**Part D.** At  $100.0^\circ\text{C}$ , another phase change occurs as the water changes from water at  $100.0^\circ\text{C}$  to steam at  $100.0^\circ\text{C}$ . Similar to the ice–water mixture in part B, the water–steam mixture remains at  $100.0^\circ\text{C}$ —even though energy is being added—until all of the liquid has been converted to steam. The energy required to convert 1.00 g of water to steam at  $100.0^\circ\text{C}$  is

$$Q = mL_v = (1.00 \times 10^{-3} \text{ kg})(2.26 \times 10^6 \text{ J/kg}) = 2.26 \times 10^3 \text{ J}$$

**Part E.** On this portion of the curve, as in parts A and C, no phase change occurs; thus, all energy added is used to increase the temperature of the steam. The energy that must be added to raise the temperature of the steam from  $100.0^\circ\text{C}$  to  $120.0^\circ\text{C}$  is

$$Q = m_s c_s \Delta T = (1.00 \times 10^{-3} \text{ kg})(2.01 \times 10^3 \text{ J/kg}\cdot^\circ\text{C})(20.0^\circ\text{C}) = 40.2 \text{ J}$$

The total amount of energy that must be added to change 1 g of ice at  $-30.0^\circ\text{C}$  to steam at  $120.0^\circ\text{C}$  is the sum of the results from all five parts of the curve, which is  $3.11 \times 10^3 \text{ J}$ . Conversely, to cool 1 g of steam at  $120.0^\circ\text{C}$  to ice at  $-30.0^\circ\text{C}$ , we must remove  $3.11 \times 10^3 \text{ J}$  of energy.

We can describe phase changes in terms of a rearrangement of molecules when energy is added to or removed from a substance. (For elemental substances in which the atoms do not combine to form molecules, the following discussion should be interpreted in terms of atoms. We use the general term *molecules* to refer to both molecular substances and elemental substances.) Consider first the liquid-to-gas phase change. The molecules in a liquid are close together, and the forces between them are stronger than those between the more widely separated molecules of a gas. Therefore, work must be done on the liquid against these attractive molecular forces if the molecules are to separate. The latent heat of vaporization is the amount of energy per unit mass that must be added to the liquid to accomplish this separation.

Similarly, for a solid, we imagine that the addition of energy causes the amplitude of vibration of the molecules about their equilibrium positions to become greater as the temperature increases. At the melting point of the solid, the amplitude is great enough to break the bonds between molecules and to allow molecules to move to new positions. The molecules in the liquid also are bound to each other, but less strongly than those in the solid phase. The latent heat of fusion is equal to the energy required per unit mass to transform the bonds among all molecules from the solid-type bond to the liquid-type bond.

As you can see from Table 20.2, the latent heat of vaporization for a given substance is usually somewhat higher than the latent heat of fusion. This is not surprising if we consider that the average distance between molecules in the gas phase is much greater than that in either the liquid or the solid phase. In the solid-to-liquid phase change, we transform solid-type bonds between molecules into liquid-type bonds between molecules, which are only slightly less strong. In the liquid-to-gas phase change, however, we break liquid-type bonds and create a situation in which the molecules of the gas essentially are not bonded to each

other. Therefore, it is not surprising that more energy is required to vaporize a given mass of substance than is required to melt it.

### Quick Quiz 20.3

Calculate the slopes for the A, C, and E portions of Figure 20.2. Rank the slopes from least to greatest and explain what this ordering means.

### Problem-Solving Hints

#### Calorimetry Problems

If you are having difficulty in solving calorimetry problems, be sure to consider the following points:

- Units of measure must be consistent. For instance, if you are using specific heats measured in  $\text{cal/g} \cdot ^\circ\text{C}$ , be sure that masses are in grams and temperatures are in Celsius degrees.
- Transfers of energy are given by the equation  $Q = mc\Delta T$  only for those processes in which no phase changes occur. Use the equations  $Q = mL_f$  and  $Q = mL_v$  only when phase changes *are* taking place.
- Often, errors in sign are made when the equation  $Q_{\text{cold}} = -Q_{\text{hot}}$  is used. Make sure that you use the negative sign in the equation, and remember that  $\Delta T$  is always the final temperature minus the initial temperature.

### EXAMPLE 20.4 Cooling the Steam

What mass of steam initially at  $130^\circ\text{C}$  is needed to warm 200 g of water in a 100-g glass container from  $20.0^\circ\text{C}$  to  $50.0^\circ\text{C}$ ?

**Solution** The steam loses energy in three stages. In the first stage, the steam is cooled to  $100^\circ\text{C}$ . The energy transfer in the process is

$$\begin{aligned} Q_1 &= m_s c_s \Delta T = m_s (2.01 \times 10^3 \text{ J/kg} \cdot ^\circ\text{C}) (-30.0^\circ\text{C}) \\ &= -m_s (6.03 \times 10^4 \text{ J/kg}) \end{aligned}$$

where  $m_s$  is the unknown mass of the steam.

In the second stage, the steam is converted to water. To find the energy transfer during this phase change, we use  $Q = -mL_v$ , where the negative sign indicates that energy is leaving the steam:

$$Q_2 = -m_s (2.26 \times 10^6 \text{ J/kg})$$

In the third stage, the temperature of the water created from the steam is reduced to  $50.0^\circ\text{C}$ . This change requires an energy transfer of

$$\begin{aligned} Q_3 &= m_s c_w \Delta T = m_s (4.19 \times 10^3 \text{ J/kg} \cdot ^\circ\text{C}) (-50.0^\circ\text{C}) \\ &= -m_s (2.09 \times 10^5 \text{ J/kg}) \end{aligned}$$

Adding the energy transfers in these three stages, we obtain

$$\begin{aligned} Q_{\text{hot}} &= Q_1 + Q_2 + Q_3 \\ &= -m_s (6.03 \times 10^4 \text{ J/kg} + 2.26 \times 10^6 \text{ J/kg} \\ &\quad + 2.09 \times 10^5 \text{ J/kg}) \\ &= -m_s (2.53 \times 10^6 \text{ J/kg}) \end{aligned}$$

Now, we turn our attention to the temperature increase of the water and the glass. Using Equation 20.4, we find that

$$\begin{aligned} Q_{\text{cold}} &= (0.200 \text{ kg}) (4.19 \times 10^3 \text{ J/kg} \cdot ^\circ\text{C}) (30.0^\circ\text{C}) \\ &\quad + (0.100 \text{ kg}) (837 \text{ J/kg} \cdot ^\circ\text{C}) (30.0^\circ\text{C}) \\ &= 2.77 \times 10^4 \text{ J} \end{aligned}$$

Using Equation 20.5, we can solve for the unknown mass:

$$\begin{aligned} Q_{\text{cold}} &= -Q_{\text{hot}} \\ 2.77 \times 10^4 \text{ J} &= -[-m_s (2.53 \times 10^6 \text{ J/kg})] \\ m_s &= 1.09 \times 10^{-2} \text{ kg} = 10.9 \text{ g} \end{aligned}$$

**EXAMPLE 20.5** Boiling Liquid Helium

Liquid helium has a very low boiling point, 4.2 K, and a very low latent heat of vaporization,  $2.09 \times 10^4$  J/kg. If energy is transferred to a container of boiling liquid helium from an immersed electric heater at a rate of 10.0 W, how long does it take to boil away 1.00 kg of the liquid?

**Solution** Because  $L_v = 2.09 \times 10^4$  J/kg, we must supply  $2.09 \times 10^4$  J of energy to boil away 1.00 kg. Because  $10.0 \text{ W} = 10.0 \text{ J/s}$ , 10.0 J of energy is transferred to the helium each second. Therefore, the time it takes to transfer  $2.09 \times 10^4$  J

of energy is

$$t = \frac{2.09 \times 10^4 \text{ J}}{10.0 \text{ J/s}} = 2.09 \times 10^3 \text{ s} \approx 35 \text{ min}$$

**Exercise** If 10.0 W of power is supplied to 1.00 kg of water at  $100^\circ\text{C}$ , how long does it take for the water to completely boil away?

**Answer** 62.8 h.

**20.4** WORK AND HEAT IN THERMODYNAMIC PROCESSES

**10.6** In the macroscopic approach to thermodynamics, we describe the *state* of a system using such variables as pressure, volume, temperature, and internal energy. The number of macroscopic variables needed to characterize a system depends on the nature of the system. For a homogeneous system, such as a gas containing only one type of molecule, usually only two variables are needed. However, it is important to note that a *macroscopic state* of an isolated system can be specified only if the system is in thermal equilibrium internally. In the case of a gas in a container, internal thermal equilibrium requires that every part of the gas be at the same pressure and temperature.

Consider a gas contained in a cylinder fitted with a movable piston (Fig. 20.3). At equilibrium, the gas occupies a volume  $V$  and exerts a uniform pressure  $P$  on the cylinder's walls and on the piston. If the piston has a cross-sectional area  $A$ , the

**Figure 20.3** Gas contained in a cylinder at a pressure  $P$  does work on a moving piston as the system expands from a volume  $V$  to a volume  $V + dV$ .

force exerted by the gas on the piston is  $F = PA$ . Now let us assume that the gas expands **quasi-statically**, that is, slowly enough to allow the system to remain essentially in thermal equilibrium at all times. As the piston moves up a distance  $dy$ , the work done by the gas on the piston is

$$dW = F dy = PA dy$$

Because  $A dy$  is the increase in volume of the gas  $dV$ , we can express the work done by the gas as

$$dW = P dV \quad (20.7)$$

Because the gas expands,  $dV$  is positive, and so the work done by the gas is positive. If the gas were compressed,  $dV$  would be negative, indicating that the work done by the gas (which can be interpreted as work done *on* the gas) was negative.

In the thermodynamics problems that we shall solve, we shall identify the system of interest as a substance that is exchanging energy with the environment. In many problems, this will be a gas contained in a vessel; however, we will also consider problems involving liquids and solids. It is an unfortunate fact that, because of the separate historical development of thermodynamics and mechanics, positive work for a thermodynamic system is commonly defined as the work done *by* the system, rather than that done *on* the system. This is the reverse of the case for our study of work in mechanics. Thus, **in thermodynamics, positive work represents a transfer of energy out of the system.** We will use this convention to be consistent with common treatments of thermodynamics.

The total work done by the gas as its volume changes from  $V_i$  to  $V_f$  is given by the integral of Equation 20.7:

$$W = \int_{V_i}^{V_f} P dV \quad (20.8)$$

To evaluate this integral, it is not enough that we know only the initial and final values of the pressure. We must also know the pressure at every instant during the expansion; we would know this if we had a functional dependence of  $P$  with respect to  $V$ . This important point is true for any process—the expansion we are discussing here, or any other. To fully specify a process, we must know the values of the thermodynamic variables at every state through which the system passes between the initial and final states. In the expansion we are considering here, we can plot the pressure and volume at each instant to create a  $PV$  diagram like the one shown in Figure 20.4. The value of the integral in Equation 20.8 is the area bounded by such a curve. Thus, we can say that

the work done by a gas in the expansion from an initial state to a final state is the area under the curve connecting the states in a  $PV$  diagram.

**Figure 20.4** A gas expands quasi-statically (slowly) from state  $i$  to state  $f$ . The work done by the gas equals the area under the  $PV$  curve.

Work equals area under the curve in a  $PV$  diagram.

As Figure 20.4 shows, the work done in the expansion from the initial state  $i$  to the final state  $f$  depends on the path taken between these two states, where the *path* on a  $PV$  diagram is a description of the thermodynamic process through which the system is taken. To illustrate this important point, consider several paths connecting  $i$  and  $f$  (Fig. 20.5). In the process depicted in Figure 20.5a, the pressure of the gas is first reduced from  $P_i$  to  $P_f$  by cooling at constant volume  $V_i$ . The gas then expands from  $V_i$  to  $V_f$  at constant pressure  $P_f$ . The value of the work done along this path is equal to the area of the shaded rectangle, which is equal to

**Figure 20.5** The work done by a gas as it is taken from an initial state to a final state depends on the path between these states.

$P_f(V_f - V_i)$ . In Figure 20.5b, the gas first expands from  $V_i$  to  $V_f$  at constant pressure  $P_i$ . Then, its pressure is reduced to  $P_f$  at constant volume  $V_f$ . The value of the work done along this path is  $P_i(V_f - V_i)$ , which is greater than that for the process described in Figure 20.5a. Finally, for the process described in Figure 20.5c, where both  $P$  and  $V$  change continuously, the work done has some value intermediate between the values obtained in the first two processes. Therefore, we see that **the work done by a system depends on the initial and final states and on the path followed by the system between these states.**

Work done depends on the path between the initial and final states.

The energy transfer by heat  $Q$  into or out of a system also depends on the process. Consider the situations depicted in Figure 20.6. In each case, the gas has the same initial volume, temperature, and pressure and is assumed to be ideal. In Figure 20.6a, the gas is thermally insulated from its surroundings except at the bottom of the gas-filled region, where it is in thermal contact with an energy reservoir. An *energy reservoir* is a source of energy that is considered to be so great that a finite transfer of energy from the reservoir does not change its temperature. The piston is held at its initial position by an external agent—a hand, for instance. When the force with which the piston is held is reduced slightly, the piston rises very slowly to its final position. Because the piston is moving upward, the gas is doing work on

**Figure 20.6** (a) A gas at temperature  $T_i$  expands slowly while absorbing energy from a reservoir in order to maintain a constant temperature. (b) A gas expands rapidly into an evacuated region after a membrane is broken.

the piston. During this expansion to the final volume  $V_f$ , just enough energy is transferred by heat from the reservoir to the gas to maintain a constant temperature  $T_i$ .

Now consider the completely thermally insulated system shown in Figure 20.6b. When the membrane is broken, the gas expands rapidly into the vacuum until it occupies a volume  $V_f$  and is at a pressure  $P_f$ . In this case, the gas does no work because there is no movable piston on which the gas applies a force. Furthermore, no energy is transferred by heat through the insulating wall.

The initial and final states of the ideal gas in Figure 20.6a are identical to the initial and final states in Figure 20.6b, but the paths are different. In the first case, the gas does work on the piston, and energy is transferred slowly to the gas. In the second case, no energy is transferred, and the value of the work done is zero. Therefore, we conclude that **energy transfer by heat, like work done, depends on the initial, final, and intermediate states of the system.** In other words, because heat and work depend on the path, neither quantity is determined solely by the end points of a thermodynamic process.

## 20.5 THE FIRST LAW OF THERMODYNAMICS

**10.6** When we introduced the law of conservation of mechanical energy in Chapter 8, we stated that the mechanical energy of a system is constant in the absence of non-conservative forces such as friction. That is, we did not include changes in the internal energy of the system in this mechanical model. The first law of thermodynamics is a generalization of the law of conservation of energy that encompasses changes in internal energy. It is a universally valid law that can be applied to many processes and provides a connection between the microscopic and macroscopic worlds.

We have discussed two ways in which energy can be transferred between a system and its surroundings. One is work done by the system, which requires that there be a macroscopic displacement of the point of application of a force (or pressure). The other is heat, which occurs through random collisions between the molecules of the system. Both mechanisms result in a change in the internal energy of the system and therefore usually result in measurable changes in the macroscopic variables of the system, such as the pressure, temperature, and volume of a gas.

To better understand these ideas on a quantitative basis, suppose that a system undergoes a change from an initial state to a final state. During this change, energy transfer by heat  $Q$  to the system occurs, and work  $W$  is done by the system. As an example, suppose that the system is a gas in which the pressure and volume change from  $P_i$  and  $V_i$  to  $P_f$  and  $V_f$ . If the quantity  $Q - W$  is measured for various paths connecting the initial and final equilibrium states, we find that it is the same for all paths connecting the two states. We conclude that the quantity  $Q - W$  is determined completely by the initial and final states of the system, and we call this quantity the **change in the internal energy** of the system. Although  $Q$  and  $W$  both depend on the path, **the quantity  $Q - W$  is independent of the path.** If we use the symbol  $E_{\text{int}}$  to represent the internal energy, then the *change* in internal energy  $\Delta E_{\text{int}}$  can be expressed as<sup>5</sup>

$$\Delta E_{\text{int}} = Q - W \quad (20.9)$$

<sup>5</sup> It is an unfortunate accident of history that the traditional symbol for internal energy is  $U$ , which is also the traditional symbol for potential energy, as introduced in Chapter 8. To avoid confusion between potential energy and internal energy, we use the symbol  $E_{\text{int}}$  for internal energy in this book. If you take an advanced course in thermodynamics, however, be prepared to see  $U$  used as the symbol for internal energy.

This device, called *Hero's engine*, was invented around 150 B.C. by Hero in Alexandria. When water is boiled in the flask, which is suspended by a cord, steam exits through two tubes at the sides (in opposite directions), creating a torque that rotates the flask.

$Q - W$  is the change in internal energy

First-law equation

where all quantities must have the same units of measure for energy.<sup>6</sup> Equation 20.9 is known as the **first-law equation** and is a key concept in many applications. As a reminder, we use the convention that  $Q$  is positive when energy enters the system and negative when energy leaves the system, and that  $W$  is positive when the system does work on the surroundings and negative when work is done on the system.

When a system undergoes an infinitesimal change in state in which a small amount of energy  $dQ$  is transferred by heat and a small amount of work  $dW$  is done, the internal energy changes by a small amount  $dE_{\text{int}}$ . Thus, for infinitesimal processes we can express the first-law equation as<sup>7</sup>

$$dE_{\text{int}} = dQ - dW$$

The first-law equation is an energy conservation equation specifying that the only type of energy that changes in the system is the internal energy  $E_{\text{int}}$ . Let us look at some special cases in which this condition exists.

First, let us consider an *isolated system*—that is, one that does not interact with its surroundings. In this case, no energy transfer by heat takes place and the value of the work done by the system is zero; hence, the internal energy remains constant. That is, because  $Q = W = 0$ , it follows that  $\Delta E_{\text{int}} = 0$ , and thus  $E_{\text{int},i} = E_{\text{int},f}$ . We conclude that **the internal energy  $E_{\text{int}}$  of an isolated system remains constant.**

Next, we consider the case of a system (one not isolated from its surroundings) that is taken through a **cyclic process**—that is, a process that starts and ends at the same state. In this case, the change in the internal energy must again be zero, and therefore the energy  $Q$  added to the system must equal the work  $W$  done by the system during the cycle. That is, in a cyclic process,

$$\Delta E_{\text{int}} = 0 \quad \text{and} \quad Q = W$$

On a  $PV$  diagram, a cyclic process appears as a closed curve. (The processes described in Figure 20.5 are represented by open curves because the initial and final states differ.) It can be shown that **in a cyclic process, the net work done by the system per cycle equals the area enclosed by the path representing the process on a  $PV$  diagram.**

If the value of the work done by the system during some process is zero, then the change in internal energy  $\Delta E_{\text{int}}$  equals the energy transfer  $Q$  into or out of the system:

$$\Delta E_{\text{int}} = Q$$

If energy enters the system, then  $Q$  is positive and the internal energy increases. For a gas, we can associate this increase in internal energy with an increase in the kinetic energy of the molecules. Conversely, if no energy transfer occurs during some process but work is done by the system, then the change in internal energy equals the negative value of the work done by the system:

$$\Delta E_{\text{int}} = -W$$

<sup>6</sup> For the definition of work from our mechanics studies, the first law would be written as  $\Delta E_{\text{int}} = Q + W$  because energy transfer into the system by either work or heat would increase the internal energy of the system. Because of the reversal of the definition of positive work discussed in Section 20.4, the first law appears as in Equation 20.9, with a minus sign.

<sup>7</sup> Note that  $dQ$  and  $dW$  are not true differential quantities; however,  $dE_{\text{int}}$  is. Because  $dQ$  and  $dW$  are *inexact differentials*, they are often represented by the symbols  $\delta Q$  and  $\delta W$ . For further details on this point, see an advanced text on thermodynamics, such as R. P. Bauman, *Modern Thermodynamics and Statistical Mechanics*, New York, Macmillan Publishing Co., 1992.

First-law equation for infinitesimal changes

Isolated system

Cyclic process

For example, if a gas is compressed by a moving piston in an insulated cylinder, no energy is transferred by heat and the work done by the gas is negative; thus, the internal energy increases because kinetic energy is transferred from the moving piston to the gas molecules.

On a microscopic scale, no distinction exists between the result of heat and that of work. Both heat and work can produce a change in the internal energy of a system. Although the macroscopic quantities  $Q$  and  $W$  are *not* properties of a system, they are related to the change of the internal energy of a system through the first-law equation. Once we define a process, or path, we can either calculate or measure  $Q$  and  $W$ , and we can find the change in the system's internal energy using the first-law equation.

One of the important consequences of the first law of thermodynamics is that there exists a quantity known as internal energy whose value is determined by the state of the system. The internal energy function is therefore called a *state function*.

## 20.6 SOME APPLICATIONS OF THE FIRST LAW OF THERMODYNAMICS

Before we apply the first law of thermodynamics to specific systems, it is useful for us to first define some common thermodynamic processes. An **adiabatic process** is one during which no energy enters or leaves the system by heat—that is,  $Q = 0$ . An adiabatic process can be achieved either by thermally insulating the system from its surroundings (as shown in Fig. 20.6b) or by performing the process rapidly, so that there is little time for energy to transfer by heat. Applying the first law of thermodynamics to an adiabatic process, we see that

$$\Delta E_{\text{int}} = -W \quad (\text{adiabatic process}) \quad (20.10)$$

From this result, we see that if a gas expands adiabatically such that  $W$  is positive, then  $\Delta E_{\text{int}}$  is negative and the temperature of the gas decreases. Conversely, the temperature of a gas increases when the gas is compressed adiabatically.

Adiabatic processes are very important in engineering practice. Some common examples are the expansion of hot gases in an internal combustion engine, the liquefaction of gases in a cooling system, and the compression stroke in a diesel engine.

The process described in Figure 20.6b, called an **adiabatic free expansion**, is unique. The process is adiabatic because it takes place in an insulated container. Because the gas expands into a vacuum, it does not apply a force on a piston as was depicted in Figure 20.6a, so no work is done on or by the gas. Thus, in this adiabatic process, both  $Q = 0$  and  $W = 0$ . As a result,  $\Delta E_{\text{int}} = 0$  for this process, as we can see from the first law. That is, **the initial and final internal energies of a gas are equal in an adiabatic free expansion**. As we shall see in the next chapter, the internal energy of an ideal gas depends only on its temperature. Thus, we expect no change in temperature during an adiabatic free expansion. This prediction is in accord with the results of experiments performed at low pressures. (Experiments performed at high pressures for real gases show a slight decrease or increase in temperature after the expansion. This change is due to intermolecular interactions, which represent a deviation from the model of an ideal gas.)

