment variables, and so on if they were added by the new component in step 1.

Since components are referenced by a GUID, and a new component GUID is generated every time you add a new component to your installation project, even a simple deletion or addition of a component that already exists can cause this behavior.

This validator applies only to major upgrades.

To perform this validation test, the validation engine compares the latest installation to an earlier version of that installation.

Corrective Action

To correct this problem, you can either configure your upgrade to uninstall the application first and then reinstall it, or you can add a component with a GUID equal to the one specified in this error message. Even though the component is empty, its existence helps Windows Installer keep accurate reference counts, and it helps to prevent components from being prematurely uninstalled.

Val0015

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

Message 1(Warning)

```
The [1] table contains new content. Therefore, if you are packaging this upgrade as a patch, you will
    not be able to make it an uninstallable patch.
```

[1] is the name of the table that is causing this message.

Description

When an end user uninstalls a patch, the product is returned to the state it was in before the patch was uninstalled. If a patch is not uninstallable, an end user who wants to remove the patch needs to uninstall the patched product and then reinstall the product without applying the patch.

Note • *If a target machine does not meet certain requirements (for example, it must have Windows Installer 3.0 or later), the patch will not be uninstallable, even if this validator warning is resolved. For more information about the requirements for uninstallable patches, see Patch Uninstallation.*

If a patch adds a row to any of the following specific tables, the patch cannot be uninstalled, even if the **Allow this patch to be uninstalled** check box is selected for the patch.

- BindImage
- Class
- Complus
- CreateFolder
- DuplicateFile
- Environment
- Extension
- Font
- IniFile
- ISLockPermissions
- IsolatedComponent
- ISSelfReg
- LockPermissions
- MIME
- MoveFile
- MsiServiceConfig
- MsiServiceConfigFailureActions
- MsiLockPermissionsEx
- ODBCAttribute
- ODBCDataSource
- ODBCDriver
- ODBCSourceAttribute

- ODBCTranslator
- ProgId
- PublishComponent
- RemoveIniFile
- SelfReg
- ServiceControl
- ServiceInstall
- TypeLib
- Verb

Note that under certain conditions, it is possible that an end user may not be able to remove a patch that adds content to the **RemoveFile** or **RemoveRegistry** tables. If the patch is designed to remove a file or registry entry that was not included in the original installation package, uninstalling the patch will not restore that file or registry entry.

This validator applies to small updates and minor upgrades only.

To perform this validation test, the validation engine compares the latest installation to an earlier version if the **Allow this patch to be uninstalled** check box is selected for the patch.

Corrective Action

This validator is designed to warn you that if you are creating a patch—or you later decide to package your upgrade as a patch—your end users will not be able to uninstall the patch unless you take corrective action to resolve it. To resolve this warning, do one of the following:

- Clear the **Allow this patch to be uninstalled** check box for the patch. If you do this, end users will not be able to uninstall the patch.
- Remove the new data from the table mentioned in the warning message. Note, however, that depending on your patch requirements, removing new table data may mean that your patch will not fix the issue in your application that led you to create the patch in the first place.

Patching Assemblies in the Global Assembly Cache

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *QuickPatch*

With Windows Installer 3.0 or later, the **MsiPatchOldAssemblyFile** and **MsiPatchOldAssemblyName** tables enable a patch package to patch an assembly in the global assembly cache (GAC) without making a run-time request for the original installation source. By default, InstallShield automatically generates entries for these tables when you build a patch or QuickPatch package. (To disable this automatic generation in a patch or QuickPatch project, set the **Generate MsiPatchOldAssembly tables** property to No. For a patch, this property is on the Advanced tab of the patch configuration item in the Patch Design view. In a QuickPatch project, this property is on the Advanced tab of the Build Settings item in the General Information view.)

Note • *To automatically generate entries for the **MsiPatchOldAssemblyFile** and **MsiPatchOldAssemblyName** tables, InstallShield must have write access to the latest version of the .msi package to which the patch applies. InstallShield modifies this package before creating the patch. InstallShield automatically attempts to make this package writable; if it cannot, a build warning is generated, and the table entries are not created.*

These table entries are applied only if the target system is running Windows Installer 3.0 or later. The patch runs if the system is running Windows Installer 2.0; however, these tables are ignored, and if the patch needs to update a file in the GAC, it makes a request for the original source package. InstallShield generates these table entries even if you include only the Windows Installer 2.0 engine in `Update.exe`, since a target system with Windows Installer 3.0 or later already installed can use them.

Working with Differential and Full Releases

Project • *This information applies to InstallScript projects.*

InstallShield provides two different mechanisms for creating upgrades for InstallScript installations:

- You can package your upgrade as a full release that updates an existing product if an earlier version is installed, or behaves as a first-time installation if no earlier version is present.
- You can package your upgrade as a differential release that contains only the changed data (byte-level file differences) between the versions to be updated.

For step-by-step instructions on how to update an InstallScript installation by either creating a differential or full release, consult this section of the help.

Creating an InstallScript Release to Update Previous Versions

Project • *This information applies to InstallScript projects.*

InstallShield enables you to create a release for an InstallScript project to update one or more existing versions of your application. You can customize any necessary criteria through the script.

Note • *If the product that you want to update was not installed by an installation created with InstallShield X or later, InstallShield DevStudio, or InstallShield Professional 6.0 or later, you must create a new project. You may also want to consider creating a new project if you plan to include extensive changes in this update.*

Task: ***To create an update release:***

1. Open a new or existing InstallScript project.
2. Verify that the product code matches the GUID with which the previous version of your product was installed. To check the product code, in the **General Information** view, inspect the value of the **Product Code** setting.

   

   Note • *If you are creating a new project and you want to update features that were installed by the original installation, ensure that each feature's GUID matches the GUID with which the previous version of that feature was installed. To check a feature's GUID, select it in the **Features** or **Setup Design** view and inspect the value of its GUID property.*
3. Specify a version number for your product update:
   c. In the View List under **Installation Information**, click **General Information**.
   d. In the **Version** setting, type the version number.
4. Indicate whether you want to build a differential or full release:
   a. In the **Releases** view, click the desired release.
   b. If you want to build a differential release, set the value of the **Differential Media** property to **Yes** and continue with step 6. If you want to build a full release, leave the property set to **No** and continue with step 5.

   

   Note • *If you are using the **Release Wizard**, the **Update** panel is where you select the release format (Full or Differential).*
5. If you are building a full release, specify the versions of your product to which the update should be applied. In the **Supported Versions** property, type the applicable version numbers using a semicolon to separate the different versions (for example, `1.2.3;1.2.4`). If you leave the **Supported Versions** property blank or select the **Non-version specific**, the update is applied to all earlier versions of your product. Continue with step 7.

   

   Note • *These version numbers can also be specified in the Release Wizard by selecting version numbers from the box on the **Update** panel. Do not specify version numbers that correspond to releases that were created by versions of InstallShield Professional earlier than 6.0 because those releases cannot be updated.*

6. If you are building a differential release, you must use the **Release Wizard** to specify one or more existing releases to which the current project is compared when creating the new differential release.

   

   Note • *Do not specify existing releases that were created by versions of InstallShield Professional earlier than 6.0 because those releases cannot be updated. Only the specified existing releases can be updated by the resulting differential release. To review the criteria that determine whether a file in the current project is included in a differential release, see Differential vs. Full Releases.*

   - To specify a release in the current project:
     a. In the **Releases** view, right-click the release name and select **Release Wizard**. The **Release Wizard** opens.
     b. In the **Update** panel, click **Add**. The **Add Existing Media** dialog box opens.
     c. Select the desired release.
     d. Click **OK**.
   - To specify a release that is not in the current project:
     a. In the **Releases** view, right-click the release name and select **Release Wizard**. The **Release Wizard** opens.
     b. In the **Update** panel, click **Import**. The **Media File Properties** dialog box opens.
     c. Specify the Data1.hdr file of the desired release by either entering the fully qualified file name in the **Media Header File** box or select or clicking the browse button to browse for the file.
     d. Click **OK**.
   - Confirm the specified release's version information is displayed in the **Differential Media** box of the **Update** panel. If no version information is displayed, do the following:
     a. Select the release in the list box and click **Modify**. The **Media File Properties** dialog box opens.
     b. Select the **Specify the version information below** option and type or select a version number in the list.
     c. Click **OK**.

7. Build the release.

See Migrating from InstallShield Professional 6.x for more information on using a version 6.x-created script with an update-enabled installation.

Notifying End Users about Upgrades Using FlexNet Connect

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.

FlexNet Connect provides a mechanism that enables you to automatically notify your Web-connected end users when patches, updates, and product information for your application are ready for release.

FlexNet Connect Implementation

There are two cycles of tasks that you perform when using FlexNet Connect to automatically inform end users about updates: initial deployment and update deployment. Once you have performed the initial deployment steps for your application, each time you want to distribute an update of that application to end users, you perform the update deployment cycle of steps. To learn about the initial deployment steps, see Preparing Installations for Update Notifications.

Update Deployment

1. Use InstallShield to create an update for your application.
2. Register your new product version and product code with the FlexNet Connect Publisher site, a Web-based management portal.
3. Publish your update to the FlexNet Connect Publisher site, and set the **Message Status** to **Test**.
4. Test your update.
5. Publish your update to the FlexNet Connect Publisher site, and set the **Message Status** to **Active**.

FlexNet Connect includes a variety of options that can be purchased together for a complete solution, or separately for a customized solution. To learn more, visit the Flexera Software Web site.

9

Additional Installation Options

In addition to helping you create an installation package that installs products, InstallShield provides other installation options to help you enhance your final installation package. Some of these options include enabling multilingual installations, building conditional statements, and defining installation prerequisites.

Read more about additional installation options in the following sections.

Creating Multilingual Installations

Edition • *The Premier edition of InstallShield includes support for creating multilingual installations.*

InstallShield supports many features that enable you to customize your installation for global distribution. Using these features, you can create a single installation project that displays end-user text in multiple languages and can handle conditional installation of language-specific files.

Creating a multilingual installation primarily involves separating code from language-specific resources and files. You may also need to distribute separate files for your installation, such as graphics, license files, or custom actions, depending on the language in which the installation is running. Another consideration is whether you need to install different application files depending on the target system's locale.

Task: ***InstallShield enables the creation of multilingual installations by dividing installation authoring into the following distinct tasks:***

- Specify the languages that your installation will include.
- Translate the strings for each supported language.
- Modify end-user dialogs as necessary for each language.
- Mark any language-dependent components.
- Select the languages to include in the release.

Globalization Tips

Consider these points when designing your product for a global audience:

- The goal of global distribution is a localized product that is international in scope and readily adaptable to specific areas of the world.
- The key to globalization is resource and code separation, plus country and language independence.
- Globalizing your installation requires a design that is simple and modular.
- Creating a worldwide specification package means incorporating global requirements into the installation specifications from the beginning.
- Make bitmaps and icons culturally sensitive. What may be acceptable in one country could be misleading or offensive in another.
- English strings are usually shorter than equivalent text strings in other languages. Translated strings grow an average of 30 to 40 percent. This implies that both static and temporary storage areas will increase in size.
- When designing prompts, use only one-half of the available space to allow for expansion.

- Avoid hard-coding element positioning and size on the screen, because these items can change when the element is translated.

Setting the Default Project Language

One of the project's supported languages must serve as its default language. The default language determines the following:

- The localizable strings that you specify throughout various views in InstallShield—such as the Display Name setting for a feature or the Description setting for a shortcut—are all from the default language's string entries, which you can see in the String Editor view. You can edit the values for the default language in the String Editor view, or in the other views throughout InstallShield.
- If your installation does not include the language selection dialog and it also does not include support for a target system's language, the default language is the language in which the installation runs on that target system. (The language selection dialog lets end users select which language version of the installation they would like to run.)

You can use the General Information view or the String Editor view to specify or change the default language.

Task: ***To use the General Information view to specify or change a project's default language:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Default Language** setting, select the appropriate language.

Task: ***To use the String Editor view to specify or change a project's default language:***

1. In the View List under **User Interface**, click **String Editor**.
2. In the **Default Language** box, select the appropriate language.

Tip • *You can override the default user interface language for a particular release. To do so, select the appropriate language in the Default Language setting on the Build tab in the Releases view.*

Settings for Languages

Edition • *The Premier edition of InstallShield includes support for creating multilingual installations.*

InstallShield lets you set languages at the project level, at the component level, and at the release level. Specifying languages at each level has different affects on your project. The following table describes various language-related settings.

Table 9-1 • Language Settings in InstallShield

Setting	Project Type	Description
General Information view setting—Setup Languages	Advanced UI, Basic MSI, DIM, InstallScript, InstallScript MSI, InstallScript Object, Merge Module, Suite/Advanced UI	 ***Project*** • *The behavior of this setting varies, depending on the project type.* In Basic MSI, InstallScript MSI, Merge Module, and Suite/Advanced UI projects, the Setup Languages setting lets you specify the languages that you want to be listed in the UI Languages setting in the Releases view. If a language is not listed for this Setup Languages setting at the project level, you cannot include that particular UI language in your project's releases. Advanced UI projects, which are available in the Professional edition of InstallShield, have support for only one language. Therefore, the Setup Languages setting in this project type is read-only. In InstallScript and InstallScript Object projects, the Setup Languages setting lets you specify the languages that you want to be listed in the Languages setting in the Components and Releases views in your project. In general, if a language is not listed for this setting at the project level, you cannot designate that a particular component in your project is targeted for that language; in addition, you cannot designate that the components and UI strings for a particular language are included in your project's releases. When you add a supported language to a Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module, or Suite/Advanced UI project through this setting, InstallShield adds string entries for that language to your project. The string entries include the built-in user-interface string resources that are already translated. In DIM projects, the Setup Languages setting lets you specify the languages that you want the project to support. When you add a language to your project through this setting, InstallShield adds string entries for that language to your project. The string entries include string resources that you would need to have translated. For more information, see Selecting the Installation Languages.

Table 9-1 • Language Settings in InstallShield (cont.)

Setting	Project Type	Description
Component setting—Languages	Basic MSI, DIM, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	The Languages setting for a component enables you to specify the languages for which the component is intended, for use in build-time filtering. By default, components are language independent, meaning that none of the component's data (such as files and registry entries) are specific to a particular language.  ***Project*** • *In InstallScript and InstallScript Object projects, if a language is not selected in the General Information view of a project, it is not listed as one of the available languages for the project's components.* To designate that the component is intended for only certain languages, click the ellipsis button (...) in this setting. The Languages dialog box opens, enabling you to select the appropriate languages for the component. For more information, see Marking Components as Language Dependent.  ***Tip*** • *To learn how to specify which language-dependent components are installed at run time, see Installing Components Based on Language.*
Releases view setting (Build tab)—Data Languages	Basic MSI, InstallScript MSI, Merge Module	If you want to include certain components and exclude others based on the language that is selected for each component, click the ellipsis button (...) in this setting and specify the appropriate languages. If the language specified for a component does not match one of the languages that is selected for this setting, InstallShield does not include the component in the release. By default, releases are language independent; that is, none of the project's components are excluded from the release.
Releases view setting (Build tab)—UI Languages	Advanced UI, Basic MSI, InstallScript MSI, Merge Module, Suite/Advanced UI	The UI Languages setting lets you specify which user interface languages you want to include in a release. To select the appropriate languages, click the ellipsis button (...) in this setting. Note that if a language is not selected in the Setup Languages setting in the General Information view of the project, it is not listed as one of the available languages for the UI Languages setting.

Table 9-1 • Language Settings in InstallShield (cont.)

Setting	Project Type	Description
Releases view setting (Build tab)—Language(s)	InstallScript, InstallScript Object	Use the Language(s) setting if you want to include certain components and exclude others based on the language that is selected for each component. This setting also lets you specify which user interface languages you want to include in a release. If the language specified for a component does not match one of the languages that is selected for this setting, InstallShield does not include the component in the release. In addition, if a UI language that is included in the project does not match one of the languages that is selected for this setting, InstallShield does not include the UI strings in the release. By default, releases are language independent; that is, none of the project's components or UI strings are excluded from the release. Note that if a language is not selected in the General Information view of a project, it is not listed as one of the available languages for the Language(s) setting.

For information about the default language in a project, see Setting the Default Project Language.

Selecting the Installation Languages

Edition • *The Premier edition of InstallShield includes support for creating multilingual installations.*

If you have the Premier edition of InstallShield, you can select the languages that you want to include in your installation. When you add a language to your project, InstallShield adds string entries for that language.

To add supported languages to your project, use the Setup Languages setting in the General Information view. The affect of this setting differs, depending on what project type you are using.

- In Basic MSI, InstallScript MSI, Merge Module, and Suite/Advanced UI projects, the Setup Languages setting in the General Information view lets you specify the languages that you want to be listed in the UI Languages setting in the Releases view. Therefore, if a language is not listed for this Setup Languages setting at the project level, you cannot include that particular UI language in your project's releases.
- In InstallScript and InstallScript Object projects, the Setup Languages setting in the General Information view lets you specify the languages that you want to be listed in the Languages setting in the Components and Releases views in your project. In general, if a language is not listed for this setting at the project level, you cannot designate that a particular component in your project is targeted for that language; in addition, you cannot designate that the components and UI strings for a particular language are included in your project's releases.

When you add a supported language to your project through this setting, InstallShield adds string entries for that language to your project. The string entries include the built-in user-interface string resources that are already translated.

The New Language Wizard in InstallShield lets you add unsupported languages to projects. An unsupported language is one in which none of the default run-time strings are translated. When you add an unsupported language to a project, that language is made available in the Setup Languages setting, and in other various language-related settings throughout InstallShield. In addition, InstallShield uses the strings from your project's default language as placeholders for the strings in that newly added unsupported language; you can use the String Editor view to provide translated strings for unsupported language.

You can build an installation for distribution in as many languages as you have support for, but InstallShield runs an installation in only one language. For more information, see How an Installation Determines Which Language to Use for the User Interface.

Marking Components as Language Dependent

All new components are language independent by default. Mark a component as specific to a language if you want the component and its data built into a package that targets that language.

Task: ***To mark a component as language dependent:***

1. In the View List under Organization, click **Setup Design** (for installation projects only) or **Components**.
2. Select the component that you want to configure as language dependent. InstallShield displays the component's settings in the right pane.
3. Click the **Languages** setting. InstallShield displays the list of languages in the bottom-right pane.
4. Select the check box for each language to which this component's data apply. Clear the check box for each language that does not apply.

Tip • *To learn how to specify which language-dependent components are installed at run time, see Installing Components Based on Language.*

Installing Components Based on Language

Assuming that its feature is selected for installation, a language-dependent component that is present in the release is installed onto the target system. The component's language setting determines which components are built into the release, not necessarily which components are installed.

Specifying Which Language-Dependent Components Are Installed at Run Time for Basic MSI and InstallScript MSI Projects

To specify whether a component is installed based on the target system's language, use the Windows Installer property **SystemLanguageID** in the component's Condition setting.

For example, the following condition allows the component—which may or may not be marked as French in InstallShield—to be installed only onto French (France) systems:

```
SystemLanguageID = 1036
```

Other properties that can be used to determine language characteristics at run time are **UserLanguageID**, which is the numeric identifier of the end user's default language, and **ProductLanguage**, which is the identifier of the language in which the installation is running.

Specifying Which Language-Dependent Components Are Installed at Run Time for InstallScript Projects

During run time of InstallScript installations, you can control the languages that your installation supports by calling the **FeatureFilterLanguage** function.

In the **OnFilterComponents** event handler, the framework typically calls this function with the languages that match the target system so that only the appropriate components are installed. By calling **FeatureFilterLanguage**, you can override this default behavior to install or prevent the installation of components based on any language criteria that you specify.

For more information, see FeatureFilterLanguage.

Including Languages in the Release

Edition • *The Premier edition of InstallShield includes support for creating multilingual installations.*

When you configure a release through the Release Wizard or the Releases view, you can specify the language of the installation's end-user interface and for filtering language-dependent application data.

You can use the same project to build a version of your release for any of the supported languages. Or you can select multiple languages in the Release Wizard or the Releases view to create a single installation that is capable of running in any one of the included languages and installing components specific to any number of languages.

Including User-Interface Resources for a Language

You decide which languages to make available in your installation in the Release Wizard or the Releases view.

While you can create a package that contains support for several languages, the installation itself is presented in only one language. For more information, see How an Installation Determines Which Language to Use for the User Interface.

Including Language-Dependent Components

Another consideration is which of your application's language-dependent data you want to include in your project. By marking a component as language dependent and then configuring the appropriate language-related setting on the Build tab in the Releases view as needed, you can automatically include or exclude (filter) that component from the release. You can also specify the language for the release in the Release Wizard.

If you do not select specific languages at the release level, InstallShield includes all components in the release. If you select a language, InstallShield builds all components that are specific to that language and all language-independent components into the release. For example, choosing to build an English-only release means that Japanese components—that is, components with Japanese selected for the Languages setting—are filtered out.

Tip • *You may have components specific to several languages depending on your selections for the language-related setting in the Releases view or the Release Wizard. To learn how to install them only on machines with a specific locale, see Installing Components Based on Language.*

Translating String Entries

Instead of hard-coding strings throughout your project, you can use string entries in areas of InstallShield that accept localizable text. Each string entry consists of a language-independent identifier and a corresponding language-specific value. At run time, the installation displays the appropriate translated string values.

To help streamline the process of localizing a project, all of the text strings that may be displayed at run time during the installation process are available in one consolidated view: the String Editor view. You can use this view to edit the strings for everything from button text to feature descriptions. You can also use this view to export each language's string entries to a file, translate the values that are listed in the file, and then import the translated file into your project.

For information on working with string entries, see Using String Entries in InstallShield.

For import and export instructions, see Exporting and Importing String Entries.

Exporting and Importing String Entries

To ease the task of translating all of the run-time strings in your project, InstallShield enables you to export the string entries for a language to a tab-delimited text (.txt) file. You can provide that .txt file to a translator who can update the file with translated text. Then you can import the .txt file back into your InstallShield project for a localized end-user interface.

Tip • *To automate the export and import process, you can use the InstallShield automation interface. To learn how, see Exporting and Importing String Entries Using the Automation Interface.*

Exporting a Language's String Entries from InstallShield to a Text File

InstallShield lets you export all of the string entries for a language, or only some of the string entries. You may want to export only the string entries that have been modified since a specific date. This is useful if you want to give the translator only the string entries that are new or have been modified since the last round of translations.

Task: ***To export all of the string entries for a language:***

1. In the View List under **User Interface**, click **String Editor**.
2. Click the **Export Strings** button. The **Select File and Language to Export** dialog box opens.
3. Browse to the location where you want InstallShield to save the text file.
4. In the **File name** box, enter the name of the text file that you want InstallShield to create.
5. In the **Language** list, select the language whose strings you want to export to the text file.
6. Click **Save**.

InstallShield exports all of the selected language's string entries to a tab-delimited Unicode text file. You can give this text file to your translator.

Tip • *By default, the export process creates a Unicode text file. Although the* ***Select file and language to export*** *dialog box has a check box that lets you export the string entries to an ANSI file, an ANSI file is not created by default. The Unicode text file is the preferred type of file, since ANSI files requires that the build machine have the appropriate code pages for double-byte languages. To learn more, see Code Page Requirements for Language Support.*

Task: ***To export only some of the string entries for a language:***

1. In the View List under **User Interface**, click **String Editor**.
2. Select the string entries that you want to export:
   - To select multiple consecutive rows, click the first row, and then press SHIFT while clicking the last row.
   - To select multiple nonconsecutive rows, click the first row, and then press CTRL while clicking each additional row.
3. Press CTRL+C to copy the string entries in the selected rows to the Clipboard.
4. Create a new text file in a text editor such as Notepad.
5. Press CTRL+V to paste the content in the Clipboard in the text file.
6. Save the text file. It is recommended that you save the file with Unicode encoding, since Unicode supports double-byte characters. To learn more, see Code Page Requirements for Language Support.

Tip • *The automation interface lets you automate the process of exporting only the string entries that have been modified since a specific date. To learn more, see Exporting and Importing String Entries Using the Automation Interface.*

Importing String Entries from a Text File Into an InstallShield Project

InstallShield lets you import translated string entries from a text file to an InstallShield project.

Task: ***To import the tab-delimited text file that has been translated:***

1. In the View List under **User Interface**, click **String Editor**.
2. Click the **Import Strings** button. The **Select File and Language to Import** dialog box opens.
3. Select the text file that you want to import.
4. In the **Language** list, select the language for the text entries that you are importing.
5. Click **Open**.

The string entry importer checks for conflicts with string identifiers. If any conflicts exist, InstallShield prompts you to indicate whether you want to overwrite the existing entry in your project with the one in the text file.

Modifying Dialogs for Each Language

When you add support for a language to your project, InstallShield provides a version of each standard dialog translated into the newly added language. You can edit these dialogs, as well as custom or imported dialogs, for each supported language in the Dialog Editor.

Task: ***To view these dialogs:***

1. In the View List under **User Interface**, click **Dialogs**.
2. In the **Dialogs** explorer, expand the **All Dialogs** item.
3. Double-click the name of a dialog to see an item for each supported language.
4. To modify a dialog's layout, select the language version.

The rule to remember is that all controls have the same properties, string entries, and behavior for each language. When you add a control to the English (United States) copy of a dialog, you are adding the same control to the German version. Setting the Sunken property of a bitmap to True makes that property True for each language-specific version.

Resizing Elements

The exceptions to the above rule are the Height and Width properties of a control. These properties are specific to each language's version. Because string lengths can vary widely from one language to another, when you resize a control, you are not affecting the control's size for any other language.

For example, you may need to enlarge a push button to accommodate a longer string after it is translated into German. The push button remains the same size for every version of the dialog since it was created. When you resize the control in the German layout, it is resized only for that language.

Modifying Strings

The strings in each dialog come from that language's string entries. When you select a string for a control that accepts localizable text, although the string identifier is the same for each language-specific version, the string value that is displayed comes from the current language's string entries. If you edit the value in the control's property sheet, you are actually editing that string identifier's value for that language.

Modifying File Resources

Several controls, such as bitmaps and check boxes, accept a file that will be streamed into the setup package. Because the file resources can be different depending on the language, when you edit the File Name value, you will be supplying a file only for that particular language.

The file name can differ for each language because every File Name property uses a string entry. Thus, the file name is originally the same for every language. When you edit strings in the String Editor view or edit the dialog layout for a specific language, you can enter a new file name only for that language.

Right-to-Left-Language Dialogs

Basic MSI and Merge Module projects include support for languages that are written and read from right to left. For more information, see Dialog Support for Right-to-Left Languages.

How an Installation Determines Which Language to Use for the User Interface

Although you can localize an installation in as many languages as your project supports, an installation can be run in only one language. When `Setup.exe` initializes, it determines which language should be used for the installation.

Determining the Language at Setup.exe Initialization

If your installation has support for more than one language (that is, if you selected more than one language in the Setup Languages panel of the Release Wizard or on the Build tab for the release in the Releases view), and if one of those languages matches one of the following items on a target system, `Setup.exe` launches the installation in the matching language. Note that the installation evaluates the following items in the order that they are listed and uses the first language that matches:

1. The language that the end user specifies through the /L command-line parameter
2. If an earlier version of the product was installed on the target system and is still present, the language that was used to install the earlier version

3. The user default language of the target system
4. The system default language of the target system
5. The system default UI language of the target system
6. The default language for the installation, which you can set in the Setup Languages panel of the Release Wizard, or on the Build tab for the release in the Releases view

If your installation has support for only one language, `Setup.exe` launches the installation in that language.

Displaying the Language Selection Dialog at Run Time

InstallShield lets you specify whether you want `Setup.exe` to display the Languages dialog that allows end users to choose the language in which the installation should run. The dialog presents a list of available languages, which are the same languages that you select in the Setup Languages panel of the Release Wizard, or on the Build tab for the release in the Releases view. The text on the Languages dialog is displayed in the language that `Setup.exe` selects at initialization.

When the end user makes a selection on the Languages dialog, a Basic MSI or InstallScript MSI installation applies a transform that contains all of the user interface resources for that language and then launches the installation in the selected language.

In an InstallScript installation, the user interface resources are stored in the _isres*.dll files. The strings are built into string table files that are included with the installation's support files, along with the _isres*.dll files.

Because the Languages dialog is displayed by `Setup.exe`, you need to create a setup launcher if you want the Languages dialog to be included in the user interface of your installation. For more information, see Creating a Setup Launcher.

Note • *The first time that the end user selects a language in the Languages dialog, the installation runs in the selected language. After an installation has been run in a particular language, it cannot be run in any other language on the same machine. This prevents the installation from running repair mode in a language that is different from the one that was used for the first-time installation. It also prevents the installation from installing features for a language that is different from the one that was used for the first-time installation.*

Customizing Language Support

Edition • *The New Language Wizard is available in the Premier edition of InstallShield.*

Project • *The New Language Wizard is available in the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*

- *Suite/Advanced UI*

If you need your installation to run in languages that are not supported by InstallShield Premier Edition, or you want to create your own translations for some of the supported languages, you can add support for those languages with the New Language Wizard. This wizard lets you to select the languages that you would like to support and the projects to which you would like to add these languages. It then adds the languages you choose to the list of available languages for your installation.

To learn more about this wizard, see New Language Wizard.

Language Identifiers

Throughout the InstallShield interface, you must refer to specific languages by their language identifiers, or LCIDs. The identifier is an integer value that identifies a specific language. The language ID is more commonly given as a hexadecimal value, but you must specify the decimal version for Windows Installer.

The following table shows the LCIDs for all of the supported languages. To learn more about language support, see Run-Time Language Support in InstallShield.

Project • *Note that Basic MSI and InstallScript MSI installations use different IDs than InstallScript installations.*

Edition • *Also note that support for Arabic (Saudi Arabia) and Hebrew is available only in Basic MSI, Merge Module, and Suite/Advanced UI projects in the Premier edition.*

Table 9-2 • Language Identifiers

Language Name	Identifier (InstallScript Projects)	Identifier (Windows Installer–Based Projects and Suite/ Advanced UI Projects)
Arabic (Saudi Arabia)	(This language is not supported.)	1025
Basque	0x042d	1069
Bulgarian	0x0402	1026
Catalan	0x0403	1027
Chinese (Simplified)	0x0804	2052
Chinese (Traditional)	0x0404	1028
Croatian	0x041a	1050
Czech	0x0405	1029

Installing Multiple Instances of Products

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

Caution • *Creating an installation that lets end users install multiple instances of a product on the same machine and in the same context requires sophisticated authoring and serious commitment on the part of the installation developer. This functionality is recommended for only advanced installation developers.*

Windows Installer allows only one instance of a product code to be installed in the machine context and only one instance to be installed in each user context. Windows Installer 3.x and later includes support for a product code–changing transform. This type of transform—called an *instance transform*—enables the same .msi package to be used to install multiple instances of the same product in the same context because it changes the product code for each instance.

Using the multiple-instance support in InstallShield reduces some of the effort needed to support multiple instances of a product. With InstallShield, you can configure one base installation or patch for a product and then configure multiple instances that correspond with each additional instance that you want to support. At build time, InstallShield creates an instance transform for each instance and streams the instance transforms into the .msi package. At run time, the installation typically displays an instance selection dialog that lets end users specify whether they want to install a new instance or maintain an existing one.

Run-Time Requirements for Multiple-Instance Support

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

The following table lists the operating system and Windows Installer requirements for multiple-instance support.

Table 9-1 • Run-Time Requirements for Multiple-Instance Support

Type of Requirement	Requirement	Implication
Target operating system	The target system must have one of the following operating systems, or a later version: • Windows Server 2003 • Windows Vista • Windows XP SP1	Consider adding a launch condition so that end users can install the product only on platforms that support installing multiple instances of products.  ***Tip*** • *You can use the Installation Requirements page of the Project Assistant to quickly add launch conditions to your project. For more information, see Specifying Operating System Requirements in the Project Assistant.*
Windows Installer version	Windows Installer 3.0 or later is required.	If target systems may not have Windows Installer 3.0 or later, consider adding the Windows Installer redistributable to your project. To learn more, see Adding Windows Installer Redistributables to Projects.

Configuring Multiple Instances in InstallShield

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

The typical process for adding multiple-instance support to a Basic MSI project is as follows:

1. For a product configuration in the Releases view, add a new instance for each instance that you want to support.
2. Set the properties for each instance.
3. Ensure that each instance will have its own isolated files and nonfile data on the target system if appropriate. For more information, see Special Considerations for Multiple-Instance Support.
4. Build your release.
5. Thoroughly test your release.

Adding an Instance to a Product Configuration

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

When you are configuring multiple instances for your product in InstallShield, you need to add and define one instance for each instance to be installed, in addition to the base instance that is permitted by your base installation package. In InstallShield, instances are defined at the product configuration level. Each instance that you create corresponds with a different instance transform that InstallShield creates at build time.

Note • *Do not add an instance for the base instance that is permitted by your installation package. Your installation does not need an instance transform for this instance.*

Task: ***To add an instance to a product configuration:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the product configuration that should contain the new instance.
3. Click the **Multiple Instances** tab.
4. Right-click the **Instances** explorer and then click **New**.

InstallShield adds a new instance with a number as the name of the instance. In addition, InstallShield adds the **ProductCode** property, with a new GUID value, to the pane on the right.

Once you have added an instance, you need to set its properties. For more information, see Setting Properties for an Instance.

Tip • *When InstallShield adds the new instance to the Instances explorer, you can enter a new name for the instance, or right-click the instance later and then click Rename. For information on naming an instance, see Naming an Instance.*

Naming an Instance

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

When you add the first instance to any product configuration in your project, InstallShield adds the Windows Installer property **InstanceId** to your project, and sets its value to 0. The 0 value is for the base installation package. Each instance that you define in your project must have a different integer for its **InstanceId** value.

InstallShield uses the name of an instance on the Multiple Instances tab in the Releases view as the **InstanceId** property value that corresponds with that instance. Therefore, when you are naming an instance, make sure that you conform to the following guidelines:

- Each instance in a product configuration must have a different name.
- Each instance name must be an integer: it cannot contain any letters or other characters.

Task: ***To assign a new InstanceId value to an instance:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the product configuration that contains the instance that you want to modify.
3. Click the **Multiple Instances** tab.
4. In the **Instances** explorer, right-click the instance whose **InstanceId** property value you want to change, and then click **Rename**.
5. Enter a new value.

Setting Properties for an Instance

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

Each instance must have a unique product code. Therefore, when you add an instance to a product configuration in the Releases view, InstallShield automatically adds the **ProductCode** property, with a new GUID value, to the pane on the right for that instance.

You should also set the **ProductName** property to a different name for each instance. This helps to make instances easily distinguishable from each other in Add or Remove Programs.

You can set additional properties for an instance. For example, you may want to define instance-specific properties that you use in conditions for components. As another example, you may want to set a property for each instance to define an instance-specific location for certain files or registry entries.

If you want to create major upgrades that can be applied to each individual instance, set the **UpgradeCode** property to a different GUID for each instance. Note that when you add a major upgrade item to your project in the Upgrades view, ensure that you select the **Products sharing my Upgrade Code** option on the Common tab for the major upgrade item.

Tip • *InstallShield automatically sets the value of the* ***InstanceId*** *property with a different identifier for each instance in a product configuration. To learn more, see Naming an Instance.*

Task: ***To set a property for an instance:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the product configuration that contains the instance.
3. Click the **Multiple Instances** tab.
4. In the **Instances** explorer, click the instance.
5. In the grid in the right pane, click the field in the **Property** column of the last row, and then enter the name of the property that you want to set.
6. In the **Value** column, enter the property value that you want to be associated with the current instance.

To set the value of a property for the base instance—the instance that is installed by the base installation package—enter the property and corresponding value in the Property Manager view. To learn more, see Creating Properties.

Deleting an Instance from a Product Configuration

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

If you want to reduce the number of instances of your product that are allowed in the machine context and in each user context, you can delete an instance from a product configuration in your project.

Task: ***To delete an instance from a product configuration:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the product configuration that contains the instance that you want to remove.
3. Click the **Multiple Instances** tab.
4. In the **Instances** explorer, right-click the instance that you want to remove, and then click **Delete**.

InstallShield deletes the instance, as well as all of its associated properties, from your project.

Special Considerations for Multiple-Instance Support

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

Caution • *Creating an installation that lets end users install multiple instances of a product on the same machine and in the same context requires sophisticated authoring and serious commitment on the part of the installation developer. This functionality is recommended for only advanced installation developers.*

Supporting the installation of multiple instances of a product requires careful advance planning to ensure that the multiple instances can exist side by side within the same context. Consider the following points when you are planning your installation.

- To ensure that uninstalling or upgrading some instances of your product does not affect other instances, you may need to isolate some or all of the files and the nonfile data that are installed on the target system for each instance.
- In some cases, you may not want to isolate some of the files. For example, if your installation includes one or more COM servers, you may want to configure each component that contains a COM server to install to a location that does not change for each instance. For these components, you can select Yes for the Shared setting so that Windows Installer uses DLL reference counting.
- You may need to create a separate set of components for each instance that your installation supports. In this scenario, you could add a condition in the Components view or the Setup Design view for each component so that each one is installed for the appropriate instance. For example, since the default **InstanceId** value for the base instance that is installed by the installation is 0, you could use the following condition for a component that contains data for the base instance:

  ```
  InstanceId=0
  ```

  The default **InstanceId** value for the next instance that is installed is 1. Therefore, you could use the following condition for a component that contains data for this next instance:

  ```
  InstanceId=1
  ```

For more information, see Authoring Multiple Instances with Instance Transforms in the Windows Installer Help Library.

Configuring and Building a Release that Includes Multiple-Instance Support

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

Configuring the Release

To include multiple-instance support in a release, you must configure your release to include a `Setup.exe` setup launcher, since it displays the instance selection dialog when appropriate. To learn how to include the `Setup.exe` setup launcher, see Creating a Setup Launcher.

Building the Release

Building a release that includes multiple-instance support is slightly different than building a release that does not include this support. For multiple-instance support, InstallShield builds some additional files: instance transforms and instance packages.

Instance Transforms

At build time, InstallShield generates instance transforms for each instance. InstallShield streams the instance transforms into the .msi file that it creates in the Disk1 folder. Depending on how you have configured the release, the .msi file may be compressed into the `Setup.exe` file, or it may be left uncompressed.

Instance Packages

At build time, InstallShield generates an .msi file for each instance. The name of each file is **InstanceIdN.msi**, where **N** represents the value of the **InstanceId** property for that instance. The .msi files are stored in a folder called *Instances* under the release location.

Creating Patches for Multiple Instances of a Product

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

To create a patch that updates multiple instances of a product, begin by creating a minor upgrade or a small update. Then configure a patch in the Patch Design view. For the previous setup, select the `Setup.exe` file or the .msi file of the earlier installation that installs the version of the product that you want to upgrade. For the latest setup, select the `Setup.exe` file or the .msi file of upgrade release.

Tip • *For detailed information about creating upgrades and patches, see Updating Applications.*

At patch build time, InstallShield creates an `Update.exe` file or an .msp file, depending on how you have configured the patch in the Patch Design view.

For an overview on the run-time behavior of a patch that includes multiple-instance support, see Run-Time Behavior for Installing Multiple Instances of a Product.

Run-Time Behavior for Installing Multiple Instances of a Product

Project • *This information applies to Basic MSI projects.*

For information on multiple-instance support for InstallScript projects, see Running an InstallScript Installation Multiple Times.

Running a First-Time Installation that Includes a Setup.exe File

The first time that an end user runs the `Setup.exe` file for your installation that supports multiple instances, Windows Installer installs the base instance that corresponds with your base installation package without any of the instance transforms. By default, the standard dialogs are displayed, regardless of whether your installation supports multiple instances.

If your product is successfully installed and the end user runs your installation again, the setup launcher displays a dialog that lets them select which instance they want to install. This instance selection dialog is displayed after the language selection dialog, if your installation includes one, but before the InstallWelcome dialog. The dialog contains two radio buttons:

- **Install a new instance**—This option lets end users install a new instance of your product. When an end user selects this option, the new instance of the product is installed.
- **Maintain or upgrade an existing instance**—This option lets end users maintain or upgrade an instance that they select from a list of already installed instances. When an end user selects this option, selects the instance that they want to change, and then clicks Next, the installation displays the following dialogs for the selected instance: the PreparingToInstall dialog, the MaintenanceWelcome dialog, and then the MaintenanceType dialog.

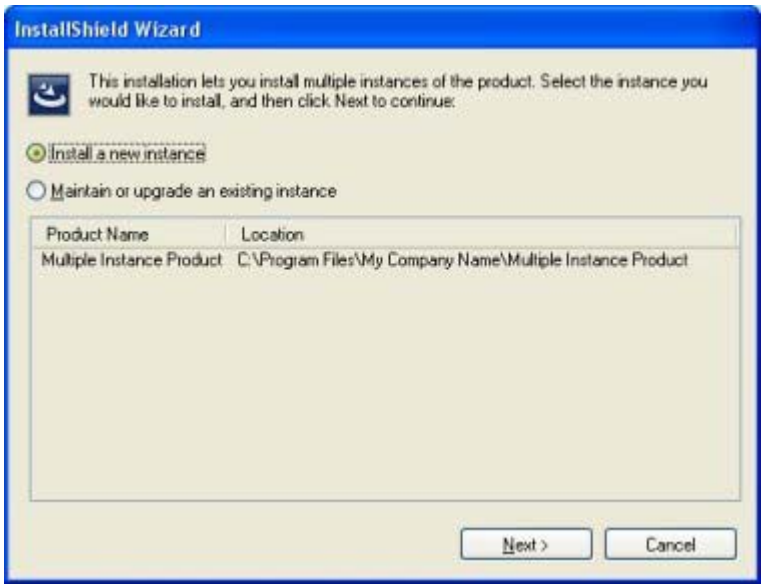

Figure 9-1: Instance Selection Dialog Displayed the Second Time the Product Is Being Installed

If an end user installs the last supported instance and then runs the installation again, the same dialog is displayed, but the **Install a new instance** option is disabled. The **Maintain or upgrade an existing instance** option is selected, and the end user can select the instance that they want to maintain or upgrade.

Tip • *To suppress the instance selection dialog, you can use the /instance command-line parameter.*

Running an Upgrade Packaged as a Full Installation that Includes a Setup.exe File

When a multiple-instance installation is an upgrade that is packaged as a full installation and that has a `Setup.exe` file, it behaves as a first-time installation if a user is installing the base instance or a new instance by launching the `Setup.exe` file. If an end user selects the **Maintain or upgrade an existing instance** option for an already installed instance, the installation lets the end user upgrade or maintain that instance, just as it would for a first-time installation.

Tip • *To suppress the instance selection dialog, you can use the /instance command-line parameter.*

Launching a First-Time Installation or an Upgrade that Is Packaged as a Full Installation Without a Setup.exe File from the Command Line

When you do not include a `Setup.exe` setup launcher with your multiple-instance installation, an end user can run your .msi file to install the base instance that corresponds with your base installation package without any of the instance transforms.

In order to install any instance that corresponds with one of the instance transforms in your package, the end user needs to include the appropriate command-line parameters for `MsiExec.exe`.

For example, the following command line installs a new instance, since the **MSINEWINSTANCE** property is set to 1. Windows Installer applies the `InstanceId1.mst` instance transform during installation of the new instance. The colon before the name of the instance transform is required because InstallShield embeds the instance transforms within the .msi file.

```
msiexec /i MyPackage.msi MSINEWINSTANCE=1 TRANSFORMS=:InstanceId1.mst
```

Note that the convention that InstallShield uses for naming instance transform files is the property name *InstanceId*, followed by the instance's value of the **InstanceId** property, followed by *.mst*. Thus, for the instance whose **InstanceId** property is set to 5, the name of the transform is `InstanceId5.mst`.

The **MSINEWINSTANCE** property should be set to 1 only if it is the first time that the end user is installing the specified instance; otherwise, an error is displayed.

To perform maintenance for an instance or to upgrade an instance, use the `/n` parameter to pass the instance's product code. For example, the following command line displays the MaintenanceType dialog, which lets the end user specify whether they want to upgrade, maintain, or remove the instance of the product that has the specified product code:

```
msiexec /i MyPackage.msi /n {00000001-0002-0000-0000-624474736554}
```

To uninstall an existing instance, use the following format at the command line:

```
msiexec /i MyPackage.msi /n {00000001-0002-0000-0000-624474736554} /x
```

Running an Upgrade that Is Packaged as a Patch with an Update.exe File

If you package your upgrade as a patch and you specify that you want to include an `Update.exe` file, the installation displays the patch version of the instance selection dialog. The dialog contains two radio buttons:

- **Patch all of the existing instances**—This option lets end users apply a patch to all installed instances of your product. When an end user selects this option, Windows Installer applies the patch to each instance separately, until all instances are updated. The instances are updated in order from the lowest **InstanceId** property value to the highest.
- **Patch an existing instance**—This option lets end users apply a patch to an instance that they select from a list of already installed instances. When an end user selects this option, selects the instance that they want to change, and then clicks Next, the installation displays the PreparingToInstall dialog and then the PatchWelcome dialog.

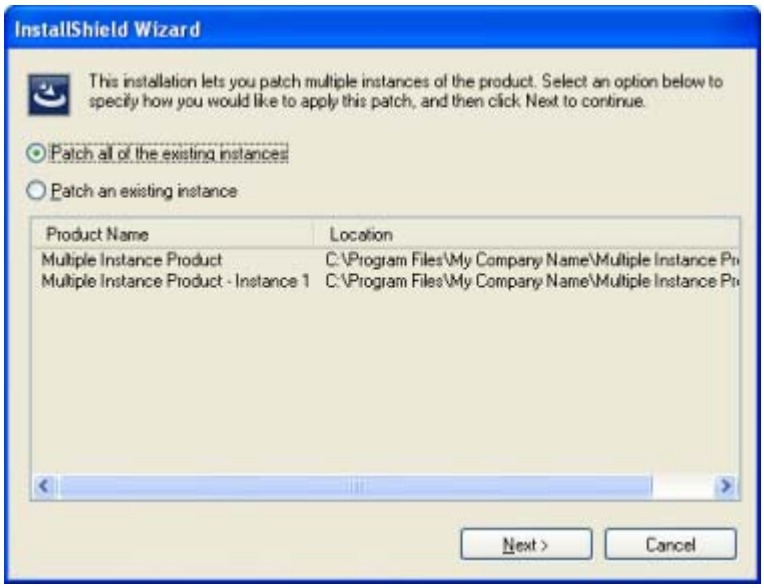

Figure 9-2: Instance Selection Dialog Displayed When an Update.exe Patch is Launched

Tip • *To suppress the patch version of the instance selection dialog, you can use the /instance command-line parameter.*

Running an Upgrade Packaged as a Patch Without an Update.exe File

If you use an .msp file without an `Update.exe` file for your patch, and the end user runs your .msp file without passing any command-line parameters, Windows Installer behaves as if the end user selected the **Patch all of the existing instances** option in the patch version of the instance selection dialog: Windows Installer applies the patch to each instance separately, until all instances are updated. The instances are updated in order from the lowest **InstanceId** property value to the highest.

To apply an .msp patch to a specific instance, pass the /p option, as well as the /n option. The /n option must specify the product code of the installed instance to which the patch should be applied. For example:

```
msiexec /p mypatch.msp /n {00000001-0002-0000-0000-624474736554}
```

Detecting Conditions on the Target System

When you are creating an installation, you may need to make sure that certain conditions exist on the target system. For example, if your product requires a particular operating system, your installation may need to check the target system to ensure that this requirement is met. If the requirement is not met, your installation might display an error to inform the end user about the requirement.

InstallShield includes support for detecting various conditions on a target system. For more information, see this section of the documentation.

Building Conditional Statements

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

A conditional statement is an expression that the Windows Installer can evaluate as True or False. Typically, conditional statements are used to perform some action or enable a component's installation based on the value or existence of a property.

You can use operators similar to those in Visual Basic for comparative and logical operations. For more information, see Conditional Statement Syntax.

Tip • *In the Components, Dialogs, Custom Actions and Sequences, and Custom Actions views of InstallShield, you can access the Condition Builder dialog box when you click the ellipsis button in the condition property to help you build conditional statements.*

Important • *When you click the OK button on this dialog box, InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Conditional Statement Syntax.*

Examples

The following table provides examples of some conditional statements and explanations of how they can be used. Consult the Windows Installer Help Library for more information on Windows Installer properties and conditional expression operators.

Table 9-1 • Examples of Conditional Statements

Purpose	Syntax
To install a component only on machines that have the client version of Windows 7 and later, specify this expression for its Condition setting.	VersionNT>=601 And MsiNTProductType=1
To install a component only on Windows Server 2008 R2 and later domain controllers and servers, specify this expression for its Condition setting.	VersionNT>=601 And MsiNTProductType>1
To install a component only on Windows XP, specify the expression for its Condition setting.	VersionNT=501  ***Note*** • *You can also use the ServicePackLevel and WindowsBuild properties to distinguish between different operating systems. For a list of values, see Operating System Property Values in the Windows Installer Help Library.*
To install a component only on machines running Windows 7 or later, specify this expression for its Condition setting.	VersionNT>=601
To execute a custom action only if the product has not been installed, check the value of the Installed property with this condition.	Not Installed
To install a component only if the target system is using U.S. English as the default language, compare the value of the SystemLanguageID property to the language ID for U.S. English by using this component condition.	SystemLanguageID=1033  ***Note*** • *Related properties include* ***UserLanguageID*** *(the default language for the current user) and* ***ProductLanguage*** *(the language being used for the setup program's user interface).*
To allow your product to be installed only if the screen resolution is a minimum of 1024 X 768, add this condition to the Install Condition setting in the General Information view.	ScreenX >= 1024 AND ScreenY >= 768

Table 9-1 • Examples of Conditional Statements (cont.)

Purpose	Syntax
To allow your product to be installed only if the target system has at least 2 GB of RAM, add this condition to the Install Condition setting in the General Information view.	PhysicalMemory >= 2048

Conditional Statement Syntax

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

Conditional statements have a strictly governed syntax that uses properties, Windows Installer table keys, literals, and evaluative operators.

Functionality

A conditional statement performs some action in an installation—such as launching a custom action or installing a component—based on whether the expression evaluates to True, which has the numeric value of 1. False returns have the numeric value of 0. The simplest of expressions, specifying a property name, is True if the property is defined. For example, the simple conditional statement `Version9X` evaluates to True when the installation is running under Windows 95 or Windows 98.

You can build more complex conditional statements using the operators and values described in the tables below.

Values

The following table describes how to use values in your conditional statements. All values except for environment variables are case sensitive.

Table 9-2 • Descriptions of Values

Value	Description
Windows Installer property	The name of the property. Nonexistent properties are evaluated as empty strings.

Table 9-2 • Descriptions of Values (cont.)

Value	Description
Integer	Any integer value from -32,767 to +32,767. You cannot use a floating point value.
String literal	Enclose the text in quotation marks. For example: `"InstallShield"`
Environment variable	Precede the variable name with a percent symbol. For example: `%TEMP`

Operators

The tables below list all of the conditional statement operators by type. Note the following:

- The operators follow the same precedence as those in Visual Basic.
- Use parentheses to override precedence.
- Operators are not case sensitive.
- Unlike in Visual Basic, there are no arithmetic operators.
- Precede the operator with a tilde (~) if you do not want the comparison to be case sensitive.
- The result is always False when you compare a string with an integer, unless you use the <> operator.

Table 9-3 • Descriptions of Logical Operators

Logical Operator	Description
Not	Performs logical negation. The result is True if the value is False, and vice versa.
And	The result is True if both values are True.
Or	The result is True if either value is True.
Xor	The result is True if only one of the values is True.
Eqv	The result is True if both values are True or both values are False.
Imp	Performs a logical implication. The result is True if the first term is False or the second is True.

Table 9-4 • Descriptions of Comparative Operators

Comparative Operator	Description
=	The result is True if the first value is equal to the second.
<>	The result is True if the first value is not equal to the second.
>	The result is True if the first value is greater than the second.
>=	The result is True if the first value is greater than or equal to the second.
<	The result is True if the first value is less than the second.
<=	The result is True if the first value is less than or equal to the second.

Table 9-5 • Descriptions of Substring Operators

Substring Operator	Description
><	The result is True if the first string contains the second.
<<	The result is True if the first string starts with the second.
>>	The result is True if the first string ends with the second.

Table 9-6 • Descriptions of Bitwise Operators

Bitwise Operator	Description
><	The result is True if both integers have any bits in common.
<<	The result is True if the high 16 bits of the first integer are equal to the second integer.
>>	The result is True if the low 16 bits of the first integer are equal to the second integer.

Detecting Administrator and Elevated Privileges

Basic MSI Projects

On systems with Windows XP and earlier or Windows Server 2003 and earlier, two properties for detecting user privileges are **AdminUser** and **Privileged**. The **AdminUser** property is set if the end user has Administrator privileges. The **Privileged** property is set if the installation is running with elevated privileges (that is, if the end user has administrative privileges, if the installation has been assigned by a system administrator, or if both the user and machine AlwaysInstallElevated policies are set to true). In most cases, the **Privileged** property is more appropriate.

On Windows Vista and later and Windows Server 2008 and later, the **AdminUser** property is by default assigned the same value as the **Privileged** property. To restore the distinction between **AdminUser** and **Privileged** on these systems, you can set the **MSIUSEREALADMINDETECTION** property to 1 in the Property Manager view.

Note that for Windows Vista and later and Windows Server 2008 and later, **AdminUser** and **Privileged** are always set during the User Interface sequence; therefore, they cannot detect whether an installation is actually running with elevated privileges during the User Interface sequence. However, custom actions running as deferred in system context have the correct value for **Privileged** (and for **AdminUser**, if **MSIUSEREALADMINDETECTION** is also set). Because only actions running as deferred in system context should modify the system, distinguishing privileged from non-privileged installations is significant only for that type of action. One consequence of this behavior is that **AdminUser** and **Privileged** should not be used in a project's install conditions for targeting Windows Vista and later or Windows Server 2008 and later.

InstallScript and InstallScript MSI Projects

The following InstallScript expression returns TRUE if the end user has Administrator privileges, except for some cases on Windows Vista or later systems and Windows Server 2008 or later systems:

```
Is(USER_ADMINISTRATOR, "");
```

On Windows Vista and later systems and Windows Server 2008 and later systems, **Is** returns TRUE if the SE_GROUP_USE_FOR_DENY_ONLY security identifier (SID) attribute is not set for the group. That is, if the current user is in the Administrators group but that user is running the installation with a standard access token on Windows Vista, **Is** returns FALSE.

Detecting First-Time Installations, Maintenance Mode, and Uninstallation

Your installation can determine whether the installation is being run for the first time on a target system.

Windows Installer–Based Projects

In the Windows Installer sequences, the following conditions detect certain types of installation:

- First-time installation: Not Installed
- Maintenance: Installed
- Uninstallation: REMOVE="ALL" (after the InstallValidate action)

You can use these conditions in any of the Condition settings of a Basic MSI or InstallScript MSI project.

InstallScript-Based Projects

In InstallScript, the MAINTENANCE variable is FALSE for a first-time installation, and TRUE for maintenance mode or uninstallation. Therefore, you can use an if-statement like the following for any code you want to run only for a first-time installation.

```
if (!MAINTENANCE) then
    // code to run for first-time installation
endif;
```

You can use that sort of code in event-driven InstallScript code of InstallScript and InstallScript MSI projects.

Triggering Behavior Only During a First-Time Installation

There may be times when you want certain behavior to occur only during a first-time installation, but not during uninstallation.

Basic MSI Projects

At run time for Basic MSI projects, the same sequences are used for first-time installations and maintenance installations (including uninstallation). There is no separate uninstallation sequence. Therefore, any custom actions that you schedule in the Installation sequences will, by default, run for both installation and uninstallation.

To specify that an action should run only for a first-time installation, you can use the Not Installed condition. The Not Installed condition is appropriate, for example, for a custom action that launches a Readme file for the application being installed.

InstallScript and InstallScript MSI Projects

In InstallScript and InstallScript MSI installations, you can use the MAINTENANCE system variable to determine whether the installation is running in maintenance mode or if it is a first-time installation. The following code sample shows how to use it in your script:

```
if (!MAINTENANCE) then
    // it is a first-time install
endif;

And for reinstall/modify/repair, it's:

if (MAINTENANCE) then
    // ...not first-time
endif;
```

Detecting If the End User Has Selected a Specific Feature

Your installation can determine whether the end user has selected to install a specific feature. The method depends on which project type you are using.

Basic MSI Projects

Windows Installer defines conditions of the form &FeatureName=*n* to detect a feature's action state. For example, to determine if a feature called ProgramFiles is selected to be installed locally, and it was not already installed, use the condition &ProgramFiles=3.

InstallScript and InstallScript MSI Projects

The InstallScript function **FeatureIsItemSelected** returns TRUE if a feature is currently selected in one the feature-selection dialogs (such as **SdFeatureTree**).

Detecting If the End User Is Running a Particular Operating System

Your installation can determine which operating system is on a target system.

Using Windows Installer Properties to Detect the Operating System

The Windows Installer properties **VersionNT**, **Version9X**, **ServicePackLevel**, and **WindowsBuild** describe the target operating system.

Project • *You can use these Windows Installer properties in conditions for items such as features, components, and custom actions in the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Note • *Property names are case-sensitive, so **Version9X** and **Version9x** are considered different properties.*

Using an InstallScript Structure Variable to Detect the Operating System

The InstallScript structure SYSINFO is automatically initialized to describe the operating system on the target system. You can use this structure in your InstallScript code to trigger specific behavior on certain platforms. For specific values to check, see SYSINFO.

Project • *You can use the SYSINFO structure in event-driven InstallScript code in the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

You can also use this structure in InstallScript custom actions in the following project types:

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

Detecting Whether the Installation Is Being Run on a Virtual Machine

InstallShield lets you determine whether an installation is running on any of the following types of virtual machines:

- Microsoft Hyper-V
- A VMware product such as VMware Player, VMware Workstation, or VMware Server
- Microsoft Virtual PC

To check for virtual machines, you can either use Windows Installer properties, or you can use an InstallScript structure or function.

Note • *Emulators such as Bochs and QEMU are not detected.*

Using Windows Installer Properties to Detect a Virtual Machine

Project • *You can use Windows Installer properties in conditions for items such as features, components, and custom actions in the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

To use Windows Installer properties to detect the presence of a virtual machine and determine the type of virtual machine, you first need to create a custom action that calls the ISDetectVM function in the `SetAllUsers.dll` file.

Task: ***To add a custom action that checks for a virtual machine:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI and InstallScript MSI projects) or **Custom Actions** (in DIM and Merge Module projects).
2. In the center pane, right-click the **Custom Actions** explorer, point to **New MSI DLL**, and click **Stored in Binary table**. InstallShield adds a new custom action.
3. Change the name of the action to something like `ISDetectVM`.
4. Configure the custom action's settings in the right pane:
   - In the **DLL Filename** setting, select the `SetAllUsers.dll` file. The typical path is:

     `<ISProductFolder>\redist\language independent\i386\SetAllUsers.dll`
   - In the **Function Name** setting, enter the following name:

     `ISDetectVM`
   - In the **In-Script Execution** setting, select **Immediate Execution**.
   - Schedule the custom action as needed by selecting the appropriate option in one or more sequence settings.

The custom action sets the following Windows Installer properties at run time:

Table 9-7 • Windows Installer Properties for Detecting Virtual Machines

Property Name	Description
IS_VM_DETECTED	If the value of this property is 1, the installation is running on one of the following virtual machine environments: • Microsoft Hyper-V • A VMware product such as VMware Player, VMware Workstation, or VMware Server • Microsoft Virtual PC If the value is not set, no virtual machine has been detected.
IS_VM_TYPE	This property indicates the type of virtual machine that is running the installation. Available values are: • **Undefined**—No virtual machine has been detected. • **1**—The installation is running on a VMware product such as VMware Player, VMware Workstation, or VMware Server. • **2**—The installation is running on a Microsoft Hyper-V machine. • **3**—The installation is running on a Microsoft Virtual PC machine. • **4**—The type of virtual machine is not known.

You can use the aforementioned properties in conditional statements. For example, if your product cannot be used on virtual machines, enter the following conditional statement in the Install Condition setting of the General Information view:

```
Not IS_VM_DETECTED
```

If you have a component that should be installed only on VMware images, enter the following conditional statement in the Condition setting of the Components view:

```
IS_VM_TYPE=1
```

Using an InstallScript Structure and Variable to Detect a Virtual Machine

Project • *You can use an InstallScript structure and variable in event-driven InstallScript code in the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

You can also use the structure and variable in InstallScript custom actions that are in the following project types:

- *Basic MSI*
- *InstallScript MSI*

- *Merge Module*

You can use the SYSINFO.bIsVirtualMachine structure in your InstallScript code to determine whether the installation is being run on a virtual machine. In addition, you can use the VIRTUAL_MACHINE_TYPE constant with the **GetSystemInfo** function to determine which type of virtual machine is present.

For example, in an InstallScript event handler such as OnFirstUIBefore or in an InstallScript custom action, you can use code such as the following snippet:

```
if (SYSINFO.bIsVirtualMachine) then
    SprintfBox (0, "VM", "This is a virtual machine. Type: %d",
        GetSystemInfo (VIRTUAL_MACHINE_TYPE, nNumber, szString));
else
    MessageBox ("This is not a virtual machine.", 0);
endif;
```

At run time, a message box is displayed. If the target system is a Microsoft Hyper-V image, a VMware image, or Microsoft Virtual PC, the message box says, “This is a virtual machine,” and it also lists the type of virtual machine. If the target system is not one of those virtual machines, the message box says, “This is not a virtual machine.”

Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Project-specific differences are noted where appropriate.

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

How Advanced UI and Suite/Advanced UI Installations Use Conditions

The Advanced UI and Suite/Advanced UI project types in InstallShield have support for building conditional statements that control different areas of the run time:

- **Exit conditions**—The Exit Condition setting in the General Information view lets you specify one or more exit error messages that you want the Advanced UI or Suite/Advanced UI installation to display under various conditions before ending the installation. If the condition that you define is true when an end user launches the Advanced UI or Suite/Advanced UI installation, the Advanced UI or Suite/Advanced UI installation displays the error message. When end users dismiss the error message, the Advanced UI or Suite/Advanced UI installation ends.

- **Detection conditions**—The Detection Condition setting for a package in the Packages view lets you specify the condition that the Advanced UI or Suite/Advanced UI installation should use to evaluate whether the package is already installed on target systems. If this does not change from false to true (or from true to false) at run time, the Advanced UI or Suite/Advanced UI installation assumes that the package failed to install (or remove) its payload. In addition, subsequent maintenance and remove operations (or subsequent maintenance and install operations) may not behave as expected.
- **Eligibility conditions**—The Eligibility Condition setting for a package in the Packages view lets you specify the condition that the Advanced UI or Suite/Advanced UI installation should use to determine whether the target system meets the requirements that are necessary for the package to be run. For example, if the package should be run only on 64-bit systems, you could set up an x64 platform requirement in a condition; the Advanced UI or Suite/Advanced UI installation would launch the package only on 64-bit systems. You may also want to set up an eligibility condition to prevent end users from being able to install the current package version over a future newer version.
- **Feature conditions**—The Condition setting in the Features view lets you build conditional statements to evaluate whether the feature should be selected for installation by default on the InstallationFeatures wizard page.
- **Action conditions**—The Condition setting for an action that is scheduled for an event in the Events view lets you build conditional statements that evaluate whether the installation should run the action.

  In addition, the settings in the Events area for a package in the Packages view let you build conditional statements that evaluate whether the installation should run an action for the selected package.

  

  Project *• Action conditions are available in Suite/Advanced UI projects.*
- **Wizard interface conditions**—The condition settings for wizard pages and controls in the Wizard Interface view let you build conditional statements that evaluate behavior such as whether the installation should invoke an action, validate an end user's response, enable a control, show a page or control.
- **Mode conditions**—InstallShield creates two types of mode conditions automatically: install mode conditions and maintenance mode conditions. The mode conditions are shown only in the project file (.issuite); this type of condition is not available for edit within InstallShield. These mode conditions determine whether an Advanced UI or Suite/Advanced UI installation runs in first-time installation mode or in maintenance mode. For more details, see Triggering Install Mode or Maintenance Mode of an Advanced UI or Suite/Advanced UI Installation.

Condition Operators

Each condition that you define in an Advanced UI or Suite/Advanced UI project begins with one of the following operators:

- **Any**—An Any condition group operates like a logical OR operation. If any of the conditions that are in the Any group evaluate to true, the entire condition group evaluates to true. If none of the conditions that are in the Any group evaluate to true, the entire condition group evaluates to false.
- **All**—An All condition group operates like a logical AND operation. All of the conditions that are in the All group must evaluate to true in order for the condition group to evaluate to true.

- **None**—A None condition group operates like a logical NOR operation. If none of the conditions that are in the None group evaluate to true, the entire condition group evaluates to true. If any of the conditions that are in the None condition group evaluate to true, the entire condition group evaluates to false. Note that if the None condition group consists of only one conditional statement, it operates like a logical NOT operation.

Types of Condition Checks

When you are building a conditional statement for an exit, detection, eligibility, feature, or wizard interface condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can select from a number of different types of checks that you want to be evaluated on target systems. Examples are operating system version, presence of a file or registry entry, and presence of an already installed product.

For detailed information about each of the types of condition checks that are supported, as well as each of the subsettings that are displayed under a condition, see Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects.

Syntax for Building Conditions

Building a conditional statement involves using one or more of the condition settings to add operators and condition checks.

To add a conditional statement to a condition setting, click the setting's New Condition button:

When you do that, InstallShield adds an operator row under the condition setting; the default operator is Any. To change the operator for the condition, click the drop-down arrow in the operator setting and then click the appropriate option.

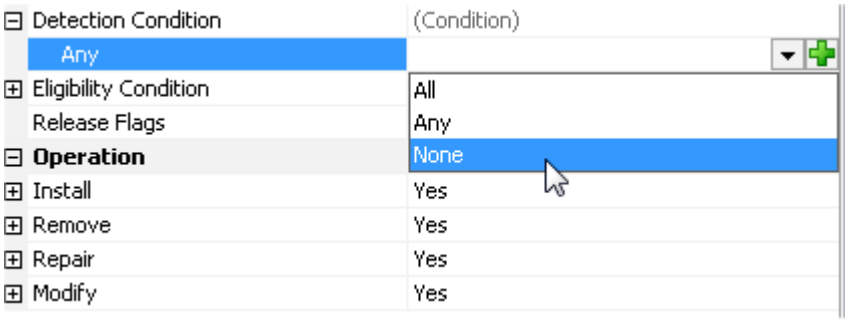

Figure 9-1: Changing the Default Operator

Once you have added an operator, click the New Condition button in the operator setting and then click the appropriate condition check type. At this point, InstallShield adds a subsetting (or more subsettings, depending on which condition check type you selected) under the operator setting.

Whenever a conditional statement is invalid (for example, if an entry is required in a setting but it is left blank), InstallShield shows a warning icon in that setting. To find out why the condition is invalid, move the pointer over an icon; InstallShield displays a tooltip that explains the issue.

To nest another condition within a condition, click the New Condition button in an operator setting and then click the appropriate operator for the nested condition. One of the Any/All/None meta-conditions is referred to as a *condition group*. All of the nested condition groups and conditions under a condition setting together form a *condition tree*.

