### ABSTRACT

Artificial bee colony (ABC) algorithm has been introduced for solving numerical optimization problems, inspired collective behavior of honey bee colonies. ABC algorithm has three phases named as employed bee, onlooker bee and scout bee. In the model of ABC, only one design parameter of the optimization problem is updated by the artificial bees at the ABC phases by using interaction in the bees. This updating has caused the slow convergence to global or near global optimum for the algorithm. In order to accelerate convergence of the method, using a control parameter (modification rate-MR) has been proposed for ABC but this approach is based on updating more design parameters than one. In this study, we added directional information to ABC algorithms, instead of updating more design parameters than one. The performance of proposed approach was examined on well-known nine numerical benchmark functions and obtained results are compared with basic ABC and ABCs with MR. The experimental results show that the proposed approach is very effective method for solving numeric benchmark functions and successful in terms of solution quality, robustness and convergence to global optimum.

#### 1. Introduction 21

Swarm intelligence is a subfield of artificial intelligence and the 22 algorithms of swarm intelligence have been developed by inspir-23 ing natural behavior of real ants [1], bees, birds, fishes [2], etc. 24 Artificial bee colony algorithm is one of the swarm intelligence 25 algorithms and has been developed by using waggle dance and for-26 aging behaviors of real honey bee colonies [3]. In the nature, the 27 28 honey bees search and forage food sources around the hive and share position information about the food sources. The honey bees 29 which work in the foraging labor are divided into three groups. 30 First group is employed bees and they move to hive nectar foraged 31 from food source and position information about the food sources. 32 Second group consists of onlooker bees and onlookers forage food 33 sources by considering information shared by employed bees. The 34 last group of the bees is scout bees. 5-10% of a bee population is 35 scout bee [3,4] and scout bees search new food source around the 36 hive and share position information of found new food sources with 37 the other bees. For sharing information, the bees use waggle dance 38 in the dance area of the hive and the time and glow of the dance 39 depend on amount and distance from hive of food source. 40

Karaboga [3] used the aforementioned natural behaviors of 41 the real honey bee in order to develop the artificial bee colony 42

http://dx.doi.org/10.1016/i.asoc.2014.10.020 1568-4946/© 2014 Published by Elsevier B.V. algorithm and solve numerical optimization problems. In the ABC algorithm, half of the population is first scout bee. For each scout bee, a new food source which is possible solution for the optimization problem is generated. After generating new food source position, all the scout bees become employed bees and all employed bees try to improve food sources by using interaction between them. If a food source could not be improved in a certain time named as limit which is a control parameter for ABC algorithm, the employed bee of this food source becomes a scout bee. For this scout bee, a new food source is produced and the scout bee becomes employed bee, again. The onlooker bees wait to be shared food sources position by the employed bees in the hive. After employed bees share position information about the food sources, each onlooker bee select one of the food source position and tries to improve the food source position.

ABC algorithm is an iterative algorithm and only one design parameter of the optimization problem is updated by the each employed or onlooker bee at the each ABC iteration and updating only one design parameter has caused slow convergence for the algorithm. In order to overcome this issue, Akay and Karaboga [5] have proposed a control parameter called as modification rate-MR. In this work, we used directional information for each design parameter in order to cope slow convergence of the algorithm and the performance of the proposed approach is investigated on the well-known numerical benchmark optimization problems.

The paper is organized as follows: Section 1 introduces the study and gives literature review on artificial bee colony algorithm. The 65

basic ABC algorithm and modifications are explained in Section
 2 and the experiments and experimental results are presented in
 Section 3. The study is discussed in Section 4 and finally, the con clusions and future works are given in Section 5.