A process that occurs at constant pressure is called an **isobaric process**. In such a process, the values of the heat and the work are both usually nonzero. The

In an adiabatic process,  $Q = 0$ .

First-law equation for an adiabatic process

In an adiabatic free expansion,  $\Delta E_{\text{int}} = 0$ .

In an isobaric process,  $P$  remains constant.

work done by the gas is simply

$$W = P(V_f - V_i) \quad (\text{isobaric process}) \quad (20.11)$$

where  $P$  is the constant pressure.

A process that takes place at constant volume is called an **isovolumetric process**. In such a process, the value of the work done is clearly zero because the volume does not change. Hence, from the first law we see that in an isovolumetric process, because  $W = 0$ ,

$$\Delta E_{\text{int}} = Q \quad (\text{isovolumetric process}) \quad (20.12)$$

This expression specifies that **if energy is added by heat to a system kept at constant volume, then all of the transferred energy remains in the system as an increase of the internal energy of the system**. For example, when a can of spray paint is thrown into a fire, energy enters the system (the gas in the can) by heat through the metal walls of the can. Consequently, the temperature, and thus the pressure, in the can increases until the can possibly explodes.

A process that occurs at constant temperature is called an **isothermal process**. A plot of  $P$  versus  $V$  at constant temperature for an ideal gas yields a hyperbolic curve called an *isotherm*. The internal energy of an ideal gas is a function of temperature only. Hence, in an isothermal process involving an ideal gas,  $\Delta E_{\text{int}} = 0$ . For an isothermal process, then, we conclude from the first law that the energy transfer  $Q$  must be equal to the work done by the gas—that is,  $Q = W$ . Any energy that enters the system by heat is transferred out of the system by work; as a result, no change of the internal energy of the system occurs.

First-law equation for a constant-volume process

In an isothermal process,  $T$  remains constant.

### Quick Quiz 20.4

In the last three columns of the following table, fill in the boxes with  $-$ ,  $+$ , or  $0$ . For each situation, the system to be considered is identified.

Situation	System	$Q$	$W$	$\Delta E_{\text{int}}$
(a) Rapidly pumping up a bicycle tire	Air in the pump			
(b) Pan of room-temperature water sitting on a hot stove	Water in the pan			
(c) Air quickly leaking out of a balloon	Air originally in balloon			

**Figure 20.7** The  $PV$  diagram for an isothermal expansion of an ideal gas from an initial state to a final state. The curve is a hyperbola.

### Isothermal Expansion of an Ideal Gas

Suppose that an ideal gas is allowed to expand quasi-statically at constant temperature, as described by the  $PV$  diagram shown in Figure 20.7. The curve is a hyperbola (see Appendix B, Eq. B.23), and the equation of state of an ideal gas with  $T$  constant indicates that the equation of this curve is  $PV = \text{constant}$ . The isothermal expansion of the gas can be achieved by placing the gas in thermal contact with an energy reservoir at the same temperature, as shown in Figure 20.6a.

Let us calculate the work done by the gas in the expansion from state  $i$  to state  $f$ . The work done by the gas is given by Equation 20.8. Because the gas is ideal and the process is quasi-static, we can use the expression  $PV = nRT$  for each point on

the path. Therefore, we have

$$W = \int_{V_i}^{V_f} P dV = \int_{V_i}^{V_f} \frac{nRT}{V} dV$$

Because  $T$  is constant in this case, it can be removed from the integral along with  $n$  and  $R$ :

$$W = nRT \int_{V_i}^{V_f} \frac{dV}{V} = nRT \ln V \Big|_{V_i}^{V_f}$$

To evaluate the integral, we used  $\int (dx/x) = \ln x$ . Evaluating this at the initial and final volumes, we have

$$W = nRT \ln \left( \frac{V_f}{V_i} \right) \quad (20.13)$$

Work done by an ideal gas in an isothermal process

Numerically, this work  $W$  equals the shaded area under the  $PV$  curve shown in Figure 20.7. Because the gas expands,  $V_f > V_i$ , and the value for the work done by the gas is positive, as we expect. If the gas is compressed, then  $V_f < V_i$ , and the work done by the gas is negative.

### Quick Quiz 20.5

Characterize the paths in Figure 20.8 as isobaric, isovolumetric, isothermal, or adiabatic. Note that  $Q = 0$  for path B.

**Figure 20.8** Identify the nature of paths A, B, C, and D.

### EXAMPLE 20.6 An Isothermal Expansion

A 1.0-mol sample of an ideal gas is kept at  $0.0^\circ\text{C}$  during an expansion from 3.0 L to 10.0 L. (a) How much work is done by the gas during the expansion?

**Solution** Substituting the values into Equation 20.13, we have

$$W = nRT \ln \left( \frac{V_f}{V_i} \right)$$

$$\begin{aligned} W &= (1.0 \text{ mol})(8.31 \text{ J/mol}\cdot\text{K})(273 \text{ K}) \ln \left( \frac{10.0}{3.0} \right) \\ &= 2.7 \times 10^3 \text{ J} \end{aligned}$$

(b) How much energy transfer by heat occurs with the surroundings in this process?

**Solution** From the first law, we find that

$$\Delta E_{\text{int}} = Q - W$$

$$0 = Q - W$$

$$Q = W = 2.7 \times 10^3 \text{ J}$$

(c) If the gas is returned to the original volume by means of an isobaric process, how much work is done by the gas?

**Solution** The work done in an isobaric process is given by Equation 20.11. We are not given the pressure, so we need to incorporate the ideal gas law:

$$\begin{aligned} W &= P(V_f - V_i) = \frac{nRT_i}{V_i}(V_f - V_i) \\ &= \frac{(1.0 \text{ mol})(8.31 \text{ J/mol}\cdot\text{K})(273 \text{ K})}{10.0 \times 10^{-3} \text{ m}^3} \\ &\quad \times (3.0 \times 10^{-3} \text{ m}^3 - 10.0 \times 10^{-3} \text{ m}^3) \\ &= -1.6 \times 10^3 \text{ J} \end{aligned}$$

Notice that we use the initial temperature and volume to determine the value of the constant pressure because we do not know the final temperature. The work done by the gas is negative because the gas is being compressed.

### EXAMPLE 20.7 Boiling Water

Suppose 1.00 g of water vaporizes isobarically at atmospheric pressure ( $1.013 \times 10^5 \text{ Pa}$ ). Its volume in the liquid state is  $V_i = V_{\text{liquid}} = 1.00 \text{ cm}^3$ , and its volume in the vapor state is  $V_f = V_{\text{vapor}} = 1.671 \text{ m}^3$ . Find the work done in the expansion and the change in internal energy of the system. Ignore any mixing of the steam and the surrounding air—imagine that the steam simply pushes the surrounding air out of the way.

**Solution** Because the expansion takes place at constant pressure, the work done by the system in pushing away the surrounding air is, from Equation 20.11,

$$\begin{aligned} W &= P(V_f - V_i) \\ &= (1.013 \times 10^5 \text{ Pa})(1.671 \times 10^{-6} \text{ m}^3 - 1.00 \times 10^{-6} \text{ m}^3) \\ &= 169 \text{ J} \end{aligned}$$

To determine the change in internal energy, we must know the energy transfer  $Q$  needed to vaporize the water. Using Equation 20.6 and the latent heat of vaporization for water, we have

$$Q = mL_v = (1.00 \times 10^{-3} \text{ kg})(2.26 \times 10^6 \text{ J/kg}) = 2.260 \text{ J}$$

Hence, from the first law, the change in internal energy is

$$\Delta E_{\text{int}} = Q - W = 2.260 \text{ J} - 169 \text{ J} = 2.09 \text{ kJ}$$

The positive value for  $\Delta E_{\text{int}}$  indicates that the internal energy of the system increases. We see that most ( $2.090 \text{ J}/2.260 \text{ J} = 93\%$ ) of the energy transferred to the liquid goes into increasing the internal energy of the system. Only  $169 \text{ J}/2.260 \text{ J} = 7\%$  leaves the system by work done by the steam on the surrounding atmosphere.

### EXAMPLE 20.8 Heating a Solid

A 1.0-kg bar of copper is heated at atmospheric pressure. If its temperature increases from  $20^\circ\text{C}$  to  $50^\circ\text{C}$ , (a) what is the work done by the copper on the surrounding atmosphere?

**Solution** Because the process is isobaric, we can find the work done by the copper using Equation 20.11,  $W = P(V_f - V_i)$ . We can calculate the change in volume of the copper using Equation 19.6. Using the average linear expansion coefficient for copper given in Table 19.2, and remembering that  $\beta = 3\alpha$ , we obtain

$$\begin{aligned} \Delta V &= \beta V_i \Delta T \\ &= [5.1 \times 10^{-5} (\text{C}^{-1})](50^\circ\text{C} - 20^\circ\text{C}) V_i = 1.5 \times 10^{-3} V_i \end{aligned}$$

The volume  $V_i$  is equal to  $m/\rho$ , and Table 15.1 indicates that the density of copper is  $8.92 \times 10^3 \text{ kg/m}^3$ . Hence,

$$\Delta V = (1.5 \times 10^{-3}) \left( \frac{1.0 \text{ kg}}{8.92 \times 10^3 \text{ kg/m}^3} \right) = 1.7 \times 10^{-7} \text{ m}^3$$

The work done is

$$\begin{aligned} W &= P\Delta V = (1.013 \times 10^5 \text{ N/m}^2)(1.7 \times 10^{-7} \text{ m}^3) \\ &= 1.7 \times 10^{-2} \text{ J} \end{aligned}$$

(b) What quantity of energy is transferred to the copper by heat?

**Solution** Taking the specific heat of copper from Table 20.1 and using Equation 20.4, we find that the energy transferred by heat is

$$Q = mc\Delta T = (1.0 \text{ kg})(387 \text{ J/kg}\cdot^\circ\text{C})(30^\circ\text{C}) = 1.2 \times 10^4 \text{ J}$$

(c) What is the increase in internal energy of the copper?

**Solution** From the first law of thermodynamics, we have

$$\Delta E_{\text{int}} = Q - W = 1.2 \times 10^4 \text{ J} - 1.7 \times 10^{-2} \text{ J} = 1.2 \times 10^4 \text{ J}$$

Note that almost all of the energy transferred into the system by heat goes into increasing the internal energy. The fraction of energy used to do work on the surrounding atmosphere is only about  $10^{-6}$ ! Hence, when analyzing the thermal expansion of a solid or a liquid, the small amount of work done by the system is usually ignored.

## 20.7 ENERGY TRANSFER MECHANISMS

It is important to understand the rate at which energy is transferred between a system and its surroundings and the mechanisms responsible for the transfer. Therefore, let us now look at three common energy transfer mechanisms that can result in a change in internal energy of a system.

### Thermal Conduction

The energy transfer process that is most clearly associated with a temperature difference is **thermal conduction**. In this process, the transfer can be represented on an atomic scale as an exchange of kinetic energy between microscopic particles—molecules, atoms, and electrons—in which less energetic particles gain energy in collisions with more energetic particles. For example, if you hold one end of a long metal bar and insert the other end into a flame, you will find that the temperature of the metal in your hand soon increases. The energy reaches your hand by means of conduction. We can understand the process of conduction by examining what is happening to the microscopic particles in the metal. Initially, before the rod is inserted into the flame, the microscopic particles are vibrating about their equilibrium positions. As the flame heats the rod, those particles near the flame begin to vibrate with greater and greater amplitudes. These particles, in turn, collide with their neighbors and transfer some of their energy in the collisions. Slowly, the amplitudes of vibration of metal atoms and electrons farther and farther from the flame increase until, eventually, those in the metal near your hand are affected. This increased vibration represents an increase in the temperature of the metal and of your potentially burned hand.

The rate of thermal conduction depends on the properties of the substance being heated. For example, it is possible to hold a piece of asbestos in a flame indefinitely. This implies that very little energy is conducted through the asbestos. In general, metals are good thermal conductors, and materials such as asbestos, cork, paper, and fiberglass are poor conductors. Gases also are poor conductors because the separation distance between the particles is so great. Metals are good thermal conductors because they contain large numbers of electrons that are relatively free to move through the metal and so can transport energy over large distances. Thus, in a good conductor, such as copper, conduction takes place both by means of the vibration of atoms and by means of the motion of free electrons.

Conduction occurs only if there is a difference in temperature between two parts of the conducting medium. Consider a slab of material of thickness  $\Delta x$  and cross-sectional area  $A$ . One face of the slab is at a temperature  $T_1$ , and the other face is at a temperature  $T_2 > T_1$  (Fig. 20.9). Experimentally, it is found that the

Melted snow pattern on a parking lot surface indicates the presence of underground hot water pipes used to aid snow removal. Energy from the water is conducted from the pipes to the pavement, where it causes the snow to melt.

energy  $Q$  transferred in a time  $\Delta t$  flows from the hotter face to the colder one. The rate  $Q/\Delta t$  at which this energy flows is found to be proportional to the cross-sectional area and the temperature difference  $\Delta T = T_2 - T_1$ , and inversely proportional to the thickness:

$$\frac{Q}{\Delta t} \propto A \frac{\Delta T}{\Delta x}$$

It is convenient to use the symbol for power  $\mathcal{P}$  to represent the **rate of energy transfer**:  $\mathcal{P} = Q/\Delta t$ . Note that  $\mathcal{P}$  has units of watts when  $Q$  is in joules and  $\Delta t$  is in seconds. For a slab of infinitesimal thickness  $dx$  and temperature difference  $dT$ , we can write the **law of thermal conduction** as

$$\mathcal{P} = kA \left| \frac{dT}{dx} \right| \quad (20.14)$$

Law of thermal conduction

**Figure 20.9** Energy transfer through a conducting slab with a cross-sectional area  $A$  and a thickness  $\Delta x$ . The opposite faces are at different temperatures  $T_1$  and  $T_2$ .

where the proportionality constant  $k$  is the **thermal conductivity** of the material and  $|dT/dx|$  is the **temperature gradient** (the variation of temperature with position).

Suppose that a long, uniform rod of length  $L$  is thermally insulated so that energy cannot escape by heat from its surface except at the ends, as shown in Figure 20.10. One end is in thermal contact with an energy reservoir at temperature  $T_1$ , and the other end is in thermal contact with a reservoir at temperature  $T_2 > T_1$ . When a steady state has been reached, the temperature at each point along the rod is constant in time. In this case if we assume that  $k$  is not a function of temperature, the temperature gradient is the same everywhere along the rod and is

$$\left| \frac{dT}{dx} \right| = \frac{T_2 - T_1}{L}$$

Thus the rate of energy transfer by conduction through the rod is

$$\mathcal{P} = kA \frac{(T_2 - T_1)}{L} \quad (20.15)$$

Substances that are good thermal conductors have large thermal conductivity values, whereas good thermal insulators have low thermal conductivity values. Table 20.3 lists thermal conductivities for various substances. Note that metals are generally better thermal conductors than nonmetals are.

**Figure 20.10** Conduction of energy through a uniform, insulated rod of length  $L$ . The opposite ends are in thermal contact with energy reservoirs at different temperatures.

### Quick Quiz 20.6

Will an ice cube wrapped in a wool blanket remain frozen for (a) a shorter length of time, (b) the same length of time, or (c) a longer length of time than an identical ice cube exposed to air at room temperature?

For a compound slab containing several materials of thicknesses  $L_1, L_2, \dots$  and thermal conductivities  $k_1, k_2, \dots$ , the rate of energy transfer through the slab at steady state is

$$\mathcal{P} = \frac{A(T_2 - T_1)}{\sum_i (L_i/k_i)} \quad (20.16)$$

**TABLE 20.3** Thermal Conductivities

Substance	Thermal Conductivity (W/m·°C)
<b>Metals (at 25°C)</b>	
Aluminum	238
Copper	397
Gold	314
Iron	79.5
Lead	34.7
Silver	427
<b>Nonmetals (approximate values)</b>	
Asbestos	0.08
Concrete	0.8
Diamond	2 300
Glass	0.8
Ice	2
Rubber	0.2
Water	0.6
Wood	0.08
<b>Gases (at 20°C)</b>	
Air	0.023 4
Helium	0.138
Hydrogen	0.172
Nitrogen	0.023 4
Oxygen	0.023 8

where  $T_1$  and  $T_2$  are the temperatures of the outer surfaces (which are held constant) and the summation is over all slabs. The following example shows how this equation results from a consideration of two thicknesses of materials.

### EXAMPLE 20.9 Energy Transfer Through Two Slabs

Two slabs of thickness  $L_1$  and  $L_2$  and thermal conductivities  $k_1$  and  $k_2$  are in thermal contact with each other, as shown in Figure 20.11. The temperatures of their outer surfaces are  $T_1$  and  $T_2$ , respectively, and  $T_2 > T_1$ . Determine the temperature at the interface and the rate of energy transfer by conduction through the slabs in the steady-state condition.

**Solution** If  $T$  is the temperature at the interface, then the rate at which energy is transferred through slab 1 is

$$(1) \quad \mathcal{P}_1 = \frac{k_1 A (T - T_1)}{L_1}$$

The rate at which energy is transferred through slab 2 is

$$(2) \quad \mathcal{P}_2 = \frac{k_2 A (T_2 - T)}{L_2}$$

When a steady state is reached, these two rates must be equal; hence,

**Figure 20.11** Energy transfer by conduction through two slabs in thermal contact with each other. At steady state, the rate of energy transfer through slab 1 equals the rate of energy transfer through slab 2.

$$\frac{k_1 A (T - T_1)}{L_1} = \frac{k_2 A (T_2 - T)}{L_2}$$

Solving for  $T$  gives

$$(3) \quad T = \frac{k_1 L_2 T_1 + k_2 L_1 T_2}{k_1 L_2 + k_2 L_1}$$

Substituting (3) into either (1) or (2), we obtain

$$\mathcal{P} = \frac{A(T_2 - T_1)}{(L_1/k_1) + (L_2/k_2)}$$

Extension of this model to several slabs of materials leads to Equation 20.16.

## Home Insulation

In engineering practice, the term  $L/k$  for a particular substance is referred to as the  **$R$  value** of the material. Thus, Equation 20.16 reduces to

$$\mathcal{P} = \frac{A(T_2 - T_1)}{\sum_i R_i} \quad (20.17)$$

where  $R_i = L_i/k_i$ . The  $R$  values for a few common building materials are given in Table 20.4. In the United States, the insulating properties of materials used in buildings are usually expressed in engineering units, not SI units. Thus, in Table 20.4, measurements of  $R$  values are given as a combination of British thermal units, feet, hours, and degrees Fahrenheit.

At any vertical surface open to the air, a very thin stagnant layer of air adheres to the surface. One must consider this layer when determining the  $R$  value for a wall. The thickness of this stagnant layer on an outside wall depends on the speed of the wind. Energy loss from a house on a windy day is greater than the loss on a day when the air is calm. A representative  $R$  value for this stagnant layer of air is given in Table 20.4.

Energy is conducted from the inside to the exterior more rapidly on the part of the roof where the snow has melted. The dormer appears to have been added and insulated. The main roof does not appear to be well insulated.

**TABLE 20.4**  $R$  Values for Some Common Building Materials

Material	$R$ value ( $\text{ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$ )
Hardwood siding (1 in. thick)	0.91
Wood shingles (lapped)	0.87
Brick (4 in. thick)	4.00
Concrete block (filled cores)	1.93
Fiberglass batting (3.5 in. thick)	10.90
Fiberglass batting (6 in. thick)	18.80
Fiberglass board (1 in. thick)	4.35
Cellulose fiber (1 in. thick)	3.70
Flat glass (0.125 in. thick)	0.89
Insulating glass (0.25-in. space)	1.54
Air space (3.5 in. thick)	1.01
Stagnant air layer	0.17
Drywall (0.5 in. thick)	0.45
Sheathing (0.5 in. thick)	1.32

This thermogram of a home, made during cold weather, shows colors ranging from white and orange (areas of greatest energy loss) to blue and purple (areas of least energy loss).

### EXAMPLE 20.10 The $R$ Value of a Typical Wall

Calculate the total  $R$  value for a wall constructed as shown in Figure 20.12a. Starting outside the house (toward the front in the figure) and moving inward, the wall consists of 4-in. brick, 0.5-in. sheathing, an air space 3.5 in. thick, and 0.5-in. drywall. Do not forget the stagnant air layers inside and outside the house.

**Solution** Referring to Table 20.4, we find that

$R_1$ (outside stagnant air layer)	=	$0.17 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$
$R_2$ (brick)	=	$4.00 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$
$R_3$ (sheathing)	=	$1.32 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$
$R_4$ (air space)	=	$1.01 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$
$R_5$ (drywall)	=	$0.45 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$
$R_6$ (inside stagnant air layer)	=	$0.17 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$

---

$R_{\text{total}}$	=	$7.12 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$
--------------------	---	--

**Exercise** If a layer of fiberglass insulation 3.5 in. thick is placed inside the wall to replace the air space, as shown in Figure 20.12b, what is the new total  $R$  value? By what factor is the energy loss reduced?

**Answer**  $R = 17 \text{ ft}^2 \cdot ^\circ\text{F} \cdot \text{h}/\text{Btu}$ ; 2.4.

**Figure 20.12** An exterior house wall containing (a) an air space and (b) insulation.

## Convection

At one time or another, you probably have warmed your hands by holding them over an open flame. In this situation, the air directly above the flame is heated and expands. As a result, the density of this air decreases and the air rises. This warmed mass of air heats your hands as it flows by. **Energy transferred by the movement of a heated substance is said to have been transferred by convection.** When the movement results from differences in density, as with air around a fire, it is referred to as *natural convection*. Air flow at a beach is an example of natural convection, as is the mixing that occurs as surface water in a lake cools and sinks (see

**Figure 20.13** Convection currents are set up in a room heated by a radiator.

Stefan's law

Chapter 19). When the heated substance is forced to move by a fan or pump, as in some hot-air and hot-water heating systems, the process is called *forced convection*.

If it were not for convection currents, it would be very difficult to boil water. As water is heated in a teakettle, the lower layers are warmed first. The heated water expands and rises to the top because its density is lowered. At the same time, the denser, cool water at the surface sinks to the bottom of the kettle and is heated.

The same process occurs when a room is heated by a radiator. The hot radiator warms the air in the lower regions of the room. The warm air expands and rises to the ceiling because of its lower density. The denser, cooler air from above sinks, and the continuous air current pattern shown in Figure 20.13 is established.