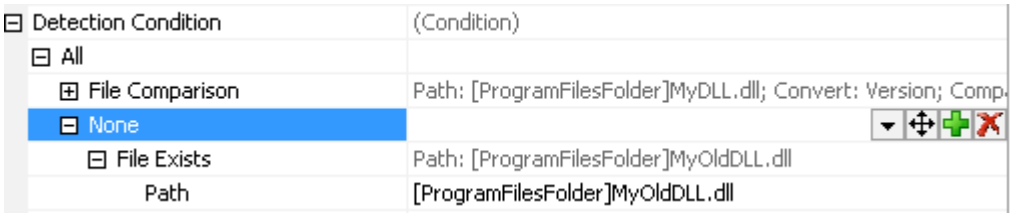

Figure 9-2: Nesting a Condition Within a Condition

To move a condition or a condition group within a condition tree, point to the Move Condition button in the setting of the item that you want to move, and then click the appropriate direction (Move Up, Move Down, Move Left, or Move Right).

Note that if you add an .msi package to your project, InstallShield automatically creates two MSI Package eligibility condition groups for the package, and uses an asterisk (*) in the condition's Product Code, Package Code, and Product Version settings as placeholders for the package's own product code, package code, and product version, as shown in the following screen shot.

Figure 9-3: Default Eligibility Condition for an .msi Package

InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from launching the package if a package with a matching product code but a later product version is already installed. You can override this built-in condition if necessary.

You can use an asterisk as a placeholder for the current package's product code and product version when you are defining eligibility and detection MSI package conditions, as long as the package that you are configuring is an .msi package.

You can also use an asterisk as a placeholder for the current package's upgrade code and either the minimum or maximum version number when you are defining eligibility and detection MSI upgrade conditions, as long as the package that you are configuring is an .msi package.

Types of Condition Checks in Advanced UI and Suite/Advanced UI Projects

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, feature, or wizard interface condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can select from a number of different types of checks that you want to be evaluated on target systems.

Each type of condition has one or more subsettings that are associated with it. The following types of conditions are available:

Table 9-8 • Types of Condition Checks

Type of Condition Check	Description
Platform	Check target systems for one or more characteristics such as the operating system version, the architecture, and other platform details on target systems. For descriptions of each of the settings that are displayed for this type of condition check, see Platform Condition Settings.
File Exists	Check target systems for the presence of a particular file. For the description of the setting that is displayed for this type of condition check, see File Exists Condition Setting.
File Comparison	Check target systems for specific information—date, version number, or content—for a particular file. For descriptions of each of the settings that are displayed for this type of condition check, see File Comparison Condition Settings.
Registry Exists	Check target systems for the presence of a particular registry key, and optionally a specific value name. For descriptions of each of the settings that are displayed for this type of condition check, see Registry Exists Condition Settings.

Table 9-8 • Types of Condition Checks (cont.)

Type of Condition Check	Description
Registry Comparison	Check target systems for specific information—DWORD, QWORD, string, multistring, file version, or product version—for a particular registry entry. If you do not specify a value name, the default value for the key that you specify is used for the comparison. For descriptions of each of the settings that are displayed for this type of condition check, see Registry Comparison Condition Settings.
Property Comparison	Check the value of a particular built-in Advanced UI or Suite/Advanced UI property, or a property that is defined in the Property Manager view. For descriptions of each of the settings that are displayed for this type of condition check, see Property Comparison Condition Settings.
MSI Package	Check target systems for the presence of a product that was installed by a particular .msi package. For descriptions of each of the settings that are displayed for this type of condition check, see MSI Package Condition Settings.
MSI Upgrade	Check target systems for the presence of a version of a product that you want to update, or for the presence of future versions of a product that you do not want to downgrade. In either case, the product whose presence is being checked is installed by an .msi package. For descriptions of each of the settings that are displayed for this type of condition check, see MSI Upgrade Condition Settings.
Eligible Package	Check whether a different package or a feature in the Advanced UI or Suite/Advanced UI installation is eligible for installation on a target system. For example, if a patch package is eligible for installation only if the base package is eligible for installation, you can create an Eligible Package condition to tie the patch's eligibility to the base package's eligibility. In this scenario, you would select the patch package in the Packages view, create the condition, and specify the package GUID of the base package in that condition. For a description of the setting that is displayed for this type of condition check, see Eligible Package Condition Setting.
InstallScript Package	Check target systems for the presence of a product that was installed by a particular InstallScript package. For descriptions of each of the settings that are displayed for this type of condition check, see InstallScript Package Condition Settings.

Table 9-8 • Types of Condition Checks (cont.)

Type of Condition Check	Description
Locale	Match one or more locale-related settings on target systems. For descriptions of each of the settings that are displayed for this type of condition check, see Locale Condition Settings.
Suite Installed	Check whether a particular version of an Advanced UI or Suite/Advanced UI installation is already installed on a target system. For descriptions of each of the settings that are displayed for this type of condition check, see Suite Installed Condition Settings.
AppX Package	Check target systems for the presence of a particular AppX app. For descriptions of each of the settings that are displayed for this type of condition check, see AppX Package Condition Settings.
Package Operation	 ***Project*** • *This type of condition is available in Suite/Advanced UI projects.* Check the target state of a particular package in the Suite/Advanced UI installation. This type of condition is available only for actions that are associated with an event in the Events view or a package in the Packages view. For descriptions of each of the settings that are displayed for this type of condition check, see Package Operation Condition Settings.
Feature Operation	 ***Project*** • *This type of condition is available in Suite/Advanced UI projects.* Check the target state of a particular feature in the Suite/Advanced UI installation. This type of condition is available only for actions that are associated with an event in the Events view or a package in the Packages view. For descriptions of each of the settings that are displayed for this type of condition check, see Feature Operation Condition Settings.
Extension Condition DLL	Use a C/C++ DLL that you created to implement your own custom condition that checks target systems for factors that the other types of condition checks do not evaluate. For descriptions of each of the settings that are displayed for this type of condition check, see Extension Condition Settings.

Table 9-8 • Types of Condition Checks (cont.)

Type of Condition Check	Description
Mode	Check the mode in which the Advanced UI or Suite/Advanced UI installation is running. This type of condition check is available for various settings of wizard interface elements in the Wizard Interface view. For descriptions of each of the settings that are displayed for this type of condition check, see Mode Condition Settings.

Platform Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a platform condition.

The Platform setting shows the platform-related conditions that are configured in the Platform subsettings. To define a condition that evaluates the operating system version, the architecture, and other platform details on target systems, configure one or more of the platform-related subsettings as needed.

The following subsettings are available for this condition.

Table 9-9 • Platform Condition Settings

Setting	Description
OS Version	To create a conditional statement that evaluates the version of Windows on target systems, do one of the following: • To check for an exact match, enter the version number of Windows in the format *major.minor*. • To specify the minimum and maximum version numbers, enter a range separated by a dash. For example, to test for version 5.0 through 6.1 of Windows, enter the following: `5.0-6.1` • To check for a minimum version number, enter the minimum version number followed by a dash. For example, to test for version 5.0 and later versions, enter the following: `5.0-` • To check for a maximum version number, enter a dash followed by the maximum version number. For example, to test for version 6.0 and earlier versions, enter the following: `-6.0` For a list of valid versions, see the dwMajorVersion and dwMinorVersion members of the OSVERSIONINFOEX structure that is documented on the MSDN Web site.  ***Important*** • *If you specify a range of operating system versions in the OS Version setting, as well as a range of service pack numbers in the Service Pack setting, ensure that the conditions evaluate as expected at run time.*

Table 9-9 • Platform Condition Settings (cont.)

Setting	Description
Service Pack	To create a conditional statement that evaluates the service pack number of Windows on target systems, do one of the following: • To check for an exact match, enter the specific service pack number of Windows. For example, to test for SP2, enter the number `2`. • To specify the minimum and maximum service pack numbers, enter a range separated by a dash. For example, to test for SP1 through SP3 of Windows, enter the following: `1-3` • To check for a minimum service pack number, enter the minimum service pack number followed by a dash. For example, to test for SP2 and later versions, enter the following: `2-` • To check for a maximum service pack number, enter a dash followed by the maximum service pack number. For example, to test for SP2 and earlier versions, enter the following: `-2` For a list of valid service pack numbers, see the wServicePackMajor and wServicePackMinor members of the OSVERSIONINFOEX structure that is documented on the MSDN Web site.  ***Important*** • *If you specify a range of operating system versions in the OS Version setting, as well as a range of service pack numbers in the Service Pack setting, ensure that the conditions evaluate as expected at run time.*
CSD Version	To create a conditional statement that evaluates the CSD version of Windows on target systems, enter the specific CSD version. **Service Pack 2** is an example of a CSD version.
Build Number	To create a conditional statement that evaluates the minimum build number version of Windows on target systems, enter the specific build number. For a list of valid build numbers, see the dwBuildNumber member OSVERSIONINFOEX structure that is documented on the MSDN Web site.

Table 9-9 • Platform Condition Settings (cont.)

Setting	Description
Product Type	To create a conditional statement that evaluates whether the target system is a domain controller, a server, or a workstation, select the appropriate option. For a list of valid types, see the wProductType member OSVERSIONINFOEX structure that is documented on the MSDN Web site.
Architecture	To create a conditional statement that evaluates the architecture (x86, x64, or IA64) of target systems, select the appropriate option.

File Exists Condition Setting

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a File Exists condition.

The File Exists setting shows the condition that is configured for checking target systems for the presence of a particular file. To define this type of condition, configure the subsetting under the File Exists setting as needed.

The following subsetting is available for this condition.

Table 9-10 • File Exists Condition Settings

Setting	Description
Path	To create a conditional statement that checks for the presence of a particular file, enter the path and name for the file. To include a predefined folder in the path, select the appropriate property in the list. If you select one of the 64-bit folder locations, the installation checks the 64-bit folder location on 64-bit target systems and the 32-bit folder location on 32-bit target systems.

File Comparison Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a File Comparison condition.

The File Comparison setting shows the condition that is configured for checking target systems for specific information—date, version number, or content—for a particular file. To define this type of condition, configure the subsettings under the File Comparison setting as needed.

The following subsettings are available for this condition.

Table 9-11 • File Comparison Condition Settings

Setting	Description
Path	To create a conditional statement that checks for specific information for a particular file, enter the path and name for the file. To include a predefined folder in the path, select the appropriate property in the list. If you select one of the 64-bit folder locations, the installation checks the 64-bit folder location on 64-bit target systems and the 32-bit folder location on 32-bit target systems.
Conversion	Select the type of data that you want to compare. Available options are: • **Content**—The data that you want to compare is a string. • **Version**—The data that you want to compare is a file version in the format *nn.nn.nn.nn*. • **Local Date and Time**—The data that you want to compare is the local date and time on the target system that is running the Advanced UI or Suite/Advanced UI installation—for example, **4/26/2004 3:57:46 PM**.

Table 9-11 • File Comparison Condition Settings (cont.)

Setting	Description
Comparison	Select the option that describes how you want to compare the value on the target system with the value that you specify in the Compare To setting. For example, consider a file version condition in which the value of the Comparison setting is Less Than or Equal To, and the value of the Compare To setting is 4.1. At run time, this condition evaluates as true if the file version on the target system is 4.0 or 4.1; it evaluates as false if the file version on the target system is 4.2.
Compare To	Specify the value that you want to compare with the value on the target system. The value that you enter depends on the option that is selected for the Conversion setting: • If Content is selected in the Conversion setting, enter the file string that you want to compare in the Compare To setting. • If Version is selected in the Conversion setting, enter the file version in the format *nn.nn.nn.nn*. • If Local Date and Time is selected in the Conversion setting, enter the date and time that is used locally on target systems that are running the Advanced UI or Suite/Advanced UI installation—for example, **4/26/2004 3:57:46 PM**. The Comparison setting is where you indicate how you want to compare the value on the target system with the value that you specify in the Compare To setting. For example, consider a file version condition in which the value of the Comparison setting is Less Than or Equal To, and the value of the Compare To setting is 4.1. At run time, this condition evaluates as true if the file version on the target system is 4.0 or 4.1; it evaluates as false if the file version on the target system is 4.2.

Registry Exists Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a Registry Exists condition.

The Registry Exists setting shows the condition that is configured for checking target systems for the presence of a particular registry key, and optionally a specific value name. To define this type of condition, configure the subsettings under the Registry Exists setting as needed.

The following subsettings are available for this condition.

Table 9-12 • Registry Exists Condition Settings

Setting	Description
Registry Key	To create a conditional statement that checks for the presence of a particular registry key, select the appropriate root key in this setting, and then enter the rest of the registry path. Available root keys are: • **HKLM**—HKEY_LOCAL_MACHINE • **HKCU**—HKEY_CURRENT_USER • **HKCR**—HKEY_CLASSES_ROOT • **HKU**—HKEY_USERS
Value Name	To create a conditional statement that checks for the presence of a particular registry value for the specified registry key, enter the appropriate registry value. If you do not want to check for the presence of a specific registry value—that is, you want to check only for the presence of a registry key—leave this setting blank.
64-Bit Key	Specify whether you want the Advanced UI or Suite/Advanced UI installation to check the 64-bit portion of the registry on 64-bit systems. If you select True, the Advanced UI or Suite/Advanced UI installation ignores this conditional statement on 32-bit target systems.

Registry Comparison Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a Registry Comparison condition.

The Registry Comparison setting shows the condition that is configured for checking target systems for specific information—DWORD, QWORD, string, multistring, file version, or product version—for a particular registry entry. If you do not specify a value name, the default value for the key that you specify is used for the comparison. To define this type of condition, configure the subsettings under the Registry Comparison setting as needed.

The following subsettings are available for this condition.

Table 9-13 • Registry Comparison Condition Settings

Setting	Description
Registry Key	To create a conditional statement that checks for specific information for a particular value name of a registry key, select the appropriate root key in this setting, and then enter the rest of the registry path. Available root keys are: • **HKLM**—HKEY_LOCAL_MACHINE • **HKCU**—HKEY_CURRENT_USER • **HKCR**—HKEY_CLASSES_ROOT • **HKU**—HKEY_USERS
Value Name	Enter the registry value that you want to check for the registry comparison condition. If you want to check the registry key's default value, leave this setting blank.
64-Bit Key	Specify whether you want the Advanced UI or Suite/Advanced UI installation to check the 64-bit portion of the registry on 64-bit systems. If you select True, the Advanced UI or Suite/Advanced UI installation ignores this conditional statement on 32-bit target systems.

Table 9-13 • Registry Comparison Condition Settings (cont.)

Setting	Description
Conversion	Select the type of value that you want to compare. Available options are: • **DWORD**—The value that you want to compare is a DWORD (32-bit) value. • **QWORD**—The value that you want to compare is a QWORD (64-bit) value. • **String**—The value that you want to compare is a string value. • **Multistring**—The value that you want to compare is a multistring value. • **File Version**—The value that you want to compare is a file version value in the format *nn.nn.nn.nn*. • **Product Version**—The value that you want to compare is a product version value. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions.
Comparison	Select the option that describes how you want to compare the value on the target system with the value that you specify in the Compare To setting. For example, consider a registry condition in which the value of the Comparison setting is Less Than or Equal To, and the value of the Compare To setting is 4.1. At run time, this condition evaluates as true if the number in the specified registry value data on the target system is 4.0 or 4.1; it evaluates as false if the version on the target system is 4.2.

Table 9-13 • Registry Comparison Condition Settings (cont.)

Setting	Description
Compare To	Specify the value that you want to compare with the value on the target system. The value that you enter depends on the option that is selected for the Conversion setting: • If DWORD is selected in the Conversion setting, enter the DWORD value that you want to compare in the Compare To setting. • If QWORD is selected in the Conversion setting, enter the QWORD value that you want to compare in the Compare To setting. • If String is selected in the Conversion setting, enter the string value that you want to compare in the Compare To setting. • If MultiString is selected in the Conversion setting, enter the multistring value that you want to compare in the Compare To setting. • If File Version is selected in the Conversion setting, enter the file version value (in the format *nn.nn.nn.nn*) that you want to compare in the Compare To setting. • If Product Version is selected in the Conversion setting, enter the product version value that you want to compare in the Compare To setting. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions. The Comparison setting is where you indicate how you want to compare the value on the target system with the value that you specify in the Compare To setting. For example, consider a registry condition in which the value of the Comparison setting is Less Than or Equal To, and the value of the Compare To setting is 4.1. At run time, this condition evaluates as true if the number in the specified registry value data on the target system is 4.0 or 4.1; it evaluates as false if the version on the target system is 4.2.

Property Comparison Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*

- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, feature, or wizard interface condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a Property Comparison condition. The Property Comparison setting shows the condition that is configured for checking the value of a particular built-in Advanced UI or Suite/Advanced UI property, or a property that is defined in the Property Manager view. To define this type of condition, configure the subsettings under the Property Comparison setting as needed.

The following subsettings are available for this condition.

Table 9-14 • Property Comparison Condition Settings

Setting	Description
Name	To create a conditional statement that checks the value of a particular Advanced UI or Suite/Advanced UI property, enter the name of the property in this setting. For a list of built-in conditions, see Advanced UI and Suite/Advanced UI Property Reference.
Conversion	Select the type of value that you want to compare. Available options are: • **DWORD**—The value that you want to compare is a DWORD (32-bit) value. • **QWORD**—The value that you want to compare is a QWORD (64-bit) value. • **String**—The value that you want to compare is a string value. • **File Version**—The value that you want to compare is a file version value in the format *nn.nn.nn.nn*. • **Product Version**—The value that you want to compare is a product version value. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions. • **Local Date Time**—The value that you want to compare is a date or a date and time.

Table 9-14 • Property Comparison Condition Settings (cont.)

Setting	Description
Comparison	Select the option that describes how you want to compare the value of the property at run time on the target system with the value that you specify in the Compare To setting. For example, consider a property comparison condition in which the value of the Conversion setting is String, the value of the Comparison setting is Equal, and the value of the Compare To setting is MyValue. At run time, this condition evaluates as true if the property value at run time is MyValue; it evaluates as false if the property value is not set or is any other value.

Table 9-14 • Property Comparison Condition Settings (cont.)

Setting	Description
Compare To	Specify the value that you want to compare with the value of the Advanced UI or Suite/Advanced UI property on the target system at run time. The value that you enter depends on the option that is selected for the Conversion setting: • If DWORD is selected in the Conversion setting, enter the DWORD value that you want to compare in the Compare To setting. • If QWORD is selected in the Conversion setting, enter the QWORD value that you want to compare in the Compare To setting. • If String is selected in the Conversion setting, enter the string value that you want to compare in the Compare To setting. • If File Version is selected in the Conversion setting, enter the file version value (in the format *nn.nn.nn.nn*) that you want to compare in the Compare To setting. • If Product Version is selected in the Conversion setting, enter the product version value that you want to compare in the Compare To setting. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions. • If Local Date Time is selected in the Conversion setting, enter the date and time that you want to compare in the Compare To setting—for example, **4/26/2004 3:57:46 PM**. The Comparison setting is where you indicate how you want to compare the value of the property at run time on the target system with the value that you specify in the Compare To setting. For example, consider a property comparison condition in which the value of the Conversion setting is String, the value of the Comparison setting is Equal, and the value of the Compare To setting is MyValue. At run time, this condition evaluates as true if the property value at run time is MyValue; it evaluates as false if the property value is not set or is any other value.

MSI Package Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*

- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create an MSI Package condition.

The MSI Package setting shows the condition that is configured for checking target systems for the presence of a product that was installed by a particular .msi package. To define this type of condition, configure the subsettings under the MSI Package setting as needed.

The following subsettings are available for this condition.

Table 9-15 • MSI Package Condition Settings

Setting	Description
Product Code	To create a conditional statement that checks for the presence of a product that was installed by an .msi package with a particular product code, click the ellipsis button (...) in this setting to browse to the package and have InstallShield enter the product code for you. As an alternative, you can manually enter the product code. A sample entry is {5D607F6A-AF48-4003-AFA8-69E019A4496F}.  ***Tip*** • *If you add an .msi package to your project, InstallShield automatically creates an MSI Package eligibility condition for the package, and uses an asterisk (*) in the condition's Product Code and Product Version settings as placeholders for the package's own product code and product version. InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from launching the package if a package with a matching product code but a later product version is already installed. In general, this built-in condition should not be overridden, except in advanced scenarios in which changing the default behavior is appropriate.* *You can use an asterisk as a placeholder for the current package's product code and product version when you are defining eligibility and detection MSI package conditions, as long as the package that you are configuring is an .msi package.*
Package Code	To create a conditional statement that checks for the presence of a product that was installed by an .msi package with a particular package code, click the ellipsis button (...) in this setting to browse to the package and have InstallShield enter the package code for you. As an alternative, you can manually enter the package code. A sample entry is {5D607F6A-AF48-4003-AFA8-69E019A4496F}.

Table 9-15 • MSI Package Condition Settings (cont.)

Setting	Description
Product Version	To create a conditional statement that checks for the presence of a product with a particular product version that was installed by an .msi package, click the ellipsis button (...) in this setting to browse to the package and have InstallShield enter the product version for you. As an alternative, you can manually enter the product version. Then use the Comparison setting to specify whether you want the product version to be less than, greater than, or equal to the value that you are specifying. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. The maximum value for the aaa and bbb portions is 255. The maximum value for *ccccc* and *ddddd* is 65,535. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions.  ***Tip*** • *If you add an .msi or .msp package to your project, InstallShield automatically creates an MSI Package eligibility condition for the package, and uses an asterisk (*) in the condition's Product Code and Product Version settings as placeholders for the package's own product code and product version. InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from launching the package if a package with a matching product code but a later product version is already installed. In general, this built-in condition should not be overridden, except in advanced scenarios in which changing the default behavior is appropriate.* *You can use an asterisk as a placeholder for the current package's product code and product version when you are defining eligibility and detection MSI package conditions, as long as the package that you are configuring is an .msi package.*
Comparison	If you specify a version number in the Product Version setting, select the appropriate option to indicate how you want to compare the version number on the target system with the one that you enter. For example, if you want the condition to be true if the version on the target system is less than or equal to 4.0.0, enter 4.0.0 in the Product Version setting, and select Less Than or Equal To in the Comparison setting.

Table 9-15 • MSI Package Condition Settings (cont.)

Setting	Description
Patch Code	To create a conditional statement that checks for the presence of a product that was installed by an .msi package with a particular patch code for a specific product code, enter the patch code in this setting, and enter the product code in the Product Code setting. A sample entry is {5D607F6A-AF48-4003-AFA8-69E019A4496F}. If you enter a value in this setting, any value that is entered in the Package Code and Product Version settings are ignored.

MSI Upgrade Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create an MSI Upgrade condition.

The MSI Upgrade setting shows the condition that is configured for checking target systems for the presence of a version of a product that you want to update, or for the presence of future versions of a product that you do not want to downgrade. In either case, the product whose presence is being checked is installed by an .msi package. To define this type of condition, configure the subsettings under the MSI Upgrade setting as needed.

The following subsettings are available for this condition.

Table 9-16 • MSI Upgrade Condition Settings

Setting	Description
Upgrade Code	To create a conditional statement that checks for the presence of a product that was installed by an .msi package with a particular upgrade code, click the ellipsis button (...) in this setting to browse to the package and have InstallShield enter the upgrade code for you. As an alternative, you can manually enter the upgrade code. A sample entry is {5D607F6A-AF48-4003-AFA8-69E019A4496F}.  ***Tip*** • *You can use an asterisk (*) as a placeholder for the current package's upgrade code and either the minimum or maximum version number when you are defining eligibility and detection MSI upgrade conditions, as long as the package that you are configuring is an .msi package.*
Minimum Version	Enter the minimum product version that the conditional statement should evaluate when determining whether to run the upgrade package, or click the ellipsis button (...) in this setting to browse to the package and have InstallShield enter the minimum version. Version numbers should be in the format xxxx.xxxx.xxxx.  ***Tip*** • *You can use an asterisk (*) as a placeholder for the current package's upgrade code and either the minimum or maximum version number when you are defining eligibility and detection MSI upgrade conditions, as long as the package that you are configuring is an .msi package.*
Include Minimum Version	Indicate whether you want to include the minimum version value in the range of product versions that you want to include in the conditional statement. This setting helps you specify whether you are using the lower bounds for a range of product versions that your upgrade package will or will not support.
Maximum Version	Enter the maximum product version that the conditional statement should evaluate when determining whether to run the upgrade package, or click the ellipsis button (...) in this setting to browse to the package and have InstallShield enter the maximum version. Version numbers should be in the format xxxx.xxxx.xxxx.  ***Tip*** • *You can use an asterisk as a placeholder for the current package's upgrade code and either the minimum or maximum version number when you are defining eligibility and detection MSI upgrade conditions, as long as the package that you are configuring is an .msi package.*

Table 9-16 • MSI Upgrade Condition Settings (cont.)

Setting	Description
Include Maximum Version	Indicate whether you want to include the maximum version value in the range of product versions that you want to include in the conditional statement. This setting helps you specify whether you are using the upper bounds for a range of product versions that your upgrade package will or will not support.

Eligible Package Condition Setting

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create an Eligible Package condition.

The Eligible Package setting shows the condition that is configured for checking whether a different package or a feature in the Advanced UI or Suite/Advanced UI installation is eligible for installation on a target system. For example, if a patch package is eligible for installation only if the base package is eligible for installation, you can create an Eligible Package condition to tie the patch's eligibility to the base package's eligibility. In this scenario, you would select the patch package in the Packages view, create the condition, and specify the package GUID of the base package in that condition.

To define this type of condition, configure the subsetting under the Eligible Package setting as needed.

The following subsetting is available for this condition.

Table 9-17 • Eligible Package Condition Setting

Setting	Description
Package GUID	To create a conditional statement that is based on whether a different package in the Advanced UI or Suite/Advanced UI installation is eligible for installation on a target system, select the other required package in the list in this setting. The list contains all of the packages in the project. As an alternative, you can enter the package GUID of that other required package. A sample entry is {5D607F6A-AF48-4003-AFA8-69E019A4496F}. For example, if a patch package is eligible for installation only if the base product is eligible for installation, you can create an Eligible Package condition to tie the patch's eligibility to the base product's eligibility. In this scenario, you would select the patch package in the Packages view, create the condition, and select the base package in that condition. The package GUID is identified in the Package GUID setting in the Packages view.

InstallScript Package Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create an InstallScript Package condition.

The InstallScript Package setting shows the condition that is configured for checking target systems for the presence of a product that was installed by a particular InstallScript package. To define this type of condition, configure the subsettings under the InstallScript Package setting as needed.

The following subsettings are available for this condition.

Table 9-18 • InstallScript Package Condition Settings

Setting	Description
Product Code	To create a conditional statement that checks for the presence of a product that was installed by a particular InstallScript package with a particular product code, click the ellipsis button (...) in this setting to browse to the `data1.hdr` file of the uncompressed InstallScript package and have InstallShield enter the product code for you. As an alternative, you can manually enter the product code. A sample entry is {5D607F6A-AF48-4003-AFA8-69E019A4496F}.
Product Version	To create a conditional statement that checks for the presence of a product with a particular product version that was installed by an InstallScript package, enter the product version. Then use the Comparison setting to specify whether you want the product version to be less than, greater than, or equal to the value that you are specifying. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. The maximum value for the aaa and bbb portions is 255. The maximum value for *ccccc* and *ddddd* is 65,535. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions.
Verify Log Exists	Select the option that describes whether you want the Advanced UI or Suite/Advanced UI installation to verify that the uninstallation log file that is registered for the product is present on target systems. If you leave this setting blank, the Advanced UI or Suite/Advanced UI installation behaves as if you selected Yes in this setting.
Check Per-User Registration	Select the option that describes whether you want the Advanced UI or Suite/Advanced UI installation to check HKEY_CURRENT_USER for uninstallation information on target systems. Available options are: • **Yes**—The installation checks both HKEY_CURRENT_USER and HKEY_LOCAL_MACHINE for uninstallation information. • **No**—The installation checks only HKEY_LOCAL_MACHINE for uninstallation information. If you leave this setting blank, the Advanced UI or Suite/Advanced UI installation behaves as if you selected Yes in this setting.

Table 9-18 • InstallScript Package Condition Settings (cont.)

Setting	Description
Comparison	If you specify a version number in the Product Version setting, select the appropriate option to indicate how you want to compare the version number on the target system with the one that you enter. For example, if you want the condition to be true if the version on the target system is less than or equal to 4.0.0, enter 4.0.0 in the Product Version setting, and select Less Than or Equal To in the Comparison setting.

Locale Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a Locale condition.

The Locale setting shows the condition that is configured for matching one or more locale-related settings on target systems. To define this type of condition, configure one or more of the subsettings under the Locale setting as needed.

The following subsettings are available for this condition.

Table 9-19 • Locale Condition Settings

Setting	Description
User Interface	To create a conditional statement that checks for the locale of the user interface on target systems, enter the locale identifier (LCID) in any of the following formats: • Decimal LCID; for example: **1033** • Hexadecimal LCID preceded with 0x; for example: **0x409** • Locale name, which is checked only on Windows Vista and later systems, and ignored on earlier systems; for example: **en-us**, **en**, **zh-CN** For a list of LCIDs, see Locale IDs Assigned by Microsoft on MSDN. For more details on entering values in this setting, see Using Locale Conditions in Advanced UI and Suite/Advanced UI Projects.
Operating System	To create a conditional statement that checks for the language of the operating system on target systems, enter the locale identifier (LCID) in either of the following formats: • Decimal LCID; for example: **1033** • Hexadecimal LCID preceded with 0x; for example: **0x409** For a list of LCIDs, see Locale IDs Assigned by Microsoft on MSDN. For more details on entering values in this setting, see Using Locale Conditions in Advanced UI and Suite/Advanced UI Projects.
ANSI Code Page	To create a conditional statement that checks for a ANSI code page on target systems, enter the code page identifier. For a list of code page identifiers, see Code Page Identifiers on MSDN. For more details on entering values in this setting, see Using Locale Conditions in Advanced UI and Suite/Advanced UI Projects.

Suite Installed Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create a Suite Installed condition.

The Suite Installed setting shows the condition that is configured for checking whether a particular version of an Advanced UI or Suite/Advanced UI installation is already installed on a target system. To define this type of condition, configure one or more of the subsettings under the Suite Installed setting as needed.

The following subsettings are available for this condition.

Table 9-20 • Suite Installed Condition Settings

Setting	Description
Suite GUID	To create a conditional statement that checks whether a particular version of an Advanced UI or Suite/Advanced UI installation is already installed on a target system, enter the Suite GUID of that installation.  ***Tip*** • *When you create an Advanced UI or Suite/Advanced UI project, InstallShield automatically creates a Suite Installed exit condition for the installation, and uses an asterisk (*) in the condition's Suite GUID and Version settings as placeholders for the project's own Suite GUID and version. InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from installing over a future newer version of the installation. In general, this built-in condition should not be overridden, except in advanced scenarios in which changing the default behavior is appropriate.* *To learn more, see Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed.*

Table 9-20 • Suite Installed Condition Settings (cont.)

Setting	Description
Version	To create a conditional statement that checks whether a particular version of an Advanced UI or Suite/Advanced UI installation is already installed on a target system, enter the version number. Then use the Comparison setting to specify whether you want the product version to be less than, greater than, or equal to the value that you are specifying. The typical format for the version number is *aaa.bbb.ccccc* or *aaa.bbb.ccccc.ddddd*, where *aaa* represents the major version number, *bbb* represents the minor version number, *ccccc* represents the build number, and *ddddd* represents the revision number. The maximum value for the aaa and bbb portions is 255. The maximum value for *ccccc* and *ddddd* is 65,535. Note that although you can include the fourth field (*ddddd*) when you specify the product version, the Advanced UI or Suite/Advanced UI installation does not use this part of the product version to distinguish between different product versions. ***Tip*** • *When you create an Advanced UI or Suite/Advanced UI project, InstallShield automatically creates a Suite Installed exit condition for the installation, and uses an asterisk (*) in the condition's Suite GUID and Version settings as placeholders for the project's own Suite GUID and version. InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from installing over a future newer version of the installation. In general, this built-in condition should not be overridden, except in advanced scenarios in which changing the default behavior is appropriate.* *To learn more, see Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed.*
Compare	Select the appropriate option to indicate how you want to compare the version number on the target system with the one that you enter. For example, if you want the condition to be true if the version on the target system is less than or equal to 4.0.0, enter 4.0.0 in the Product Version setting, and select Less Than or Equal To in the Comparison setting. ***Tip*** • *When you create an Advanced UI or Suite/Advanced UI project, InstallShield automatically creates a Suite Installed exit condition for the installation, and uses an asterisk (*) in the condition's Suite GUID and Version settings as placeholders for the project's own Suite GUID and version. InstallShield adds this built-in condition to prevent the Advanced UI or Suite/Advanced UI installation from installing over a future newer version of the installation. In general, this built-in condition should not be overridden, except in advanced scenarios in which changing the default behavior is appropriate.* *To learn more, see Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed.*

AppX Package Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create an AppX Package condition.

The AppX Package setting shows the condition that is configured for checking target systems for the presence of a particular AppX app. To define this type of condition, click the ellipsis button (...) in the AppX Package setting to browse to the package and have InstallShield enter the appropriate information in the subsettings for you. As an alternative, you can manually configure the subsettings under the AppX Package setting as needed.

Note • *Support for browsing to the .appx package by using the ellipsis button in the AppX Package setting requires Windows Vista or later or Windows Server 2008 or later on the machine that has InstallShield or the Standalone Build.*

The following subsettings are available for this condition.

Table 9-21 • AppX Package Condition Settings

Setting	Description
Name	To create a conditional statement that checks for the presence of a particular AppX app, enter the name that is used to identify the AppX app to the operating system. To browse to the appropriate .appx package and have InstallShield enter the value in this setting for you, click the ellipsis button (...) in the AppX Package setting.
Publisher	This setting specifies the publisher that is specified in the subject field of the certificate that was used to sign the package. To browse to the appropriate .appx package and have InstallShield enter the value in this setting for you, click the ellipsis button (...) in the AppX Package setting.

Table 9-21 • AppX Package Condition Settings (cont.)

Setting	Description
Version	This setting specifies the version number of the package. To browse to the appropriate .appx package and have InstallShield enter the value in this setting for you, click the ellipsis button (...) in the AppX Package setting.
Comparison	If you specify a version number in the Version setting, select the appropriate option to indicate how you want to compare the version number on the target system with the one that you enter. For example, if you want the condition to be true if the version on the target system is less than or equal to 4.0.0, enter 4.0.0 in the Version setting, and select Less Than or Equal To in the Comparison setting.
Processor Architecture	This setting identifies the architecture (x86, x64, or neutral) that must be present on target systems for this package. To browse to the appropriate .appx package and have InstallShield enter the value in this setting for you, click the ellipsis button (...) in the AppX Package setting.

Package Operation Condition Settings

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an action condition in a Suite/Advanced UI project, you can create a Package Operation condition.

The Package Operation setting shows the condition that is configured for checking the target state of a particular package in a Suite/Advanced UI installation. This type of condition is available only for actions that are associated with an event in the Events view or a package in the Packages view. If you associate the action with an event in the Events view, the earliest event for which you can schedule the action is OnStaging.

To define this type of condition, configure the subsettings under the Package Operation setting as needed.

The following subsettings are available for this condition.

Table 9-22 • Package Operation Condition Settings

Setting	Description
Package	To create a conditional statement that checks the target operation of a particular package in the Suite/Advanced UI installation, select the name of the package in this setting.
Operation	Select the type of operation that you want to check for the package operation condition. Available options are: • **none**—The package is not set to be installed, removed, repaired, or modified. • **install**—The package is set to be installed. • **remove**—The package is set to be removed. • **repair**—The package is set to be repaired. • **modify**—The package is set to be modified.

Feature Operation Condition Settings

Project • *This information applies to Suite/Advanced UI projects.*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an action condition in a Suite/Advanced UI project, you can create a Feature Operation condition.

The Feature Operation setting shows the condition that is configured for checking the target state of a particular feature in a Suite/Advanced UI installation. This type of condition is available only for actions that are associated with an event in the Events view or a package in the Packages view. If you associate the action with an event in the Events view, the earliest event for which you can schedule the action is OnStaging; feature states are not available before the OnStaging event.

To define this type of condition, configure the subsettings under the Feature Operation setting as needed.

The following subsettings are available for this condition.

Table 9-23 • Feature Operation Condition Settings

Setting	Description
Feature	To create a conditional statement that checks the target operation of a particular feature in the Suite/Advanced UI installation, select the name of the feature in this setting.
Operation	Select the type of operation that you want to check for the feature operation condition. Available options are: • **none**—The feature is not set to be installed or removed. • **install**—The feature is set to be installed. • **remove**—The feature is set to be removed.

Extension Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can create an extension condition that calls a C/C++ DLL that you have created to implement your own custom condition. The custom condition could check target systems for factors that the built-in types of condition checks do not evaluate. For instructions on how to create the DLL and add it to your project, see Creating a Custom Condition for an Advanced UI or Suite/Advanced UI Installation.

When you add an extension condition DLL, InstallShield adds a row for the condition. The row consists of two fields. The left field of this row uses the following syntax to describe your condition:

ExtensionDLLName:Condition

where *ExtensionDLLName* is the name of the DLL file, but without the .dll part of the name.

The right field of this row is a read-only field that shows the parameter-and-value pairs that you have defined for the condition. This setting also contains an **Add Parameter** button, which lets you define parameters and their values, as well as a **Delete this condition** button, which lets you delete the extension condition.

To add a parameter and value, click the **Add Parameter** button in the right field of the extension condition row. The **Configure Extension Condition** dialog box opens, enabling you to enter the name of the parameter. InstallShield adds a new row for the parameter. Configure the value of the parameter in the field on the right.

Mode Condition Settings

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for a wizard interface condition in an Advanced UI or Suite/Advanced UI project, you can create a Mode condition. The Mode setting shows the condition that is configured for checking the mode in which the Advanced UI or Suite/Advanced UI installation is running. To define this type of condition, configure the subsetting under the Mode setting as needed.

The following subsetting is available for this condition.

Table 9-24 • Mode Condition Settings

Setting	Description
Value	To create a conditional statement that checks the mode in which the Advanced UI or Suite/Advanced UI installation is running, select the appropriate mode in this setting. Available options are: • **install**—The installation is running in first-time installation mode. • **stage**—The installation is being staged; that is, it is being uncompressed and copied to a specified location. Note that none of the packages in the installation are run in this mode. • **maintenance**—The installation is running in maintenance mode (modify, remove, or repair). • **modify**—The product is being modified. • **remove**—The product is being removed. • **repair**—The product is being repaired.

Guidelines for Defining Conditions in an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Following are some guidelines on defining conditions in an Advanced UI or Suite/Advanced UI project.

Define an Eligibility Condition for Each .exe Package to Prevent Downgrades

InstallShield creates an eligibility condition automatically for each .msi package in the Advanced UI or Suite/Advanced UI project by default; the eligibility condition checks to ensure that a later version of the package is not already present on target systems.

For .exe packages, set up the same behavior: create an appropriate eligibility condition to ensure that the Advanced UI or Suite/Advanced UI installation does not downgrade your product by allowing an earlier version to install over a later version.

Note that if your product supports side-by-side versions of, for example, version 3 with version 4 on the same system, ensure that your conditions support this. If your product does not support these versions on the same system, ensure that your conditions block this scenario.

Consider Defining an Eligibility Condition for Each Package to Check for Requirements and Dependencies

A package may fail to install or the product may not run as expected on target systems that do not meet its requirements (such as the minimum operating system version) or that do not have its dependencies (such as the .NET Framework, Microsoft SQL Server, or a third-party library). To prevent the Advanced UI or Suite/Advanced UI package from attempting to download (if applicable) and launch packages on a target system on which they will fail, define an eligibility condition that checks for requirements and dependencies. And whenever you have a package that contains one or more launch conditions, ensure that you add corresponding eligibility conditions to the package.

Because .msp packages require their target .msi package to be present, create an eligibility condition that checks target systems for the presence of the product that you want to update.

Review the Default Exit Condition for Relevance

By default, when you create a new Advanced UI or Suite/Advanced UI project, InstallShield automatically creates an exit condition that aborts the Advanced UI or Suite/Advanced UI installation if none of the primary packages are eligible for installation. The exit condition has an Eligible Package type of condition check, and it uses an asterisk (*) in the condition's package ID setting as a placeholder for each primary package's ID.

You can indirectly control this default exit condition by modifying the eligibility condition of each package.

The default exit message assumes that your eligibility conditions only prevent downgrades. If any of the primary packages in your project have an eligibility condition that checks for something else, you may need to edit the default message to properly reflect the reason for the Advanced UI or Suite/Advanced UI installation aborting.

For example, if your Advanced UI or Suite/Advanced UI project includes one 64-bit primary package, this package may have an eligibility condition that checks for an x64 architecture. In this case, you may need to edit the exit message and condition to account for the fact that the package is not eligible on a 32-bit target system. However, if your Advanced UI or Suite/Advanced UI package includes one 64-bit primary package and one 32-bit primary package, and you configure the eligibility conditions for these packages so that the appropriate one is launched on target systems that have the corresponding architecture, the default exit message and condition may be suitable as is.

Define a Detection Condition for Each .exe Package

Every .exe package in an Advanced UI or Suite/Advanced UI project must have at least one defined detection condition. The detection condition should evaluate whether the package is already installed on target systems. At build time, InstallShield combines the detection conditions from all of the primary packages in an Advanced UI or Suite/Advanced UI project to form part of the mode conditions of the Advanced UI or Suite/Advanced UI installation.

The Advanced UI or Suite/Advanced UI `Setup.exe` file can determine whether .msi packages and InstallScript packages in the Advanced UI or Suite/Advanced UI installation have already been installed on target systems. It can also determine whether an .msp package in the Advanced UI or Suite/Advanced UI installation has already been applied to an earlier version of the product. Similarly, it can determine whether .appx packages in the Suite/Advanced UI installation have already been installed on target systems. Therefore, manually defining a detection condition for these three types of packages is not a requirement.

Be Very Explicit

Make sure that you are creating conditions for all of the possible results; that way, you have full control over the appropriate behavior. For example, if you are checking for a specific version of a file or for a particular registry value, make sure to also check for the existence of the file or registry entry. Sometimes a missing file is fine but a given version number of a file is bad; sometimes a missing file is bad.

Test, Test Some More, and Then Test Again

Test your conditions on various target systems and under different scenarios to make sure that the Advanced UI or Suite/Advanced UI installation behaves as expected. Use clean machines, machines that have earlier versions of your products, and machines that have the current version. Also consider building a future version of your product to test that your current installation does not downgrade future versions.

Detecting Whether a Specific Version of an Advanced UI or Suite/Advanced UI Installation Is Already Installed

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Advanced UI and Suite/Advanced UI projects include support for determining whether a particular version of an Advanced UI or Suite/Advanced UI installation is already installed on target systems. This type of condition check is called a *Suite Installed condition*, and it checks the target system's registry for the Advanced UI or Suite/Advanced UI installation's Uninstall key.

When an end user successfully installs a product through an Advanced UI or Suite/Advanced UI installation, the installation creates an Uninstall registry key in the following 32-bit location in the registry:

SOFTWARE\Microsoft\Windows\CurrentVersion\Uninstall*{Suite GUID}*

The Uninstall key contains uninstallation information for the installation. The name that is used for the registry key is the Suite GUID of the Advanced UI or Suite/Advanced UI installation. One of the registry values that this registry key contains is a DisplayVersion value; the data for this value is the version number of the Advanced UI or Suite/Advanced UI installation. Both the Suite GUID and the version number are defined in the General Information view of the project.

InstallShield includes two Suite Installed conditions in each Advanced UI or Suite/Advanced UI project by default. You can also add your own Suite Installed conditions to a project as needed.

Default Suite Installed Conditions in Advanced UI and Suite/Advanced UI Projects

When you create an Advanced UI or Suite/Advanced UI project, InstallShield creates two Suite Installed conditions in your project by default:

- **An exit condition**—This default exit condition is shown in the General Information view of the project. The Suite Installed exit condition prevents end users from being able to install the current version of the Advanced UI or Suite/Advanced UI installation over a future newer version of the same Advanced UI or Suite/Advanced UI installation.

  That is, the installation compares the version number that is stored in the DisplayVersion value of the Uninstall key on the target system with the value that is configured in the project. If the version in the target system's registry is greater than the version that is configured in the project, the installation displays an error message. When the end user dismisses the message, the installation exists. This default Suite Installed exit condition prevents downgrades of the Advanced UI or Suite/Advanced UI installation.

- **An install mode condition**—The install mode condition is shown only in the project file (.issuite). This type of condition is not available for edit within InstallShield. The Suite Installed mode condition causes the Advanced UI or Suite/Advanced UI installation to run in first-time installation mode if end users install a new version of the Advanced UI or Suite/Advanced UI installation over an older version of the same Advanced UI or Suite/Advanced UI installation. Furthermore, the Suite Installed mode condition may prevent the installation from running in first-time installation mode if the same version of the Advanced UI or Suite/Advanced UI installation is already installed.

  The default install mode condition compares the DisplayVersion value of the Uninstall key on the target system with the value that is configured in the project. If these values are not the same, the Suite Installed part of the install mode condition evaluates as true.

  Note that an install mode condition also evaluates the detection conditions of all of the primary packages in the installation. Thus, even though the Suite Installed part of the install mode condition may evaluate as false (meaning that it appears that the target system has the same version that is configured in the project), the Advanced UI or Suite/Advanced UI installation may run in first-time installation mode. This may occur if none of the detection conditions for the primary packages in the installation evaluate as true.

In general, these built-in Suite Installed conditions should not be overridden, except in advanced scenarios in which changing the default behavior is appropriate.

Note that InstallShield uses an asterisk (*) in the default Suite Installed condition's Suite GUID and Version settings as placeholders for the project's own Suite GUID and version. At build time, InstallShield replaces the asterisks with the appropriate values in the resulting build.

Using the Suite Installed Condition Check in Your Own Conditions

If you want your Advanced UI or Suite/Advanced UI installation to check target systems for the presence of a particular version of the installation, you can add your own Suite Installed condition check for an exit condition, a detection condition, or other any other condition.

Using Locale Conditions in Advanced UI and Suite/Advanced UI Projects

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

The locale type of condition in an Advanced UI or Suite/Advanced UI project has several subsettings. The following table describes the formats that you can use for specifying the languages in each of these subsettings.

Table 9-25 • Subsettings Under the Locale Condition Setting

Setting	Format for Values in This Setting	Notes
User Interface	Enter locale identifiers (LCIDs) in any of the following formats: • Decimal LCID; for example: **1033** • Hexadecimal LCID preceded with 0x; for example: **0x409** • Locale name, which is checked only on Windows Vista and later systems, and ignored on earlier systems; for example: **en-us**, **en**, **zh-CN** You can optionally precede an LCID or name with a tilde (~) to check for a language-only match, ignoring the country or region. For example, an entry of **~1033**—for English (United States)—results in a match on a target system that uses Australian English, UK English, U.S. English, or other regional variants of English.	At run time, the installation uses the following functions to check the user interface on target systems: • GetUserDefaultLCID • GetSystemDefaultLCID • GetUserDefaultLocaleName (only on Windows Vista and later systems) • GetSystemDefaultLocaleName (only on Windows Vista and later systems) For a list of LCIDs, see Locale IDs Assigned by Microsoft on MSDN.
Operating System	Enter LCIDs in either of the following formats: • Decimal LCID; for example: **1033** • Hexadecimal LCID preceded with 0x; for example: **0x409** You can optionally precede an LCID with a tilde to check for a language-only match, ignoring the country or region. For example, an entry of **~1033**—for English (United States)—results in a match on a target system that uses Australian English, UK English, U.S. English, or other regional variants of English.	One example of when this condition is useful is for .NET Framework 1.1 service packs for Windows Server 2003; these service packs target specific operating system languages. At run time, the installation uses the function GetSystemDefaultUILanguage to check the language of the operating system on target systems. For a list of LCIDs, see Locale IDs Assigned by Microsoft on MSDN.

Table 9-25 • Subsettings Under the Locale Condition Setting (cont.)

Setting	Format for Values in This Setting	Notes
ANSI Code Page	Code page identifiers; for example: **932**	At run time, the installation uses the GetACP function to check the ANSI code page of the target system. For a list of code page identifiers, see Code Page Identifiers on MSDN.

If you want to check the user interface, operating system, or ANSI code page on target systems for any one of two or more languages, you can specify multiple values and separate them with a comma (,). Any spaces that are included in the setting are ignored. For example, to check for either a U.S. English or Japanese user interface, you could enter the following value in the User Interface setting:

```
0x409, 0x411
```

In this scenario, the User Interface condition is met if the target system's UI is U.S. English or Japanese.

Note that if you specify values in two or more locale settings, each of those locale settings must have a match in order for the condition to be met. For example, if you specify languages in the User Interface and ANSI Code Page settings, the condition evaluates as true whenever one of the User Interface languages are a match and also one of the ANSI Code Page languages are a match.

Creating a Custom Condition for an Advanced UI or Suite/Advanced UI Installation

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

When you are building a conditional statement for an exit, detection, eligibility, or feature condition in an Advanced UI or Suite/Advanced UI project, or for an action condition in a Suite/Advanced UI project, you can select from a number of different built-in types of checks that you want to be evaluated on target systems. Examples are operating system version, presence of a file or registry entry, and presence of an already installed product.

The built-in types of condition checks may not cover all of the scenarios that you want your Advanced UI or Suite/Advanced UI installation to evaluate on target systems. Therefore, InstallShield lets you create your own type of custom condition called an *extension condition*. An extension condition calls a C/C++ DLL that you have created.

For example, if you want to check for the existence of an IIS Web site, you can create a DLL that checks target systems and then include this DLL in your Advanced UI or Suite/Advanced UI project.

For guidance on how to create the extension condition DLL, see Creating an Extension Condition DLL for an Advanced UI or Suite/Advanced UI Project.

For instructions on how to incorporate the extension condition DLL in your project, see Adding an Extension Condition DLL to an Advanced UI or Suite/Advanced UI Project.

Creating an Extension Condition DLL for an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Note • *Flexera Software does not provide technical support for Windows programming or DLL debugging. You are responsible for correctly writing any DLL functions. Prototype your custom DLL functions as explained below. Any variation in return type can cause the extension condition DLL to fail.*

The first step in creating an extension condition is to create the DLL. You can create an extension condition DLL with any recent version of Visual C++ or any tool or language that supports COM and DLL exports.

The Advanced UI and Suite/Advanced UI engine requires two entry points per condition—one to validate the condition and one to evaluate the condition. Both entry points must be based on the name of the extension condition. For example, for a condition called **MyCondition**, the DLL that tests the condition must export the following entry points:

- **MyCondition_Validate**
- **MyCondition_Evaluate**

These functions should be defined as follows:

```
HRESULT __stdcall MyCondition_Validate(IDispatch *pCondition);
HRESULT __stdcall MyCondition_Evaluate(IDispatch *pCondition, VARIANT_BOOL *pbResult);
```

To be able to call these functions from the Advanced UI or Suite/Advanced UI installation, you must include a definition file (.def) when you build the DLL to export the function properly. The following is the contents of a sample .def file. The name after LIBRARY should be the name that you are using for the DLL.

```
LIBRARY "MyConditionLibrary"
EXPORTS
```

```
MyCondition_Validate
MyCondition_Evaluate
```

The Advanced UI or Suite/Advanced UI installation calls the validation entry point while parsing the conditions that were defined in the project. This enables the extension condition to ensure that the condition parameters that were defined in the project are suitable for the condition to evaluate in a predictable manner. This entry point is called any time an extension condition of this type is found for an exit condition, a detection condition, or any other type of condition. Returning S_OK from this entry point indicates to the Advanced UI or Suite/Advanced UI installation that the condition is valid. Returning a failed HRESULT status causes the Advanced UI or Suite/Advanced UI installation to abort with an error for the condition that was last validated.

The Advanced UI or Suite/Advanced UI installation calls the evaluation entry point any time that an extension condition of this type is referenced by a condition that was configured in the project. The evaluation is allowed to perform any action that is necessary to evaluate the condition to a true or false result. The result is returned in the form of a VARIANT_BOOL in the pbEvalResult parameter. A result of VARIANT_TRUE is treated as a true result and a result of VARIANT_FALSE is treated as a false result. A success status (S_OK) should be returned from an evaluation function. A failure status aborts the evaluation of the current condition block being evaluated, but it does not cause the installation to abort.

Note that although the Advanced UI or Suite/Advanced UI installation allows any action to be performed, extension conditions run with the privileges of the Advanced UI or Suite/Advanced UI installation from which they are called. Some actions may require administrator privileges (such as reading IIS 7.x configuration data). In such cases, in order for the condition to access the required data successfully, the installation would need to be run with administrator privileges, or it would need to include an administrator manifest.

The IDispatch interface that is passed to the validation and evaluation entry points implements the ISuiteExtension interface. To obtain a pointer to an ISuiteExtension, call the QueryInterface method on the IDispatch interface. The ISuiteExtension interface allows the condition functions to access the attribute parameters that are defined for the extension condition in the Advanced UI or Suite/Advanced UI project. Note that each condition in the project receives a different interface pointer that is specific to each condition instance. Therefore, the interface pointer that is passed to the entry point function should always be used and should not be saved across calls to the extension DLL.

The interface is defined as follows:

```
interface ISuiteExtension : IDispatch {
  [propget, id(1), helpstring("Attribute")]
    HRESULT Attribute([in]BSTR bstrName, [out, retval]BSTR *bstrValue);

  [id(2), helpstring("method LogInfo")]
    HRESULT LogInfo([in]BSTR bstr);

  [propget, id(3), helpstring("Property")]
    HRESULT Property([in]BSTR bstrName, [out, retval]BSTR *bstrValue);

  [propput, id(3), helpstring("Property")]
    HRESULT Property([in]BSTR bstrName, [in]BSTR bstrValue);

  [id(4), helpstring("FormatProperty")]
    HRESULT FormatProperty([in]BSTR bstrValue, [out, retval]BSTR *bstrReturnValue);

  [id(5), helpstring("ResolveString")]
    HRESULT ResolveString([in]BSTR bstrStringId, [out, retval]BSTR *bstrReturnValue);
```

```
};
```

Advanced UI and Suite/Advanced UI projects use the function prototype to pass the ISuiteExtension COM interface pointer to an extension condition DLL, which enables you to access the following functions:

- **get_Attribute**

  ```
  HRESULT get_Attribute([in]BSTR bstrName, [out, retval]BSTR *bstrValue);
  ```

  This method retrieves the value of an attribute for the current condition instance. The attribute name is passed in bstrName, and its corresponding value is returned in bstrValue.

- **LogInfo**

  ```
  HRESULT LogInfo([in]BSTR bstr);
  ```

  This method writes any information that is needed to the Advanced UI or Suite/Advanced UI debug log, making it available for debugging or other informational purposes. The bstr parameter contains the string to be written to the log.

- **get_Property**

  ```
  HRESULT get_Property([in]BSTR bstrName, [out, retval]BSTR *bstrValue);
  ```

  This method retrieves the value of any property that is currently defined in the running Advanced UI or Suite/Advanced UI installation. Properties that are not defined return an empty value. The bstrName parameter specifies the name of the property whose value is being obtained. The value for the property is returned in the bstrValue parameter.

- **put_Property**

  ```
  HRESULT put_Property([in]BSTR bstrName, [in]BSTR bstrValue);
  ```

  This method sets the value of a new property or changes the value of an existing property in the currently running Advanced UI or Suite/Advanced UI installation. Passing an empty value effectively deletes the property. The bstrName parameter specifies the name of the property to set. The bstrValue parameter specifies the value to set for the specified property.

- **FormatProperty**

  ```
  HRESULT FormatProperty([in]BSTR bstrValue, [out, retval]BSTR *bstrReturnValue);
  ```

  This method formats a string that contains embedded property references (in the form '[PROPERTYNAME]') in the string that is provided in the bstrValue parameter. The formatted value is returned in the bstrReturnValue parameter.

  Note that only one level of property references is formatted. If one property's formatted value contains another property reference, this method does not format the second property.

- **ResolveString**

  ```
  HRESULT ResolveString([in]BSTR bstrStringId, [out, retval]BSTR *bstrReturnValue);
  ```

  This method resolves an Advanced UI or Suite/Advanced UI string identifier into the corresponding string value for the currently running Advanced UI or Suite/Advanced UI installation in the currently selected UI language. The bstrStringId parameter specifies the string identifier to resolve, and the resolved string is returned in bstrReturnValue. If no such string identifier exists, the returned string is empty.

To access the ISuiteExtension interface from your DLL, you can use `#import` to incorporate the type library information from the `SetupSuite.exe` file that is installed with InstallShield. The path is:

`InstallShield Program Files Folder``\Redist\Language Independent\i386\SetupSuite.exe"`

For example, to import the type library in a VC++ project (such as in `stdafx.h`), use the following statement:

```
#import "C:\Program Files\InstallShield\2013\Redist\Language Independent\i386\SetupSuite.exe"
no_namespace raw_interfaces_only named_guids
```

Note that if InstallShield is installed to a different location, adjust the path in the #import statement accordingly.

Once you have created your extension condition DLL, you can add it to your project. To learn how, see Adding an Extension Condition DLL to an Advanced UI or Suite/Advanced UI Project.

Adding an Extension Condition DLL to an Advanced UI or Suite/Advanced UI Project

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

Once you have created an extension condition DLL, you can add it to your project.

Task: ***To add an extension condition DLL to an Advanced UI or Suite/Advanced UI project:***

1. Find the setting for the detection condition, eligibility condition, or other condition in your project that you want to use your extension condition DLL.

   To learn more about setting up these conditions, see Building Conditional Statements in Advanced UI and Suite/Advanced UI Projects.

2. If necessary, add an **Any**, **All**, or **None** operator to the condition group.
3. In the **Any**, **All**, or **None** setting, click the **New Condition** button and then click **Browse for an Extension Condition DLL**. The **Open** dialog box opens.
4. Select the extension condition DLL that you created, and then click **Open**. The **Configure Extension Condition** dialog box opens.

   Note that the DLL must be written according to the instructions in Creating an Extension Condition DLL for an Advanced UI or Suite/Advanced UI Project.

5. Click the condition that you want to use. InstallShield adds the DLL to your project as a support file. InstallShield also adds a new row for the condition. The row consists of two fields. The left field of this row uses the following syntax to describe your condition:

   ExtensionDLLName:Condition

   where *ExtensionDLLName* is the name of the DLL file, but without the .dll part of the name.

   The right field of this row is a read-only field that shows the parameter-and-value pairs that you have defined for the condition. This setting also contains an **Add Parameter** button, which lets you define parameters and their values, as well as a **Delete this condition** button, which lets you delete the extension condition.

6. To add a parameter and value, click the **Add Parameter** button in the right field of the extension condition row. The **Configure Extension Condition** dialog box opens.

7. Enter the name of the parameter, and then click **OK**. InstallShield adds a new row for the parameter. Configure the value of the parameter in the field on the right.

Searching for Installed Data

InstallShield provides support for the Windows Installer capability of searching for installed data on a target system at run time. Depending on the results of the search, the installation can store a value in a property and even use the property in an installation condition. Examples of system searches that your installation can perform include:

- Search for a file or folder on the target system at run time and store the full path to the file or folder, if found, in a property. This includes support for XML files.
- Read data from the registry or from an .ini file located in the target system's WindowsFolder directory and store the data in a property. Then use the property in an installation condition.

InstallShield includes several predefined system searches that you can add to your project. In addition, system searches that have been defined in one project and published to a repository can be reused in other projects. Use the System Search view to add a predefined system search—whether it is a search that is included with InstallShield or one that is stored in a repository—to your project. You can also use the System Search view to customize any predefined searches or define your own system searches for your installation.

Adding a Predefined System Search

Use the System Search view to add a predefined system search—whether it is a search that is included with InstallShield or one that is stored in a repository—to your project.

Task: ***To add a predefined system search:***

1. Open the **System Search** view.
2. Right-click the grid and then click **Add predefined search**. The Add Predefined Search Dialog Box opens.
3. If you want system searches that have been published to a repository to be displayed, select the **Show Searches in Repository** check box.
4. Select the value for the system search that you would like to add.
5. Click **OK**.

InstallShield adds the search to the **grid in the System Search view.** If you need to make changes to the predefined search after you have added it to your project, see Modifying a System Search to learn how.

Adding a System Search

Your installation can include system searches for different types of installed data on a target system. To add to your project one of the predefined system searches available in InstallShield or a system search that is stored in a repository, see Adding a Predefined System Search. To define your own custom system search, follow the steps below.

Task: ***To add a system search:***

1. Open the **System Search** view.
2. Right-click the grid and then click **Add**. The **System Search Wizard** opens.
3. Complete the panels in the System Search Wizard.

InstallShield adds the search to the grid in the **System Search** view.

Modifying a System Search

Task: ***To modify a system search:***

1. Open the **System Search** view.
2. Right-click the grid entry for the system search that you want to modify and then click **Modify**. The **System Search Wizard** opens.
3. Complete the panels in the System Search Wizard.

Publishing a System Search to a Repository

If your project contains a system search that you would like to reuse in other projects or share with other users, you can publish it to a repository.

Task: ***To publish a system search to a repository:***

1. Open the **System Search** view.
2. In the grid, right-click the system search and then click **Publish Wizard**. The **Publish Wizard** opens.
3. Complete the panels in the Publish Wizard.

After you have imported a system search from a repository into a project, there is no link between the current system search and the existing repository system search. If you make a change to the system search and then republish it to the repository, it does not affect the system search in the project to which it was imported. However, you can reimport the system search from the repository into your project.

Removing a System Search

Task: ***To remove a system search:***

1. Open the **System Search** view.
2. Right-click the grid entry for the system search that you want to remove and then click **Delete**.

The deleted system search will no longer be included in your installation.

Searching for XML Data

Application and configuration settings are sometimes stored in XML files. Use the System Search view to define a search for data in an XML file that may exist on the target system at run time. You can search for a specific attribute, a specific element, or a specific element content string. The results are stored in a property; you can use that property in an installation condition, as the destination for a component in your installation, or in other areas of your installation.

Example

This section presents an example that shows how to search for XML data on target systems at run time. For this example, the product called **MyProduct** has an executable file called **MyProduct.exe**. The path for this .exe file is written to a file called `Configuration.xml` at run time.

Tip • *For information on how to use properties to change XML files at run time, see Using Windows Installer Properties to Dynamically Modify XML Files.*

Following is sample code from the `Configuration.xml` file:

```
<?xml version="1.0" encoding="utf-8"?>
<configuration>
  <startup>
    <requiredRuntime version="1.0.0" safemode="true" />
  </startup>
  <appSettings>
    <add value="MyProduct" path="C:\Program Files\MyCompany\MyProduct\MyProduct.exe"/>
  </appSettings>
</configuration>
```

The value of the **path** attribute in the above XML code depends on where end users install **MyProduct**.

The main objective of this example is to find the value of the **path** attribute and store that value in a property.

Task: ***To configure the system search for the XML data:***

1. In the View List under **Behavior and Logic**, click **System Search**.
2. Right-click the grid and then click **Add**. The System Search Wizard opens.
3. Complete each of the wizard panels as follows:
   a. On the **What do you want to find?** panel: In the list, select **XML file value**.
   b. On the **Specify the file details** panel:
      - In the **File Name** box, type the following:

        ```
        Configuration.xml
        ```

      - In the **Look In** area, select **A full path**, and type the following path:

        ```
        [ProgramFilesFolder]MyCompany\MyProduct
        ```

   c. On the **Specify the data** panel:
      - In the **XPath to XML Element** box, type the following XPath expression:

        ```
        /configuration/appSettings/add[@value='MyProduct']
        ```

      - In the **Look For** area, select **Value of Attribute in this Element**, and type the following in the **Attribute Name** box:

        ```
        path
        ```

   d. On the **What do you want to do with the value?** panel:
      - In the **Store the value in this property** box, type the following:

        ```
        PATH_IN_XML_FILE
        ```

      - In the **Additional Options** area, select **Just store the value in the property**.

You can use the value of the search property in another area of your project. For example, to display the value of the property in a dialog in your installation, add a text control to the dialog, and set the Text value of the control to something like this:

```
PATH_IN_XML_FILE = [PATH_IN_XML_FILE]
```

If the value of the path attribute in the XML file is **C:\Program Files\MyCompany\MyProduct\MyProduct.exe**, the dialog displays the following text:

PATH_IN_XML_FILE = C:\Program Files\MyCompany\MyProduct\MyProduct.exe

Editing Installation and Project Tables

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

Important • *Editing the installation and project tables directly, rather than using the dedicated views in InstallShield, is for advanced users who are very familiar with the Windows Installer database format.*

The Windows Installer databases that are built with InstallShield consist of tables. InstallShield project files (.ism files) use the Windows Installer table format. In addition to providing a graphical user interface for working with the content of the Windows Installer and .ism tables, InstallShield also lets you manipulate the tables directly through the Direct Editor view.

The Direct Editor supports different types of tables:

- Standard tables, which are defined by Windows Installer
- InstallShield tables, which InstallShield creates to add functionality to your installation
- Custom tables, which you create and which you can read from or write to with a custom action

The Direct Editor can run in two different modes:

- **Project edit mode**—This mode lets you edit tables in the project file (.ism). The changes that are made in the Direct Editor are incorporated into the Windows Installer package that InstallShield creates at build time.

  When you are working in any of the following Windows Installer–based project types, you are working in project edit mode: Basic MSI, DIM, InstallScript MSI, Merge Module, and QuickPatch.

- **Direct edit mode**—This mode lets you edit tables in the Windows Installer database (.msi, .msm, or .mst file). When you save the changes that you have made in the Direct Editor, InstallShield updates the Windows Installer database.

  When you are working in any of the following Windows Installer–based project types, you are working in direct edit mode: MSI Database, MSM Database, and Transform.

Editing Project Tables

Project *• The Direct Editor in the following project types lets you view and edit the tables in your project file (.ism):*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *QuickPatch*

The Direct Editor in InstallScript and InstallScript Object projects lets you see all of the tables in your .ism file; however, it is recommended that you use the other views in InstallShield to modify these types of projects.

InstallShield project files (.ism files) use the Windows Installer table format. The Direct Editor is a view in InstallShield that lets you review all of the tables in your project file (.ism). This view also offers functionality for advanced users who are very familiar with the Windows Installer database format. For example, you can use the Direct Editor to perform the following tasks:

- View all of the tables in the project file (.ism).
- Add and remove records from tables.
- Cut, copy, and paste records or fields.
- Edit individual fields in the tables.
- Add custom tables.
- Filter the table records that are shown to hide ones that do not contain a specific string.
- Search one table or all tables for a specific string and replace it if necessary.
- Resize and reorder the columns in a table.

Adding New Tables Through the Direct Editor

Project *• This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

InstallShield lets you add tables to your project file (.ism) or Windows Installer database (.msi, .msm, or .mst).

Task: ***To add a new table through the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. Right-click the **Tables** explorer and then click **Add Table**. The **Create Table Wizard** opens.
3. Complete all of the panels in the wizard.

Windows Logo • *The Windows logo program requires that you avoid naming a custom table with the MSI (in uppercase, lowercase, or mixed-case letters). The MSI prefix is reserved for future use in new standard properties and tables.*

Adding Records to a Table

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

The Direct Editor view lets you add records (or rows) to a table in your project or database.

Task: ***To add a record (row) to a table:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. Select the table to which you want to add a record.
3. Click the **New Record** button. The **Add Record to Table** dialog box opens.
4. Complete each of the fields as needed.
5. Click **OK**.