### 74 1.1. Literature review

The ABC algorithm was first introduced in 2005 and its perfor-75 mance is analyzed on three numerical problems [3]. It is mentioned 76 that ABC algorithm has developed for solving numeric optimiza-77 tion problems [6] and proposed modifications and improvements 78 for the methods have also been tested by using numeric prob-79 lems. We give the literature review based on modifications and 80 improvements of the method, and the studies on applications and 81 hybridizations which use basic ABC algorithm can be found in a 82 comprehensive literature review on ABC in [6]. The performance 83 of ABC has been investigated on the numeric benchmark functions 84 in [7–10]. Akay and Karaboga [5] introduced a modified version of 85 ABC and used it for real-parameter optimization. In the modified 86 ABC, Karaboga and Akay added two new control parameters named 87 as modification rate-MR which is used for increasing convergence 88 89 rate of ABC and scaling factor-SF which is used for controlling magnitude of perturbation to ABC. Dongli et al. [11] proposed three 90 modified versions of ABC in order to obtain better quality results for 91 the optimization problems. In the first modification, the neighbor-92 hood structure is changed in the solution updating equation of ABC, 93 in the second modification, a new selection equation is proposed for 94 onlooker bees in order to choose an employed bee and the last mod-95 ified version of ABC is based on modification #1 and #2. Tsai et al. 96 [12] proposed a model based on ABC, by employing Newtonian law 97 of universal gravitation in onlooker bee phase of ABC. Alatas [13] 98 proposed an ABC model that uses chaotic maps for parameter adap-99 tation so as to prevent the ABC to get stuck local minimums. Zhu and 100 Kwong [14] modified ABC algorithm (named as GABC) by append-101 ing the global best information of the population to exploitation 102 103 equation of ABC in order to increase exploitation ability of ABC. Gao and Liu [15] modified search equation of the basic ABC by 104 using chaotic systems and opposition-based learning methods 105 and applied the modified ABC (called as MABC) to 28 benchmark 106 functions. Banharnsakun et al. [16] improved the capability of con-107 vergence of ABC to a global optimum by using the best-so-far 108 selection for onlooker bees and they tested performance of their 109 method on the numerical benchmark functions and image regis-110 tration. The Rosenbrock's rotational direction method which was 111 designed to cope with specific features of "Rosenbrock's banana 112 function" was applied to ABC in order to increase exploitation and 113 local search abilities of the basic ABC [17]. Karaboga and Akay [18] 114 adapted the basic ABC for constrained optimization problems by 115 using the Deb's Rules and evaluated the performance of the adapted 116 model on the 13 constrained optimizations in the literature. Kıran 117 and Gündüz [19] proposed a crossover-based improvement for 118 neighbor bee selection in onlooker bee phase of basic ABC algo-119 rithm. Horng [20] proposed maximum entropy thresholding based 120 on the ABC for image segmentation and Omkar et al. [21] pre-121 sented vector evaluated ABC (VEABC) for multi-objective design optimization of laminated composite components and compared 123 performance of VEABC with other population based methods. Liu 124 et al. [22] have published a variant of ABC algorithm which is 125 improved by using mutual learning which tunes the produced can-126 didate food source with the higher fitness between two individuals 127 selected by a mutual learning factor. Gao et al. [23] proposed two 128 ABC-based algorithms which use two update rules of differential 129 evolution (DE), and they are called as ABC/best/1 and ABC/best/2. 130 The global best-based ABC methods also use chaotic initialization in 131 132 order to properly distribute the agents to the search space, and the 133 performance and accuracy of the methods are examined on 26

numerical benchmark functions [23]. Due to premature convergence and getting trap of local minima in ABC/best/1, Gao and Liu [24] proposed to use the update rule of ABC/best/1 algorithm for employed bees and the update rule of basic ABC for onlooker bees in order to reinforce exploration ability of the method, and they tested the variant of ABC on 28 numerical benchmark functions. In another study, Gao et al. [25] defined a new update rule for ABC algorithm, and the new update rule uses random solutions for obtaining the candidate solution. New update rule looks like to crossover operator of GA, and the method is named as CABC. In this study, the orthogonal learning strategy is proposed for ABC methods such as basic ABC (OABC), GABC (OGABC), CABC (OCABC), and their accuracies and performances are examined on numerical benchmark functions and compared with the other nature-inspired optimization algorithm.

Being analyzed literature review, it is seen that the update rule of ABC algorithm was modified, and the local search capability of the method is tried to improve in most of the papers which are based on improvement of the ABC algorithm. Therefore, we propose the same update rule with a bit modification in order to improve convergence characteristic of the basic ABC algorithm instead of local search capability. But it should be mentioned that this modification provides local search capability besides improvement convergence characteristics of the basic ABC algorithm.

## 2. ABC algorithm

By simulating intelligent behavior of real honey bee colonies, ABC algorithm tries to find a global optimum or near optimum solution for the optimization problems. In the ABC algorithm, number of food sources is equals to number of employed bees and also number of employed bees equals to number of onlooker bees. All the employed bees are scout bees in the starting of the algorithm and a food source position is produced for each scout bee using Eq. (1):

$$P_{ij} = X_j^{\min} + r \times (X_j^{\max} - X_j^{\min}), \quad i = 1, 2, \dots, \text{NE} \text{ and}$$
  
 $i = 1, 2, \dots, D$  (1)

where  $P_{ij}$  is the *j*th dimension of *i*th food source which will be assigned to *i*th employed bee,  $X_j^{\min}$  and  $X_j^{\max}$  are the lower and upper bounds of the *j*th dimension, respectively, *r* is a random number between [0,1], NE is the number of employed bee and *D* is the dimensionality (the number of decision variables) of the problem or function optimized.