## Radiation

The third means of energy transfer that we shall discuss is **radiation**. All objects radiate energy continuously in the form of electromagnetic waves (see Chapter 34) produced by thermal vibrations of the molecules. You are likely familiar with electromagnetic radiation in the form of the orange glow from an electric stove burner, an electric space heater, or the coils of a toaster.

The rate at which an object radiates energy is proportional to the fourth power of its absolute temperature. This is known as **Stefan's law** and is expressed in equation form as

$$\mathcal{P} = \sigma A e T^4 \quad (20.18)$$

where  $\mathcal{P}$  is the power in watts radiated by the object,  $\sigma$  is a constant equal to  $5.6696 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$ ,  $A$  is the surface area of the object in square meters,  $e$  is the **emissivity** constant, and  $T$  is the surface temperature in kelvins. The value of  $e$  can vary between zero and unity, depending on the properties of the surface of the object. The emissivity is equal to the fraction of the incoming radiation that the surface absorbs.

Approximately  $1\,340 \text{ J}$  of electromagnetic radiation from the Sun passes perpendicularly through each  $1 \text{ m}^2$  at the top of the Earth's atmosphere every second. This radiation is primarily visible and infrared light accompanied by a significant amount of ultraviolet radiation. We shall study these types of radiation in detail in Chapter 34. Some of this energy is reflected back into space, and some is absorbed by the atmosphere. However, enough energy arrives at the surface of the Earth each day to supply all our energy needs on this planet hundreds of times over—if only it could be captured and used efficiently. The growth in the number of solar energy-powered houses built in this country reflects the increasing efforts being made to use this abundant energy. Radiant energy from the Sun affects our day-to-day existence in a number of ways. For example, it influences the Earth's average temperature, ocean currents, agriculture, and rain patterns.

What happens to the atmospheric temperature at night is another example of the effects of energy transfer by radiation. If there is a cloud cover above the Earth, the water vapor in the clouds absorbs part of the infrared radiation emitted by the Earth and re-emits it back to the surface. Consequently, temperature levels at the surface remain moderate. In the absence of this cloud cover, there is nothing to prevent this radiation from escaping into space; thus the temperature decreases more on a clear night than on a cloudy one.

As an object radiates energy at a rate given by Equation 20.18, it also absorbs electromagnetic radiation. If the latter process did not occur, an object would eventually radiate all its energy, and its temperature would reach absolute zero. The energy an object absorbs comes from its surroundings, which consist of other objects that radiate energy. If an object is at a temperature  $T$  and its surroundings

are at a temperature  $T_0$ , then the net energy gained or lost each second by the object as a result of radiation is

$$\mathcal{P}_{\text{net}} = \sigma A e (T^4 - T_0^4) \quad (20.19)$$

When an object is in equilibrium with its surroundings, it radiates and absorbs energy at the same rate, and so its temperature remains constant. When an object is hotter than its surroundings, it radiates more energy than it absorbs, and its temperature decreases. An **ideal absorber** is defined as an object that absorbs all the energy incident on it, and for such a body,  $e = 1$ . Such an object is often referred to as a **black body**. An ideal absorber is also an ideal radiator of energy. In contrast, an object for which  $e = 0$  absorbs none of the energy incident on it. Such an object reflects all the incident energy, and thus is an **ideal reflector**.

### The Dewar Flask

The *Dewar flask*<sup>8</sup> is a container designed to minimize energy losses by conduction, convection, and radiation. Such a container is used to store either cold or hot liquids for long periods of time. (A Thermos bottle is a common household equivalent of a Dewar flask.) The standard construction (Fig. 20.14) consists of a double-walled Pyrex glass vessel with silvered walls. The space between the walls is evacuated to minimize energy transfer by conduction and convection. The silvered surfaces minimize energy transfer by radiation because silver is a very good reflector and has very low emissivity. A further reduction in energy loss is obtained by reducing the size of the neck. Dewar flasks are commonly used to store liquid nitrogen (boiling point: 77 K) and liquid oxygen (boiling point: 90 K).

To confine liquid helium (boiling point: 4.2 K), which has a very low heat of vaporization, it is often necessary to use a double Dewar system in which the Dewar flask containing the liquid is surrounded by a second Dewar flask. The space between the two flasks is filled with liquid nitrogen.

Newer designs of storage containers use “super insulation” that consists of many layers of reflecting material separated by fiberglass. All of this is in a vacuum, and no liquid nitrogen is needed with this design.

**Figure 20.14** A cross-sectional view of a Dewar flask, which is used to store hot or cold substances.

### EXAMPLE 20.11 Who Turned Down the Thermostat?

A student is trying to decide what to wear. The surroundings (his bedroom) are at  $20.0^\circ\text{C}$ . If the skin temperature of the unclothed student is  $35^\circ\text{C}$ , what is the net energy loss from his body in 10.0 min by radiation? Assume that the emissivity of skin is 0.900 and that the surface area of the student is  $1.50\text{ m}^2$ .

**Solution** Using Equation 20.19, we find that the net rate of energy loss from the skin is

$$\begin{aligned} \mathcal{P}_{\text{net}} &= \sigma A e (T^4 - T_0^4) \\ &= (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) (1.50 \text{ m}^2) \\ &\quad \times (0.900) [(308 \text{ K})^4 - (293 \text{ K})^4] = 125 \text{ W} \end{aligned}$$

(Why is the temperature given in kelvins?) At this rate, the total energy lost by the skin in 10 min is

$$Q = \mathcal{P}_{\text{net}} \times \Delta t = (125 \text{ W})(600 \text{ s}) = 7.5 \times 10^4 \text{ J}$$

Note that the energy radiated by the student is roughly equivalent to that produced by two 60-W light bulbs!

<sup>8</sup> Invented by Sir James Dewar (1842–1923).

## SUMMARY

**Internal energy** is all of a system's energy that is associated with the system's microscopic components. Internal energy includes kinetic energy of translation, rotation, and vibration of molecules, potential energy within molecules, and potential energy between molecules.

**Heat** is the transfer of energy across the boundary of a system resulting from a temperature difference between the system and its surroundings. We use the symbol  $Q$  for the amount of energy transferred by this process.

The **calorie** is the amount of energy necessary to raise the temperature of 1 g of water from 14.5°C to 15.5°C. The **mechanical equivalent of heat** is 1 cal = 4.186 J.

The **heat capacity**  $C$  of any sample is the amount of energy needed to raise the temperature of the sample by 1°C. The energy  $Q$  required to change the temperature of a mass  $m$  of a substance by an amount  $\Delta T$  is

$$Q = mc\Delta T \quad (20.4)$$

where  $c$  is the **specific heat** of the substance.

The energy required to change the phase of a pure substance of mass  $m$  is

$$Q = mL \quad (20.6)$$

where  $L$  is the **latent heat** of the substance and depends on the nature of the phase change and the properties of the substance.

The **work done** by a gas as its volume changes from some initial value  $V_i$  to some final value  $V_f$  is

$$W = \int_{V_i}^{V_f} P dV \quad (20.8)$$

where  $P$  is the pressure, which may vary during the process. In order to evaluate  $W$ , the process must be fully specified—that is,  $P$  and  $V$  must be known during each step. In other words, the work done depends on the path taken between the initial and final states.

The **first law of thermodynamics** states that when a system undergoes a change from one state to another, the change in its internal energy is

$$\Delta E_{\text{int}} = Q - W \quad (20.9)$$

where  $Q$  is the energy transferred into the system by heat and  $W$  is the work done by the system. Although  $Q$  and  $W$  both depend on the path taken from the initial state to the final state, the quantity  $\Delta E_{\text{int}}$  is path-independent. This central equation is a statement of conservation of energy that includes changes in internal energy.

In a **cyclic process** (one that originates and terminates at the same state),  $\Delta E_{\text{int}} = 0$  and, therefore,  $Q = W$ . That is, the energy transferred into the system by heat equals the work done by the system during the process.

In an **adiabatic process**, no energy is transferred by heat between the system and its surroundings ( $Q = 0$ ). In this case, the first law gives  $\Delta E_{\text{int}} = -W$ . That is, the internal energy changes as a consequence of work being done by the system. In the **adiabatic free expansion** of a gas,  $Q = 0$  and  $W = 0$ ; thus,  $\Delta E_{\text{int}} = 0$ . That is, the internal energy of the gas does not change in such a process.

An **isobaric process** is one that occurs at constant pressure. The work done in such a process is  $W = P(V_f - V_i)$ .

An **isovolumetric process** is one that occurs at constant volume. No work is done in such a process, so  $\Delta E_{\text{int}} = Q$ .

An **isothermal process** is one that occurs at constant temperature. The work done by an ideal gas during an isothermal process is

$$W = nRT \ln\left(\frac{V_f}{V_i}\right) \quad (20.13)$$

Energy may be transferred by work, which we addressed in Chapter 7, and by conduction, convection, or radiation. **Conduction** can be viewed as an exchange of kinetic energy between colliding molecules or electrons. The rate at which energy flows by conduction through a slab of area  $A$  is

$$\mathcal{P} = kA \left| \frac{dT}{dx} \right| \quad (20.14)$$

where  $k$  is the **thermal conductivity** of the material from which the slab is made and  $|dT/dx|$  is the **temperature gradient**. This equation can be used in many situations in which the rate of transfer of energy through materials is important.

In **convection**, a heated substance moves from one place to another.

All bodies emit **radiation** in the form of electromagnetic waves at the rate

$$\mathcal{P} = \sigma A \epsilon T^4 \quad (20.18)$$

A body that is hotter than its surroundings radiates more energy than it absorbs, whereas a body that is cooler than its surroundings absorbs more energy than it radiates.

## QUESTIONS

- The specific heat of water is about two times that of ethyl alcohol. Equal masses of alcohol and water are contained in separate beakers and are supplied with the same amount of energy. Compare the temperature increases of the two liquids.
- Give one reason why coastal regions tend to have a more moderate climate than inland regions do.
- A small metal crucible is taken from a  $200^\circ\text{C}$  oven and immersed in a tub full of water at room temperature (this process is often referred to as *quenching*). What is the approximate final equilibrium temperature?
- What is the major problem that arises in measuring specific heats if a sample with a temperature greater than  $100^\circ\text{C}$  is placed in water?
- In a daring lecture demonstration, an instructor dips his wetted fingers into molten lead ( $327^\circ\text{C}$ ) and withdraws them quickly, without getting burned. How is this possible? (This is a dangerous experiment that you should *not* attempt.)
- The pioneers found that placing a large tub of water in a storage cellar would prevent their food from freezing on really cold nights. Explain why.
- What is wrong with the statement, "Given any two bodies, the one with the higher temperature contains more heat."
- Why is it possible for you to hold a lighted match, even when it is burned to within a few millimeters of your fingertips?
- Why is it more comfortable to hold a cup of hot tea by the handle than by wrapping your hands around the cup itself?

- Figure Q20.10 shows a pattern formed by snow on the roof of a barn. What causes the alternating pattern of snowcover and exposed roof?

**Figure Q20.10** Alternating pattern on a snow-covered roof.

- Why is a person able to remove a piece of dry aluminum foil from a hot oven with bare fingers but burns his or her fingers if there is moisture on the foil?
- A tile floor in a bathroom may feel uncomfortably cold to your bare feet, but a carpeted floor in an adjoining room at the same temperature feels warm. Why?

13. Why can potatoes be baked more quickly when a metal skewer has been inserted through them?
14. Explain why a Thermos bottle has silvered walls and a vacuum jacket.
15. A piece of paper is wrapped around a rod made half of wood and half of copper. When held over a flame, the paper in contact with the wood burns but the paper in contact with the metal does not. Explain.
16. Why is it necessary to store liquid nitrogen or liquid oxygen in vessels equipped with either polystyrene insulation or a double-evacuated wall?
17. Why do heavy draperies hung over the windows help keep a home warm in the winter and cool in the summer?
18. If you wish to cook a piece of meat thoroughly on an open fire, why should you not use a high flame? (*Note:* Carbon is a good thermal insulator.)
19. When insulating a wood-frame house, is it better to place the insulation against the cooler, outside wall or against the warmer, inside wall? (In either case, an air barrier must be considered.)
20. In an experimental house, polystyrene beads were pumped into the air space between the panes of glass in double-pane windows at night in the winter, and they were pumped out to holding bins during the day. How would this procedure assist in conserving energy in the house?
21. Pioneers stored fruits and vegetables in underground cellars. Discuss the advantages of choosing this location as a storage site.
22. Concrete has a higher specific heat than soil does. Use this fact to explain (partially) why cities have a higher average night-time temperature than the surrounding countryside does. If a city is hotter than the surrounding countryside, would you expect breezes to blow from city to country or from country to city? Explain.
23. When camping in a canyon on a still night, a hiker notices that a breeze begins to stir as soon as the Sun strikes the surrounding peaks. What causes the breeze?
24. Updrafts of air are familiar to all pilots and are used to keep non-motorized gliders aloft. What causes these currents?
25. If water is a poor thermal conductor, why can it be heated quickly when placed over a flame?
26. The United States penny is now made of copper-coated zinc. Can a calorimetric experiment be devised to test for the metal content in a collection of pennies? If so, describe such a procedure.
27. If you hold water in a paper cup over a flame, you can bring the water to a boil without burning the cup. How is this possible?
28. When a sealed Thermos bottle full of hot coffee is shaken, what are the changes, if any, in (a) the temperature of the coffee and (b) the internal energy of the coffee?
29. Using the first law of thermodynamics, explain why the total energy of an isolated system is always constant.
30. Is it possible to convert internal energy into mechanical energy? Explain using examples.
31. Suppose that you pour hot coffee for your guests and one of them chooses to drink the coffee after it has been in the cup for several minutes. For the coffee to be warmest, should the person add the cream just after the coffee is poured or just before drinking it? Explain.
32. Suppose that you fill two identical cups both at room temperature with the same amount of hot coffee. One cup contains a metal spoon, while the other does not. If you wait for several minutes, which of the two contains the warmer coffee? Which energy transfer process accounts for this result?
33. A warning sign often seen on highways just before a bridge is "Caution—Bridge Surface Freezes Before Road Surface." Which of the three energy transfer processes is most important in causing a bridge surface to freeze before a road surface on very cold days?

## PROBLEMS

 = paired numerical/symbolic problems

### Section 20.1 Heat and Internal Energy

1. Water at the top of Niagara Falls has a temperature of  $10.0^{\circ}\text{C}$ . It falls through a distance of 50.0 m. Assuming that all of its potential energy goes into warming of the water, calculate the temperature of the water at the bottom of the Falls.
2. Consider Joule's apparatus described in Figure 20.1. Each of the two masses is 1.50 kg, and the tank is filled with 200 g of water. What is the increase in the temperature of the water after the masses fall through a distance of 3.00 m?

### Section 20.2 Heat Capacity and Specific Heat

3. The temperature of a silver bar rises by  $10.0^{\circ}\text{C}$  when it absorbs 1.23 kJ of energy by heat. The mass of the bar is 525 g. Determine the specific heat of silver.
4. A 50.0-g sample of copper is at  $25.0^{\circ}\text{C}$ . If 1 200 J of energy is added to it by heat, what is its final temperature?
- WEB 5. A 1.50-kg iron horseshoe initially at  $600^{\circ}\text{C}$  is dropped into a bucket containing 20.0 kg of water at  $25.0^{\circ}\text{C}$ . What is the final temperature? (Neglect the heat capacity of the container and assume that a negligible amount of water boils away.)

- An aluminum cup with a mass of 200 g contains 800 g of water in thermal equilibrium at  $80.0^\circ\text{C}$ . The combination of cup and water is cooled uniformly so that the temperature decreases at a rate of  $1.50^\circ\text{C}/\text{min}$ . At what rate is energy being removed by heat? Express your answer in watts.
- An aluminum calorimeter with a mass of 100 g contains 250 g of water. The calorimeter and water are in thermal equilibrium at  $10.0^\circ\text{C}$ . Two metallic blocks are placed into the water. One is a 50.0-g piece of copper at  $80.0^\circ\text{C}$ ; the other block has a mass of 70.0 g and is originally at a temperature of  $100^\circ\text{C}$ . The entire system stabilizes at a final temperature of  $20.0^\circ\text{C}$ . (a) Determine the specific heat of the unknown sample. (b) Guess the material of the unknown, using the data given in Table 20.1.
- Lake Erie contains roughly  $4.00 \times 10^{11} \text{ m}^3$  of water. (a) How much energy is required to raise the temperature of this volume of water from  $11.0^\circ\text{C}$  to  $12.0^\circ\text{C}$ ? (b) Approximately how many years would it take to supply this amount of energy with the use of a 1 000-MW wasted energy output of an electric power plant?
- A 3.00-g copper penny at  $25.0^\circ\text{C}$  drops from a height of 50.0 m to the ground. (a) If 60.0% of the change in potential energy goes into increasing the internal energy, what is its final temperature? (b) Does the result you obtained in (a) depend on the mass of the penny? Explain.
- If a mass  $m_h$  of water at  $T_h$  is poured into an aluminum cup of mass  $m_{Al}$  containing mass  $m_c$  of water at  $T_c$ , where  $T_h > T_c$ , what is the equilibrium temperature of the system?
- A water heater is operated by solar power. If the solar collector has an area of  $6.00 \text{ m}^2$  and the power delivered by sunlight is  $550 \text{ W}/\text{m}^2$ , how long does it take to increase the temperature of  $1.00 \text{ m}^3$  of water from  $20.0^\circ\text{C}$  to  $60.0^\circ\text{C}$ ?

### Section 20.3 Latent Heat

- How much energy is required to change a 40.0-g ice cube from ice at  $-10.0^\circ\text{C}$  to steam at  $110^\circ\text{C}$ ?
- A 3.00-g lead bullet at  $30.0^\circ\text{C}$  is fired at a speed of 240 m/s into a large block of ice at  $0^\circ\text{C}$ , in which it becomes embedded. What quantity of ice melts?
- Steam at  $100^\circ\text{C}$  is added to ice at  $0^\circ\text{C}$ . (a) Find the amount of ice melted and the final temperature when the mass of steam is 10.0 g and the mass of ice is 50.0 g. (b) Repeat this calculation, taking the mass of steam as 1.00 g and the mass of ice as 50.0 g.
- A 1.00-kg block of copper at  $20.0^\circ\text{C}$  is dropped into a large vessel of liquid nitrogen at 77.3 K. How many kilograms of nitrogen boil away by the time the copper reaches 77.3 K? (The specific heat of copper is  $0.0920 \text{ cal}/\text{g}\cdot^\circ\text{C}$ . The latent heat of vaporization of nitrogen is  $48.0 \text{ cal}/\text{g}$ .)
- A 50.0-g copper calorimeter contains 250 g of water at  $20.0^\circ\text{C}$ . How much steam must be condensed into the water if the final temperature of the system is to reach  $50.0^\circ\text{C}$ ?
- In an insulated vessel, 250 g of ice at  $0^\circ\text{C}$  is added to 600 g of water at  $18.0^\circ\text{C}$ . (a) What is the final temperature of the system? (b) How much ice remains when the system reaches equilibrium?
- Review Problem.** Two speeding lead bullets, each having a mass of 5.00 g, a temperature of  $20.0^\circ\text{C}$ , and a speed of 500 m/s, collide head-on. Assuming a perfectly inelastic collision and no loss of energy to the atmosphere, describe the final state of the two-bullet system.
- If 90.0 g of molten lead at  $327.3^\circ\text{C}$  is poured into a 300-g casting form made of iron and initially at  $20.0^\circ\text{C}$ , what is the final temperature of the system? (Assume that no energy loss to the environment occurs.)

### Section 20.4 Work and Heat in Thermodynamic Processes

- Gas in a container is at a pressure of 1.50 atm and a volume of  $4.00 \text{ m}^3$ . What is the work done by the gas (a) if it expands at constant pressure to twice its initial volume? (b) If it is compressed at constant pressure to one quarter of its initial volume?
- A sample of ideal gas is expanded to twice its original volume of  $1.00 \text{ m}^3$  in a quasi-static process for which  $P = \alpha V^2$ , with  $\alpha = 5.00 \text{ atm}/\text{m}^6$ , as shown in Figure P20.21. How much work is done by the expanding gas?

Figure P20.21

- (a) Determine the work done by a fluid that expands from  $i$  to  $f$  as indicated in Figure P20.22. (b) How much

Figure P20.22

work is performed by the fluid if it is compressed from  $f$  to  $i$  along the same path?

23. One mole of an ideal gas is heated slowly so that it goes from  $PV$  state  $(P_i, V_i)$  to  $(3P_i, 3V_i)$  in such a way that the pressure of the gas is directly proportional to the volume. (a) How much work is done in the process? (b) How is the temperature of the gas related to its volume during this process?
24. A sample of helium behaves as an ideal gas as energy is added by heat at constant pressure from 273 K to 373 K. If the gas does 20.0 J of work, what is the mass of helium present?
- WEB 25. An ideal gas is enclosed in a cylinder with a movable piston on top. The piston has a mass of 8 000 g and an area of  $5.00 \text{ cm}^2$  and is free to slide up and down, keeping the pressure of the gas constant. How much work is done as the temperature of 0.200 mol of the gas is raised from  $20.0^\circ\text{C}$  to  $300^\circ\text{C}$ ?
26. An ideal gas is enclosed in a cylinder that has a movable piston on top. The piston has a mass  $m$  and an area  $A$  and is free to slide up and down, keeping the pressure of the gas constant. How much work is done as the temperature of  $n$  mol of the gas is raised from  $T_1$  to  $T_2$ ?
27. A gas expands from  $I$  to  $F$  along three possible paths, as indicated in Figure P20.27. Calculate the work in joules done by the gas along the paths  $IAF$ ,  $IF$ , and  $IBF$ .

Figure P20.27

### Section 20.5 The First Law of Thermodynamics

28. A gas is compressed from 9.00 L to 2.00 L at a constant pressure of 0.800 atm. In the process, 400 J of energy leaves the gas by heat. (a) What is the work done by the gas? (b) What is the change in its internal energy?
29. A thermodynamic system undergoes a process in which its internal energy decreases by 500 J. If, at the same time, 220 J of work is done on the system, what is the energy transferred to or from it by heat?
30. A gas is taken through the cyclic process described in Figure P20.30. (a) Find the net energy transferred to the system by heat during one complete cycle. (b) If the

Figure P20.30 Problems 30 and 31.