Finding and Replacing in the Direct Editor

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

The Direct Editor includes support for standard find-and-replace functionality. This functionality may be useful if you want to search for specific data or strings in your project or database and replace them with revised data or strings.

Finding Data in the Direct Editor

Task: ***To find data in the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, select one of the tables that you want to search.
3. Click the **Find String** button. The **Find** dialog box opens.
4. In the **Find what** box, type the string that you want to find.
5. Select any other options that you want.

   To search only the selected table, select the **Search in current table only** check box. To search all tables in the Direct Editor, clear this check box.
6. Click **Find Next**.

InstallShield finds the first instance of the string that you specified.

Finding and Replacing Data in the Direct Editor

Task: ***To find and replace data in the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, select the table in which you want to find and replace data.
3. Click the **Find and Replace** button. The **Replace** dialog box opens.

4. In the **Find what** box, type the string that you want to replace.
5. In the **Replace with** box, type the new string.
6. Select any other options that you want.
7. Click **Find Next**, **Replace**, or **Replace All**.

InstallShield replaces strings as needed.

Editing a Table Record

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

The Direct Editor view lets you edit a record—or row—in a table of your project or database.

Task: ***To edit a record in a table through the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, select the table that contains the record that you want to edit, and then select the row.
3. Click the **Edit Selected Record** button. InstallShield displays the **Edit Record in Table** dialog box. This dialog box lets you edit any of the data in the selected row.
4. Edit the record as needed.
5. Click **OK**.

Note • *The Direct Editor performs field-level validation to help you avoid using an improper data type.*

To maintain referential integrity when editing tables in the Direct Editor, select the ***Maintain referential integrity*** *check box on the Preferences tab of the Options dialog box. You can access this dialog box by clicking Options on the Tools menu. The check box is selected by default.*

Editing Fields in a Table

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

The Direct Editor view contains spreadsheetlike tables that let you modify strings and other data in your project or database.

Task: ***To edit fields in a table through the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. Select the table that contains the field that you want to edit.
3. Do any of the following:
   - To overwrite all of the text in a table cell, click the table cell and then type the new value.
   - To place the cursor at a particular place within a table cell, double-click that place. Then type your change.
   - If a field takes a foreign key into another table, you can select the appropriate foreign key from the list in the cell.

Tip • *The parenthetical note in each column heading indicates the type and size of data that you can enter in the column. For example, S255 indicates a string with up to 255 characters; I2 indicates a 2-byte integer.*

Note • *The Direct Editor performs field-level validation to help you avoid using an improper data type.*

To maintain referential integrity when editing tables in the Direct Editor, select the ***Maintain referential integrity*** *check box on the Preferences tab of the Options dialog box. You can access this dialog box by clicking Options on the Tools menu. The check box is selected by default.*

Exporting Tables from the Direct Editor

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

The Direct Editor lets you export one or more tables as .idt files. You can then import the .idt files into another project or database through the Direct Editor.

Task: ***To export one or more tables from the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, right-click one of the tables that you want to export, and then click **Export Table(s)**. The **Export Table(s)** dialog box opens.
3. In the **Output Directory** box, specify the directory where you want InstallShield to save the .idt files, or click the **Browse** button to navigate to the location.
4. In the **Tables** box, select the check boxes of the tables that you want to export.
5. Click **OK**.

InstallShield creates a separate .idt file for each table that you selected to export.

Importing Tables with the Direct Editor

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*

- *Transform*

You can use the Direct Editor to import a table (.idt file) into your InstallShield project file (.ism) or Windows Installer database (.msi, .msm, or .mst).

Task: ***To import a table (.idt file) using the Direct Editor:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. Right-click the **Tables** explorer and click **Import Table**.
3. Select the table that you want to import.
4. Click **Open**.

InstallShield imports the table into your project or database.

Deleting Records from a Table

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

You can use the Direct Editor to delete a record in your InstallShield project file (.ism) or Windows Installer database (.msi, .msm, or .mst).

Task: ***To delete a record (row) from a table:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, select the table that contains the record that you want to delete.
3. In the table grid, select the record that you want to delete.
4. Click the **Delete Selected Records** button or press DELETE.

Removing Tables Through the Direct Editor

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

You can use the Direct Editor to delete a custom table in your InstallShield project file (.ism) or Windows Installer database (.msi, .msm, or .mst).

Task: ***To remove a custom table:***

1. In the View List under **Additional Tools**, click **Direct Editor**.
2. In the **Tables** explorer, right-click the custom table that you want to delete, and then click **Drop Table**.

Note • *You can remove (drop) only user-defined tables. InstallShield tables and standard tables cannot be removed.*

In-Place Windows Installer Database and Project File Differencing

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

InstallShield provides .msi file differencing functionality, which allows you to have two .msi packages open in the Direct Editor for comparison purposes. When you are editing a transform (.mst file), the differences between the base package and the applied transform are highlighted in the Direct Editor.

The base package is the current file that you have open in the InstallShield interface. The compared file is any package you have on your system that you want to compare with the base package. Therefore, if you see a red X icon in front of a table in the Direct Editor after you initiate a difference, then that suggests that the table exists in the base file and not the compared file.

In-place differencing is not just limited to .msi packages and transforms. You can also compare other files such as .msm, .ism, and .pcp files.

In the Direct Editor, you can undo or accept the difference. Icons in the first column of the Direct Editor tables indicate whether the row is a deletion or an addition, or if the row contains a change. The comparison file also displays added or removed columns in a table.

Table 9-1 • Icons in the Direct Editor Tables

Icon	Description
	Row has been changed.
	Row has been added.
	Row has been deleted.

To see the specific change that has been made, move your mouse over a column to see a tooltip that describes the difference.

Task: ***To compare two projects or databases:***

1. Open the base project file (.ism) or database (.msi, .msm, .mst, or .pcp).
2. On the **Tools** menu, point to **Difference**, and then click **Compare to File**. The **Select Compare File** dialog box opens.
3. In the **Files of type** box, select the type of file that you want to compare with your base file, and then browse to select it.
4. Click **Open**.

InstallShield indicates any differences between the two files in the Direct Editor.

Task: ***To end the compare session:***

On the **Tools** menu, point to **Difference**, and then click **End Compare**.

InstallShield removes all of the in-place differencing from the Direct Editor.

Entering Binary Data in a Table

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

When you are working in any of the following Windows Installer–based project types, you are working in project edit mode: Basic MSI, DIM, InstallScript MSI, Merge Module, and QuickPatch. In project edit mode, tables such as the **Binary**, **Icon**, and **Patch** tables do not store binary data; they store links to build-source paths. Therefore, if you use the Direct Editor to edit these tables, ensure that you include the fully qualified path and file name. Otherwise, InstallShield cannot include the file in the release that it builds.

When you are working in any of the following Windows Installer–based project types, you are working in direct edit mode: MSI Database, MSM Database, and Transform. In these project types, tables such as the **Binary**, **Icon**, and **Patch** tables store binary data. If you use the Direct Editor to edit these tables, InstallShield enables you to browse to select the file that should be streamed into the table.

Orphaned Directory Entries

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *QuickPatch*
- *Transform*

Directory entries are orphaned when they are improperly or inappropriately modified—possibly in the Direct Editor. This happens when the path is broken in the **Directory** table.

For example, **INSTALLDIR** is built by combining the three records that make up the full path:

```
ProgramFilesFolder\ISYourCompanyDir\ISYourProductDir
```

This typically resolves to:

```
C:\Program Files\Your Company Name\Your Product Name
```

If any record of `ProgramFilesFolder\ISYourCompanyDir\ISYourProductDir` is modified to be invalid, **INSTALLDIR** or any other directory path that contains the invalid record will not be resolved correctly. In this example, if you rename the **Directory** record ISYourCompanyDir to MyCompany (in the Directory column), but do not update the Directory_Parent of the ISYourProductDir record to MyCompany, the **INSTALLDIR** path is broken.

Using InstallShield Tools

InstallShield includes various tools to help you troubleshoot complex issues with Windows Installer packages and InstallScript installations. To find out more, refer to this section of the documentation.

InstallShield MSI Tools

Edition • *The InstallShield MSI tools are included with the Premier and Professional editions of InstallShield. The Premier edition also includes a separate installation and extra licenses that let you install just the tools, without InstallShield, on separate machines. For specific terms, see the End-User License Agreement for the InstallShield MSI tools.*

InstallShield includes tools that help you troubleshoot complex issues with Windows Installer packages:

- InstallShield MSI Diff enables you to quickly compare two .msi, .msm, or .pcp files. It lets you apply one or more .msp and .mst files to an .msi file and see the changes in the resulting .msi database. You can also use this tool to compare two InstallShield project files (.ism or .ise) that are saved in binary format. This tool uses color coding to show additions, modifications, deletions, and schema differences. You can easily integrate InstallShield MSI Diff with most source code control systems.
- InstallShield MSI Query lets you test SQL statements using the Windows Installer version of SQL before you run them in your build script. You can quickly see if a SQL statement is formatted correctly and view the results that it generates.
- InstallShield MSI Sleuth is a diagnostic tool that lets you view the current installed state of a target system. InstallShield MSI Sleuth displays a list of all of the .msi packages that are installed. You can click any .msi package in the list to see the status of its features and components, its known source locations, as well as tables and binary streams within the database. This tool also helps you identify the installed product or products whose packages contain a specific component code.
- InstallShield MSI Grep searches a collection of .msi and .msm packages for specific text. You can narrow the search to show results for only certain tables or columns.

You can launch any of these tools from the InstallShield Tools subfolder on the Windows Start menu.

Note • *All of these tools require .NET Framework 2.0 to be installed.*

InstallShield MSI Diff

InstallShield MSI Diff enables you to quickly compare two .msi, .msm, or .pcp files. It lets you apply one or more .msp and .mst files to an .msi file and see the changes in the resulting .msi database. You can also use this tool to compare two InstallShield project files (.ism or .ise) that are saved in binary format. You can easily integrate it with most source code control systems.

This tool uses color coding to show additions, modifications, deletions, and schema differences. The color code in the lower-right corner of InstallShield MSI Diff shows the legend that identifies which colors indicate each type of difference.

You can launch InstallShield MSI Diff from the InstallShield Tools subfolder on the Windows Start menu. You can also launch this tool from within InstallShield: On the Tools menu, point to Difference, and then click InstallShield MSI Diff.

Tip • *To show or hide unchanged rows in the various database tables: On the View menu, click Unchanged Rows. This menu command has a check mark if the unchanged rows are displayed; it does not have a check mark if the unchanged rows are hidden.*

To show or hide unchanged database tables: On the View menu, click Unchanged Tables. This menu command has a check mark if the unchanged tables are displayed; it does not have a check mark if the unchanged tables are hidden.

Determining the Changes that a Transform (.mst File) Makes

You can use InstallShield MSI Diff to see how an .msi package changes when a transform (.mst file) is applied to it.

Task: ***To determine the changes that a transform makes:***

1. Open InstallShield MSI Diff.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the .msi package, and then click **Open**. InstallShield MSI Diff opens the .msi database.
4. On the **File** menu, point to **Transforms**, and then click **Apply Transform**. The **Open** dialog box opens.
5. Select the .mst transform, and then click **Open**. InstallShield MSI Diff applies the transform to the .msi database that is open.
6. Examine the changes.

If you want to apply a series of transforms to an .msi package, you can repeat steps 4 and 5 for each transform.

Tip • *Note that InstallShield MSI Diff also lets you apply a series of multiple transforms and patches to an .msi package, and see the changes in the resulting .msi database.*

To learn how to apply a patch to an .msi package, see Determining the Run-Time Effects of a Patch.

Determining Whether a Patch Is Valid for an .msi Package

You can use InstallShield MSI Diff to determine whether a patch is valid for a specific .msi package. InstallShield MSI Diff analyzes the internal transforms that are contained within the patch.

Task: ***To determine whether a patch is valid for an .msi package:***

1. Open InstallShield MSI Diff.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the .msi package, and then click **Open**. InstallShield MSI Diff opens the .msi database.
4. On the **File** menu, point to **Patches**, and then click **Apply Patch**. The **Open** dialog box opens.
5. Select the patch (.msp file), and then click **Open**.

If the patch applies to the selected .msi database, InstallShield MSI Diff applies the patch to the database that is open. If the patch is not applicable, InstallShield MSI Diff displays a message box to inform you that the patch is not valid for the selected database.

Determining the Run-Time Effects of a Patch

You can use InstallShield MSI Diff to determine what Windows Installer will do with a given patch file and how that will affect the cached .msi package on a target system.

Task: ***To determine the run-time effects of a patch:***

1. Open InstallShield MSI Diff.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the .msi package, and then click **Open**. InstallShield MSI Diff opens the .msi database.
4. On the **File** menu, point to **Patches**, and then click **Apply Patch**. The **Open** dialog box opens.
5. Select the patch (.msp file), and then click **Open**. InstallShield MSI Diff applies the patch to the database that is open.
6. Examine the changes.

If you want to apply a series of patches to an .msi package, you can repeat steps 4 and 5 for each patch.

Tip • *Note that InstallShield MSI Diff also lets you apply a series of multiple transforms and patches to an .msi package, and see the changes in the resulting .msi database.*

To learn how to apply a transform to an .msi package, see Determining the Changes that a Transform (.mst File) Makes.

Determining the Differences Between Two .msi Packages

You can use InstallShield MSI Diff to determine the differences between two .msi packages.

Task: ***To determine the differences between two .msi packages:***

1. Open InstallShield MSI Diff.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the base .msi package, and then click **Open**. InstallShield MSI Diff opens the .msi database.
4. On the **File** menu, click **Compare To**. The **Open** dialog box opens.
5. Select the second .msi package, and then click **Open**.

InstallShield MSI Diff compares the data from the second .msi package with the data in the base .msi package, and displays the results.

Running InstallShield MSI Diff from the Command Line to Generate a Log File of Differences

You can run InstallShield MSI Diff from the command line to generate a log file that identifies the differences between two .msi, .msm, or .pcp files, or that shows the differences that are applied to a Windows Installer database by a transform (.mst) or patch file (.msp). You can also use this tool from the command line to generate a log file that identifies the differences between two InstallShield project files (.ism or .ise) that are saved in binary format.

InstallShield MSI Diff is installed to the following location:

InstallShield Program Files Folder\System\MsiDiff.exe

To generate a log file that shows the differences, use the following syntax when you launch InstallShield MSI Diff from the command line:

```
msidiff.exe <BaseFile> <ComparisonFile> /out <diff.xml>
```

Following is a sample command line:

```
"C:\Program Files\InstallShield\2013\System\MsiDiff.exe" "C:\InstallShield 2013
    Projects\MyProject1.ism" "C:\InstallShield 2013 Projects\MyProject2.ism" /out "C:\Log File.xml"
```

Determining the Differences Between Two InstallShield Projects

You can use InstallShield MSI Diff to determine the differences between two InstallShield projects (.ism or .ise files) that are saved in binary format.

Task: ***To determine the differences between two InstallShield projects:***

1. Open InstallShield MSI Diff.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select one of the InstallShield project files, and then click **Open**. InstallShield MSI Diff opens the project file.
4. On the **File** menu, click **Compare To**. The **Open** dialog box opens.

5. Select the second InstallShield project file, and then click **Open**.

InstallShield MSI Diff compares the data from the second project with the data in the first project, and displays the results.

InstallShield MSI Query

InstallShield MSI Query lets you test SQL statements using the Windows Installer version of SQL before you run them in your build script. You can quickly see if a SQL statement is formatted correctly and view the results that it generates.

You can launch InstallShield MSI Query from the InstallShield Tools subfolder on the Windows Start menu.

To learn about valid SQL query strings for Windows Installer, see SQL Syntax in the Windows Installer Help Library.

Running a SQL Query for a Specific Windows Installer Database

You can use InstallShield MSI Query to test SQL statements using the Windows Installer version of SQL before you run them in your build script. You can quickly see if a SQL statement is formatted correctly and view the results that it generates.

Task: ***To run a query:***

1. Open InstallShield MSI Query.
2. On the **File** menu, click **Open**. The **Open** dialog box opens.
3. Select the database (.msi or .msm file) that you want to use for your test, and then click **OK**. InstallShield MSI Query lists the name of the file in its title bar.
4. In the **Query** box, enter the query that you want to run.

   InstallShield MSI Query lets you enter one or more parameter values as question marks (?). If you include question marks in your query, InstallShield MSI Query displays an Arguments row below the Query box. Each question mark corresponds with a different Arguments box. Use the Arguments boxes to specify the replacement values.

   To learn about valid SQL query strings for Windows Installer, see SQL Syntax in the Windows Installer Help Library.
5. Click the **Execute** button.

InstallShield MSI Query runs the specified query for the selected database. If you would like to save any changes that occurred as a result of the query, click Save on the File menu.

InstallShield MSI Sleuth

InstallShield MSI Sleuth is a diagnostic tool that lets you view the current installed state of a target system. InstallShield MSI Sleuth displays a list of all of the .msi packages that are installed. You can click any .msi package in the list to see the tables in that database and all of the streamed files that are embedded within the database. This tool also helps you identify the installed product or products whose packages contain a specific component code.

You can launch InstallShield MSI Sleuth from the InstallShield Tools subfolder on the Windows Start menu.

Viewing Details about an .msi Package that Was Run on a Target System

You can use InstallShield MSI Sleuth to view details about an .msi package that was run a target system.

Task: ***To view details about an .msi package:***

1. Open InstallShield MSI Sleuth.
2. On the **File** menu, click **Open Package**. The **Installed Packages** dialog box opens. It contains a list of all of the packages that have been installed on the target system.
3. Select the package that you want to analyze, and then click **OK**.

InstallShield MSI Sleuth displays details about the selected .msi package

Tip • *You can save the details in a .sleuth.xml and then reopen the file within MSI Sleuth. To save the details: On the File menu, click Save Package Details, and then specify a file name.*

To later open the .sleuth.xml file: On the File menu, click Open Package Summary. Select the file that you want to open.

Searching for All Installed Packages that Include a Specific Component

You can use InstallShield MSI Sleuth to identify all of the packages that have installed a component with a specified component code to resolve issues with files not being uninstalled. You can also determine whether a component was installed by multiple products.

Task: ***To search for all installed packages that include a specific component:***

1. Open InstallShield MSI Sleuth.
2. On the **File** menu, point to **Open by Component Code**, and then point to **Component Code**. InstallShield MSI Sleuth changes this menu command to an edit field.

3. Enter the component code, and then press ENTER. Note that if you have the component code saved in the Clipboard, you can press CTRL+V to paste it in the menu command field. The **Installed Packages** dialog box opens.

The Installed Packages dialog box lists all of the installed packages that contain the specified component code. If you want to view a package, select it, and then click OK.

InstallShield MSI Grep

InstallShield MSI Grep searches a collection of .msi and .msm packages for specific text. You can narrow the search to show results for only certain tables or columns.

You can launch InstallShield MSI Grep from the InstallShield Tools subfolder on the Windows Start menu.

Searching .msi Packages for Specific Text

You can use InstallShield MSI Grep to search a collection of .msi and .msm packages for specific text. You can narrow the search to show results for only certain tables or columns.

Task: ***To search one or more .msi and .msm packages for specific text:***

1. Open InstallShield MSI Grep.
2. In the **Find** box, enter the string for which you want to search.
3. To narrow your search, do one or more of the following:
   - In the **Table** box, specify the name of the database table that you want InstallShield MSI Grep to search through.
   - In the **Column** box, specify the name of the database column that you want InstallShield MSI Grep to search through.
   - To modify the list of folders that InstallShield MSI Grep should search, click the ellipsis button, and then select one or more folders.
   - To search in all of the subfolders of the specified directories, select the **Recurse** check box.
   - To limit the search to certain database types or file names, enter the file names in the **Files** box. Use an asterisk (*) as a wild-card character. If you specify multiple file names or patterns, separate each with a semicolon (;).
4. Click the **Search** button.

InstallShield MSI Grep displays the search results. You can click a search result, and then click a table from that search results to see details.

InstallShield Cabinet and Log File Viewer

Use the InstallShield Cabinet and Log File Viewer to do the following:

- View an InstallScript cabinet file (.cab) or InstallScript header file (.hdr), as well as their compressed files, registry entries, components, features, and other data. This tool also lets you extract files from the .cab file. This functionality applies to InstallScript and InstallScript Object projects.
- View InstallScript log files (.ilg) that are created by InstallScript installations. This tool enables you to see what your installation has recorded in the log file, which contains important uninstallation information in a binary format. This functionality applies to the following project types: InstallScript and InstallScript MSI.

Task: ***To launch the InstallShield Cabinet and Log File Viewer from within InstallShield:***

On the **Tools** menu, point to **InstallScript**, and then point to **Cabinet/Log File Viewer**.

Tip • *You can also launch this tool from the InstallShield Tools subfolder on the Windows Start menu.*

To learn more, see the following sections of the documentation:

- Viewing InstallScript Cabinet Files (.cab) and Header Files (.hdr)
- Viewing InstallScript Log Files (.ilg)

Viewing InstallScript Cabinet Files (.cab) and Header Files (.hdr)

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The InstallShield Cabinet and Log File Viewer lets you open the `data1.cab` (the InstallScript cabinet file) and `data1.hdr` (the InstallScript header file that InstallShield creates for InstallScript and InstallScript Object projects). The InstallShield Cabinet and Log File Viewer also lets you extract files from those files.

When a `data1.cab` or `data1.hdr` file is open, the interface of the InstallShield Cabinet and Log File Viewer is divided into two panes. The left pane shows the `data1.cab` file or `data1.hdr` file as a directory structure, similar to Windows Explorer; the right pane shows information that is associated with the item that is selected in the left pane.

The folders in the right pane represent information that is used by your installation. In most cases, the folders do not contain files; when you select those types of folders, the viewer shows a grid of corresponding settings in the right pane. Click a folder to see the settings that are associated with that folder.

You cannot edit or alter `data1.cab` and `data1.hdr` files through the InstallShield Cabinet and Log File Viewer. However, you can save information about a `data1.cab` file or `data1.hdr` file and edit the resulting text file. For more information, see Generating a Report about an InstallScript .cab or .hdr File.

The InstallShield Cabinet and Log File Viewer includes an export mode that you can enable or disable, depending on how much information you want to see in the `data1.cab` or `data1.hdr` file:

- If you disable expert mode, the viewer shows only the files, registry entries, and other information that you added to your installation project.
- If you enable expert mode, the viewer shows all of the files, registry entries, and other information that you added to your installation project. The viewer also shows the files that InstallShield added to the `data1.cab` file; this includes files such as the InstallScript engine and the compiled script file (`Setup.inx`). In addition, the viewer shows InstallScript Objects that you included in the installation project.

Task: ***To enable or disable expert mode in the InstallShield Cabinet and Log File Viewer:***

On the **View** menu, click **Expert Mode**.

Expert mode is enabled if the Expert Mode command has a check mark; this mode is disabled if the command does not have a check mark.

Overview of InstallScript .cab and .hdr Files

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

When you build an InstallScript installation, InstallShield may create an InstallScript cabinet file (.cab) called `data1.cab`, plus additional .cab files if necessary. InstallShield also creates an InstallScript header file called `data1.hdr`. Depending on your project's release settings, these files may be left uncompressed, or they may be or streamed into the `Setup.exe` file.

An InstallScript .cab file is a compressed file that contains the files that your installation installs on an end user's system. Cabinet files serve as a container for files that you directed your installation to install, either through InstallShield or through your script. Cabinet files also contain information and files about language and system dependencies. In addition, they store other files—such as the InstallScript engine—that InstallShield adds to your installation at build time.

The `data1.hdr` file is an InstallScript header file (.hdr) is a file that references the corresponding `data1.cab` file. It contains general information that you entered in your installation project. It also includes information about each of the files, components, features, and other data in your installation.

Important • *You can open `data1.cab` and `data1.hdr` files in the InstallShield Cabinet and Log File Viewer. Although InstallShield may create other .cab files such as `data2.cab` for your installation, the viewer can open only the `data1.cab` and `data1.hdr` files. Note that the `data1.cab` file, the `data1.hdr` file, and all other .cab files that are part of an InstallScript installation must be in the same folder when you are using the InstallShield Cabinet and Log File Viewer.*

Opening InstallScript .cab and .hdr Files

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

Important • *You can open `data1.cab` and `data1.hdr` files in the InstallShield Cabinet and Log File Viewer. Although InstallShield may create other .cab files such as `data2.cab` for your installation, the viewer can open only the `data1.cab` and `data1.hdr` files. Note that the `data1.cab` file, the `data1.hdr` file, and all other .cab files that are part of an InstallScript installation must be in the same folder when you are using the InstallShield Cabinet and Log File Viewer.*

Task: ***To open a data1.cab or data1.hdr file in the InstallShield Cabinet and Log File Viewer:***

1. On the **File** menu, click **Open**. The **Open** dialog box opens.
2. Browse to the location that contains the file that you want to open, and then select that file.
3. Click the **Open** button.

The InstallShield Cabinet and Log File Viewer shows the following information for a `data1.hdr` or `data1.cab` file:

- **Features**—The viewer shows the settings that are configured for each feature in the installation. It also shows the components that are associated with each feature.
- **Components**—The viewer shows the settings that are configured for each component in the installation. Expand a component to see the files that are included in that component. You can extract any of the files.
- **Setup Types**—The viewer displays the settings that are configured for each setup type in the installation. This area of the viewer also shows the features that are associated with each setup type.
- **Explorer Shell**—The viewer lists each of the shell objects that you added to your project in InstallShield. For example, if you included any shortcuts or program folders in your installation, they are displayed in this area of the viewer.
- **Registry Entries**—The viewer lists all of the entries that are to be installed to the target system's registry.
- **Media Settings**—The viewer shows project settings that were configured in the General Information view. It also includes information about the version of InstallShield that created the file.

To view any of that information for a `data1.hdr` or `data1.cab` file, expand that node in the left pane of the InstallShield Cabinet and Log File Viewer, and click any of the nodes or subnodes.

Extracting a File from an InstallScript .cab or .hdr File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

When a `data1.cab` or `data1.hdr` file is open in the InstallShield Cabinet and Log File Viewer, you can extract any of the files that are compressed into your installation's `cab` files and save them elsewhere.

Task: ***To extract a file:***

1. In the left pane, expand the **Components** node, expand the component that contains the file that you want to extract, and then click the **Files** node under that component.
2. In the right pane, select the record for the file that you want to extract.
3. On the **Tools** menu, click **Extract File**. The **Save** dialog box opens.
4. Browse to the location where you want the InstallShield Cabinet and Log File Viewer to extract the file, and then click the **Save** button.

Note • *Media files and components may be password protected. If the entire media are password protected, you must enter the correct password before you can open the cabinet files that are associated with that media. If individual components are password protected, you must enter the correct password before you can extract the compressed files that are associated with that component.*

Generating a Report about an InstallScript .cab or .hdr File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

You can use the InstallShield Cabinet and Log File Viewer to generate a text-file report that contains summary information about the files, components, features, and other data in the open `data1.cab` or `data1.hdr` file.

Task: ***To generate a report about the open data1.cab or data1.hdr file:***

On the **Tools** menu, click **Report**.

The InstallShield Cabinet and Log File Viewer generates a report (.txt file) and opens it in a text editor such as Notepad.

Viewing InstallScript Log Files (.ilg)

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The InstallShield Cabinet and Log File Viewer enables you to view the log files that are created by your InstallScript or InstallScript MSI installations. The viewer lets you see what your installation has recorded in the log file, which contains important uninstallation information in a binary format.

When an InstallScript log file (.ilg) is open in the InstallShield Cabinet and Log File Viewer, the interface of the viewer is divided into two panes. The left pane shows log file entries divided into folders. When you select an item in the left pane, the right pane shows information about that item. For example, if you select a feature in the left pane, the right pane shows the State property, which indicates whether the feature is installed. If you select a File Operations item in the left pane, the right pane shows the information such as the files that were transferred to the target system, and whether those files were marked as permanent.

The <Support> folder and its subitems provide information about setup file operations. The <Data> folder and its subitems provide information about application file operations. The Disk<1> folder and its subitems provide information about the installation files that enable maintenance mode and uninstallation.

Overview of InstallScript Log Files

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Usually, an InstallScript log file is accessed only when your product is uninstalled or when an installation is aborted. Log files record the procedures that your installation performs when logging is enabled. These procedures may include the following:

- General information on the product being installed, such as the product name.
- The locations and values of an installed product's registry keys.
- Changes made to the system's file structure, including the files that were transferred, the folders that were created, and shortcuts or icons that were created.
- Information about the files that you added to your InstallShield project.

The name of the log file is `setup.ilg`. The installation creates it automatically at run time on a target system during normal file transfer. The default location for the log file is:

```
<PROGRAMFILES>\InstallShield Installation Information\{Product Code}
```

However, you can change the location by changing the value of the DISK1TARGET system variable before the Move Data event.

The InstallScript log file is a binary file. You can use the InstallShield Cabinet and Log File Viewer to see the contents of the log file.

***Tip** • Logging of procedures is enabled by default. You can disable and re-enable logging by calling the Disable(LOGGING) and Enable(LOGGING) functions in your InstallScript code. For more information, see Disable and Enable.*

Opening InstallScript Log Files

***Project** • This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Use the InstallShield Cabinet and Log File Viewer to see the contents of an InstallScript log file (.ilg).

Task: ***To open an InstallScript log file in the InstallShield Cabinet and Log File Viewer:***

1. On the **File** menu, click **Open**. The **Open** dialog box opens.
2. Browse to the location that contains the file that you want to open, and then select that file.
3. Click the **Open** button.

Searching InstallScript Log Files

***Project** • This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

The InstallShield Cabinet and Log File Viewer lets you search for text in an InstallScript log file (.ilg).

Task: ***To search for text in a log file:***

1. On the **Search** menu, **click** Find. The **Find** dialog box opens.
2. In the **Find What** box, type the text to be found.

3. Click **Find Next**. The first log entry (if any) that matches your search criteria is selected in the right pane.
4. To find the next item (if any) that matches your criteria, press the F3 key. Repeat this step as necessary.

Converting an InstallScript Log File to a Text File

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*

Use the InstallShield Cabinet and Log File Viewer to create a text file (.txt) version of an InstallScript log file (.ilg).

Task: ***To create a .txt file version of a log file:***

On the **Tools** menu, click **Report**.

The InstallShield Cabinet and Log File Viewer creates a .txt file version of the log file and opens it in a text editor such as Notepad.

Working with Windows Installer and Advanced UI or Suite/Advanced UI Properties

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Suite/Advanced UI*
- *Transform*

Note that some differences between properties in Windows Installer–based projects and that in Advanced UI or Suite/Advanced UI projects exist; these differences are noted where appropriate.

The Windows Installer, Advanced UI, and Suite/Advanced UI engines maintain global information using properties. The Property Manager view displays a list of installation properties that are used by the Windows Installer engine or the Advanced UI or Suite/Advanced UI engine at run time. You can modify, create, and delete installer properties in the Property Manager view. At build time, InstallShield writes the properties in the Property Manager view to installation that it creates.

For background information on property support in Windows Installer–based projects, see:

- Overview of Windows Installer Properties
- Windows Installer Property Reference

For background information on property support in Advanced UI and Suite/Advanced UI projects, see Advanced UI and Suite/Advanced UI Property Reference.

Overview of Windows Installer Properties

The built-in InstallShield properties are outlined in the Windows Installer Property Reference.

Property Types

There are four general types of Windows Installer properties:

- Public
- Private
- Restricted public
- Required

Note *• Some of these categories overlap. For example, the* ***ProductCode*** *property is a required private property.*

Public Properties

Public properties have names that contain only uppercase letters. For example, **INSTALLDIR** is a public property. Public properties can be specified at the command line used to launch the installation or chosen by using an authored user interface. If you are creating your own properties, use all uppercase letters if you want end users to have access to these properties.

In order to allow the end user or administrator to change the destination via the user interface or from the command line, the Directory Identifier for the component's destination must be a public property.

Note *• Only public properties have their values preserved from an installation's user interface to the point where the installation is changing the target system. If you set the value of a property in a dialog box displayed to the end user, use a public property (for example, MY_PUBLIC_PROPERTY) if you want its value written to a file or to the registry.*

Private Properties

Private properties have at least one lowercase letter in their name and cannot be changed from the user interface. For example, ProgramFilesFolder is a private property. End users have no control over the values of private properties, as they cannot be set from the command line.

Restricted Public Properties

Restricted public properties allow network administrators to define public properties that can be changed only by a system administrator. This way, the administrator can change settings quickly without having to worry that other users on the network may tamper with the setup. Refer to Specifying that a Public Property Should Be a Restricted Public Property for more information.

Required Properties

The Windows Installer service relies on five properties that are required in every Windows Installer setup. By default, these properties are included in every installation you create using InstallShield. If you delete any of the following properties from your project, you need to reinsert them for your installation to function correctly.

- ProductCode
- ProductLanguage
- Manufacturer
- ProductVersion
- ProductName

Conditions

Many properties are not set until the installation is launched. These properties are populated with information from the target system. For example, the VersionNT property is not set until the installation is launched. This property is set to the version of Windows that the target machine is running, if the operating system is a Windows NT–based system. For example, the value of VersionNT is 600 on a Windows Vista system.

Properties set at run time can be used to create conditional installations. If you want your product to be installed only on Windows Vista, you can use conditional logic to check the end user's system, and install the product if all conditions are met.

Windows Installer Property Reference

Many properties can be set during an installation. The following tables list most of them with their functions and, in many cases, the syntax needed to put these properties into action. Many of the properties can be set from within InstallShield, while others are initialized by the Windows Installer service at run time.

Note *• By default, Windows Installer writes the final value of every Windows Installer property contained in your project to a log file generated by launching MsiExec with the /L argument. Starting with Windows Installer version 2.0, you can prevent certain properties (such as those containing passwords) from being written to the log file by creating a property called* ***MsiHiddenProperties*** *in the Property Manager and setting its value to a semicolon-delimited list of property names. For more information about this property, see MsiHiddenProperties in the Windows Installer Help Library.*

Any of the properties that are with all-uppercase names can be set at the command line. Properties with all-uppercase names are called *public properties*. The following lists are organized according to the functions of the properties. Each table has a brief description of the kinds of properties it contains.

The following categories of Windows Installer properties are described in this topic. Click a link to go directly to a category.

- Virtual Machine Properties
- Status Properties Updated by the Installer
- Date and Time Properties
- InstallScript Engine-Related Properties
- SQL-Related Properties
- MDAC Properties

Note • *Do not confuse installer properties with path variables, which are surrounded by angle brackets (<>). While they both represent directories, you can use Windows Installer properties at run time, but path variables are used to point to source files only during setup design and at build time.*

Special Folder and File Properties

Special folder properties are those properties that define where files are stored or installed on the target system. File properties refer to specific files.

To use a folder property in your installation, enclose it in square brackets: []. For example, to install a component to a Bin folder under the default destination folder, enter `[INSTALLDIR]Bin` in the component's Destination Folder setting.

Table 9-1 • Folder Properties

Property Name	Description
INSTALLDIR	This property contains the default destination folder for the files in your features and components. For more information, see Setting the Default Product Destination Folder (INSTALLDIR). INSTALLDIR is available directly as a variable in your InstallScript code.
ISDEBUGLOG	To generate a log file for the feature prerequisites in the installation, set this property to the full path and file name for the log file. You can use directory properties and environment variables in the path. This property is used for troubleshooting feature prerequisites, and it is typically set through the command line when the `/debuglog` command-line parameter is used, as follows: `Setup.exe /debuglog"C:\Path\setup.log" /v"ISDEBUGLOG=prereq.log"`

Table 9-1 • Folder Properties (cont.)

Property Name	Description
ISPREREQDIR	This property identifies the path to the running InstallShield prerequisite. The path includes the final slash. You can use this property to refer to files within the InstallShield prerequisite—for example: `[ISPREREQDIR]MyConfigFile.ini` For more information, see Specifying Command-Line Parameters for an InstallShield Prerequisite.
SETUPEXEDIR	This property stores the path to `Setup.exe`. For example, if the path to `Setup.exe` is `C:\MySetups\MyApp\Setup.exe`, the value of **SETUPEXEDIR** is `C:\MySetups\MyApp`. For more information, see SETUPEXEDIR.
SETUPEXENAME	This property identifies the name of the setup launcher file that was created when the project was built. The installation updates the value of this property at run time if the setup launcher file was renamed. The following path identifies the full path to this file: `[SETUPEXEDIR]\[SETUPEXENAME]`
SourceDir	This property stores the folder where the running .msi file is located.
TARGETDIR	The **TARGETDIR** property is the location where the Windows Installer package is copied (and its data files uncompressed) during an Administrative installation. In an InstallScript MSI project, this value is represented by the InstallScript *MSI_TARGETDIR* variable.

Feature Installation Properties

The following section provides information on feature installation properties, with which the end user can specify how features should be installed.

Table 9-2 • Feature Installation Properties

Property Name	Description
ADDDEFAULT	The **ADDDEFAULT** property stores a list of features, separated by commas, that are to be installed in their default configuration. Users can install all features in their default configuration by setting the value of this property to **ALL**.

Table 9-2 • Feature Installation Properties (cont.)

Property Name	Description
ADDLOCAL	This property stores a list of features, separated by commas, that are to be installed locally. Each feature has a Remote Installation property that determines whether features selected for installation are to be installed locally or run from the source medium.
ADDSOURCE	This property stores a list of features, separated by commas, that are to be run from the source medium. If this property is set to **ALL**, all the features will run from the source medium.
ADVERTISE	This property stores a list of features, separated by commas, that are to be advertised.
REINSTALL	This property stores a list of features, separated by commas, that are to be reinstalled. If **REINSTALL** is set to **ALL**, all of the features that are already installed on the user's system will be reinstalled.
REINSTALLMODE	This property contains a string of letters that specify the reinstall type. These options correspond to the values available for the Msiexec.exe `/f` command-line parameter. For more information on this property, see REINSTALLMODE Property in the Windows Installer Help Library. **REINSTALLMODE** is always set in conjunction with **REINSTALL**.
ReinstallModeText	This property contains the reinstallation options that will be set when the user selects Repair in the MaintenanceType dialog. The value of ReinstallModeText is passed as an argument to the control event ReinstallMode, which accepts the same options that are available for the **REINSTALLMODE** property. ReinstallModeText is not a predefined Windows Installer property. Nonetheless, it is provided in the Property Manager for every new project, with a default value of *omus*, for use in the control event described above.
REMOVE	This property stores a list of features, separated by commas, that will be removed. If **REMOVE** is set to **ALL**, all features will be removed.
COMPADDLOCAL	This property stores a list of component IDs, separated by commas, that are to be installed locally. The feature for the component that takes up the least amount of disk space will be installed.

Table 9-2 • Feature Installation Properties (cont.)

Property Name	Description
COMPADDSOURCE	This property stores a list of component IDs, separated by commas, that are to be run from the source medium. The feature for the component that takes up the least amount of disk space will be installed.
PATCH	When installing a patch, this property contains the full path to the patch package.

Other Configurable Properties

The following section contains information on various other configurable properties.

Table 9-3 • Additional Configurable Properties

Property Name	Description
ACTION	This property specifies which sequence to perform (installation, advertisement, or administration). Possible values are INSTALL, ADVERTISE, and ADMIN. The **ACTION** property is automatically set based on the command line used to launch the installation.

Table 9-3 • Additional Configurable Properties (cont.)

Property Name	Description
ALLUSERS	Specifies whether Windows Installer should attempt to perform a per-machine or per-user installation. If the value of **ALLUSERS** is set to 1, Windows Installer attempts a per-machine installation. For per-machine installations, configuration information such as shortcuts and registry entries are stored in the All Users profile: • On Windows Vista and later systems, if User Account Control is enabled and the user does not have administrative privileges, the user must be able to provide administrative credentials in order to install the product. • On other systems, if the user does not have administrative privileges, the installation displays an error message and exits.  ***Project*** • *This property is set to 1 by default in Basic MSI and InstallScript MSI projects. To learn more, see Per-User vs. Per-Machine Installations.* If the value of **ALLUSERS** is not set or it is an empty string (“”), Windows Installer performs a per-user installation, and the configuration information is stored in the user’s personal profile. If the value of **ALLUSERS** is set to 2, Windows Installer attempts to perform a per-machine installation on Windows Vista and later systems. On earlier platforms, if the user has administrative privileges, Windows Installer attempts to perform a per-machine installation; otherwise, Windows Installer performs a per-user installation.  ***Project*** • *This property is set to 1 in InstallScript MSI projects to help avoid **ALLUSERS**-related issues when the installation is run silently. The property can be overridden with the **SdCustomerInformation** or **SdCustomerInformationEx** dialog functions in InstallScript MSI projects.*  ***Note*** • ***ALLUSERS** has no effect on InstallScript variables like FOLDER_PROGRAMS. **ALLUSERS** has no effect until the Execute sequence runs.*
ARPAUTHORIZEDCDFPREFIX	This property stores the URL for the update channel of the application.

Table 9-3 • Additional Configurable Properties (cont.)

Property Name	Description
ARPCOMMENTS	This property contains the comments about this product that are displayed in Add or Remove Programs. This value is set in the ARP Comments setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.
ARPCONTACT	This property contains support contact information, such as an email address or a telephone number. This value is set in the Support Contact setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.
ARPINSTALLLOCATION	This property stores the fully qualified path to the application's primary folder. You can set **ARPINSTALLLOCATION** to the value of **INSTALLDIR** with a custom action of type "Set a property".
ARPNOREPAIR	If this property is set to 1, no Repair button will be displayed in the Programs Wizard.
ARPREADME	Holds the fully qualified path or the URL for the product's Readme file. This value is set in the Read Me setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.
ARPSIZE	This property stores the estimated size, in kilobytes, of the application.
ARPSYSTEMCOMPONENT	Set this property to 1 to keep your program from appearing in Add or Remove Programs.
ARPURLINFOABOUT	This property stores the URL for the application's home page or the publisher's home page. This value is set in the Publisher/Product URL setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.
ARPURLUPDATEINFO	This property stores the URL for update information on your application. This value is set in the Product Update URL setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.

Table 9-3 • Additional Configurable Properties (cont.)

Property Name	Description
ARPNOMODIFY	Setting this property prevents the product from being modified from Add or Remove Programs.
ARPNOREMOVE	Setting this property prevents the product from being removed through Add or Remove Programs.
AVAILABLEFREEREG	This property allows you to set the amount of additional free registry space, in kilobytes, required by your application.
CCP_DRIVE	This property holds the root path on the installation disk for any of the qualifying products for a competitive upgrade.
DISABLEADVTSHORTCUTS	Setting this property disables the creation of advertised shortcuts.
DISABLEMEDIA	This setting prevents the installer from adding media information to the source list.
DISABLEROLLBACK	Set this property to 1 to stop the installer from creating a rollback script that will save copies of changed or deleted files during the installation process.
EXECUTEACTION	This property sets the top-level action initiated by the ExecuteAction action.
EXECUTEMODE	This property sets the mode of execution performed by the installer. The value None means that no changes are made to the system. The default value, Script, means that all changes made to the system are run through a script execution.
INSTALLLEVEL	This property holds a value that corresponds to the values of the features. If the level of features to be installed is less than or equal to the **INSTALLLEVEL** property, then a feature is installed. This is primarily used for different setup types, such as Typical or Custom.
LOGACTION	List of action names, separated by semicolons, that will be logged.

Table 9-3 • Additional Configurable Properties (cont.)

Property Name	Description
MSIINSTALLPERUSER	This property indicates that the Windows Installer should install the package for only the current user: • If the **ALLUSERS** property is set to 2 and **MSIINSTALLPERUSER** is set to an empty string (""), the Windows Installer performs a per-machine installation. • If the **ALLUSERS** property is set to 2 and **MSIINSTALLPERUSER** is set to 1, the Windows Installer performs a per-user installation. This property is available with Windows Installer 5 and on Windows 7 or Windows Server 2008 R2. Earlier versions of Windows Installer and Windows ignore this property. For more information, see the following: • Per-User vs. Per-Machine Installations • MSIINSTALLPERUSER Property on the MSDN Web site
Privileged	This property will run an installation with elevated privileges if the user is an administrator or if the application is an administrator-assigned application.
PROMPTROLLBACKCOST	This property specifies what will happen if there is insufficient disk space to continue the installation. Depending on the user interface level, the rollback could happen automatically, without any input from the user, or it could ask the user to continue with rollback disabled.
PRIMARYFOLDER	The folder that you specify with this property will be the “primary” folder for the installation. The path to this folder will be used to determine the values for the **PrimaryVolumePath** property, the **PrimaryVolumeSpaceAvailable** property, the **PrimaryVolumeSpaceRequired** property, and the **PrimaryVolumeSpaceRemaining** property.
REBOOT	This property allows you to force or suppress a reboot after the installation completes. Possible values are: • **F**—To force a reboot when your installation is complete. • **S**—To suppress any reboot except one caused by the ForceReboot action. • **R**—To suppress any reboot caused by Windows Installer actions.

Table 9-3 • Additional Configurable Properties (cont.)

Property Name	Description
ROOTDRIVE	In Administration mode this property sets the default drive to the first writable network drive found. In all other modes, this property sets the default drive to the writable local drive with the most disk space available.
SCRIPTFILE	This property defines the location of the script file that contains all operations executed during the installation.
SEQUENCE	This property specifies an .msi database table that lists the order in which the actions in the table will run.
SHORTFILENAMES	In Administration mode, this property may be set to indicate that only short file names should be used.
TRANSFORMS	This property stores a list of transforms to be applied to an MSI database. These transforms can be set only in Installation and Advertisement mode. The syntax for this property, if you are applying a transform to two tables, is as follows: c:\transforms\trans1;:trans2. Note that transforms are applied in the order that they appear in the string.
TRANSFORMSATSOURCE	By setting this property to 1, you are specifying the installer to look for the transforms at the installation source.
LIMITUI	Setting this property limits the user interface level at basic. This is useful if you do not create a custom user interface to interact with the installer's built-in UI.
DefaultUIFont	This property should be set to one of the predefined styles found in the TextStyle table in order to specify your default font. If this property is not set, the installer will use the system font, which may disrupt your formatting.

User-Supplied Information

The following section contains information about input taken from the end user. Such input can include the end user's name, company, or language.

Table 9-4 • User-Supplied Information

Property Name	Description
AdminProperties	**AdminProperties** holds a list of properties set during an administration installation. These properties can be external (user name) or they can be internal (other properties on this page).

Table 9-4 • User-Supplied Information (cont.)

Property Name	Description
COMPANYNAME	This property stores the organization name for the end user performing the installation. This information is taken from the **Customer Information** dialog box (for Basic MSI projects), or from the SdCustomerInformation or SdCustomerInformationEx dialogs (for InstallScript MSI projects).
ISX_SERIALNUM	This property stores the serial number that the end user enters in the Serial Number field on the CustomerInformation dialog.
UserLanguageID	This property retains the default language identifier for the end user.
USERNAME	This property stores the name of the end user performing the installation, which is taken from the **Customer Information** dialog (for Basic MSI projects), or from the **SdCustomerInformation** or **SdCustomerInformationEx** dialogs (for InstallScript MSI projects).
ProductLanguage	This property stores the numeric language ID for the product.

Properties for Creating Predetermined User Accounts

The following table describes the properties that let you create one or more Windows user accounts without using logon dialogs.

Table 9-5 • Properties for Creating Predetermined User Accounts

Property Name	Description
ISNetApiLogonUsername	Set the value of this property to the user account that you want the installation to create. Use either of the following formats: • *MachineName**UserName* • *DomainName**UserName* For more information, see Creating Predetermined User Accounts and Groups at Run Time.
ISNetApiLogonGroup	Set the value of this property to the group to which you want the user account to belong. For more information, see Creating Predetermined User Accounts and Groups at Run Time.

Table 9-5 • Properties for Creating Predetermined User Accounts (cont.)

Property Name	Description
ISNetApiLogonPassword	**ISNetApiLogonPassword**—Set the value of this property to the password that you want to be configured for the user account. For more information, see Creating Predetermined User Accounts and Groups at Run Time.

Product-Specific Properties

Information on product-specific properties that can be set in the Property table is listed below. Examples of these types of properties include technical support numbers, product name, and serial number.

Table 9-6 • Product-Specific Properties

Property Name	Description
ARPHELPLINK	This property retains the Internet address for technical support. This value is set in the Support URL setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.
ARPHELPTELEPHONE	This property retains your technical support telephone numbers. This value is set in the Support Phone Number setting in the General Information view. You should provide a string entry to facilitate globalizing your installation.
ProductCode	The ProductCode is the GUID for this particular version of the product. This ID must be different for different language versions and different release versions. This property is set in the General Information view.
ProductName	This property stores the name of the product—for example, InstallShield. This property is set in the General Information view.
ProductState	The installer sets this property to the installed state of the product. This property can hold one of four numeric values: **-1**—The product has not been installed or advertised. **1**—The product has been advertised, but not installed. **2**—The product has been installed for another user. **5**—The product has been installed and is available to the current user.

Table 9-6 • Product-Specific Properties (cont.)

Property Name	Description
ProductVersion	The **ProductVersion** property stores the major, minor, and build version numbers in the format *AA.BB.CCCC*. This property is set in the General Information view.
Manufacturer	Stores the name of the product manufacturer. This value is set in the **Publisher** setting in the General Information view. You should provide a string entry to facilitate globalizing your project.
DiskPrompt	This property holds a string which is displayed by a message box prompting for a disk. You should also include empty text for additional information printed on the disk label, as in "Disk 1".
DiskSerial	The **DiskSerial** property should be set to the internal serial number for this release.
ComponentDownload	This property retains the URL for downloading a product by its string identifier (GUID).
LeftUnit	This property places units to the left of the number. This is necessary for languages that require this structure.
UpgradeCode	This is a GUID used to search for a related set of products that are already installed.
IsAdminPackage	This property is set to 1 if the current installation package was created through an administrative installation. You can use this property to detect post-administrative installations.

System Folders Set by the Installer

The following properties hold the fully qualified path to many of the folders on the end user's system. Many of these properties can be used directly in your script, without having to call MsiGetProperty.

Table 9-7 • System Folder Properties

Property Name	Description
AppDataFolder	This property holds the full path to the current user's Application Data folder.
CommonAppDataFolder	This property holds the full path to the All Users Application Data folder.

Table 9-7 • System Folder Properties (cont.)

Property Name	Description
CommonFilesFolder	The value of this property is the full path to the 32-bit Common Files folder.
CommonFiles64Folder	The value of this property is the full path to the 64-bit Common Files folder. This property requires Windows Installer version 2.0.
DesktopFolder	This property is used to hold the full path to the Desktop folder for the current user. If the **ALLUSERS** property is set, the DesktopFolder property should hold the full path to the All Users desktop folder.
FavoritesFolder	The **FavoritesFolder** property retains the full path to the Favorites folder for the current user.
FontsFolder	This property holds the full path to the Fonts folder.
PersonalFolder	This property holds the full path to the current user's Personal folder.
ProgramFilesFolder	This property holds the full path to the current user's Program Files folder.
ProgramFiles64Folder	This property holds the full path to the current user's 64-bit Program Files folder. This property requires Windows Installer version 2.0.
ProgramMenuFolder	This property is used to hold the full path to the **Program** menu for the current user. If the **ALLUSERS** property is set, the **ProgramMenuFolder** property should hold the full path to the All Users Programs menu.
SendToFolder	This property holds the full path to the current user's SendTo folder.
StartMenuFolder	This property is used to hold the full path to the Start menu folder for the current user. If the **ALLUSERS** property is set, the **StartMenuFolder** property should hold the full path to the All Users Start Menu folder.
StartupFolder	This property is used to hold the full path to the Startup folder for the current user. If the **ALLUSERS** property is set, the **StartupFolder** property should hold the full path to the All Users Startup menu.

Table 9-7 • System Folder Properties (cont.)

Property Name	Description
SystemFolder	This property holds the full path to the 32-bit System folder.
System64Folder	This property holds the full path to the 64-bit System folder. This property requires Windows Installer version 2.0.
TempFolder	This property holds the full path to the Temp folder.
TemplateFolder	This property holds the full path to the current user's Template folder.
WindowsFolder	This property holds the full path to the user's Windows folder.
WindowsVolume	This property is set to the drive where Windows is installed.

Operating System Properties Set by the Installer

The following properties are set by the installer at run time. They refer to environment variables on the target system.

Table 9-8 • Operating System Properties

Property Name	Description
AdminUser	This property is set by the installer at installation and is only set if the user has administrative privileges.
ComputerName	This property stores the name of the computer that the installation is running on. It is set by a call to the Windows API **GetComputerName** at the initialization of the installer.
LogonUser	This property stores the name of the user performing the installation. It is set by a call to the Windows API **GetUserName**.
OLEAdvtSupport	This property is set by the installer during initialization.
ServicePackLevel	If an operating system service pack is installed, this property stores the numeric value for that update.
SharedWindows	This property is set when **Shared Windows** is being used on the target system.
ShellAdvtSupport	This property is set by the installer during initialization if the target system supports feature advertisement. This property is automatically set on Windows 98 or later, or on earlier systems if Internet Explorer 4.01 is installed.

Table 9-8 • Operating System Properties (cont.)

Property Name	Description
SystemLanguageID	This property stores the default language identifier for the target system. The value is defined by the installer by calling GetSystemDefaultLangID at initialization.
TerminalServer	This property is set by the installer at initialization if the target system is a server with Windows Terminal Server.
TTCSupport	This property is set by the installer at initialization if the target system supports true type font collections (TTC). The following systems support TTC: JPN - 932, Taiwan - 950, China - 936, Korea - 949, Hong Kong - 950.
Version9X	This property stores the version number of Windows 95 and 98 operating systems as an integer. The following formula is used to determine this integer: (MajorVersion * 100) + MinorVersion. On Windows 95, Version9X is set to 400, on Windows 98 it is set to 410, and on Windows Millennium Edition it is set to 490. Version9X is not set on Windows NT-based systems.
VersionDatabase	This property stores a version number of the database used during the installation.
VersionNT	This property stores the version number of Windows NT-based operating systems as an integer. The following formula is used to determine this integer: (MajorVersion * 100) + MinorVersion. Refer to the Windows Installer Help Library to learn the VersionNT property for a specific operating system.
VersionNT64	This property stores the version number of a Windows NT-based operating system as an integer on 64-bit systems only. The following formula is used to determine this integer: (MajorVersion * 100) + MinorVersion. This property requires Windows Installer version 2.0.
WindowsBuild	This property stores the build number for the operating system being run.
MsiNTProductType	This property stores the type of NT operating system being run on the target machine. This property requires Windows Installer version 2.0.
MsiNTSuiteBackOffice	This property is set to 1 if Microsoft BackOffice components are installed. In all other cases this property is not set. This property requires Windows Installer version 2.0.

Table 9-8 • Operating System Properties (cont.)

Property Name	Description
MsiNTSuiteDataCenter	This property is set to 1 if Windows 2000 Datacenter Server is installed. In all other cases this property is not set.
MsiNTSuiteEnterprise	This property is set to 1 if Windows 2000 Advanced Server is installed. In all other cases this property is not set.
MsiNTSuiteEnterprise	This property is set to 1 if Windows 2000 Advanced Server is installed. In all other cases this property is not set.
MsiNTSuiteSmallBusiness	This property is set to 1 if Microsoft Small Business Server is installed. In all other cases this property is not set.
MsiNTSuiteSmallBusinessRestricted	This property is set to 1 if Microsoft Small Business Server is installed with the restrictive client license. In all other cases this property is not set.
MsiNTSuitePersonal	This property is set to 1 if the operating system is Workstation Personal. In all other cases this property is not set.
MsiNetAssemblySupport	This property is set if the operating system supports .NET Framework assemblies. In all other cases this property is not set.
MsiWin32AssemblySupport	This property is set if the operating system supports Win32 assemblies. In all other cases this property is not set.

Hardware Properties Set by the Installer

The following properties are set by the installer at run time and store settings on certain hardware profiles for the end user's system.

Table 9-9 • Hardware Properties

Property Name	Description
Alpha	This property stores the numeric value of the processor level, and it is only defined if the setup is running on an Alpha processor. (This property is supported only with Windows Installer version 1.0.)
BorderSide	This property sets the pixel width of the side window borders.
BorderTop	This property sets the pixel width of the top window border.
CaptionHeight	This property sets the pixel height of the caption area.

Table 9-9 • Hardware Properties (cont.)

Property Name	Description
ColorBits	This property stores the number of adjacent color bits for each pixel (that is, the color depth of the user's monitor). For example, if the user's monitor is using 256 colors, ColorBits is set to 8.
Intel	This property stores the numeric value of the processor level, and it is defined only if the setup is running on an Intel 32-bit processor.
Intel64	This property stores the numeric value of the processor level, and it is defined only if the setup is running on an Intel 64-bit processor. This property requires Windows Installer version 2.0.
PhysicalMemory	This property stores the installed amount of physical memory, in megabytes.
ScreenX	This property defines the width of the screen, in pixels.
ScreenY	This property defines the height of the screen, in pixels.
TextHeight	This property sets the height of text characters.
VirtualMemory	The amount of available page file space, in megabytes, is stored in this property.

PowerShell Properties

The following PowerShell-related properties are available at run time:

Table 9-10 • PowerShell Properties

Property Name	Description
POWERSHELLVERSION	The predefined PowerShell system search sets the value of this property if PowerShell is installed. To learn more, see Calling a PowerShell Custom Action.
IS_PS_EXECUTIONPOLICY	This property lets you override the PowerShell execution policy on target systems with an appropriate one for your installation's PowerShell custom actions. Setting this property affects how the PowerShell custom actions that are run in your installation; however, it does not alter the policy of the target system. Thus, any PowerShell scripts that are run subsequently outside of your installation, or during other subsequent installations, are not affected by use of the **IS_PS_EXECUTIONPOLICY** property. To learn more, see Calling a PowerShell Custom Action.

Virtual Machine Properties

To use Windows Installer properties to detect the presence of a virtual machine and determine the type of virtual machine, you first need to create a custom action that calls the ISDetectVM function in the `SetAllUsers.dll` file. For instructions, see Detecting Whether the Installation Is Being Run on a Virtual Machine.

The custom action sets the following Windows Installer properties at run time:

Table 9-11 • Virtual Machine Properties

Property Name	Description
IS_VM_DETECTED	If the value of this property is 1, one of the following virtual machine environments is present: • Microsoft Hyper-V • A VMware product such as VMware Player, VMware Workstation, or VMware Server • Microsoft Virtual PC If the value is not set, no virtual machine has been detected.
IS_VM_TYPE	This property indicates the type of virtual machine that is present on a target system. Available values are: • **0**—No virtual machine has been detected. • **1**—The installation is running on a VMware product such as VMware Player, VMware Workstation, or VMware Server. • **2**—The installation is running on a Microsoft Hyper-V machine. • **3**—The installation is running on a Microsoft Virtual PC machine. • **4**—The type of virtual machine is not known.

Status Properties Updated by the Installer

The following properties are set by the installer at run time. These properties identify the status of the installation.

Table 9-12 • Status Properties

Property Name	Description
AFTERREBOOT	This property is set to 1 by the installer after a reboot triggered by the ForceReboot action.
CostingComplete	This property is set to 1 as soon as costing has begun and is set to 0 when costing is complete.
RollbackDisabled	The installer sets the **RollbackDisabled** property whenever rollback has been disabled. This property is not set by default.
Installed	This property determines if the product is already installed.

Table 9-12 • Status Properties (cont.)

Property Name	Description
OutOfDiskSpace	This property is set to True if any of the drives that are targets for the install do not have enough disk space. Otherwise, it is set to False.
OutOfNoRbDiskSpace	This property is set to True if any disk targeted during an installation does not have enough free disk space and if rollback capability is turned off. It is set to False if all of the target disks have sufficient space.
Preselected	This property determines if features have been preselected, and if so, does not display the selection dialog.
PrimaryVolumePath	The installer sets this property to the path specified in the PRIMARYFOLDER property.
PrimaryVolumeSpaceAvailable	This installer sets this property to a string representing the total number of bytes, in units of 512, available on the volume specified by the **PRIMARYFOLDER** property.
PrimaryVolumeSpaceRequired	This property stores a string representing the total amount of disk space required, in bytes (expressed in units of 512 bytes), by the currently selected features.
PrimaryVolumeSpaceRemaining	The installer sets this property to a string representing the number of remaining bytes available on the system, in units of 512, if all selected features were to be installed.
Resume	This property stores the text string displayed to the user when an installation is resumed from a suspended setup.
UpdateStarted	This property is set once changes to the system have taken place as a result of the installation process.
ReplacedInUseFiles	This property is set if a file that is currently in use is overwritten. Custom actions that check to see if a reboot is required will use this property.
NOUSERNAME	Setting this property to 1 stops the installer from setting the **USERNAME** property. By default, this property is not set and the **USERNAME** property is set from the registry.
NOCOMPANYNAME	Setting this property to 1 stops the installer from setting the **COMPANYNAME** property. By default, this property is not set and the **COMPANYNAME** property is set from the registry.

Date and Time Properties

Table 9-13 • Date and Time Properties

Property Name	Description
Date	This property holds the current date.
Time	This property holds the current time.

InstallScript Engine-Related Properties

These properties contain information related to the InstallScript engine.

Table 9-14 • InstallScript Engine-Related Properties

Property Name	Description
STANDARD_USE_SETUPEXE	 ***Project*** • *This property applies to InstallScript MSI projects.* InstallScript MSI projects must be run by launching `Setup.exe`. This localizable property holds the message that is displayed to an end user who launches your .msi database directly, instead of launching `Setup.exe`.

SQL-Related Properties

These properties contain data related to SQL connections and SQL scripts that are configured in the SQL Scripts view.

Table 9-15 • InstallScript Engine-Related Properties

Property Name	Description
IS_SQLSERVER_ALIAS_ONLY	Specify to show only the SQL Server aliases in the SQL Server browse combo box and list box controls. To learn more, see Overriding the Default SQL Run-Time Behavior.
IS_SQLSERVER_AUTHENTICATION	This property identifies the type of authentication that you want to use to connect to the specified catalog. The default property is **IS_SQLSERVER_AUTHENTICATION**. The following numbers are valid property values: • **0**—Windows authentication credential of the current user • **1**—Server authentication To learn more, see Using Windows Installer Properties for SQL Login Settings.

Table 9-15 • InstallScript Engine-Related Properties (cont.)

Property Name	Description
IS_SQLSERVER_CONNECTIONS_TO_VALIDATE	Overrides the connections that will be tested when clicking the Next button on the SQLLogin dialog. To learn more, see Overriding the Default SQL Run-Time Behavior.
IS_SQLSERVER_CXNS_ABSENT_FROM_INSTALL	Specifies one or more SQL connections that should be skipped during installation or uninstallation. To learn more, see Overriding the Default SQL Run-Time Behavior.
IS_SQLSERVER_DATABASE	This property identifies the name of the SQL catalog to which you want to create a connection during the installation. To learn more, see Using Windows Installer Properties for SQL Login Settings.
IS_SQLSERVER_DO_NOT_USE_REG	Specifies not to use the stored SQL Server login information written in the registry. To learn more, see Overriding the Default SQL Run-Time Behavior.
IS_SQLSERVER_LOCAL_ONLY	Specifies to show only the local SQL Server in the SQL Server browse combo box and list box controls. To learn more, see Overriding the Default SQL Run-Time Behavior.
IS_SQLSERVER_PASSWORD	This property identifies the password that should be used for server authentication. To learn more, see Using Windows Installer Properties for SQL Login Settings.
IS_SQLSERVER_REMOTE_ONLY	Specifies to show only the remote SQL Servers in the SQL Server browse combo box and list box controls. To learn more, see Overriding the Default SQL Run-Time Behavior.
IS_SQLSERVER_SERVER	This property identifies the name of the target server instance (for Microsoft SQL Server and MySQL) or the connect URL string or local net service name (for Oracle). To learn more, see Using Windows Installer Properties for SQL Login Settings.
IS_SQLSERVER_USERNAME	This property identifies the login ID that should be used for server authentication. To learn more, see Using Windows Installer Properties for SQL Login Settings.

MDAC Properties

These properties apply to version checking for MDAC.

Table 9-16 • MDAC Properties

Property Name	Description
ISINSTALL_MDAC_BYVERSION	Create and set this property to Yes if you want InstallShield to perform default version checking.
ISINSTALL_MDAC_SKIP	Create and set this property in the Project Manager if you are performing your own version checking and do not want InstallShield to install MDAC.

SETUPEXEDIR

Project • *The following project types support the* ***SETUPEXEDIR*** *property:*

- *InstallScript MSI*
- *Basic MSI*

To determine the location from which an InstallScript installation was run, use SRCDIR or PACKAGE_LOCATION.

SETUPEXEDIR is a property that contains the path to `Setup.exe`. For example, if the path to `Setup.exe` is `C:\MySetups\MyApp\Setup.exe`, the value of **SETUPEXEDIR** is `C:\MySetups\MyApp`.

Using SETUPEXEDIR

SETUPEXEDIR is an alternative to the directory identifier **SourceDir**. A potential problem with using **SourceDir** is that it points to the location of the running .msi package. In the case of a compressed installation, the .msi package is streamed to a temporary location and run from there. Because of this, the value of **SourceDir** will be some temporary location on the end user's machine, which might not be the value that you want.

Limitations of SETUPEXEDIR

There are two limitations to using **SETUPEXEDIR**:

- **SETUPEXEDIR** is set by `Setup.exe`. If the end user runs the .msi package directly, **SETUPEXEDIR** is not set. To account for this, you could have a dual implementation in your installation—one that uses **SETUPEXEDIR** and one that uses **SourceDir**. You could test for the existence of **SETUPEXEDIR** and, if it does not exist, you could conditionally use your **SourceDir** implementation.
- **SETUPEXEDIR** might not be set at uninstallation. If the end user triggers the uninstallation by running `Setup.exe`, **SETUPEXEDIR** is set. If they run the uninstallation from Add or Remove Programs, **SETUPEXEDIR** is not set.

Note • *In an uncompressed installation,* ***SourceDir*** *and* ***SETUPEXEDIR*** *have the same value.*

Advanced UI and Suite/Advanced UI Property Reference

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

A number of properties are set during Advanced UI and Suite/Advanced UI installations. You can set the values of some of the properties from within InstallShield, while others are initialized by the Advanced UI or Suite/Advanced UI engine at run time.

Unlike Basic MSI projects, Advanced UI and Suite/Advanced UI projects do not distinguish between public properties and private properties. However, capitalization must be maintained; if you use mixed uppercase and lowercase for the name of the Advanced UI or Suite/Advanced UI property, ensure that you use the same capitalization every time that you refer to that property in your project.

Note that if a property that you define in the Property Manager view is set to a value that references a second property, and if you want the second property to be resolved in the first property's value, you may need to select the Formatted check box for the first property. To learn more, see Property Manager View.

The following categories of built-in Advanced UI and Suite/Advanced UI properties are available:

- Special Advanced UI and Suite/Advanced UI Properties
- Advanced UI and Suite/Advanced UI Folder Properties
- System Folder Properties

Note • *Do not confuse Advanced UI and Suite/Advanced UI properties with path variables, which are surrounded by angle brackets (<>). While they both may represent directories, Advanced UI and Suite/Advanced UI properties are evaluated at run time, but path variables are used to point to source files only during installation authoring and at build time.*

Special Advanced UI and Suite/Advanced UI Properties

The following properties indicate various miscellaneous information for the Advanced UI and Suite/Advanced UI installation.