After producing a food source position for each scout bee, all the scout bees become employed bee. The qualities of the food sources of the employed bees are measured by using Eq. (2):

$$fit_{i} = \begin{cases} 1/(1+f_{i}) & if(f_{i} \ge 0) \\ 1 + abs(f_{i}) & if(f_{i}, 0) \end{cases}$$
(2) 177

where fit<sub>i</sub> is the fitness of the *i*th food source and  $f_i$  is the objective function value specific for the optimization problem. In addition, a trial counter is defined and reset for each food source and limit value for the population is described in the initialization of the algorithm.

The employed bees search around the self-food sources for new food sources. A new food source position around the food source of employed bee is obtained as follows:

$$V_{ij} = S_{ij} + \varphi \times (S_{ij} - N_j), \quad i = 1, 2, ..., NE, \quad k \in \{1, 2, ..., NE\}$$
 and

$$j \in \{1, 2, \dots, D\}$$
 (3)

where *V* is the candidate food source position produced for food source position *S*, *N* is the randomly selected neighbor food source for food source *S* and  $\varphi$  is a random number in range of [-1,1]. It is mentioned that only one dimension of the food source position

..., NE,  $k \in \{1, 2, ..., NE\}$  and 185 (3) 186 rce position produced for food 187

Initialization Phase
Determine the number of food sources
Define <i>Limit</i> for the population
Produce the food sources using equation 1.
Define trial counters for the food sources.
Assign the food sources to the employed bees
Calculate fitness of the food sources using Eq. 2.
Employed Bee Phase
For Each Employed Bee
Produce new food source position using Eq.3.
Calculate fitness of the candidate food source.
If the fitness of candidate food source is better than old one, memorize new position and reset trial
counter; otherwise increase its trial counter by 1.
Onlooker Bee Phase
Calculate being selected probabilities of the employed bees using Eq. 4
For each onlooker bee
Produce new food source position using Eq.3.
Calculate fitness of the candidate food source.
If the fitness of candidate food source is better than old one, memorize new position and reset trial
counter; otherwise increase its trial counter by 1.
Save the best solution obtained so far.
Scout Bee Phase
If a scout bee occurs
Produce a new food source position by using Eq.1.
Calculate fitness of the produced food source position by using Eq.2

Fig. 1. The ABC algorithm.

S is updated for each the iteration and the dimension is randomly
 selected. The fitness of the candidate food source is obtained by
 using Eq. (2) and if the fitness of candidate food source is better
 than the old one, the employed bee memorizes the new food source
 position and trial counter of the food source is reset; otherwise the
 trial counter of the food source is increased by 1.

Reset its trial counter.

ELSE go to Employed Bee Phase

IF a termination condition is met THEN report the best solution

After the employed bees return to the hive, the employed bees share self-food source positions with the onlooker bees. An onlooker bee selects an employed bee and memorizes its food source position in order to improve its food source by using roulette-wheel selection mechanism given as follows:

$$p_i = \frac{\text{fit}_i}{\sum_{j=1}^{\text{NE}} \text{fit}_j}$$
(4)

where  $p_i$  is the being selected probability of the *i*th employed bee 203 by an onlooker bee. Thereafter, the onlooker bee searches around 204 205 the food source position of the employed bee by using Eq. (3). If the fitness of the food source found by onlooker bee is better than 206 fitness of the food source of the employed bee, the employed bee 207 memorizes the food source position of the onlooker bee and trial 208 counter of this food source is reset; otherwise the trial counter of 209 the food source is increased by 1. 210

The occurrence of the scout bee in the ABC depends on limit and trial counters of the food sources. After onlooker's search, the trial counter with maximum content (H) is fixed and if H is higher than the limit, a new food source position is produced for this bee by using Eq. (1) and its trial counter is reset. It is mentioned that only one scout bee can occur at the each ABC iteration.

The ABC algorithm is an iterative algorithm and consists of four phases sequentially realized named as initialization, employed bee, onlooker bee and scout bee phases. In order to terminate the algorithm, the maximum iteration number, meeting an error tolerance, etc can be used. The detailed algorithm of ABC is also shown in Fig. 1.