- cycle is reversed—that is, if the process follows the path  $ACBA$ —what is the net energy input per cycle by heat?
31. Consider the cyclic process depicted in Figure P20.30. If  $Q$  is negative for the process  $BC$ , and if  $\Delta E_{\text{int}}$  is negative for the process  $CA$ , what are the signs of  $Q$ ,  $W$ , and  $\Delta E_{\text{int}}$  that are associated with each process?
32. A sample of an ideal gas goes through the process shown in Figure P20.32. From  $A$  to  $B$ , the process is adiabatic; from  $B$  to  $C$ , it is isobaric, with 100 kJ of energy flowing into the system by heat. From  $C$  to  $D$ , the process is isothermal; from  $D$  to  $A$ , it is isobaric, with 150 kJ of energy flowing out of the system by heat. Determine the difference in internal energy,  $E_{\text{int}, B} - E_{\text{int}, A}$ .

Figure P20.32

### Section 20.6 Some Applications of the First Law of Thermodynamics

33. An ideal gas initially at 300 K undergoes an isobaric expansion at 2.50 kPa. If the volume increases from  $1.00 \text{ m}^3$  to  $3.00 \text{ m}^3$  and if 12.5 kJ of energy is transferred to the gas by heat, what are (a) the change in its internal energy and (b) its final temperature?
34. One mole of an ideal gas does 3 000 J of work on its surroundings as it expands isothermally to a final pressure of 1.00 atm and a volume of 25.0 L. Determine (a) the initial volume and (b) the temperature of the gas.
35. How much work is done by the steam when 1.00 mol of water at  $100^\circ\text{C}$  boils and becomes 1.00 mol of steam at

100°C and at 1.00 atm pressure? Assuming the steam to be an ideal gas, determine the change in internal energy of the steam as it vaporizes.

36. A 1.00-kg block of aluminum is heated at atmospheric pressure such that its temperature increases from 22.0°C to 40.0°C. Find (a) the work done by the aluminum, (b) the energy added to it by heat, and (c) the change in its internal energy.
37. A 2.00-mol sample of helium gas initially at 300 K and 0.400 atm is compressed isothermally to 1.20 atm. Assuming the behavior of helium to be that of an ideal gas, find (a) the final volume of the gas, (b) the work done by the gas, and (c) the energy transferred by heat.
38. One mole of water vapor at a temperature of 373 K cools down to 283 K. The energy given off from the cooling vapor by heat is absorbed by 10.0 mol of an ideal gas, causing it to expand at a constant temperature of 273 K. If the final volume of the ideal gas is 20.0 L, what is the initial volume of the ideal gas?
39. An ideal gas is carried through a thermodynamic cycle consisting of two isobaric and two isothermal processes, as shown in Figure P20.39. Show that the net work done in the entire cycle is given by the equation

$$W_{\text{net}} = P_1(V_2 - V_1) \ln \frac{P_2}{P_1}$$

Figure P20.39

40. In Figure P20.40, the change in internal energy of a gas that is taken from A to C is +800 J. The work done along the path ABC is +500 J. (a) How much energy must be added to the system by heat as it goes from A through B and on to C? (b) If the pressure at point A is five times that at point C, what is the work done by the system in going from C to D? (c) What is the energy exchanged with the surroundings by heat as the gas is taken from C to A along the green path? (d) If the change in internal energy in going from point D to point A is +500 J, how much energy must be added to the system by heat as it goes from point C to point D?

Figure P20.40

- How much energy is lost every second by heat when the steam is at 200°C and the surrounding air is at 20.0°C? The pipe has a circumference of 20.0 cm and a length of 50.0 m. Neglect losses through the ends of the pipe.
42. A box with a total surface area of 1.20 m<sup>2</sup> and a wall thickness of 4.00 cm is made of an insulating material. A 10.0-W electric heater inside the box maintains the inside temperature at 15.0°C above the outside temperature. Find the thermal conductivity  $k$  of the insulating material.
43. A glass window pane has an area of 3.00 m<sup>2</sup> and a thickness of 0.600 cm. If the temperature difference between its surfaces is 25.0°C, what is the rate of energy transfer by conduction through the window?
44. A thermal window with an area of 6.00 m<sup>2</sup> is constructed of two layers of glass, each 4.00 mm thick and separated from each other by an air space of 5.00 mm. If the inside surface is at 20.0°C and the outside is at -30.0°C, what is the rate of energy transfer by conduction through the window?
45. A bar of gold is in thermal contact with a bar of silver of the same length and area (Fig. P20.45). One end of the compound bar is maintained at 80.0°C, while the opposite end is at 30.0°C. When the rate of energy transfer by conduction reaches steady state, what is the temperature at the junction?

Figure P20.45

### Section 20.7 Energy Transfer Mechanisms

41. A steam pipe is covered with 1.50-cm-thick insulating material with a thermal conductivity of 0.200 cal/cm·°C·s.

46. Two rods of the same length but made of different materials and having different cross-sectional areas are placed side by side, as shown in Figure P20.46. Deter-

Figure P20.46

mine the rate of energy transfer by conduction in terms of the thermal conductivity and the area of each rod. Generalize your result to a system consisting of several rods.

47. Calculate the  $R$  value of (a) a window made of a single pane of flat glass  $\frac{1}{8}$  in. thick; (b) a thermal window made of two single panes, each  $\frac{1}{8}$  in. thick and separated by a  $\frac{1}{4}$ -in. air space. (c) By what factor is the thermal conduction reduced if the thermal window replaces the single-pane window?
48. The surface of the Sun has a temperature of about 5 800 K. The radius of the Sun is  $6.96 \times 10^8$  m. Calculate the total energy radiated by the Sun each second. (Assume that  $e = 0.965$ .)
49. A large, hot pizza floats in outer space. What is the order of magnitude (a) of its rate of energy loss? (b) of its rate of temperature change? List the quantities you estimate and the value you estimate for each.
50. The tungsten filament of a certain 100-W light bulb radiates 2.00 W of light. (The other 98 W is carried away by convection and conduction.) The filament has a surface area of  $0.250 \text{ mm}^2$  and an emissivity of 0.950. Find the filament's temperature. (The melting point of tungsten is 3 683 K.)
51. At high noon, the Sun delivers 1 000 W to each square meter of a blacktop road. If the hot asphalt loses energy only by radiation, what is its equilibrium temperature?
52. At our distance from the Sun, the intensity of solar radiation is  $1\,340 \text{ W/m}^2$ . The temperature of the Earth is affected by the so-called "greenhouse effect" of the atmosphere. This effect makes our planet's emissivity for visible light higher than its emissivity for infrared light. For comparison, consider a spherical object with no atmosphere at the same distance from the Sun as the Earth. Assume that its emissivity is the same for all kinds of electromagnetic waves and that its temperature is uniform over its surface. Identify the projected area over which it absorbs sunlight and the surface area over which it radiates. Compute its equilibrium temperature. Chilly, isn't it? Your calculation applies to (a) the average temperature of the Moon, (b) astronauts in mortal danger aboard the crippled *Apollo 13* spacecraft, and (c) global catastrophe on the Earth if widespread fires caused a layer of soot to accumulate throughout the upper atmosphere so that most of the radiation from the Sun was absorbed there rather than at the surface below the atmosphere.

### ADDITIONAL PROBLEMS

53. One hundred grams of liquid nitrogen at 77.3 K is stirred into a beaker containing 200 g of water at  $5.00^\circ\text{C}$ . If the nitrogen leaves the solution as soon as it turns to gas, how much water freezes? (The latent heat of vaporization of nitrogen is  $48.0 \text{ cal/g}$ , and the latent heat of fusion of water is  $79.6 \text{ cal/g}$ .)
54. A 75.0-kg cross-country skier moves across the snow (Fig. P20.54). The coefficient of friction between the skis and the snow is 0.200. Assume that all the snow beneath his skis is at  $0^\circ\text{C}$  and that all the internal energy generated by friction is added to the snow, which sticks to his skis until it melts. How far would he have to ski to melt 1.00 kg of snow?

Figure P20.54 A cross-country skier. (Nathan Bilow/Leo de Wjys, Inc.)

55. An aluminum rod 0.500 m in length and with a cross-sectional area  $2.50 \text{ cm}^2$  is inserted into a thermally insulated vessel containing liquid helium at 4.20 K. The rod is initially at 300 K. (a) If one half of the rod is inserted into the helium, how many liters of helium boil off by the time the inserted half cools to 4.20 K? (Assume that the upper half does not yet cool.) (b) If the upper end of the rod is maintained at 300 K, what is the approximate boil-off rate of liquid helium after the lower half has reached 4.20 K? (Aluminum has thermal conductivity of  $31.0 \text{ J/s} \cdot \text{cm} \cdot \text{K}$  at 4.2 K; ignore its temperature variation. Aluminum has a specific heat of  $0.210 \text{ cal/g} \cdot ^\circ\text{C}$  and density of  $2.70 \text{ g/cm}^3$ . The density of liquid helium is  $0.125 \text{ g/cm}^3$ .)
56. On a cold winter day, you buy a hot dog from a street vendor. Into the pocket of your down parka you put the change he gives you: coins consisting of 9.00 g of copper at  $-12.0^\circ\text{C}$ . Your pocket already contains 14.0 g of silver coins at  $30.0^\circ\text{C}$ . A short time later, the temperature of the copper coins is  $4.00^\circ\text{C}$  and is increasing at a rate of  $0.500^\circ\text{C/s}$ . At this time (a) what is the temperature of the silver coins, and (b) at what rate is it changing? (Neglect energy transferred to the surroundings.)

57. A *flow calorimeter* is an apparatus used to measure the specific heat of a liquid. The technique of flow calorimetry involves measuring the temperature difference between the input and output points of a flowing stream of the liquid while energy is added by heat at a known rate. In one particular experiment, a liquid with a density of  $0.780 \text{ g/cm}^3$  flows through the calorimeter at the rate of  $4.00 \text{ cm}^3/\text{s}$ . At steady state, a temperature difference of  $4.80^\circ\text{C}$  is established between the input and output points when energy is supplied by heat at the rate of  $30.0 \text{ J/s}$ . What is the specific heat of the liquid?

58. A *flow calorimeter* is an apparatus used to measure the specific heat of a liquid. The technique of flow calorimetry involves measuring the temperature difference between the input and output points of a flowing stream of the liquid while energy is added by heat at a known rate. In one particular experiment, a liquid of density  $\rho$  flows through the calorimeter with volume flow rate  $R$ . At steady state, a temperature difference  $\Delta T$  is established between the input and output points when energy is supplied at the rate  $\mathcal{P}$ . What is the specific heat of the liquid?

59. One mole of an ideal gas, initially at  $300 \text{ K}$ , is cooled at constant volume so that the final pressure is one-fourth the initial pressure. The gas then expands at constant pressure until it reaches the initial temperature. Determine the work done by the gas.

60. One mole of an ideal gas is contained in a cylinder with a movable piston. The initial pressure, volume, and temperature are  $P_i$ ,  $V_i$ , and  $T_i$ , respectively. Find the work done by the gas for the following processes and show each process on a  $PV$  diagram: (a) An isobaric compression in which the final volume is one-half the initial volume. (b) An isothermal compression in which the final pressure is four times the initial pressure. (c) An isovolumetric process in which the final pressure is triple the initial pressure.

61. An ideal gas initially at  $P_i$ ,  $V_i$ , and  $T_i$  is taken through a cycle as shown in Figure P20.61. (a) Find the net work done by the gas per cycle. (b) What is the net energy added by heat to the system per cycle? (c) Obtain a nu-

Figure P20.61

merical value for the net work done per cycle for  $1.00 \text{ mol}$  of gas initially at  $0^\circ\text{C}$ .

62. **Review Problem.** An iron plate is held against an iron wheel so that a sliding frictional force of  $50.0 \text{ N}$  acts between the two pieces of metal. The relative speed at which the two surfaces slide over each other is  $40.0 \text{ m/s}$ . (a) Calculate the rate at which mechanical energy is converted to internal energy. (b) The plate and the wheel each have a mass of  $5.00 \text{ kg}$ , and each receives  $50.0\%$  of the internal energy. If the system is run as described for  $10.0 \text{ s}$  and each object is then allowed to reach a uniform internal temperature, what is the resultant temperature increase?

WEB 63. A “solar cooker” consists of a curved reflecting mirror that focuses sunlight onto the object to be warmed (Fig. P20.63). The solar power per unit area reaching the Earth at the location is  $600 \text{ W/m}^2$ , and the cooker has a diameter of  $0.600 \text{ m}$ . Assuming that  $40.0\%$  of the incident energy is transferred to the water, how long does it take to completely boil off  $0.500 \text{ L}$  of water initially at  $20.0^\circ\text{C}$ ? (Neglect the heat capacity of the container.)

Figure P20.63

64. Water in an electric teakettle is boiling. The power absorbed by the water is  $1.00 \text{ kW}$ . Assuming that the pressure of the vapor in the kettle equals atmospheric pressure, determine the speed of effusion of vapor from the kettle’s spout if the spout has a cross-sectional area of  $2.00 \text{ cm}^2$ .

65. Liquid water evaporates and even boils at temperatures other than  $100^\circ\text{C}$ , depending on the ambient pressure. Suppose that the latent heat of vaporization in Table 20.2 describes the liquid–vapor transition at all temperatures. A chamber contains  $1.00 \text{ kg}$  of water at  $0^\circ\text{C}$  under a piston, which just touches the water’s surface. The piston is then raised quickly so that part of the water is vaporized and the other part is frozen (no liquid remains). Assuming that the temperature remains con-

stant at  $0^\circ\text{C}$ , determine the mass of the ice that forms in the chamber.

66. A cooking vessel on a slow burner contains 10.0 kg of water and an unknown mass of ice in equilibrium at  $0^\circ\text{C}$  at time  $t = 0$ . The temperature of the mixture is measured at various times, and the result is plotted in Figure P20.66. During the first 50.0 min, the mixture remains at  $0^\circ\text{C}$ . From 50.0 min to 60.0 min, the temperature increases to  $2.00^\circ\text{C}$ . Neglecting the heat capacity of the vessel, determine the initial mass of the ice.

Figure P20.66

67. **Review Problem.** (a) In air at  $0^\circ\text{C}$ , a 1.60-kg copper block at  $0^\circ\text{C}$  is set sliding at 2.50 m/s over a sheet of ice at  $0^\circ\text{C}$ . Friction brings the block to rest. Find the mass of the ice that melts. To describe the process of slowing down, identify the energy input  $Q$ , the work output  $W$ , the change in internal energy  $\Delta E_{\text{int}}$ , and the change in mechanical energy  $\Delta K$  for both the block and the ice. (b) A 1.60-kg block of ice at  $0^\circ\text{C}$  is set sliding at 2.50 m/s over a sheet of copper at  $0^\circ\text{C}$ . Friction brings the block to rest. Find the mass of the ice that melts. Identify  $Q$ ,  $W$ ,  $\Delta E_{\text{int}}$ , and  $\Delta K$  for the block and for the metal sheet during the process. (c) A thin 1.60-kg slab of copper at  $20^\circ\text{C}$  is set sliding at 2.50 m/s over an identical stationary slab at the same temperature. Friction quickly stops the motion. If no energy is lost to the environment by heat, find the change in temperature of both objects. Identify  $Q$ ,  $W$ ,  $\Delta E_{\text{int}}$ , and  $\Delta K$  for each object during the process.
68. The average thermal conductivity of the walls (including the windows) and roof of the house depicted in Figure P20.68 is  $0.480 \text{ W/m}\cdot^\circ\text{C}$ , and their average thickness is 21.0 cm. The house is heated with natural gas having a heat of combustion (that is, the energy provided per cubic meter of gas burned) of  $9\,300 \text{ kcal/m}^3$ . How many cubic meters of gas must be burned each day to maintain an inside temperature of  $25.0^\circ\text{C}$  if the out-

Figure P20.68

side temperature is  $0.0^\circ\text{C}$ ? Disregard radiation and the energy lost by heat through the ground.

69. A pond of water at  $0^\circ\text{C}$  is covered with a layer of ice 4.00 cm thick. If the air temperature stays constant at  $-10.0^\circ\text{C}$ , how long does it take the ice's thickness to increase to 8.00 cm? (*Hint:* To solve this problem, use Equation 20.14 in the form

$$\frac{dQ}{dt} = kA \frac{\Delta T}{x}$$

and note that the incremental energy  $dQ$  extracted from the water through the thickness  $x$  of ice is the amount required to freeze a thickness  $dx$  of ice. That is,  $dQ = L\rho A dx$ , where  $\rho$  is the density of the ice,  $A$  is the area, and  $L$  is the latent heat of fusion.)

70. The inside of a hollow cylinder is maintained at a temperature  $T_a$  while the outside is at a lower temperature  $T_b$  (Fig. P20.70). The wall of the cylinder has a thermal conductivity  $k$ . Neglecting end effects, show that the rate of energy conduction from the inner to the outer wall in the radial direction is

$$\frac{dQ}{dt} = 2\pi Lk \left[ \frac{T_a - T_b}{\ln(b/a)} \right]$$

(*Hint:* The temperature gradient is  $dT/dr$ . Note that a radial flow of energy occurs through a concentric cylinder of area  $2\pi rL$ .)

Figure P20.70

- 71.** The passenger section of a jet airliner has the shape of a cylindrical tube with a length of 35.0 m and an inner radius of 2.50 m. Its walls are lined with an insulating material 6.00 cm in thickness and having a thermal conductivity of  $4.00 \times 10^{-5} \text{ cal/s} \cdot \text{cm} \cdot ^\circ\text{C}$ . A heater must maintain the interior temperature at  $25.0^\circ\text{C}$  while the outside temperature is at  $-35.0^\circ\text{C}$ . What power must be supplied to the heater if this temperature difference is to be maintained? (Use the result you obtained in Problem 70.)
- 72.** A student obtains the following data in a calorimetry experiment designed to measure the specific heat of aluminum:

Initial temperature of water and calorimeter	$70^\circ\text{C}$
Mass of water	0.400 kg
Mass of calorimeter	0.040 kg
Specific heat of calorimeter	$0.63 \text{ kJ/kg} \cdot ^\circ\text{C}$
Initial temperature of aluminum	$27^\circ\text{C}$
Mass of aluminum	0.200 kg
Final temperature of mixture	$66.3^\circ\text{C}$

Use these data to determine the specific heat of aluminum. Your result should be within 15% of the value listed in Table 20.1.

## ANSWERS TO QUICK QUIZZES

- 20.1** (a) Water, glass, iron. Because water has the highest specific heat ( $4186 \text{ J/kg} \cdot ^\circ\text{C}$ ), it has the smallest change in temperature. Glass is next ( $837 \text{ J/kg} \cdot ^\circ\text{C}$ ), and iron is last ( $448 \text{ J/kg} \cdot ^\circ\text{C}$ ). (b) Iron, glass, water. For a given temperature increase, the energy transfer by heat is proportional to the specific heat.
- 20.2** Steam. According to Table 20.2, a kilogram of  $100^\circ\text{C}$  steam releases  $2.26 \times 10^6 \text{ J}$  of energy as it condenses to  $100^\circ\text{C}$  water. After it releases this much energy into your skin, it is identical to  $100^\circ\text{C}$  water and will continue to burn you.
- 20.3** C, A, E. The slope is the ratio of the temperature change to the amount of energy input. Thus, the slope is proportional to the reciprocal of the specific heat. Water, which has the highest specific heat, has the least slope.
- 20.4**

Situation	System	$Q$	$W$	$\Delta E_{\text{int}}$
(a) Rapidly pumping up a bicycle tire	Air in the pump	0	-	+
(b) Pan of room-temperature water sitting on a hot stove	Water in the pan	+	0	+
(c) Air quickly leaking out of a balloon	Air originally in the balloon	0	+	-

- (a) Because the pumping is rapid, no energy enters or leaves the system by heat; thus,  $Q = 0$ . Because work is done *on* the system, this work is negative. Thus,  $\Delta E_{\text{int}} = Q - W$  must be positive. The air in the pump is warmer. (b) No work is done either by or on the system, but energy flows into the water by heat from the hot burner, making both  $Q$  and  $\Delta E_{\text{int}}$  positive. (c) Because the leak is rapid, no energy flows into or out of the system by heat; hence,  $Q = 0$ . The air molecules escaping from the balloon do work on the surrounding air molecules as they push them out of the way. Thus,  $W$  is positive and  $\Delta E_{\text{int}}$  is negative. The decrease in internal energy is evidenced by the fact that the escaping air becomes cooler.
- 20.5**  $A$  is isovolumetric,  $B$  is adiabatic,  $C$  is isothermal, and  $D$  is isobaric.
- 20.6** c. The blanket acts as a thermal insulator, slowing the transfer of energy by heat from the air into the cube.

## # PUZZLER

During periods of strenuous exertion, our bodies generate excess internal energy that must be released into our surroundings. To facilitate this release, humans perspire. Dogs and other animals pant to accomplish the same goal. Both actions involve the evaporation of a liquid. How does this process help cool the body?

## The Kinetic Theory of Gases

### Chapter Outline

- 21.1** Molecular Model of an Ideal Gas
- 21.2** Molar Specific Heat of an Ideal Gas
- 21.3** Adiabatic Processes for an Ideal Gas
- 21.4** The Equipartition of Energy
- 21.5** The Boltzmann Distribution Law
- 21.6** Distribution of Molecular Speeds
- 21.7** *(Optional)* Mean Free Path

In Chapter 19 we discussed the properties of an ideal gas, using such macroscopic variables as pressure, volume, and temperature. We shall now show that such large-scale properties can be described on a microscopic scale, where matter is treated as a collection of molecules. Newton's laws of motion applied in a statistical manner to a collection of particles provide a reasonable description of thermodynamic processes. To keep the mathematics relatively simple, we shall consider molecular behavior of gases only, because in gases the interactions between molecules are much weaker than they are in liquids or solids. In the current view of gas behavior, called the *kinetic theory*, gas molecules move about in a random fashion, colliding with the walls of their container and with each other. Perhaps the most important feature of this theory is that it demonstrates that the kinetic energy of molecular motion and the internal energy of a gas system are equivalent. Furthermore, the kinetic theory provides us with a physical basis for our understanding of the concept of temperature.

In the simplest model of a gas, each molecule is considered to be a hard sphere that collides elastically with other molecules and with the container's walls. The hard-sphere model assumes that the molecules do not interact with each other except during collisions and that they are not deformed by collisions. This description is adequate only for monatomic gases, for which the energy is entirely translational kinetic energy. One must modify the theory for more complex molecules, such as oxygen ( $O_2$ ) and carbon dioxide ( $CO_2$ ), to include the internal energy associated with rotations and vibrations of the molecules.