Table 9-17 • Special Advanced UI and Suite/Advanced UI Properties

Property	Description
ISFeatureInstall	This property stores a comma-delimited list of feature names that are defined in the Advanced UI or Suite/Advanced UI `Setup.xml` file for command-line feature selection that will be selected for installation.
ISFeatureRemove	This property stores a comma-delimited list of feature names that are defined in the Advanced UI or Suite/Advanced UI `Setup.xml` file for command-line feature selection that will be selected for removal.
ISInstallMode	This read-only property stores a value that indicates the mode in which the Advanced UI or Suite/Advanced UI installation is running. Possible values are: • **0**—First-time installation • **1**—Maintenance/UI maintenance mode selection • **2**—Maintenance/modify • **3**—Maintenance/remove • **4**—Maintenance/repair • **5**—Stage only (The installation is run in stage mode, in which the Advanced UI or Suite/Advanced UI installation is staged—or uncompressed and copied to a specified location. Note that none of the packages in the installation are run in this mode.)
ISInstallProgress	This property stores the percentage of how much of the entire Advanced UI or Suite/Advanced UI installation has been completed. It is typically used for a progress circle control on the InstallationProgress wizard page.
ISInstallStatus	This property stores progress messages from the Advanced UI or Suite/Advanced UI installation.
ISOnRebooted	If the Advanced UI or Suite/Advanced UI installation is resuming after a reboot, this property is set to True.
ISParcelProgress	This property stores the percentage of how much of the currently running package installation has been completed. It is typically used for the Interior Property setting of the progress circle control.

Table 9-17 • Special Advanced UI and Suite/Advanced UI Properties (cont.)

Property	Description
ISPassword	If you configure your Advanced UI or Suite/Advanced UI release to be password protected, the Advanced UI or Suite/Advanced UI user interface sets the *ISPassword* property. When the password is set and a password is populated in the Advanced UI or Suite/Advanced UI `Setup.xml` file, the value of this property is validated against the password from `Setup.xml`.
ISPerformDelayedReboot	This property is set to True by the Advanced UI or Suite/Advanced UI user interface if the target system should be restarted when the Advanced UI or Suite/Advanced UI installation exits.
ISParcelStatus	This property stores progress messages from the currently running package.
ISRootStagePath	This property is used when the installation is run in stage mode. The property stores the path to the location where the Advanced UI or Suite/Advanced UI installation is staged—or uncompressed and copied to a specified location.
ISSelectedLanguage	This property stores a string that contains the decimal language identifier of the language that the installation is currently displaying. Changing this property at run time, such as in the InstallationLanguage wizard page, changes the current language of the Advanced UI or Suite/Advanced UI installation. You can use this property to set the language of the packages in your Advanced UI or Suite/Advanced UI installation.
ISSilentInstall	If the Advanced UI or Suite/Advanced UI installation is running silently (without a user interface), this property is set to True.

Advanced UI and Suite/Advanced UI Folder Properties

The following properties define where files are stored or installed on the target system.

Table 9-18 • Advanced UI and Suite/Advanced UI Folder Properties

Property	Description
ISLogDir	If logging is enabled and configured for one or more of the packages in the Advanced UI or Suite/Advanced UI installation, and if an end user launches the Advanced UI or Suite/Advanced UI installation from the command line with the `/log` parameter, this property stores path to the directory that contains the package log files. For more information, see Supporting the Creation of Package Log Files for Command-Line Launching of an Advanced UI or Suite/Advanced UI Installation.

Table 9-18 • Advanced UI and Suite/Advanced UI Folder Properties (cont.)

Property	Description
ISPREREQDIR	This property stores the path to an Advanced UI or Suite/Advanced UI package's files when the package is staged, or copied to the target system for use temporarily during run time.
SETUPEXEDIR	This property stores the path to the Advanced UI or Suite/Advanced UI installation's `Setup.exe` file. For example, if the path to `Setup.exe` is `C:\MySetups\MyApp\Setup.exe`, the value of *SETUPEXEDIR* is `C:\MySetups\MyApp`.
SETUPEXENAME	This property identifies the name of the setup launcher file that was created when the project was built. The installation updates the value of this property at run time if the setup launcher file was renamed. The following path identifies the full path to this file: `[SETUPEXEDIR]\[SETUPEXENAME]`
SETUPSUPPORTDIR	This property stores the path to the folder that contains the support folders and files that are used temporarily by the Advanced UI or Suite/Advanced UI installation at run time and then removed. This location is sometimes referred to as the *default staging path*. To refer to a file that is in the Language Independent node in the Support Files view, use the following syntax: `[SETUPSUPPORTDIR]\MyLanguageIndependentFile.txt` To refer to a file that is in one of the language-specific nodes in the Support Files view, include the language identifier in the path. For example, the language identifier for English is 1033: `[SETUPSUPPORTDIR]\1033\MyEnglishFile.txt`
TempFolder	This property stores the path to the current temporary folder in the user context in which the Advanced UI or Suite/Advanced UI installation is running.

System Folder Properties

The following properties define paths to various folders on end users' systems.

Table 9-19 • System Folder Properties

Property	Description
AdminToolsFolder	The value of this property is the full path to the end user's folder that contains administrative tools.

Table 9-19 • System Folder Properties (cont.)

Property	Description
AppDataFolder	The value of this property is the full path to the end user's Application Data folder.
CommonAppDataFolder	The value of this property is the full path to the All Users Application Data folder.
CommonDocuments	The value of this property is the full path to the folder that contains documents that are common to all users.
CommonFilesFolder	The value of this property is the full path to the 32-bit Common Files folder.
CommonFiles64Folder	The value of this property is the full path to the 64-bit Common Files folder on 64-bit systems. This property is undefined on 32-bit systems.
LocalAppDataFolder	The value of this property is the full path to the folder that contains data files for local (non-roaming) applications.
PersonalFolder	The value of this property is the full path to the end user's Personal folder.
ProgramFilesFolder	The value of this property is the full path to the end user's Program Files folder. On 64-bit systems, this property refers to the 32-bit location.
ProgramFiles64Folder	The value of this property is the full path to the end user's 64-bit Program Files folder. This property is undefined on 32-bit systems.
SystemFolder	The value of this property is the full path to the 32-bit system folder.
System64Folder	The value of this property is the full path to the 64-bit native system folder on 64-bit systems. This property is undefined on 32-bit systems.
WindowsFolder	The value of this property is the full path to the end user's Windows folder.

Creating Properties

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

- *MSI Database*
- *MSM Database*
- *Suite/Advanced UI*
- *Transform*

Project-specific differences are noted where applicable.

You can create your own project-wide properties through the Property Manager. These properties allow you to set a value in one place and use it throughout your project. The procedure is essentially the same regardless of whether you are creating a Windows Installer property in a Windows Installer–based project (Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, or Transform), or an Advanced UI or Suite/Advanced UI property in an Advanced UI or Suite/Advanced UI project.

Task: ***To create a property:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Click the **New Property** button. InstallShield adds a new row at the bottom of the view.
3. In the **Name** column, enter a name for the new property.
4. In the **Value** column, enter a value for the property.
5. in a Windows Installer–based projects: In the **Comments** column, optionally enter comments about the property.
6. In Advanced UI or Suite Advanced UI projects: In the **Formatted** column, select or clear the check box, which lets you indicate whether you want the properties in the **Value** column to be resolved and replaced by their property values at run time.

   To replace properties (and their surrounding square brackets) such as **[PropertyName]** at run time, select the check box.

   To leave square brackets and the content within them as is, clear the check box.

Tip *• Use the following guidelines when entering values in the Property Manager view:*

- *To overwrite all of the text in a table cell, click the table cell and then type your new property name, value, or comments.*
- *To place the cursor at a particular place within a table cell, double-click that place. Then type your change.*

Tips for Creating Windows Installer Properties in Windows Installer–Based Projects

If you want to create a property that can be changed at the command line, use all uppercase letters in the property's name. For example, INSTALLDIR is a property that can be set or changed from the command line. For more information, see Overview of Windows Installer Properties.

Windows Logo • *InstallShield does not verify whether the information that you enter in the Property Manager view is valid. For example, if you change the value of the* ***ARPHELPLINK*** *property to* ***MyCompany*** *instead of* ***http://www.mycompany.com****, the link fails when an end user clicks it. InstallShield does not display an error message when you enter the data in the Property Manager or at build time. To check whether you have the correct information and syntax for a built-in Windows Installer property, see the Windows Installer Property Reference.*

Changing an Existing Property

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Suite/Advanced UI*
- *Transform*

Task: ***To change an existing property in your project:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Do one of the following:
   - To overwrite all of the text in a table cell, click the table cell and then type your new property name, value, or comments.
   - To place the cursor at a particular place within a table cell, double-click that place. Then type your change.

Creating a Localizable Property

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

If you want a property that can have different values based on the language that your installation uses, you can create a localizable property.

Task: ***To create a localizable property:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Click the arrow next to the **New Property** button, and then click **Localizable Property**. InstallShield adds a new row at the bottom of the view. A new string identifier is listed in the Value column for that property.
3. In the **Name** column, enter a name for the new property.

Tip • *You can use the String Editor view to set a different property value for each language that your project supports.*

To learn how string identifiers and values are used in projects, see Using String Entries in InstallShield.

Making an Existing Property Localizable

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

If you want a property that can have different values based on the language that your installation uses, you can make that property localizable.

Task: ***To make a property localizable:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Select one or more properties that you want to localize.

   To select multiple consecutive properties, select the first property, press and hold SHIFT, and select the last property. To select multiple nonconsecutive properties, select the first property, press and hold CTRL, and select each additional property.
3. Click the **Make Selected Properties Localizable** button.

InstallShield adds a new string identifier in the Value column for that property.

Tip • *You can use the String Editor view to set a different property value for each language that your project supports.*

To learn how string identifiers and values are used in projects, see Using String Entries in InstallShield.

Preventing a Property Value from Being Written in Log Files

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

By default, Windows Installer writes the final value of every Windows Installer property contained in your installation to a log file generated by launching MsiExec with the `/L` argument. Starting with Windows Installer version 2.0, you can prevent certain properties (such as those containing passwords) from being written in the log file.

Task: ***To prevent a property from being written in the log file:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. In the **Name** column, find the **MsiHiddenProperties** property.

   If this property is not listed, click the **New Property** button to create this property, and in the **Name** column, enter `MsiHiddenProperties`.
3. In the **Value** column, enter the name of the property that you want to be hidden. To list more than one property, separate each with a semicolon (;).

For more information about this property, see MsiHiddenProperties in the Windows Installer Help Library.

Specifying that a Public Property Should Be a Restricted Public Property

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

Restricted public properties allow network administrators to define public properties that can be changed only by a system administrator or by someone who has elevated privileges. This way, the administrator can change settings quickly without having to worry that unauthorized users on the network may tamper with the installation.

Windows Installer considers a number of public properties to be restricted public properties. For the full list of restricted public properties, see Restricted Public Properties in the Windows Installer Help Library.

To include additional public properties, add them to the **SecureCustomProperties** property.

If you perform tasks such as the following ones, InstallShield automatically adds the applicable property to the **SecureCustomProperties** property:

- When you use a public property in a system search, InstallShield adds the public property to the **SecureCustomProperties** property.
- When you add or import a dialog to a Basic MSI or Merge Module project, and the dialog contains a control that is set through a property, InstallShield adds that property to the **SecureCustomProperties** property.
- When you add a major upgrade item to your project, InstallShield adds the value of the Detect Property setting on the Advanced tab for that upgrade item to the **SecureCustomProperties** property.

This enables the custom public properties to be set in the user interface sequence and then be passed to the execute sequence.

Task: ***To manually specify that a custom public property should be a restricted property:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. In the **Name** column, find the **SecureCustomProperties** property.

   If this property is not listed, click the **New Property** button to create this property, and in the **Name** column, enter `SecureCustomProperties`.
3. In the **Value** column, enter the public properties that you would like to restrict. Separate multiple entries with a semicolon (;).

Getting or Setting Windows Installer Properties in InstallScript

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

The **MsiGetProperty** and **MsiSetProperty** functions get and set Windows Installer properties. For an example, see Getting and Setting Properties.

You must include the statement `#include "iswi.h"` or `#include "ifx.h"` in order for the Windows Installer APIs to be available to your script.

Removing a Value from a Property

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Suite/Advanced UI*
- *Transform*

Advanced UI and Suite/Advanced UI projects do not have support for localizable properties.

You can clear a property's value without deleting the property from the Property Manager. This functionality works for localizable and non-localizable properties. For example, you might want to clear a localizable property such as **ARPCOMMENTS**.

Task: ***To clear a property value:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Select one or more properties whose values you want to clear.

To select multiple consecutive properties, select the first property, press and hold SHIFT, and select the last property. To select multiple nonconsecutive properties, select the first property, press and hold CTRL, and select each additional property.

3. Click the **Clear Selected Properties** button.

Note • *Clearing a property makes the property non-localizable because it does not have a string identifier.*

Deleting a Property

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Suite/Advanced UI*
- *Transform*

If you no longer need a property in your project, you can delete it from the Property Manager view.

Task: ***To delete a property from your project:***

1. In the View List under **Behavior and Logic**, click **Property Manager**.
2. Select one or more properties that you want to delete.

   To select multiple consecutive properties, select the first property, press and hold SHIFT, and select the last property. To select multiple nonconsecutive properties, select the first property, press and hold CTRL, and select each additional property.
3. Click the **Delete Selected Properties** button.

InstallShield displays a message box that lets you specify whether you want to delete just the selected properties, or the selected properties plus any associated string entries.

Directly Editing .msi and .msm Databases

The MSI Database and MSM Database project types let you edit Windows Installer installation databases and merge module databases directly, rather than working through an intermediate project format (.ism file). These project types extend the Direct Editor functionality to include different views that are supported in standard installation projects. The views that are supported in these project types are intended to function as they do for an .ism project.

Project • *There is no string entry or path variable support in an MSI Database or MSM Database project.*

You can directly edit an existing .msi file or .msm file, or directly create a new database by opening a new MSI Database or MSM Database project.

Opening Windows Installer Packages

InstallShield provides the option to either edit .msi packages directly in InstallShield by using direct edit mode or convert it to an InstallShield project (.ism), and then edit it as a Basic MSI project in InstallShield.

Note • *Some functionality is limited when editing an .msi package in direct edit mode.*

Task: ***To open an .msi package in direct edit mode of InstallShield:***

1. On the **File** menu, click **Open**. The **Open** dialog box opens.
2. In the **Files of Type** list, select **Windows Installer Packages (*.msi)**.
3. Select the .msi package that you want to open.
4. In the **Open as** box, ensure that **Auto** is selected.
5. Click **Open**.

Note • *By default, InstallShield opens an .msi package in direct edit mode.*

The Open MSI/MSM Wizard can convert an existing Windows installer (.msi) package to an InstallShield project (.ism) file, and open the new project to modify in InstallShield.

Note • *You can also open patch creation project files (.pcp files) in InstallShield and edit them in the Direct Editor.*

Editing .msi and .msm Databases in Direct Edit Mode

If you want to directly edit a Windows Installer package (.msi file) or merge module (.msm file), you can open it in InstallShield in direct edit mode and then make the required changes.

Task: ***To open an .msi or .msm file:***

1. On the **File** menu, click **Open**.
2. In the **Files of Type** list, select **Windows Installer Packages (*.msi)** or **Windows Installer Modules (*.msm)**.
3. Browse to the Windows Installer package or merge module that you want to open.
4. Click **Open**.

The selected package or merge module opens in a limited view of the InstallShield interface. Any changes made in the direct edit mode are made directly to the .msi or .msm file when you save your changes.

Adding Files in Direct Edit Mode

When adding files in direct edit mode, you have the option to add files to the media in an uncompressed, a compressed, or a compressed and streamed state into the MSI format (MSI package or MSI database). These options appear in the Select Media Location dialog box when you drag and drop new files in the Files and Folders view in direct edit mode. You also have the option to extract COM information in that dialog box. However, this option is enabled only when dragging files to a folder or when adding a single file to a component that does not already have any existing files. As a result, the COM file is the only file in that particular component.

Deleting files removes the entry from the **File** table. Files on the media are not deleted, and files that have yet to be added to the media are not added until you save.

Note • *In direct edit mode, file and media tables are updated during the save process.*

When a file is added, a record is created with a default sequence value. No **Media** table entry is made at this time. When the media or project is saved, the sequence for the newly added files is updated to correctly reflect the media, and media entries are created in the **Media** table.

Adding Merge Modules in Direct Edit Mode

When you add a configurable merge module or object in the Redistributables view to an .msi database in direct edit mode, the Merge Module Properties dialog box opens. You can review or configure the merge module's properties through that dialog box. However, you can do this only when the merge module is initially merged with your installation database. That is when this dialog box is first opened. You should also note that a merge occurs as soon as you select a merge module in direct edit mode.

Note • *You cannot configure or set the destination of dependent merge modules.*

You cannot un-merge modules that are not found in the merge module catalog. For example, a file is not found in the Modules\i386 folder. In that case, the check box next to the respective merge module is selected but disabled.

Once you add, configure, and merge the merge modules, any files included in the merged modules will be copied to the source media upon saving the database in InstallShield.

10

Integrating InstallShield with External Applications

An important aspect of InstallShield is how it coexists and integrates with other software development tools such as Visual Studio as well as source code control software that complies with the Microsoft Source Control Interface.

Consult the help topics in this section for specific details on the extent of external application support in InstallShield.

Using Source Code Control

InstallShield enables you to manage different versions of your project file in source code control software. InstallShield is capable of interacting with any source control system that complies with the Microsoft Source Control Interface and uses the default program on the development system. If none is installed, the source control options are not available.

Tip • *InstallShield also includes support for integrating with Team Foundation source control. To learn more, see* *Integrating with Microsoft Visual Studio Team Foundation Server*.

When you add an installation project to source control, InstallShield automatically converts the project file format to text (XML format) and maintains it in the source control system by default. If you choose not to check in your file in XML format, then the file will be checked in as a binary file.

Note • *When a project file format is converted to either XML or binary format, the project file extension remains .ism.*

Script File Support

InstallShield also supports the addition of any InstallScript files and SQL scripts, regardless of whether you insert, import, or add new files. It also supports all path variable types that you define in the Path Variables view to define the location of these script files. However, it is important to be aware that a corresponding folder structure exists in your source code database so that your source code control software can resolve paths.

Using Source Code Control Integration

Task: ***A typical scenario for using InstallShield's source code control integration is outlined below:***

1. Create an InstallShield installation project.
2. Add the setup project to your source control program.
3. Check the project out of source control.
4. Edit the project.
5. Save the project.
6. Check the project back in to source control.

Tip • *You can streamline this process by having InstallShield automatically add new projects to source control or check out edited projects. For more information, see the Source Control tab of the Options dialog box; InstallShield displays this dialog box when you click Options on the Tools menu.*

Adding Projects to Source Control

InstallShield lets you add an InstallShield project to your source code control system after you have created your InstallShield project.

Tip • *You can omit steps 1 and 2 if you selected the* ***Add new projects to source control*** *check box on the Source Control tab of the Options dialog box; InstallShield displays this dialog box when you click Options on the Tools menu. As soon as you create the project, InstallShield adds it to your source code control system.*

Task: ***To add a project to your source control system after you have created the project:***

1. Open the project in InstallShield.
2. On the **Project** menu, point to **Source Control**, and click **Add to Source Control**. The Add to Source Control dialog box opens.
3. Add comments (if applicable) and indicate whether you want to keep the project checked out.
4. Click **OK**. A log-on dialog box for your organization's source control system opens.
5. Enter your log-on information.
6. Browse to the location in your source control database where you want to add the project file.

Note • *Linked files are not added to source control.*

When you add a file to source control, most programs make the local copy read only. If this is the case with your source control software, you need to check out the project file before making any changes.

Checking Projects out of Source Control

InstallShield lets you check out an InstallShield project from your source code control system.

Tip • *You can omit steps 1 and 2 if you selected the* ***Check out the project when edited*** *check box on the Source Control tab of the Options dialog box; InstallShield displays this dialog box when you click Options on the Tools menu. As soon as you make a change to the project (anything that enables the Save button on the toolbar), InstallShield adds it to your source code control system.*

Task: ***To check a project out of your source code control program:***

1. Open the project in InstallShield.
2. On the **Project** menu, point to **Source Control**, and click **Check Out**.
3. If you selected the **Use dialog for checkout** check box on the **Source Control** tab of the **Options** dialog box, you are prompted for your comments in the **Check Out** dialog box.
4. Enter comments as appropriate, and then click **OK**.

Your project is now checked out of your source control program, and you can edit the local copy before checking it in.

Note • *The project is not automatically checked in to source control when you close the project in InstallShield. Check your project in (from within InstallShield) before closing it.*

Checking Projects in to Source Control

Task: ***To check a project in to your source control program from within InstallShield:***

1. Open the project in InstallShield.
2. On the **Project** menu, point to **Source Control**, and click **Check In**.
3. The **Check In** dialog box prompts you for options for checking in the file. Click **OK**.

Your project is now checked into your source control program, which typically means that your project file is set to read only until you check it out of source control.

Note • *The project is not automatically checked in to source control when you close the project in InstallShield. Check your project in (from within InstallShield) before closing it.*

Unlinking Projects from Source Control

Task: ***To break the link between the project on your local machine and the one in your source control application:***

On the **Project** menu, select **Source Control**, and point to **Unlink from Source Control**.

Integrating with Microsoft Visual Studio

With InstallShield, you can create your installation projects directly in Microsoft Visual Studio. InstallShield enables you to create, modify, or build your installation from within Microsoft Visual Studio.

Integration Features

InstallShield is fully integrated within the Visual Studio shell. Some of the unique features of the integration include:

- All InstallShield navigation is presented within the Solution Explorer.
- Each InstallShield view is presented in a separate window so no scrolling is necessary and side-by-side viewing options are available.
- You can run InstallShield external to Visual Studio.
- InstallShield dynamically links your installation project to other Visual Studio project outputs, automatically updating your installation with your latest source files every time your product is built.
- Items identified by the InstallShield Debugger can be moved directly into the Visual Studio task list.

Integration Benefits

Some additional benefits of using InstallShield's integrated installation authoring solution are:

- You can create and customize your installation without leaving the Visual Studio user interface, enabling use of familiar navigation and layout options.
- Your installation is automatically updated with your latest source files every time your solution is built, always staying current.
- The installation reflects the Build Configuration for the solution—for example, Debug, Release, automatically included source files from the proper build directory.

- .NET properties and dependencies can be scanned and included in an installation automatically.

Note • *If you want to create, edit, and build your InstallShield projects directly within Visual Studio, you must use Visual Studio 2005 or later. InstallShield cannot be integrated with Visual Studio 2003 or earlier.*

Visual Studio can be integrated with only one version of InstallShield at a time. The last version of InstallShield that is installed or repaired on a system is the one that is used for Visual Studio integration.

Creating InstallShield Projects in Microsoft Visual Studio

InstallShield is integrated with Microsoft Visual Studio. From within the Visual Studio workspace, you can create InstallShield installations for solutions.

Task: ***To create an InstallShield project from within Microsoft Visual Studio:***

1. On the **File** menu, point to **New** and click **Project**. The **New Project** dialog box opens.
2. *Beginning with Visual Studio 2010:* In the **Installed Templates** box, click **InstallShield Projects**. Then select the appropriate project type.

   For earlier versions of Visual Studio: In the **Project Types** box, click **InstallShield Projects**. Then in the **Templates** box, select the appropriate project type.
3. Configure the settings for the name and project location as needed.
4. Click **OK**.

Opening InstallShield Projects in Microsoft Visual Studio

InstallShield is integrated with Microsoft Visual Studio. From within the Visual Studio workspace, you can open InstallShield installations for solutions.

Task: ***To open an InstallShield project from within Microsoft Visual Studio:***

1. On the **File** menu, point to **Open**, and choose **Project** to display the **Open Project** dialog.
2. Browse to the InstallShield file you want to open, and select it.
3. Click **Open**.

Note • *From within Microsoft Visual Studio, you can open only .ism files created with InstallShield X or later, InstallShield DevStudio, InstallShield Developer, InstallShield—Windows Installer Edition, or InstallShield Express,*

version 3.x or later. Files created in InstallShield Professional or pre-3.x versions of InstallShield Express cannot be opened.

Adding References to Visual Studio Solutions

Use the Files and Folders view to add Visual Studio references to your installation project.

Task: ***To add a reference:***

1. In the **Solution Explorer** under **Application Data**, double-click **Files and Folders**.
2. The **Visual Studio Solution** node in the **Source computer's folders pane** contains sub-nodes for all projects contained in the current solution. Click a project to display the output groups for the project. The output groups are displayed in the **Source computer's files pane**.
3. To add a reference to an output to your installation project, drag and drop the output to the target folder in the **Destination computer's folders** pane.

Note • *To view a reference for a project, right-click the project and select Resolve Project Output. The Outputs dialog is displayed to show what files the output group resolves to.*

Using the Toolbox to Add Dialog Controls

To add dialog controls when your setup project is open in Microsoft Visual Studio, use the Toolbox.

Accessing the Toolbox

Task: ***To access the InstallShield Dialogs Toolbox:***

1. Do one of the following:
   - On the **View** menu, click **Toolbox**.
   - Press **CTRL+ALT+X**.
2. Click the **InstallShield Dialogs** tab, if it is not already expanded.

Adding Controls

Task: ***To add controls to a dialog:***

1. Click on the type of control you want to add to the dialog.
2. Click on the dialog, hold the mouse button down, and drag the mouse to draw the dimensions of the control. You can adjust the control's size by setting the height and width properties.

   As soon as you release the mouse button, the cursor changes to the Select Tool, which you can use to resize the new control.
3. Set the control's properties. For more information, see Editing Dialog Layout in Basic MSI Projects or Editing the Layout of a Dialog in an InstallScript or InstallScript MSI Project.

Using Sticky-State Mode

The toolbox control also has a *sticky-state* mode that allows you to create additional controls of the same type without returning to the Toolbox. To enable sticky-state mode, press the CTRL key while you drag the cursor from the toolbox to the dialog.

Using Auto Hide

The Dialog Toolbox has an auto-hide feature that allows you to hide the toolbox when it is not in use. To enable Auto Hide, click the Auto Hide button in the top-right corner of the toolbox. The toolbox is hidden on the side of the screen when you are not using it.

Adding InstallShield Toolbars or Commands to the Visual Studio Toolbar

You can add InstallShield toolbars and individual toolbar command buttons to the Microsoft Visual Studio workspace.

Adding InstallShield Toolbars

Task: ***To add an InstallShield toolbar:***

1. Right-click anywhere in the toolbar to display the toolbar options.
2. Select a toolbar to add it to the top of the Visual Studio workspace. The available InstallShield toolbars are InstallShield, InstallScript, InstallShield Layout, and MSI Debugger.

Adding InstallShield Toolbar Command Buttons

Task: ***To add an individual command button to the toolbar:***

1. Right-click anywhere in the toolbar to display the toolbar options.
2. Select **Customize** from the bottom of the list. The **Customize** dialog is displayed.
3. Click the **Commands** tab.
4. Select a category from the **Categories** list to display the commands available within that particular category.
5. From the **Commands** list, click a command button and drag it to the toolbar.

Note • *InstallShield Layout and MSI Debugger toolbar commands are not available as individual toolbar buttons.*

Building Releases in Microsoft Visual Studio

Project • *Some of the following information is project specific, as noted where applicable.*

Building a release of an InstallShield project in Visual Studio is different than building a release in InstallShield. When you are building in Visual Studio, you have the option to either build your entire solution, including the installation project, or build only the installation project.

When you create an InstallShield installation project in Visual Studio, the project has two releases by default—Debug and Release. You can use these default releases, or you can create new release. Before you can build a release, the release must be associated with a solution configuration. The Configuration Manager in Visual Studio is where you associate a release with a solution configuration.

Project • *In Basic MSI, InstallScript MSI, and Merge Module projects, every release is a member of a product configuration. A product configuration provides a means for grouping together releases that share similar settings, such as the product name, product code, and package code. When you build a release for any of these project types, the default product configuration is always used. If you want to build releases in a different product configuration, make that product configuration the default.*

Selecting the Default Product Configuration (Basic MSI, InstallScript MSI, and Merge Module Projects Only)

If you want to build a release in a Basic MSI, InstallScript MSI, or Merge Module project, it must be under the default or *active* product configuration. This is indicated by a red check box icon in the Releases view:

Task: ***To make a product configuration the default configuration in your InstallShield project:***

1. In the **Solution Explorer** under **Media**, double-click **Releases**.
2. In the **Releases** explorer, right-click the product configuration that contains the release that you want to build, and then click **Default Product Configuration**.

Tip • *To create a new product configuration, right-click the* ***Releases*** *explorer and then click* ***New Product Configuration****. Once you have created it, you can make it the default product configuration.*

Building a Release

Visual Studio enables you to build your entire solution, including the installation project, or only the installation project.

Task: ***To build a release from within Visual Studio:***

1. Use the Configuration Manager in Visual Studio to map a project configuration to the appropriate solution configuration.
   a. On the **Build** menu, click **Configuration Manager**.

      As an alternative: On the **Standard** toolbar, in the **Solution Configurations** list, select **Configuration Manager**.

   b. In the **Active solution configuration** list, select a configuration.

   c. In the **Project contexts** box, map the project configuration to the appropriate release in the **Configuration** column.

Note • *If the Build check box is cleared and you build the solution, the deselected project configuration is not built.*

   d. Click the **Close** button.
2. On the **Build** menu, select the appropriate command:

Table 10-1 • Build Menu Commands

Command	Description
Build Solution	Build the entire solution, according to what is mapped in the Configuration Manager for each project that is included in the solution.

Table 10-1 • Build Menu Commands (cont.)

Command	Description
Build *Installation Project Name*	Build only the installation project, according to the release that is specified in the Configuration column of the Configuration Manager. This option is available if your installation project is selected in the Solution Explorer.

Tip • *To build the entire solution, you can also press CTRL+SHIFT+B.*

Adding .NET Assemblies to Installation Projects

InstallShield allows you to add a .NET assembly to your installation project by adding the .NET assembly file to a component.

Task: ***The recommended way to add a .NET assembly to your installation project is as follows:***

1. In the **Setup Design** view, create a component to hold the .NET assembly.
2. (Windows Installer based projects only) Make the file the key file of a component by right-clicking on the file and selecting **Set Key File** from the context menu.
3. Set the project to scan for dependencies by doing one of the following:
   - Set the **.NET Scan at Build component** property to Dependencies and Properties. In this case, the .NET assembly's Manifest, Application, and related entries are not populated in your project file. Instead, they are added to the .msi file at build time.
   - Run the Static Scanning Wizard. In this case, the .NET assembly's values are added during the scan. You can edit these values in the **Assembly** node under the component's **Advanced Settings**.

Adding Project Output from a Web Service or Web Application Project

InstallShield provides enhanced Web services support. If you add a project output (any project output) from a Web Service or Web Application project, InstallShield will prompt you to add the project as a Web Service. If you choose No, the project output that you have selected is added normally. If you select Yes, InstallShield performs the following:

1. Creates a Destination Folder called IISROOTFOLDER.
2. Deploys the following Visual Studio Project Outputs into the IISROOTFOLDER:
   [Content Files] goes to the [IISROOTFOLDER]{VSIPProjectName}
   [Primary Output] goes to the [IISROOTFOLDER]{VSIPProjectName}\bin"

3. Creates an IISVirtualDirectory with a target of [IISROOTFOLDER]{VSIPProjectName}.

Integrating with Microsoft Visual Studio Team Foundation Server

Microsoft Visual Studio Team Foundation Server (TFS) is a set of tools and technologies that enable a team to collaborate and coordinate the tasks for developing a product. InstallShield has support for integrating with Team Foundation Server. Some highlights of this integration are:

- **Source control**—Use the Source Control Explorer to integrate your InstallShield project with Team Foundation version control and manage changes to your InstallShield projects and your Visual Studio solutions.
- **Automated builds**—Use Team Foundation Build to compile, test, and deploy your InstallShield projects and your Visual Studio solutions on a regular basis. Your installation is automatically updated with your latest source files every time your solution is built, always staying current.
- **Project management**—Track work items such as bugs, tasks, and project documentation for your InstallShield projects and your Visual Studio solutions. The project status is available to your entire team from within Team System Web Access, and from within Team Explorer.

Integration Requirements

To integrate InstallShield with Team Foundation Server, install InstallShield on each machine that you want to be able to create, update, or build InstallShield projects. Thus, InstallShield should be installed on each machine on which you want to create and update InstallShield projects. It should also be installed on a machine that is designated as a build agent for InstallShield projects that are stored in Team Foundation Server. For InstallShield licensing details, refer to the InstallShield End-User License Agreement (EULA).

***Note** • The Standalone Build is a build engine that enables you to build InstallShield projects without installing the full version of InstallShield on a build machine. If you have the Standalone Build, you can install it on a machine that is designated as a build agent for Team Foundation Server.*

In order for a build agent to build some types of projects and solutions, you may need to install additional software on the build machine. For example, to build a C++ project, which requires the C++ compiler and possibly other dependencies, install Visual Studio on the build machine.

If you are using multiple build agents to build your Team Foundation Server projects, you may want to assign a particular build tag to any agents that are on machines that have InstallShield; you could also apply that special build tag to each build definition that is created for an InstallShield project. That way, only build machines that have InstallShield installed would be used to build InstallShield installations. For more information about creating build tags and assigning them to agents and build definitions, see the Visual Studio Team Foundation Server documentation.

If you are queuing a build on a 64-bit build machine, ensure that you have configured the build definition for your InstallShield project so that the 32-bit version of MSBuild is used to load the `InstallShield.Tasks.dll` file (which is a 32-bit file); otherwise, you will encounter a build error informing you that the `InstallShield.Tasks.dll` file

could not be loaded. To select the 32-bit version of MSBuild, click the Process tab of your build definition in Team Explorer. Then, under the Advanced node, find the MSBuild Platform setting, and select x86. Note that if you are using a 32-bit build machine, you can select either Auto or x86 for the MSBuild Platform setting.

If you install Team Explorer on the same machine that has InstallShield and Visual Studio, you can use Team Explorer from within your InstallShield projects that are open in Visual Studio. This enables you to perform tasks such as the following:

- Use Source Control Explorer when you are working on your InstallShield projects.
- Configure builds for your InstallShield projects and Visual Studio solutions.
- Queue new builds.

Note that when you queue a build for a solution that includes an InstallShield project, the installation that is built is copied to an Install subfolder within the drop folder. When the InstallShield build detects that it is running under Team Foundation Build, it copies the installation to the final output location for the solution (OutDir)—namely, the binaries directory, which in turn is copied to the drop folder at the end of the Team Foundation Build process.

If you want to use Team Foundation source control when you are working on your InstallShield projects directly from within InstallShield (without Visual Studio integration), you can do so. To use this functionality, you need to install the Team Foundation Server MSSCCI Provider, which you can obtain from the Visual Studio Gallery on the MSDN Web site. Once the Team Foundation Server MSSCCI Provider is installed, you can add InstallShield projects to Team Foundation source control, check out InstallShield projects from Team Foundation source control, and check in projects to Team Foundation source control—all from within InstallShield. To learn more about source control integration within InstallShield, see Using Source Code Control.

Adding InstallShield Projects to Team Explorer

If you have Team Explorer installed on the same machine that has InstallShield and Visual Studio, you can add your InstallShield projects (.ism and .isproj files, as well as any corresponding InstallScript files and SQL scripts) to the Team Foundation Server through Team Explorer.

If you want to add an InstallShield project to Source Control Explorer when you create the project from within Visual Studio, select the **Add to source control** check box on the New Project dialog box. Note that if you do this, you may later need to add InstallScript files and SQL script files to source control using the same method that you use for adding other files.

To add an existing InstallShield project to Source Control Explorer, add it using the same method that you use for adding other projects. (In the Solution Explorer, right-click your InstallShield project and then click Add Solution to Source Control.)

11

Automating Build Processes

An automation interface is loosely defined as a programming interface that can be accessed by any programming language that supports COM—most importantly, usability from the late binding scripting languages like VBScript and JScript. In InstallShield, the automation interface is an automation interface to the InstallShield project file.

InstallShield enables you to automate build processes through the automation interface without having to directly open the InstallShield interface and make changes in different views. By calling methods, setting properties, accessing collections, and so on, through the automation interface, you can open a project and modify its features and component data in many of the same ways that you would in the InstallShield interface. In addition, you can build a release using the Build method of the InstallShield automation interface.

Read more about the automation interface as well as other aspects of automating build processes in this section of the documentation.

Linking Subfolders to Features Using VBScript

The VBScript example simulates dynamically linking to subfolders. By editing .ini files, you tell the script which folders and subfolders to link to, how to create the components for the files, and with which features to associate the new components.

The following are requirements for using the VBScript example:

- You must have Windows Scripting Host to run a .vbs file.
- InstallShield must be installed on the system before you can use the automation interface and .ini file reader.
- The script expects two command-line arguments:
  - The fully qualified path to an existing setup project (.ism file).
  - The fully qualified path to an .ini file (Links.ini in this example) that describes each feature that you want a given folder's files and subfolders added to. Furthermore, each feature can point to a different .ini file (Template.ini) that describes the properties of the components that will be created for the files in each folder and subfolder.

The source files for this example are found in the following directory:

InstallShield Program Files Folder\Samples\WindowsInstaller\Automation Interface\Add Files and Components

Each of the files is described below.

LinkToFeature.vbs

The script in the LinkToFeature.vbs file is designed to read the associated Links.ini file and add the files from the specified folders and subfolders to the specified features. It organizes them into components based on the model you construct in Template.ini. To start the script, pass it the path to your setup project and the path to Links.ini, respectively, at the command line:

```
LinkToFeature.vbs "C:\MySetups\Malaprop.ism" "C:\Automation Interface\Links.ini"
```

You can examine some of the relevant sections of LinkToFeature.vbs to see exactly how it works. After opening the .ism file specified at the command line, the script creates a collection of every feature in the project starting at line 53. This collection is later used to make sure that the features listed in Links.ini are present in the project.

```
' The scripting dictionary is defined in Scrrun.dll
Dim pFeatCol
Set pFeatCol = CreateObject("Scripting.Dictionary")

' Create a collection of all of the feature names in the project
For Each ISWIFeature In ISWIProject.ISWIFeatures
    pFeatCol.Add ISWIFeature, ISWIFeature.Name
    DoSubFeature ISWIFeature, pFeatCol
Next
```

Next, LinkToFeature.vbs opens Links.ini using the InstallShield IniReader. As the comment on line 70 explains, you can use this utility if it serves your needs or otherwise substitute your own. Once Links.ini is open, the rest of the script is controlled by the For loop beginning at line 80 and ending at line 202:

```
For Each pLinksSection In LinksIniFile.Sections
```

The purpose of this loop is to read each section in Links.ini. Each section contains the name of a feature that you want to add the new components to and the folder where the files and subfolders can be found. After getting each key's value, there is a nested For loop, stretching from line 102 to 201, which loops through every feature in the collection pFeatCol and compares it to the name of the feature in Links.ini:

```
  For Each ISWIFeature In pFeatCol
        ' See if the feature in Links.ini matches one in the setup project.
        If (ISWIFeature.Name = linksFeature) Then
```

Since this loop is used for almost the remainder of the script, you can assume that everything that is done acts on the current feature. Next, it checks if the Action key in this Links.ini section is set to Delete and deletes all of the feature's components if so:

```
If (linksAction = "Delete") Then
    For Each ISWIComponent In ISWIFeature.ISWiComponents
        ISWIProject.DeleteComponent ISWIComponent
    Next
End If
```

At line 27, the script creates a collection of the specified folder and each subfolder:

```
Set pFolders = CreateObject("Scripting.Dictionary")
pFolders.Add folder, folder.Path
GetSubFolders pFolders, folder
```

From line 136 to 163, the script opens the `Template.ini` file that contains the template for all of the components that will be added to the current feature:

```
Set iniFile = CreateObject("IniReader.IniFile")
iniFile.Load (linksTemplateFile)
```

`LinkToFeature.vbs` does its real work in the For loop that begins on line 169 and ends on 199:

```
' Create a component for the root folder and all of its subfolders.
For Each folder In pFolders
```

Based on the description in Template.ini, it forms the component's name, adds it to the project, associates it with the current feature, sets the component's properties, and then adds the files in the current folder to the component.

Finally, the .vbs file saves and closes the setup project.

Links.ini

Each section of this .ini file contains the following keys, which LinkToFeature.vbs reads to determine which folders and subfolders to add to each feature in your project:

Table 11-1 • .ini File Keys in Sample File

Key	Description
[LinkN]	`;Unique section name`
Feature=FeatureName	`;Name of existing feature in the project`
Source=C:\Data Files\Executables	`;Path to the root folder`
TemplateFile=Template.ini	`;Path to the component template .ini file`
ComponentTemplate=Template1	`;Section name in Template.ini for this feature's components`
Action=Delete	`;Delete tells LinkToFeature.vbs to permanently delete all of this feature's components before recreating them. Leave this value blank if you do not want the components destroyed.`

Template.ini

Each section in Template.ini contains information for creating all of the components that will be associated with a feature. Each section in Links.ini must point to a specific component template file and section. The template file and sections are described below:

Table 11-2 • Template.ini File Sections

Section	Description
[TemplateName]	`;Unique section name that identifies a particular template`
Name=DefaultName	`;This value is used to build the component's name in the format DLS_DefaultName_N`
Destination=[ProgramFilesFolder]	`;This is the root destination folder for the components. The names of the subfolders are then added to the root so that the files are installed to the correct relative folders.`
Languages=1033	`;List the decimal value of all of the component's languages, separated by a comma`
Condition=VersionNT	`;Author any condition you want to attach to each component`

Exporting and Importing String Entries Using the Automation Interface

InstallShield stores string entries in the **ISString** table of the main project file (.ism file). InstallShield lets you export the string entries of a language to a text file, which you can send out for translation. After the strings have been translated, you can import the text files into the InstallShield project file.

The String Editor view in InstallShield enables you to manually export and import string entries for a particular language. To automate this process, you can use the InstallShield automation interface.

One of the functions of the automation interface is to provide you with a mechanism for exporting string entries from and importing string entries into a project. What follows is an example of how to achieve this.

Running the Sample VBScript File

To run this sample, you must first copy the sample code shown below into a file called `ImportExportStrings.vbs`. Then use the command line to export or import the string entries.

Exporting a Language's String Entries

To export string entries using the code sample, type the following at the command line.

```
wscript.exe ImportExportStrings.vbs "C:\MyProject.ism" "C:\1033.txt" "1033" "E"
```

Importing a Language's String Entries

To import string entries using the code sample, type the following at the command line.

```
wscript.exe ImportExportStrings.vbs "C:\MyProject.ism" "C:\1033.txt" "1033" "I"
```

Sample ImportExportStrings.vbs Code

```
'//////////////////////////////////////////////////////////////////////////
'BEGIN ImportExportStrings.vbs
'
'  This utility was designed to assist in the exporting and importing of string entries
'
'
'  File Name: ImportExportStrings.vbs
'
'  Description: Sample VBScript file exports or imports string entries in a text file
'
'  Usage:  To use the objects in this script, make sure you have the
'          following items in place on your system:
'          1. InstallShield must be installed so that
'             the end-user automation is available.
'          2. You must have Windows Scripting Host (Wscript.exe) installed.
'          3. The script expects the following command-line arguments,
'             in this order:
'             a. The fully qualified path to an existing .ism file.
'             b. The fully qualified path to a text file that contains the string entries
'             c. Decimal language identifier
'             d. Import or Export
'
'//////////////////////////////////////////////////////////////////////////

If Wscript.Arguments.Count < 1 Then
    Wscript.Echo "InstallShield Subfolder Utility" & _
        vbNewLine & "1st argument is the full path to the .ism file" & _
        vbNewLine & "2nd argument is the full path to the string text file" & _
        vbNewLine & "3rd argument is the decimal language identifier" & _
        vbNewLine & "4th argument is either E or I for Export or Import"
    Wscript.Quit 1
End If

' Create the end-user automation object
Dim ISWIProject
Set ISWIProject = CreateObject("IswiAuto20.ISWiProject"): CheckError

' Open the project specified at the command line
ISWIProject.OpenProject Wscript.Arguments(0): CheckError

if(Wscript.Arguments(3)="E")then
    StringsExport ISWIProject,Wscript.Arguments(1),Wscript.Arguments(2)
elseif(Wscript.Arguments(3)="I")then
    StringsImport ISWIProject,Wscript.Arguments(1),Wscript.Arguments(2)
end if

' Save and close the project
ISWIProject.SaveProject: CheckError
```

```
ISWIProject.CloseProject: CheckError

'////////////////////////////////////////////////////////////////////////
' Export the language's string entries
Sub StringsExport(byref p,byval path, byval language)
    p.ExportStrings path, Date , language
    Wscript.Echo "Exported String entries for language " & language & " to " & path
End Sub

'////////////////////////////////////////////////////////////////////////
' Import the string entries
Sub StringsImport(byref p,byval path, byval language)
    p.ImportStrings path, language
    Wscript.Echo "Imported string entries for language " & language & " from " & path
End Sub

'////////////////////////////////////////////////////////////////////////
Sub CheckError()
    Dim message, errRec
    If Err = 0 Then Exit Sub
    message = Err.Source & " " & Hex(Err) & ": " & Err.Description
    Wscript.Echo message
    Wscript.Quit 2
End Sub

'END ImportExportStrings.vbs
```

Running Project Reports Using the Automation Interface

This VBScript example below accesses objects in a setup project to display a report of the total number of features, components, files, and various types of files. The output is displayed in a message box, but you could also write this information to a text file.

Requirements

The following requirements should be met:

- You must have Windows Scripting Host to run a .vbs file. (It would be very simple to modify this script to run in a Visual Basic program.)
- InstallShield must be installed on the system before you can use the automation interface.
- Before running the script, assign the fully qualified path of an existing setup project (.ism file) to the string variable sProj.

Example Script

```
Option Explicit

' Create automation object
Dim pProj
```

```
Set pProj = CreateObject("IswiAuto20.ISWiProject")

' Open a setup project--make sure it is not already open in the IDE
Dim sProj
sProj = "C:\MySetups\TestProject.ism"
pProj.OpenProject sProj

' Start building string that lists features, components, and files
Dim sItems
sItems = "Project Report" & vbNewLine
sItems = sItems & "For project: " & sProj & vbNewLine
sItems = sItems & "Number of features: " & pProj.ISWiFeatures.Count & vbNewLine
sItems = sItems & "Number of components: " & pProj.ISWiComponents.Count & vbNewLine

' Declare and initialize counters for files and file types
Dim i, nEXE, nDLL, nOCX
i = 0
nEXE = 0: nDLL = 0: nOCX = 0

' Loop through components to get the number of files and individual file names
Dim sFileName
Dim pComp, pFile
For Each pComp In pProj.ISWiComponents
  For Each pFile In pComp.ISWiFiles
    i = i + 1
    sFileName = pFile.DisplayName
    If Instr (1, sFileName, ".exe", vbTextCompare) > 0 Then
      nEXE = nEXE + 1
    ElseIf Instr (1, sFileName, ".dll", vbTextCompare) > 0 Then
      nDLL = nDLL + 1
    ElseIf Instr (1, sFileName, ".ocx", vbTextCompare) > 0 Then
      nOCX = nOCX + 1
    End If
  Next
Next

sItems = sItems & "Number of files: " & i & vbNewLine
sItems = sItems & vbTab & "EXEs: " & nEXE & vbNewLine
sItems = sItems & vbTab & "DLLs: " & nDLL & vbNewLine
sItems = sItems & vbTab & "OCXs: " & nOCX & vbNewLine

' Display report
Wscript.Echo sItems

' Close project
pProj.CloseProject
```

Using Source Code Control at the Command Line

Access to installation projects stored in a source control system can be achieved through a combination of command-line calls to your source control application and limited use of the InstallShield Automation Interface—which gives you command-line-type access to much of InstallShield's functionality. Checking in, checking out, and getting the latest version of the project is handled through your source control's command-line support, if any.

Below are two examples of how you might use this functionality. Both examples use Microsoft Visual SourceSafe as the source control application and are written using VBScript.

You can copy and paste either example into a .vbs file, change the paths so that they are valid for your environment, and run them.

Note • *With earlier versions of InstallShield products, you were required to convert the source control (.isv) files to InstallShield project (.ism) files, and then back to .isv files. However, with the latest versions of InstallShield products, this is no longer necessary because you can save .ism files as text files for your source control application.*

Getting the Latest Version and Building Your Installation

```
    Const VSSFLAG_USERRONO   = 1
    Const VSSFLAG_TIMEMOD    = 8
    Const VSSFLAG_REPREPLACE = 128

    Const PROJECT_SCC_INI_LOC = "\\Server\srcsafe.ini"
    Const PROJECT_SCC_FOLDER = "$/MyFiles/"
    Const PROJECT_SCC_BASE_NAME = "MyProject"
    Const PROJECT_SCC_LOCAL_FOLDER = "C:\Project"

    ' Create a ref to Microsoft Visual SourceSafe
    Set VSS = CreateObject("SourceSafe")
    ' Point to the VSS database
    VSS.open PROJECT_SCC_INI_LOC

    ' Get the project file
    Set VSSISVFile = VSS.VSSItem (PROJECT_SCC_FOLDER + PROJECT_SCC_BASE_NAME + ".ism")
    VSSISVFile.Get PROJECT_SCC_LOCAL_FOLDER + PROJECT_SCC_BASE_NAME + ".ism", SSFLAG_TIMEMOD +
VSSFLAG_USERRONO + VSSFLAG_REPREPLACE

    'Get all remaining files
    Set VSSIDTFolder = VSS.VSSItem (PROJECT_SCC_FOLDER + PROJECT_SCC_BASE_NAME)
    VSSIDTFolder.LocalSpec = PROJECT_SCC_LOCAL_FOLDER + PROJECT_SCC_BASE_NAME
    For Each VSSObj In VSSIDTFolder.Items(False)
        VSSObj.Get , VSSFLAG_TIMEMOD + VSSFLAG_USERRONO + VSSFLAG_REPREPLACE
    Next

    strFileBasePath = PROJECT_SCC_LOCAL_FOLDER + PROJECT_SCC_BASE_NAME + ".ism"
    strCmdLine = "ISCmdBld.exe -p """ + strFileBasePath + ".ism"""
    ' Build your installation
```

```
    Set wshshell = CreateObject("Wscript.Shell")
    RunCmdLine = wshshell.Run(strCmdLine, 1, True)
```

Checking Out, Making Changes, and Checking In

```
    Const VSSFLAG_USERRONO = 1
    Const VSSITEM_FILE     = 1

    Const PROJECT_SCC_INI_LOC = "\\Server\srcsafe.ini"
    Const PROJECT_SCC_FOLDER = "$/MyFiles/"
    Const PROJECT_SCC_BASE_NAME = "MyProject"
    Const PROJECT_SCC_LOCAL_FOLDER = "C:\Project"

    ' Create a ref to Microsoft Visual SourceSafe
    Set VSS = CreateObject("SourceSafe")
    ' Point to the VSS database
    VSS.open PROJECT_SCC_INI_LOC

    ' Check out the project file
    Set VSSISVFile = VSS.VSSItem (PROJECT_SCC_FOLDER + PROJECT_SCC_BASE_NAME + ".ism")
    VSSISVFile.CheckOut , PROJECT_SCC_LOCAL_FOLDER + PROJECT_SCC_BASE_NAME + ".ism",
VSSFLAG_USERRONO

    'Check out all remaining files
    Set VSSIDTFolder = VSS.VSSItem (PROJECT_SCC_FOLDER + PROJECT_SCC_BASE_NAME)
    VSSIDTFolder.LocalSpec = PROJECT_SCC_LOCAL_FOLDER + PROJECT_SCC_BASE_NAME
    For Each VSSObj In VSSIDTFolder.Items(False)
        If VSSObj.Type = VSSITEM_FILE Then
            VSSObj.CheckOut , , VSSFLAG_USERRONO
        End If
    Next

    ' Create a reference to the InstallShield Automation Interface
    Set m_ISWiProject = CreateObject("IswiAuto20.ISWiProject")
    strFileBasePath = PROJECT_SCC_LOCAL_FOLDER + PROJECT_SCC_BASE_NAME + ".ism"
    ' Open your project
    m_ISWiProject.OpenProject strFileBasePath
    ' Add a feature
    m_ISWiProject.AddFeature "Robofeature1"
    ' Save the project
    m_ISWiProject.SaveProject
    ' Close the project
    m_ISWiProject.CloseProject

    ' Check in the project file
    Set VSSISVFile = VSS.VSSItem (PROJECT_SCC_FOLDER + PROJECT_SCC_BASE_NAME + ".ism")
    VSSISVFile.CheckIn

    'Check in all remaining files
    Set VSSIDTFolder = VSS.VSSItem (PROJECT_SCC_FOLDER + PROJECT_SCC_BASE_NAME)
    For Each VSSObj In VSSIDTFolder.Items(False)
        If VSSObj.Type = VSSITEM_FILE Then
            VSSObj.CheckIn "Check In Comment"
        End If
    Next
```

Using Build Status Events

The automation interface includes build status events—ProgressIncrement, ProgressMax, and StatusMessage—that you can use to show the progress of the build and see status updates. The following Visual Basic 6 code demonstrates how to use these events in a build script.

```
Public WithEvents pISWiRelease As ISWiAuto20.ISWiRelease

Private Sub Foo()
    Dim pISWiProject As IswiAuto20.ISWiProject
    Set pISWiProject = CreateObject("IswiAuto20.ISWiProject")
    pISWiProject.OpenProject "C:\InstallShield 2013 Projects\My Project Name-1.ism", False
    Set pISWiRelease = pISWiProject20.ISWiProductConfigs("Product Configuration
1").ISWiReleases("Release 1")
    pISWiRelease.Build
    pISWiProject.CloseProject
    Set pISWiRelease = Nothing
    Set pISWiProject = Nothing
End Sub

Private Sub pISWiRelease_ProgressIncrement(ByVal lIncrement As Long, pbCancel As Boolean)
    ' Place your code here
End Sub

Private Sub pISWiRelease_ProgressMax(ByVal lMax As Long, pbCancel As Boolean)
    ' Place your code here
End Sub

Private Sub pISWiRelease_StatusMessage(ByVal sMessage As String, pbCancel As Boolean)
    ' Place your code here
End Sub
```

Using the Automation Interface on a 64-Bit System

The automation interface is a 32-bit interface; therefore, it must be loaded from a 32-bit process. If you are using the automation interface on a 64-bit machine, you may need to load the automation interface through a 32-bit executable file.

For example, if you are using VBScript with the automation interface, you may need to launch `cscript.exe` from the 32-bit system folder (SysWow64). Otherwise, the 64-bit scripting host may encounter an error such as the following one when creating the automation object:

```
Microsoft VBScript runtime error: ActiveX component can't create object: 'ISWiAuto20.ISWiProject'
```

12

Reference

Reference information for InstallShield is organized into the following sections:

Table 12-1 • Reference Selections

Section	Description
Menu, Toolbar, and Window Reference	Describes the various components of the InstallShield user interface, including menus, toolbars, and windows.
Dialog Box Reference	Contains reference information on each of the dialog boxes that are displayed in InstallShield.
Wizard Reference	Provides details about each of the wizards that are available in InstallShield.
View Reference	Describes each of the views that are displayed in InstallShield.
InstallShield Prerequisite Editor Reference	Introduces you to the InstallShield Prerequisite Editor, which is available with InstallShield. Use this tool to create InstallShield prerequisites that you can include in your projects, or to edit existing ones.
Errors and Warnings	Provides information about error codes and warnings that might occur when you create, compile, build, or run your installation. This section also includes reference information about errors and warnings that may occur when you migrate a project from an earlier version of an InstallShield product to the latest version.
Automation Interface	Contains reference material that describes the objects, methods, properties, and collections used to modify an installation project through the automation interface.
InstallShield Custom Action Reference	Explains each of the custom actions that are available in InstallShield.

Table 12-1 • Reference Selections (cont.)

Section	Description
Command-Line Tools	Introduces tools that you can use from the command line to perform tasks such as building a release and running an installation.
InstallScript Language Reference	Provides in-depth information about functions, data types, event handlers, operators, and other aspects of InstallScript, a simple but powerful programming language that you can use to design your installations. This section also contains sample code that you can use in your script file.

Menu, Toolbar, and Window Reference

This section describes the various components of the InstallShield user interface, including menus, toolbars, and windows.

Menus

The menus in InstallShield are located on the menu bar, which is at the top of the InstallShield user interface. Each menu contains a list of commands. Some of these commands have icons next to them so that you can quickly associate the command with the icon.

Each of the menus in InstallShield is described in this section:

- File
- Edit
- View
- Go
- Project
- Build
- Tools
- Window
- Help

File Menu

The following table lists the File menu commands, as well as associated keyboard shortcuts and icons.

Table 12-1 • File Menu Commands

Command	Shortcut	Icon	Description
New	Ctrl+N		Creates a new installation project.
Open	Ctrl+O		Opens an existing installation project.

Table 12-1 • File Menu Commands (cont.)

Command	Shortcut	Icon	Description
Application Manager			This command is available in the version of InstallShield that is included with AdminStudio. Provides several commands: • **Open**—Displays the Open Application Manager Package dialog box, which lets you select the package in the AdminStudio Application Catalog that you want to open. • **Check Out**—Lets you check out from the AdminStudio software repository the package that is open in InstallShield. • **Check In As**—Lets you check in to the AdminStudio software repository the package that is open in InstallShield. This command offers two different options: **New Package Version** (a new build is treated as a new package in the software repository) and **Overwrite Existing Version** (a new build overwrites the existing version in the software repository). • **Get Latest Version**—Obtains the latest version of the package from the AdminStudio software repository. • **Undo Check Out**—Cancels the check-out request for the package. • **Add**—Lets you add the package that is open in direct edit mode to the AdminStudio Application Catalog. • **Conflicts**—Launches the Conflict Wizard. • **Refresh**—Refreshes the status of the package. These commands are also available from within Application Manager.
Close			Closes the current project.
Save	Ctrl+S		Saves the current project.
Save As			Enables you to save the current project file with a new name and location.
Print	Ctrl+P		Prints the script file that is displayed in the active script window.
1, 2, 3, 4			Opens one of the most recently accessed projects.
Exit			Closes the current project and closes InstallShield.

Edit Menu

The following table lists the Edit menu commands, as well as associated keyboard shortcuts and icons.

Table 12-2 • Edit Menu Commands

Command	Shortcut	Icon	Description
Undo	Ctrl+Z		Undoes the last action performed.
Redo	Ctrl+Y		Reverses the last action that was performed with the Undo command.
Cut	Ctrl+X		Removes the currently selected text and places it on the Clipboard.
Copy	Ctrl+C		Copies the currently selected text to the Clipboard.
Paste	Ctrl+V		Inserts the contents of the Clipboard at the insertion point, and replaces any selected text.
Find	Ctrl+F		Searches for the specified text, file, or folder.
Replace	Ctrl+H		Searches for and replaces the specified text.
Find Next	F3		Searches for the next occurrence of the specified text.
Go To	Ctrl+G		Moves the insertion point to the specified line number in the active script window.
Find String ID in Project			Searches the entire installation project for occurrences of a specified string entry.
Repeat			Opens the Set Repeat Count dialog box, where you can specify the total number of times that the next character you type should be inserted.
Insert			Provides two commands: • **InstallScript Function**— Opens the Function Wizard, which automates the process of adding a function call to the active script displayed in the InstallScript view. • **String Entry**— Opens the Select String Dialog Box, which lets you select a string entry that you want to add to the active script displayed in the InstallScript view.

View Menu

The following table lists the View menu commands, as well as associated keyboard shortcuts and icons.

Table 12-3 • View Menu Commands

Command	Shortcut	Icon	Description
Output Window			Shows or hides the Output window.
View List	F4		Shows or hides the View List.
View Bar			Shows or hides the View Bar.
Header Bar			Shows or hides the header bar, which has the tabs for the Start Page, the Project Assistant, and the Installation Designer.
Standard			Shows or hides the Standard toolbar.
MSI Debugger			Shows or hides the MSI Debugger toolbar.
Layout			Shows or hides the Layout toolbar.
Controls			Shows or hides the Controls toolbar.
Status Bar			Shows or hides the status bar.
Watch			Shows or hides the Watch window in the InstallScript Debugger.
Variable			Shows or hides the Variable window in the InstallScript Debugger.
Maximize	Ctrl+M		Changes the width of the script or dialog editor window that is currently open.
Project Assistant			Displays the Project Assistant.
Microsoft App-V			Displays the Microsoft App-V tab.
VMware ThinApp			Displays the VMware ThinApp tab.

Go Menu

The following table lists the Go menu commands, as well as associated keyboard shortcuts and icons. Some of the view-related commands are not available from the Go menu, depending on which project type you have open in InstallShield.

Table 12-4 • Go Menu Commands

Command	Shortcut	Icon	Description
Previous View	ALT+UP ARROW		Takes you to the view directly above the current view as shown in the View List.
Next View	ALT+DOWN ARROW		Takes you to the view directly below the current view as shown in the View List.
Back	ALT+LEFT ARROW		Takes you to the view that you last visited in the history of your view selections. You can use this multiple times, as long as there are multiple entries in your view history.
Forward	ALT+RIGHT ARROW		Takes you to the next view in the history of your view selections. You can continue until you reach the view you were at when you first clicked Back.
Start Page			Takes you to the Start Page.
Help			Takes you to the Help view.
Project Assistant			Displays the Project Assistant.
Microsoft App-V			Displays the Microsoft App-V tab.
VMware ThinApp			Displays the VMware ThinApp tab.
Installation Information			Enables you to open the General Information view. In Basic MSI and InstallScript MSI projects, this menu also enables you to open the Update Notifications view.
Organization			Enables you to display the Setup Design, Features, Components, and Setup Types.
Application Data			Enables you to display the Files and Folders, Redistributables (or Objects in InstallScript projects), and Prerequisites views.

Table 12-4 • Go Menu Commands (cont.)

Command	Shortcut	Icon	Description
System Configuration			Enables you to display the Shortcuts, Registry, ODBC Resources, INI File Changes, Environment Variables, XML File Changes, and Text File Changes views.
Server Configuration			Enables you to display the Internet Information Services, Component Services, and SQL Scripts views.
Behavior and Logic			Enables you to display the InstallScript, Custom Actions and Sequences (or Custom Actions), Support Files (or Support Files/Billboards in InstallScript and InstallScript MSI projects), System Search, and Property Manager views.
User Interface			Enables you to display the Dialogs, Billboards, and String Editor views.
Media			Enables you to display the Path Variables, Upgrades, Releases, and Patch Design views.
Additional Tools			Enables you to display the Dependency Scanners, MSI Debugger, and Direct Editor views.
Patch Settings			Enables you to display the General Information, Files, Registry, and Patch Variables views.

Project Menu

The following table lists the Project menu commands, as well as associated icons.

Table 12-5 • Project Menu Commands

Command	Icon	Description
Export Components Wizard		Opens the Export Components Wizard, which simplifies the process of exporting a component from a file to a new or existing project.
Device Driver Wizard		Opens the Device Driver Wizard, which guides you through the process of adding a device driver to your installation.
Reg-Free COM Wizard		Opens the Reg-Free COM Wizard, which guides you through the process of adding a COM manifest file to your project or configuring an existing manifest file.

Table 12-5 • Project Menu Commands (cont.)

Command	Icon	Description
Perform Static Scan		Opens the Static Scanning Wizard, which scans the files already added to your project for any dependencies that they require.
Perform Dynamic Scan		Opens the Dynamic Scanning Wizard, which monitors a running executable for all .dll and .ocx dependencies files and automatically adds them to your project.
Convert Source Paths		Opens the Convert Source Paths Wizard, which lets you convert existing hard-coded paths with path variables, thereby enhancing the portability of your installation project.
Project Converters		Provides several commands: • **Convert to InstallScript MSI Project**—Converts your Basic MSI project to an InstallScript MSI project. For more information, see Converting a Basic MSI Project to an InstallScript MSI Project. • **Convert to InstallScript Project**—Opens the Convert InstallScript MSI Dialog Box to help you convert your InstallScript MSI project to an InstallScript project.

Table 12-5 • Project Menu Commands (cont.)

Command	Icon	Description
Source Control		Provides several commands: • **Get Latest Version**— Copies the most recent version of the current project into your project folder. The project placed in your project folder is read-only. • **Check Out**— Places a writable copy of the project into your project folder, enabling you to modify it. • **Check In**— Stores your changes to the current project in your source control application. • **Undo Check Out**— Undoes your checkout, canceling your changes both in the source control application and in your project folder. Your project reverts to the way it was before you checked it out. • **Add to Source Control**— Adds the current project to your source control application. • **Unlink from Source Control**— Breaks the link between the current project and your source control application. • **Show History**— Displays a record of changes to your project since it was initially added to your source control application. While viewing the history, you can return to any point in your project's history and recover the file as it existed at that point. • **Show Differences**— Compares two files, then shows you the differences, if any. • **Refresh Status**— Refreshes the source control status. • **Launch Source Control Program**— Opens your source code control application.
Settings		Opens the Project Settings Dialog Box.

Build Menu

The following table lists the Build menu commands, as well as associated keyboard shortcuts and icons.

Table 12-6 • Build Menu Commands

Command	Shortcut	Icon	Description
Release Wizard			Opens the Release Wizard, which lets you specify the settings for a release and build it.
Compile	Ctrl+F7		Compiles your script file.

Table 12-6 • Build Menu Commands (cont.)

Command	Shortcut	Icon	Description
Build	F7		Builds your release with default settings, or—if you have already built your release—rebuilds your release with your most recently saved settings.
Build Tables Only	SHIFT+F7		Rebuilds only the .msi file tables of your installation to enable you to see your changes take effect more quickly than with a complete rebuild.
Build Tables & Refresh Files	ALT+F7		Rebuilds only the .msi file tables and updates only the modified files of your installation. This type of build works only when the media is an uncompressed network image. This command is available for Windows Installer–based projects only.
Refresh Build	ALT+F7		Rebuilds the active media. This command regenerates only those items that you changed since the media was last built. This command is available for InstallScript projects only.
Batch Build			Lets you rebuild multiple releases with different configurations simultaneously.
Stop Build	Ctrl+Break		Cancels the current build process.
Test	Ctrl+T		Enables you to run through the user interface portion of your installation without making any changes to your system. All custom actions are executed.
Debug	F5		Starts debugging.
Run	Ctrl+F5		Enables you to run your completed installation without leaving InstallShield.
Uninstall			Uninstalls the most recently run release.  ***Project*** • *This command is available for the following project types:* • *Basic MSI* • *InstallScript MSI*
Run Package			Enables you to run the installation package. This command is available only for InstallScript projects with the Network Image media type and with all files compressed into an .exe file.

Table 12-6 • Build Menu Commands (cont.)

Command	Shortcut	Icon	Description
Debug Package			Enables you to debug the installation package. This command is available only for InstallScript projects with the Network Image media type and with all files compressed into an .exe file.
Run from Web			Displays the One-Click Install Web page, which lets you run your completed installation without leaving InstallShield.
MSI Debugger			Provides several commands: • **Start MSI Debugging**— Starts debugging in the MSI Debugger view. • **Toggle Breakpoint**—F9 or —Sets or removes the breakpoint in the line that has the insertion point. • **Remove All Breakpoints**—SHIFT+F9 or —Removes all breakpoints set in the debugger. • **Step Over**—F10 or —Steps through the current action or dialog and continues the execution in the debugger. • **Step Into**—F11 or —Steps into the current custom action in the debugger. • **Stop MSI Debugging**—SHIFT+F5 or —Stops debugging in the MSI Debugger view.