## 2.1. ABC algorithm with MR control parameter

In order to increase convergence rate of the method, Akay and Karaboga [5] proposed a control parameter named as modification rate-MR. In the basic ABC, only one dimension of the food source position is updated by the employed or onlooker bees, but in the ABC with MR (called as  $ABC_{MR}$ ), whether a dimension will be updated is decided by using MR value which is a number in range of [0,1]. By using MR parameter, the Eq. (2) is changed as follows:

$$V_{ij} = \begin{cases} S_{ij} + \varphi \times (S_{ij} - N_j) & \text{if}(R_{ij} < MR) \\ S_{ij} & \text{otherwise} \end{cases}$$
(5) 231

where  $R_{ij}$  is a random number produced in range of [0,1]. If random number is less than MR, the dimension *j* is modified and at least one dimension is updated by using Eq. (3). The lower value for MR may cause solutions to improve slowly while higher value for MR can be caused too much diversification in the population [5]. Therefore, we used 0.3 and 0.7 values for the MR in the experiments by obtaining from [5].

The searching around the food source in the basic ABC is fully random in terms of direction because  $\varphi$  is a random number between [-1,1]. This undirected search has caused the slow convergence of the algorithm to the optimum or near optimum. Therefore, we added direction information for each dimension of for each food source position. By using direction information for the dimensions, the Eq. (3) is modified as follows:

$$V_{ij} = \begin{cases} S_{ij} + \varphi \times (S_{ij} - N_j) & \text{if}(d_{ij} = 0) \\ S_{ij} + r \times \operatorname{abs}(S_{ij} - N_j) & \text{if}(d_{ij} = 1) \\ S_{ij} - r \times \operatorname{abs}(S_{ij} - N_j) & \text{if}(d_{ij} = -1) \end{cases}$$
(6) 24

where abs is absolute function,  $d_{ij}$  is the direction information for *j*th dimension of the *i*th food source position and while  $\varphi$  is a random

Fig. 3. The convergence graph of the methods on the sphere function with 30-D.

number in range of [-1,+1], r is a random number produced in range 250 of [0,1].

The Eq. (6) identifies the direction of searching. In the initializa-252 tion of the algorithm, the direction of information for all dimensions 253 equals to 0. If the new solution obtained by Eq. (6) is better than 254 old one (the better solution is determined by using fitness values 255 of the old and new solutions via Eq. (2)), the direction information 256 is updated. If previous value of the dimension is less than current 257 258 value, the direction information of this dimension is set to -1; oth-259 erwise the direction information of this dimension is set to 1. If new solution obtained by Eq. (6) is worse than old one, the direction 260 information of the dimension is set to 0. In this way, the direction 261 information of each dimension of each food source position is used 262 and also, the local search capability and convergence rate of the 263 algorithm are improved. This situation is also shown by using an 264 illustrative example in Fig. 2. Based on Fig. 2, a worse value can be 265 obtained for Fx because an undirected search is performed on the 266 search field for Fx. If we use direction information for Fx, the search 267 tends to optimum (Figs. 3-10). 2602

#### 3. Experiments 269

251

The performance of the method is investigated on the well-270 known eight benchmark functions taken from [5] and collected 271 from the literature. The experiments are conducted on IBM-272 compatible PC with 3.01 GHZ, 4GB Ram and Matlab® 7.04 platform. 273 Each experiment is repeated 30 times with random seeds and the 274

best, the worst, mean and standard deviations are reported on the comparisons.

#### 3.1. Benchmark functions

The benchmark functions are given in Table 1. D, C, Range and  $f(x^*)$  in Table 1, are dimensions, characteristics, lower and upper bounds of search spaces and global minimum values of the functions, respectively. The numerical functions used in the experiments have some characteristics. If a function has more than one local minimum, this function is called as multimodal (M) and the multimodal functions such as Rastrigin. Griewank tests search ability of the algorithms. Unimodal functions (U) such as Sphere has only one local optimum and this is global optimum. The exploitation ability of the algorithms is examined on this kind of functions. If a function with *n*-variable can be written as sum of the *n* functions of one variable, then this function is called as separable (S) function (Sphere, Rastrigin). Non-separable functions such as Rosenbrock functions cannot be written in this form because there is interrelation among variables of these functions. Therefore, to optimize non-separable functions is more difficult than optimizing the separable functions. The dimensionality of the search space is also an important issue with the problem for the algorithms [9,26]. If the global optimum of the function is in the narrow curving valley such as Rosenbrock's Banana function, the methods should keep up the direction changes in the functions. In the experiments, we investigated and compared the performance of the methods on the numeric functions with 10, 30 and 50 dimensionalities (Table 1X). 03 300