## 21.1 MOLECULAR MODEL OF AN IDEAL GAS

 We begin this chapter by developing a microscopic model of an ideal gas. The model shows that the pressure that a gas exerts on the walls of its container is a consequence of the collisions of the gas molecules with the walls. As we shall see, the model is consistent with the macroscopic description of Chapter 19. In developing this model, we make the following assumptions:

- The number of molecules is large, and the average separation between molecules is great compared with their dimensions. This means that the volume of the molecules is negligible when compared with the volume of the container.
- The molecules obey Newton's laws of motion, but as a whole they move randomly. By "randomly" we mean that any molecule can move in any direction with equal probability. We also assume that the distribution of speeds does not change in time, despite the collisions between molecules. That is, at any given moment, a certain percentage of molecules move at high speeds, a certain percentage move at low speeds, and a certain percentage move at speeds intermediate between high and low.
- The molecules undergo elastic collisions with each other and with the walls of the container. Thus, in the collisions, both kinetic energy and momentum are constant.
- The forces between molecules are negligible except during a collision. The forces between molecules are short-range, so the molecules interact with each other only during collisions.
- The gas under consideration is a pure substance. That is, all of its molecules are identical.

Assumptions of the molecular model of an ideal gas

Although we often picture an ideal gas as consisting of single atoms, we can assume that the behavior of molecular gases approximates that of ideal gases rather

**Figure 21.1** A cubical box with sides of length  $d$  containing an ideal gas. The molecule shown moves with velocity  $\mathbf{v}$ .

**Figure 21.2** A molecule makes an elastic collision with the wall of the container. Its  $x$  component of momentum is reversed, while its  $y$  component remains unchanged. In this construction, we assume that the molecule moves in the  $xy$  plane.

well at low pressures. Molecular rotations or vibrations have no effect, on the average, on the motions that we considered here.

Now let us derive an expression for the pressure of an ideal gas consisting of  $N$  molecules in a container of volume  $V$ . The container is a cube with edges of length  $d$  (Fig. 21.1). Consider the collision of one molecule moving with a velocity  $\mathbf{v}$  toward the right-hand face of the box. The molecule has velocity components  $v_x$ ,  $v_y$ , and  $v_z$ . Previously, we used  $m$  to represent the mass of a sample, but throughout this chapter we shall use  $m$  to represent the mass of one molecule. As the molecule collides with the wall elastically, its  $x$  component of velocity is reversed, while its  $y$  and  $z$  components of velocity remain unaltered (Fig. 21.2). Because the  $x$  component of the momentum of the molecule is  $mv_x$  before the collision and  $-mv_x$  after the collision, the change in momentum of the molecule is

$$\Delta p_x = -mv_x - (mv_x) = -2mv_x$$

Applying the impulse–momentum theorem (Eq. 9.9) to the molecule gives

$$F_1 \Delta t = \Delta p_x = -2mv_x$$

where  $F_1$  is the magnitude of the average force exerted by the wall on the molecule in the time  $\Delta t$ . The subscript 1 indicates that we are currently considering only *one* molecule. For the molecule to collide twice with the same wall, it must travel a distance  $2d$  in the  $x$  direction. Therefore, the time interval between two collisions with the same wall is  $\Delta t = 2d/v_x$ . Over a time interval that is long compared with  $\Delta t$ , the average force exerted on the molecule for each collision is

$$F_1 = \frac{-2mv_x}{\Delta t} = \frac{-2mv_x}{2d/v_x} = \frac{-mv_x^2}{d} \quad (21.1)$$

According to Newton's third law, the average force exerted by the molecule on the wall is equal in magnitude and opposite in direction to the force in Equation 21.1:

$$F_{1, \text{ on wall}} = -F_1 = -\left(\frac{-mv_x^2}{d}\right) = \frac{mv_x^2}{d}$$

Each molecule of the gas exerts a force  $F_1$  on the wall. We find the total force  $F$  exerted by all the molecules on the wall by adding the forces exerted by the individual molecules:

$$F = \frac{m}{d} (v_{x1}^2 + v_{x2}^2 + \cdots)$$

In this equation,  $v_{x1}$  is the  $x$  component of velocity of molecule 1,  $v_{x2}$  is the  $x$  component of velocity of molecule 2, and so on. The summation terminates when we reach  $N$  molecules because there are  $N$  molecules in the container.

To proceed further, we must note that the average value of the square of the velocity in the  $x$  direction for  $N$  molecules is

$$\overline{v_x^2} = \frac{v_{x1}^2 + v_{x2}^2 + \cdots + v_{xN}^2}{N}$$

Thus, the total force exerted on the wall can be written

$$F = \frac{Nm}{d} \overline{v_x^2}$$

Now let us focus on one molecule in the container whose velocity components are  $v_x$ ,  $v_y$ , and  $v_z$ . The Pythagorean theorem relates the square of the speed of this

molecule to the squares of these components:

$$v^2 = v_x^2 + v_y^2 + v_z^2$$

Hence, the average value of  $v^2$  for all the molecules in the container is related to the average values of  $v_x^2$ ,  $v_y^2$ , and  $v_z^2$  according to the expression

$$\overline{v^2} = \overline{v_x^2} + \overline{v_y^2} + \overline{v_z^2}$$

Because the motion is completely random, the average values  $\overline{v_x^2}$ ,  $\overline{v_y^2}$ , and  $\overline{v_z^2}$  are equal to each other. Using this fact and the previous equation, we find that

$$\overline{v^2} = 3\overline{v_x^2}$$

Thus, the total force exerted on the wall is

$$F = \frac{N}{3} \left( \frac{m\overline{v^2}}{d} \right)$$

Using this expression, we can find the total pressure exerted on the wall:

$$P = \frac{F}{A} = \frac{F}{d^2} = \frac{1}{3} \left( \frac{N}{d^3} m\overline{v^2} \right) = \frac{1}{3} \left( \frac{N}{V} \right) m\overline{v^2}$$

$$P = \frac{2}{3} \left( \frac{N}{V} \right) \left( \frac{1}{2} m\overline{v^2} \right) \quad (21.2)$$

This result indicates that **the pressure is proportional to the number of molecules per unit volume and to the average translational kinetic energy of the molecules,  $\frac{1}{2}m\overline{v^2}$** . In deriving this simplified model of an ideal gas, we obtain an important result that relates the large-scale quantity of pressure to an atomic quantity—the average value of the square of the molecular speed. Thus, we have established a key link between the atomic world and the large-scale world.

You should note that Equation 21.2 verifies some features of pressure with which you are probably familiar. One way to increase the pressure inside a container is to increase the number of molecules per unit volume in the container. This is what you do when you add air to a tire. The pressure in the tire can also be increased by increasing the average translational kinetic energy of the air molecules in the tire. As we shall soon see, this can be accomplished by increasing the temperature of that air. It is for this reason that the pressure inside a tire increases as the tire warms up during long trips. The continuous flexing of the tire as it moves along the surface of a road results in work done as parts of the tire distort and in an increase in internal energy of the rubber. The increased temperature of the rubber results in the transfer of energy by heat into the air inside the tire. This transfer increases the air's temperature, and this increase in temperature in turn produces an increase in pressure.

### Molecular Interpretation of Temperature

 We can gain some insight into the meaning of temperature by first writing Equation 21.2 in the more familiar form

$$PV = \frac{2}{3} N \left( \frac{1}{2} m\overline{v^2} \right)$$

Let us now compare this with the equation of state for an ideal gas (Eq. 19.10):

$$PV = Nk_B T$$

**Ludwig Boltzmann** Austrian theoretical physicist (1844–1906)

Boltzmann made many important contributions to the development of the kinetic theory of gases, electromagnetism, and thermodynamics. His pioneering work in the field of kinetic theory led to the branch of physics known as *statistical mechanics*.

(Courtesy of AIP Niels Bohr Library, Lande Collection)

Relationship between pressure and molecular kinetic energy

Recall that the equation of state is based on experimental facts concerning the macroscopic behavior of gases. Equating the right sides of these expressions, we find that

Temperature is proportional to average kinetic energy

$$T = \frac{2}{3k_B} \left( \frac{1}{2} m \overline{v^2} \right) \quad (21.3)$$

That is, **temperature is a direct measure of average molecular kinetic energy.**

By rearranging Equation 21.3, we can relate the translational molecular kinetic energy to the temperature:

Average kinetic energy per molecule

$$\frac{1}{2} m \overline{v^2} = \frac{3}{2} k_B T \quad (21.4)$$

That is, the average translational kinetic energy per molecule is  $\frac{3}{2} k_B T$ . Because  $\overline{v_x^2} = \frac{1}{3} \overline{v^2}$ , it follows that

$$\frac{1}{2} m \overline{v_x^2} = \frac{1}{2} k_B T \quad (21.5)$$

In a similar manner, it follows that the motions in the  $y$  and  $z$  directions give us

$$\frac{1}{2} m \overline{v_y^2} = \frac{1}{2} k_B T \quad \text{and} \quad \frac{1}{2} m \overline{v_z^2} = \frac{1}{2} k_B T$$

Thus, each translational degree of freedom contributes an equal amount of energy to the gas, namely,  $\frac{1}{2} k_B T$ . (In general, “degrees of freedom” refers to the number of independent means by which a molecule can possess energy.) A generalization of this result, known as the **theorem of equipartition of energy**, states that

Theorem of equipartition of energy

each degree of freedom contributes  $\frac{1}{2} k_B T$  to the energy of a system.

The total translational kinetic energy of  $N$  molecules of gas is simply  $N$  times the average energy per molecule, which is given by Equation 21.4:

Total translational kinetic energy of  $N$  molecules

$$E_{\text{trans}} = N \left( \frac{1}{2} m \overline{v^2} \right) = \frac{3}{2} N k_B T = \frac{3}{2} n R T \quad (21.6)$$

where we have used  $k_B = R/N_A$  for Boltzmann’s constant and  $n = N/N_A$  for the number of moles of gas. If we consider a gas for which the only type of energy for the molecules is translational kinetic energy, we can use Equation 21.6 to express

**TABLE 21.1** Some rms Speeds

Gas	Molar Mass (g/mol)	$v_{\text{rms}}$ at 20°C (m/s)
H <sub>2</sub>	2.02	1904
He	4.00	1352
H <sub>2</sub> O	18.0	637
Ne	20.2	602
N <sub>2</sub> or CO	28.0	511
NO	30.0	494
CO <sub>2</sub>	44.0	408
SO <sub>2</sub>	64.1	338

the internal energy of the gas. This result implies that the internal energy of an ideal gas depends only on the temperature.

The square root of  $\overline{v^2}$  is called the *root-mean-square (rms) speed* of the molecules. From Equation 21.4 we obtain, for the rms speed,

$$v_{\text{rms}} = \sqrt{\overline{v^2}} = \sqrt{\frac{3k_{\text{B}}T}{m}} = \sqrt{\frac{3RT}{M}} \quad (21.7)$$

Root-mean-square speed

where  $M$  is the molar mass in kilograms per mole. This expression shows that, at a given temperature, lighter molecules move faster, on the average, than do heavier molecules. For example, at a given temperature, hydrogen molecules, whose molar mass is  $2 \times 10^{-3}$  kg/mol, have an average speed four times that of oxygen molecules, whose molar mass is  $32 \times 10^{-3}$  kg/mol. Table 21.1 lists the rms speeds for various molecules at  $20^\circ\text{C}$ .

### EXAMPLE 21.1 A Tank of Helium

A tank used for filling helium balloons has a volume of  $0.300 \text{ m}^3$  and contains  $2.00 \text{ mol}$  of helium gas at  $20.0^\circ\text{C}$ . Assuming that the helium behaves like an ideal gas, (a) what is the total translational kinetic energy of the molecules of the gas?

**Solution** Using Equation 21.6 with  $n = 2.00 \text{ mol}$  and  $T = 293 \text{ K}$ , we find that

$$\begin{aligned} E_{\text{trans}} &= \frac{3}{2} nRT = \frac{3}{2} (2.00 \text{ mol}) (8.31 \text{ J/mol} \cdot \text{K}) (293 \text{ K}) \\ &= 7.30 \times 10^3 \text{ J} \end{aligned}$$

(b) What is the average kinetic energy per molecule?

**Solution** Using Equation 21.4, we find that the average kinetic energy per molecule is

$$\begin{aligned} \frac{1}{2} m\overline{v^2} &= \frac{3}{2} k_{\text{B}}T = \frac{3}{2} (1.38 \times 10^{-23} \text{ J/K}) (293 \text{ K}) \\ &= 6.07 \times 10^{-21} \text{ J} \end{aligned}$$

**Exercise** Using the fact that the molar mass of helium is  $4.00 \times 10^{-3}$  kg/mol, determine the rms speed of the atoms at  $20.0^\circ\text{C}$ .

**Answer**  $1.35 \times 10^3 \text{ m/s}$ .

### Quick Quiz 21.1

At room temperature, the average speed of an air molecule is several hundred meters per second. A molecule traveling at this speed should travel across a room in a small fraction of a second. In view of this, why does it take the odor of perfume (or other smells) several minutes to travel across the room?

## 21.2 MOLAR SPECIFIC HEAT OF AN IDEAL GAS

**10.5** The energy required to raise the temperature of  $n$  moles of gas from  $T_i$  to  $T_f$  depends on the path taken between the initial and final states. To understand this, let us consider an ideal gas undergoing several processes such that the change in temperature is  $\Delta T = T_f - T_i$  for all processes. The temperature change can be achieved by taking a variety of paths from one isotherm to another, as shown in Figure 21.3. Because  $\Delta T$  is the same for each path, the change in internal energy  $\Delta E_{\text{int}}$  is the same for all paths. However, we know from the first law,  $Q = \Delta E_{\text{int}} + W$ , that the heat  $Q$  is different for each path because  $W$  (the area under the curves) is different for each path. Thus, the heat associated with a given change in temperature does not have a unique value.

**Figure 21.3** An ideal gas is taken from one isotherm at temperature  $T$  to another at temperature  $T + \Delta T$  along three different paths.

We can address this difficulty by defining specific heats for two processes that frequently occur: changes at constant volume and changes at constant pressure. Because the number of moles is a convenient measure of the amount of gas, we define the **molar specific heats** associated with these processes with the following equations:

$$Q = nC_V\Delta T \quad (\text{constant volume}) \quad (21.8)$$

$$Q = nC_P\Delta T \quad (\text{constant pressure}) \quad (21.9)$$

where  $C_V$  is the **molar specific heat at constant volume** and  $C_P$  is the **molar specific heat at constant pressure**. When we heat a gas at constant pressure, not only does the internal energy of the gas increase, but the gas also does work because of the change in volume. Therefore, the heat  $Q_{\text{constant } P}$  must account for both the increase in internal energy and the transfer of energy out of the system by work, and so  $Q_{\text{constant } P}$  is greater than  $Q_{\text{constant } V}$ . Thus,  $C_P$  is greater than  $C_V$ .

In the previous section, we found that the temperature of a gas is a measure of the average translational kinetic energy of the gas molecules. This kinetic energy is associated with the motion of the center of mass of each molecule. It does not include the energy associated with the internal motion of the molecule—namely, vibrations and rotations about the center of mass. This should not be surprising because the simple kinetic theory model assumes a structureless molecule.

In view of this, let us first consider the simplest case of an ideal monatomic gas, that is, a gas containing one atom per molecule, such as helium, neon, or argon. When energy is added to a monatomic gas in a container of fixed volume (by heating, for example), all of the added energy goes into increasing the translational kinetic energy of the atoms. There is no other way to store the energy in a monatomic gas. Therefore, from Equation 21.6, we see that the total internal energy  $E_{\text{int}}$  of  $N$  molecules (or  $n$  mol) of an ideal monatomic gas is

$$E_{\text{int}} = \frac{3}{2}Nk_B T = \frac{3}{2}nRT \quad (21.10)$$

Note that for a monatomic ideal gas,  $E_{\text{int}}$  is a function of  $T$  only, and the functional relationship is given by Equation 21.10. In general, the internal energy of an ideal gas is a function of  $T$  only, and the exact relationship depends on the type of gas, as we shall soon explore.

Internal energy of an ideal monatomic gas is proportional to its temperature

### Quick Quiz 21.2

How does the internal energy of a gas change as its pressure is decreased while its volume is increased in such a way that the process follows the isotherm labeled  $T$  in Figure 21.4? (a)  $E_{\text{int}}$  increases. (b)  $E_{\text{int}}$  decreases. (c)  $E_{\text{int}}$  stays the same. (d) There is not enough information to determine  $\Delta E_{\text{int}}$ .

If energy is transferred by heat to a system at *constant volume*, then no work is done by the system. That is,  $W = \int P dV = 0$  for a constant-volume process. Hence, from the first law of thermodynamics, we see that

$$Q = \Delta E_{\text{int}} \quad (21.11)$$

In other words, all of the energy transferred by heat goes into increasing the internal energy (and temperature) of the system. A constant-volume process from  $i$  to  $f$  is described in Figure 21.4, where  $\Delta T$  is the temperature difference between the two isotherms. Substituting the expression for  $Q$  given by Equation 21.8 into

Equation 21.11, we obtain

$$\Delta E_{\text{int}} = nC_V \Delta T \quad (21.12)$$

If the molar specific heat is constant, we can express the internal energy of a gas as

$$E_{\text{int}} = nC_V T$$

This equation applies to all ideal gases—to gases having more than one atom per molecule, as well as to monatomic ideal gases.

In the limit of infinitesimal changes, we can use Equation 21.12 to express the molar specific heat at constant volume as

$$C_V = \frac{1}{n} \frac{dE_{\text{int}}}{dT} \quad (21.13)$$

Let us now apply the results of this discussion to the monatomic gas that we have been studying. Substituting the internal energy from Equation 21.10 into Equation 21.13, we find that

$$C_V = \frac{3}{2} R \quad (21.14)$$

This expression predicts a value of  $C_V = \frac{3}{2} R = 12.5 \text{ J/mol} \cdot \text{K}$  for all monatomic gases. This is in excellent agreement with measured values of molar specific heats for such gases as helium, neon, argon, and xenon over a wide range of temperatures (Table 21.2).

Now suppose that the gas is taken along the constant-pressure path  $i \rightarrow f'$  shown in Figure 21.4. Along this path, the temperature again increases by  $\Delta T$ . The energy that must be transferred by heat to the gas in this process is  $Q = nC_P \Delta T$ . Because the volume increases in this process, the work done by the gas is  $W = P\Delta V$ , where  $P$  is the constant pressure at which the process occurs. Applying

**Figure 21.4** Energy is transferred by heat to an ideal gas in two ways. For the constant-volume path  $i \rightarrow f$ , all the energy goes into increasing the internal energy of the gas because no work is done. Along the constant-pressure path  $i \rightarrow f'$ , part of the energy transferred in by heat is transferred out by work done by the gas.

**TABLE 21.2** Molar Specific Heats of Various Gases

Gas	Molar Specific Heat ( $\text{J/mol} \cdot \text{K}$ ) <sup>a</sup>

the first law to this process, we have

$$\Delta E_{\text{int}} = Q - W = nC_p \Delta T - P\Delta V \quad (21.15)$$

In this case, the energy added to the gas by heat is channeled as follows: Part of it does external work (that is, it goes into moving a piston), and the remainder increases the internal energy of the gas. But the change in internal energy for the process  $i \rightarrow f'$  is equal to that for the process  $i \rightarrow f$  because  $E_{\text{int}}$  depends only on temperature for an ideal gas and because  $\Delta T$  is the same for both processes. In addition, because  $PV = nRT$ , we note that for a constant-pressure process,  $P\Delta V = nR\Delta T$ . Substituting this value for  $P\Delta V$  into Equation 21.15 with  $\Delta E_{\text{int}} = nC_V \Delta T$  (Eq. 21.12) gives

$$\begin{aligned} nC_V \Delta T &= nC_p \Delta T - nR\Delta T \\ C_p - C_V &= R \end{aligned} \quad (21.16)$$

This expression applies to *any* ideal gas. It predicts that the molar specific heat of an ideal gas at constant pressure is greater than the molar specific heat at constant volume by an amount  $R$ , the universal gas constant (which has the value  $8.31 \text{ J/mol} \cdot \text{K}$ ). This expression is applicable to real gases, as the data in Table 21.2 show.

Because  $C_V = \frac{3}{2}R$  for a monatomic ideal gas, Equation 21.16 predicts a value  $C_p = \frac{5}{2}R = 20.8 \text{ J/mol} \cdot \text{K}$  for the molar specific heat of a monatomic gas at constant pressure. The ratio of these heat capacities is a dimensionless quantity  $\gamma$  (Greek letter gamma):

Ratio of molar specific heats for a monatomic ideal gas

$$\gamma = \frac{C_p}{C_V} = \frac{(5/2)R}{(3/2)R} = \frac{5}{3} = 1.67 \quad (21.17)$$

Theoretical values of  $C_p$  and  $\gamma$  are in excellent agreement with experimental values obtained for monatomic gases, but they are in serious disagreement with the values for the more complex gases (see Table 21.2). This is not surprising because the value  $C_V = \frac{3}{2}R$  was derived for a monatomic ideal gas, and we expect some additional contribution to the molar specific heat from the internal structure of the more complex molecules. In Section 21.4, we describe the effect of molecular structure on the molar specific heat of a gas. We shall find that the internal energy—and, hence, the molar specific heat—of a complex gas must include contributions from the rotational and the vibrational motions of the molecule.

We have seen that the molar specific heats of gases at constant pressure are greater than the molar specific heats at constant volume. This difference is a consequence of the fact that in a constant-volume process, no work is done and all of the energy transferred by heat goes into increasing the internal energy (and temperature) of the gas, whereas in a constant-pressure process, some of the energy transferred by heat is transferred out as work done by the gas as it expands. In the case of solids and liquids heated at constant pressure, very little work is done because the thermal expansion is small. Consequently,  $C_p$  and  $C_V$  are approximately equal for solids and liquids.

### EXAMPLE 21.2 Heating a Cylinder of Helium

A cylinder contains 3.00 mol of helium gas at a temperature of 300 K. (a) If the gas is heated at constant volume, how much energy must be transferred by heat to the gas for its temperature to increase to 500 K?

**Solution** For the constant-volume process, we have

$$Q_1 = nC_V \Delta T$$

Because  $C_V = 12.5 \text{ J/mol} \cdot \text{K}$  for helium and  $\Delta T = 200 \text{ K}$ , we

obtain

$$Q_1 = (3.00 \text{ mol})(12.5 \text{ J/mol}\cdot\text{K})(200 \text{ K}) = 7.50 \times 10^3 \text{ J}$$

(b) How much energy must be transferred by heat to the gas at constant pressure to raise the temperature to 500 K?