Table 12-6 • Build Menu Commands (cont.)

Command	Shortcut	Icon	Description
Validate			Provides several commands: • **Upgrade Validation Wizard**—Opens the Upgrade Validation Wizard, which performs a set of tests to determine if your Basic MSI or InstallScript MSI installation will properly upgrade earlier versions of your product. • **Browse for a New Validation Module (.cub)**—Lets you browse to select a new or custom validation (.cub) file. • **InstallShield Validation Suite for Windows 7**—This suite consists of a number of InstallShield internal consistency evaluators (ISICEs) that help you identify issues that may make your installation behave unexpectedly on Windows 7 systems. This suite checks for issues that may not be revealed in the Full MSI Validation Suite. • **InstallShield Merge Module Validation Suite for Windows 7**—This suite consists of a number of InstallShield internal consistency evaluators (ISICEs) that help you identify issues that may make your merge module behave unexpectedly on Windows 7 systems. This suite checks for issues that may not be revealed in the Merge Module Validation Suite. • **InstallShield Certified for Windows Vista Validation Suite**—This suite consists of a number of InstallShield internal consistency evaluators (ISICEs) that help you identify issues that may make your installation behave unexpectedly on Windows Vista systems. This suite checks for issues that may not be revealed in the Full MSI Validation Suite. • **InstallShield Certified for Windows Vista Merge Module Validation Suite**—This suite consists of a number of InstallShield internal consistency evaluators (ISICEs) that help you identify issues that may make your merge module behave unexpectedly on Windows Vista systems. This suite checks for issues that may not be revealed in the Merge Module Validation Suite.

Table 12-6 • Build Menu Commands (cont.)

Command	Shortcut	Icon	Description
Validate (cont.)			• **InstallShield Best Practice Suite**— Scans your Basic MSI or InstallScript MSI installation to determine whether it meets best-practice guidelines.  ***Edition*** • *The InstallShield Best Practice Suite is available in the Premier edition of InstallShield.* • **Full MSI Validation Suite**— Scans your Basic MSI or InstallScript MSI installation to determine whether it is valid. Your built .msi package is compared against the ICE rules. • **Windows 2000 Logo Validation Suite**— Scans your Basic MSI or InstallScript MSI installation to determine whether it meets the Designed for Windows 2000 logo requirements. • **Windows XP Logo Validation Suite**— Scans your Basic MSI or InstallScript MSI installation to determine whether it meets the Designed for Windows XP logo requirements. • **Windows Vista Logo Validation Suite**— Scans your Basic MSI or InstallScript MSI installation to determine whether it meets the Certified for Windows Vista logo requirements. • **Merge Module Validation Suite**— Scans your merge module package. The Merge Module Validation tool is the merge module version of the Full MSI Validation Suite. Your built merge module is compared against ICE rules to help you determine whether it will function properly. • **Recent Validation Modules**—Displays a list of recently used validation (.cub) files. To learn more, see Validating Projects.
Settings	ALT+F6		Opens the Settings dialog box, which enables you to set preferences for how InstallShield builds your installation.

Tools Menu

The following table lists the Tools menu commands, as well as associated icons.

Table 12-7 • Tools Menu Commands

Command	Icon	Description
Open Release Folder		Launches Windows Explorer, open in the DISK1 folder of the current release. If there is no release or if a release has not been built, Windows Explorer opens to your default project location.
Add New Language		Opens the New Language Wizard, which enables you to add support for almost any language to one or more projects.
Create/Apply Transform		Opens the Transform Wizard, which walks you through the steps of creating and applying transforms for your installation projects.
MSI Command-Line Builder		Launches the InstallShield MSI Command-Line Builder. This tool enables you to quickly build complex command-line strings for executing Windows Installer–related tasks.
Difference		Provides several commands: • **Compare to File**—Opens a dialog box that lets you specify which project should be compared with the currently open project. • **End Compare**—Ends the previously started compare session. • **InstallShield MSI Diff**—Opens InstallShield MSI Diff, a tool that enables you to compare Windows Installer tables in two different Windows Installer databases. It also enables you to apply transforms and patches to Windows Installer packages and then see how the database tables are affected. To learn more, see InstallShield MSI Diff.

Table 12-7 • Tools Menu Commands (cont.)

Command	Icon	Description
InstallScript		Provides several commands: • **Standard Dialog Sampler**— Opens the Standard Dialog Sampler, which enables you to view examples of end-user dialogs. The sample dialogs are displayed without a skin. • **Skinned Dialog Sampler**— Opens the Skinned Dialog Sampler, which enables you to view examples of end-user dialogs. The sample dialogs are displayed with the skin that is selected in the Dialogs view. • **Cabinet File Viewer**— Opens the Cabinet File Viewer, a tool that lets you select a cabinet (.cab) file and view its compressed files, file groups, components, and setup types, as well as the properties of those items. It also lets you extract files from the cabinet file. • **Log File Viewer**— Opens the Log File Viewer, a tool that enables you to view the installation log file. The log file is created when your installation is first run and it is maintained when your installation is running in maintenance mode. You can use the log file to determine the current state of each component in the installation.
Check for Updates		Checks for service packs and other updates to InstallShield. If updates are available, you can select which ones you would like to download and install.
Redistributable Downloader		Launches the Redistributable Downloader Wizard to quickly download third-party redistributables, merge modules, and other files to your local machine.
Prerequisite Editor		Opens the InstallShield Prerequisite Editor, which enables you to create or modify InstallShield prerequisites that you can include in your installation project.
Customize		Displays the Customize dialog box, which enables you to customize the toolbars displayed in the InstallShield user interface.
Options		Displays the Options dialog box, which enables you to specify preferences for creating projects and working in InstallShield.

Window Menu

The following table lists the Window menu commands, as well as associated keyboard shortcuts and icons.

Table 12-8 • Window Menu Commands

Command	Shortcut	Icon	Description
Next	Ctrl+Tab		Opens the InstallScript view and displays the next script file in your project as shown at the bottom of the Window menu.
Previous	Ctrl+Shift+Tab		Opens the InstallScript view and displays the next script file in your project as shown at the bottom of the Window menu.
1, 2, 3			Opens the InstallScript view and displays one of the script files included your project.

Help Menu

The following table lists the Help menu commands, as well as associated icons.

Table 12-9 • Help Menu Commands

Command	Icon	Description
Contents		Displays the Contents tab of the online help library.
Index		Displays the Index tab of the online help library.
Search		Displays the Search tab of the online help library.
Support Central		Displays Support Central on the Web.
InstallShield Community		Displays the Community on the Web.
Release Notes		Displays InstallShield release notes.
Flexera Software on the Web		Connects to the Flexera Software Web site.
Help View		Displays the Help view.
About InstallShield		Displays the About InstallShield dialog box, where you can find version information and register InstallShield.

Toolbars

The InstallShield user interface offers several toolbars that give you quick access to frequently used menu items and provide graphical tools for use in the Dialog Editor.

Built-in Toolbars

The following toolbars are available in the InstallShield interface. When you open InstallShield, only the Standard toolbar is displayed near the top of the user interface. The Control and Dialog Layout toolbars open when you work in the Dialogs view and disappear when you leave that view.

All toolbars can be resized and repositioned, and docked and undocked.

- Standard Toolbar
- Controls Toolbar
- Layout Toolbar
- MSI Debugger Toolbar

Standard Toolbar

Below is a description of all the buttons on the Standard toolbar.

Table 12-10 • Standard Toolbar Buttons

Button	Name	Description
	New Project	Launches the New Project dialog box, which enables you to select a project type and begin a new project.
	Open	Enables you to open project files or convert installation package (.msi) files to an InstallShield installation project (.ism) file.
	Save	Saves changes to the project file.
	Undo	Click the Undo button in the Dialog Editor or the Script Editor to reverse the last change you made.
	Redo	Click the Redo button in the Dialog Editor or the Script Editor to restore the last action you reversed by clicking the Undo button.
	Viewbar	Hides or shows the viewbar, which appears on the left side of the interface.

Table 12-10 • Standard Toolbar Buttons (cont.)

Button	Name	Description
	View List	Hides or shows the View List, which shows all the views available in the InstallShield interface.  ***Note*** • *You can also press F4 to hide or show the View List.*
	Previous View	Displays the view directly above the current view, as shown in the View List.
	Next View	Displays the view directly below the current view, as shown in the View List.
	Back	Displays the view that you last visited in the history of your view selections. You can click this button multiple times, if there are multiple entries in your view history.
	Forward	Displays the next view in the history of your view selections. You can continue clicking this button until you reach the view in which you first clicked the Back button.
	Insert InstallScript Function	Launches the Function Wizard, which eases the process of writing built-in InstallScript functions.
	Release Wizard	Launches the Release Wizard, which turns a project into either a shippable Windows Installer setup package or completed merge module. The options you select in the wizard determine the layout and contents of your release.
	Compile	Compiles the InstallScript files in your project without building the entire setup.
	Build	Builds your release with default settings, or—if you have already built your release—rebuilds your release with your most recently saved settings.
	Stop Build	Cancels the current build process.
	Test User Interface	Runs through the user interface portion of your installation project without making any changes to your system. All custom actions are executed.  ***Project*** • *The Test button is available for the following project types:* • Basic MSI • InstallScript MSI

Table 12-10 • Standard Toolbar Buttons (cont.)

Button	Name	Description
	Run	Runs your completed installation project. ***Project*** *• For Basic MSI and InstallScript MSI projects—If you selected the* ***Uninstall the product automatically before installing or debugging*** *check box, InstallShield uninstalls your product before rerunning the installation or before starting the debugger. This check box is available on the Preferences tab of the Options dialog box.*
	Uninstall	Uninstalls the most recently run release. ***Project*** *• This button is available for the following project types:* • *Basic MSI* • *InstallScript MSI*
	Debug	Runs the appropriate debugger, depending on the type of installation you are creating. If your project is InstallScript or InstallScript MSI, clicking Debug launches the InstallScript Debugger. If your project is Basic MSI or a Transform, clicking Debug launches the MSI Debugger. ***Project*** *• For Basic MSI and InstallScript MSI projects—If you selected the* ***Uninstall the product automatically before installing or debugging*** *check box, InstallShield uninstalls your product before rerunning the installation or before starting the debugger. This check box is available on the Preferences tab of the Options dialog box.*
	Open Release Folder	Launches Windows Explorer, open in the DISK1 folder of the current release. If there is no release or if a release has not been built, Windows Explorer opens to your default project location.
	Help View	Displays the IDE Help view where you can find answers to many of your questions regarding InstallShield.

Controls Toolbar

The Controls toolbar provides every standard control that is available in a run-time dialog. This toolbar is displayed when you edit a dialog's layout in the Dialog Editor.

Task: ***To draw a control on a dialog:***

Click the control's button, click anywhere on the face of the dialog, drag the mouse pointer while continuing to press the mouse button, and then release the button when you have reached the intended dimensions of the control.

Table 12-11 • Controls Toolbar Buttons

Button	Name	Description
	Select Tool	Lets you give focus to a control on a dialog. You can then move, resize, delete, or align the control.
	Check Box	Lets you draw a check box control on a dialog.
	Push Button	Lets you draw a push button control on a dialog.
	Edit Field	Lets you draw an edit field control on a dialog.
	Combo Box	Lets you draw a combo box control on a dialog.
	Text Area	Lets you draw a text area control on a dialog.
	List Box	Lets you draw a list box control on a dialog.
	Radio Button	Lets you draw a radio button control on a dialog. A radio button must be added to a radio button group control.
	Bitmap	Lets you draw a bitmap control on a dialog.
	Group Box	Lets you draw a group box control on a dialog.
	Billboard	Lets you draw a billboard control on a dialog.
	Line	Lets you draw a line control on a dialog.
	Radio Button Group	Lets you draw a radio button group control on a dialog.
	Selection Tree	Lets you draw a selection tree control on a dialog.

Table 12-11 • Controls Toolbar Buttons (cont.)

Button	Name	Description
	Progress Bar	Lets you draw a progress bar control on a dialog.
	List View	Lets you draw a list view control on a dialog.
	Scrollable Text	Lets you draw a scrollable text control on a dialog.
	Icon	Lets you draw an icon control on a dialog.
	Directory List	Lets you draw a directory list control on a dialog.
	Directory Combo	Lets you draw a directory combo control on a dialog.
	Volume Cost List	Lets you draw a volume cost list control on a dialog.
	Volume Select Combo	Lets you draw a volume select combo control on a dialog.
	Masked Edit	Lets you draw a masked edit control on a dialog.
	Path Edit	Lets you draw a path edit control on a dialog.
	Hyperlink	Lets you draw a hyperlink control. This control displays an HTML link to an address; when the end user clicks the link, the page opens in the default browser.

Layout Toolbar

The Layout toolbar provides several tools for aligning and resizing controls in a dialog. This toolbar is displayed when you edit a dialog's layout in the Dialog Editor.

Most buttons on this toolbar are enabled only when you have selected more than one control. To select multiple controls, select one, press the SHIFT key, and select the other; or hold the mouse button down and drag the cursor across several controls. The Layout toolbar contains the following buttons:

Table 12-12 • Layout Toolbar Buttons

Button	Name	Description
	Align Left	Select two or more controls and click the Align Left button to align all of the selected controls with the left edge of the leftmost control.

Table 12-12 • Layout Toolbar Buttons (cont.)

Button	Name	Description
	Align Right	Select two or more controls and click the Align Right button to align all of the selected controls with the right edge of the rightmost control.
	Align Top	Select two or more controls and click the Align Top button to align all of the selected controls with the top edge of the uppermost control.
	Align Bottom	Select two or more controls and click the Align Bottom button to align all of the selected controls with the bottom edge of the lowermost control.
	Center Vertical	Select a control and click the Center Vertical button to reposition the element in the vertical (x-axis) center of the dialog.
	Center Horizontal	Select a control and click the Center Horizontal button to reposition the element in the horizontal (y-axis) center of the dialog.
	Space Across	Select three or more controls on the dialog and click the Space Across button to have them evenly distributed horizontally across the dialog.
	Space Down	Select three or more controls on the dialog and click the Space Down button to have them evenly distributed vertically along the dialog.
	Make Same Width	Select two or more controls and click the Make Same Width button to resize the width of the smaller controls to the width of the largest control.
	Make Same Height	Select two or more controls and click the Make Same Height button to resize the height of the smaller controls to the height of the largest control.
	Make Same Size	Select two or more controls and click the Make Same Size button to make the smaller controls the exact size of the largest control.
	Bring to Front	Select a control and click the Bring to Front button to place it on top of any overlapping controls. See note below.
	Send to Back	Select a control and click the Send to Back button to place it behind any overlapping controls. See note below.
	Show Grid	Click the Show Grid button to place design-time grid lines on the dialog, or to remove the grid if it is present.

Note • *The Bring to Front and Send to Back actions are not saved when you close and reopen your project. These actions are for use during design only. For example, you might have a dialog that displays different controls based*

on a condition. You can use the Bring to Front and Send to Back actions to work on these different controls while you are designing your dialog.

MSI Debugger Toolbar

Below is a description of all the buttons in the MSI Debugger toolbar.

Table 12-13 • MSI Debugger Toolbar Buttons

Button	Name	Description
	Toggle Breakpoint	Click this button to set a breakpoint on an action or dialog.
	MSI Debugging	Click this button to start debugging or, while debugging, to continue stepping through the setup.
	Step Over	Click this button to step over the current action or dialog.
	Step Into	Click this button to step into the current action and launch your registered debugger.
	Remove All Breakpoints	Click this button to clear all breakpoints you have set in the MSI Debugger.
	Stop MSI Debugger	Click this button to stop debugging.

Output Window

When you build a release for your project, the Output window opens if it is not already open, and it displays build information. It also provides other task-specific information. For example, if you validate your project, InstallShield displays validation results in the Output window. If you open a project that was created with an earlier version of InstallShield, the Output window shows upgrade information.

The following tabs appear in the Output window:

Table 12-14 • Output Window Tabs

Tab	Description
Build	Stores distribution output information and displays build output; a link to the output file saved as a text file is included.
Validate	Displays validation results.
Results	Displays project conversion information or details about testing changes to XML files.
Compile	Displays InstallScript information when you click Compile on the Build menu.
Tasks	Provides descriptions of error and warning codes when you build, compile, or validate your project; each error or warning code is a link to a Knowledge Base article.  ***Tip*** • *You can right-click a code for an error or warning and select Direct Editor. The affected area associated with the error or warning will be highlighted in the Direct Editor.*

Dialog Box Reference

Each of the dialog boxes available in the user interface of InstallShield is described in this section:

- Create a New Feature Dialog Box
- Custom Error Handling Dialog Box
- Custom Errors Dialog Box
- Customize Validation Settings Dialog Box
- Data Languages Dialog Box
- Delete Property Dialog Box
- Dependencies Dialog Box
- Dialog Images Dialog Box
- Digitally Sign Setup Dialog Box
- Differences Dialog Box
- Dynamic File Link Settings Dialog Box
- Edit Data Dialog Box
- Edit Registry Data Dialog Box
- Error Mapping Properties Dialog Box
- Exclusion Languages Dialog Box
- Export Tables Dialog Box
- Feature Condition Builder Dialog Box
- File Details Dialog Box
- File Properties Dialog Box
- File Properties Dialog Box (InstallScript Installation Projects)
- Find and Replace Dialog Box
- Find String ID in Project Dialog Box
- Folder Properties Dialog Box
- Function Signature Dialog Box
- General Options - Advanced Dialog Box
- General Options - Other Disk Files Dialog Box
- History Dialog Box
- Import Dialog Dialog Box
- Import InstallScript Files Dialog Box
- Import SQL Script Files Dialog Box
- Insert Action Dialog Box

- Permissions Dialog Boxes for Files and Directories
- Permissions Dialog Boxes for Registry Keys
- Platform Suites Dialog Box
- Platforms Dialog Box
- Postbuild Event Dialog Box
- Prebuild Event Dialog Box
- Precompression Event Dialog Box
- Prerequisite Condition Dialog Box
- Privileges Dialog Box
- Product Condition Builder Dialog Box
- Project Settings Dialog Box
- Rename Key Dialog Box
- Required Features Dialog Box
- Resolve Conflict Dialog Box
- Save As Dialog Box
- Script Conversion Dialog Box
- Script Editor Properties Dialog Box
- SCM Pre-shutdown Delay Dialog Box
- Security Descriptor Dialog Box
- Select File Dialog Box
- Select Media Location Dialog Box
- Select String Dialog Box
- Serial Number Violation Dialog Box
- Server Locations Dialog Box
- Service Options Dialog Box for a Time Delay of an Auto-Start Service
- Service Options Dialog Box for Running Recovery Actions
- Service SID Dialog Box
- Set File(s) URL Dialog Box
- Settings Dialog Box
- Setup Languages Dialog Box
- SQL Server Requirement Dialog Box

.NET 1.1/2.0 Core Language Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Use the .NET 1.1/2.0 Core Language dialog box to select the .NET core language that you want to distribute. This is the language that is used while the .NET 1.1 core redistributable is installed.

If the 2.0 version of the .NET Framework is selected in the .NET Framework Version setting, the language options are all selected and disabled since they are all included with this version of the redistributable.

If you do not have a particular language installed on your system, the check box for that language is disabled in this dialog box.

Tip • *To download one or more language versions of the .NET Framework redistributables to your system, click the Download More Languages button; doing so launches the Redistributable Downloader Wizard, which enables you to download one or more redistributables to your system.*

.NET 1.1/2.0 Language Packs Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

Use the .NET 1.1/2.0 Language Packs dialog box to select the languages that correspond with the .NET language packs that you want to be installed on target systems. This dialog box opens when you click the ellipsis button (...) in the .NET 1.1/2.0 Language Packs setting on the .NET/J# tab for a release in the Releases view.

If you do not have a particular language pack installed on your system, the check box for that language is disabled in this dialog box.

Tip *• To download one or more language packs to your system, click the Download More Languages button; doing so launches the Redistributable Downloader Wizard, which enables you to download language packs to your system.*

.NET Installer Class Arguments Dialog Box

The .NET Installer Class Arguments dialog box displays the arguments that you want to pass to the .NET Installer class. To launch the dialog box, click the ellipsis button (...) for the .NET Installer Class Arguments component setting. Click the Add Argument button beneath the argument that you want to add to launch the Add an Argument/Value Pair dialog box.

There are four methods on the Installer class that are called at various points during the installation: Install, Commit, Uninstall, and Rollback. You use this dialog to specify additional argument lists for the Installer class for each of the execution contexts.

Note *• Install custom actions are run when the component containing the Installer class custom action is installed. Uninstall custom actions are run when the component containing the Installer class custom action is uninstalled. These two types are run in the Execute sequence, right after StartServices and before RegisterUser.*

Using Arguments

For all methods, */LogFile=* is the default argument. This results in no log being generated when these methods are run. You can complete this argument by using Windows Installer properties in [brackets]. To add arguments, type in the appropriate edit field or use the Add Argument button.

Syntax Rules

When you click **OK**, InstallShield validates what is in the edit fields and displays a warning if the syntax is incorrect. The syntax rules include the following:

- All quotes must be matched.
- Escape characters are valid. If you use \" in your argument, it is not counted it when checking the quote matching.
- Every space-separated argument token must consist of a name preceded by a slash and followed by an equal sign (=). A value to the right of the equal sign is optional.
- Spaces inside quotes do not count when determining what is and is not part of an argument token. For example, in the argument */arg=“hi there”*, *“hi there”* is all part of the argument token beginning with */arg*. In the argument */arg=hi there*, *there* is its own argument token and an invalid one.

Add an Argument/Value Pair Dialog Box

This dialog is displayed when you click one of the Add Argument buttons in the .NET Installer Class Arguments dialog box. When you are finished creating an argument, click OK to add the argument.

Dialog Options

Argument Name

Provide a name for the argument in the edit field.

Argument Value

Select one of the values from the option button list to create an argument. To create a custom argument, select the Custom option.

Property

Select a property from the menu to reference a property that exists in your installation project.

Directory

Use the drop-down menu to add a reference to a directory that exists in your installation project.

Custom

To create a custom argument, type an argument value in the edit field.

Add Existing Media Dialog Box

The Add Existing Media dialog box opens when you click the Add button in the Release Wizard's Update panel. This dialog box lets you select a release that is in the current project from a list of releases (excluding the current release).

Add Files for This Package Dialog Box

Project • *This information applies to the following project types:*

- *Advanced UI*
- *Suite/Advanced UI*

Edition • *The Advanced UI project type is available in the Professional edition of InstallShield. The Suite/Advanced UI project type is available in the Premier edition of InstallShield. For information about the differences between these two project types, see Advanced UI Projects vs. Suite/Advanced UI Projects.*

The Add Files for This Package dialog box opens when you add a package—for example, an .msi package or an .exe patch—in the Packages view of an Advanced UI or Suite/Advanced UI project.

This dialog box lets you specify whether the package file that you are adding requires other files and folders that are near the package that you are adding. For example, if you are adding an uncompressed .msi package to your project, you may need to include folders and other files that contain the files that the .msi package installs on target systems. These folders and other files are typically in the same folder that contains the .msi package.

The Add Files for This Package dialog box also lets you specify whether you want to use dynamic file linking for the additional files.

The options that are available on the Add Files for This Package dialog box are:

Table 12-1 • Add Files for This Package Dialog Box Settings

Setting	Description
Add Nothing	InstallShield includes only the package file in your project. If the package that you are adding to the project does not require any additional files, select this option. You may want to select this option if the package is compressed.
Add Adjacent Files	InstallShield includes the files that are in the same folder as the package file. InstallShield does not include any subfolders that are in the same folder as the package file, or any files that are in the subfolders.
Add Files in Subfolders	InstallShield includes the files that are in the subfolders of the folder that contains the package file that you are adding. InstallShield does not include any files that are in the same folder as the package file.
Add adjacent Files and Files in Subfolders	InstallShield includes the files that are in the same folder as the package file. InstallShield also includes the files that are in the subfolders of the folder that contains the package file that you are adding.

Table 12-1 • Add Files for This Package Dialog Box Settings (cont.)

Setting	Description
Add files dynamically found during build	To include the additional files as dynamic file links, select this check box. To include the additional files as static file links, clear this check box; by default, this check box is cleared. If the names of all of the additional files are known when you add the package to your project, you may want to use static file links for any additional files. If the additional files for your package may change over time, you may want to use dynamic file links for any additional files. ***Note*** • *InstallShield always includes a static link for the package file (.msi, .msp, InstallScript package, or .exe). Therefore, the name of the package file should be consistent from one build to another.* *Selecting this check box has no effect if you click the Add Nothing option.* For more information about static and dynamic file linking, see Static vs. Dynamic Files for Packages in an Advanced UI or Suite/Advanced UI Project.

Add MIME Type Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

Use the Add MIME Type dialog box to add or modify the mapping between a file extension and the program or interpreter that processes those files. This dialog box opens when you click Add or Edit on the MIME Types dialog box.

Table 12-2 • Add MIME Type Dialog Box Settings

Setting	Description
File Name Extension	Type the file name extension (for example, **.abc**). This is a static file name extension. To use a wild-card application mapping for an executable file, enter an asterisk (*).
MIME Type	Type the MIME type (for example, **application/octet-stream**).

Add New Method Dialog Box

Project • *This information applies to InstallScript Object projects.*

This dialog box lets you specify the name, return type, and parameter types of a new method and automatically paste corresponding code into your object script. This dialog box opens when you right-click the InstallScript view's Methods folder and select Add New Method.

Properties

Table 12-3 • Methods Properties

Property	Description
Name	Enter the name for your method.
Return Type	Select the data type that your method returns. You can choose from String, Number, and Boolean.
Parameter List	Enter the parameter types that can be passed to your method.

Add New Property Dialog Box

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The Add New Property dialog box lets you specify the name and attributes of a new property and automatically paste corresponding code into your script. This dialog box opens when you right-click the InstallScript view's Properties folder and then click Add New Property.

Table 12-4 • Add New Property Dialog Box Settings

Setting	Description
Property Name	This is the global name of this property. Therefore, when trying to read from or write to this property from script, you will need to use this name. The name you enter in this box will be appended to the local variable name property.
Data Type	Select String, Number, or Boolean, depending on the type of data that your property requires. The local variable name will change depending on the selection that you make.

Table 12-4 • Add New Property Dialog Box Settings

Setting	Description
Access Method	Select the appropriate level of access for the property. Available options are Read/Write, Read Only, and Write Only.
Array	If your property is an array, select this check box.  ***Note*** • *If you plan on using the InstallShield stock wizard for your object's design-time interface, you cannot use array properties. You can create a custom wizard that accepts array properties or you can redesign the property without using an array.*
Local Variable Name	You can accept the default name or create your own variable name. This variable name is used when calling your variable from within the script.
Default Value	Enter the starting value for your property. Be sure to match the value to the data type that you chose. When you are specifying a string value, type it exactly as you would in the script; enclose the string value in quotation marks and use the appropriate escape sequences for special characters (for example, enter a backslash as \\). Do not enter a string identifier or a system variable in an InstallScript Object project; the initialization of the property's value is performed when the object is added to a project, at which time string identifiers and system variables are not yet initialized.

Add Predefined Search Dialog Box

The Add Predefined Search dialog box opens when you right-click the grid in the System Search view and then click Add predefined search.

Select a predefined value from the list in this dialog box and then click OK to add the search to the grid in the System Search view.

If you want system searches that have been published to a repository to be displayed in this dialog box, select the Show Searches in Repository check box.

Add to Source Control Dialog Box

This dialog is displayed when you add a project to your source control program through InstallShield.

Dialog Options

Comments

Enter the comments describing the file. These comments are stored in your source control program.

Keep checked out

Select this option to add the .ism file (in text format), but keep it checked out in your working directory.

Convert to XML

This option causes the .ism file to use the XML representation, which is better suited for source control. If you add a project in Binary format to source control, this option is available and is selected by default. It is recommended that you leave this option selected.

Note • *When a project file format is converted to either XML or binary format, the project file extension remains *.ism.*

Application Extension Mapping Dialog Box

Use the Application Extension Mapping dialog box to add or modify the mapping between a file extension and the program or interpreter that processes those files. This dialog box is launched when you click Add on the Application Mappings dialog box.

Table 12-5 • Application Extension Mapping Dialog Box Settings

Setting	Description
Extension	Type the file name extension that is associated with your application (for example, *.abc*). To use a wild-card application mapping for an executable file, enter an asterisk (*).
Executable	Type the path, or click Browse to launch the Select Executable dialog box. This enables you to specify the executable in your project to which you want to map. Type the name of the executable file (.exe or .dll) or use the Browse button to search for the file. The executable file must be located on your Web server's local hard drive.
Verbs	The Verbs section enables you to specify which HTTP verbs should be passed to the application. • **All verbs**—Select this option to include all verbs. This option passes all requests to an application. • **Limit to**—Select this option to specify the HTTP verbs that should be passed to an application. Separate verbs with a comma.

Table 12-5 • Application Extension Mapping Dialog Box Settings (cont.)

Setting	Description
Script Engine (IIS 6 and earlier only)	If you want the application to run in a directory without Execute permissions, select this check box. This setting is intended primarily for script-based applications, such as ASP and IDC, that are mapped to an interpreter. For a script-mapped application to run, either the Scripts Only or Scripts and Executables option must be selected for the Execute Permissions property. To allow only script-mapped applications to run, select the Scripts Only option. To allow both script-mapped applications and executable files (.exe and .dll) to run, select Scripts and Executables. This setting applies to IIS 6 and earlier. IIS 7 ignores this setting.
Check that file exists (IIS 6 and earlier only)	To instruct the Web server to verify the existence of the requested script file and to specify that the requesting user should have access permission for that script file, select this check box. If the script does not exist or the end user does not have permission, the appropriate warning message is returned to the browser and the script engine is not invoked. This option can be useful for scripts mapped to non-CGI executable files like the Perl interpreter that do not send a CGI response if the script is not accessible.  ***Note*** • *Because the script is opened twice—once by the server and once by the script engine—there is some performance cost when this check box is selected.* This setting applies to IIS 6 and earlier. IIS 7 ignores this setting.

Application Mappings Dialog Box

The Application Mappings dialog box lets you add, edit, and delete a mapping between a file name extension and the application that processes those files.

The Application Mappings dialog box is available from within the Internet Information Services view. To open this dialog box, click a Web site, application, or virtual directory in the explorer. Then click the ellipsis button (...) in the Application Mappings setting.

Note • *If an asterisk (*) appears in the Verbs column, all verbs will be used for the specified extension.*

Table 12-6 • Application Mappings Dialog Box Settings

Setting	Description
Add	To add an entry for mapping a file name extension and the program or interpreter that processes those files, click this button. This opens the Application Extension Mapping dialog box.
Edit	To edit an existing application mapping, select the mapping and click this button.
Remove	To delete an existing application mapping, select the extension and click this button.

Associate Components Dialog Box

The Associate Components dialog box enables you to associate components with features in the Setup Design view. Select the component or components that you want to associate with the current feature and click OK.

Note • *Components that are not associated with a feature are displayed with the orphaned component icon.*

For more information on component-feature relationships, see Associating New Components with Features.

Associate DIMs Dialog Box

The Associate DIMs dialog box enables you to associate DIMs with features in the Setup Design view. Select the DIM or DIMs that you want to associate with the current feature and click OK.

Note • *DIMs that are not associated with a feature are displayed with the orphaned component icon.*

For more information on DIM-feature relationships, see Associating a DIM Reference with a Feature.

Batch Build Dialog Box

This dialog displays a tree control containing all the product configurations and releases you have defined in the current project. Select the releases that you want to include in your batch build.

Dialog Options

Tree Control

Select the releases that you would like to build by checking the appropriate boxes. Selecting a product configuration icon selects all the releases associated with that product configuration.

Select All

Click this button to select all the releases in the tree.

Unselect All

Click this button to deselect all the releases in the tree.

Build

Click this button to build all the selected releases.

Browse for Directory Dialog Box

Use the Browse for Directory dialog box to browse to a directory, create a new directory, rename a directory, or delete a directory.

Dialog Box Options

Destination Directories

This field lists all of the currently available destination directories. You can select, create, rename, or delete directories in this field.

Selecting a Directory

Task: ***To select a directory:***

1. Click on a directory to select it.
2. Click **OK**.

Creating a New Directory

Task: ***To create a new directory:***

1. Select a directory or the Destination Computer and press the **Insert** key, or right-click and select **New** from the context menu. This creates a directory beneath the selected folder or beneath the Destination Computer.
2. Type the directory name.

3. Provide a directory identifier, if necessary.

Renaming a Directory

Task: ***To rename a directory:***

1. Select a directory or the Destination Computer and press F2, or right-click and select **Rename** from the context menu.
2. Type the new directory name. Note that you cannot rename predefined directories.
3. Rename the directory identifier, if necessary, to be consistent with the directory's new name.

Deleting a Directory

Task: ***To delete a directory:***

Select a directory and press the **Delete** key, or right-click and select **Delete** from the context menu.

Note that you cannot delete predefined directories.

Note • *When you delete a directory, any subdirectories beneath the selected directory are also deleted.*

Directory Identifier

You can use the **Directory Identifier** field to provide a user-friendly name for a directory. For example, if you have a directory—`ProgramFilesFolder\MyProgram\Graphics\Jpg`—you can use just JPG to identify the directory path. The **Component Destination** field in the IDE displays the path as {JPG} [ProgramFilesFolder]MyProgram\Graphics\Jpg.

Note • *The directory identifier must be a valid Windows Installer identifier. For features, the directory identifier must contain all capital letters.*

Browse for Directory/Shortcut Target Dialog Box

Use the Browse for Directory dialog box to browse to a directory, create a new directory, rename a directory, or delete a directory. Use the Browse for Shortcut Target dialog box to browse to a directory or file, create a new directory, rename a directory, delete a directory.

Dialog Box Options

Destination Directories

This field lists all of the currently available destination directories. You can select, create, rename, or delete directories in this field.

Selecting a Directory

Task: ***To select a directory:***

1. Click on a directory to select it.
2. Click **OK.**

Creating a New Directory

Task: ***To create a new directory:***

1. Select a directory or the Destination Computer and press the Insert key, or right-click and select **New** from the context menu. This creates a directory beneath the selected folder or beneath the Destination Computer.
2. Type the directory name.
3. Provide a directory identifier, if necessary.

Renaming a Directory

Task: ***To rename a directory:***

1. Select a directory or the Destination Computer and press F2, or right-click and select **Rename** from the context menu.
2. Type the new directory name. Note that you cannot rename predefined directories.
3. Rename the directory identifier, if necessary, to be consistent with the directory's new name.

Deleting a Directory

Task: ***To delete a directory:***

Select a directory and press the **Delete** key, or right-click and select **Delete** from the context menu. Note that you cannot delete predefined directories.

Note • *When you delete a directory, any subdirectories beneath the selected directory are also deleted.*

Hard-Coding a Shortcut

Task: ***To hard code a shortcut to a path such as C:\Winnt\Notepad.exe:***

First create two folders — "C:" and "Winnt." Then enter "Notepad.exe" in the filename field of the **Browse for Directory** dialog or select the root node, and enter "C:\Winnt\Notepad.exe" in the filename field.

Directory Identifier

You can use the **Directory Identifier** field to provide a user-friendly name for a directory. For example, if you have a directory—`ProgramFilesFolder\MyProgram\Graphics\Jpg`—you can use just JPG to identify the directory path. The **Component Destination** field in the InstallShield interface displays the path as {JPG} [ProgramFilesFolder]MyProgram\Graphics\Jpg.

Note • *The directory identifier must be a valid MSI identifier. For features, the directory identifier must contain all uppercase letters.*

You can enter the file name in the **File name** edit box, which means that you are entering the selected directory\filename as the target of the shortcut.

Browse for File Dialog Box

The Browse for File dialog box is displayed when you click the ellipsis button (...) in the Include Patterns and Files setting or the Exclude Patterns and Files setting on the Signing tab for a release in the Releases view. The Browse for File dialog box lets you specify which static files in your project should or should not be signed. It also lets you use an asterisk (*) as a wild-card character. This is especially helpful if you include dynamically linked files in your project and you want to sign all files that match a certain pattern.

Table 12-7 • Settings on the Browse for File Dialog Box

Setting	Description
Select files to sign	This box is displayed if you click the ellipsis button (...) in the Include Patterns and Files setting. This box lists all of the statically included files in your project that match the file types that are selected in the **Show files of type** list. It also lists some default file patterns, such as *.dll. Select the check boxes for the files and file patterns that correspond with the types of files in your project that you want InstallShield to sign at build time.

Table 12-7 • Settings on the Browse for File Dialog Box (cont.)

Setting	Description
Select files to skip signing	This box is displayed if you click the ellipsis button (...) in the Exclude Patterns and Files setting. This box lists all of the statically included files in your project that match the file types that are selected in the **Show files of type** list. It also lists some default file patterns, such as *.dll. If you want to prevent certain files or file patterns from being signed by InstallShield at build time, select the check boxes for the appropriate files and file patterns.
Show files of type	Use this list to filter the types of files that are displayed in the **Select files to sign** box or the **Select files to skip signing** box.

Windows Logo • *All executable files (including .exe, .dll, .ocx, .sys, .cpl, .drv, and .scr files) in an installation must be digitally signed for the Windows logo program.*

When you click OK on this dialog box, InstallShield adds new Include settings under the Include Patterns and Files setting or new Exclude settings under the Exclude Patterns and Files setting.

Note that the files and file patterns that should not be signed override any files and file patterns that should be signed. For example, if you specify *.exe in an Include setting and in an Exclude setting, InstallShield does not sign any .exe files.

Browse for File to Run Dialog Box

The Browse for File to Run dialog box opens when you click the ellipsis button (...) in the Target setting in the Scheduled Task view. This dialog box lets you specify the file name and location on the target system for the file that you want the scheduled task to run.

Table 12-8 • Settings on the Browse for File to Run Dialog Box

Setting	Description
Destination Directories	Select the directory on the target system that will contain the file that you want to be run as a scheduled task. To specify a new directory, right-click the location that you want to contain the new directory, and then click New Directory. To hide or show empty predefined directories in this box, right-click in this box and then click Show Empty Predefined Directories.

Table 12-8 • Settings on the Browse for File to Run Dialog Box (cont.)

Setting	Description
Directory Identifier	If you select a destination directory that you created in the Destination Directories box, you can use this setting to enter a user-friendly name for the directory. For example, if you have a directory such as `[ProgramFilesFolder]\MyProgram\Graphics\JPG`, you can use just JPG to identify the directory path. The Component Destination field in InstallShield displays the path as `{JPG}` `[ProgramFilesFolder]MyProgram\Graphics\JPG`. If you select a predefined directory in the Destination Directories box, this setting is read-only.
File Name	Enter the name of the file that you want the scheduled task to launch.

Browse for Shortcut Icon Dialog Box

Project • *This applies to InstallScript projects.*

Use the Browse for Shortcut Icon dialog box to specify to the location on the target system of the icon file (.ico) or the .exe or .dll file that contains the icon resource. This dialog box opens when you click the ellipsis button (...) in the Icon setting in the Shortcuts view.

Table 12-9 • Browse for Shortcut Icon Dialog Box Settings

Setting	Description
Destination Directories	Select the directory on the target system that contains the icon file.
Current Value	This read-only setting shows the selected directory that contains the icon file.
File Name	Enter the name of the icon file (.ico) or the .exe or .dll file that contains the icon resource.

Tip • *To use a hard-coded path for a file, enter the path in the Icon File setting manually, instead of using the Browse for Shortcut Icon dialog box to use system variables for directories. The Icon File setting is under the Icon setting in the Shortcuts view.*

Check In Dialog Box

This dialog is displayed when you check a project in to your source control program through the interface.

Dialog Options

Comments

Enter comments describing the changes you have made to the file. These comments are stored in your source control program.

Keep checked out

Select this option to check in the changed version of the .isv file, but keep it checked out in your working directory.

Differences

Click the Differences button to view a line-by-line comparison between the .ism file (in text format) being checked in and the previous version.

Check Out Dialog Box

If you select the **Use** dialog for checkout check box on the Source Control tab of the Options dialog box, the Check Out dialog box is displayed when you check out a project from your source control program through InstallShield.

Dialog Box Options

Table 12-10 • Check Out Dialog Box Options

Option	Description
Comments	Type comments about your reasons for checking out the .ism file.
Advanced	Click the **Advanced** button to specify your source control program's complete options for checking out the project file.

Component Properties Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

- *MSI Database*
- *MSM Database*
- *Transform*

The Component Properties dialog box lets you set some component properties—including dynamic file link settings and associated features—from the Files and Folders view.

Task: ***To launch the dialog box:***

1. In the View List under **Application Data**, click **Files and Folders**.
2. Ensure that components are displayed in the **Destination computer's folders** pane.

   If components are not displayed: In the **Destination computer's folders** pane, right-click **Destination Computer** and click **Show Components** (in Windows Installer–based projects) or **Show Components and Subfolders** (in InstallScript projects).
3. Right-click a component and then click **Properties**. The **Component Properties** dialog box opens.

The following tabs are available on this dialog box:

- General tab
- File Linking tab
- Features tab

General Tab

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The General tab on the Component Properties dialog box is where you set the properties for the selected component.

Table 12-11 • Settings on the General Tab of the Component Properties Dialog Box

Setting	Project Type	Description
Shared	Basic MSI, DIM, InstallScript, InstallScript MSI, InstallScript Object, Merge Module, MSI Database, MSM Database, Transform	If the files that are contained within this component are shared files, select this check box. To learn more, see Managing Reference Counts for Shared Files.
Never Overwrite	Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	If you do not want to replace an existing version of the same file that is already present on the target machine, select this check box. To learn more, see Checking File Versions Before Installing.
Permanent	Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	If the files in this component should not be removed from the system during uninstallation, select this check box. For example, validation rule ICE09 requires any component with a destination of [SystemFolder] to be marked as Permanent. To learn more, see Specifying Whether a Component's Files and Other Associated Data Are Uninstalled During Uninstallation.
Uninstall	InstallScript, InstallScript Object	If the files in this component should be removed when the application is uninstalled, select this check box. To learn more, see Specifying Whether a Component's Files and Other Associated Data Are Uninstalled During Uninstallation.
64-bit	Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, MSM Database, Transform	To mark this component as 64 bit, select this check box. If a 64-bit component is included in your installation, the installation cannot be run on 32-bit machines.

Table 12-11 • Settings on the General Tab of the Component Properties Dialog Box (cont.)

Setting	Project Type	Description
Extract COM Info At Build	Basic MSI, DIM, InstallScript MSI, Merge Module	If you want InstallShield to extract the COM information each time you build a release, select this check box. If your COM interfaces are subject to change, this option is preferable to maintaining statically acquired or provided data in the COM Registration advanced setting. If you have marked the component's COM server file as Self-Registering, you should not select this check box.
Self-register	InstallScript, InstallScript Object	If the component's files are self-registering, select this check box. A self-registering file is an OLE server that can place information about itself in the registry so that it is seen by other OLE applications. Such a file can also remove this information from the registry when it is uninstalled.  ***Project*** • *InstallScript and InstallScript Object projects support self-registration of .dll files, .exe files, and type libraries; that is, .tlb and .olb files. In Windows Installer–based projects, self-registration is set at the file level, rather than the component level.*

File Linking Tab

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The File Linking tab on the Component Properties dialog box shows all of the settings for your dynamic link.

Table 12-12 • Settings on the File Linking Tab of the Component Properties Dialog Box

Setting	Description
Source	This column shows where the source files are stored. A path variable is typically used.

Table 12-12 • Settings on the File Linking Tab of the Component Properties Dialog Box (cont.)

Setting	Description
Include Subfolders	This column indicates whether InstallShield should dynamically link the files in each subfolder. For information on how InstallShield creates components for the dynamically linked files in subfolders, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.
Self-Register	This column indicates whether you want InstallShield to self-register every file in the dynamic link. If the file are part of a 64-bit component and the Self-Register column indicates Yes for a dynamic link, the installation performs 64-bit self-registration on the target system. For more information, see Targeting 64-Bit Operating Systems.
Create Components	This column indicates how you want InstallShield to create the components when it adds the dynamic files to your release at build time. The valid options are: • **Best Practice**—InstallShield adheres to best practices when creating components for the dynamically linked files. • **By Directory**—InstallShield creates one component for each folder and subfolder. To learn about these two methods, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.
Details	This column indicates the filter criteria for including files in and excluding files from the dynamic link.

Tip • *Note the following guidelines for working with the File Linking tab:*

- *To add a new dynamic link, click the New Link button. InstallShield displays the Dynamic File Link Settings dialog box.*
- *To modify the settings for an existing link, select the link and then click the Modify button. InstallShield displays the Dynamic File Link Settings dialog box.*
- *To remove a link and its associated dynamically linked files, select the link and then click the Delete button.*

Features Tab

Project • *This information applies to the following project types:*

- *Basic MSI*

- *InstallScript*
- *InstallScript Object*
- *MSI Database*
- *Transform*

The Features tab on the Component Properties dialog box is where you specify the features with which the component is associated. Select the check box next to the feature or features with which you want the component to be associated.

Condition Builder Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Condition Builder dialog box simplifies the process of creating a condition for a component, a dialog, a custom action, a SQL script, a system search, or other installation element by providing a selection of valid Windows Installer properties and conditional expression operators.

The Condition Builder dialog box contains the following settings.

Table 12-13 • Condition Builder Dialog Box Settings

Setting	Description
Conditions	This box is where you define the condition for your component, dialog, custom action, or other installation element. You can type a condition directly in this box, or you can use the Properties list, the Operators list, and the Add buttons to build a condition statement.  ***Important*** • *When you click the OK button on this dialog box, InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Building Conditional Statements.*

Table 12-13 • Condition Builder Dialog Box Settings (cont.)

Setting	Description
Properties	This list contains common Windows Installer properties, as well as any properties that have been added in the Property Manager view. Select the property that you want to evaluate, and then click the **Add** button next to this list. If the list does not contain the property that you want to evaluate, you can type the appropriate property name in the Conditions box.
Operators	This list contains all of the valid operators that are recognized by the Windows Installer. If your conditional statement should contain an operator, select the operator that you want to use and then click the **Add** button. InstallShield adds the operator to the conditional statement. If you add an operator, type the appropriate value after the operator.

Content Source Path Dialog Box

The Content Source Path dialog box opens when you click the UNC button in the Content Source Path (Local or UNC) setting for a Web site in the Internet Information Services view. This dialog box contains the following setting.

Table 12-14 • Content Source Path Dialog Box Setting

Setting	Description
Universal Naming Convention content source path	Specify the UNC path for the IIS Web site's files. For example: **\\server\share**

Convert InstallScript MSI Dialog Box

The Convert InstallScript MSI dialog box lets you convert an InstallScript MSI project to an InstallScript project. An InstallScript project offers the advantages of InstallScript MSI—such as dialog box skins, a flexible end-user interface, and a powerful scripting model—without any of the limitations or overhead of Windows Installer.

This dialog box is displayed when you select the Project menu's Convert to InstallScript Project command.

If you click Yes, most project elements are converted, many with no change. The following changes take place (the conversion process issues many messages to let you know what is happening):

- INSTALLDIR is changed to TARGETDIR in the following IDE elements:
  - Component destinations
  - Path specifications in the Files and Folders view
  - Target specifications in the Shortcuts view

Note that the value of TARGETDIR must be set in your script, as it is in the following default code in the OnFirstUIBefore event handler function:

```
if ( ALLUSERS ) then
    TARGETDIR = PROGRAMFILES ^ IFX_COMPANY_NAME ^ IFX_PRODUCT_NAME;
else
    TARGETDIR = FOLDER_APPDATA ^ IFX_COMPANY_NAME ^ IFX_PRODUCT_NAME;
endif;
```

- A new product code is generated.
- A registry set is created for each component that had registry data associated with it.
- Each component with multiple dynamic file links is split into multiple components with one dynamic file link in each.
- The script file Setup.rul is renamed OldSetup.rul and is displayed in the InstallScript view. Note that no changes are made to this script file.
- Warnings are issued for the following unsupported items:
  - Unsupported folder specifiers in path specifications in the Files and Folders view, or destinations or target specifications in the Shortcuts view
  - Win32 assemblies that are associated with components
  - Global assembly caches that are associated with components
  - Registry value names that contain a hyphen (-) or asterisk (*)
  - Advertised shortcuts
  - Folders under the Support Files view's Disk1 folder
  - Merge modules (you can re-include these in the converted project from the Objects view)
  - Unsupported MSI tables that contain data

Releases and your scripts are not converted. At a minimum, you need to modify your scripts to set TARGETDIR, as mentioned above, change all INSTALLDIR references to TARGETDIR, and remove calls to Windows Installer API functions (whose names begin with Msi). Furthermore, the obsolete string entry PRODUCT_NAME is not converted; IFX_PRODUCT_NAME can be used instead.

Note that setting SHELL_OBJECT_FOLDER in OnFirstUIBefore is not necessary and the default script line SHELL_OBJECT_FOLDER = @PRODUCT_NAME; should be deleted.

The following Windows Installer folder specifiers are not supported in InstallScript projects:

- ALLUSERSPROFILE
- AdminToolsFolder
- AppDataFolder
- CommonAppDataFolder
- CommonFiles64Folder
- FavoritesFolder

- FontsFolder
- GlobalAssemblyCache
- LocalAppDataFolder
- MyPicturesFolder
- PersonalFolder
- PrimaryVolumePath
- ProgramFiles64Folder
- SendToFolder
- System16Folder
- System64Folder
- TempFolder
- TemplateFolder
- USERPROFILE
- WindowsVolume

In addition, the following folder specifiers are not supported for shortcut destinations:

- ProgramFilesFolder
- CommonFilesFolder
- WindowsFolder
- SystemFolder

Create a New Component Dialog Box

Some aspects of your installation project must be associated with a component. For example, if no component exists when a shortcut or an .ini file change is created, InstallShield prompts you to create a new component.

Dialog Options

New component name

InstallShield provides a default name for the component. Type a meaningful name into this field. The name you provide is for your reference only and is never displayed to end users.

Select the features to associate this component with

Project • *This property applies to the following project types:*

- *Basic MSI*
- *InstallScript*

Select from the list the feature or features with which you want to associate the new component. If no features appear in this field, you can add one by clicking New Feature. You are not required to associate your new component with a feature; however, if you do not, this component will not be installed.

New Feature

Project *• This property applies to the following project types:*

- *Basic MSI*
- *InstallScript*

Click New Feature to add a feature to your setup project. When you have created a feature, you can associate your new component with it by clicking the box next to the feature name.

Do not show this dialog again

Select this option if you want InstallShield to automatically create any necessary components in the future.

Create a New Feature Dialog Box

Some aspects of your installation project must be associated with a feature. For example, if no feature exists when a merge module is added, or an ODBC resource is configured, InstallShield prompts you to create a feature.

Dialog Options

New feature name

InstallShield creates a default feature name for you. Provide a meaningful name for the feature. The name you enter here is for your reference only and is never displayed to end users.

Do not show this dialog again

Select this check box if you want InstallShield to automatically create components and features when required.

Custom Error Handling Dialog Box

Specify how to handle specific SQL errors in the Custom Error Handling dialog box. Any error you define will override the script's default error handling. You can define how to handle an error for all scripts in your project or simply for this script.

Error Number

Enter the SQL error number for which you want to customize error handling.

Behavior

Override the default behavior by choosing one of the following options:

- On Error, Abort Installation
- On Error, Go to Next Script
- On Error, Go to Next Statement

Project Wide

To apply the customized error handling to all scripts in your project, select Yes. To apply it to only this script, select No.

Custom Errors Dialog Box

The Custom Errors dialog box lists all of the HTTP errors that can be customized for a Web site, application, or virtual directory. A custom error can be a URL or a pointer to a file on the server.

Task: ***To configure error messages:***

1. In the **Custom Errors** dialog box, select one or more errors.
2. Click **Edit**. The **Error Mapping Properties** dialog box opens.
3. Select a message type and specify a file or URL as appropriate.
4. Click **OK**.

You can click the Set to Default button to restore default settings for the selected error.

Customize Validation Settings Dialog Box

The Customize Validation Settings dialog box lets you specify which internal consistency evaluators (ICEs) should be used for a specific validation suite. This dialog box opens when you click Customize on the Validation tab of the Options dialog box.

To customize the list of ICEs that are performed during a particular type of validation, select the validation suite in the CUB file list. Then select the check boxes for each of the ICEs that should be performed, and clear the check boxes for each of the ICEs that should be ignored.

To learn about specific ICEs, see ICE Reference in the Windows Installer Help Library.

For information about each of the InstallShield ICEs that were added to the InstallShield validation suites, see ISICEs.

Data Languages Dialog Box

Edition • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*

The Data Languages dialog box lets you include certain components and exclude others based on the language that is selected for each component. If the language specified for a component does not match one of the languages that is selected in this dialog box, InstallShield does not include the component in the release.

To open the Data Languages dialog box, open the Releases view and select a release. Then click the ellipsis button (...) in the Data Languages setting on the Build tab.

By default, releases are language independent; that is, none of the project's components are excluded from the release.

Delete Property Dialog Box

The Delete Property dialog box is displayed when you delete a system search associated with a property in your installation project. The goal of the dialog box is to determine whether or not you want to delete that property along with the search.

Note • *Deleting the property may affect other areas of your setup.*

Select Yes if you are certain that your project will not be affected in the absence of that property. Select No if you are uncertain whether it will affect your installation.

Dependencies Dialog Box

The Dependencies dialog box displays the list of dependencies for a selected file. To access this dialog box, right-click a file in the **Destination computer's files** pane of the Files and Folders view, and then click **Dependencies from scan at build**.

The dialog box provides results for assembly DLLs. If you launch the dialog box from Microsoft Visual Studio, the dialog box shows results for project outputs. If launched from InstallShield outside of Visual Studio, scan at build dependencies is disabled for project outputs.

Note • *This is enabled only for key files and when the .NET Scan at Build property is set to Dependencies and Properties. If the dependency or one of its dependencies cannot be located, a red icon is displayed.*

Dialog Box Options

Dependency

This section lists all of the dependencies with a check box next to each. To exclude a dependency from the build, clear the check box next to the dependency. To close the dialog, click OK.

Note • *Any new dependencies detected at build time—for files added after closing the Dependencies dialog box—are added to the build.*

Dialog Images Dialog Box

Use the Dialog Images dialog box to add an image (.bmp, .gif, .jpg, .jpeg, or .ibd) that you want to display on your installation's dialogs.

Full Screen Image

Browse to a graphic file that will serve as the full-screen background for your *exterior* dialogs. Exterior dialogs are dialogs that appear at the beginning or end of the installation, including InstallWelcome and SetupCompleteSuccess (the final dialog upon successful installation). The full-screen image should measure 499 by 312 pixels.

Banner Image

Browse to a graphic file that will run across the top of interior dialogs. Interior dialogs, which appear between the first and last installation dialogs, include the LicenseAgreement and CustomSetup dialogs. The banner image should be 499 by 58 pixels.

Digitally Sign Setup Dialog Box

The Digitally Sign Setup dialog box is displayed when you click Digitally Sign Setup on the Build Installation page of the Project Assistant. This dialog box enables you to assure your end users that the code within your application has not been modified or corrupted since publication.

Table 12-15 • Digitally Sign Setup Dialog Box Settings

Setting	Description
Digitally sign setup	Select this check box to digitally sign your installation. The other settings on this dialog box are enabled when you select this check box.
Certificate URL	Type a fully qualified URL—for example, **http://www.mydomain.com**. This URL is used in your digital certificate to link to a location you would like end users to visit in order to learn more about your product, organization, or company.

Table 12-15 • Digitally Sign Setup Dialog Box Settings (cont.)

Setting	Description
Digital certificate file (SPC or PFX)	Specify the location of your digital certificate file (.spc or .pfx) provided by a certification authority. You can type the path to the file or use the Browse button to navigate to the file location. If you specify an .spc file, you must also specify a .pvk file.
Private key file (PVK)	If you are using an .spc file, you must also specify the location of your private key file (.pvk) provided by a certification authority. You can type the path to the file or use the Browse button to navigate to the file location.
Certificate password	If you would like to pass the password for the .pvk file or the .pfx file to `ISCmdBld.exe` to digitally sign your application while building the release from the command line, type the password in this box. InstallShield encrypts this password and stores it in your project (.ism) file. If you do not specify a password in this box but you are digitally signing the release while building it from the command line, you will need to manually enter the password when you are prompted each time that you build the release from the command line.

Tip • *The Signing tab in the Releases view lets you specify which portions of your installation should be digitally signed at build time. InstallShield enables you to sign any and all of the following files in a release, depending on what type of project you are using:*

- *Windows Installer package (.msi file) for Basic MSI and InstallScript MSI projects*
- *Merge module package (.msm file) for Merge Module projects*
- *`Setup.exe` file for Basic MSI and InstallScript MSI projects*
- *Media header file for InstallScript projects*
- *Package (self-extracting single-executable file) for InstallScript projects*
- *Any files in your release, including your application files*

To learn more, see Digitally Signing a Release and Its Files at Build Time.

Windows Logo • *All executable files (including .exe, .dll, .ocx, .sys, .cpl, .drv, and .scr files) in an installation must be digitally signed for the Windows logo program.*

Differences Dialog Box

The Differences dialog box is displayed when you click the Show Differences command, which is available from the Project menu's Source Control menu. The dialog box has a list that contains all of the Windows Installer tables in your installation project.

Task: ***To view the table's differences in your source control program:***

Select a table from the list and click **OK**.

Dynamic File Link Settings Dialog Box

The Dynamic File Link Settings dialog box enables you to specify the source folder for your dynamic link. You can then choose to include all the files in that folder or only specified file types.

The Dynamic Link Settings dialog box is available from the File Linking tab of the Component Properties dialog box, as well as the Modify Dynamic Links dialog box.

Table 12-16 • Settings on the Dynamic File Link Settings Dialog Box

Setting	Description
Source folder	Enter the full path to the folder that you want to have dynamically linked, or click the Browse button to navigate to it. You can identify the source folder with any of the following methods: • Enter an absolute path to the folder, such as `C:\Build\MySourceFolder\Bitmaps`. • Enter a path variable. Follow the path variable with a backslash to specify a subfolder—for example, `<CommonFilesFolder>\InstallShield\IScript`. • Click the Browse button to navigate to a folder.
Include subfolders	To dynamically link the files in each subfolder, select this check box. For information on how InstallShield creates components for the dynamically linked files in subfolders, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.
Self-register all files	To self-register every file in the dynamic link, select this check box. If the files are part of a 64-bit component and you select this check box, the installation performs 64-bit self-registration on the target system. For more information, see Targeting 64-Bit Operating Systems.

Table 12-16 • Settings on the Dynamic File Link Settings Dialog Box (cont.)

Setting	Description
Create best practice components	To specify that InstallShield should adhere to best practices when creating the components for dynamically linked files, select this check box. When best practices for component creation are followed, InstallShield performs the following tasks at build time for all of the files that meet the include and exclude filter criteria: • InstallShield creates a separate component for each portable executable (PE) file in the dynamically linked folder. Each PE file is the key file of its component. • InstallShield adds all non-PE files at the root level of the dynamic link to the component that contains the link. • If the dynamic link includes a subfolder, InstallShield creates a new component for all of the non-PE files in that subfolder. If the dynamic link includes more than one subfolder, InstallShield creates a separate component for all of the non-PE files in each subfolder. To specify that InstallShield should not follow best practices when creating the components for dynamically linked files, clear this check box. For this component creation method, InstallShield performs the following tasks at build time for all of the files that meet the include and exclude filter criteria: • InstallShield creates one component for all of the files that are in the root-level dynamically linked folder, regardless of the file types. • If the dynamic link includes one or more subfolders, InstallShield creates a separate component for all of the files in each subfolder, regardless of the file types. The first dynamically linked file in a subfolder's component is the key file of that component. This check box is selected by default for all new dynamic links. For more information, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.
Include all files	To include the entire contents of your linked directory in your installation, select this option.

Table 12-16 • Settings on the Dynamic File Link Settings Dialog Box (cont.)

Setting	Description
Include/exclude files based on the following wild-card patterns	To include or exclude file types, select this option. Enter the file extension in the include or exclude field, preceded by an asterisk (*). Separate multiple entries with a comma. For example, if all of your image files are in one folder along with sound files and you want to dynamically link only the image files, you could specify that you would like to include only .bmp and .ico files in the dynamically linked folder. To do so, you would use an asterisk (*) in your include pattern, as in the following example: `*.bmp, *.ico` To include or exclude a specific file, you would enter the full file name in the include or exclude pattern box.

Edit Data Dialog Box

The Edit Data dialog is available from within the Application Registry panel in the Project Assistant. To access the dialog, double-click on a registry value in the Destination computer's registry data pane. The Multi-Line String Value dialog box is displayed for multi-string values.

Dialog Options

Value name

The name of the registry value as it appears in the Destination computer's registry data pane. To change the value name, right-click on the value and select Rename.

Value data

Contains the information that should be stored in the registry value. To change or edit the data, type in the edit field.

Edit IIS Metabase Value Dialog Box

InstallShield displays the Edit IIS Metabase Value dialog box if you click the Change Value button on the Other IIS Properties dialog box. The Other IIS Properties dialog box is displayed if you click the ellipsis button (...) in the Other IIS Properties setting for a selected Web site, application, or virtual directory in the Internet Information Services view.

The Edit IIS Metabase Value dialog box is where you specify the value for an IIS setting that is not displayed in the other areas of the Internet Information Services view.

If you change the default value for any advanced property, InstallShield adds the property, the value that you specify, and the additional required information to the **ISIISProperty** table.

Table 12-17 • Edit IIS Metabase Value Dialog Box Settings

Setting	Description
Property Name	This read-only setting shows the property that you selected to configure.
Value	Specify the value that you want to use for the selected IIS property.

Edit Registry Data Dialog Box

The Edit Registry dialog box allows you to edit the registry data within your setup project. To launch this dialog box, right-click a value in the Registry view and select Modify.

Dialog Options

Value Name

The value name is read-only in this dialog box.

Task: ***To change the name of a value:***

1. Exit the **Edit Registry Data** dialog box.
2. Select the value you want to rename, and press F2.
3. Type the new name.

Value Data

Enter the data for this registry value as you would like it to appear on the target machine.

Tip • *To write the value of a Windows Installer property called PropertyName to the registry, use the expression "[PropertyName]" in the value data.*

Error Mapping Properties Dialog Box

The Error Mapping Properties dialog box displays an IIS error code and its default properties. Use the Message Type list to set the message to a URL or a pointer to a file on the server. When you set the error message to a URL, you must specify the full URL. When you set the error message to a file pointer, you can browse for the file that you want to use as the error message or you can type the full path of the file to be used. This can include files that are not in your project but are pre-existing on the system.

Exclusion Languages Dialog Box

Project • *This information applies to the following project types:*

- *Merge Module*
- *MSM Database*

The Exclusion Languages dialog box opens when you click the ellipsis button (...) in the Language setting for a merge module exclusion in the General Information view. This dialog box lets you specify the language requirements for the merge module that is not compatible with the merge module that you are creating.

To specify language requirements for the merge module exclusion, do one of the following:

- To exclude a merge module if its language is a particular language, select the language in the language list, and then select the **matches** option.
- To exclude a merge module if its language is not a particular language, select the language in the language list, and then select the **does not match** option.
- If the language should not be used to exclude a merge module, select Language Independent in the language list.

Export Tables Dialog Box

The Export Tables dialog box provides a way to export one or more tables through the Direct Editor as .idt files.

Table 12-18 • Export Tables Dialog Box Settings

Setting	Description
Output Directory	Specify the directory where the tables are to be exported. You can also click Browse to navigate to the directory.
Tables	This box lists check boxes for all of the tables in your project. Select the check boxes of the tables that you want to export.
Select All	Selects all tables for export.
Clear All	Deselects all tables.
Invert	Simultaneously deselects any selected tables and selects any deselected tables.

Feature Condition Builder Dialog Box

The Feature Condition Builder dialog box simplifies the process of creating feature conditions by providing a selection of valid Windows Installer properties and conditional expression operators.

You can create as many conditions as required for a feature. For information on creating the conditions, see Setting Feature Conditions.

The Feature Condition Builder dialog box contains the following settings.

Table 12-19 • Feature Condition Builder Dialog Box Settings

Setting	Description
Conditions	This box displays a grid with the following columns: • **Level**—This column is where you assign the install level that should be used for the feature if the condition evaluates as true. • **Condition**—This column is where you define the condition. You can type a condition directly in this column, or you can use the Properties list, the Operators list, and the Add buttons to build a condition statement. To add a new condition to this box, click the New Condition button, and then enter the appropriate information in the Level and Condition columns. To delete a condition in this box, select the condition, and then click the Delete Conditions button.  ***Important*** • *When you click the OK button on this dialog box, InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Building Conditional Statements.*
Properties	This list contains common Windows Installer properties, as well as any properties that have been added in the Property Manager view. Select the property that you want to evaluate, and then click the **Add** button next to this list. If the list does not contain the property that you want to evaluate, you can type the appropriate property name in the Condition column.
Operators	This list contains all of the valid operators that are recognized by the Windows Installer. If your conditional statement should contain an operator, select the operator that you want to use and then click the **Add** button. InstallShield adds the operator to the conditional statement.

File Details Dialog Box

Access this dialog by clicking the Details button in the System Search Wizard. This button becomes active after you define a search method and specify the file you are locating. In this dialog, you have the ability to enhance a search by specifying the following details:

Table 12-20 • File Details Dialog Box Settings

Setting	Description
Minimum Version	The search is successful if the file exists on the target system and the version is equal to or higher than the version entered.
Maximum Version	The search is successful if the file exists on the target system and the version is equal to or lower than what is entered.
Minimum Date	Select the check box to search by a minimum date. The search is successful if the file exists on the target system and the date is equal to or later than the date entered.
Maximum Date	Select the check box to search by a maximum date. The search is successful if the file exists on the target system and the date is earlier or equal to the date entered.
Minimum Size	The search is successful if the file exists on the target system and is equal to or larger than the size indicated (in bytes).
Maximum Size	The search is successful if the file exists on the target system and is smaller than or equal to the size indicated (in bytes).
Languages	Click the Browse (...) button to display the Languages dialog. You can select multiple languages as a condition of your search. The search is successful if at least one of the languages listed is a match.

Note • *The information you provide in the edit fields is optional. You can leave any field blank.*

File Properties Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*

- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Properties dialog box lets you override various properties for a file when it is installed on the target system.

Task: ***To open the File Properties dialog box:***

1. In the View List under **Application Data**, click **Files and Folders**.
2. Right-click a file and click **Properties**.