### 3.2. Setting control parameters for methods

In order to make a clear and consistent comparison, the control parameters values of the methods are equal to each other. Akay and Karaboga [27] show that there is no need to a huge colony size for basic ABC algorithm. Therefore, the population size is taken as 40 in the experiments. The limit value which is a specific control parameter for ABC algorithms for the population is calculated as follows [9]:

$$limit = NE \times D \tag{7}$$

where limit is used for controlling occurrence of scout bee, NE is the number of food source or employed bee and D is dimensionality of the optimization problem. By using Eq. (7), the occurrence of scout

bee is properly controlled by depending on population size and dimensionality of the problem.

The ABC<sub>MR</sub> algorithm with lower MR value likes to basic ABC algorithm and ABC<sub>MR</sub> algorithm with higher MR value has caused more diversification in the population [5]. Therefore, we used 0.3 and 0.7 values for the MR parameter in the experiments.

The termination condition for the methods is used maximum 319 cycle number (MCN) and MCN is taken as 500, 1000 and 1500 for 320 10, 30 and 50-dimensional numeric functions, respectively.

#### 3.3. Comparison of the methods 322

Comparisons of the basic ABC, ABC<sub>MR</sub>, dABC algorithms are given in Tables 2-4. Based on the comparisons, the dABC algorithm is very effectiveness for solving numeric functions.

While the dimensionality of the functions is increased, the per-326 formance of the methods is decreased but when the performance 327 of the methods is compared, it is shown that the dABC algorithm 328 is better than the other methods in terms of solution quality and 329 robustness by considering mean results and standard deviations. 330 Wilcoxon non-parametric signed-rank statistical test with 0.05 p 331 value is performed to the results of 30 independent runs and the 332 statistical tests results are shown in Tables 5-7 for 10, 30 and 50-333 dimensional functions, respectively. According to statistical test 334 results, the proposed method is significantly different from the 335 basic or other ABC variants in most cases. The convergence graphs 336 of the methods are also figured for the 30-D functions and the con-337 338 vergence rate of dABC algorithm is better than the other methods 339 except Weierstrass function. In addition, the experimental results

http://dx.doi.org/10.1016/j.asoc.2014.10.020

and convergence graphs of the ABC<sub>MR</sub> show that 0.3 value for MR parameter is more appropriate than 0.7 value.

## 4. Discussion

The swarm intelligence-based optimization methods start with random initial solutions to search solution space. For obtaining an optimum or near optimum solution, the interactions between the agents in the population are used. In the ABC algorithm, the dance behavior is performed for sharing position information about the food sources. In this point, the direction information is important factor for finding a good solution although basic ABC algorithm is undirected and this information is not shared in the artificial hive of ABC. This issue has caused to slow convergence and decreased local search ability of basic ABC algorithm. In this work, for each dimension of each food source is described a field for direction information and this is used for updating position of food sources. Obtained results show that the proposed approach is better than the other versions of ABC algorithm in terms of solution quality, robustness and convergence characteristics. ABC<sub>MR</sub> method use the technique based on updating more than one decision variable or dimension at the each iteration of ABC for improving convergence and local search characteristics of basic ABC algorithm. Instead of more than one decision variable, dABC method uses direction information for improving convergence characteristic and local search capability of basic ABC algorithm and this mechanism is better than the other technique in terms of solution quality and convergence to optima according to experiments.

### 5. Conclusion and future works

In this study, a new version of basic ABC algorithm named as dABC is described, and performance of the proposed approach is investigated on the numeric benchmark functions. Obtained results are compared with basic ABC and ABC<sub>MR</sub> algorithms and experimental results show that dABC algorithm is better than the other methods in terms of solution quality and convergence characteristics. This is originated from giving the direction information to the bee population. The direction information is used to constrict the search space for obtaining better solutions. Therefore, obtained new solutions guide for the search process and the solution information about search space are shared in the bee population. This version of dABC algorithm uses the update rule of basic ABC algorithm and the other update rules proposed in the literature can be replaced with the basic update rule of ABC algorithm. We will apply the other update rules for dABC algorithm in our future works.