**Solution** Making use of Table 21.2, we obtain

$$\begin{aligned} Q_2 &= nC_p \Delta T = (3.00 \text{ mol})(20.8 \text{ J/mol}\cdot\text{K})(200 \text{ K}) \\ &= 12.5 \times 10^3 \text{ J} \end{aligned}$$

**Exercise** What is the work done by the gas in this isobaric process?

**Answer**  $W = Q_2 - Q_1 = 5.00 \times 10^3 \text{ J}$ .

## 21.3 ADIABATIC PROCESSES FOR AN IDEAL GAS

As we noted in Section 20.6, an adiabatic process is one in which no energy is transferred by heat between a system and its surroundings. For example, if a gas is compressed (or expanded) very rapidly, very little energy is transferred out of (or into) the system by heat, and so the process is nearly adiabatic. (We must remember that the temperature of a system changes in an adiabatic process even though no energy is transferred by heat.) Such processes occur in the cycle of a gasoline engine, which we discuss in detail in the next chapter.

Another example of an adiabatic process is the very slow expansion of a gas that is thermally insulated from its surroundings. In general,

an **adiabatic process** is one in which no energy is exchanged by heat between a system and its surroundings.

Definition of an adiabatic process

Let us suppose that an ideal gas undergoes an adiabatic expansion. At any time during the process, we assume that the gas is in an equilibrium state, so that the equation of state  $PV = nRT$  is valid. As we shall soon see, the pressure and volume at any time during an adiabatic process are related by the expression

$$PV^\gamma = \text{constant} \quad (21.18)$$

Relationship between  $P$  and  $V$  for an adiabatic process involving an ideal gas

where  $\gamma = C_p/C_V$  is assumed to be constant during the process. Thus, we see that all three variables in the ideal gas law— $P$ ,  $V$ , and  $T$ —change during an adiabatic process.

### Proof That $PV^\gamma = \text{constant}$ for an Adiabatic Process

When a gas expands adiabatically in a thermally insulated cylinder, no energy is transferred by heat between the gas and its surroundings; thus,  $Q = 0$ . Let us take the infinitesimal change in volume to be  $dV$  and the infinitesimal change in temperature to be  $dT$ . The work done by the gas is  $P dV$ . Because the internal energy of an ideal gas depends only on temperature, the change in the internal energy in an adiabatic expansion is the same as that for an isovolumetric process between the same temperatures,  $dE_{\text{int}} = nC_V dT$  (Eq. 21.12). Hence, the first law of thermodynamics,  $\Delta E_{\text{int}} = Q - W$ , with  $Q = 0$ , becomes

$$dE_{\text{int}} = nC_V dT = -P dV$$

Taking the total differential of the equation of state of an ideal gas,  $PV = nRT$ , we

### QuickLab

Rapidly pump up a bicycle tire and then feel the coupling at the end of the hose. Why is the coupling warm?

**Figure 21.5** The  $PV$  diagram for an adiabatic expansion. Note that  $T_f < T_i$  in this process.

Adiabatic process

see that

$$P dV + V dP = nR dT$$

Eliminating  $dT$  from these two equations, we find that

$$P dV + V dP = -\frac{R}{C_V} P dV$$

Substituting  $R = C_P - C_V$  and dividing by  $PV$ , we obtain

$$\frac{dV}{V} + \frac{dP}{P} = -\left(\frac{C_P - C_V}{C_V}\right) \frac{dV}{V} = (1 - \gamma) \frac{dV}{V}$$

$$\frac{dP}{P} + \gamma \frac{dV}{V} = 0$$

Integrating this expression, we have

$$\ln P + \gamma \ln V = \text{constant}$$

which is equivalent to Equation 21.18:

$$PV^\gamma = \text{constant}$$

The  $PV$  diagram for an adiabatic expansion is shown in Figure 21.5. Because  $\gamma > 1$ , the  $PV$  curve is steeper than it would be for an isothermal expansion. By the definition of an adiabatic process, no energy is transferred by heat into or out of the system. Hence, from the first law, we see that  $\Delta E_{\text{int}}$  is negative (the gas does work, so its internal energy decreases) and so  $\Delta T$  also is negative. Thus, we see that the gas cools ( $T_f < T_i$ ) during an adiabatic expansion. Conversely, the temperature increases if the gas is compressed adiabatically. Applying Equation 21.18 to the initial and final states, we see that

$$P_i V_i^\gamma = P_f V_f^\gamma \quad (21.19)$$

Using the ideal gas law, we can express Equation 21.19 as

$$T_i V_i^{\gamma-1} = T_f V_f^{\gamma-1} \quad (21.20)$$

### EXAMPLE 21.3 A Diesel Engine Cylinder

Air at  $20.0^\circ\text{C}$  in the cylinder of a diesel engine is compressed from an initial pressure of  $1.00 \text{ atm}$  and volume of  $800.0 \text{ cm}^3$  to a volume of  $60.0 \text{ cm}^3$ . Assume that air behaves as an ideal gas with  $\gamma = 1.40$  and that the compression is adiabatic. Find the final pressure and temperature of the air.

**Solution** Using Equation 21.19, we find that

$$\begin{aligned} P_f &= P_i \left(\frac{V_i}{V_f}\right)^\gamma = (1.00 \text{ atm}) \left(\frac{800.0 \text{ cm}^3}{60.0 \text{ cm}^3}\right)^{1.40} \\ &= 37.6 \text{ atm} \end{aligned}$$

Because  $PV = nRT$  is valid during any process and because

no gas escapes from the cylinder,

$$\begin{aligned} \frac{P_i V_i}{T_i} &= \frac{P_f V_f}{T_f} \\ T_f &= \frac{P_f V_f}{P_i V_i} T_i = \frac{(37.6 \text{ atm})(60.0 \text{ cm}^3)}{(1.00 \text{ atm})(800.0 \text{ cm}^3)} (293 \text{ K}) \\ &= 826 \text{ K} = 553^\circ\text{C} \end{aligned}$$

The high compression in a diesel engine raises the temperature of the fuel enough to cause its combustion without the use of spark plugs.

## 21.4 THE EQUIPARTITION OF ENERGY

We have found that model predictions based on molar specific heat agree quite well with the behavior of monatomic gases but not with the behavior of complex gases (see Table 21.2). Furthermore, the value predicted by the model for the quantity  $C_p - C_v = R$  is the same for all gases. This is not surprising because this difference is the result of the work done by the gas, which is independent of its molecular structure.

To clarify the variations in  $C_v$  and  $C_p$  in gases more complex than monatomic gases, let us first explain the origin of molar specific heat. So far, we have assumed that the sole contribution to the internal energy of a gas is the translational kinetic energy of the molecules. However, the internal energy of a gas actually includes contributions from the translational, vibrational, and rotational motion of the molecules. The rotational and vibrational motions of molecules can be activated by collisions and therefore are “coupled” to the translational motion of the molecules. The branch of physics known as *statistical mechanics* has shown that, for a large number of particles obeying the laws of Newtonian mechanics, the available energy is, on the average, shared equally by each independent degree of freedom. Recall from Section 21.1 that the equipartition theorem states that, at equilibrium, each degree of freedom contributes  $\frac{1}{2}k_B T$  of energy per molecule.

Let us consider a diatomic gas whose molecules have the shape of a dumbbell (Fig. 21.6). In this model, the center of mass of the molecule can translate in the  $x$ ,  $y$ , and  $z$  directions (Fig. 21.6a). In addition, the molecule can rotate about three mutually perpendicular axes (Fig. 21.6b). We can neglect the rotation about the  $y$  axis because the moment of inertia  $I_y$  and the rotational energy  $\frac{1}{2}I_y\omega^2$  about this axis are negligible compared with those associated with the  $x$  and  $z$  axes. (If the two atoms are taken to be point masses, then  $I_y$  is identically zero.) Thus, there are five degrees of freedom: three associated with the translational motion and two associated with the rotational motion. Because each degree of freedom contributes, on the average,  $\frac{1}{2}k_B T$  of energy per molecule, the total internal energy for a system of  $N$  molecules is

$$E_{\text{int}} = 3N\left(\frac{1}{2}k_B T\right) + 2N\left(\frac{1}{2}k_B T\right) = \frac{5}{2}Nk_B T = \frac{5}{2}nRT$$

We can use this result and Equation 21.13 to find the molar specific heat at constant volume:

$$C_v = \frac{1}{n} \frac{dE_{\text{int}}}{dT} = \frac{1}{n} \frac{d}{dT} \left( \frac{5}{2} nRT \right) = \frac{5}{2} R$$

From Equations 21.16 and 21.17, we find that

$$\begin{aligned} C_p &= C_v + R = \frac{7}{2} R \\ \gamma &= \frac{C_p}{C_v} = \frac{\frac{7}{2} R}{\frac{5}{2} R} = \frac{7}{5} = 1.40 \end{aligned}$$

These results agree quite well with most of the data for diatomic molecules given in Table 21.2. This is rather surprising because we have not yet accounted for the possible vibrations of the molecule. In the vibratory model, the two atoms are joined by an imaginary spring (see Fig. 21.6c). The vibrational motion adds two more degrees of freedom, which correspond to the kinetic energy and the potential energy associated with vibrations along the length of the molecule. Hence, classical physics and the equipartition theorem predict an internal energy of

$$E_{\text{int}} = 3N\left(\frac{1}{2}k_B T\right) + 2N\left(\frac{1}{2}k_B T\right) + 2N\left(\frac{1}{2}k_B T\right) = \frac{7}{2}Nk_B T = \frac{7}{2}nRT$$

**Figure 21.6** Possible motions of a diatomic molecule: (a) translational motion of the center of mass, (b) rotational motion about the various axes, and (c) vibrational motion along the molecular axis.

**Figure 21.7** The molar specific heat of hydrogen as a function of temperature. The horizontal scale is logarithmic. Note that hydrogen liquefies at 20 K.

and a molar specific heat at constant volume of

$$C_V = \frac{1}{n} \frac{dE_{\text{int}}}{dT} = \frac{1}{n} \frac{d}{dT} \left( \frac{7}{2} nRT \right) = \frac{7}{2} R$$

This value is inconsistent with experimental data for molecules such as  $\text{H}_2$  and  $\text{N}_2$  (see Table 21.2) and suggests a breakdown of our model based on classical physics.

For molecules consisting of more than two atoms, the number of degrees of freedom is even larger and the vibrations are more complex. This results in an even higher predicted molar specific heat, which is in qualitative agreement with experiment. The more degrees of freedom available to a molecule, the more “ways” it can store internal energy; this results in a higher molar specific heat.

We have seen that the equipartition theorem is successful in explaining some features of the molar specific heat of gas molecules with structure. However, the theorem does not account for the observed temperature variation in molar specific heats. As an example of such a temperature variation,  $C_V$  for  $\text{H}_2$  is  $\frac{5}{2}R$  from about 250 K to 750 K and then increases steadily to about  $\frac{7}{2}R$  well above 750 K (Fig. 21.7). This suggests that much more significant vibrations occur at very high temperatures. At temperatures well below 250 K,  $C_V$  has a value of about  $\frac{3}{2}R$ , suggesting that the molecule has only translational energy at low temperatures.

### A Hint of Energy Quantization

The failure of the equipartition theorem to explain such phenomena is due to the inadequacy of classical mechanics applied to molecular systems. For a more satisfactory description, it is necessary to use a quantum-mechanical model, in which the energy of an individual molecule is quantized. The energy separation between adjacent vibrational energy levels for a molecule such as  $\text{H}_2$  is about ten times greater than the average kinetic energy of the molecule at room temperature. Consequently, collisions between molecules at low temperatures do not provide enough energy to change the vibrational state of the molecule. It is often stated that such degrees of freedom are “frozen out.” This explains why the vibrational energy does not contribute to the molar specific heats of molecules at low temperatures.

The rotational energy levels also are quantized, but their spacing at ordinary temperatures is small compared with  $k_B T$ . Because the spacing between quantized energy levels is small compared with the available energy, the system behaves in accordance with classical mechanics. However, at sufficiently low temperatures (typically less than 50 K), where  $k_B T$  is small compared with the spacing between rotational levels, intermolecular collisions may not be sufficiently energetic to alter the rotational states. This explains why  $C_V$  reduces to  $\frac{3}{2}R$  for  $H_2$  in the range from 20 K to approximately 100 K.

### The Molar Specific Heat of Solids

The molar specific heats of solids also demonstrate a marked temperature dependence. Solids have molar specific heats that generally decrease in a nonlinear manner with decreasing temperature and approach zero as the temperature approaches absolute zero. At high temperatures (usually above 300 K), the molar specific heats approach the value of  $3R \approx 25 \text{ J/mol}\cdot\text{K}$ , a result known as the *Dulong–Petit law*. The typical data shown in Figure 21.8 demonstrate the temperature dependence of the molar specific heats for two semiconducting solids, silicon and germanium.

We can explain the molar specific heat of a solid at high temperatures using the equipartition theorem. For small displacements of an atom from its equilibrium position, each atom executes simple harmonic motion in the  $x$ ,  $y$ , and  $z$  directions. The energy associated with vibrational motion in the  $x$  direction is

$$E = \frac{1}{2}mv_x^2 + \frac{1}{2}kx^2$$

The expressions for vibrational motions in the  $y$  and  $z$  directions are analogous. Therefore, each atom of the solid has six degrees of freedom. According to the equipartition theorem, this corresponds to an average vibrational energy of  $6(\frac{1}{2}k_B T) = 3k_B T$  per atom. Therefore, the total internal energy of a solid consisting of  $N$  atoms is

$$E_{\text{int}} = 3Nk_B T = 3nRT \quad (21.21)$$

From this result, we find that the molar specific heat of a solid at constant volume is

$$C_V = \frac{1}{n} \frac{dE_{\text{int}}}{dT} = 3R \quad (21.22)$$

This result is in agreement with the empirical DuLong–Petit law. The discrepancies between this model and the experimental data at low temperatures are again due to the inadequacy of classical physics in describing the microscopic world.

**Figure 21.8** Molar specific heat of silicon and germanium. As  $T$  approaches zero, the molar specific heat also approaches zero. (From C. Kittel, *Introduction to Solid State Physics*, New York, Wiley, 1971.)

Total internal energy of a solid

Molar specific heat of a solid at constant volume

## 21.5 THE BOLTZMANN DISTRIBUTION LAW

Thus far we have neglected the fact that not all molecules in a gas have the same speed and energy. In reality, their motion is extremely chaotic. Any individual molecule is colliding with others at an enormous rate—typically, a billion times per second. Each collision results in a change in the speed and direction of motion of each of the participant molecules. From Equation 21.7, we see that average molecular speeds increase with increasing temperature. What we would like to know now is the relative number of molecules that possess some characteristic, such as a certain percentage of the total energy or speed. The ratio of the number of molecules

that have the desired characteristic to the total number of molecules is the probability that a particular molecule has that characteristic.

## The Exponential Atmosphere

We begin by considering the distribution of molecules in our atmosphere. Let us determine how the number of molecules per unit volume varies with altitude. Our model assumes that the atmosphere is at a constant temperature  $T$ . (This assumption is not entirely correct because the temperature of our atmosphere decreases by about  $2^\circ\text{C}$  for every 300-m increase in altitude. However, the model does illustrate the basic features of the distribution.)

According to the ideal gas law, a gas containing  $N$  molecules in thermal equilibrium obeys the relationship  $PV = Nk_B T$ . It is convenient to rewrite this equation in terms of the **number density**  $n_V = N/V$ , which represents the number of molecules per unit volume of gas. This quantity is important because it can vary from one point to another. In fact, our goal is to determine how  $n_V$  changes in our atmosphere. We can express the ideal gas law in terms of  $n_V$  as  $P = n_V k_B T$ . Thus, if the number density  $n_V$  is known, we can find the pressure, and vice versa. The pressure in the atmosphere decreases with increasing altitude because a given layer of air must support the weight of all the atmosphere above it—that is, the greater the altitude, the less the weight of the air above that layer, and the lower the pressure.

**Figure 21.9** An atmospheric layer of gas in equilibrium.

To determine the variation in pressure with altitude, let us consider an atmospheric layer of thickness  $dy$  and cross-sectional area  $A$ , as shown in Figure 21.9. Because the air is in static equilibrium, the magnitude  $PA$  of the upward force exerted on the bottom of this layer must exceed the magnitude of the downward force on the top of the layer,  $(P + dP)A$ , by an amount equal to the weight of gas in this thin layer. If the mass of a gas molecule in the layer is  $m$ , and if a total of  $N$  molecules are in the layer, then the weight of the layer is given by  $mgN = mgn_V V = mgn_V A dy$ . Thus, we see that

$$PA - (P + dP)A = mgn_V A dy$$

This expression reduces to

$$dP = -mgn_V dy$$

Because  $P = n_V k_B T$  and  $T$  is assumed to remain constant, we see that  $dP = k_B T dn_V$ . Substituting this result into the previous expression for  $dP$  and rearranging terms, we have

$$\frac{dn_V}{n_V} = -\frac{mg}{k_B T} dy$$

Integrating this expression, we find that

$$n_V(y) = n_0 e^{-mgy/k_B T} \quad (21.23)$$

where the constant  $n_0$  is the number density at  $y = 0$ . This result is known as the **law of atmospheres**.

According to Equation 21.23, the number density decreases exponentially with increasing altitude when the temperature is constant. The number density of our atmosphere at sea level is about  $n_0 = 2.69 \times 10^{25}$  molecules/ $\text{m}^3$ . Because the pressure is  $P = n_V k_B T$ , we see from Equation 21.23 that the pressure of our atmosphere varies with altitude according to the expression

$$P = P_0 e^{-mgy/k_B T} \quad (21.24)$$

where  $P_0 = n_0 k_B T$ . A comparison of this model with the actual atmospheric pressure as a function of altitude shows that the exponential form is a reasonable approximation to the Earth's atmosphere.

### EXAMPLE 21.4 High-Flying Molecules

What is the number density of air at an altitude of 11.0 km (the cruising altitude of a commercial jetliner) compared with its number density at sea level? Assume that the air temperature at this height is the same as that at the ground, 20°C.

**Solution** The number density of our atmosphere decreases exponentially with altitude according to the law of atmospheres, Equation 21.23. We assume an average molecular mass of  $28.9 \text{ u} = 4.80 \times 10^{-26} \text{ kg}$ . Taking  $y = 11.0 \text{ km}$ , we calculate the power of the exponential in Equation 21.23 to be

$$\frac{mgy}{k_B T} = \frac{(4.80 \times 10^{-26} \text{ kg})(9.80 \text{ m/s}^2)(11\,000 \text{ m})}{(1.38 \times 10^{-23} \text{ J/K})(293 \text{ K})} = 1.28$$

Thus, Equation 21.23 gives

$$n_V = n_0 e^{-mgy/k_B T} = n_0 e^{-1.28} = 0.278 n_0$$

That is, the number density of air at an altitude of 11.0 km is only 27.8% of the number density at sea level, if we assume constant temperature. Because the temperature actually decreases with altitude, the number density of air is less than this in reality.

The pressure at this height is reduced in the same manner. For this reason, high-flying aircraft must have pressurized cabins to ensure passenger comfort and safety.

## Computing Average Values

The exponential function  $e^{-mgy/k_B T}$  that appears in Equation 21.23 can be interpreted as a probability distribution that gives the relative probability of finding a gas molecule at some height  $y$ . Thus, the probability distribution  $p(y)$  is proportional to the number density distribution  $n_V(y)$ . This concept enables us to determine many properties of the atmosphere, such as the fraction of molecules below a certain height or the average potential energy of a molecule.

As an example, let us determine the average height  $\bar{y}$  of a molecule in the atmosphere at temperature  $T$ . The expression for this average height is

$$\bar{y} = \frac{\int_0^{\infty} y n_V(y) dy}{\int_0^{\infty} n_V(y) dy} = \frac{\int_0^{\infty} y e^{-mgy/k_B T} dy}{\int_0^{\infty} e^{-mgy/k_B T} dy}$$

where the height of a molecule can range from 0 to  $\infty$ . The numerator in this expression represents the sum of the heights of the molecules times their number, while the denominator is the sum of the number of molecules. That is, the denominator is the total number of molecules. After performing the indicated integrations, we find that

$$\bar{y} = \frac{(k_B T/mg)^2}{k_B T/mg} = \frac{k_B T}{mg}$$

This expression states that the average height of a molecule increases as  $T$  increases, as expected.

We can use a similar procedure to determine the average potential energy of a gas molecule. Because the gravitational potential energy of a molecule at height  $y$  is  $U = mgy$ , the average potential energy is equal to  $mgy$ . Because  $\bar{y} = k_B T/mg$ , we

see that  $\bar{U} = mg(k_B T/mg) = k_B T$ . This important result indicates that the average gravitational potential energy of a molecule depends only on temperature, and not on  $m$  or  $g$ .

### The Boltzmann Distribution

Because the gravitational potential energy of a molecule at height  $y$  is  $U = mgy$ , we can express the law of atmospheres (Eq. 21.23) as

$$n_V = n_0 e^{-U/k_B T}$$

This means that gas molecules in thermal equilibrium are distributed in space with a probability that depends on gravitational potential energy according to the exponential factor  $e^{-U/k_B T}$ .

This exponential expression describing the distribution of molecules in the atmosphere is powerful and applies to any type of energy. In general, the number density of molecules having energy  $E$  is

$$n_V(E) = n_0 e^{-E/k_B T} \quad (21.25)$$

This equation is known as the **Boltzmann distribution law** and is important in describing the statistical mechanics of a large number of molecules. It states that **the probability of finding the molecules in a particular energy state varies exponentially as the negative of the energy divided by  $k_B T$** . All the molecules would fall into the lowest energy level if the thermal agitation at a temperature  $T$  did not excite the molecules to higher energy levels.

Boltzmann distribution law

### EXAMPLE 21.5 Thermal Excitation of Atomic Energy Levels

As we discussed briefly in Section 8.10, atoms can occupy only certain discrete energy levels. Consider a gas at a temperature of 2 500 K whose atoms can occupy only two energy levels separated by 1.50 eV, where 1 eV (electron volt) is an energy unit equal to  $1.6 \times 10^{-19}$  J (Fig. 21.10). Determine the ratio of the number of atoms in the higher energy level to the number in the lower energy level.