Important • *File properties cannot be set for dynamically linked files.*

Table 12-21 • Properties Dialog Box Settings

Setting	Description
Location	This read-only setting displays the directory in which this file will be installed on a target system, based on the destination of the component that contains the file. To modify the destination, change the destination of the component that contains the file.
Font title	If you are installing a font, you can specify the font title in this box using the format **FontTitle (FontType)**—for example, **Roman (All res)**. InstallShield provides the name of the font if it is registered on your system. You should not specify a font title for .ttf or .ttc fonts because Windows Installer reads the embedded font name and registers it for you. Thus, for .ttf or .ttc files, InstallShield sets the value of this setting to **[Title read from file]**. For more information, see ICE07 in the Windows Installer Help Library.
Self Register	To self-register the file during installation, select this check box. The Self Register setting is valid for .dll, .ocx, .exe, .tlb, and .olb files. If the file is part of a 64-bit component, the installation performs 64-bit self-registration on the target system. For more information, see Targeting 64-Bit Operating Systems.  ***Note*** • *It is recommended that you extract COM information from your self-registering files, instead of using self-registration. For more information, see Registering COM Servers.*

Table 12-21 • Properties Dialog Box Settings (cont.)

Setting	Description
Override system attributes	To install this file using the same system properties that are currently set for this file on the development system, clear this check box. To override one or more of the file's properties, select the **Override system attributes** check box and then select one or more of the following check boxes. • **Read-only**—If you want the file to be read-only when Windows Installer installs it, select this check box. • **Hidden**—If you want the file to be hidden when Windows Installer installs it, select this check box. • **Use File Hash**—This option is applicable for unversioned files only. Windows Installer can use file hashing to detect and avoid unnecessary copying of unversioned files. If you want Windows Installer to compare the hash of the file in your installation with the hash of the corresponding file on the target system when deciding whether to upgrade an existing file, select this check box. • **System**—If you want Windows Installer to install the file as a system file, select this check box. • **Vital**—To indicate that this file is vital to the operation of its component, select this check box. A vital file's component is not installed if the file cannot be installed for any reason. If a vital file cannot be installed, the end user sees an error message with Retry and Cancel buttons, instead of the usual Abort, Retry, and Ignore buttons (which enable the end user to complete the installation successfully without installing that file). ***Note*** • *If No is selected for the Generate File Hash Values setting on the Build tab for a release in the Releases view, no file hash entries are created for any files, regardless of whether an individual file's Use File Hash check box is selected.*
Override system size	The Size setting shows the file's size when the **Override system size** setting is cleared. If you want Windows Installer to ignore the actual size of the selected file when it is calculating the required disk space requirements for your installation, and instead consider the size to be a value that you specify, select this check box and enter the appropriate value (in bytes) in the Size setting.

Table 12-21 • Properties Dialog Box Settings (cont.)

Setting	Description
Always Overwrite	If you want Windows Installer to ignore the actual version number of the selected file, and instead always try to overwrite the file if it is already present on the target system, select this check box. At run time, if this file has the same name and target location as one on the target system, Windows Installer considers the version of the file in your installation to be 65535.0.0.0 when it is determining whether to update the target system's file with the version in your current installation, or to leave the file as is. For more details about how Windows Installer determines whether to overwrite an existing file, see Overwriting Files and Components on the Target System. The maximum version number for a file is 65535.65535.65535.65535.
Override system version	If the file is a versioned file, the Version setting shows the file's version when the **Override system version** setting is cleared. If you want Windows Installer to ignore the actual version number of the selected file, and instead consider the version to be a number that you specify, select this check box and enter the appropriate version number in the Version setting. At run time, if this file has the same name and target location as one on the target system, Windows Installer uses the version number that you specify when it is determining whether to update the target system's file with the version in your current installation, or to leave the file as is. For example, if the file in your project is version 2.0.0.0, and you enter an override version of 3.0.0.0, Windows Installer may replace the file on the target system if it is version 3.0.0.1 or later, but not if it is earlier than 3.0.0.0. For more details about how Windows Installer determines whether to overwrite an existing file, see Overwriting Files and Components on the Target System. The maximum version number for a file is 65535.65535.65535.65535.
Override system language	If you want Windows Installer to ignore the language of the selected file and instead consider the language to be one that you specify, select this check box and type the decimal value for the language identifier code in the Language box. At run time, if this file has the same name and target location as one on the target system, Windows Installer considers the language of the file in your installation to be the one that you specified when it is determining whether to update the file with the version in your current installation, or to leave the file as is. For more details about how Windows Installer determines whether to overwrite an existing file, see Overwriting Files and Components on the Target System. Font files should not be authored with a language ID because fonts do not have an embedded language ID resource. Leave this entry blank for font files.

Table 12-21 • Properties Dialog Box Settings (cont.)

Setting	Description
Permissions	To set permissions for the file, click this button.

File Properties Dialog Box (InstallScript Installation Projects)

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

This dialog box displays the properties that are set for a file when it is installed on the target system.

Task: ***To open the File Properties dialog box:***

Right-click a file and click **Properties**. This option is disabled for files in components whose Link Type property is set to **Dynamic**.

In InstallScript projects, the File Properties dialog box displays information about the selected file. The information in the dialog box is taken directly from the file system and the dialog box is read only except for the following controls:

Register Font File

If this box is checked, the file is marked internally to be registered on the target machine if you have enabled global font registration. If this box is unchecked, the file is not registered on the target machine.

Font title

For an .fon file, this text specifies the font title that the installation registers for the font. By default, the InstallShield user interface reads the font title from the registry of the source system and enters that font title in this edit box. For a TrueType file (.ttf or .ttc file), by default no text is displayed in this edit box and the installation reads the font title from the file at run time. For all three types of files, if you enter non-default text in this edit box, the installation registers that text as the font title.

Find and Replace Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

The Find and Replace dialog box lets you search for strings in your SQL script file and replace them with different strings at run time. The Find and Replace dialog box opens when you click the Add button on the Text Replacement tab for a SQL script that is selected in the SQL Scripts view.

In Basic MSI, DIM, and InstallScript MSI projects, you can replace a string with a Windows Installer property; at run time, Windows Installer writes the value of the property in your SQL script file.

In InstallScript projects, you can use text substitution to replace a string variable with the appropriate value.

Caution • *You should only replace text that is unique and will not cause script syntax errors.*

The following settings are available on the Find and Replace dialog box.

Table 12-22 • Find and Replace Dialog Box Settings

Setting	Description
Find What	Enter the string that you want to replace in your SQL script at run time.  ***Project*** • *In Basic MSI, DIM, and InstallScript MSI projects—You can use Windows Installer public properties to specify the replacement strings. To learn more, see Using Windows Installer Properties to Dynamically Replace Strings in SQL Scripts.* *In InstallScript projects—You can use InstallScript text substitution to specify the replacement strings. To learn more, see Using InstallScript Text Substitution to Dynamically Replace Strings in SQL Scripts.* *Specifying Windows Installer properties or InstallScript text substitution enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's SQL script is modified.*
Replace With	Enter the new string that should replace the existing string that is found in your SQL script at run time.  ***Project*** • *In Basic MSI, DIM, and InstallScript MSI projects—You can use Windows Installer public properties to specify the replacement strings. To learn more, see Using Windows Installer Properties to Dynamically Replace Strings in SQL Scripts.* *In InstallScript projects—You can use InstallScript text substitution to specify the replacement strings. To learn more, see Using InstallScript Text Substitution to Dynamically Replace Strings in SQL Scripts.* *Specifying Windows Installer properties or InstallScript text substitution enables you to use data that end users enter in dialogs, or other configuration information that is determined at run time, when your product's SQL script is modified.*

Table 12-22 • Find and Replace Dialog Box Settings (cont.)

Setting	Description
Match case	This check box lets you indicate whether you want to restrict your search to strings with the same capitalization that you use in the Find What setting. For example, if you select this check box and enter `install` for the Find What setting, the installation searches only for all-lowercase instances of that string. If you clear this check box, the installation searches for *install*, as well as *INSTALL*, *Install*, and other mixed-case instances.
Match whole word only	This check box lets you indicate whether you want to find only whole-word instances of the value that you have entered for the Find What setting. For example, if you select this check box and enter `install` for the Find What setting, the installation searches only for instances of *install*; it does not search for other forms of the word, such as *installs*, *installation*, or *uninstall*. For another example, you may have something like the following line in your SQL script: `PASSWORD = N'%PASSWORD%'` If you select this check box, enter `%PASSWORD%` in the Find What setting, and enter `1234` in the Replace With setting, the installation replaces the string. The resulting SQL script shows the following: `PASSWORD = N'1234'`
Preserve case	This check box lets you indicate whether you want the replacement string to use the same capitalization that is used in the Find What string. For example, if you select this check box and enter `databasedir` for the Find What setting and `mydatabasedir` for the Replace With setting, the installation replaces *Databasedir* with *Mydatabasedir*. It also replaces *databasedir* with *mydatabasedir*.
Replace once only	This check box lets you indicate whether you want the installation to replace only the first occurrence of the search string. If you clear this check box, the installation replaces all instances of the search string.

Find String ID in Project Dialog Box

The Find String ID dialog box lets you search your entire project for occurrences of a particular string entry. Select from the list the string entry you would like to find and click OK. The results of your search are displayed in the Output window at the bottom of the screen.

Folder Properties Dialog Box

A folder's Properties dialog box determines the properties that are set for a folder when it is installed on the target system. To access this dialog box, right-click a folder in the Files and Folders view, and then click Properties.

The Properties dialog box is organized into the following tabs:

- General
- Sharing

General Tab

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The General tab on a folder's Properties dialog box lets you configure basic properties about a folder.

Table 12-23 • General Tab Settings

Setting	Description
Directory Identifier	This setting identifies the current directory identifier for the selected folder.
Source Location	This setting identifies from where files will be copied to the disk image folders when you build an uncompressed release.
Target	This setting identifies the location to which the folder will be installed on target systems.

The Permissions button lets you configure permissions for the folder. To learn more, see Permissions Dialog Boxes for Files and Directories.

Sharing Tab

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The General tab on a folder's Properties dialog box lets you configure basic properties about a folder.

Table 12-24 • General Tab Settings

Setting	Description
Share this folder on the network	To share this folder on the network, select this check box.
Share name	If you are enabling sharing for this folder, specify the name that users need to use to connect to the shared folder.
Limit the number of simultaneous users to	If you are enabling sharing for this folder, specify the maximum number of users who can connect to the shared folder at one time.  ***Note*** • *Windows imposes limits for the maximum number of simultaneous users. These limits vary, depending on the version and edition of Windows. An installation cannot override this Windows-imposed limit. Thus, if you specify a larger number than a target system can support, the installation sets the limit at the maximum that is allowed by that target system's operating system.* *To determine the limit for a specific version and edition of Windows, use the following command-line statement on that version and edition of Windows:* `Net Config Server` *The Maximum Logged On Users value that the Command Prompt window displays indicates the maximum that the operating system supports.* *You can also find the maximum number in the "Device Connections" section of a Windows end-user license agreement.*
Allow network users to change my files	If you are enabling sharing for this folder and you want to allow network users to change the files in this folder, select this check box.
Component	Select the component in this folder that should include this network share.

Function Signature Dialog Box

The Function Signature dialog box is where you specify the parameters for the entry-point function in your standard .dll file.

Task: ***To access the Function Signature dialog box:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences** (in Basic MSI, InstallScript MSI, MSI Database, and Transform projects) or **Custom Actions** (in DIM, Merge Module, and MSM Database projects).
2. In the **Custom Actions** explorer, select the custom action whose parameters you would like to specify.
3. In the **Function Signature** property, click the ellipsis button (**...**).

Dialog Box Options

Name

Specify the name of the function that you want to call. The .dll file can have a single entry point for each custom action.

Arguments

Build the list of arguments—in order—that you want to pass to the function.

First, click the last row of the Arguments list to add a new argument. Next, complete the Type, Source, and Value columns for each argument.

Type

In this list, select the data type of the parameter. Note that there are two special cases for argument types, and these cases are identified below.

Task: ***To initialize a pointer to null:***

1. In the Type list, select **POINTER**.
2. In the **Source** list, select **Constant**.
3. In the **Value** list, select **NULL**. Do not enter 0 (zero) instead of **NULL**, because it is interpreted as a pointer pointing to the number 0.

Task: ***To set a handle to the .msi database or the Windows Installer window:***

1. In the **Type** list, select **HANDLE**.
2. In the **Source** list, select **Constant**.

3. In the **Value** list, select **MsiHandle** or **MsiWindowHandle**, depending whether you want a handle to the .msi database or the Windows Installer window.

Source

Indicate how you want to pass the data to the function. The following options are available in this list.

Table 12-25 • Function Signature Dialog Box Options

Option	Description
Constant	The value that you want to pass is stored as a literal in your installation project. After you select **Constant** for the argument's source, enter its definition in the Value column. This "constant" does not require a name or identifier. Do not enclose string literals in quotation marks.
in Property	Select **in Property** for the source to specify the name of a Windows Installer property whose value will be passed to the function. This type of argument is suitable for a ByVal parameter.
inout Property	This source type is similar to a ByRef parameter. Select **inout Property** for the source to specify the name of a Windows Installer property whose value will be passed to the function and can be modified by the function.
out Property	An **out property** serves as a placeholder for a value that can be set by the function. No value is passed to the function, but the function requires the name of a property whose value it can modify.

When you select a property for the argument's source, you must specify the name of the property in the Value column.

Value

The value can be one of two types:

- A number or string literal that you enter when the argument's source is a constant
- A Windows Installer property when the argument's source is a property

Note • *When you set the Type list to HANDLE and the Source list to Constant, the Value column contains two options: MsiHandle and MsiWindowHandle. These constants can be used to get a handle to either the .msi database or the Windows Installer window.*

When the source is a property, the Value list provides the name of every property in the Property Manager. You can select an existing property or enter a new name, in which case the new property is added to the Property Manager.

Remember that a property is merely a container for a value. If your parameter stores its value in an in property or inout property, ensure that you specify a value for the property in the Property Manager.

(Context Menu)

The context menu provides you with options for working with your arguments. To access the context menu, right-click an argument in the Arguments grid. The context menu options are described below.

Table 12-26 • Context Menu Options

Option	Description
Add	Click Add to add an argument to the Arguments grid.
Remove	Click Remove to delete the argument.
Move Up	The arguments must be in the precise order in which the function expects to receive them. Click Move Up to place the argument higher in the list.
Move Down	Click Move Down to place the argument lower in the list.

Return Type

Select the data type of the function's return value. If you do not need to check the return value, you can accept void.

Return Property

Select the name of a property whose value will be set to the function's return value. If you are going to check the return value elsewhere in your installation, you may want to initialize the return property's value.

Note • *The property cannot be set to the function's return value unless the action is configured for immediate execution. Thus, if the action is scheduled for deferred, rollback, or commit execution, the Return Property setting is ignored at run time.*

General Options - Advanced Dialog Box

The General Options - Advanced dialog box opens when you click the Advanced button on the General Options panel of the Release Wizard. This dialog box allows you to specify a custom location for the built files, (in installation projects only) the space that is reserved in the disk images folders, whether the installation performs MD5 checking, and (in object projects only) how InstallShield handles subobjects contained in the object project during the build of the object.

Panel Options

Build the media to the custom folder location

If unchecked, the release's Disk Images, Log Files, and Report Files folders are created in the default location:

```
<project folder>\Media\<release name>
```

Check this box to specify another location by typing in the combo box, selecting and completing one of the list items, which are defined relative to path variables, or clicking the browse button and selecting a folder.

Reserved Space

Project • *This option is available in installation projects. If you are building an object project, this setting is not displayed.*

Disabled if the current release's media type produces a single disk image—which is true for Network Image. Lets you reserve (leave empty) specified amounts of space in particular disk image folders. Select a disk image folder number in the Disk list box (for example, a value of 1 specifies disk image folder Disk1) and enter the space (in kilobytes) to be reserved in that folder in the Reserved Space edit box.

Verify MD5 signature

Project • *This option is available in installation projects. If you are building an object project, this setting is not displayed.*

If this check box is checked, the setup compares each installed file's MD5 hash value to the value stored in the .cab file. This setting is stored in the CheckMD5 key of the [Startup] section in the Setup.ini file.

Tip • *MD5 checking can detect corrupted files, which is useful during Internet setups; not doing MD5 checking can make file transfer proceed faster.*

Object Inclusion - Embedded

Project • *This option is available in object projects.*

If the object project includes any subobjects, the release includes those subobjects themselves rather than references to the subobjects. A release built with this option can be used by InstallShield users who do not have the subobjects registered on their systems.

Object Inclusion - Reference

Project • *This option is available in object projects.*

If the object project includes any subobjects, the release includes references to those subobjects rather than the subobjects themselves. A release built with this option cannot be used by InstallShield users who do not have the subobjects registered on their systems.

General Options - Other Disk Files Dialog Box

The **General Options - Other Disk Files** dialog box opens when you click the Other Disk Files button on the General Options panel of the Release Wizard. This dialog box allows you to specify a location in the disk image folders for each file that is in the Other folder under Advanced Files in the Support Files/Billboards view.

Panel Options

File name

Select the file for which you want to specify a disk image folder number.

Disk

Select the desired disk image folder for the selected file (for example, selecting 3 places the selected file in disk image folder Disk3).

History Dialog Box

The History dialog is displayed when you select **Show History from the Project/Source Control** menu. The dialog contains a drop-down list box that contains all of the Windows Installer tables in your setup project.

Task: ***To display view the table's history in your source control program:***

Select a table from the list and click **OK**.

Import Dialog Dialog Box

The Import Dialog dialog box lets you select a dialog that you want to import into your installation project. The file for the dialog (.isd file) can be stored in a repository, or it can be stored in some other location.

Task: ***To access the Import Dialog dialog box:***

1. Open the **Dialogs** view.
2. In the Dialogs explorer, right-click **All Dialogs** and then click **Import Dialog.** The **Import Dialog** dialog box opens.

Dialog Box Options

Repository Items

This box lists all of the dialogs that are available in the repository. Select the dialog that you want to add to your project.

If the file for the dialog box (.isd file) that you want to import is not stored in the repository, click the Browse button to select it.

Import InstallScript Files Dialog Box

The Import InstallScript Files dialog box lets you select one or more InstallScript (.rul) or InstallScript header (.h) files that you want to import into your installation project. The files can be stored in a repository, or they can be stored in some other location.

Task: ***To access the Import InstallScript Files dialog box:***

1. Open the **InstallScript** view.
2. In the InstallScript explorer, right-click **Files** and then click **Import Script File**. The **Import InstallScript Files** dialog box opens.

Dialog Box Options

Repository Items

This box lists all of the InstallScript files that are available in the repository. Select one or more InstallScript files that you want to add to your project.

If the InstallScript file that you want to import is not stored in the repository, click the Browse button to select it.

Import SQL Script Files Dialog Box

The Import SQL Script Files dialog box lets you select one or more SQL script files that you want to import into your installation project. The SQL script (.sql) file can be stored in a repository, or it can be stored in some other location.

Task: ***To access the Import SQL Script Files dialog box:***

1. Open the **SQL Scripts** view.
2. In the SQL Scripts explorer, right-click Files and then click **Import Script File**. The **Import SQL Script Files** dialog box opens.

Dialog Box Options

Repository Items

This box lists all of the SQL script files that are available in the repository. Select one or more SQL script files that you want to add to your project.

If the SQL script file that you want to import is not stored in the repository, click the Browse button to select it.

Insert Action Dialog Box

Project • *The Insert Action dialog box is available in the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Insert Action dialog box enables you to insert a standard action, custom action, or dialog into one of your project's sequences.

Task: ***To launch the Insert Action dialog box:***

1. In the View List under **Behavior and Logic**, click **Custom Actions and Sequences**.
2. Right-click a sequence, dialog, custom action, or standard action, and then click **Insert**.

Tip • *You can also launch this dialog box from the DIM References view in a Basic MSI project: In this view, click a DIM reference, and then click the Sequences tab. Right-click a sequence, dialog, custom action, or standard action, and then click Insert.*

Dialog Options

Table 12-27 • Insert Action Dialog Box Options

Option	Description
Action Type	Select the type of action to insert: • **Custom Actions**—You can create custom actions with the Custom Action Wizard. • **Dialogs**—You can insert dialogs into the User Interface sequence. To create custom dialogs, use the Dialogs view. • **DIM Custom Actions**—These custom actions are stored within one or more DIM references that you have added to your installation project. The GUID for that DIM is appended to the name of the custom action. For example, if you have a LaunchUtility action called LaunchUtility stored within a DIM, it appears as LaunchNotepad.xxxxxxxx_xxxx_xxxx_xxxx_xxxxxxxx, where x is the GUID for that DIM. • **DIM Dialogs**—These dialogs are stored within one or more DIM references that you have added to your installation project. The GUID for that DIM is appended to the name of the dialog. For example, if you have a dialog called CustomerInfo stored within a DIM, it appears as CustomerInfo.xxxxxxxx_xxxx_xxxx_xxxx_xxxxxxxx, where x is the GUID for that DIM. • **Merge Module Custom Actions**—These custom actions are stored within one or more merge modules that you have associated with your installation project. The GUID for that merge module is appended to the name of the custom action. For example, if you have a custom action called LaunchNotepad stored within a merge module, it appears as LaunchNotepad.xxxxxxxx_xxxx_xxxx_xxxx_xxxxxxxx, where x is the GUID for that module. • **Merge Module Dialogs**—These dialogs are stored within one or more merge modules that you have associated with your installation project. The GUID for that merge module is appended to the name of the dialog. For example, if you have a dialog called CustomerInfo stored within a merge module, it appears as CustomerInfo.xxxxxxxx_xxxx_xxxx_xxxx_xxxxxxxx, where x is the GUID for that module. • **Standard Actions**—These actions are built into Windows Installer.  ***Note*** • *When you delete a merge module from your project that contains custom actions or dialogs inserted within one of your sequences, InstallShield removes those actions and dialogs automatically from the sequence. The same is true for DIM references.*
Select an Action	After you have selected the action type, you need to select the specific action. To do this, highlight the action you want to insert.

Table 12-27 • Insert Action Dialog Box Options (cont.)

Option	Description
Condition	You can set a condition upon this action. If the condition does not evaluate to true, the action does not execute. For more information on conditions, see Conditional Statement Syntax.
Comments	Enter comments in this field. These comments are for internal use only and are not displayed to the end user.

InstallShield Prerequisite Properties Dialog Box

The InstallShield Prerequisites Properties dialog box opens when you right-click a selected InstallShield prerequisite in the Redistributables view or in the Prerequisites view and then click Properties. This dialog box enables you to specify a location for the selected InstallShield prerequisite. To learn more, see Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level.

Project • *In Basic MSI and InstallScript MSI projects, the InstallShield Prerequisite Properties dialog box also enables you to set release flags for InstallShield prerequisites that you want to exclude from certain builds. For example, if you have an InstallShield prerequisite that should be included only in a special edition of your product*

that contains a special add-on that requires the prerequisite, you can flag that prerequisite and include it only when it is needed.

Table 12-28 • InstallShield Prerequisite Dialog Box Settings

Setting	Description
Build Location	When you package an installation that includes InstallShield prerequisites, you can use any one several methods for supplying the prerequisite files to end users: • **Download From The Web**—Download the InstallShield prerequisite files (if necessary) from the URL that is specified for this InstallShield prerequisite . This option is recommended if your installation will be downloaded from the Internet and you want to minimize the package size and download time. An InstallShield prerequisite will not be downloaded if the correct version is already present on the target machine. This option is available for Basic MSI, InstallScript, and InstallScript MSI projects. • **Extract From Setup.exe**—Compress the InstallShield prerequisite files into `Setup.exe`, to be extracted at run time, if necessary. Select this option if the entire installation must be self-contained in `Setup.exe`. Note that the Download From The Web option results in smaller installations and shorter download time; however, the Extract From Setup.exe option provides for a completely self-contained installation. This option is available for Basic MSI and InstallScript MSI projects. • **Copy From Source Media**—Store the InstallShield prerequisite files on the source media. Use this option if the installation will be run uncompressed from fixed media—CD, DVD, or local network. This option is available for Basic MSI and InstallScript MSI projects. • **Include with Media**—Store the InstallShield prerequisite files on the source media. This option is available for InstallScript projects. Note that the option that you select in the Build Location setting may be overridden in the Releases view. For more information, see Specifying the Run-Time Location for InstallShield Prerequisites at the Release Level.  ***Note*** • *Note that if an InstallShield prerequisite is added to a project as a dependency of another prerequisite, the location for the prerequisite dependency follows the location setting of the prerequisite that requires it.*

Table 12-28 • InstallShield Prerequisite Dialog Box Settings (cont.)

Setting	Description
Release Flags	 ***Project*** • *This setting is available in Basic MSI and InstallScript MSI projects.* Type a string. The string can be any combination of letters or numbers. To have more than one flag on an InstallShield prerequisite, use a comma to separate the flags

Languages Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The Languages dialog box opens when you click the ellipsis button (...) for the Languages setting in the Components view. This dialog box enables you to specify the languages for which the component is intended, for use in build-time filtering. By default, components are language independent, meaning that none of the component's data (such as files and registry entries) are specific to a particular language.

To designate that the component is intended for only certain languages, select the check boxes for the appropriate languages.

Project • *In InstallScript and InstallScript Object projects, if a language is not selected in the General Information view of a project, it is not listed as one of the available languages for the project's components.*

Link Type Dialog Box

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The Link Type dialog box opens when you click the browse button in the Link Type setting in the Components and Setup Design views. It also opens when you right-click a component in the **Destination computer's folders** pane in the Files and Folders view and then click File Linking.

The Link Type dialog box lets you specify whether the file links of the selected component are static or dynamic and, if the latter, how the links are determined at the time of the media build.

Dialog Box Settings

Static Links

The component contains file links to files specified by explicit fully qualified file names.

Dynamic Links

The component contains file links to files whose names can be specified by wild cards (for example, *.* or *.exe) and whose folder can be specified by an explicit path or by a build variable.

Note • *The following settings are enabled only if the Dynamic Links option is selected.*

Specify the folder which contains the files to include

This setting specifies the folder that contains the linked files. Type an explicit path, select or type a build variable, or select and optionally append to a predefined path variable.

Caution • *Entering a relative path (for example, .\MyFolder) will give unpredictable results.*

Browse

Clicking this button opens the Browse for Folder dialog box, in which you can specify an explicit path.

Include subfolders

If you select this check box, InstallShield dynamically links the files that are included in any subfolders of the folder that you identified for the **Specify the folder which contains the files to include** setting.

Tip • *The InstallScript engine does not support the concept of subcomponents. When you include subfolders in a dynamic file link, InstallShield creates separate components for each subfolder.*

Wildcard(s)

The file list is constructed by first including all files that match the specification you enter in the Inclusion combo box, and then excluding from those files all the ones that match the specification you enter in the Exclusion combo box.

Inclusion

Specify the names of the files to which the component contains file links. By typing an entry or selecting a path variable, you can enter the name of a single file or use wild cards in this filename specification, for example *.* or *.exe. To specify multiple wild cards, separate them with semicolons and no spaces, for example,

.txt;.doc

Exclusion

Specify the names of the files to which the component does not contain file links. By typing an entry or selecting a path variable, you can enter the name of a single file or use wild cards in this filename specification, for example *.* or *.exe. To specify multiple wild cards, separate them with semicolons and no spaces, for example,

.exe;.dll

In the above example, no .exe or DLL files are included in the component.

Logging Options for Windows Installer 4.0 and Later Dialog Box

InstallShield displays the Logging Options for Windows Installer 4.0 and Later dialog box when you click the ellipsis button (...) for the Create MSI Logs setting in the General Information view. This dialog box enables you to specify on a project-wide basis—without having to use the command line or configure log parameters through the registry—whether Windows Installer should log your installation. You can also use this dialog box to customize the types of messages that are logged.

Table 12-29 • Options for the Logging Options for Windows Installer 4.0 and Later Dialog Box

Option	Description
No	Installations are not logged. This is the default value.

Table 12-29 • Options for the Logging Options for Windows Installer 4.0 and Later Dialog Box (cont.)

Option	Description
Yes (MsiLogging set to default value of voicewarmupx)	InstallShield populates the **MsiLogging** property with the default value of **voicewarmupx**. If the installation is run on a target system that has Windows Installer 4.0 or later, as well as Windows Vista or later or Windows Server 2008 or later, the following occurs: • The installer creates a log file according to the default logging mode of voicewarmupx. • The installer populates the **MsiLogFileLocation** property with the log file's path. • A **Show the Windows Installer log** check box is added to the SetupCompleteSuccess, SetupCompleteError, and SetupInterrupted dialogs. If the end user selects that check box and then clicks Finish, the log file is opened in a text file viewer or editor. This setting applies to installations that are run with Windows Installer 4.0 or later on Windows Vista and later systems or Windows Server 2008 and later systems. The **Show the Windows Installer log** check box is not visible in run-time dialogs that are displayed on earlier systems that are running earlier versions of Windows Installer.
Custom MsiLogging value	InstallShield populates the **MsiLogging** property with the value that you specify in the box. If the installation is run on a target system that has Windows Installer 4.0 or later, as well as Windows Vista or later or Windows Server 2008 or later, the following occurs: • The installer creates a log file according to the custom value that you specified in the box. • The installer populates the **MsiLogFileLocation** property with the log file's path. • A **Show the Windows Installer log** check box is added to the SetupCompleteSuccess, SetupCompleteError, and SetupInterrupted dialogs. If the end user selects that check box and then clicks Finish, the log file is opened in a text file viewer or editor. This setting applies to installations that are run with Windows Installer 4.0 or later on Windows Vista and later systems and Windows Server 2008 or later systems. The **Show the Windows Installer log** check box is not visible in run-time dialogs that are displayed on earlier systems that are running earlier versions of Windows Installer.

Important • *The **MsiLogFileLocation** property is read-only; it cannot be used to set or change the log file location.*

Lowercase Component Directory Warning

This dialog appears when you declare a Directory Identifier in lowercase or in mixed-case letters when setting a component's destination.

Declaring a Directory Identifier in uppercase letters makes that value a public property that can be set from the user interface. Using mixed-case or lowercase letters for the Directory Identifier defines the directory entry as a private property. Private properties cannot be changed from the user interface.

Note • *To suppress this warning, select the **Do not show this dialog again** option.*

Media File Properties Dialog Box

Opens when you click the Import or Modify button in the Release Wizard's Update panel. Lets you specify a release that is not in the current project and the method for determining its version information.

Media Header File

Type, or select and complete, the fully qualified name of the desired release's header file (such files have extension .hdr and are typically named Data1.hdr), or click the browse button to browse for the header file.

Read the version information ...

Specifies that the version information is automatically read from the release's header file.

Specify the version information below

Specifies that the version information is what you type or select in the combo box.

Merge Module Configurable Values Dialog Box

A configurable redistributable is a merge module or an object that has at least one row in the **ModuleConfiguration** table that is referenced by at least one row in the **ModuleSubstitution** table. This allows you to change a value in the redistributable.

Displaying the Merge Modules Configurable Values Dialog Box

The Merge Module Configurable Values dialog box opens when you select a configurable merge module or object whose check box is selected in the Redistributables view. If the redistributable selected is an object, the Merge Module Configurable Values dialog box is displayed when the object wizard finishes.

You can also right-click a configurable merge module or object and select Configure Merge Module.

Dialog Box Settings

The Merge Module Configurable Values dialog box contains a grid in which you can modify the configurable values. The left column contains the name of the configurable value. The right column contains the value options. You can select a new value from the drop-down menu. Refer to the redistributable vendor's documentation for information about the values.

After you specify the values that you want, click OK to save the new values. When you build your project, these values are used to build the .msi package.

Restore Defaults

Click this button to restore the redistributable's default settings. All of the configurable values in the redistributable are returned to their defaults.

Merge Module Properties Dialog Box

The Merge Module Properties dialog opens when you right-click a selected merge module or object in the Redistributables view and then click Properties. The following tabs are associated with this dialog box:

- Media
- Destination
- Configurable Values

Media Tab

File Location

Use the Media tab to specify the destination and format of your output.

On the source media (uncompressed)

Choose this option to copy the files uncompressed to the media.

In a new .CAB file

When you choose this option, InstallShield puts the source media in the same location as the .msi package. However, you can choose to stream the .cab into the .msi package.

Stream the new .CAB file into the Windows Installer Package

Choose this option to stream the .cab into the .msi package.

Note *• For transform (*.mst) project types, the option to stream the .cab into the .msi package is disabled because the transform project cannot store the .cab fie internally. It can only add uncompressed files or files stored in an external cab.*

Destination Tab

Use the Destination tab on the Merge Module Properties dialog box to configure destination information.

Settings

GUID

Displays the merge module's unique GUID.

Author

Displays the merge module's author.

Version

Displays the merge module version.

Destination

Specifies the destination of the merge module's files. It is recommended you use the default setting "(Use merge module's default destination)".

Method Browser Dialog Box

The Method Browser dialog box is where you specify the class and method in your managed assembly that your custom action should invoke. The Custom Action Wizard displays this dialog box when you click the Browse button on the Managed Method Definition panel. In addition, this dialog box is also displayed if you click the Browse button on the Method Signature dialog box.

Note *• Only public methods of public classes are available for selection. In addition, overloaded methods cannot be selected.*

The browse functionality is available only if the .NET Framework is installed. In addition, it is available only if the location of the managed assembly is set to the ***Binary*** *table or installed with the product—not if the assembly's path references a property or a directory in the* ***Directory*** *table.*
Also note that the browse functionality is available for only 32-bit assemblies and for Microsoft intermediate language (MSIL) files. It is not available for 64-bit assemblies.

Method Signature Dialog Box

InstallShield displays the Method Signature dialog box when you click the ellipsis button (...) in the Method Signature setting for a managed custom action in the Custom Actions and Sequences view (or the Custom Actions view). This dialog box lets you specify the public class method that you want your custom action to invoke.

The Method Signature dialog box has the following settings.

Table 12-30 • Settings on the Method Signature Panel

Setting	Description
Class	Enter the name of the public class—including the full namespace—with which the method is associated. Use the following format: `MyNamespace.MyClass` As an alternative, click the Browse button to display the Method Browser dialog box. This dialog box lets you select the public method from the list of public classes that are available in the managed assembly that you selected on the Action Parameters panel.  ***Note*** • *The browse functionality is available only if the .NET Framework is installed. In addition, it is available only if the location of the managed assembly is set to the **Binary** table or installed with the product—not if the assembly's path references a property or a directory in the **Directory** table.* *Also note that the browse functionality is available for only 32-bit assemblies and for Microsoft intermediate language (MSIL) files. It is not available for 64-bit assemblies.*
Method	Enter the public method that you want your installation to call. As an alternative, click the Browse button to display the Method Browser dialog box. This dialog box lets you select the public method from the list of public classes that are available in the managed assembly that you selected on the Action Parameters panel.  ***Note*** • *The browse functionality is available only if the .NET Framework is installed. In addition, it is available only if the location of the managed assembly is set to the **Binary** table or installed with the product—not if the assembly's path references a property or a directory in the **Directory** table.* *Also note that the browse functionality is available for only 32-bit assemblies and for Microsoft intermediate language (MSIL) files. It is not available for 64-bit assemblies.*

Table 12-30 • Settings on the Method Signature Panel (cont.)

Setting	Description
Use custom method signature	To use the default method signature, clear this check box. For the default method signature, the installation calls the method with an MsiHandle parameter if the signature has one or more void parameters, or if it has a single MsiHandle parameter. To use a custom method signature, select this check box. Then specify the arguments and return property as needed. If you specified a class and a method by clicking the Browse button, InstallShield automatically adds any associated parameters. Specify the value for each parameter that you want to pass to the method. For detailed information about specifying the method's signature, see Specifying the Signature for a Managed Method in an Assembly Custom Action.
Arguments	If you are using a custom method signature, specify the list of arguments that you want to pass to the selected method. If you specified a class and a method by clicking the Browse button, InstallShield automatically adds any associated parameters to the grid in this area. To use a property as an argument, click the value field for the parameter, and then select the property from the list. You can also use a property that is not included in the list by typing the name of the property. The property must be defined at run time. The context menu provides you with options for working with arguments. To access the context menu, right-click an argument in the Arguments grid. The available context menu commands are: • **Add**—Add an argument to the grid. • **Remove**—Delete an argument from the grid. This grid is available only if the **Use custom method signature check box** is selected. For more information about specifying the arguments, see Specifying the Signature for a Managed Method in an Assembly Custom Action.
Return Property	Select or type the name of the property whose value will be set to the method's return value. This list is available only if the **Use custom method signature check box** is selected. For more information about specifying the return property, see Specifying the Signature for a Managed Method in an Assembly Custom Action.

MIME Types Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*

The MIME Types dialog box lets you add, edit, and delete mappings between file name extensions and the corresponding content types that are served as static files by the Web server to a browser or mail client.

The MIME Types dialog box is available from within the Internet Information Services view. To open this dialog box, click a Web site, application, or virtual directory in the explorer. Then click the ellipsis button (...) in the MIME Types setting.

Table 12-31 • MIME Types Dialog Box Settings

Setting	Description
Add	To add an entry for mapping a file name extension and the corresponding content type that is served as a static file by the Web server to a browser or mail client, click this button. This opens the Add MIME Types dialog box.
Edit	To edit an existing MIME type, select the MIME type and click this button.
Delete	To delete an existing MIME type, select the MIME type and click this button.

Modify Dynamic Links Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The Modify Dynamic Links dialog box shows all of the settings for your dynamic link.

Task: ***To launch the dialog box:***

1. Open the **Components** view or the **Setup Design** view.
2. In the explorer, expand the component whose dynamic link you would like to modify and then click Files.
3. Right-click in the Files pane and then click **Dynamic File Linking**. The **Modify Dynamic Links** dialog box opens.

Table 12-32 • Settings on the File Linking Tab of the Component Properties Dialog Box

Setting	Description
Source	This column shows where the source files are stored. A path variable is typically used.
Include SubFolders	This column indicates whether InstallShield should dynamically link the files in each subfolder. For information on how InstallShield creates components for the dynamically linked files in subfolders, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.
Self-Register	This column indicates whether you want InstallShield to self-register every file in the dynamic link. If the file are part of a 64-bit component and the Self-Register column indicates Yes for a dynamic link, the installation performs 64-bit self-registration on the target system. For more information, see Targeting 64-Bit Operating Systems.
Create Components	This column indicates how you want InstallShield to create the components when it adds the dynamic files to your release at build time. The valid options are: • **Best Practice**—InstallShield adheres to best practices when creating components for the dynamically linked files. • **By Directory**—InstallShield creates one component for each folder and subfolder. To learn about these two methods, see Determining the Appropriate Component Creation Method for Dynamically Linked Files.
Details	This column indicates the filter criteria for including files in and excluding files from the dynamic link.

Tip • *Note the following guidelines for working with the File Linking tab:*

- *To add a new dynamic link, click the New Link button. InstallShield displays the Dynamic File Link Settings dialog box.*

- *To modify the settings for an existing link, select the link and then click the Modify button. InstallShield displays the Dynamic File Link Settings dialog box.*
- *To remove a link and its associated dynamically linked files, select the link and then click the Delete button.*

Modify Property Dialog Box/Release Wizard—Platforms Panel

Project • *The following information applies to InstallScript projects.*

The Modify property dialog box and the Platforms panel in the Release Wizard let you specify whether a release is specific to one or more platforms. If the platform specified for a component does not match one of the platforms that is selected for the release, the component is not included in the release.

Task: ***To access the Modify Property dialog box:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, click the release that you want to configure.
3. Click the **Build** tab.
4. Click the value of the **Platform(s)** setting, and then click the ellipsis button (**...**).

Task: ***To access the Platforms Panel in the Release Wizard:***

1. In the View List under **Media**, click **Releases**.
2. In the **Releases** explorer, right-click the release that you want to configure, and then click **Release Wizard**.
3. Complete each of the panels in the wizard until you reach the **Platforms** panel.

The following table shows the settings that are displayed on the Modify Property dialog box and the Platforms panel in the Release Wizard.

Table 12-33 • Settings on the Modify Property Dialog Box and the Platforms Panel in the Release Wizard

Setting	Description
Use platforms specified by the Platform Filtering setting	If the selected release supports all of the platforms that are specified for the Platform Filtering setting in the General Information view, select this option. If you select this option, none of the components are excluded from the release at build time.

Table 12-33 • Settings on the Modify Property Dialog Box and the Platforms Panel in the Release Wizard (cont.)

Setting	Description
Specify the platforms to support below	If the selected release is specific to one or more operating systems, select this option and then select the appropriate operating systems. If the platform specified for a component does not match one of the platforms that is selected for this setting, InstallShield does not include the component in the release.  ***Tip*** • *To select multiple consecutive operating systems, select the first file, press and hold SHIFT, and select the last operating systems. To select multiple nonconsecutive operating systems, select the first operating systems, press and hold CTRL, and select each additional operating systems.*  ***Project*** • *For InstallScript projects, the list of operating systems that are displayed in this dialog box excludes any of the operating systems whose check box is cleared at the project level.*

Module Dependencies Dialog Box

Project • *This information applies to the following project types:*

- *Merge Module*
- *MSM Database*

The Module Dependencies dialog box opens when you click the ellipsis button (...) in the Module Dependencies setting of the General Information view. This dialog box lets you select the merge modules that are required for the merge module that you are creating.

Tip • *The dialog box lists the merge modules that are found in the directories that are specified on the Merge Modules tab of the Options dialog box. If you want to add a dependency that is not present on your machine, you can do so by clicking the* ***Add a new module dependency*** *button in the Module Dependencies setting of the General Information view.*

Module Exclusions Dialog Box

Project • *This information applies to the following project types:*

- *Merge Module*
- *MSM Database*

Some merge modules do not operate correctly in the presence of certain other merge modules. This may occur because an earlier version of a module might not be compatible with your new module. As a result, you need to ensure that the incompatible module is excluded from any installation that will contain your new module.

The Module Exclusions dialog box opens when you click the ellipsis button (...) in the Module Exclusions setting of the General Information view. This dialog box lets you select the merge modules that are compatible with the merge module that you are creating.

If you add a merge module that has exclusions to an installation project, and those excluded modules have already been added to your installation project, InstallShield silently removes any reference to the exclusions from your project.

Caution *• Any excluded modules that are added to the installation project after the excluding module has been added will not be removed; in addition, you will not receive any warning that they are incompatible.*

Tip *• The dialog box lists the merge modules that are found in the directories that are specified on the Merge Modules tab of the Options dialog box. If you want to add an exclusion that is not present on your machine, you can do so by clicking the* ***Add a new module dependency*** *button in the Module Exclusions setting of the General Information view.*

MSI Value Dialog Box

The MSI Value dialog box enables you to create or modify a primary key for an entry in the resulting Windows Installer package's **Registry** table. For more information, see Specifying a Primary Key for the Registry Table.

MST SIS Settings Dialog Box

This dialog allows you suppress errors and specify validation options for the transform and base MSI package. For more information, see Database.CreateTransformSummaryInfo in the Windows Installer Help Library.

Dialog Options

Suppress Errors Options

Select the check boxes next to the error conditions that you want to suppress.

Table 12-34 • Suppress Errors Options

Condition	Description
Add existing row	Adds a row that already exists.

Table 12-34 • Suppress Errors Options (cont.)

Condition	Description
Add existing table	Adds a table that already exists.
Delete missing row	Deletes a row that does not exist.
Delete missing table	Deletes a table that does not exist.
Modify missing row	Updates or modifies a row that does not exist.
Change codepage	The transform and .msi code pages do not match and neither code page is neutral.

Validation Options

In this section, you can indicate the information that you want the transform package to validate on the base MSI package before the transform is applied.

Table 12-35 • Validation Options

Validation Option	Description
Match languages	Validates the languages in both the base MSI and the transform. The transform is not applied if the languages do not match.
Match Upgrade Code	Validates the Upgrade Codes in both the base MSI and the transform. The transform is not applied if the Upgrade Codes do not match.
Match Product Code	Validates the Product Codes in both the base MSI and the transform. The transform is not applied if the Product Codes do not match.

Version comparison

Select the type of comparison you want to make.

Version level

Select whether you want only the major versions compared or both the major and minor versions.

Multi-Line String Value Dialog Box

The Multi-Line String Value dialog box lets you enter a multi-line registry value. This dialog box opens when you are adding or editing a multi-line string value for a registry key in the Registry view.

(Multi-line edit field)

In the multi-line edit field, enter a line for each null-delimited string or modify it. Right-click the grid to display the context menu or press the following keys in the grid below associated with the following actions.

Table 12-36 • Multi-line Edit Field Actions

Action	Shortcut Keys
Add String	INSERT
Rename String	F2
Delete String	DELETE
Move Up	UP ARROW
Move Down	DOWN ARROW

Click OK when you are finished entering a line for each null-delimited string. The strings are automatically concatenated.

Note • *Strings that contain only spaces are allowed, but strings cannot be empty or "[~]", which is the separator for the strings as they are stored in the project and displayed in the Destination computer's registry data pane. This separator is not included when the registry value is created on the target system.*

Select how you want to modify the registry value

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

For Windows Installer–based projects, you can choose from the following options to indicate where you want to add the value.

Table 12-37 • Options for Modifying the Registry Value

Option	Description
Append	Add to the end of the existing registry value string.
Prepend	Add to the front of the existing registry value string.
Replace	Replace the existing registry value string.

New Dependency Dialog Box

The New Dependency dialog box opens when you click the Add or Modify button on the Dependencies tab of the InstallShield Prerequisite Editor. This dialog box lets you specify other InstallShield prerequisites (.prq files) on which this prerequisite depends.

Table 12-38 • New Dependency Dialog Box Options

Dialog Option	Description
File	Type the path and name of the .prq file that is required for the current InstallShield prerequisite. To find the .prq file by browsing, click the ellipsis (...) button. InstallShield prerequisite files are stored in the following location by default: *InstallShield Program Files Folder*\SetupPrerequisites For more information about the locations where InstallShield prerequisites are stored, see Specifying the Directories that Contain InstallShield Prerequisites.

New File Dialog Box

The New File dialog box opens when you click the Add button on the Files to Include tab of the InstallShield Prerequisite Editor. This dialog box lets you specify a file for your InstallShield prerequisite.

Table 12-39 • New File Dialog Box Options

Option	Description
File	Type the path and name of the file. To find the file by browsing, click the ellipsis (...) button.
URL to file	If end users should be able to download the file from the Web, specify the uniform resource locator (URL) in this box. This URL is the same one that InstallShield uses when installation authors use the Redistributables view to download an InstallShield prerequisite from the Internet to their local machines. For example, if the URL for the file is http://www.mywebsite.com/Folder1/Notepad.exe, enter the following in this box: http://www.mywebsite.com/Folder1

New Project Dialog Box

This dialog box is displayed when you create a new project in InstallShield. In the dialog box, you can select a project type, name your project, and provide a location for the project's files. After you select a project type and click OK, your project opens in InstallShield.

Project • *If you select an installation project such as InstallScript, Basic MSI, or InstallScript MSI, the Project Assistant launches to help you create your project.*

Dialog Box Tabs

Table 12-40 • New Project Dialog Box Tabs

Tab	Description
Common	This tab displays some of the most-often-used project types.
InstallScript	This tab displays all of the project types that use the InstallShield installation engine, including the InstallScript installation project. If you previously used InstallShield Professional, you will be familiar with these project types.
Windows Installer	This tab includes projects that use the Microsoft Windows Installer engine, including the Basic MSI installation project.
All Types	This tab displays all of the project types available in InstallShield. It also includes any project templates that you previously saved, as well as any templates that are available in your repository.

Dialog Box Options

Table 12-41 • New Project Dialog Box Options

Option	Description
Project Name	Type a name for your project in this box.  ***Project*** • *When you create a Merge Module project, the name that you specify in this box should have 35 characters or fewer. This is because the name that you enter is used with the GUID in the ModuleID field of the* ***ModuleSignature*** *table of your object or module file, and the limit for the name portion of the ModuleID field is a maximum of 35 characters.* *When you create a DIM project, the name that you specify in this box should have 35 characters or fewer.*
Project Language	Select the language that should be used for your installation project.
Location	Type a location or click Browse to navigate to a project location. To change the default project location displayed, change the Project Location path, which is specified on the File Locations tab of the Options dialog box.
Create the project in Project Name subfolder	Select this check box if you want InstallShield to create a subfolder with your project's name in your Projects location.

Operating Systems Dialog Box

This dialog lets you specify the operating systems with which a component (in an InstallScript MSI project) is associated.

Dialog Options

Operating Systems

Select the operating systems on which the component should be installed. Leaving all operating systems unselected causes the component to be installed regardless of the target operating system.

Options Dialog Box

The Options dialog box enables you to specify preferences for creating projects and working in InstallShield.

Task: ***To access the Options dialog box:***

On the **Tools** menu, click **Options**.

The Options dialog box is organized into multiple task-related tabs:

- General tab
- File Locations tab
- Path Variables tab
- User Interface tab
- Preferences tab
- Updates tab
- Application Manager tab
- .NET tab
- Files View tab
- File Extensions tab
- Prerequisites tab
- Source Control tab
- Directory tab
- Resource tab
- Validation tab
- Repository tab
- SQL Scripts tab

- Merge Modules tab
- Quality tab
- Configure Trialware tab

General Tab

The General tab on the Options dialog box enables you to set general project options.

Table 12-42 • General Tab Settings

Setting	Project Types	Description
Enforce Setup Best Practices	Basic MSI, InstallScript MSI	Select this check box to indicate that you want InstallShield to monitor your installation design to help you comply with Setup Best Practices.
Help window on top	All	Select this check box to have the help window remain on top of the InstallShield interface. If you want the help window to fall to the background when focus is given to InstallShield, clear this check box.
Stop build process when first error is encountered	Basic MSI, InstallScript, InstallScript MSI	Select this check box to abort the build process when a build error occurs.
Automatically create ISSetAllUsers action	Basic MSI, InstallScript MSI	Select this check box to add the ISSetAllUsers action to your sequences when your project contains one or more records in the Upgrade table.

File Locations Tab

The File Locations tab on the Options dialog box enables you to set the default directories for where your project files are located and where all of your merge modules can be found.

Table 12-43 • File Locations Tab Settings

Setting	Project Type	Description
Project Location	All	The project location becomes your Favorite folder for new installation projects. All of your source and release files, such as your project (.ism) file, installation package (.msi file), and disk image files, are stored in subfolders of your Favorites location, currently [unknown]. You can enter a complete path or click the Browse button to navigate to the folder. By default, your project is stored in the following location: `C:\InstallShield 2013 Projects`  ***Tip*** • *Changing the project location does not move existing folders and files in the previous project location. You must build a release with a new name or manually move the folders to change their location.*
Dialogs Location	Basic MSI	Enter the path where the Dialog Wizard should search for dialogs. Dialogs in this location appear in the list presented in the Dialog Wizard's Dialog Template panel. Separate additional paths with a comma.

Path Variables Tab

The Path Variables tab enables you to set user-level path variables options.

Table 12-44 • Path Variable Tab Settings

Setting	Project Types	Description
Always recommend path variables	Advanced UI, Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, Suite/Advanced UI	Select this option if you want InstallShield to automatically assign existing path variables to your files. For example, if you are adding a file to your installation project that is stored in your Program Files folder, InstallShield uses <ProgramFilesFolder> rather than a hard-coded path. Select the check box below this option to have InstallShield automatically create a path variable for you. When a new variable is created, it is titled <MYVAR#> (where # is a successive number). You can change the name of this variable in the Path Variables editor.
Don't recommend path variables	Advanced UI, Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, Suite/Advanced UI	Select this option if you want to use hard-coded paths for all of your file links. InstallShield does not suggest path variables for you if this option is selected.
Always display the Path Variable Recommendation dialog to me	Advanced UI, Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module, Suite/Advanced UI	Select this option if you want the Path Variable Recommendation dialog box to be displayed every time you associate a file with your installation project.

User Interface Tab

The User Interface tab on the Options dialog box sets your user interface preferences. These settings are maintained across all projects that you create on this system.

Table 12-45 • User Interface Tab Settings

Setting	Project Type	Description
Always create new components and features	Basic MSI, InstallScript, InstallScript MSI	If you want InstallShield to automatically create components and features when needed, select this check box. If you do not select this check box, InstallShield prompts you to create components and features when necessary.

Table 12-45 • User Interface Tab Settings (cont.)

Setting	Project Type	Description
Always confirm feature, component, and release deletion	Basic MSI, InstallScript, InstallScript MSI	If you want InstallShield to display a confirmation dialog box each time that you delete a feature, component, or release, select this check box.
Always confirm script terminology conversion	Basic MSI, InstallScript, InstallScript MSI	If you want InstallShield to display a confirmation dialog box when you open a project that was created in InstallShield Professional, select this check box. The dialog box asks if you want to convert your script to use the InstallScript lexicon.
Automatically determine best feature or component	Basic MSI, InstallScript, InstallScript MSI	If you want InstallShield to automatically determine the feature or component that should contain the registry data that you configure in the Registry view, select this check box. If this check box is cleared, InstallShield displays a dialog box that you can use to specify the appropriate feature or component name when you create registry data for the All Application data option or a Feature option in the View Filter.
Show Welcome panel for IDE wizards	Basic MSI, InstallScript, InstallScript MSI	If you want InstallShield to display a Welcome panel every time you run a wizard, select this check box.
Warn about Web site deletion	Basic MSI, DIM, InstallScript, InstallScript MSI, Merge Module	If you want InstallShield to display a confirmation dialog box when you delete a Web site in the Internet Information Services view and the Web site contains one or more IIS applications or virtual directories, select this check box. The confirmation dialog box alerts you that the Web site's applications and virtual directories will be deleted from your project if you proceed with deleting the Web site.
Show InstallScript project types	InstallScript	This check box is available in the version of InstallShield that is included with AdminStudio. By default, this check box is cleared. If you want InstallShield to hide the InstallScript and InstallScript MSI project types on the New dialog box, select this check box.

Preferences Tab

The Preferences tab on the Options dialog box sets your program preferences. These settings are maintained across all installation projects you create on this system.

Table 12-46 • Preferences Tab Settings

Setting	Project Type	Description
Self-Registration	Basic MSI, InstallScript MSI	This section enables you to select the self-registration method that InstallShield should use when you indicate that a file is self-registering. Changing this setting applies only to future self-registration settings and does not affect files that were previously designated as self-registering. • **InstallShield Self-Registration Table (ISSelfReg)**—Select this option to use the InstallShield Self-Registration table for all files designated as self registering. • **Windows Installer Self-Registration Table (SelfReg)**—Select this option to use the Windows Installer Self-Registration table for all files designated as self registering. This section also enables you to select the default timing for COM extraction of self-registering files. This is the default setting used if a self-registering file is added via the Files and Folders view or through the Component Wizard. • **COM Extraction will occur during the build**—Select this option to perform extraction during the build. COM information will appear in the build log file. • **COM Extraction will occur immediately when the file is added**—Select this option to extract COM data right after you add a COM file. When you select this option, InstallShield populates the component's COM Registration Advanced Settings view.
Run Commands	Basic MSI, InstallScript MSI	If you want InstallShield to automatically uninstall your product before you debug your installation or before you rerun it by relaunching it from the Build menu, select the **Uninstall the product automatically before installing or debugging** check box.
Referential Integrity	Basic MSI, InstallScript, InstallScript MSI	Select the **Maintain referential integrity** check box if you want InstallShield to automatically maintain referential integrity when you are working in the Direct Editor. For example, the Control table has a Dialog_ column, meaning that the column is a foreign key to the Dialog table. If you rename the key in the Dialog table, the key in the Control table is also renamed. Also, if you delete the entire dialog, all of the controls should be deleted. This is true for any tables with this type of foreign key relationship.

Table 12-46 • Preferences Tab Settings (cont.)

Setting	Project Type	Description
Project Reload	All	Select the **Reload last opened project on startup** check box if you want InstallShield to automatically reload the most recently opened project when you launch InstallShield.

Updates Tab

The Updates tab on the Options dialog box enables you to configure how often FlexNet Connect checks for updates to InstallShield. It also lets you specify whether automatic update notification should be enabled by default for all new projects that you create in InstallShield.

Table 12-47 • Updates Tab Settings

Setting	Project Types	Description
Check for software updates	All	Select an option from this list to indicate how often you want InstallShield to check for software updates. ***Note*** • *In order to configure this option, you must be running InstallShield with administrative privileges. If you do not have administrative privileges, this option is disabled. To learn more, see Launching InstallShield with vs. Without Administrative Privileges.*
Enable automatic update notification in all new projects	Basic MSI, InstallScript MSI	Select this check box if automatic update notification should be enabled in all new projects that you create in InstallShield. You can override this automatic update notification setting for specific projects if necessary. ***Note*** • *FlexNet Connect cannot be used to deploy an upgrade for your installation if FlexNet Connect was not enabled in the original installation.* ***Project*** • *For information on adding FlexNet Connect support to an InstallScript project, consult the Knowledge Base.*

Application Manager Tab

Edition • *This tab is available in the version of InstallShield that is included with AdminStudio.*

The Application Manager tab on the Options dialog box enables you to configure how InstallShield interacts with the AdminStudio Application Manager.

Table 12-48 • Application Manager Tab Settings

Setting	Description
Default Application Catalog	This setting displays the Application Catalog database to which InstallShield connects when you are using the integrated Application Manager functionality in InstallShield. To connect to a different Application Catalog, click the Browse button.
Advanced	To configure additional settings that are related to the Application Manager, click the Advanced setting. For information on any of the individual settings, click the Help button on the advanced settings dialog box.

.NET Tab

The .NET tab on the Options dialog box is where you specify preferences for .NET projects. It is also where you specify the location of the Regasm.exe and InstallUtilLib.dll files, which are utilities that are included with the .NET Framework. These utilities are used for COM interop and .NET custom actions.

Table 12-49 • .NET Tab Settings

Setting	Project Type	Description
Default .NET Scan at Build Component Setting	Basic MSI, InstallScript MSI	In this list, select how the .NET Scan at Build setting should be configured for new components. This applies to components that are automatically created when you add files to your project.

Table 12-49 • .NET Tab Settings (cont.)

Setting	Project Type	Description
.NET Framework File Locations	Basic MSI, InstallScript MSI	`Regasm.exe` and `InstallUtilLib.dll` are utilities that are included with each version of the .NET Framework. Specify the path for the directory that contains the version of these files that you want to use at build time for releases that include .NET installer classes and COM interop. • **32-Bit Location**—Type the path or browse to the location of `Regasm.exe` and `InstallUtilLib.dll`. • **64-Bit Location**—This option is disabled if you are using InstallShield on a 32-bit system. If you are using InstallShield on a 64-bit system, type the path or browse to the location of `Regasm.exe` and `InstallUtilLib.dll`.  ***Note*** • *In order to configure these options, you must be running InstallShield with administrative privileges. If you do not have administrative privileges, these options are disabled. To learn more, see Launching InstallShield with vs. Without Administrative Privileges.*

Files View Tab

In the Files View tab on the Options dialog box, you can select the columns that you want displayed in the several views of InstallShield.

Size

Select this check box to display a Size column in the following areas of InstallShield:

- For Basic MSI, InstallScript, and InstallScript MSI projects—Files and Folders view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Files subview in the Components view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Application Files page of the Project Assistant

Link To

Select this check box to display a Link To column in the following areas of InstallShield:

- For Basic MSI, InstallScript, and InstallScript MSI projects—Files and Folders view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Files subview in the Components view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Application Files page of the Project Assistant

Modified Date

Select this check box to display a Modified column in the following areas of InstallShield:

- For Basic MSI, InstallScript, and InstallScript MSI projects—Files and Folders view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Files subview in the Components view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Application Files page of the Project Assistant

Destination

Select this check box to display a Destination column in Application Files page of the Project Assistant for Basic MSI, InstallScript, and InstallScript MSI projects.

Version

Select this check box to display a Version column in the following areas of InstallShield:

- For Basic MSI, InstallScript, and InstallScript MSI projects—Files and Folders view
- For Basic MSI, InstallScript, and InstallScript MSI projects—Files subview in the Components view

Note • *Selecting the Version check box will slow the performance of the above views.*

File Key

Select this check box to display a Key column in the Files subview of the Components view for Basic MSI and InstallScript MSI projects.

File Extensions Tab

Project • *The File Extensions tab is applicable to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*

The File Extensions tab on the Options dialog box is where you specify preferences for Portable Executable (PE) files. InstallShield refers to this list of PE files on several different occasions. For example:

- When you add a PE file to a folder in the **Destination computer's folders** pane in the Files and Folders view, InstallShield creates a new component for it and sets it as the component's key file.
- When you create components by using the best practice option in the Component Wizard, InstallShield creates a new component for PE files and sets each PE file as the key file of its component.
- When you use the best practice method of component creation for dynamic file links, InstallShield creates at build time a separate component for each PE file in the dynamically linked folder. Each PE file is the key file of its component.

The following setting is available on this tab:

Table 12-50 • File Extensions Tab Settings

Setting	Description
Portable Executable File Extensions	In this box, type the file extensions that you would like InstallShield to consider to be PE files. Separate extensions with a comma. The default entry for this box is the following: `EXE,DLL,OCX,VXD,CHM,HLP,TLB, AX`

Prerequisites Tab

The Prerequisites tab on the Options dialog box enables you to set preferences for InstallShield prerequisites.

Table 12-51 • Prerequisites Tab Settings

Setting	Project Type	Description
Prerequisite File Locations (Current User) and Prerequisite File Locations (All Users)	Basic MSI, InstallScript, InstallScript MSI	Specify the paths for the folders where you store InstallShield prerequisite files (.prq files). To specify more than one location, separate each path with a comma, as in the following example: `C:\Prerequisites,C:\My Files\Prerequisites` Note that you can use path variables in the path, as in the following example: `<ISProductFolder>\SetupPrerequisites,<ISProjectFolder>\MyCustomPrerequisites` The All Users option is available if you want to run a command-line build under a system account for which you cannot easily update the user settings. InstallShield provides additional ways for specifying the folders that contain InstallShield prerequisite files. For more information, see Specifying the Directories that Contain InstallShield Prerequisites.  ***Note*** • *In order to configure the All Users option, you must be running InstallShield with administrative privileges. If you do not have administrative privileges, this option is disabled. To learn more, see Launching InstallShield with vs. Without Administrative Privileges.*

Source Control Tab

Edit the settings on the Source Control tab of the Options dialog box to control how InstallShield interacts with your source code control program. All of the settings on this tab apply to every project the current user opens on this system.

Project *• The following options apply to both Windows Installer–based and InstallScript-based projects unless otherwise noted.*

- ***Use dialog for checkout****—When this check box is selected, a checkout dialog box is displayed when you check out a project through InstallShield. If this check box is cleared, InstallShield automatically checks out the file without a comment when you select the* ***Check out project when edited*** *check box or if, on the Project menu, you point to Source Control and then click Check Out.*
- ***Get latest version when opening the project****—Select this check box to retrieve the latest version of your project from your source control program when you open the project in InstallShield. If you do not get the latest version, you might edit an older version in your working directory—if someone else modified the project file that exists in source control in the interim.*
- ***Check out project when edited****—Select this check box to have InstallShield automatically check your project file out of your source control program whenever you modify it in InstallShield. If your project file is not checked out, it is likely read only and you cannot save changes to it until you check it out.*
- ***Add new projects to source control****—Select this check box if you want new projects automatically added to source control upon creating them in InstallShield.*
- ***Use XML format when creating new Windows Installer-based projects****—When this check box is selected, XML is the default file format for Windows Installer projects that you create using the New Project dialog box. If this check box is cleared, binary is the default file format setting for Windows Installer projects. You can change the project's file format at any time by changing the value for the Project File Format setting in the General Information view.*

Note *• When a project file format is converted to either XML or binary format, the project file extension remains .ism.*

Project *• The* ***Use XML Format when creating new Windows Installer-based projects*** *option applies only to Windows Installer–based projects.*

User name

Specify the name you use to log on to the source control project.

Advanced

Click this button to view the source control program's Properties dialog box and make advanced modifications.

Directory Tab

On the Directory tab of the Options dialog box, you can set various design-time directory options for Windows Installer and InstallScript MSI projects.

Table 12-52 • Directory Tab Settings

Setting	Project Type	Description
Show INSTALLDIR	Basic MSI, InstallScript MSI	Select this check box to display INSTALLDIR as a predefined folder at the root level of the folder structure. If the check box not cleared, INSTALLDIR appears in its location relative to other folders. In the Files and Folders view, it appears as a subfolder beneath the ProgramFilesFolder and the “Your Company Name” folder.
Always show directory nodes with different IDs separately	Basic MSI, InstallScript MSI	In the Files and Folders view, the default behavior for displaying two directory identifiers with the same path is to display them as a single directory. To show different directory identifiers with the same path as two separate directories in the Files and Folders view, select this check box.
Clean up unused directories	Basic MSI, InstallScript MSI	Select this check box to remove unused user-defined directories from your installation project. For example, if you set a component’s destination to {MYDIR}[INSTALLDIR]MYDIR1 and subsequently change the destination to [INSTALLDIR], MYDIR1 is automatically deleted from your project if it is not used elsewhere in your project.

Resource Tab

On the Resource tab of the Options dialog box, you can specify the location of the resource compiler and resource linker programs on your system. These programs are required in order to display modified dialogs in an InstallScript MSI installation project

These fields are automatically populated with the default file locations and command-line options for each program, but you can edit them if necessary.

Table 12-53 • Resource Tab Settings

Setting	Project Type	Description
Resource Compiler Settings	Basic MSI, InstallScript, InstallScript MSI	In this section, you can specify the location of a resource compiler and provide command line options. • **Resource compiler location**—The default resource compiler (`rc.exe`) location appears in this field. To edit the resource compiler location, type or browse to the location of a resource compiler that is currently installed on your system. • **Resource compiler command line options**—To edit the resource compiler command line options, type over the existing command line options in the field. The default command line option string is /r "%1".
Resource Linker Settings	Basic MSI, InstallScript, InstallScript MSI	In this section, you can specify the location of a resource linker and provide command line options. • **Resource linker location**—The default resource linker (`link.exe`) location appears in this field. To edit the resource linker location, type or browse to the location of a resource linker that is currently installed on your system. • **Resource linker command line option**—To edit the resource linker command line options, type over the existing command line options in the field. The default command line option string is "%1" /DLL /NOENTRY /NODEFAULTLIB /MACHINE:iX86 /OUT:"%2".

Validation Tab

On the Validation tab of the Options dialog box, you can specify the type of validation you want InstallShield to perform after a successful build.

Table 12-54 • Validation Tab Settings

Setting	Project Type	Description
Perform Patching & Upgrading validation	Basic MSI, InstallScript MSI	Select this check box to perform validation on both patches and upgrades.

Table 12-54 • Validation Tab Settings (cont.)

Setting	Project Type	Description
Perform validation using	Basic MSI, InstallScript MSI	To perform validation every time that you build an installation project, select this check box and then select the check box of one or more validation suites. You can also browse for a new validation module (.cub file).
Perform merge module validation using	Merge Module	To perform validation every time that you build a merge module, select this check box and then select the check box of one or more validation suites. You can also browse for a new validation module (.cub file).

Click the Customize button to specify which internal consistency evaluators (ICEs) should be used for a specific validation suite. For more information, see Specifying Which ICEs, ISICEs, ISVICEs and ISBPs Should Be Run During Validation.

Repository Tab

Edition • *The boxes on the Repository tab are available in the Premier edition of InstallShield only.*

If you want to set up a network repository or change its location, name, or description, you can do so through the Repository tab on the Options dialog box.

Table 12-55 • Repository Tab Settings

Setting	Description
Network Repository XML File	This is the path and file name of the .xml file that InstallShield creates for the network repository. InstallShield also automatically creates subfolders in the same directory as the .xml file; these subfolders contain items that are published to the network repository.
Name	This is the name of the network repository.
Description	This is a description of the network repository.

SQL Scripts Tab

Project • *This information applies to the following project types:*

- *Basic MSI*

- *DIM*
- *InstallScript MSI*

On the SQL Scripts tab of the Options dialog box, you can set one option for SQL script support.

Table 12-56 • SQL Script Tab Settings

Setting	Description
Generate unique Windows Installer properties for new connections	To share Windows Installer properties between any new database connections that you add to your project, clear this check box. To use different Windows Installer properties for any new connections that you add, select this check box. This check box is cleared by default. For more information, see Specifying Whether New SQL Connections Should Share the Same Windows Installer Properties.

Merge Modules Tab

The Merge Modules tab on the Options dialog box enables you to set preferences for merge modules and merge module projects.

Table 12-57 • Merge Module Tab Settings

Setting	Project Type	Description
Merge Module Locations (Current User) and Merge Module Locations (All Users)	Basic MSI, InstallScript, InstallScript MSI	Enter the paths where you store merge modules (.msm files). Separate additional paths with a comma, as in the following example: `C:\MergeModules,C:\My Files\MergeModules` Note that you can use path variables in the path, as in the following example: `<ISProductFolder>\Modules\i386,<ISProjectFolder>\MyCustomModules` You can also use environment variables in the path. The All Users option is available if you want to run a command-line build under a system account for which you cannot easily update the user settings. The first path that you list is where InstallShield should copy a merge module after it is built. The file is copied only if you select **Copy to Modules folder** in the Merge Module Options panel of the Release Wizard, if you select the **Copy to Merge Modules folder** option in the Publish Merge Module setting on the Events tab in the Releases view, or if you run `ISCmdBld.exe` with the `-e` command-line option. InstallShield creates the folder if it does not exist. InstallShield provides additional ways for specifying the folders that contain merge modules. For more information, see Specifying the Directories that Contain Merge Modules.  ***Note*** • *In order to configure the All Users option, you must be running InstallShield with administrative privileges. If you do not have administrative privileges, this option is disabled. To learn more, see Launching InstallShield with vs. Without Administrative Privileges.*

Table 12-57 • Merge Module Tab Settings (cont.)

Setting	Project Type	Description
Merge Module File Search Behavior	Basic MSI, InstallScript MSI	When you add a file to your project via the Best Practices Component Wizard or the Files view (with Best Practices active), InstallShield searches the merge modules to see if there is a module that contains that file and notifies you of any matches. In this section, you can select options that InstallShield uses to determine whether the files match.

Quality Tab

The Quality tab on the Options dialog box provides the option to join the Customer Experience Improvement Program, which works on improving the quality, reliability, and improvement of software and services from Flexera Software.

Participation is not mandatory, but Flexera Software appreciates your input.

Configure Trialware Tab

Edition • *Trialware functionality is available in the Premier edition of InstallShield.*

The Configure Trialware tab enables you to set default values for the user name and the corresponding password that you want to use on the Configure Trialware Credentials panel of the Acquire New License Wizard.

Table 12-58 • Project-specific Settings

Setting	Project Type	Description
InstallShield user name	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Type the user name that you use to log on to the InstallShield Activation Service Publisher Web Site. Your user account must have write access to the licensing part of the Web site. To obtain a new user name or to retrieve your password, visit the InstallShield Activation Service Publisher Web Site
Password	Basic MSI, InstallScript, InstallScript MSI, InstallScript Object, Merge Module	Type the password for your user name. The password is encrypted.

Other IIS Properties Dialog Box

When you select a Web site, application, or virtual directory in the Internet Information Services view, InstallShield displays a grid that contains many settings. The Other IIS Properties dialog box opens when you click the ellipsis button (...) in the Other IIS Properties setting in the Advanced area of the grid. This dialog box is where you specify values for IIS settings that are not displayed in the other areas of this view.

To customize the value of a property, click the property name, and then click the Change Value button. The Edit ISIISMetaData Value dialog box opens, enabling you to set the value as needed.

Note • *The other IIS property settings apply to IIS 6 and earlier. IIS 7 ignores these settings.*

For help on specific settings, see “Metabase Property Reference” on the MSDN Web site.

Other Window Styles Dialog Box

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The Other Window Styles dialog box provides additional window style options for the dialog or control that is in the Dialogs view. This dialog box opens when you click the ellipsis button (...) in the Other Window Styles setting. The Other Window Styles setting is displayed when you click a dialog or a certain type of control in the Dialogs view.

The options that are available depend on the type of dialog control that is active when you open the Other Windows Style dialog box.

- Dialogs
- Bitmap, icon, and text area controls
- Button controls (check box, radio button group, push button, and group box)
- Combo box controls
- List view controls
- Edit field and list box controls
- Line controls
- Progress bar controls
- Selection tree controls

For more information about the values, refer to the MSDN Library.

Other Window Styles for Dialogs

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for a dialog. For additional information, see the MSDN Library.

Table 12-59 • Window Styles for Dialogs

Value	Description
WS_POPUP	Creates a pop-up window.
DS_NOIDLEMSG	Suppresses WM_ENTERIDLE messages that the system sends to the owner of a dialog box while the dialog box is displayed.
DS_CONTROL	Creates a dialog box that can function as a child window of another dialog box. This allows the user to tab among the control windows of a child dialog box and use its accelerator keys.
DS_SYSMODAL	This style is obsolete and is included for compatibility with 16-bit versions of Windows. If you specify this style, the system creates the dialog box with the WS_EX_TOPMOST style. This style does not prevent the user from accessing other windows on the desktop. Do not combine with the DS_CONTROL style.
DS_3DLOOK	Displays text in the dialog box in non-bold font and draws three-dimensional borders around control windows in the dialog box.
DS_CENTER	Centers the dialog box in the working area of the end user's screen.
DS_LOCALEDIT	Specifies that edit controls in the dialog box use memory in the applications data section. By default, all edit controls in dialog boxes use memory outside the applications data section.
DS_FIXEDSYS	Causes the dialog box to use the SYSTEM_FIXED_FONT instead of the default SYSTEM_FONT. This is a monospaced font compatible with the System font in 16-bit versions of Windows operating systems earlier than 3.0.
DS_CENTERMOUSE	Centers the cursor in the dialog box.

Table 12-59 • Window Styles for Dialogs (cont.)

Value	Description
DS_SETFONT	Indicates that the header of the dialog box template contains additional data specifying the font to use for text in the client area and controls of the dialog box. The font data begins on the WORD boundary that follows the title array. It specifies a 16-bit point size value and a Unicode font name string. If this style is not specified, the dialog box template does not include the font data.
DS_ABSALIGN	Indicates that the coordinates of the dialog box are screen coordinates.
DS_CONTEXTHELP	Displays a question mark in the title bar of the dialog box. When the end user clicks the question mark, the cursor changes to a question mark with a pointer. If the end user then clicks a control in the dialog box, the control receives a WM_HELP message. The control should pass the message to the dialog box procedure. The help application displays a pop-up window that typically contains help for the control. DS_CONTEXTHELP is only a placeholder. When the dialog box is created, the system checks for DS_CONTEXTHELP and—if it is there—adds WS_EX_CONTEXTHELP to the extended style of the dialog box. WS_EX_CONTEXTHELP cannot be used with the WS_MAXIMIZEBOX or WS_MINIMIZEBOX styles.
DS_MODALFRAME	Creates a dialog box with a modal dialog box frame that can be combined with a title bar and window menu by specifying the WS_CAPTION and WS_SYSMENU styles.
DS_NOFAILCREATE	Creates the dialog box even if errors occur—for example, if a child window cannot be created or if the system cannot create a special data segment for an edit control.
DS_SETFOREGROUND	Causes the system to use the **SetForegroundWindow** function to bring the dialog box to the foreground.

Other Window Styles for Bitmap, Icon, and Text Area Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for bitmap, icon, and text area controls. For additional information, see the MSDN Library.

Table 12-60 • Window Style Options for Bitmap, Icon, and Text Area Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
SS_CENTERIMAGE	Specifies that, if the bitmap or icon is smaller than the client area of the static control, the rest of the client area is filled with the color of the pixel in the top left corner of the bitmap or icon. If the static control contains a single line of text, the text is centered vertically in the client area of the control.
SS_NOTIFY	Sends the parent window STN_CLICKED, STN_DBLCLK, STN_DISABLE, and STN_ENABLE notification messages when the user clicks or double-clicks the control.
SS_RIGHTJUST	Specifies that the lower right corner of a static control with the SS_BITMAP or SS_ICON style is to remain fixed when the control is resized. Only the top and left sides are adjusted to accommodate a new bitmap or icon.
WS_VSCROLL	Creates a window with a vertical scroll bar.
SS_REALSIZEIMAGE	Prevents a static icon or bitmap control (that is, static controls that have the SS_ICON or SS_BITMAP style) from being resized as it is loaded or drawn. If the icon or bitmap is larger than the destination area, the image is clipped.
SS_ENDELLIPSIS	If the end of a string does not fit in the rectangle, it is truncated and ellipses are added. If a word that is not at the end of the string goes beyond the limits of the rectangle, it is truncated without ellipses. Compare with SS_PATHELLIPSIS and SS_WORDELLIPSIS.  ***Note*** • *SS_ENDELLIPSIS, SS_PATHELLIPSIS, and SS_WORDELLIPSIS are mutually exclusive.*
SS_PATHELLIPSIS	Replaces characters in the middle of the string with ellipses so that the result fits in the specified rectangle. If the string contains backslash (\) characters, SS_PATHELLIPSIS preserves as much as possible of the text after the last backslash. Compare with SS_ENDELLIPSIS and SS_WORDELLIPSIS.  ***Note*** • *SS_ENDELLIPSIS, SS_PATHELLIPSIS, and SS_WORDELLIPSIS are mutually exclusive.*

Table 12-60 • Window Style Options for Bitmap, Icon, and Text Area Controls (cont.)

Value	Description
SS_WORDELLIPSIS	Truncates any word that does not fit in the rectangle and adds ellipses. Compare with SS_ENDELLIPSIS and SS_PATHELLIPSIS. ***Note*** • *SS_ENDELLIPSIS, SS_PATHELLIPSIS, and SS_WORDELLIPSIS are mutually exclusive.*

Other Window Styles for Button Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for button controls (check box, radio button group, push button, and group box controls). For additional information, see the MSDN Library.

Table 12-61 • Window Styles for Button Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
BS_LEFTTEXT	Places text on the left side of the radio button or check box when combined with a radio button or check box style.
BS_CENTER	Centers text horizontally in the button rectangle.
BS_BOTTOM	Places text at the bottom of the button rectangle.
WS_VSCROLL	Creates a window with a vertical scroll bar.
BS_VCENTER	Places text in the middle (vertically) of the button rectangle.
BS_PUSHLIKE	Makes a button—such as a check box, three-state check box, or radio button—look and act like a push button. The button looks raised when it is not pushed or selected, and sunken when it is pushed or checked.
BS_FLAT	Specifies that the button is two-dimensional. It does not use the default shading to create a three-dimensional image.

Table 12-61 • Window Styles for Button Controls (cont.)

Value	Description
BS_NOTIFY	Enables a button to send BN_KILLFOCUS and BN_SETFOCUS notification messages to its parent window. Buttons send the BN_CLICKED notification message regardless of whether it has this style. To get BN_DBLCLK notification messages, the button must have the BS_RADIOBUTTON or BS_OWNERDRAW style.
BS_MULTILINE	Wraps the button text to multiple lines if the text string is too long to fit on a single line in the button rectangle.

Other Window Styles for Push Button Controls

The following values apply only to push button controls. They are mutually exclusive.

Table 12-62 • Window Styles for Push Button Controls

Value	Description
BS_OWNERDRAW	Creates an owner-drawn button. The owner window receives a WM_DRAWITEM message when a visual aspect of the button has changed. Do not combine the BS_OWNERDRAW style with any other button styles.
BS_USERBUTTON	Obsolete, but provided for compatibility with 16-bit versions of Windows. Win32-based applications should use BS_OWNERDRAW instead.

Other Window Styles for Check Box Controls

The following values apply only to check box controls. They are mutually exclusive.

Table 12-63 • Window Styles for Check Box Controls

Value	Description
BS_AUTOCHECKBOX	Creates a button that is the same as a check box, except that the check state automatically toggles between checked and cleared each time the user selects the check box.
BS_3STATE	Creates a button that is the same as a check box, except that the box can be grayed as well as checked or cleared. Use the grayed state to show that the state of the check box is not determined.
BS_AUTO3STATE	Creates a button that is the same as a three-state check box, except that the box changes its state when the user selects it. The state cycles through checked, grayed, and cleared.

Other Window Styles for Combo Box Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for combo box controls. For additional information, see the MSDN Library.

Table 12-64 • Window Styles for Combo Box Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
WS_VSCROLL	Creates a window with a vertical scroll bar.
CBS_SIMPLE	Displays the list box at all times. The current selection in the list box is displayed in the edit control.
CBS_DROPDOWN	Similar to CBS_SIMPLE, except that the list box is not displayed unless the user selects an icon next to the edit control.
CBS_OEMCONVERT	Converts text entered in the combo box edit control from the Windows character set to the OEM character set and then back to the Windows set. This results in proper character conversion when the application calls the **CharToOem** function to convert a Windows string in the combo box to OEM characters. This style is useful for combo boxes that contain file names and applies only to combo boxes created with the CBS_SIMPLE or CBS_DROPDOWN style.
CBS_HASSTRINGS	Specifies that an owner-drawn combo box contains items consisting of strings. The combo box maintains the memory and address for the strings so the application can use the CB_GETLBTEXT message to retrieve the text for a particular item.
CBS_UPPERCASE	Converts to uppercase all text in both the selection field and the list.
CBS_AUTOHSCROLL	Automatically scrolls the text in an edit control to the right when the user types a character at the end of the line. If this style is not set, only text that fits within the rectangular boundary is allowed.

Table 12-64 • Window Styles for Combo Box Controls (cont.)

Value	Description
CBS_DISABLENOSCROLL	Shows a disabled vertical scroll bar in the list box when the box does not contain enough items to scroll. Without this style, the scroll bar is hidden when the list box does not contain enough items.
CBS_NOINTEGRALHEIGHT	Specifies that the size of the combo box is exactly the size specified by the application when it created the combo box. Normally, the system sizes a combo box so that it does not display partial items.
CBS_OWNERDRAWFIXED	Specifies that the owner of the list box is responsible for drawing its contents and that the items in the list box are all the same height. The owner window receives a WM_MEASUREITEM message when the combo box is created and a WM_DRAWITEM message when a visual aspect of the combo box has changed.
CBS_OWNERDRAWVARIABLE	Specifies that the owner of the list box is responsible for drawing its contents and that the items in the list box are variable in height. The owner window receives a WM_MEASUREITEM message for each item in the combo box when you create the combo box and a WM_DRAWITEM message when a visual aspect of the combo box has changed.

Other Window Styles for List View Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for list view controls. For additional information, see the MSDN Library.

Table 12-65 • Window Styles for List View Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
LVS_SINGLESEL	Enables only one item to be selected at a time. By default, multiple items can be selected.

Table 12-65 • Window Styles for List View Controls (cont.)

Value	Description
LVS_NOLABELWRAP	Displays item text on a single line in icon view. By default, item text might wrap in icon view.
LVS_AUTOARRANGE	Specifies that icons automatically remain arranged in icon view and small icon view.
LVS_SHOWSELALWAYS	Always shows the selection highlighted, even if the control is not activated.
LVS_SORTASCENDING	Sorts items based on item text in ascending order.
LVS_SORTDESCENDING	Sorts items based on item text in descending order.
LVS_EDITLABELS	Enables item text to be edited in place. The parent window must process the LVN_ENDLABELEDIT notification message.
LVS_OWNERDATA	Creates a virtual list view control.
LVS_NOSCROLL	Disables scrolling, so all items must be displayed within the client area.
LVS_NOSORTHEADER	Specifies that column headers do not work like buttons. This style is useful if clicking a column header in report view does not carry out any action, such as sorting.
LVS_OWNERDRAWFIXED	Enables the owner window to paint items in report view. The list view control sends a WM_DRAWITEM message to paint each item; it does not send separate messages for each subitem. The itemData member of the DRAWITEMSTRUCT structure contains the item data for the specified list view item.
LVS_NOCOLUMNHEADER	Specifies that no column header is displayed in report view, which is the default view.
LVS_SHAREIMAGELISTS	Specifies that the control does not destroy the image lists assigned to it when it is destroyed. This style enables the same image lists to be used with multiple list view controls.

Types

Note • *The following values are mutually exclusive.*

Table 12-66 • Type Values

Value	Description
LVS_ICON	Specifies icon view.
LVS_REPORT	Specifies report view.
LVS_LIST	Specifies list view.
LVS_SMALLICON	Specifies small icon view.

Align

Note • *The following values are mutually exclusive.*

Table 12-67 • Alignment Values

Value	Description
LVS_ALIGNTOP	Specifies that items are aligned with the top of the list view control in icon view and small icon view.
LVS_ALIGNLEFT	Specifies that items are left-aligned in icon view and small icon view.

Other Window Styles for Edit Field and List Box Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for edit field and list box controls. For additional information, see the MSDN Library.

Table 12-68 • Window Styles for Edit Field and List Box Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
WS_VSCROLL	Creates a window with a vertical scroll bar.
LBS_STANDARD	Creates a bordered list box.
LBS_NOTIFY	The parent window receives an input message whenever the end user clicks or double-clicks a string.
LBS_NODATA	Specifies a no-data list box. Specify this style when the count of items in the list box will exceed one thousand. A no-data list box must also have the LBS_OWNERDRAWFIXED style, but must not have the LBS_SORT or LBS_HASSTRINGS style. A no-data list box resembles an owner-drawn list box except that it contains no string or bitmap data for an item. Commands to add, insert, or delete an item always ignore any specified item data; requests to find a string within the list box always fail. The system sends the WM_DRAWITEM message to the owner window when an item must be drawn. The itemID member of the DRAWITEMSTRUCT structure passed with the WM_DRAWITEM message specifies the line number of the item to be drawn. A no-data list box does not send a WM_DELETEITEM message.
LBS_NOINTEGRALHEIGHT	Creates a list box that is precisely the size specified by the application when it created the list box.
LBS_NOREDRAW	List box is not updated when changes are made.
LBS_MULTIPLESEL	Toggles string selection each time the end user clicks or double-clicks the string.
LBS_HASSTRINGS	Specifies that a list box contains items consisting of strings. The list box maintains the memory and addresses for the strings so that the application can use the LB_GETTEXT message to retrieve the text for a particular item. By default, all list boxes except owner-drawn list boxes have this style. You can create an owner-drawn list box either with or without this style.
LBS_USETABSTOPS	Allows a list box to recognize and expand tab characters when drawing strings.
LBS_MULTICOLUMN	Creates a multicolumn list box that scrolls horizontally.

Table 12-68 • Window Styles for Edit Field and List Box Controls (cont.)

Value	Description
LBS_EXTENDEDSEL	Allows the end user to select multiple items using the SHIFT key and the mouse, or key combinations.
LBS_DISABLENOSCROLL	Displays a disabled vertical scroll bar when the list box does not contain enough items to scroll.
LBS_WANTKEYBOARDINPUT	Passes WM_VKEYTOITEM or WM_CHARTOITEM messages when the end user presses a key while the list box has focus. This allows an application to perform special processing on the keyboard input.
LBS_OWNERDRAWFIXED	Indicates that the owner of the list box is responsible for drawing the list box's contents. Items in the list box are the same height.
LBS_OWNERDRAWVARIABLE	Indicates that the owner of the list box is responsible for drawing the list box's contents. Items in the list box are of variable height.

Other Window Styles for Line Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for line controls. For additional information, see the MSDN Library.

Table 12-69 • Window Styles for Line Controls

Value	Description
SS_SIMPLE	Specifies a simple rectangle and displays a single line of left-aligned text in the rectangle. The text line cannot be shortened or altered in any way. Also, if the control is disabled, the control does not gray its text.
SS_ETCHEDVERT	Draws the left and right edges of the static control using the EDGE_ETCHED edge style. For more information, see the **DrawEdge** Windows API function in the MSDN Library.
SS_ETCHEDFRAME	Draws the frame of the static control using the EDGE_ETCHED edge style. For more information, see the DrawEdge Windows API function in the MSDN Library.

Table 12-69 • Window Styles for Line Controls (cont.)

Value	Description
SS_ETCHEDHORZ	Draws the top and bottom edges of the static control using the EDGE_ETCHED edge style. For more information, see the DrawEdge Windows API function in the MSDN Library.
SS_BLACKRECT	Specifies a rectangle filled with the current window frame color. This color is black in the default color scheme.
SS_BLACKFRAME	Specifies a box with a frame drawn in the same color as the window frames. This color is black in the default color scheme.
SS_WHITERECT	Specifies a rectangle filled with the current window background color. This color is white in the default color scheme.
SS_WHITEFRAME	Specifies a box with a frame drawn with the same color as the window background. This color is white in the default color scheme.
SS_GRAYRECT	Specifies a rectangle filled with the current screen background color. This color is gray in the default color scheme.
SS_GRAYFRAME	Specifies a box with a frame drawn with the same color as the screen background (desktop). This color is gray in the default color scheme.
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
WS_VSCROLL	Creates a window with a vertical scroll bar.
SS_NOTIFY	Sends the parent window STN_CLICKED, STN_DBLCLK, STN_DISABLE, and STN_ENABLE notification messages when the user clicks or double-clicks the control.
SS_RIGHTJUST	Specifies that the lower right corner of a static control with the SS_BITMAP or SS_ICON style is to remain fixed when the control is resized. Only the top and left sides are adjusted to accommodate a new bitmap or icon.
SS_CENTERIMAGE	Specifies that, if the bitmap or icon is smaller than the client area of the static control, the rest of the client area is filled with the color of the pixel in the top left corner of the bitmap or icon. If the static control contains a single line of text, the text is centered vertically in the client area of the control.
SS_REALSIZEIMAGE	Prevents a static icon or bitmap control (that is, static controls that have the SS_ICON or SS_BITMAP style) from being resized as it is loaded or drawn. If the icon or bitmap is larger than the destination area, the image is clipped.

Table 12-69 • Window Styles for Line Controls (cont.)

Value	Description
SS_ENDELLIPSIS	If the end of a string does not fit in the rectangle, it is truncated and ellipses are added. If a word that is not at the end of the string goes beyond the limits of the rectangle, it is truncated without ellipses. Compare with SS_PATHELLIPSIS and SS_WORDELLIPSIS.  ***Note*** • *SS_ENDELLIPSIS, SS_PATHELLIPSIS, and SS_WORDELLIPSIS are mutually exclusive.*
SS_PATHELLIPSIS	Replaces characters in the middle of the string with ellipses so that the result fits in the specified rectangle. If the string contains backslash (\) characters, SS_PATHELLIPSIS preserves as much as possible of the text after the last backslash. Compare with SS_ENDELLIPSIS and SS_WORDELLIPSIS.  ***Note*** • *SS_ENDELLIPSIS, SS_PATHELLIPSIS, and SS_WORDELLIPSIS are mutually exclusive.*
SS_WORDELLIPSIS	Truncates any word that does not fit in the rectangle and adds ellipses. Compare with SS_ENDELLIPSIS and SS_PATHELLIPSIS.  ***Note*** • *SS_ENDELLIPSIS, SS_PATHELLIPSIS, and SS_WORDELLIPSIS are mutually exclusive.*

Other Window Styles for Progress Bar Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for progress bar controls. For additional information, see the MSDN Library.

Table 12-70 • Window Styles for Progress Bar Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.

Table 12-70 • Window Styles for Progress Bar Controls (cont.)

Value	Description
PBS_VERTICAL	The progress bar displays progress status vertically, from bottom to top.

Other Window Styles for Selection Tree Controls

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The following window style options are available for selection tree controls. For additional information, see the MSDN Library.

Table 12-71 • Window Styles for Selection Tree Controls

Value	Description
WS_GROUP	Specifies the first control in a group of controls. All controls defined with this style after the first control belong to the same group.
TVS_EDITLABELS	Enables the user to edit the labels of tree view items.
TVS_HASBUTTONS	Displays plus (+) and minus (-) buttons next to parent items. The user taps the buttons to expand or collapse a parent items list of child items. To include buttons with items at the root of the tree view, you must also specify the TVS_LINESATROOT style.
TVS_DISABLEDRAGDROP	Prevents the tree view control from sending TVN_BEGINDRAG notification messages.
TVS_SHOWSELALWAYS	Uses the system highlight colors to draw the selected item.
TVS_FULLROWSELECT	Enables full-row selection in the tree view. The entire row of the selected item is highlighted, and clicking anywhere on an item's row causes it to be selected. This style cannot be used in conjunction with the TVS_HASLINES style.
TVS_HASLINES	Uses lines to show the hierarchy of items.
TVS_LINESATROOT	Uses lines to link items at the root of the tree view control. This value is ignored if the TVS_HASLINES control is not also specified.

Table 12-71 • Window Styles for Selection Tree Controls (cont.)

Value	Description
TVS_RTLREADING	Causes text to be displayed from right-to-left (RTL). Usually, windows display text left-to-right (LTR). Windows can be mirrored to display languages such as Hebrew or Arabic that read RTL. Typically, tree-view text is displayed in the same direction as the text in its parent window. If TVS_RTLREADING is set, tree-view text reads in the opposite direction from the text in the parent window.
TVS_NOTOOLTIPS	Disables ToolTips.
TVS_CHECKBOXES	Enables items in a tree view control to be displayed as check boxes. This style uses item state images to produce the check box effect.
TVS_TRACKSELECT	Enables hot tracking in a tree-view control.
TVS_SINGLEEXPAND	Causes the item being selected to expand and the item being unselected to collapse upon selection in the tree view. If the mouse is used to single-click the selected item and that item is closed, it will be expanded. If the user holds down the Ctrl key while selecting an item, the item being unselected will not be collapsed.
TVS_INFOTIP	Obtains ToolTip information by sending the TVN_GETINFOTIP notification.
TVS_NOSCROLL	Disables horizontal scrolling in the control. The control will not display any horizontal scroll bars.
TVS_NONEVENHEIGHT	Sets the height of the items to an odd height with the TVM_SETITEMHEIGHT message. By default, the height of items must be an even value.

Outputs Dialog Box

The Outputs dialog displays information about a project output group in the File System Editor. This dialog is available for InstallShield projects created in Microsoft Visual Studio.

Task: ***To access the Outputs dialog, do one of the following:***

1. Select the **Outputs** property in the **Properties** window when a project output group is selected in the **File System Editor**.
2. In the **Files and Folders** view, right-click an item in the **Source computer's files** pane and click **Resolve Project Output**.
3. In the **Files and Folders** view, right-click an item in the **Destination computer's files** pane and click **Resolve Project Output**.

Note • *If multiple project output groups are selected, information is displayed only for the first group selected.*

Dialog Options

Target Name

Displays the file name for the selected project output group as it will be displayed on a target computer. This field is read only.

Source Path

Displays the path to the project output group files on the development computer. This field is read only.

Overwrite Dialog Box

This dialog box lets you specify whether the files of the active component (the component selected in the Setup Design or Components view) overwrite already-existing versions on the target system always, never, or conditionally based on date/time stamp or version number.

Dialog Options

list box

Select whether files on the target system are always overwritten, never overwritten, or conditionally overwritten based on date/time stamp or version number.

The following controls are enabled only if "Overwrite files BY VERSION" or "Overwrite files BY VERSION THEN DATE (if necessary)" is selected in the list *box.*

Note • *If a file on the target system has a version number and the file on your distribution media does not, or vice versa, the file with no version number is treated as if it had a lower version number.*

Version: Newer

A file on the target system is overwritten if the file on your distribution media has a higher version number.

If the file on your distribution media and the file on the target system have the same version number, or if neither file has a version number, and you selected Overwrite files BY VERSION THEN DATE (if necessary) from the list box, then whether the file on the target system is overwritten is determined by which Date/Time option you select.

If neither file has a version number and you selected Overwrite files BY VERSION from the list box, then the file on the target system is not overwritten.

Version: Newer or Same

A file on the target system is overwritten if the file on your distribution media has a higher or the same version number.

If neither file has a version number and you selected Overwrite files BY VERSION THEN DATE (if necessary) from the list box, then whether the file on the target system is overwritten is determined by which Data/Time option you select.

If neither file has a version number and you selected Overwrite files BY VERSION from the list box, then the file on the target system is not overwritten.

Version: Older

A file on the target system is overwritten if the file on your distribution media has a lower version number.

If the file on your distribution media and the file on the target system have the same version number, or if neither file has a version number, and you selected Overwrite files BY VERSION THEN DATE (if necessary) from the list box, then whether the file on the target system is overwritten is determined by which Date/Time option you select.

If neither file has a version number and you selected Overwrite files BY VERSION from the list box, then the file on the target system is not overwritten.

The following controls are enabled only if Overwrite files BY DATE or Overwrite files BY VERSION THEN DATE (if necessary) is selected in the list box.

Date/Time: Newer

A file on the target system is overwritten if the file on your distribution media has a more recent date and time stamp.

Date/Time: Newer or Same

A file on the target system is overwritten if the file on your distribution media has a more recent or the same date and time stamp.

Date/Time: Older

A file on the target system is overwritten if the file on your distribution media has a less recent date and time stamp.

Patch Sequence Dialog Box

The Patch Sequence dialog box opens when you are creating a patch sequence in the Patch Design view.

Table 12-72 • Patch Sequence Dialog Box Options

Option	Description
Family Name	Specify the name of the family of patches to which this patch belongs. Windows Installer 3.0 and later uses the patch family to compare small-update patches with all of the other patches within the same family and determine the order in which each of the patches should be applied to the target machine. To identify that a patch configuration belongs to multiple families, create a separate row on the Sequence tab for every patch family. You may want a patch to belong to multiple families, for example, if the patch can update more than one product.
Target	Type the product code GUID in this box if you want to associate the patch configuration with a specific product. Entry in this box is not required. To identify that a patch configuration should target multiple GUIDs, create a separate row on the Sequence tab for every GUID and family combination.
Sequence Number	Specify the sequence number for the patch configuration. This value indicates the placement of the patch configuration within sequence of patches that belong to the same patch family and the same target GUID (if identified).
Supersede previous versions	If you want the patch to be used instead of all of the patches that have a lower sequence value and that are in the same patch family, select this check box. Selecting this check box does not guarantee that the patch will always supersede all earlier patches, since the earlier patches might belong to multiple patch families. Note that a small-update patch cannot supersede a minor upgrade patch or a major upgrade patch, regardless of whether this check box is selected.

Path Variable Overrides Dialog Box

The Path Variable Overrides dialog box opens when you click the ellipsis button (...) in the Path Variable Overrides setting. The Path Variable Overrides setting is on the Build tab for a release in the Releases view. Use this setting to override one or more path variables in your project at build time for the selected release.

The Path Variable Overrides dialog box shows a check box for the path variables, environment variables, and registry variables that are configured in the Path Variables view. Note that it does not include check boxes for any predefined path variables, or for path variables that are already overridden for the same release in the Releases view.

Select the check box for each path variable that you would like to override. Then click the OK button. Under the Path Variable Overrides setting, InstallShield adds a new setting for each path variable that you selected. Use those settings to specify the new values for the path variables.

At build time, InstallShield overrides the values that are set in the Path Variables view with the values that are configured for the release in the Releases view.

Path Variable Recommendation Dialog Box

If you have selected the **Always display the Path Variable Recommendation dialog to me** option on the Path Variables tab of the Options dialog box, InstallShield displays the Path Variable Recommendation dialog box every time you associate a new source folder with your installation project.

The dialog box is also displayed if you selected the **Always recommend path variables** option on the Path Variables tab of the Options dialog box and one of the following is true:

- InstallShield can recommend more than one path variable for a particular source folder.
- InstallShield cannot recommend a path variable based on an existing path variable and you have not selected the auto-create check box on the Path Variables tab.

Dialog Options

Use the following path variable-based folder representation for the source folder

This option provides suggested path variables or path variable combinations for you to use instead of an absolute path. For example, if you have a path variable called <MyFiles> that points to `C:\Work\Files` and you add a file to your installation from `C:\Work\Files\Images`, it is recommended that you use `<MyFiles>\Images` rather than the full hard-coded path `C:\Work\Files\Images`.

This option is available only if InstallShield can recommend a path variable for the source folder.

Create a new path variable

To create a path variable for the source folder in which your files are located, select the Create a new path variable option. Selecting this option creates a standard path variable that is mapped to the folder in which your new files are located. Enter the new variable path name in the Path Variable Name box.

Caution *• Do not enclose the path variable's name in angle brackets. InstallShield automatically adds the angle brackets when you click OK.*

Use the following absolute path

If you do not want to use a path variable to represent a particular link, select the **Use the following absolute path** option. The absolute path to your source folder appears below this button.

Permissions Dialog Boxes for Files and Directories

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Permissions Dialog Box

The Permissions dialog box lets you configure settings for securing files and folders for end users who run your product in a locked-down environment. You can assign permissions for a file or folder to specific groups and users. For example, you may assign Read, Write, and Delete permissions for a particular file to the Administrators group, but only Read permissions for all of the users in a different group.

Depending on what is selected for the Locked-Down Permissions setting in the General Information view of your project, InstallShield adds permissions data to either the **ISLockPermissions** table or the **LockPermissions** table. To learn more, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.

The following table describes the different areas on the Permissions dialog box.

Table 12-73 • Areas of the Permissions Dialog Box

Area	Description
Name(s)	In this grid, you can enter any combination of domain and user names. To add an entry, right-click the grid and click New. You can modify or delete entries using the same context menu. To specify the current user's domain, select `[%USERDOMAIN]` in the Domain field. To specify the user that is currently running the installation, select `[LogonUser]` in the User field. To set permissions for user accounts on a local system, leave the Domain field blank. Note that you can enter in the Domain or User fields any Windows Installer property that is set at run time—for example, `[MYPROPERTY]`. If the custom InstallShield handling option is selected for the Locked-Down Permissions setting in the General Information view, the User field contains a list of well-known security identifiers (SIDs). Most of the SIDs are not supported by the traditional Windows Installer handling option. The custom InstallShield handling option supports localized names for all of the SIDs that are listed in the User field. With the traditional option, if you try to use a localized name to set permissions on a non-English system, the installation may fail.  ***Tip*** • *For more information on the custom InstallShield handling option and the traditional Windows Installer handling option, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.*
Permissions	Select a name in the Name(s) area, and then select or clear the check boxes in the Permissions box to configure the corresponding permissions for the file or folder. Once you have selected a permission, you can click the Advanced button to specify other associated permissions and advanced settings.
Deny Access	If you want to explicitly deny the permissions that you are selecting in the Permissions box, select this check box. This check box is available only if the custom InstallShield handling option is selected for the Locked-Down Permissions setting in the General Information view. The traditional Windows Installer handling option does not include support for this behavior.  ***Tip*** • *For more information on the custom InstallShield handling option and the traditional Windows Installer handling option, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.*

Advanced Permissions Dialog Box

If you click the Advanced button on the Permissions dialog box, the Advanced Permissions dialog box opens. The following table describes the different areas on the Advanced Permissions dialog box.

Table 12-74 • Areas of the Advanced Permissions Dialog Box

Area	Description
Advanced Permissions	In this box, select the check boxes for the permissions that you want to set.
Apply these permissions to child objects	If you are configuring permissions for a folder and you want the permissions to be applied to all of the folder's subfolders and files, select this check box. This check box is available only if the custom InstallShield handling option is selected for the Locked-Down Permissions setting in the General Information view. The traditional Windows Installer handling option does not include support for this behavior. ***Tip*** • *For more information on the custom InstallShield handling option and the traditional Windows Installer handling option, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.*

Permissions Dialog Boxes for Registry Keys

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

Permissions Dialog Box

The Permissions dialog box lets you configure settings for securing registry keys for end users who run your product in a locked-down environment. You can assign permissions for a registry key to specific groups and users. For example, you may assign Read, Write, and Delete permissions for a particular registry key to the Administrators group, but only Read permissions for all of the users in a different group.

Depending on what is selected for the Locked-Down Permissions setting in the General Information view of your project, InstallShield adds permissions data to either the **ISLockPermissions** table or the **LockPermissions** table. To learn more, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.

The following table describes the different areas on the Permissions dialog box.

Table 12-75 • Areas of the Permissions Dialog Box

Area	Description
Name(s)	In this grid, you can enter any combination of domain and user names. To add an entry, right-click the grid and click New. You can modify or delete entries using the same context menu. To specify the current user's domain, select `[%USERDOMAIN]` in the Domain field. To specify the user that is currently running the installation, select `[LogonUser]` in the User field. To set permissions for user accounts on a local system, leave the Domain field blank. Note that you can enter in the Domain or User fields any Windows Installer property that is set at run time—for example, `[MYPROPERTY]`. If the custom InstallShield handling option is selected for the Locked-Down Permissions setting in the General Information view, the User field contains a list of well-known security identifiers (SIDs). Most of the SIDs are not supported by the traditional Windows Installer handling option. The custom InstallShield handling option supports localized names for all of the SIDs that are listed in the User field. With the traditional option, if you try to use a localized name to set permissions on a non-English system, the installation may fail.  ***Tip*** • *For more information on the custom InstallShield handling option and the traditional Windows Installer handling option, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.*
Permissions	Select a name in the Name(s) area, and then select or clear the check boxes in the Permissions box to configure the corresponding permissions for the registry key. Once you have selected a permission, you can click the Advanced button to specify other associated permissions and advanced settings.

Table 12-75 • Areas of the Permissions Dialog Box (cont.)

Area	Description
Deny Access	If you want to explicitly deny the permissions that you are selecting in the Permissions box, select this check box. This check box is available only if the custom InstallShield handling option is selected for the Locked-Down Permissions setting in the General Information view. The traditional Windows Installer handling option does not include support for this behavior.  ***Tip*** • *For more information on the custom InstallShield handling option and the traditional Windows Installer handling option, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.*

Advanced Permissions Dialog Box

If you click the Advanced button on the Permissions dialog box, the Advanced Permissions dialog box opens. The following table describes the different areas on the Advanced Permissions dialog box.

Table 12-76 • Areas of the Advanced Permissions Dialog Box

Area	Description
Advanced Permissions	In this box, select the check boxes for the permissions that you want to set.
Apply these permissions to child objects	If you are configuring permissions for a registry key and you want the permissions to be applied to all of the key's subkey, select this check box. This check box is available only if the custom InstallShield handling option is selected for the Locked-Down Permissions setting in the General Information view. The traditional Windows Installer handling option does not include support for this behavior.  ***Tip*** • *For more information on the custom InstallShield handling option and the traditional Windows Installer handling option, see Securing Files, Folders, Registry Keys, and Windows Services in a Locked-Down Environment.*

Platform Suites Dialog Box

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The Platform Suites dialog box lets you specify the platform suites with which the selected component is associated. To access this dialog box, click the ellipsis button (...) in the Platform Suite(s) setting for a component in the Components view or the Setup Design view.

Table 12-77 • Platform Suites Dialog Box Settings

Setting	Description
Install without performing platform suite verification on the target system	The installation of the component's files does not depend on the target system's suite.
Install when the target system has one or more of the specified platform suite(s)	The installation installs the component's files only if at least one of the selected suites exists on the target system. If you select this option, select the check boxes of the appropriate platform suites.
Install only when the target system has all the specified platform suite(s)	The installation installs the component's files only if all of the selected suites exist on the target system. If you select this option, select the check boxes of the appropriate platform suites.
Show all platform suites	To see all of the available suites, select this check box. The full list are those that can be specified in the Windows API's OSVERSIONINFOEX data structure (as documented on MSDN). To see only the most common suites, clear this check box.

Platforms Dialog Box

Project • *Some of this information applies to InstallScript projects, and some of this information applies to InstallScript MSI projects.*

Depending on how you launch the Platforms dialog box, you can specify either of the following:

- The platforms that you want to be available when you to select operating system requirements for components or releases in your project. This is available for InstallScript projects.
- The platform requirements for a component. This is available for InstallScript and InstallScript MSI projects.

Platform Support at the Project Level (InstallScript Projects)

If you access the Platforms dialog box at the project level, you can specify the platforms that you want to be available when you to select operating system requirements for components or releases in your project.

Note • *Specifying platforms at the project level does not create target system requirements for running the installation. To create target system requirements in an InstallScript project, you can use the SYSINFO structure to identify the operating platform of the target system.*

Task: ***To access the Platforms dialog box at the project level:***

1. In the View List under **Installation Information**, click **General Information**.
2. In the **Platform Filtering** setting, click the ellipsis button (**...**).

The following table shows the settings that are displayed on the Platforms dialog box when you are accessing it at the project level.

Table 12-78 • Platforms Dialog Box Settings for a Project

Setting	Description
The project supports all platforms that InstallShield supports	Select this option if you want InstallShield to list all of the supported run-time platforms for the following settings: • Operating Systems setting at the component level (InstallScript and InstallScript MSI projects) • Platform(s) setting at the release level (InstallScript projects) If you select this option, you can designate that a particular component or release in your project is targeted for any one or more supported platforms.

Table 12-78 • Platforms Dialog Box Settings for a Project (cont.)

Setting	Description
The project supports only the platforms that are selected below	Select this option if you want InstallShield to list only some platforms that are displayed for the following settings: • Operating Systems setting at the component level (InstallScript and InstallScript MSI projects) • Platform(s) setting at the release level (InstallScript projects) Then select the platforms that should be displayed.  ***Tip*** • *To select multiple consecutive operating systems, select the first file, press and hold SHIFT, and select the last operating systems. To select multiple nonconsecutive operating systems, select the first operating systems, press and hold CTRL, and select each additional operating systems.* In general, if a platform is not listed for this setting at the project level, you cannot designate that a particular component or release in your project is targeted for that platform.

Platform Support at the Component Level (InstallScript and InstallScript MSI Projects)

If you access the Platforms dialog box at the component level, you can specify which platforms are supported by the selected component.

Task: ***To access the Platforms dialog box at the component level:***

1. In the View List under **Organization**, click **Components**.
2. In the **Components** explorer, click the component whose platform requirements you want to configure.
3. Click the value of the **Operating Systems** setting, and then click the ellipsis button (**...**).

The following table shows the settings that are displayed on the Platforms dialog box when you are accessing it at the component level.

Table 12-79 • Platforms Dialog Box Settings for a Component

Setting	Description
The files in this component should be installed when the setup is running on any platform	If the selected component is operating system independent—that is, if none of the component's data are specific to certain operating systems—select this option.

Table 12-79 • Platforms Dialog Box Settings for a Component (cont.)

Setting	Description
The files in this component should be installed only when the setup is running on one of the platforms checked below	If the selected component is specific to one or more operating systems, select this option and then select the appropriate operating systems. If the target machine's operating system does not match one of the operating systems that are specified for this setting, the component is not installed. ***Tip*** • *To select multiple consecutive operating systems, select the first file, press and hold SHIFT, and select the last operating systems. To select multiple nonconsecutive operating systems, select the first operating systems, press and hold CTRL, and select each additional operating systems.* ***Project*** • *For InstallScript projects, the list of operating systems that are displayed in this dialog box excludes any of the operating systems whose check box is cleared at the project level.* *Note that if the selected component supports platforms that are not supported by a release, InstallShield does not include the component in the release at build time.*

Postbuild Event Dialog Box

Edition • *This information applies to the Premier edition of InstallShield.*

The Postbuild Event dialog box opens when you click the ellipsis button (...) in the Postbuild Event setting. The Postbuild Event setting is on the Events tab for a release in the Releases view.

Use the Postbuild Event dialog box to specify one or more commands that you want to be run after InstallShield has built and signed the release.

To specify more than one command, enter each command on a separate line. At build time, InstallShield runs each command in the order that they are listed. The build waits until a command finishes before proceeding to the next one.

When you are entering a command, you can use any path variables and environment variables that are defined in your project, instead of using a hard-coded path. You can also use certain variables that are defined specifically for build event commands.

For more information, see Specifying Commands that Run Before, During, and After Builds.

Prebuild Event Dialog Box

Edition • *This information applies to the Premier edition of InstallShield.*

The Prebuild Event dialog box opens when you click the ellipsis button (...) in the Prebuild Event setting. The Prebuild Event setting is on the Events tab for a release in the Releases view.

Use the Prebuild Event dialog box to specify one or more commands that you want to be run before InstallShield starts building the release. This event runs after InstallShield creates the release folder and log file, but before InstallShield starts building the release.

To specify more than one command, enter each command on a separate line. At build time, InstallShield runs each command in the order that they are listed. The build waits until a command finishes before proceeding to the next one.

When you are entering a command, you can use any path variables and environment variables that are defined in your project, instead of using a hard-coded path. You can also use certain variables that are defined specifically for build event commands.

For more information, see Specifying Commands that Run Before, During, and After Builds.

Precompression Event Dialog Box

Edition • *This information applies to the Premier edition of InstallShield.*

The Precompression Event dialog box opens when you click the ellipsis button (...) in the Precompression Event setting. The Precompression Event setting is on the Events tab for a release in the Releases view.

Use the Precompression Event dialog box to specify one or more commands that you want to be run after InstallShield has built the .msi package and the .cab files (if your product's data files are to be stored in .cab files). Note that this event occurs after .cab files are streamed into the .msi package, but before the .msi package has been digitally signed and streamed into the `Setup.exe` file.

To specify more than one command, enter each command on a separate line. At build time, InstallShield runs each command in the order that they are listed. The build waits until a command finishes before proceeding to the next one.

When you are entering a command, you can use any path variables and environment variables that are defined in your project, instead of using a hard-coded path. You can also use certain variables that are defined specifically for build event commands.

For more information, see Specifying Commands that Run Before, During, and After Builds.

Prerequisite Condition Dialog Box

The Prerequisite Condition dialog box opens when you click the Add button on the Conditions tab of the InstallShield Prerequisite Editor. It also opens when you select an existing condition on this tab and then click the Modify button.

The Prerequisite Condition dialog box lets you define installation conditions that determine whether an InstallShield prerequisite is already installed on the target machine. Failure to do so causes problems because the target system behaves as if the prerequisite was not properly installed. You can also create installation conditions that specify operating system, registry, or file requirements.

Table 12-80 • Prerequisite Condition Dialog Box Options

Option	Description
A registry key does or does not exist	If you select this option, type the name of the registry key and select the appropriate option for 64-bit machines. If target machines that have this registry key should meet this installation condition, select **If the specified registry key exists**. If target machines that do not have this registry key should meet this installation condition, select **If the specified registry key does not exist**.
A registry entry has a specified value	If you select this option, type the name of the registry key, the name of the value, and the value data. Also, select the appropriate option for 64-bit machines. In addition, select the option that should be used to compare the registry entry specified in this dialog box with the registry entry on the target machine. For example, if you specify **1.4.2** in the Value data box and select **is greater than**, target machines that have a value greater than 1.4.2 for this registry entry meet this installation condition.
A registry entry has a specified version value	If you select this option, type the name of the registry key, the name of the value, and the value data. The value data should be a version number. Note that all leading zeros for every field of the version number are ignored. For example, 3.5.3.0010 is greater than 3.5.3.009, and 3.5.3.009 is greater than 3.5.3.01. Select the appropriate option for 64-bit machines. In addition, select the option that should be used to compare the registry entry specified in this dialog box with the registry entry on the target machine.

Table 12-80 • Prerequisite Condition Dialog Box Options (cont.)

Option	Description
A file does or does not exist	If you select this option, do one of the following: • Specify the path and name for the file. To specify a predefined folder, select the appropriate property in the list. The available properties are [CommonFiles64Folder], [CommonFilesFolder], [ProgramFiles64Folder], [ProgramFilesFolder], [System64Folder], [SystemFolder], and [WindowsFolder]. If you select one of the 64-bit folder locations, the installation checks the 64-folder location on 64-bit target systems and the 32-folder location on 32-bit target systems. • Specify just the file name—without the path or a property. The installation will search for the specified file in all directories defined for the PATH environment variable on the target machine. • Specify a registry key as a property. If you do this, the installation will resolve the registry key with the registry value. Note that the last element of the registry path is treated as a value name. If a backslash is the last character of the path, the value of the default registry entry for that registry key is used. For example, if you type the following as the value, the installation checks if the path specified as the value for the HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ORACLE_HOME registry entry contains a bin directory with a file named `oci.dll`: `[HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ORACLE_HOME]bin\oci.dll` If target machines that have this file should meet this installation condition, select **If the specified file is found in the location specified above**. If target machines that do not have this file should meet this installation condition, select **If the specified file is not found in the location specified above**.

Table 12-80 • Prerequisite Condition Dialog Box Options (cont.)

Option	Description
A file with a certain date exists	If you select this option, do one of the following: • Specify the path and name for the file. To specify a predefined folder, select the appropriate property in the list. The available properties are [CommonFiles64Folder], [CommonFilesFolder], [ProgramFiles64Folder], [ProgramFilesFolder], [System64Folder], [SystemFolder], and [WindowsFolder]. If you select one of the 64-bit folder locations, the installation checks the 64-folder location on 64-bit target systems and the 32-folder location on 32-bit target systems. • Specify just the file name—without the path or a property. The installation will search for the specified file in all directories defined for the PATH environment variable on the target machine. • Specify a registry key as a property. If you do this, the installation will resolve the registry key with the registry value. Note that the last element of the registry path is treated as a value name. If a backslash is the last character of the path, the value of the default registry entry for that registry key is used. For example, if you type the following as the value, the installation checks if the path specified as the value for the HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ORACLE_HOME registry entry contains a bin directory with a file named `oci.dll`: `[HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ORACLE_HOME]bin\oci.dll` In addition, type the date and—if appropriate—the time. For example: `4/26/2004 3:57:46 PM` Then select the appropriate match option to indicate when to run the InstallShield prerequisite.

Table 12-80 • Prerequisite Condition Dialog Box Options (cont.)

Option	Description
A file with a certain version exists	If you select this option, do one of the following: • Specify the path and name for the file. To specify a predefined folder, select the appropriate property in the list. The available properties are [CommonFiles64Folder], [CommonFilesFolder], [ProgramFiles64Folder], [ProgramFilesFolder], [System64Folder], [SystemFolder], and [WindowsFolder]. If you select one of the 64-bit folder locations, the installation checks the 64-folder location on 64-bit target systems and the 32-folder location on 32-bit target systems. • Specify just the file name—without the path or a property. The installation will search for the specified file in all directories defined for the PATH environment variable on the target machine. • Specify a registry key as a property. If you do this, the installation will resolve the registry key with the registry value. Note that the last element of the registry path is treated as a value name. If a backslash is the last character of the path, the value of the default registry entry for that registry key is used. For example, if you type the following as the value, the installation checks if the path specified as the value for the HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ORACLE_HOME registry entry contains a bin directory with a file named `oci.dll`: `[HKEY_LOCAL_MACHINE\SOFTWARE\ORACLE\ORACLE_HOME]bin\oci.dll` In addition, type the version number of the file. For example: `6.7.8.9` Then select the appropriate match option to indicate when to run the InstallShield prerequisite.

Table 12-80 • Prerequisite Condition Dialog Box Options (cont.)

Option	Description
Setup is running on a specified platform	If you select this option, click one of the predefined platforms in the **Select which platform the prerequisite should be run on** box, or select Custom to define your own platform requirements. To specify a range of service pack numbers for which this prerequisite condition is true, use the Service Packs boxes. For example, if target system must have service pack 2, 3, or 4, enter 2 in the first box and 4 in the second box. To target all future service packs, leave the second box blank. To target only service pack 3, enter 3 in both boxes. If you select Custom to define your own operating system requirements, you can configure any one or more of the following settings in the Custom area: • **Platform ID**—Select the required platform. If the value that you select matches the dwPlatformId member of the OSVERSIONINFOEX structure of the target system's operating system, this part of the operating system condition evaluates as true. • **Major Version**—Specify the required major version of the operating system. If the value that you specify matches the dwMajorVersion member of the OSVERSIONINFOEX structure of the target system's operating system, this part of the operating system condition evaluates as true. If you type **0** in this box, the operating system condition that InstallShield creates does not include any major version or minor version requirements; the behavior is the same if you leave the Major Version and Minor Version boxes blank. • **Minor Version**—Specify the required minor version of the operating system. If the value that you specify matches the dwMinorVersion member of the OSVERSIONINFOEX structure of the target system's operating system, this part of the operating system condition evaluates as true. Note that **0** is a valid value for this box.

Table 12-80 • Prerequisite Condition Dialog Box Options (cont.)

Option	Description
Setup is running on a specified platform (cont.)	• **Product (OS) Type**—Select the required operating system type. If the value that you select matches the wProductType member of the OSVERSIONINFOEX structure of the target system's operating system, this part of the condition evaluates as true. Note that if the InstallShield prerequisite supports both servers and domain controllers, you can select the **Server or Domain Controller** option. • **Processor Architecture**—Select the required processor architecture (for example, 32-bit or 64-bit Windows). If the architecture that you select matches the architecture of the target system's operating system, this part of the operating system condition evaluates as true. • **Minimum CSD Version**—Specify the minimum required service pack or other version information for the operating system. Note that this setting is provided for compatibility with InstallShield prerequisites that were created with earlier versions of InstallShield, and to enable subversions of Windows 9x platforms to be distinguished. Using this setting to specify a particular service pack is not recommended; if you need to specify a particular service pack, use the Minimum Service Pack box. If the value that you specify is the same version as or an earlier version than the szCSDVersion member of the OSVERSIONINFOEX structure of the target system's operating system, this part of the operating system condition evaluates as true. For example, if you specify " A" and the szCSDVersion value on the target machine is " B", this part of the operating system condition evaluates as true. It evaluates as false if you specify " B" but the value on the target machine is " A". Similarly, if you specify "Service Pack 1" and the value on the target machine is "Service Pack 2", this part of the operating system condition evaluates as true. It evaluates as false if you specify "Service Pack 2" but the value on the target machine is "Service Pack 1". Note that to prevent comparison problems, any leading and trailing spaces in the version that you specify and in the value of the szCSDVersion member on the target system are ignored.

Table 12-80 • Prerequisite Condition Dialog Box Options (cont.)

Option	Description
Setup is running on a specified platform (cont.)	• **Minimum Build No**—Specify the minimum required build number of the operating system. If the value that you specify is the same version as or an earlier version than the dwBuildNumber member of the OSVERSIONINFOEX structure of the target system's operating system, this part of the operating system condition evaluates as true. For more information on specifying an operating system condition, see Adding an Operating System Condition for an InstallShield Prerequisite. For details about the OSVERSIONINFOEX structure, see OSVERSIONINFOEX on the MSDN Web site.

Privileges Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Privileges dialog box lets you specify one or more privileges that are required by the service that you are configuring. This dialog box opens in the following scenario:

- You are configuring a service in the Services view, or in the Advanced Settings area for a component in the Setup Design view (installation projects only) or the Components view.
- The **Change list of required privileges** option is selected in the Configuration Type setting for an event in the Configure Settings category of settings in the right pane, and you click the ellipsis button (...) in the Arguments setting for that event.

Select one or more check boxes.

The change takes effect the next time that the system is started.

Product Condition Builder Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *MSI Database*
- *Transform*

The Product Condition Builder dialog box simplifies the process of creating install conditions by providing a selection of valid Windows Installer properties and conditional expression operators.

For example, if your product requires 64 MB of RAM in order to run properly, you can use the Product Condition Builder dialog box to create a condition. At run time, the Windows Installer checks the target system to determine how much RAM is installed. If it is less than 64 MB, the Windows Installer displays an error message and exits the installation.

Table 12-81 • Product Condition Builder Dialog Box Settings

Setting	Description
Conditions	This box displays a grid with the following columns: • **Condition**—This column is where you define the conditions. You can type a condition directly in this column, or you can use the Properties list, the Operators list, and the Add buttons to build a condition statement. • **Message**—This column is where you specify the error message that should be displayed if the condition evaluates to false. When you type a value for this column, you are creating a string entry and setting its initial value for all of the languages that are currently in the project. As an alternative to typing a new value, you can click the ellipsis button (**...**) in this setting to select an existing string. For more information, see Using String Entries in InstallShield. To add a new condition to this box, click the New Condition button, and then enter the appropriate information in the Condition and Message columns. To delete a condition in this box, select the condition, and then click the Delete Conditions button.  ***Important*** • *When you click the OK button on this dialog box, InstallShield performs basic condition validation; however, you should still double-check that your condition statements evaluate to the expected outcome. For more information and example conditions, see Building Conditional Statements.* *Windows Installer dialogs, which display the text that you specify in the Message column, do not recognize the escape sequences \r (carriage return), \n (new line), or \t (tab).*

Table 12-81 • Product Condition Builder Dialog Box Settings (cont.)

Setting	Description
Properties	This list contains common Windows Installer properties, as well as any properties that have been added in the Property Manager view. Select the property that you want to evaluate, and then click the **Add** button next to this list. If the list does not contain the property that you want to evaluate, you can type the appropriate property name in the Condition column.
Operators	This list contains all of the valid operators that are recognized by the Windows Installer. Select the operator that you want to use and then click the Add button next to this list. InstallShield appends the operator to the conditional statement in the Conditions box.

Project Settings Dialog Box

The Project Settings dialog box lets you modify information about the open project.

This dialog box is displayed with the following tabs when you select the Project menu's Settings command. This dialog box is displayed with only the last two of the following tabs when you right-click an item in the Objects view's "InstallShield Objects/Merge Modules" pane and select Register new object or Properties. In the last case, all properties are uneditable.

- Project Tab
- Application Tab (in InstallScript Projects) (in Windows Installer–based projects)
- Application Tab (in InstallScript Projects) (in InstallScript and InstallScript Object projects)
- Platforms Tab (in InstallScript and InstallScript Object projects)
- Languages Tab
- Maintenance Tab (in InstallScript projects)
- Language-Independent Object Properties Tab (in InstallScript Object projects)
- Language-Specific Object Properties Tab (in InstallScript Object projects)

Project Tab

The Project tab on the Settings dialog box displays basic information about the open project. This dialog box opens when you select the Project menu's Settings command.

Author

(Optional) Enter the name of the project author.

Comments

(Optional) Enter any comments about the project.

Application Tab (in Windows Installer–Based Projects)

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The Application tab on the Settings dialog box lets you view and modify information about the product that is installed by the open project. This dialog box opens when you click the Settings command on the Project menu.

Table 12-82 • Application Tab Settings

Setting	Description
Product Code	This setting displays a GUID that uniquely identifies this product. To have InstallShield generate a different GUID for you, click the Change button next to this setting. Since this code uniquely identifies your product, changing the product code after you have already distributed your release is not recommended. For more information, see Setting the Product Code in a Windows Installer–Based Project.
Upgrade Code	This setting displays the GUID that can be used for your product's upgrade code. To have InstallShield generate a different GUID for you, click the **Generate a new GUID** button ({...}) in this setting. The upgrade code is a GUID that identifies a related set of products. The Windows Installer uses a product's upgrade code when performing major upgrades of an installed product. The upgrade code, stored in the **UpgradeCode** property, should remain the same for all versions of a product. For more information, see Setting the Upgrade Code.
Product Name	Enter the name of the product. For information on how the product name is used, see Specifying a Product Name.

Table 12-82 • Application Tab Settings

Setting	Description
Product Version	Enter the version number for your product. The version number must contain only numbers, and it must be in the format *aaa.bbb.ccccc*, where *aaa* represents the major version number, *bbb* represents the minor version number, and *ccccc* represents the build number. The maximum value for the *aaa* and *bbb* portions is 255. The maximum value for *ccccc* is 65,535. For more information, see Specifying the Product Version.
Application Type	Select the type of application from the list or type the name of an application type if it is not listed. This information is stored in the project file and is for your reference only. It is never displayed to the end user.

Tip • *You can also configure the aforementioned settings in the General Information view.*

Application Tab (in InstallScript Projects)

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The Application tab on the Settings dialog box lets you view and modify information about the project that is installed by the open project. This dialog box opens when you click the Settings command on the Project menu.

Table 12-83 • Application Tab Settings

Setting	Description
Product Code	Enter a GUID that uniquely identifies this product. To have InstallShield generate a different GUID for you, click the **Generate a new GUID** button ({...}) in this setting. The product code is used to associate uninstallation or maintenance with the original installation. A new GUID is automatically generated for each new project that you create, including copies of existing projects. Once you have changed a project's product code, its previous GUID cannot be recovered. For these reasons, changing a project's product code is typically not necessary and should be approached with caution. For more information, see Setting the Product Code in an InstallScript-Based Project.

Table 12-83 • Application Tab Settings

Setting	Description
Product Name	Enter the name of the product. For information on how the product name is used, see Specifying a Product Name.  ***Tip*** • *Instead of hard-coding a value, you can use a path variable that is defined in the Path Variables view. At build time, InstallShield replaces the path variable with the appropriate value.* *The product name is stored in the InstallScript system variable IFX_PRODUCT_NAME.*
Product Version	Enter the version number for your product. The version number must contain only numbers, and it must be in the format *aaa.bbb.ccccc*, where *aaa* represents the major version number, *bbb* represents the minor version number, and *ccccc* represents the build number. The maximum value for the *aaa* and *bbb* portions is 255. The maximum value for *ccccc* is 65,535. For more information, see Specifying the Product Version.  ***Tip*** • *Instead of hard-coding a value, you can use a path variable that is defined in the Path Variables view. At build time, InstallShield replaces the path variable with the appropriate value.*
Company Name	Enter the name of your company. This value is used in the default script to set TARGETDIR (if the string entry COMPANY_NAME does not exist); it can be retrieved at run time by calling the **MediaGetData** function.  ***Tip*** • *Instead of hard-coding a value, you can use a path variable that is defined in the Path Variables view. At build time, InstallShield replaces the path variable with the appropriate value.*
Executable File	Enter the name of the application's main executable file. This value can be retrieved at run time by calling the **MediaGetData** function.  ***Tip*** • *Instead of hard-coding a value, you can use a path variable that is defined in the Path Variables view. At build time, InstallShield replaces the path variable with the appropriate value.*

Table 12-83 • Application Tab Settings

Setting	Description
Application Type	Select the type of application from the list or type the name of an application type if it is not listed. This information is stored in the project file and is for your reference only. It is never displayed to the end user.
URL	Enter a product URL. This information is stored in the project file and is for your reference only. It is never displayed to the end user.  ***Tip*** • *Instead of hard-coding a value, you can use a path variable that is defined in the Path Variables view. At build time, InstallShield replaces the path variable with the appropriate value.*

Tip • *You can also configure the aforementioned settings in the General Information view.*

Caution • *You must specify a non-null value in the Product Version box; otherwise, build error -7044 occurs.*

Platforms Tab

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The Platforms tab on the Settings dialog box is where you specify the platforms that you want to be available when you to select operating system requirements for components or releases in your project.

Note • *Specifying platforms at the project level does not create target system requirements for running the installation. To create target system requirements in an InstallScript project, you can use the SYSINFO structure to identify the operating platform of the target system.*

The following table shows the settings that are displayed in the Platforms tab.

Table 12-84 • Platforms Dialog Box Settings for a Project

Setting	Description
The project supports all platforms that InstallShield supports	Select this option if you want InstallShield to list all of the supported run-time platforms for the following settings: • Operating Systems setting at the component level (InstallScript and InstallScript MSI projects) • Platform(s) setting at the release level (InstallScript projects) If you select this option, you can designate that a particular component or release in your project is targeted for any one or more supported platforms.
The project supports only the platforms that are selected below	Select this option if you want InstallShield to list only some platforms that are displayed for the following settings: • Operating Systems setting at the component level (InstallScript and InstallScript MSI projects) • Platform(s) setting at the release level (InstallScript projects) Then select the platforms that should be displayed.  ***Tip*** • *To select multiple consecutive operating systems, select the first file, press and hold SHIFT, and select the last operating systems. To select multiple nonconsecutive operating systems, select the first operating systems, press and hold CTRL, and select each additional operating systems.* In general, if a platform is not listed for this setting at the project level, you cannot designate that a particular component or release in your project is targeted for that platform.

Languages Tab

The Languages tab on the Settings dialog box lets you view and modify the list of languages included in the open project. This dialog box opens when you click the Settings command on the Project menu.

check boxes

A checked check box next to a language indicates that the language is included in the project; an unchecked check box indicates that the language is not included. To add or remove a language from the project, click its check box to toggle it to the desired state.

Removing a language from the project also removes it from any components or releases that had been using that language.

Maintenance Tab

Project • *This information applies to InstallScript projects.*

The Maintenance tab on the Settings dialog box lets you select an option for the behavior of your setup when your end user reruns it. This dialog box opens when you click the Settings command on the Project menu.

The Multi-Instance option lets your end users run a setup multiple times as a first setup, rather than a maintenance setup. For more information on these options, see Running an InstallScript Installation Multiple Times.

Language-Independent Object Properties Tab

Project • *This information applies to InstallScript Object projects.*

The Language-Independent Object Properties tab contains basic information about your object, such as the name of the object, the company that created it, and the location of the object. This dialog box opens when you select the Project menu's Settings command in an InstallScript object project. This dialog box also opens in an InstallScript project when you register an object from within the Objects view, or you right-click an object in the Objects view and click Properties. In the last case, all properties are uneditable.

Object Wizard

This option allows you to specify the type of wizard, if any, that you would like to use for your object's default language. The following wizard choices are available:

- **No Wizard**—Select this option if your object does not require a wizard.
- **Use InstallShield Object Stock Wizard**—Select this option to have InstallShield create a wizard for you based on the properties you created for your object. All read-only properties will be displayed but will not be editable. All read/write properties will be changeable by the user. Write-only properties will not be displayed.

  

  Note • *The InstallShield stock wizard does not support array properties. If your object's properties require array properties, you will need to create your own wizard.*

- **Use My Custom Wizard**—Select this option to use a wizard you created. InstallShield allows you to use a wizard created with either Visual C++ or Visual Basic. To use a wizard created with one of these two programs, enter the path to the DLL you created, or click the browse (...) button to navigate to that file.

The following controls are not displayed when you select the Project menu's Settings command.

Company

Enter the name of the company responsible for creating this object.

Version

Enter the version of this object.

Media File

Enter the path to the object's media file (Data1.hdr file), or click the browse button to navigate to that file.

Language-Specific Object Properties Tab

Project • *This information applies to InstallScript Object projects.*

The Language-Specific Object Properties tab contains basic information about your object, such as the name of the object, the company that created it, and the location of the object. This dialog box opens when you select the Project menu's Settings command in an InstallScript object project. This dialog box also opens in an InstallScript project when you register an object from within the Objects view, or you right-click an object in the Objects view and click Properties. In the last case, all properties are uneditable.

IDE Language

Select the language for which you want to specify object information. Available options are English and Japanese.

Use Default

Disabled if the default language, English, is selected. Check this box to specify that the object, when displayed in the selected language, use the same information that you specified for the default language.

The following controls are enabled only if the **Use Default** *check box is unchecked:*

Display Name

Enter the name of your object as you would like it to appear in the object gallery.

Short Name

Enter a shortened version of your object's name, if necessary. You can enter the same name as entered in the Display Name field.

HTML Help

Enter the path to the help file for this object, or click the browse (...) button to navigate to this file. This help file must consist of a single .htm file.

Icon File

Enter the path to the icon file for your object, or click the browse (...) button to navigate to this file. The icon you choose will be displayed next to your object in the object gallery. The icon you use for your object needs to be sized to 16x16 with a maximum of 16 colors.

Rename Key Dialog Box

The Rename Key dialog box is displayed if you click Edit after selecting Rename on the Resolve Conflict dialog box. The Rename Key dialog box displays a setting in which you can provide a new key value for the exported dialog, component, or custom action. When you rename the exported item, you avoid the conflict, assuming that no objects with the new name exist in the target project file.