**Solution** Equation 21.25 gives the relative number of atoms in a given energy level. In this case, the atom has two possible energies,  $E_1$  and  $E_2$ , where  $E_1$  is the lower energy level. Hence, the ratio of the number of atoms in the higher energy level to the number in the lower energy level is

$$\frac{n_V(E_2)}{n_V(E_1)} = \frac{n_0 e^{-E_2/k_B T}}{n_0 e^{-E_1/k_B T}} = e^{-(E_2 - E_1)/k_B T}$$

In this problem,  $E_2 - E_1 = 1.50$  eV, and the denominator of the exponent is

$$\begin{aligned} k_B T &= (1.38 \times 10^{-23} \text{ J/K})(2\,500 \text{ K})/1.60 \times 10^{-19} \text{ J/eV} \\ &= 0.216 \text{ eV} \end{aligned}$$

Therefore, the required ratio is

$$\frac{n(E_2)}{n(E_1)} = e^{-1.50 \text{ eV}/0.216 \text{ eV}} = e^{-6.94} = 9.64 \times 10^{-4}$$

This result indicates that at  $T = 2\,500$  K, only a small fraction of the atoms are in the higher energy level. In fact, for every atom in the higher energy level, there are about 1 000 atoms in the lower level. The number of atoms in the higher level increases at even higher temperatures, but the distribution law specifies that at equilibrium there are always more atoms in the lower level than in the higher level.

**Figure 21.10** Energy level diagram for a gas whose atoms can occupy two energy levels.

## 21.6 DISTRIBUTION OF MOLECULAR SPEEDS

In 1860 James Clerk Maxwell (1831–1879) derived an expression that describes the distribution of molecular speeds in a very definite manner. His work and subsequent developments by other scientists were highly controversial because direct detection of molecules could not be achieved experimentally at that time. However, about 60 years later, experiments were devised that confirmed Maxwell's predictions.

Let us consider a container of gas whose molecules have some distribution of speeds. Suppose we want to determine how many gas molecules have a speed in the range from, for example, 400 to 410 m/s. Intuitively, we expect that the speed distribution depends on temperature. Furthermore, we expect that the distribution peaks in the vicinity of  $v_{\text{rms}}$ . That is, few molecules are expected to have speeds much less than or much greater than  $v_{\text{rms}}$  because these extreme speeds result only from an unlikely chain of collisions.

The observed speed distribution of gas molecules in thermal equilibrium is shown in Figure 21.11. The quantity  $N_v$ , called the **Maxwell–Boltzmann distribution function**, is defined as follows: If  $N$  is the total number of molecules, then the number of molecules with speeds between  $v$  and  $v + dv$  is  $dN = N_v dv$ . This number is also equal to the area of the shaded rectangle in Figure 21.11. Furthermore, the fraction of molecules with speeds between  $v$  and  $v + dv$  is  $N_v dv/N$ . This fraction is also equal to the probability that a molecule has a speed in the range  $v$  to  $v + dv$ .

The fundamental expression that describes the distribution of speeds of  $N$  gas molecules is

$$N_v = 4\pi N \left( \frac{m}{2\pi k_B T} \right)^{3/2} v^2 e^{-mv^2/2k_B T} \quad (21.26)$$

where  $m$  is the mass of a gas molecule,  $k_B$  is Boltzmann's constant, and  $T$  is the absolute temperature.<sup>1</sup> Observe the appearance of the Boltzmann factor  $e^{-E/k_B T}$  with  $E = \frac{1}{2}mv^2$ .

As indicated in Figure 21.11, the average speed  $\bar{v}$  is somewhat lower than the rms speed. The *most probable speed*  $v_{\text{mp}}$  is the speed at which the distribution curve reaches a peak. Using Equation 21.26, one finds that

$$v_{\text{rms}} = \sqrt{v^2} = \sqrt{3k_B T/m} = 1.73 \sqrt{k_B T/m} \quad (21.27)$$

$$\bar{v} = \sqrt{8k_B T/\pi m} = 1.60 \sqrt{k_B T/m} \quad (21.28)$$

$$v_{\text{mp}} = \sqrt{2k_B T/m} = 1.41 \sqrt{k_B T/m} \quad (21.29)$$

The details of these calculations are left for the student (see Problems 41 and 62). From these equations, we see that

$$v_{\text{rms}} > \bar{v} > v_{\text{mp}}$$

Figure 21.12 represents speed distribution curves for  $\text{N}_2$ . The curves were obtained by using Equation 21.26 to evaluate the distribution function at various speeds and at two temperatures. Note that the peak in the curve shifts to the right

**Figure 21.11** The speed distribution of gas molecules at some temperature. The number of molecules having speeds in the range  $dv$  is equal to the area of the shaded rectangle,  $N_v dv$ . The function  $N_v$  approaches zero as  $v$  approaches infinity.

Maxwell speed distribution function

rms speed

Average speed

Most probable speed

<sup>1</sup> For the derivation of this expression, see an advanced textbook on thermodynamics, such as that by R. P. Bauman, *Modern Thermodynamics with Statistical Mechanics*, New York, Macmillan Publishing Co., 1992.

**Figure 21.12** The speed distribution function for  $10^5$  nitrogen molecules at 300 K and 900 K. The total area under either curve is equal to the total number of molecules, which in this case equals  $10^5$ . Note that  $v_{\text{rms}} > \bar{v} > v_{\text{mp}}$ .

as  $T$  increases, indicating that the average speed increases with increasing temperature, as expected. The asymmetric shape of the curves is due to the fact that the lowest speed possible is zero while the upper classical limit of the speed is infinity.

### Quick Quiz 21.3

Consider the two curves in Figure 21.12. What is represented by the area under each of the curves between the 800-m/s and 1 000-m/s marks on the horizontal axis?

### QuickLab

Fill one glass with very hot tap water and another with very cold water. Put a single drop of food coloring in each glass. Which drop disperses faster? Why?

Equation 21.26 shows that the distribution of molecular speeds in a gas depends both on mass and on temperature. At a given temperature, the fraction of molecules with speeds exceeding a fixed value increases as the mass decreases. This explains why lighter molecules, such as  $\text{H}_2$  and  $\text{He}$ , escape more readily from the Earth's atmosphere than do heavier molecules, such as  $\text{N}_2$  and  $\text{O}_2$ . (See the discussion of escape speed in Chapter 14. Gas molecules escape even more readily from the Moon's surface than from the Earth's because the escape speed on the Moon is lower than that on the Earth.)

The speed distribution curves for molecules in a liquid are similar to those shown in Figure 21.12. We can understand the phenomenon of evaporation of a liquid from this distribution in speeds, using the fact that some molecules in the liquid are more energetic than others. Some of the faster-moving molecules in the liquid penetrate the surface and leave the liquid even at temperatures well below the boiling point. The molecules that escape the liquid by evaporation are those that have sufficient energy to overcome the attractive forces of the molecules in the liquid phase. Consequently, the molecules left behind in the liquid phase have a lower average kinetic energy; as a result, the temperature of the liquid decreases. Hence, evaporation is a cooling process. For example, an alcohol-soaked cloth often is placed on a feverish head to cool and comfort a patient.

The evaporation process

**EXAMPLE 21.6** A System of Nine Particles

Nine particles have speeds of 5.00, 8.00, 12.0, 12.0, 12.0, 14.0, 14.0, 17.0, and 20.0 m/s. (a) Find the particles' average speed.

**Solution** The average speed is the sum of the speeds divided by the total number of particles:

$$\bar{v} = \frac{(5.00 + 8.00 + 12.0 + 12.0 + 12.0 + 14.0 + 14.0 + 17.0 + 20.0) \text{ m/s}}{9}$$

$$= 12.7 \text{ m/s}$$

(b) What is the rms speed?

**Solution** The average value of the square of the speed is

$$\overline{v^2} = \frac{(5.00^2 + 8.00^2 + 12.0^2 + 12.0^2 + 12.0^2 + 14.0^2 + 14.0^2 + 17.0^2 + 20.0^2) \text{ m}^2}{9}$$

$$= 178 \text{ m}^2/\text{s}^2$$

Hence, the rms speed is

$$v_{\text{rms}} = \sqrt{\overline{v^2}} = \sqrt{178 \text{ m}^2/\text{s}^2} = 13.3 \text{ m/s}$$

(c) What is the most probable speed of the particles?

**Solution** Three of the particles have a speed of 12 m/s, two have a speed of 14 m/s, and the remaining have different speeds. Hence, we see that the most probable speed  $v_{\text{mp}}$  is

12 m/s.

Optional Section**21.7 MEAN FREE PATH**

Most of us are familiar with the fact that the strong odor associated with a gas such as ammonia may take a fraction of a minute to diffuse throughout a room. However, because average molecular speeds are typically several hundred meters per second at room temperature, we might expect a diffusion time much less than 1 s. But, as we saw in Quick Quiz 21.1, molecules collide with one other because they are not geometrical points. Therefore, they do not travel from one side of a room to the other in a straight line. Between collisions, the molecules move with constant speed along straight lines. The average distance between collisions is called the **mean free path**. The path of an individual molecule is random and resembles that shown in Figure 21.13. As we would expect from this description, the mean free path is related to the diameter of the molecules and the density of the gas.

We now describe how to estimate the mean free path for a gas molecule. For this calculation, we assume that the molecules are spheres of diameter  $d$ . We see from Figure 21.14a that no two molecules collide unless their centers are less than a distance  $d$  apart as they approach each other. An equivalent way to describe the

**Figure 21.14** (a) Two spherical molecules, each of diameter  $d$ , collide if their centers are within a distance  $d$  of each other. (b) The collision between the two molecules is equivalent to a point molecule's colliding with a molecule having an effective diameter of  $2d$ .

**Figure 21.13** A molecule moving through a gas collides with other molecules in a random fashion. This behavior is sometimes referred to as a *random-walk process*. The mean free path increases as the number of molecules per unit volume decreases. Note that the motion is not limited to the plane of the paper.

**Figure 21.15** In a time  $t$ , a molecule of effective diameter  $2d$  sweeps out a cylinder of length  $\bar{v}t$ , where  $\bar{v}$  is its average speed. In this time, it collides with every point molecule within this cylinder.

collisions is to imagine that one of the molecules has a diameter  $2d$  and that the rest are geometrical points (Fig. 21.14b). Let us choose the large molecule to be one moving with the average speed  $\bar{v}$ . In a time  $t$ , this molecule travels a distance  $\bar{v}t$ . In this time interval, the molecule sweeps out a cylinder having a cross-sectional area  $\pi d^2$  and a length  $\bar{v}t$  (Fig. 21.15). Hence, the volume of the cylinder is  $\pi d^2 \bar{v}t$ . If  $n_V$  is the number of molecules per unit volume, then the number of point-size molecules in the cylinder is  $(\pi d^2 \bar{v}t) n_V$ . The molecule of equivalent diameter  $2d$  collides with every molecule in this cylinder in the time  $t$ . Hence, the number of collisions in the time  $t$  is equal to the number of molecules in the cylinder,  $(\pi d^2 \bar{v}t) n_V$ .

The mean free path  $\ell$  equals the average distance  $\bar{v}t$  traveled in a time  $t$  divided by the number of collisions that occur in that time:

$$\ell = \frac{\bar{v}t}{(\pi d^2 \bar{v}t) n_V} = \frac{1}{\pi d^2 n_V}$$

Because the number of collisions in a time  $t$  is  $(\pi d^2 \bar{v}t) n_V$ , the number of collisions per unit time, or **collision frequency**  $f$ , is

$$f = \pi d^2 \bar{v} n_V$$

The inverse of the collision frequency is the average time between collisions, known as the **mean free time**.

Our analysis has assumed that molecules in the cylinder are stationary. When the motion of these molecules is included in the calculation, the correct results are

Mean free path

$$\ell = \frac{1}{\sqrt{2} \pi d^2 n_V} \quad (21.30)$$

Collision frequency

$$f = \sqrt{2} \pi d^2 \bar{v} n_V = \frac{\bar{v}}{\ell} \quad (21.31)$$

### EXAMPLE 21.7 Bouncing Around in the Air

Approximate the air around you as a collection of nitrogen molecules, each of which has a diameter of  $2.00 \times 10^{-10}$  m.

(a) How far does a typical molecule move before it collides with another molecule?

**Solution** Assuming that the gas is ideal, we can use the equation  $PV = Nk_B T$  to obtain the number of molecules per unit volume under typical room conditions:

$$\begin{aligned} n_V &= \frac{N}{V} = \frac{P}{k_B T} = \frac{1.01 \times 10^5 \text{ N/m}^2}{(1.38 \times 10^{-23} \text{ J/K})(293 \text{ K})} \\ &= 2.50 \times 10^{25} \text{ molecules/m}^3 \end{aligned}$$

Hence, the mean free path is

$$\begin{aligned} \ell &= \frac{1}{\sqrt{2} \pi d^2 n_V} \\ &= \frac{1}{\sqrt{2} \pi (2.00 \times 10^{-10} \text{ m})^2 (2.50 \times 10^{25} \text{ molecules/m}^3)} \\ &= 2.25 \times 10^{-7} \text{ m} \end{aligned}$$

This value is about  $10^3$  times greater than the molecular diameter.

(b) On average, how frequently does one molecule collide with another?

**Solution** Because the rms speed of a nitrogen molecule at  $20.0^\circ\text{C}$  is 511 m/s (see Table 21.1), we know from Equations 21.27 and 21.28 that  $\bar{v} = (1.60/1.73)(511 \text{ m/s}) = 473 \text{ m/s}$ . Therefore, the collision frequency is

$$f = \frac{\bar{v}}{\ell} = \frac{473 \text{ m/s}}{2.25 \times 10^{-7} \text{ m}} = 2.10 \times 10^9/\text{s}$$

The molecule collides with other molecules at the average rate of about two billion times each second!

The mean free path  $\ell$  is *not* the same as the average separation between particles. In fact, the average separation  $d$  between particles is approximately  $n_V^{-1/3}$ . In this example, the average molecular separation is

$$d = \frac{1}{n_V^{1/3}} = \frac{1}{(2.5 \times 10^{25})^{1/3}} = 3.4 \times 10^{-9} \text{ m}$$

## SUMMARY

The pressure of  $N$  molecules of an ideal gas contained in a volume  $V$  is

$$P = \frac{2}{3} \frac{N}{V} \left( \frac{1}{2} m \overline{v^2} \right) \quad (21.2)$$

The average translational kinetic energy per molecule of a gas,  $\frac{1}{2} m \overline{v^2}$ , is related to the temperature  $T$  of the gas through the expression

$$\frac{1}{2} m \overline{v^2} = \frac{3}{2} k_B T \quad (21.4)$$

where  $k_B$  is Boltzmann's constant. Each translational degree of freedom ( $x$ ,  $y$ , or  $z$ ) has  $\frac{1}{2} k_B T$  of energy associated with it.

The **theorem of equipartition of energy** states that the energy of a system in thermal equilibrium is equally divided among all degrees of freedom.

The total energy of  $N$  molecules (or  $n$  mol) of an ideal monatomic gas is

$$E_{\text{int}} = \frac{3}{2} N k_B T = \frac{3}{2} n R T \quad (21.10)$$

The change in internal energy for  $n$  mol of any ideal gas that undergoes a change in temperature  $\Delta T$  is

$$\Delta E_{\text{int}} = n C_V \Delta T \quad (21.12)$$

where  $C_V$  is the molar specific heat at constant volume.

The molar specific heat of an ideal monatomic gas at constant volume is  $C_V = \frac{3}{2} R$ ; the molar specific heat at constant pressure is  $C_P = \frac{5}{2} R$ . The ratio of specific heats is  $\gamma = C_P / C_V = \frac{5}{3}$ .

If an ideal gas undergoes an adiabatic expansion or compression, the first law of thermodynamics, together with the equation of state, shows that

$$P V^\gamma = \text{constant} \quad (21.18)$$

The **Boltzmann distribution law** describes the distribution of particles among available energy states. The relative number of particles having energy  $E$  is

$$n_V(E) = n_0 e^{-E/k_B T} \quad (21.25)$$

The **Maxwell-Boltzmann distribution function** describes the distribution of speeds of molecules in a gas:

$$N_v = 4\pi N \left( \frac{m}{2\pi k_B T} \right)^{3/2} v^2 e^{-mv^2/2k_B T} \quad (21.26)$$

This expression enables us to calculate the **root-mean-square speed**, the **average speed**, and the **most probable speed**:

$$v_{\text{rms}} = \sqrt{\overline{v^2}} = \sqrt{3k_B T/m} = 1.73 \sqrt{k_B T/m} \quad (21.27)$$

$$\bar{v} = \sqrt{8k_B T/\pi m} = 1.60 \sqrt{k_B T/m} \quad (21.28)$$

$$v_{\text{mp}} = \sqrt{2k_B T/m} = 1.41 \sqrt{k_B T/m} \quad (21.29)$$

## QUESTIONS

- Dalton's law of partial pressures states that the total pressure of a mixture of gases is equal to the sum of the partial pressures of gases making up the mixture. Give a convincing argument for this law on the basis of the kinetic theory of gases.
- One container is filled with helium gas and another with argon gas. If both containers are at the same temperature, which gas molecules have the higher rms speed? Explain.
- A gas consists of a mixture of He and  $N_2$  molecules. Do the lighter He molecules travel faster than the  $N_2$  molecules? Explain.
- Although the average speed of gas molecules in thermal equilibrium at some temperature is greater than zero, the average velocity is zero. Explain why this statement must be true.
- When alcohol is rubbed on your body, your body temperature decreases. Explain this effect.
- A liquid partially fills a container. Explain why the temperature of the liquid decreases if the container is then partially evacuated. (Using this technique, one can freeze water at temperatures above  $0^\circ\text{C}$ .)
- A vessel containing a fixed volume of gas is cooled. Does the mean free path of the gas molecules increase, decrease, or remain constant during the cooling process? What about the collision frequency?
- A gas is compressed at a constant temperature. What happens to the mean free path of the molecules in the process?
- If a helium-filled balloon initially at room temperature is placed in a freezer, will its volume increase, decrease, or remain the same?
- What happens to a helium-filled balloon released into the air? Will it expand or contract? Will it stop rising at some height?
- Which is heavier, dry air or air saturated with water vapor? Explain.
- Why does a diatomic gas have a greater energy content per mole than a monatomic gas at the same temperature?
- An ideal gas is contained in a vessel at 300 K. If the temperature is increased to 900 K, (a) by what factor does the rms speed of each molecule change? (b) By what factor does the pressure in the vessel change?
- A vessel is filled with gas at some equilibrium pressure and temperature. Can all gas molecules in the vessel have the same speed?
- In our model of the kinetic theory of gases, molecules were viewed as hard spheres colliding elastically with the walls of the container. Is this model realistic?
- In view of the fact that hot air rises, why does it generally become cooler as you climb a mountain? (Note that air is a poor thermal conductor.)

### Section 21.1 Molecular Model of an Ideal Gas

- Use the definition of Avogadro's number to find the mass of a helium atom.
- A sealed cubical container 20.0 cm on a side contains three times Avogadro's number of molecules at a temperature of  $20.0^\circ\text{C}$ . Find the force exerted by the gas on one of the walls of the container.
- In a 30.0-s interval, 500 hailstones strike a glass window with an area of  $0.600\text{ m}^2$  at an angle of  $45.0^\circ$  to the window surface. Each hailstone has a mass of 5.00 g and a speed of 8.00 m/s. If the collisions are elastic, what are the average force and pressure on the window?
- In a time  $t$ ,  $N$  hailstones strike a glass window of area  $A$  at an angle  $\theta$  to the window surface. Each hailstone has a mass  $m$  and a speed  $v$ . If the collisions are elastic, what are the average force and pressure on the window?
- In a period of 1.00 s,  $5.00 \times 10^{23}$  nitrogen molecules strike a wall with an area of  $8.00\text{ cm}^2$ . If the molecules move with a speed of 300 m/s and strike the wall head-on in perfectly elastic collisions, what is the pressure exerted on the wall? (The mass of one  $N_2$  molecule is  $4.68 \times 10^{-26}\text{ kg}$ .)
- A 5.00-L vessel contains 2 mol of oxygen gas at a pressure of 8.00 atm. Find the average translational kinetic energy of an oxygen molecule under these conditions.
- A spherical balloon with a volume of  $4\,000\text{ cm}^3$  contains helium at an (inside) pressure of  $1.20 \times 10^5\text{ Pa}$ . How many moles of helium are in the balloon if each helium atom has an average kinetic energy of  $3.60 \times 10^{-22}\text{ J}$ ?
- The rms speed of a helium atom at a certain temperature is 1 350 m/s. Find by proportion the rms speed of an oxygen molecule at this temperature. (The molar mass of  $O_2$  is 32.0 g/mol, and the molar mass of He is 4.00 g/mol.)
- (a) How many atoms of helium gas fill a balloon of diameter 30.0 cm at  $20.0^\circ\text{C}$  and 1.00 atm? (b) What is the average kinetic energy of the helium atoms? (c) What is the root-mean-square speed of each helium atom?

10. A 5.00-liter vessel contains nitrogen gas at  $27.0^\circ\text{C}$  and 3.00 atm. Find (a) the total translational kinetic energy of the gas molecules and (b) the average kinetic energy per molecule.
- WEB 11. A cylinder contains a mixture of helium and argon gas in equilibrium at  $150^\circ\text{C}$ . (a) What is the average kinetic energy for each type of gas molecule? (b) What is the root-mean-square speed for each type of molecule?
12. (a) Show that  $1\text{ Pa} = 1\text{ J/m}^3$ . (b) Show that the density in space of the translational kinetic energy of an ideal gas is  $3P/2$ .

### Section 21.2 Molar Specific Heat of an Ideal Gas

Note: You may use the data given in Table 21.2.