Settings

Table 12-85 • Rename Key Dialog Box Settings

Setting	Description
Key Value	Type a new key value or name for the item in this field and press OK to rename the item.

Required Features Dialog Box

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*

The Required Features dialog box lets you specify features that must be installed if the current feature is installed. This dialog box is launched when you click the ellipsis button (...) in the Required Features setting for a feature in the Setup Design view or the Features view.

The Required Features dialog box has a Required Features for *SelectedFeatureName* box that shows all of the features in your project. Select the check box for each feature that the current feature requires.

Project • *The check box for the current feature is automatically selected in InstallScript MSI projects. It is automatically cleared in InstallScript and InstallScript Object projects; in either case, the selection status cannot be changed, and it does not affect whether the feature is installed.*

Resolve Conflict Dialog Box

The Resolve Conflict dialog box identifies a conflict when you are exporting a dialog, component, or custom action to another project, or when you are importing a DIM into an installation project. A conflict occurs when the target project has an item with the same name as but different values in its settings than the one you are exporting. Resolve the conflict by selecting one of the options and clicking OK, or by renaming the item in a key column.

If you click Cancel, the item is not exported to another project, or the DIM is not imported into the installation project.

Dialog Box Settings

Table 12-86 • Resolve Conflict Dialog Box Settings

Setting	Description
Table	The table shows all of the data that pertains to the dialog, control, component, custom action, or other item. If you are exporting an item to a different project, the Source Data column shows the values of the settings for the item that you are exporting from the current project to a different project. The Target Data column shows the values of the settings of the existing item in the project to which you are exporting. If you are importing a DIM project into an installation project, the Source Data column shows the values of the settings for the item in the DIM project. The Target Data column shows the values of the settings of the setting for the item in the installation project. Key icons identify key columns in the record. If there is a conflict between the values, that row appears in red. Your selection for resolving the conflict determines whether InstallShield overwrites the existing item and its settings.
Resolution	Indicate how you want to resolve the conflict. Available options are: • **Skip**—Use the value in the Source Data column. If additional conflicts remain, show the next conflict. • **Skip All**— Use the value in the Source Data column for the current conflict as well as any remaining conflicts. • **Overwrite**—Use the value in the Target Data column. If additional conflicts remain, show the next conflict. • **Overwrite All**—Use the value in the Target Data column for the current conflict as well as any remaining conflicts. • **Rename**—Use a different value for the key column so that there is no conflict for the item. To use this option, first select the row that contains the key that you want to rename, select the Rename option, and then click the Edit button. The Rename Key dialog box opens, letting you specify the new value for the key column.

Save As Dialog Box

On the File menu, click Save As to open the Save As dialog box. This lets you save a copy of the open project as a template or as a new project with a different name and location.

Dialog Box Settings

The Save As dialog box is a standard Windows dialog box. To display detailed help for any control except the following ones, select the control and press F1.

Table 12-87 • InstallShield-Specific Settings on the Save As Dialog Box

Setting	Description
Save as type	 ***Project*** • *The **Save as type** option is available for the following project types:* • *Basic MSI* • *DIM* • *InstallScript* • *InstallScript MSI* • *Merge Module* The **Save as type** list enables you to specify the type of file that you are saving. To create a template from the current project, select InstallShield Template (.ist).
Create 'Project Name' subfolder and save the project in the created folder	This check box controls where the project file is located on your system. To create a <Project Name> subfolder in the location specified in the Project Location box (on the File Locations tab of the Options dialog box) and to save the project in that subfolder, select this check box. For projects that contain InstallScript, the Script Files folder is also created in this subfolder. To save the .ism project in the location specified in the Project Location box, clear this check box.
Create and assign a new project GUID to the saved project	If the new project's GUID should be different than the GUID of the original project, select this check box. If the new project's GUID should be the same GUID of the original project, clear this check box.
Update the project settings appropriately based on the new project name	To use the name that you specified in the **File name** box as the value for the Project Name setting in the General Information view of the new project, select this check box. If the value of the new project's Name setting should be the same as that of the original project, clear this check box.

Script Conversion Dialog Box

InstallShield uses different terminology for InstallScript function names. For example, InstallShield uses the term *feature* where InstallShield Professional uses *component*, and vice versa. See Script Changes: Lexicon Conversion for more information.

When you open an .ipr file in InstallShield, this dialog allows you to indicate whether you want InstallShield to automatically update your script (.rul) file to use the InstallShield lexicon.

Note • *The InstallShield Help Library and other documentation uses the InstallShield script terminology.*

Script Editor Properties Dialog Box

The Script Editor Properties dialog box is where you specify how script code should be displayed in various views throughout InstallShield. This dialog box is available in views that enables you to edit a script file (for example, the InstallScript, SQL Scripts, and Custom Actions and Sequences views).

To open the Script Editor Properties dialog box, right-click in a script editor pane and then click Properties.

Tip • *Note that the script editor properties are global per-user settings that affect all InstallShield script editors. For example, the same font is used for all script editors. If you change the font in the SQL Scripts view, the font is also changed in the InstallScript view the next time that the InstallScript is reloaded in that view.*

The settings on the Script Editor Properties dialog box are organized into the following main categories:

- General
- Colors

General Settings

The following settings are available in the General area on the Script Editor Properties dialog box.

Table 12-88 • General Settings on the Script Editor Properties DIalog Box

Setting	Description
Font	This setting displays the font, style, and size that is used for the content in the script editor. To change the option that is selected, click the ellipsis button in this setting. Doing so opens the Font dialog box, which enables you to view and modify the font, style, and size of script content.
Syntax highlighting	Specify whether you want to InstallShield to use color coding for various script elements that are displayed in all of the script editors. If you select Yes, InstallShield uses color coding according to the selections that are made for the settings in the Colors area of the Script Editor Properties dialog box. For more information, see Changing Colors for Syntax Highlighting in the Script Editors.

Table 12-88 • General Settings on the Script Editor Properties DIalog Box (cont.)

Setting	Description
Auto completion	Specify whether you want InstallShield to display a pop-up list of alphabetically ordered functions, keywords, constants, and other script words that begin with the letters that you are typing. Auto completion also displays a list of available string identifiers when you enter the string constant operator (@) in the InstallScript view. The default value is Yes. Auto completion can increase your efficiency because it can reduce the time that you spend typing code. It can also help you avoid typographical errors in your code. For more information, see Using Auto Completion when Writing Code in the Script Editors.
Include local variables	Specify whether you want InstallShield to include in the pop-up list all of the local variables that are defined in the selected script. The default value is Yes. Note that if you select No, the Functions, Properties, and Methods folders in the center pane of the InstallScript view does not list any functions, properties, or methods from your script files. If Yes is selected for this setting and you notice performance issues when you are typing code in the InstallScript view, you might want to change this setting to No. This setting is ignored if you select No for the **Auto completion** setting. For more information, see Using Auto Completion when Writing Code in the Script Editors.
Show function call tips	Specify whether you want InstallShield to display a function call tip—a type of tooltip—when you are typing a function call in your script. The function call tip shows the function's parameter information. It also shows a description of the function, as well as a description of the parameter that you are entering. The default value is Yes. For more information, see Viewing Function Call Tips for an InstallScript Function in the Script Editor.
Line numbering	Specify whether you want the left margin of the script editor to contain line numbers. The default value is No. For more information, see Going to a Line Number in a Script that Is Displayed in a Script Editor.

Table 12-88 • General Settings on the Script Editor Properties Dlalog Box (cont.)

Setting	Description
Syntax folding	Specify whether you want to use syntax folding for your script. If you select Yes, InstallShield adds a plus sign (+) or a minus sign (–) in the margin next to each line of code that starts an expandable or collapsible block of script. Click the plus sign to expand the hidden code. Click the minus sign to hide the code. The default value is No. Syntax folding can help you minimize the clutter of large scripts and focus on the code that is relevant to the work that you are currently doing. It can also help you see the overall structure of a script.
Automatic indentation	Specify whether you want InstallShield to indent new lines of code in your script. The default value is Yes. For more information, see Enabling or Disabling Automatic Indentation in the Script Editors.
Show whitespace	Specify whether you want InstallShield to display a symbol or other mark in place of each instance of white space in your script. For example, if you select Yes, InstallShield displays each space character in the script as a middle dot (·) and each tab character as an arrow. InstallShield also identifies line breaks when whitespace is enabled. The default value is No
Tab width	Specify the tab size as a multiple of the character space size. For example, setting a tab space of 5 causes the cursor to move five character spaces when you press the TAB key.

Colors Settings

The Colors area on the Script Editor Properties dialog box is where you view and modify the foreground color and—in some cases—the background color for various script elements.

The following settings are available in the Colors area on the Script Editor Properties dialog box.

Table 12-89 • Color Settings on the Script Editor Properties Dlalog Box

Setting	Description
Default	Specify the colors for the text that is not one of the predefined types of script words.
Selection	Specify the colors for text that is selected in the script editor.
Cursor	Specify the colors for the blinking cursor.

Table 12-89 • Color Settings on the Script Editor Properties Dlalog Box (cont.)

Setting	Description
Keywords	Specify the colors for script keywords such as built-in functions, data types, and constants.
Identifiers	Specify the colors that are used to show identifiers. This includes variables.
Operators	Specify the colors that are used to show operators. Examples include parentheses, brackets, and braces; arithmetic symbols like plus, minus, asterisk, and slash; and comma.
Comments	Specify the colors for the comments in your code; this includes the comment delimiters such as /*, */, or //.
Strings	Specify the colors for strings; this includes the surrounding quotes.
Unterminated strings	Specify color overrides for strings that have not been closed with a terminating quote; this helps you find strings that could cause compilation errors.
Preprocessor directives	Specify the colors that are used to show preprocessor directives; this includes any lines that start with a pound sign (#).
Constants	Specify the colors that are used to show script constants.
Labels	Specify the colors that are used to show labels.
Errors	Specify the colors that are used to show script errors.
Line numbers	Specify the colors that are used to show line numbers in the left margin, if line numbering is enabled.
Function call tips	Specify the colors that are used to call tips for InstallScript functions.
Matching braces	Specify the colors that are used to show opening and corresponding closing braces—{ }. This is used whenever the insertion point is within parentheses, brackets, or braces. The syntax coloring takes into account nesting (for example, **Foo(array[array.GetLength() - 1])**).
Unmatched braces	Specify the colors that are used to show an opening brace—{—that is missing its corresponding closing brace—}. This is used whenever the insertion point is after the opening parenthesis, bracket, or brace that is missing a closing mark. The syntax coloring takes into account nesting (for example, **Foo(array[array.GetLength() - 1])**).

To learn more about changing colors in the script editors, see Changing Colors for Syntax Highlighting in the Script Editors.

SCM Pre-shutdown Delay Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The SCM Pre-shutdown Delay dialog box lets you specify the length of the time that the Service Control Manager should wait before proceeding with other shutdown tasks. This dialog box opens in the following scenario:

- You are configuring a service in the Services view, or in the Advanced Settings area for a component in the Setup Design view (installation projects only) or the Components view.
- The **Configure SCM pre-shutdown delay** option is selected in the Configuration Type setting for an event in the Configure Settings category of settings in the right pane, and you click the ellipsis button (...) in the Arguments setting for that event.

Select the appropriate option. To reset the time delay to the default of 3 minutes, select the Default option.

The Service Control Manager waits for the specified period of time after sending the SERVICE_CONTROL_PRESHUTDOWN notification to the service. The change takes effect the next time that the system is started.

Security Descriptor Dialog Box

The Security Descriptor dialog box opens when you click the ellipsis button (...) in the Security Descriptor setting; this setting is displayed under the Permissions setting when you are configuring permissions for a service that you have added to the Services view, or to the Services node in the Advanced Settings area for a component in the Setup Design view (in installation projects) or the Components view.

The Security Descriptor dialog box is where you use valid security descriptor definition language (SDDL) to enter a valid SDDL string for service permissions. For more information about SDDL, see the “Access Control” section of the Microsoft Windows Software Development Kit (SDK).

Tip *• You can use angle brackets (for example, <DomainName\UserName>) or environment variables (for example, [%UserDomain][%UserName]) to indicate the domain and user name of the user whose account SID is going to be determined at run time.*

Note *• The permission settings are supported beginning with Windows Installer 5. Earlier versions of Windows Installer ignore these settings.*

An installation should not contain both the ***MsiLockPermissionsEx*** *table and the* ***LockPermissions*** *table. If you use the Permissions setting for a service, and the settings under it, you are configuring the* ***MsiLockPermissionsEx*** *table of the package. If* ***Traditional Windows Installer handling*** *is selected for the Locked-Down Permissions setting in the General Information view and you have set permissions for one or more files, folders, or registry keys in your project, you are configuring the* ***LockPermissions*** *table of the package.*

Select File Dialog Box

Use the Select File dialog box to enter a file into the **DuplicateFile** table in the Direct Editor.

Dialog Options

Component

Select the component that contains the file you want to enter in this table.

Files (*.*)

Select the file that you want to include in this table.

Select Media Location Dialog Box

For MSI Databases, choose where you want to place the new file(s) on the source media. If you are creating a .cab file, you can choose to stream the file(s) into the package.

Project *• For MSM Databases, the File Location options are disabled since merge modules require you to store your files in a .cab file that is internal to the .msm database.*

Note *• The option to extract COM information is only enabled when you drag files to a folder or when you add a single file to a component that does not already have any existing files. As a result, the COM file is the only file in the particular component.*

Select SQL Server Dialog Box

The Select SQL Server dialog box opens when you are using the Database Import Wizard and you click the Browse button for the server name on the SQL Server panel.

The Select SQL Server dialog box enables you to select the SQL Server whose database you are importing.

Select String Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The Select String dialog box shows the collection of language-independent identifiers and corresponding language-specific values for the default language of your project. This dialog box lets you select or create a string identifier that you can use in place of a hard-coded text string.

Accessing the Select String Dialog Box

The Select String dialog box is available from within the script editor pane in the InstallScript view. It is also available in other places throughout InstallShield. For example, if you click the ellipsis button (...) in one of the settings that accepts localizable text, the Select String dialog box opens, enabling you to select or create a string entry that you want to use for the selected setting. The Display Name and Description settings for a feature are two examples of a setting that accepts localizable text.

Working with the Select String Dialog Box

The Select String dialog box consists of the following elements:

- A row of buttons and other controls
- A group box area (below the row of buttons)
- A spreadsheetlike table

Each row in the table represents a string entry in your project.

The following table describes all of the buttons and other controls that are displayed in the Select String dialog box.

Table 12-90 • Controls on the Select String Dialog Box

Name of Control	Description
New	Displays the String Entry dialog box, which lets you specify a new string identifier, a value, and internal comments.
Delete	Deletes the selected string entry or string entries.
Search Grid	Filters the strings that are displayed in the Select String dialog box according to the string that you specify in this text box.
Drag a column header here to group that column	Use this group box area to group rows in the Select String dialog box. This dialog box supports multiple levels of grouping simply by dragging the column headings and dropping them onto the group box. InstallShield displays the rows in the dialog box hierarchically according to column arrangement in the group box.

The following table describes each of the columns in the Select String dialog box.

Table 12-91 • Columns in the Select String Dialog Box

Column	Description
Identifier	This column contains the language-independent ID for the string. Each string identifier in a project is linked to one or more values.
Value	This column shows the run-time string.  ***Project*** • *In Basic MSI, DIM, InstallScript MSI, and Merge Module projects, some of the string values contain Windows Installer properties inside square brackets—for example,* ***Install [ProductName]****. At run time, the property and brackets are replaced by the property value.* *String values in these same project types may also contain font information in curly brackets—for example,* ***{&MSSansBold8}OK****. The font information indicates style details that should be used to display the strings at run time.*
Comments	This column contains internal note about the string entries. The comments are not displayed at run time.
Modified	This column lists the date and time that the string entry was last modified.

Serial Number Violation Dialog Box

The Serial Number Violation dialog box opens when InstallShield detects that the serial number entered is already in use. InstallShield will not start for 20 minutes unless a unique, valid serial number is entered.

Task: ***To change the serial number:***

1. Click **Change**. The **Serial Number** dialog box opens.
2. In the **Serial Number** box, type a unique, valid serial number. Dashes are not required.

For information on securing valid licensing, visit http://www.installshield.com.

Server Locations Dialog Box

Project • *This information applies to Transform projects.*

The Server Locations dialog box opens when you click the ellipsis button (...) in the Server Locations setting of the General Information view. The Server Locations dialog box lets you specify network and URL paths to the product's installation package and related files so that Windows Installer can find them if they are needed. For example, if an end user installs the product from a network server or Web site and one or more of the features were set to be installed on first use, Windows Installer may need access to the .msi package and related files on the server or Web site sometime after the initial installation.

InstallShield adds the paths that you specify to the **SOURCELIST** property. Windows Installer appends this list to the end of an end user's existing source list for the product at run time.

The validity of the server location that you specify is determined when the installation needs to access the server remotely. That is, if a server is not available, or if you added an invalid server, the entry will be ignored if the resource is needed, and errors might be generated. Each location that is specified must have the complete source for the installation. The entire directory tree at each source location must be the same and must include all of the required source files, including any .cab files. Each location must have an .msi file with the same file name and product code.

Tip • *Server paths can contain environment variables that are identified with a percent sign (%). For example, the following path uses the Home environment variable:*

```
\\Server1\%Home%\Office
```

Table 12-92 • Server Locations Dialog Box Settings

Setting	Description
Source Paths	This box shows the list of paths that you have specified.

Table 12-92 • Server Locations Dialog Box Settings (cont.)

Setting	Description
New	Click this button to add a new path to the Source Paths box.
Delete	Click this button to delete the selected path from the Source Paths box.
Move Up	Click this button to move the selected path higher in the list of paths.
Move Down	Click this button to move the selected path lower in the list of paths.

Service Options Dialog Box for a Time Delay of an Auto-Start Service

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Service Options dialog box lets you specify whether the Windows service that you are configuring should be started after other auto-start services plus a time delay have elapsed. This dialog box opens in the following scenario:

- You are configuring a service in the Services view, or in the Advanced Settings area for a component in the Setup Design view (installation projects only) or the Components view.
- The **Configure time delay of an auto-start** option is selected in the Configuration Type setting for an event in the Configure Settings category of settings in the right pane, and you click the ellipsis button (...) in the Arguments setting for that event.

Select the appropriate option.

The change takes effect the next time that the system is started.

Service Options Dialog Box for Running Recovery Actions

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Service Options dialog box lets you specify when the recovery actions should be run for the service that you are configuring. This dialog box opens in the following scenario:

- You are configuring a service in the Services view, or in the Advanced Settings area for a component in the Setup Design view (installation projects only) or the Components view.
- The **Configure when to run recovery actions** option is selected in the Configuration Type setting for an event in the Configure Settings category of settings in the right pane, and you click the ellipsis button (...) in the Arguments setting for that event.

Select the appropriate option.

The change takes effect the next time that the system is started.

Service SID Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*
- *Transform*

The Service SID dialog box lets you specify the appropriate service security identifier (SID) that you want to add. This dialog box opens in the following scenario:

- You are configuring a service in the Services view, or in the Advanced Settings area for a component in the Setup Design view (installation projects only) or the Components view.

- The **Add a service SID type to the process token** option is selected in the Configuration Type setting for an event in the Configure Settings category of settings in the right pane, and you click the ellipsis button (...) in the Arguments setting for that event.

Select the appropriate option.

Note that if multiple services are hosted in the same process and one service has the restricted service SID, all services must have the restricted service SID.

The change takes effect the next time that the system is started.

Set File(s) URL Dialog Box

The **Set File(s) URL** dialog box opens when you click the **Set File(s) URL** button on the Files to Include tab of the InstallShield Prerequisite Editor. This dialog box lets you specify a file for your InstallShield prerequisite.

Table 12-93 • Set File(s) URL Dialog Box Settings

Setting	Description
URL to file's parent folder	Type the URL for the parent directory of the selected file or files. This URL is the same one that InstallShield uses when installation authors use the Redistributables view to download an InstallShield prerequisite from the Internet to their local machines. For example, if you selected files called Notepad.exe and Paint.exe, and the URLs for these files are http://www.mywebsite.com/Folder1/Notepad.exe and http://www.mywebsite.com/Folder1/Paint.exe, enter the following in this box: http://www.mywebsite.com/Folder1

Settings Dialog Box

The Settings dialog box enables you to set preferences for how InstallShield builds the installation for the project that is currently open.

Task: ***To open the Settings dialog box:***

On the **Build** menu, click **Settings**.

The following tabs are associated with this Settings dialog box:

- Compile/Link tab
- Run/Debug tab (InstallScript projects only)
- MSI Log File tab (Windows Installer projects only)

Compile/Link Tab

The Compile/Link tab on the Settings dialog box lets you specify settings for compiling your script. These settings apply to `Setup.rul` and any files included in it.

Table 12-94 • Compile/Link Tab Settings

Setting	Description
Preprocessor Defines	Specify any preprocessor definitions. Use the following format, with no spaces before or after equal signs or commas: `MYVARIABLE1=123,MYVARIABLE2=456` You can test those types of constants in your script by using #if and #ifdef statements that control the flow of the script. For example, type MYVARIABLE in this box, and the code in the following #ifdef loop will be executed: `#ifdef MYVARIABLE` `    // Commands` `#endif` After you add or change a preprocessor definition in this box, you must compile your script for the addition or change to take effect.  ***Note*** • *Many Windows API functions are declared in the header file `ISRTWindows.h`, which is automatically included when you include `Ifx.h` in your script. You can prevent the automatic definition of Windows APIs by placing the preprocessor constant ISINCLUDE_NO_WINAPI_H in the Preprocessor Defines box on the Compile/Link tab of the Settings dialog box.*

Table 12-94 • Compile/Link Tab Settings (cont.)

Setting	Description
Include Paths	Specify which directories InstallShield should search for source files that have been included in the main installation's InstallScript code through #include statements. Use the following guidelines for this setting: • To specify multiple paths, separate each one with a comma. • You can use any valid path variable in a path. • Do not use quotation marks to specify a path. • Since the current directory is not necessarily constant, do not use the dot (.) operator in the paths that you specify. Instead, use an explicit path variable such as *<ISProjectFolder>* to indicate a known folder location. • When InstallShield passes the values that you have specified in this setting to `Compile.exe`, InstallShield automatically parses the specified string to determine comma-delimited paths. In addition, InstallShield handles path variable replacement, surrounds the paths with quotation marks, and then passes each path separately to `Compile.exe` using multiple `/i` switches. However, if you separate the paths with semicolons instead of commas, InstallShield considers the specified paths as a single path, and it passes the single path string to the compiler as is. In this case, no path variable substitution or quotation mark additions occurs. ***Note*** • *InstallShield searches any paths that you specify before it searches the standard InstallShield paths. Thus, if two include files share the same name but one include file is in one of your custom include paths and one is in a standard InstallShield include path, InstallShield links to the include file in the custom include path, not the version in the standard InstallShield include path.* For more information, see #include.
Max Warnings	Specifies the maximum number of warning messages that are displayed.
Maximum Errors	Specifies the maximum number of error messages that are displayed.
Warning Level	Specifies the types of warnings that are displayed in the Output window. • **None**—Displays no warning messages. • **Level** 1—Displays any system warning message that InstallShield is unable to handle. • **Level 2**—Displays Level 1 messages, plus a message if string length exceeds the limit. • **Level 3 (Default)**—Displays all warning messages. For more information, see Defining Constants Through the Compiler.

Table 12-94 • Compile/Link Tab Settings (cont.)

Setting	Description
Compile before build	To compile your InstallScript automatically every time that you build a release, select this check box. Note the following behavior that occurs if you select this check box: • If you select the Refresh Build command on the Build menu, your script is recompiled only if changes have been made to it since the last compile. • If you select the Build *<name of release>* command on the Build menu, your script is recompiled, even if no changes have been made to it since the last compile.  ***Note*** • *The compiled script is not copied to the disk images folder before the build begins because the build process automatically copies the compiled script to the folder during the build. If the script fails to compile because of compiler errors, the build does not continue.*
Generate inline debugging information	If this check box is selected, debugging information is included in the compiled script file so a debugging information file is not needed. If you want to debug an installation that includes an object that you have created, and you want to obtain debugging information from the object, you must have compiled the object's script with this check box selected.  ***Caution*** • *Selecting this check box makes the compiled script larger and the installation slower, and it makes it easier for others to reverse engineer your code. Therefore, in most cases, it should not be used when you are creating your final installation for distribution to end users.*
Warnings as errors	If warnings should be treated as errors (that is, if the installation should not be run if there were any compile warnings when the InstallScript was compiled), select this check box.

Table 12-94 • Compile/Link Tab Settings (cont.)

Setting	Description
Additional Library Paths	 ***Project*** *• For InstallScript and InstallScript Object projects, InstallShield automatically searches for script libraries in the following directories at compile time:* • *<ISProductFolder>\Script\Ifx\Lib* • *<ISProductFolder>\Script\Isrt\Lib* *For Basic MSI and InstallScript MSI projects, InstallShield automatically searches for script libraries in the following directories at compile time:* • *<ISProductFolder>\Script\Iswi\Lib* • *<ISProductFolder>\Script\Isrt\Lib* *The aforementioned directories contain the libraries that define the built-in InstallScript functions and that are listed in the Libraries (.obl) box by default.* If you want InstallShield to search any additional directories that contain your own script libraries, you can specify the directory path in the Additional Library Paths box. Use the following guidelines for this setting: • To specify multiple paths, separate each one with a comma. • You can use any valid path variable in a path. • Do not use quotation marks to specify a path. • Since the current directory is not necessarily constant, do not use the dot (.) operator in the paths that you specify. Instead, use an explicit path variable such as *<ISProjectFolder>* to indicate a known folder location. • When InstallShield passes the values that you have specified in this setting to `Compile.exe`, InstallShield automatically parses the specified string to determine comma-delimited paths. In addition, InstallShield handles path variable replacement, surrounds the paths with quotation marks, and then passes each path separately to `Compile.exe` using multiple `/libpath` switches. However, if you separate the paths with semicolons instead of commas, InstallShield considers the specified paths as a single path, and it passes the single path string to the compiler as is. In this case, no path variable substitution or quotation mark additions occurs.  ***Note*** *• InstallShield searches any paths that you specify before it searches the standard InstallShield paths. Thus, if two libraries share the same name but one library is in one of your custom library paths and one is in a standard InstallShield library path, InstallShield links to the library in the custom library path, not the version in the standard InstallShield library path.*

Table 12-94 • Compile/Link Tab Settings (cont.)

Setting	Description
Libraries (.obl)	Specify the names of script libraries (compiled .obl files) to which you want the compiler to link. Separate each file with a comma. ***Note*** • *It is not necessary to include the path of each library, as long as either the path is identified explicitly in the Additional Library Paths box or the path is one of the built-in library paths that InstallShield automatically searches at compile time.* ***Project*** • *The following built-in libraries are listed by default for InstallScript projects: ifx.obl,isrt.obl.* *The following built-in libraries are listed by default for Basic MSI and InstallScript MSI projects: iswi.obl,isrt.obl.* *The following built-in libraries are listed by default for InstallScript Object projects: ifxobject.obl,isrt.obl.* *Additional built-in libraries may also be listed, depending on which views in InstallShield you use when you are developing your project.*

Run/Debug Tab

Project • *This information applies to the following project types:*

- *InstallScript*
- *InstallScript Object*

The Run/Debug tab lets you configure settings relevant to the running and debugging of your installation.

Table 12-95 • Run/Debug Tab Settings

Settings	Description
Setup Command Line Arguments	Text placed in this box is written to the system variable CMDLINE when you run the installation from within InstallShield; this variable can be accessed in the script.
Generate MIF File	If you select this check box, the installation automatically generates a Management Information Format (.mif) file when you run the installation from within InstallShield. For information on generating .mif files in the installation that you distribute, see The [Mif] Section.
MIF Filename	Specifies the name of the .mif file generated by the installation when you run the installation from within InstallShield. If you leave this box blank, the .mif file is named Status.mif.

Table 12-95 • Run/Debug Tab Settings (cont.)

Settings	Description
Product Serial Number	If you specify a serial number, the installation adds it to the .mif file it generates when you run the installation from within InstallShield.

MSI Log File Tab

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*

The MSI Log File tab on the Settings dialog box enables you to create a log file that you can use when you are running your installation from within InstallShield. In addition, this tab lets you select the type of information that you would like written to the log file.

Table 12-96 • MSI Log File Tab Settings

Setting	Description
MSI Log File Options	Select the check boxes for the types of messages that you want to be displayed in your log file. When you select a check box, the corresponding argument is added to the MsiExec.EXE Command-Line Arguments box.
MsiExec.EXE Command-Line Arguments	Enter the command-line arguments that you would like to pass to `MsiExec.exe` when your installation is run. When check boxes are selected in the MSI Log File Options area, the corresponding command-line parameters are added to this box.
Log File	Type the name of the log file that will be created when your installation is run.  ***Project*** • *For InstallScript MSI projects, you need to type the full path to the log file in this box.*

Setup Languages Dialog Box

Project • *This information applies to the following project types:*

- *Basic MSI*
- *InstallScript*
- *InstallScript MSI*
- *InstallScript Object*
- *Merge Module*

The behavior of the Setup Languages dialog box varies, depending on whether the project type is Windows Installer based (a Basic MSI, InstallScript MSI, or Merge Module project) or InstallScript based (an InstallScript or InstallScript Object project).

The Setup Languages dialog box opens when you click the ellipsis button (...) for the Setup Languages setting in the General Information view.

In Basic MSI, InstallScript MSI, and Merge Module projects, the Setup Languages dialog box lets you specify the languages that you want to be listed in the UI Languages setting in the Releases view. Therefore, if a language is not listed in this dialog box at the project level, you cannot include that particular UI language in your project's releases.

In InstallScript and InstallScript Object projects, the Setup Languages dialog box lets you specify the languages that you want to be listed in the Languages setting in the Components and Releases views in your project. In general, if a language is not listed for this setting at the project level, you cannot designate that a particular component in your project is targeted for that language; in addition, you cannot designate that the components and UI strings for a particular language are included in your project's releases.

When you add a supported language to your project through this setting, InstallShield adds string entries for that language to your project. The string entries include the built-in user-interface string resources that are already translated.

Table 12-97 • Settings on the Setup Languages Dialog Box

Setting	Description
Languages	If you want the strings of a particular language to be included in your project, select its check box. To exclude all of the strings for a particular language, clear its check box.  ***Edition*** • *Language support varies, depending on the edition of InstallShield that you are using, the project type, and the language of the InstallShield interface (English or Japanese). For example, if you are using the English version of InstallShield Professional Edition, only one language is available for selection in this dialog box; if other language check boxes are listed, they are disabled.* *For general information about language support, see Run-Time Language Support in InstallShield.*
Show only selected languages	If you want the languages box to list only languages whose check boxes are selected, select this check box.

Table 12-97 • Settings on the Setup Languages Dialog Box (cont.)

Setting	Description
Show only available languages	If you want the languages box to list only languages that are available to you with the edition of InstallShield that you are using, select this check box.

SQL Server Requirement Dialog Box

Use the SQL Server Requirement dialog box to define the server requirements for your database.

Predefined Minimum Database Server Version

Select a predefined minimum database server version that your application supports. Choose from the list of available options.

Note • *At runtime, the installation verifies that all database servers that are selected by the end user meet the specified requirements.*

Customize

Rarely, you will want to define your own database server version, but in the cases that you must, check the Customize box and any of the following options that apply:

Table 12-98 • Customize Options

Option	Description
Major Version	This is the major version returned by a SQL Server. For example, SQL Server version 7 returns 7.00
Service Pack Level	This is the server pack level number returned by a SQL Server. For example, SQL Server version 7 RTM returns 623.
Any Greater than Major Version	Check this option to support future major versions.
Any Greater than Service Pack Level	Check this option to support future service packs.

Supersedence Dialog Box

Edition • *This information applies to Basic MSI projects.*

The Supersedence dialog box opens when you click the ellipsis button (...) in the Supersedence setting of the General Information view. This dialog box lets you specify one or more other .msi packages that you want to be superseded by the installation that you are creating. InstallShield includes the list of .msi packages that you provide in a software identification tag, which provides data that AdminStudio includes when users import packages into the AdminStudio Application Catalog. AdminStudio makes this information available to users for review and tests before publishing to Microsoft System Center 2012 Configuration Manager.

When you are selecting superseded .msi packages, you can specify earlier versions of the current installation. You can also optionally select .msi packages of other tools. For example, if you are working on an installation for an image editing tool, you can have your installation supersede other image editing tools that your enterprise no longer supports.

To specify an .msi package that should be superseded by the current installation, click the Add Superseded .msi File button, and then select the package that you want to include in the list.

UI Languages Dialog Box

Edition • *This information applies to the following project types:*

- *Advanced UI*
- *Basic MSI*
- *InstallScript MSI*
- *Merge Module*
- *Suite/Advanced UI*

The UI Languages dialog box lets you specify which user interface languages you want to include in the release that is selected in the Releases view. To open this dialog box, open the Releases view and select a release. Then click the ellipsis button (...) in the UI Languages setting on the Build tab.

Note that if a language is not selected in the Setup Languages setting in the General Information view of the project, it is not listed as one of the available languages for the UI Languages setting.

Update Merge Module Search Path Dialog Box

The Update Merge Module Search Path dialog box opens when you use the Browse for Merge Module option to add a merge module to your installation project. It displays the path that will be added to the merge module search path.

Click OK to approve the action.

To learn more about why this dialog box appears, see What Happens When You Browse for a Merge Module.

Wizard Reference

InstallShield includes many wizards to assist you in creating your installation project.

Project • *Not all wizards are available with all project types.*

The following wizards are available in InstallShield.

- Acquire New License Wizard
- Component Wizard
- Convert Source Paths Wizard
- Create New QuickPatch Wizard
- Create Table Wizard
- Custom Action Wizard
- Database Import Wizard
- Device Driver Wizard
- Dialog Wizard
- DirectX Object Wizard
- Dynamic Scanning Wizard
- Export Components Wizard
- Function Wizard
- Import DIM Wizard
- Import REG File Wizard
- Import XML Settings Wizard
- Microsoft .NET Framework Object Wizard
- New Language Wizard
- Open MSI/MSM Wizard
- Open MSP Wizard
- Open Transform Wizard
- Publish Wizard
- Redistributable Downloader Wizard
- Reg-Free COM Wizard
- Release Wizard

- Setup Best Practices Wizard
- Static Scanning Wizard
- System Search Wizard
- Transform Wizard
- Upgrade Validation Wizard
- User Interface Wizard
- Visual Studio .NET Wizard for Visual Basic .NET, C# .NET, and Visual C++ .NET
- Visual Studio Deployment Project Import Wizard

Acquire New License Wizard

Use the Acquire New License Wizard to obtain a license for your trialware. InstallShield uses the license to wrap a trialware shell around your product's executable file (.exe, .dll, .ocx, or .scr file). The executable file can be unwrapped and used only according to the license settings that you configure, such as the trial limit (a specified number of days or a specified number of uses).

In most cases, you should acquire a unique license for each version of your product. For more information, see Acquiring a License.

The following panels are associated with the Acquire New License Wizard:

- Welcome Panel
- Configure Trialware Credentials Panel
- Communicating with the License Server Panel

Welcome Panel

The Welcome panel is where you create a user name and password to log on to the InstallShield Activation Service Publisher Web Site if do not already have them. You need a user name and password in order to be able to connect to the license server and download a license. Your user name must have write access to the licensing part of the Web site.

Configure Trialware Credentials Panel

The Configure Trialware Credentials panel is where you enter information needed to obtain a license.

Table 12-1 • Options in the Configure Trialware Credentials Wizard Panel

Option	Description
Description	Type a description for the license that you are obtaining. The description that you enter is for your reference only; it is not displayed to end users of your product.

Table 12-1 • Options in the Configure Trialware Credentials Wizard Panel (cont.)

Option	Description
Version	Type the version number of your product.
User name	Type your user name for the InstallShield Activation Service Publisher Web Site. The default value for this box is the value entered on the Configure Trialware tab of the Options dialog box.
Password	Type the password for your user name. The default value for this box is the value entered on the Configure Trialware tab of the Options dialog box.

Communicating with the License Server Panel

The Communicating with the License Server panel shows a progress bar as the license server is contacted and a license is created for your executable file.

When you have obtained the license and closed the wizard, the new license is added to the License(s) list for your executable file on the General tab of the Trialware view.

Component Wizard

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Although there are several ways to create Windows Installer components and specify advanced settings for them, the Component Wizard simplifies the process. The wizard assists you by organizing your files into components and making settings for files with advanced installation requirements—often by automatically retrieving information about the files.

Task: ***To launch the Component Wizard, do one of the following:***

- For installation projects only: In the **Setup Design** view, right-click a feature and click **Component Wizard**.
- For Basic MSI, DIM, InstallScript MSI, Merge Module, MSI Database, and MSM Database projects: In the **Components** view, right-click the **Components** explorer and click **Component Wizard**.

When you launch the Component Wizard, you are presented with the following options on the Welcome panel:

Table 12-2 • Welcome Panel Settings

Setting	Description
Create components for me using Best Practices	Select this option to specify all of your application's files and have InstallShield create all of the necessary components for you according to Setup Best Practices.
Let me select a type and define the component myself	This option creates components containing files that need special treatment upon installation and uninstallation. The wizard can create components for only one of the following file categories at a time. Run the Component Wizard again to build components for another type of file. • COM Server • Install Service • Control Service • Fonts  ***Note*** • *If you want to create a component that installs, starts, stops, or deletes a service during installation or uninstallation, you can use the Services view. You can also use this view to configure extended service customization options, which are not configurable through the Component Wizard. For more information, see Installing, Controlling, and Configuring Windows Services.*

Welcome Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Although there are several ways to create Windows Installer components and specify advanced settings for them, the Component Wizard simplifies the process. The wizard assists you by organizing your files into components and making settings for files with advanced installation requirements—often by automatically retrieving information about the files.

Tip • *The Component Wizard should not be used to modify existing components. When you have created your components, you can edit their properties, files, and advanced settings in the Setup Design view or the Components view.*

Table 12-3 • Welcome Panel Settings

Setting	Description
Create components for me using Best Practices	Select this option to specify all of your application's files and have InstallShield create all of the necessary components for you according to Setup Best Practices.
Let me select a type and define the component myself	This option creates components containing files that need special treatment upon installation and uninstallation. The wizard can create components for only one of the following file categories at a time. Run the Component Wizard again to build components for another type of file. • COM server • Install Service • Control Service • Fonts  ***Note*** • *If you want to create a component that installs, starts, stops, or deletes a service during installation or uninstallation, you can use the Services view. You can also use this view to configure extended service customization options, which are not configurable through the Component Wizard. For more information, see Installing, Controlling, and Configuring Windows Services.*

Setup Best Practices

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

This Component Wizard path is the easiest means for organizing all of your application's files into components. The wizard also handles installing files with special installation requirements, such as COM servers and fonts, if it detects them among the files that you provide. For more information on how the Component Wizard organizes your files according to Best Practices, see Best Practice Rules for Creating Components.

After selecting the Best Practices option in the Component Wizard, the next panel you see is the Best Practices–Destination Panel.

Destination Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The first step is to specify the folder where the components' files will be installed on the target system.

Note • *The Destination setting is disabled if you launch the Component Wizard by right-clicking on a destination in the Files and Folders view. The destination that you selected before launching the Component Wizard becomes the destination for the component that you create.*

Table 12-4 • Destination Panel Settings

Setting	Description
Destination	The wizard uses the same destination folder for all of the components it creates. The destination you select in this field becomes the Destination Folder setting for every component that is created in this wizard session. Select a Windows Installer folder property, in square brackets, from the drop-down list of standard destination folders. The default value points to the root of INSTALLDIR, which is initialized in the product's Destination Folder setting. Select **Browse, create, or modify a directory entry** from the drop-down list to display the Browse for Directory dialog box.

Files Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

In the Files panel, specify the files that should be grouped into components.

Table 12-5 • Files Panel Settings

Setting	Description
Files	The Files list displays information about each file associated with this component. Add files to the list in either of the following ways: • Drag and drop files from Windows Explorer onto the file list. • Click Add Files and browse to your application's files.  ***Note*** • *The path to each file is a hard-coded link. If the file is moved or renamed, the Link To value reads *** File Not Found ***, and the Release Wizard will be unable to resolve the file link when you build your setup package.*
Extract COM Info Immediately	If this option is selected, the component's COM Extract at Build setting is set to No and the COM data is extracted immediately. If you clear this check box, the COM data is extracted at build time.
Add Files	Click Add Files to browse to the files you want to add to the list. In the resulting dialog you can select as many files as you want from a single folder by pressing the SHIFT or CTRL key and clicking on the files. You can also use the Insert key to add files.
Add Folder	Click Add Folder to browse to a folder that you would like to add to the list. All the files under this folder, including any files in subfolders, will be added to your project.
Remove Files	Select one or more files and click Remove Files to permanently delete them from the list. You can also use the Delete key to delete files.

Summary Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The Summary panel displays the components' settings. Review the summary, and click Finish to complete the component creation process and organize the files into components.

If you launched the wizard by right-clicking a feature, the new components are associated with that feature. Otherwise, you must open the Setup Design view, right-click one or more features, and select Insert Components to associate your new components with features.

The Component Wizard provides smart defaults for most of your component settings and any necessary advanced settings. To edit them, select a component in the Components view and modify the component's settings.

Note • *Components that are not associated with a feature are displayed with the orphaned component icon.*

Component Type Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The Component Type panel enables you to create components of a single type. Since these components all have unique installation and uninstallation requirements, subsequent panels of the Component Wizard differ, depending on the type of component that you are installing.

Table 12-6 • Component Type Panel Settings

Setting	Description
Component Name	When you click a component type, the wizard suggests a unique name for your new component in the Component Name field. To change the name, type a new name over the suggested name.  ***Note*** • *Although you can specify a single component type for multiple font files or multiple services in one file, these are all placed into a single component and require only one component name.* *This setting is disabled if you are creating the font type of component. InstallShield uses the font file name as the name of font components.*
Component Types	Select the type of component that you want to create. • COM Server • Install Service • Control Service • Fonts  ***Note*** • *If you want to create a component that installs, starts, stops, or deletes a service during installation or uninstallation, you can use the Services view. You can also use this view to configure extended service customization options, which are not configurable through the Component Wizard. For more information, see Installing, Controlling, and Configuring Windows Services.*

COM Server Component Type

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The COM server component type in the Component Wizard accepts a single COM server (.exe, .dll, or .ocx) file and creates a component for it in your installation project.

Since these files require special registration so that they can operate on the target system, the wizard attempts to extract the information for you. If the wizard fails to extract the file's registry settings, it prompts you for the CLSID, progID, and so on.

All of the registration information that maps to the COM Registration advanced setting is written there. The wizard creates any additional entries, such as the InProcServer32 ThreadingModel value, in the component's registry data.

Tip • *If you are using InstallShield on a 64-bit system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit. To learn more about 64-bit support, see Targeting 64-Bit Operating Systems.*

Using the component's data, the installer registers the file during installation and unregisters it during uninstallation instead of calling self-registration functions, which would be a violation of Setup Best Practices.

Note • *The PATH system variable on the build machine must be set to include the directories of all of the .dll files to which the COM server links; otherwise, the file will fail to register and COM information will not be extracted.*

The wizard asks if your COM server runs as a service, so you can specify installation parameters for the service.

COM Server File Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The COM Server File panel is where you identify basic information about your COM server's executable file.

Table 12-7 • COM Server File Panel Settings

Setting	Description
COM Server File	Enter the path and file name of your COM server (.exe, .dll, or .ocx) file, or click the Browse button to navigate to the file. You can specify only one portable executable file per component according to Setup Best Practices. Launch the wizard again to install additional COM servers, or create the components using the Component Wizard's Best Practices option.

Table 12-7 • COM Server File Panel Settings (cont.)

Setting	Description
Extract registration information	Select this check box to have the wizard scan your file to extract all of the file's registration information. If the extraction is successful, the next panel displayed is the Summary confirmation dialog.  ***Project*** • *If you are working on a Basic MSI, InstallScript MSI, or Merge Module project, an alternative to extracting the COM information through the wizard and maintaining it in the COM Registration advanced setting is to have the data dynamically extracted at build time. If you are working in Direct Edit Mode, COM information cannot be extracted at build time; it is extracted at design time.* If you do not select this check box or if the wizard cannot read the file's registration, the Classes panel is displayed next.  ***Tip*** • *If you are using InstallShield on a 64-bit system, InstallShield can extract COM data from a 64-bit COM server. In order to install the data to the correct locations, the component must be marked as 64 bit. To learn more about 64-bit support, see Targeting 64-Bit Operating Systems.*
This file also runs as a service	This check box is enabled only if your COM server is an .exe file. If you select this option, the wizard displays panels that enable you to specify installation parameters for services. If you select this check box and specify the service information, InstallShield enters the information in the Services area under the Advanced Settings node of your component in the Components view. You do not have to launch the wizard again to create a service component for this COM server.
Custom EXE Command Line	This check box is enabled only if your COM server is an .exe file. Once it is enabled, you can enter a command line argument. The command line argument overrides the default `/regserver` command line to an .exe file. If you select the service option and specify parameters in the Custom EXE Command Line box, `/service` is passed as the command line. By default, the `/service` command line does everything that the `/regserver` command line does but it also adds registry values for service support. If you select all the options on this panel, the command line that you enter in this box is the command line that is passed to the .exe file.

If the COM server is part of a 64-bit component and you are running InstallShield on a 64-bit machine, InstallShield performs 64-bit COM extraction. For more information, see Targeting 64-Bit Operating Systems.

Classes Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

This panel is where you begin providing registration information for your COM server—including your file's classes, identified by their progIDs and CLSIDs.

This panel and the next few registration information panels are displayed only if you elected not to have the wizard extract the information, or if the wizard failed for any reason (for example, if the .exe, .dll, or .ocx file does not indeed contain a COM server). Otherwise, the wizard would continue with the Service Executable panel—if the COM server is a service, or the Summary panel—if the COM server is not a service.

Table 12-8 • Classes Panel Settings

Setting	Description
ProgID	Enter the COM server's programmatic identifier, or progID in this panel. Each progID corresponds to a COM class in your file. To add a new progID in the format Program.Component.N, click the Add button or press the Insert key. Enter the same value in both the ProgID and Version-Independent ProgID fields if the progID is version independent (in the format Program.Component). All of the other information in this panel corresponds to the class you named in this field with a progID. Click on each progID to set its class ID and version-independent progID and to check whether it is DCOM/COM+ enabled.
Add	Click Add to register a new class for this COM server. To rename the service, type the new name immediately after clicking the Add button, or press F2 and then type the new name. You can also use the Insert key to add a new service.
Remove	Click Remove to permanently delete a progID from the list. You can also use the Delete key to remove a service.
Class ID	Click on a progID to provide the corresponding class ID. Enter a string GUID for the CLSID that Windows Installer will register for this class.

Table 12-8 • Classes Panel Settings (cont.)

Setting	Description
Version-Independent ProgID	Click on a progID to provide the corresponding version-independent progID, if any, in the format *Program.Component*. If the progID itself is version independent, enter the same progID in this field.
This COM server is DCOM/ COM+ enabled	If the COM class is enabled for DCOM or COM+, and therefore requires additional registry entries, check this box. The wizard prompts you for this information in the AppID General Information and AppID Advanced Information panels.

Context Types Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Indicate the type of file in which your COM server resides. The available context types are:

- InprocServer—16-bit DLL or OCX
- InprocServer32—32-bit DLL or OCX
- LocalServer—16-bit EXE
- LocalServer32—32-bit EXE

Type Library Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Specify the type library, if any, referenced by this COM server.

Table 12-9 • Type Library Panel Settings

Setting	Description
Type Library Description	Provide a brief description of the type library. This value is used in the component's COM Registration advanced setting as the type library's name in the COM Registration Explorer. The description is registered as the default value under HKEY_CLASSES_ROOT\TypeLib*libID**version*.
Type Library GUID	Enter the GUID (LibID) that identifies this type library. You can paste (Ctrl+V) your COM server's LibID into this field.
Language	Enter the decimal value of the type library's locale ID. Since type libraries are usually language neutral, 0 (zero) is the most common language of type libraries.
Version	Provide the version number of the type library. If this field is blank, Windows Installer automatically determines the version of the type library at run time.

AppID General Information Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

In this panel, you provide basic information about your DCOM or COM+ file's AppID. An AppID is a GUID registered under HKEY_CLASSES_ROOT\AppID used for grouping all of the security and configuration options of distributed COM objects. The information you provide in this panel and in the AppID Advanced Information panel are registered under this key.

This panel is not displayed unless you selected the **This COM server is DCOM/COM+ enabled** check box on the Classes panel.

Table 12-10 • AppID Information Panel Settings

Setting	Description
AppID GUID	Enter the string GUID (AppID) for this COM+ or DCOM component. You can paste (Ctrl+V) the AppID into this field.
Remote Server Name	Enter the name of the computer on which this component should run.

AppID Advanced Information Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

In this panel, you provide more advanced information about your DCOM or COM+ file's AppID than you provided in the AppID General Information panel.

This panel is not displayed unless you selected the **This COM server is DCOM/COM+ enabled** check box on the Classes panel.

Table 12-11 • AppID Advanced Information Panel Settings

Setting	Description
Activate at Storage	Select this check box to indicate that the distributed COM server resides on the same machine as its data. When a DCOM file is activated at storage, its objects are instantiated on the same machine as the data it uses, thereby reducing network traffic. Note that calling applications can override this default behavior with DCOM API functions.
Run as Interactive User	Select this check box to have the COM server run under the same account as the user currently logged onto the system. This option allows the server to be connected with the interactive desktop. Since COM servers that also run as services are not designed to run as the interactive user, this check box is disabled if you select the Run as a Win32 Service check box.

Table 12-11 • AppID Advanced Information Panel Settings (cont.)

Setting	Description
Run as a Win32 Service	Select this option if the distributed COM .exe file is intended to run as a service. When this option is selected, you should provide the name of the service and any parameters it takes. ***Note*** • *If you indicated—in the COM Server Executable panel—that this file runs as a service, the next panel displayed is the Service Executable panel, in which you must enter information about this file's services.*
Service Name	Enter the name of the service.
Service Parameters	Enter the parameters you want passed to the service when it is launched.

Summary Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Review the component's description and click Finish to have the wizard create the described components. Click Back if you need to change any of the information you provided.

All of the registration information that maps to the COM Registration advanced setting is written there. The wizard creates any additional entries, such as the InProcServer32 ThreadingModel value, in the component's registry data.

If the wizard lists **Please enter this information in the IDE**, go to the component's COM Registration (or Install Services for components that also run as a service) advanced setting and provide the values.

If you launched the wizard by right-clicking a feature, the new components are associated with that feature. Otherwise, you must open the Setup Design view, right-click one or more features, and select Insert Components to associate your new components with features.

Note • *Components that are not associated with a feature are displayed with the orphaned component icon.*

Control Service Component Type

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Note • *If you want to create a component that installs, starts, stops, or deletes a service during installation or uninstallation, you can use the Services view. You can also use this view to configure extended service customization options, which are not configurable through the Component Wizard. For more information, see Installing, Controlling, and Configuring Windows Services.*

The Control Service component type is used start or stop a single service during installation or uninstallation. For example, you might need to delete a running service before updating it in your setup.

The wizard takes you through a series of panels prompting you for information about the service you want to control. Once you have completed the wizard, you have a new component consisting only of default properties and the advanced settings necessary for controlling a service. Later you can add data such as files, shortcuts, and registry entries to your component through the Setup Design or Components view.

Task: ***To control another service:***

Launch the wizard again or modify the component's Control Service advanced setting.

Task: ***To install a service:***

Launch the wizard again and select the Install Services component type or add the service's file to the Control Service component you have created in the wizard and edit its Services node in the Advanced Setting area of the Components view.

Specify Service Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The first step is to specify which service you want to install. Everything else you do in the wizard refers to this service.

You can use the Component Wizard to control a single service at installation and uninstallation. To control another service in a new component, launch this wizard again.

Note • *To control more than one service in the same component, you must modify the component's Services node under the Advanced Settings area of the Components view.*

Table 12-12 • Specify Service Panel Settings

Setting	Description
Service is present on target system	Select this option to control a service that you are certain will be installed on the target system when your setup runs or that will be when your product is uninstalled.
Service Name	Enter the name of the service. This is the name that InstallShield, Windows Installer, and the Service Control Manager (which maintains the system's database of services and exposes an interface for controlling these services) use to identify a service—not its display name.
Service is included in this setup	Select this option to choose from among the services you have created in your setup project.  ***Note*** • *This option is disabled if none of your components has a service in its Services node under the Advanced Settings area in the Components view.*

Installation Events Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

This panel offers you standard options for controlling the service during your product's installation.

Table 12-13 • Installation Events Panel Settings

Setting	Description
Trigger the following events when the component is installed	Click this option to enable the installation control events.
Start the service	This event starts the service when the component is installed. Specifically, it is started by the Start Services action in your setup's Installation sequence. Specify any command-line parameters to be used for launching the service in the Arguments field.
Arguments	Specify any arguments that you want passed to the service when it is started. Separate each argument with a comma.
Stop the service	This event stops the service when the component is installed. It is stopped by the Stop Services action in your setup's Installation sequence.
Delete the service	This event deletes the service when the component is installed. It is deleted by the Delete Services action in your setup's Installation sequence.
No event (do nothing)	Select this option if you do not need to control this service during your product's setup. This option cancels any of the above events.

Uninstallation Events Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

This panel is prompting you for the same control events that were available for the product's installation, except that they will be triggered only when this component is uninstalled.

Table 12-14 • Uninstallation Events Panel Settings

Setting	Description
Trigger the following events when the component is uninstalled	Click this option to enable the uninstallation control events.
Start the service	This event starts the service when the component is uninstalled. Specifically, it is started by the Start Services action in your setup's Installation sequence. Specify any command-line parameters to be used for launching the service in the Arguments field.
Arguments	Specify any arguments that you want passed to the service when it is started. Separate each argument with a comma.
Stop the service	This event stops the service when the component is uninstalled. It is stopped by the Stop Services action in your setup's Installation sequence.
Delete the service	This event deletes the service when the component is uninstalled. It is deleted by the Delete Services action in your setup's Installation sequence.
No event (do nothing)	Select this option if you do not need to control this service during your product's setup. This option cancels any of the above events. If you selected the **No event (do nothing)** option on the Installation Events panel, it is disabled in this panel. You must select a control event at either installation or uninstallation.

Wait Type Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

In this panel, you can set the wait option for all events in your product's installation and uninstallation. Windows Installer proceeds as specified in this panel, following the control event.

Select **Wait for the service to complete the event before continuing** if the event is critical to the installation or uninstallation.

If you selected the **No event (do nothing)** option in the Installation Events or Uninstallation Events panel, the corresponding wait settings are disabled in this panel.

Summary Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Review the information the wizard has collected, and click Finish to create your Control Service component.

You can review and edit the new component's settings in the Components view or the Setup Design view.

If you launched the wizard by right-clicking a feature, the new components are associated with that feature. Otherwise, you must open the Setup Design view, right-click one or more features, and select Insert Components to associate your new components with features.

Note • *Components that are not associated with a feature are displayed with the orphaned component icon.*

Install Service Component Type

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Note • *If you want to create a component that installs, starts, stops, or deletes a service during installation or uninstallation, you can use the Services view. You can also use this view to configure extended service customization options, which are not configurable through the Component Wizard. For more information, see Installing, Controlling, and Configuring Windows Services.*

The Install Service component type is used to create a component that contains the information necessary to install all of the Win32 services that are present in a single .exe file.

Tip • *If the file also runs as a COM server, a better way to create the component is to select the COM Server component type and specify that it contains a service. Once you have provided all the COM registration data, the Component Wizard will the prompt you for the same information about the service that you must provide for the Install Services component type.*

The wizard takes you through a series of panels prompting you for information about the services you want to install. Once you have completed the wizard, you have a new component consisting of your file, the default component properties, and the advanced settings necessary for installing and uninstalling the services.

You can edit the services' installation information in the Services node under the Advanced Setting area of the Components view. Windows Installer will pass these values to the Windows API function CreateService() to install each service onto the target system and register it with the Service Control Manager (which maintains the system's database of services and exposes an interface for controlling these services).

Service Executable Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Provide the fully qualified path for your file and list all of its services. Only .exe files are allowed. Driver services (.sys files) are not supported in the wizard.

Table 12-15 • Service Executable Panel Settings

Setting	Description
Service Executable	Enter the fully qualified path to the executable file for the services in this component or click the Browse button to navigate to the service's executable file. In compliance with Setup Best Practices, the component can contain only one executable file. Launch the wizard again later to add another file to a new component. If you have arrived at this wizard panel as the result of having a COM Server component that contains services, the Service Executable box is disabled. The wizard uses the same executable that you entered in the COM Server Executable panel.  ***Caution*** • *If you use the Browse button to navigate to and select a file, the new value overwrites anything that was entered in the Service Executable box.*
Services	This list contains all of the services found in the file.
Add	Click Add to add a new service. To rename the service, type the new name immediately after clicking the Add button, or press F2 and then type the new name. This is the name that InstallShield, Windows Installer, CreateService(), and the Service Control Manager (which maintains the system's database of services and exposes an interface for controlling these services) use to identify the service—not its display name. You can also use the Insert key to add a new service.
Remove	Select a service and click Remove to permanently delete it from the Services list. You can also use the Delete key to remove a service.

Service Type Information Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Select each service in the drop-down list and provide the necessary details.

Table 12-16 • Service Type Information Panel Settings

Setting	Description
Service	Select the services that you entered in the Services list of the Service Executable panel and then specify the Display Name and Service Type installation properties for each.
Display Name	Enter a display name for the service. This is the name that is displayed to users in the SCM. If you leave the Display Name field blank, the name you gave the service is used as the display name.  ***Note*** • *Other service properties, such as the service description to display on target systems, are available in the component's advanced settings.*
Service Type	Specify whether the service runs in its own process or shares a process with others. Select the **Service shares a process with others** option only if there is more than one service in the component. If you are familiar with the source code for the service, select **This service runs in its own process** if it is of type SERVICE_WIN32_OWN_PROCESS, and **Service shares a process with others** if it is of type SERVICE_WIN32_SHARE_PROCESS.  ***Note*** • *You are limited to the options provided under Service Type. The Component Wizard does not support driver services.*
Arguments	Enter command-line arguments to pass to the service when it runs. Expressions of the form [PropertyName] will be expanded to the value of the Windows Installer property called PropertyName.

Service Start Type Information Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Select each service in the drop-down list and indicate the way in which you want the service started—or if you want the service disabled.

Start Type

Select the service's start type from the list.

- Automatically when the system starts up
- On demand through the Service Control Manager
- Not started (Disabled)

Service Load Order Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Select each service in this file and enter its load-ordering group and dependency information. Having dependencies and membership in a load-ordering group means that the service requires other services to be running before it can be started. (Service load-ordering groups are listed under HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\ServiceGroupOrder. The service's Start Type property determines when it loads within its group.)

Table 12-17 • Service Load Order Panel Settings

Setting	Description
Service	Select each of the services that you entered in the Services list of the Service Executable panel and then specify its load-ordering and dependency information.
Load-Ordering Group	Enter the name of the load-ordering group of which this service is a member. Leave this field blank if the service does not belong to a group.
Dependencies	List the service's dependencies in the edit field. A service's dependency can be another service—in which case enter the service's name, or it can be a load-ordering group—in which case precede the name of the load-ordering group with a plus sign (+) so that the SCM can distinguish it from a service. Separate each dependency with a comma.

Error Control Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Select each of the services that you entered in the Services list of the Service Executable panel and—for each service—specify which action you would like the Service Control Manager to take if it receives an error while attempting to start the service.

- Log the error and continue starting the service.
- Log the error, display a message box, and continue starting the service.
- Log the error and, if possible, restart the system with the last known good configuration.

Service Logon Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Select each service in the list and specify the type of account you want the service to log on as when it starts up.

Caution • *Because of potential password conflicts, Microsoft recommends that all services log on under the local system account.*

Table 12-18 • Service Logon Panel Settings

Setting	Description
Service	Select each of the services that you entered in the Services list of the Service Executable panel and then specify how the service should log on.

Table 12-18 • Service Logon Panel Settings (cont.)

Setting	Description
Local system account	Select this option to have the service log on under the local system account.
Allow service to interact with the desktop	If the service has a user interface, click this option.
This account	Select this option if you want the service to impersonate a specific user when it logs on. You must enter a user name and password, or the local system account will be used.
Domain/User Name	Enter accounts in the form **DomainName\UserName**. You can use a dot for the built-in domain, such as **.\UserName**.
Password	Enter the password for this account. The password will not be used if you do not specify a user name, and the service will log on under the local system account.

Summary Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Review the information the wizard has collected, and click Finish to create your service component.

The wizard provides smart defaults for all of your component's properties. You can review the property sheet in the Setup Design views. Of particular importance for an service is the Remote Installation setting, since Windows Installer cannot install a service that does not reside on the local system.

If you launched the wizard by right-clicking on a feature, the new component is associated with that feature. Otherwise, you must open the Setup Design view, right-click on one or more features, and select Insert Components to associate your new component with a feature.

Note • *Components that are not associated with a feature are displayed with the orphaned component icon.*

After the wizard finishes, you can modify any of the installation options for the component's Services node under the Advanced Setting area of the Components view.

InstallShield provides functionality for controlling this service or others on the target system. For more information, see Installing, Controlling, and Configuring Windows Services.

Font Component Type

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

Although you can create a component in one of several ways, the easiest way to install a font (a .ttf, .fon, or .ttc file) in a setup is to create a Fonts component in the Component Wizard.

Unlike the other component types offered in the wizard, there is no corresponding advanced setting for Fonts components. The setting that distinguishes a Fonts component and tells Windows Installer to install it differently is the file's Font Title property.

An alternative to creating a Fonts component is to select the Setup Best Practices option in the Component Wizard and let InstallShield create a Fonts component for you from your font files.

Note • *If you want a font to remain on the system after the application has been uninstalled, set its component's Permanent property to Yes.*

Add Installed Fonts Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

The wizard searches for all fonts that are registered on the development system. You can create a component containing any of these fonts by selecting them in the list.

Table 12-19 • Add Installed Fonts Panel Settings

Setting	Description
Fonts	Select the fonts you want to include in your Fonts component.
I also want to add fonts not installed on this system	Click this option to be able to browse to additional fonts in the Add New Fonts panel. If you do not select this option, the wizard displays the Summary panel next.

Add New Fonts Panel

Project • *This information applies to the following project types:*

- *Basic MSI*
- *DIM*
- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

This panel lets you add any .ttf, .fon, or .ttc file to your Fonts component.

Note • *This panel is designed to allow you to add fonts to your installation that are not installed on your machine. For example, you might have a font file that is stored on a network drive. As a result, you cannot select fonts from your Fonts folder since those fonts are already installed on your local machine. If you want to add a font that is installed on your machine to your installation, click Back and select the appropriate font from the list.*

Table 12-20 • New Fonts Panel Settings

Setting	Description
Fonts	Drag and drop files into the list, or click Add Fonts to browse to and add new fonts to your component. InstallShield reads the font title from the font file. If no title is specified within the font file, click on the font title to specify a title in the format FontTitle (FontType)—for example, Marlett (TrueType).
Add Fonts	Click Add Fonts to browse to new font files.

Table 12-20 • New Fonts Panel Settings (cont.)

Setting	Description
Remove Fonts	Select a font in the list and click Remove Fonts to permanently remove the selected font from the component.

Summary Panel

***Project** • This information applies to the following project types:*

- *Basic MSI*
- *InstallScript MSI*
- *DIM*
- *Merge Module*
- *MSI Database*
- *MSM Database*

If you launched the wizard by right-clicking on a feature, the new component is associated with that feature. Otherwise, you must open the Setup Design view, right-click on one or more features, and select Insert Components to associate your new Font component with a feature.

***Note** • Components that are not associated with a feature are displayed with the orphaned component icon.*

When the font's feature is selected for installation, it is automatically registered by Windows Installer.

All Font components are installed by default to the location stored in the FontsFolder property. You can edit the component's Destination Folder or set additional properties by editing the component's property sheet.

***Note** • If you would like a font to remain on the system even after the program has been uninstalled, be sure to set the Font component's Permanent property to Yes.*

Unlike the other component types offered in the wizard, there is no corresponding advanced setting for Fonts components. The setting that distinguishes a Fonts component and tells Windows Installer to install it differently is the file's Font Title property.

Component Wizard General Summary Panel

***Project** • This information applies to the following project types:*

- *Basic MSI*
- *DIM*

- *InstallScript MSI*
- *Merge Module*
- *MSI Database*
- *MSM Database*

This panel appears at the end of the wizard's component creation process. For help with a specific component type, see the following information.

- Setup Best Practices Option
- COM Server Component Type
- Install Services Component Type
- Control Service Component Type
- Fonts Component Type

Note • *Components that are not associated with a feature are displayed with the orphaned component icon.*

Convert Source Paths Wizard

With the Convert Source Paths Wizard, you can convert existing hard-coded paths to path variables, thereby enhancing the portability of your setup project.

Task: ***To launch the Convert Source Paths Wizard:***

On the **Project** menu, click **Convert Source Paths**.

Welcome Panel

The Convert Source Paths Wizard allows you to convert your setup's hard-coded paths to path variables. The wizard scans your project for any use of hard-coded paths and then replaces the paths with standard path variables.

If you have files that evaluate to existing path variables, the wizard automatically converts these paths without providing the option of selecting a new variable. For example, if you have a file in the Program Files folder, this path is automatically converted to the predefined path variable <ProgramFilesFolder>.

Search Panel

The Search panel displays the search status. At this time the wizard is scanning the current project for any absolute paths. If your files evaluate to existing path variables, these files are converted automatically.

Search Results and Recommendations Panel

The Search Results and Recommendations panel lists all the path variable options for the files and links in your project that are not located in directories that already have path variables. For example, if your file is `C:\App Files\Executable\App.exe`, you are given the option of creating a path variable called Executable that equates to that path.

Panel Options

Path Variable Recommendation

Indicate the variables that you want to create by selecting the corresponding boxes. If you do not want to create one of the suggested variables, clear the check box next to it.

Rename

Select the variable that you want to rename and click the Rename button. Type the new variable name in the Path Variable Recommendation column.

Deselect All

Click the Deselect All button to clear the check boxes next to all the corresponding suggested path variables.

Select All

Click the Select All button to select all the path variable suggestions. When you click Apply, these variables are created and added to your project.

Updating Your Project Panel

This panel displays the wizard's progress in updating the hard-coded paths in your project to path variables.

Update Completed Panel

This panel signifies the end of the Convert Source Paths Wizard. Click the Finish button to return to the IDE.

Create New QuickPatch Wizard

Project • *This information applies to QuickPatch projects.*

A QuickPatch project is recommended for installation authors who want to ship small, single updates to their users. QuickPatch authoring provides a simple alternative to creating a patch in the Patch Design view, even though it provides less customization. Fundamentally, both patch creation methods produce the same deliverable types: .msp and .exe files.

To create a QuickPatch project for an existing .msi file or an existing QuickPatch, use the Create New QuickPatch Wizard.

Caution • *Creating a QuickPatch project for an earlier QuickPatch without first building the earlier QuickPatch project may cause unexpected behavior.*

Task: ***To open the Create New QuickPatch Wizard:***

Create a new project in InstallShield and select QuickPatch Project as the project type.