13. Calculate the change in internal energy of 3.00 mol of helium gas when its temperature is increased by 2.00 K.
14. One mole of air ( $C_V = 5R/2$ ) at 300 K and confined in a cylinder under a heavy piston occupies a volume of 5.00 L. Determine the new volume of the gas if 4.40 kJ of energy is transferred to the air by heat.
- WEB 15. One mole of hydrogen gas is heated at constant pressure from 300 K to 420 K. Calculate (a) the energy transferred by heat to the gas, (b) the increase in its internal energy, and (c) the work done by the gas.
16. In a constant-volume process, 209 J of energy is transferred by heat to 1.00 mol of an ideal monatomic gas initially at 300 K. Find (a) the increase in internal energy of the gas, (b) the work it does, and (c) its final temperature.
17. A house has well-insulated walls. It contains a volume of  $100\text{ m}^3$  of air at 300 K. (a) Calculate the energy required to increase the temperature of this air by  $1.00^\circ\text{C}$ . (b) If this energy could be used to lift an object of mass  $m$  through a height of 2.00 m, what is the value of  $m$ ?
18. A vertical cylinder with a heavy piston contains air at 300 K. The initial pressure is 200 kPa, and the initial volume is  $0.350\text{ m}^3$ . Take the molar mass of air as  $28.9\text{ g/mol}$  and assume that  $C_V = 5R/2$ . (a) Find the specific heat of air at constant volume in units of  $\text{J/kg}\cdot^\circ\text{C}$ . (b) Calculate the mass of the air in the cylinder. (c) Suppose the piston is held fixed. Find the energy input required to raise the temperature of the air to 700 K. (d) Assume again the conditions of the initial state and that the heavy piston is free to move. Find the energy input required to raise the temperature to 700 K.
19. A 1-L Thermos bottle is full of tea at  $90^\circ\text{C}$ . You pour out one cup and immediately screw the stopper back on. Make an order-of-magnitude estimate of the change in temperature of the tea remaining in the flask that results from the admission of air at room temperature. State the quantities you take as data and the values you measure or estimate for them.
20. For a diatomic ideal gas,  $C_V = 5R/2$ . One mole of this gas has pressure  $P$  and volume  $V$ . When the gas is heated, its pressure triples and its volume doubles. If this heating process includes two steps, the first at constant pressure and the second at constant volume, determine the amount of energy transferred to the gas by heat.
21. One mole of an ideal monatomic gas is at an initial temperature of 300 K. The gas undergoes an isovolumetric process, acquiring 500 J of energy by heat. It then undergoes an isobaric process, losing this same amount of energy by heat. Determine (a) the new temperature of the gas and (b) the work done on the gas.
22. A container has a mixture of two gases:  $n_1$  moles of gas 1, which has a molar specific heat  $C_1$ ; and  $n_2$  moles of gas 2, which has a molar specific heat  $C_2$ . (a) Find the molar specific heat of the mixture. (b) What is the molar specific heat if the mixture has  $m$  gases in the amounts  $n_1, n_2, n_3, \dots, n_m$ , and molar specific heats  $C_1, C_2, C_3, \dots, C_m$ , respectively?
23. One mole of an ideal diatomic gas with  $C_V = 5R/2$  occupies a volume  $V_i$  at a pressure  $P_i$ . The gas undergoes a process in which the pressure is proportional to the volume. At the end of the process, it is found that the rms speed of the gas molecules has doubled from its initial value. Determine the amount of energy transferred to the gas by heat.

### Section 21.3 Adiabatic Processes for an Ideal Gas

24. During the compression stroke of a certain gasoline engine, the pressure increases from 1.00 atm to 20.0 atm. Assuming that the process is adiabatic and that the gas is ideal, with  $\gamma = 1.40$ , (a) by what factor does the volume change and (b) by what factor does the temperature change? (c) If the compression starts with 0.016 0 mol of gas at  $27.0^\circ\text{C}$ , find the values of  $Q$ ,  $W$ , and  $\Delta E_{\text{int}}$  that characterize the process.
25. Two moles of an ideal gas ( $\gamma = 1.40$ ) expands slowly and adiabatically from a pressure of 5.00 atm and a volume of 12.0 L to a final volume of 30.0 L. (a) What is the final pressure of the gas? (b) What are the initial and final temperatures? (c) Find  $Q$ ,  $W$ , and  $\Delta E_{\text{int}}$ .
26. Air ( $\gamma = 1.40$ ) at  $27.0^\circ\text{C}$  and at atmospheric pressure is drawn into a bicycle pump that has a cylinder with an inner diameter of 2.50 cm and a length of 50.0 cm. The down stroke adiabatically compresses the air, which reaches a gauge pressure of 800 kPa before entering the tire. Determine (a) the volume of the compressed air and (b) the temperature of the compressed air. (c) The pump is made of steel and has an inner wall that is 2.00 mm thick. Assume that 4.00 cm of the cylinder's length is allowed to come to thermal equilibrium with the air. What will be the increase in wall temperature?
27. Air in a thundercloud expands as it rises. If its initial temperature was 300 K, and if no energy is lost by thermal conduction on expansion, what is its temperature when the initial volume has doubled?
28. How much work is required to compress 5.00 mol of air at  $20.0^\circ\text{C}$  and 1.00 atm to one tenth of the original vol-

ume by (a) an isothermal process and (b) an adiabatic process? (c) What is the final pressure in each of these two cases?

29. Four liters of a diatomic ideal gas ( $\gamma = 1.40$ ) confined to a cylinder is subject to a closed cycle. Initially, the gas is at 1.00 atm and at 300 K. First, its pressure is tripled under constant volume. Then, it expands adiabatically to its original pressure. Finally, the gas is compressed isobarically to its original volume. (a) Draw a  $PV$  diagram of this cycle. (b) Determine the volume of the gas at the end of the adiabatic expansion. (c) Find the temperature of the gas at the start of the adiabatic expansion. (d) Find the temperature at the end of the cycle. (e) What was the net work done for this cycle?
30. A diatomic ideal gas ( $\gamma = 1.40$ ) confined to a cylinder is subjected to a closed cycle. Initially, the gas is at  $P_i$ ,  $V_i$ , and  $T_i$ . First, its pressure is tripled under constant volume. Then, it expands adiabatically to its original pressure. Finally, the gas is compressed isobarically to its original volume. (a) Draw a  $PV$  diagram of this cycle. (b) Determine the volume of the gas at the end of the adiabatic expansion. (c) Find the temperature of the gas at the start of the adiabatic expansion. (d) Find the temperature at the end of the cycle. (e) What was the net work done for this cycle?
31. During the power stroke in a four-stroke automobile engine, the piston is forced down as the mixture of gas and air undergoes an adiabatic expansion. Assume that (1) the engine is running at 2 500 rpm, (2) the gauge pressure right before the expansion is 20.0 atm, (3) the volumes of the mixture right before and after the expansion are 50.0 and 400 cm<sup>3</sup>, respectively (Fig.

Figure P21.31

P21.31), (4) the time involved in the expansion is one-fourth that of the total cycle, and (5) the mixture behaves like an ideal gas, with  $\gamma = 1.40$ . Find the average power generated during the expansion.

### Section 21.4 The Equipartition of Energy

32. A certain molecule has  $f$  degrees of freedom. Show that a gas consisting of such molecules has the following properties: (1) its total internal energy is  $f n R T / 2$ ; (2) its molar specific heat at constant volume is  $f R / 2$ ; (3) its molar specific heat at constant pressure is  $(f + 2) R / 2$ ; (4) the ratio  $\gamma = C_p / C_v = (f + 2) / f$ .
- WEB 33. Consider 2.00 mol of an ideal diatomic gas. Find the total heat capacity at constant volume and at constant pressure (a) if the molecules rotate but do not vibrate and (b) if the molecules both rotate and vibrate.
34. Inspecting the magnitudes of  $C_V$  and  $C_P$  for the diatomic and polyatomic gases in Table 21.2, we find that the values increase with increasing molecular mass. Give a qualitative explanation of this observation.
35. In a crude model (Fig. P21.35) of a rotating diatomic molecule of chlorine ( $\text{Cl}_2$ ), the two Cl atoms are  $2.00 \times 10^{-10}$  m apart and rotate about their center of mass with angular speed  $\omega = 2.00 \times 10^{12}$  rad/s. What is the rotational kinetic energy of one molecule of  $\text{Cl}_2$ , which has a molar mass of 70.0 g/mol?

Figure P21.35

### Section 21.5 The Boltzmann Distribution Law

#### Section 21.6 Distribution of Molecular Speeds

36. One cubic meter of atomic hydrogen at 0°C contains approximately  $2.70 \times 10^{25}$  atoms at atmospheric pressure. The first excited state of the hydrogen atom has an energy of 10.2 eV above the lowest energy level, which is called the *ground state*. Use the Boltzmann factor to find the number of atoms in the first excited state at 0°C and at 10 000°C.
37. If convection currents (weather) did not keep the Earth's lower atmosphere stirred up, its chemical composition would change somewhat with altitude because the various molecules have different masses. Use the law of atmospheres to determine how the equilibrium ratio of oxygen to nitrogen molecules changes between sea level and 10.0 km. Assume a uniform temperature of 300 K and take the masses to be 32.0 u for oxygen ( $\text{O}_2$ ) and 28.0 u for nitrogen ( $\text{N}_2$ ).

38. A mixture of two gases diffuses through a filter at rates proportional to the gases' rms speeds. (a) Find the ratio of speeds for the two isotopes of chlorine,  $^{35}\text{Cl}$  and  $^{37}\text{Cl}$ , as they diffuse through the air. (b) Which isotope moves faster?
39. Fifteen identical particles have various speeds: one has a speed of 2.00 m/s; two have a speed of 3.00 m/s; three have a speed of 5.00 m/s; four have a speed of 7.00 m/s; three have a speed of 9.00 m/s; and two have a speed of 12.0 m/s. Find (a) the average speed, (b) the rms speed, and (c) the most probable speed of these particles.
40. Gaseous helium is in thermal equilibrium with liquid helium at 4.20 K. Even though it is on the point of condensation, model the gas as ideal and determine the most probable speed of a helium atom (mass =  $6.64 \times 10^{-27}$  kg) in it.
41. From the Maxwell–Boltzmann speed distribution, show that the most probable speed of a gas molecule is given by Equation 21.29. Note that the most probable speed corresponds to the point at which the slope of the speed distribution curve,  $dN_v/dv$ , is zero.
42. **Review Problem.** At what temperature would the average speed of helium atoms equal (a) the escape speed from Earth,  $1.12 \times 10^4$  m/s, and (b) the escape speed from the Moon,  $2.37 \times 10^3$  m/s? (See Chapter 14 for a discussion of escape speed, and note that the mass of a helium atom is  $6.64 \times 10^{-27}$  kg.)
43. A gas is at  $0^\circ\text{C}$ . If we wish to double the rms speed of the gas's molecules, by how much must we raise its temperature?
44. The latent heat of vaporization for water at room temperature is 2 430 J/g. (a) How much kinetic energy does each water molecule that evaporates possess before it evaporates? (b) Find the pre-evaporation rms speed of a water molecule that is evaporating. (c) What is the effective temperature of these molecules (modeled as if they were already in a thin gas)? Why do these molecules not burn you?

(Optional)

**Section 21.7 Mean Free Path**

45. In an ultrahigh vacuum system, the pressure is measured to be  $1.00 \times 10^{-10}$  torr (where 1 torr = 133 Pa). Assume that the gas molecules have a molecular diameter of  $3.00 \times 10^{-10}$  m and that the temperature is 300 K. Find (a) the number of molecules in a volume of  $1.00 \text{ m}^3$ , (b) the mean free path of the molecules, and (c) the collision frequency, assuming an average speed of 500 m/s.
46. In deep space it is reported that there is only one particle per cubic meter. Using the average temperature of 3.00 K and assuming that the particle is  $\text{H}_2$  (with a diameter of 0.200 nm), (a) determine the mean free path of the particle and the average time between collisions. (b) Repeat part (a), assuming that there is only one particle per cubic centimeter.
47. Show that the mean free path for the molecules of an ideal gas at temperature  $T$  and pressure  $P$  is
- $$\ell = \frac{k_B T}{\sqrt{2} \pi d^2 P}$$
- where  $d$  is the molecular diameter.
48. In a tank full of oxygen, how many molecular diameters  $d$  (on average) does an oxygen molecule travel (at 1.00 atm and  $20.0^\circ\text{C}$ ) before colliding with another  $\text{O}_2$  molecule? (The diameter of the  $\text{O}_2$  molecule is approximately  $3.60 \times 10^{-10}$  m.)
49. Argon gas at atmospheric pressure and  $20.0^\circ\text{C}$  is confined in a  $1.00\text{-m}^3$  vessel. The effective hard-sphere diameter of the argon atom is  $3.10 \times 10^{-10}$  m. (a) Determine the mean free path  $\ell$ . (b) Find the pressure when the mean free path is  $\ell = 1.00$  m. (c) Find the pressure when  $\ell = 3.10 \times 10^{-10}$  m.

**ADDITIONAL PROBLEMS**

50. The dimensions of a room are  $4.20 \text{ m} \times 3.00 \text{ m} \times 2.50 \text{ m}$ . (a) Find the number of molecules of air in it at atmospheric pressure and  $20.0^\circ\text{C}$ . (b) Find the mass of this air, assuming that the air consists of diatomic molecules with a molar mass of 28.9 g/mol. (c) Find the average kinetic energy of a molecule. (d) Find the root-mean-square molecular speed. (e) On the assumption that the specific heat is a constant independent of temperature, we have  $E_{\text{int}} = 5nRT/2$ . Find the internal energy in the air. (f) Find the internal energy of the air in the room at  $25.0^\circ\text{C}$ .
51. The function  $E_{\text{int}} = 3.50nRT$  describes the internal energy of a certain ideal gas. A sample comprising 2.00 mol of the gas always starts at pressure 100 kPa and temperature 300 K. For each one of the following processes, determine the final pressure, volume, and temperature; the change in internal energy of the gas; the energy added to the gas by heat; and the work done by the gas: (a) The gas is heated at constant pressure to 400 K. (b) The gas is heated at constant volume to 400 K. (c) The gas is compressed at constant temperature to 120 kPa. (d) The gas is compressed adiabatically to 120 kPa.
52. Twenty particles, each of mass  $m$  and confined to a volume  $V$ , have various speeds: two have speed  $v$ ; three have speed  $2v$ ; five have speed  $3v$ ; four have speed  $4v$ ; three have speed  $5v$ ; two have speed  $6v$ ; one has speed  $7v$ . Find (a) the average speed, (b) the rms speed, (c) the most probable speed, (d) the pressure that the particles exert on the walls of the vessel, and (e) the average kinetic energy per particle.
- WEB 53. A cylinder contains  $n$  mol of an ideal gas that undergoes an adiabatic process. (a) Starting with the expression

$W = \int P dV$  and using the expression  $PV^\gamma = \text{constant}$ , show that the work done is

$$W = \left( \frac{1}{\gamma - 1} \right) (P_i V_i - P_f V_f)$$

(b) Starting with the first law equation in differential form, prove that the work done also is equal to  $nC_V(T_i - T_f)$ . Show that this result is consistent with the equation given in part (a).

54. A vessel contains  $1.00 \times 10^4$  oxygen molecules at 500 K. (a) Make an accurate graph of the Maxwell speed distribution function versus speed with points at speed intervals of 100 m/s. (b) Determine the most probable speed from this graph. (c) Calculate the average and rms speeds for the molecules and label these points on your graph. (d) From the graph, estimate the fraction of molecules having speeds in the range of 300 m/s to 600 m/s.
55. **Review Problem.** Oxygen at pressures much greater than 1 atm is toxic to lung cells. By weight, what ratio of helium gas (He) to oxygen gas (O<sub>2</sub>) must be used by a scuba diver who is to descend to an ocean depth of 50.0 m?
56. A cylinder with a piston contains 1.20 kg of air at 25.0°C and 200 kPa. Energy is transferred into the system by heat as it is allowed to expand, with the pressure rising to 400 kPa. Throughout the expansion, the relationship between pressure and volume is given by

$$P = CV^{1/2}$$

where  $C$  is a constant. (a) Find the initial volume. (b) Find the final volume. (c) Find the final temperature. (d) Find the work that the air does. (e) Find the energy transferred by heat. Take  $M = 28.9$  g/mol.

- WEB 57. The compressibility  $\kappa$  of a substance is defined as the fractional change in volume of that substance for a given change in pressure:

$$\kappa = -\frac{1}{V} \frac{dV}{dP}$$

(a) Explain why the negative sign in this expression ensures that  $\kappa$  is always positive. (b) Show that if an ideal gas is compressed isothermally, its compressibility is given by  $\kappa_1 = 1/P$ . (c) Show that if an ideal gas is compressed adiabatically, its compressibility is given by  $\kappa_2 = 1/\gamma P$ . (d) Determine values for  $\kappa_1$  and  $\kappa_2$  for a monatomic ideal gas at a pressure of 2.00 atm.

58. **Review Problem.** (a) Show that the speed of sound in an ideal gas is

$$v = \sqrt{\frac{\gamma RT}{M}}$$

where  $M$  is the molar mass. Use the general expression for the speed of sound in a fluid from Section 17.1; the definition of the bulk modulus from Section 12.4; and the result of Problem 57 in this chapter. As a sound

wave passes through a gas, the compressions are either so rapid or so far apart that energy flow by heat is prevented by lack of time or by effective thickness of insulation. The compressions and rarefactions are adiabatic. (b) Compute the theoretical speed of sound in air at 20°C and compare it with the value given in Table 17.1. Take  $M = 28.9$  g/mol. (c) Show that the speed of sound in an ideal gas is

$$v = \sqrt{\frac{\gamma k_B T}{m}}$$

where  $m$  is the mass of one molecule. Compare your result with the most probable, the average, and the rms molecular speeds.

59. For a Maxwellian gas, use a computer or programmable calculator to find the numerical value of the ratio  $N_v(v)/N_v(v_{mp})$  for the following values of  $v$ :  $v = (v_{mp}/50)$ ,  $(v_{mp}/10)$ ,  $(v_{mp}/2)$ ,  $v_{mp}$ ,  $2v_{mp}$ ,  $10v_{mp}$ ,  $50v_{mp}$ . Give your results to three significant figures.
60. A pitcher throws a 0.142-kg baseball at 47.2 m/s (Fig. P21.60). As it travels 19.4 m, the ball slows to 42.5 m/s because of air resistance. Find the change in temperature of the air through which it passes. To find the greatest possible temperature change, you may make the following assumptions: Air has a molar heat capacity of  $C_p = 7R/2$  and an equivalent molar mass of 28.9 g/mol. The process is so rapid that the cover of the baseball acts as thermal insulation, and the temperature of the ball itself does not change. A change in temperature happens initially only for the air in a cylinder 19.4 m in length and 3.70 cm in radius. This air is initially at 20.0°C.

**Figure P21.60** Nolan Ryan hurls the baseball for his 5 000th strikeout. (Joe Patronite/ALLSPORT)

61. Consider the particles in a *gas centrifuge*, a device that separates particles of different mass by whirling them in a circular path of radius  $r$  at angular speed  $\omega$ . Newton's second law applied to circular motion states that a force of magnitude equal to  $m\omega^2 r$  acts on a particle. (a) Discuss how a gas centrifuge can be used to separate particles of different mass. (b) Show that the density of the particles as a function of  $r$  is

$$n(r) = n_0 e^{m\omega^2 r^2 / 2k_B T}$$

62. Verify Equations 21.27 and 21.28 for the rms and average speeds of the molecules of a gas at a temperature  $T$ . Note that the average value of  $v^n$  is

$$\overline{v^n} = \frac{1}{N} \int_0^\infty v^n N_v dv$$

and make use of the definite integrals

$$\int_0^\infty x^3 e^{-ax^2} dx = \frac{1}{2a^2} \quad \int_0^\infty x^4 e^{-ax^2} dx = \frac{3}{8a^2} \sqrt{\frac{\pi}{a}}$$

63. A sample of a monatomic ideal gas occupies 5.00 L at atmospheric pressure and 300 K (point  $A$  in Figure P21.63). It is heated at constant volume to 3.00 atm (point  $B$ ). Then, it is allowed to expand isothermally to 1.00 atm (point  $C$ ) and at last is compressed isobarically to its original state. (a) Find the number of moles in the sample. (b) Find the temperatures at points  $B$  and  $C$  and the volume at point  $C$ . (c) Assuming that the specific heat does not depend on temperature, so that  $E_{\text{int}} = 3nRT/2$ , find the internal energy at points  $A$ ,  $B$ ,

Figure P21.63

and  $C$ . (d) Tabulate  $P$ ,  $V$ ,  $T$ , and  $E_{\text{int}}$  at the states at points  $A$ ,  $B$ , and  $C$ . (e) Now consider the processes  $A \rightarrow B$ ,  $B \rightarrow C$ , and  $C \rightarrow A$ . Describe just how to carry out each process experimentally. (f) Find  $Q$ ,  $W$ , and  $\Delta E_{\text{int}}$  for each of the processes. (g) For the whole cycle  $A \rightarrow B \rightarrow C \rightarrow A$ , find  $Q$ ,  $W$ , and  $\Delta E_{\text{int}}$ .

64. If you can't walk to outer space, can you walk at least half way? (a) Show that the fraction of particles below an altitude  $h$  in the atmosphere is

$$f = 1 - e^{(-mgh/k_B T)}$$

(b) Use this result to show that half the particles are below the altitude  $h' = k_B T \ln(2)/mg$ . What is the value of  $h'$  for the Earth? (Assume a temperature of 270 K, and note that the average molar mass for air is 28.9 g/mol.)

65. This problem will help you to think about the size of molecules. In the city of Beijing, a restaurant keeps a pot of chicken broth simmering continuously. Every morning it is topped off to contain 10.0 L of water, along with a fresh chicken, vegetables, and spices. The soup is thoroughly stirred. The molar mass of water is 18.0 g/mol. (a) Find the number of molecules of water in the pot. (b) During a certain month, 90.0% of the broth was served each day to people who then emigrated immediately. Of the water molecules present in the pot on the first day of the month, when was the last one likely to have been ladled out of the pot? (c) The broth has been simmering for centuries, through wars, earthquakes, and stove repairs. Suppose that the water that was in the pot long ago has thoroughly mixed into the Earth's hydrosphere, of mass  $1.32 \times 10^{21}$  kg. How many of the water molecules originally in the pot are likely to be present in it again today?
66. **Review Problem.** (a) If it has enough kinetic energy, a molecule at the surface of the Earth can escape the Earth's gravitation. Using the principle of conservation of energy, show that the minimum kinetic energy needed for escape is  $mgR$ , where  $m$  is the mass of the molecule,  $g$  is the free-fall acceleration at the surface of the Earth, and  $R$  is the radius of the Earth. (b) Calculate the temperature for which the minimum escape kinetic energy is ten times the average kinetic energy of an oxygen molecule.

67. Using multiple laser beams, physicists have been able to cool and trap sodium atoms in a small region. In one experiment, the temperature of the atoms was reduced to 0.240 mK. (a) Determine the rms speed of the sodium atoms at this temperature. The atoms can be trapped for about 1.00 s. The trap has a linear dimension of roughly 1.00 cm. (b) Approximately how long would it take an atom to wander out of the trap region if there were no trapping action?

## ANSWERS TO QUICK QUIZZES

**21.1** Although a molecule moves very rapidly, it does not travel far before it collides with another molecule. The collision deflects the molecule from its original path. Eventually, a perfume molecule will make its way from one end of the room to the other, but the path it takes is much longer than the straight-line distance from the perfume bottle to your nose.

**21.2** (c)  $E_{\text{int}}$  stays the same. According to Equation 21.10,  $E_{\text{int}}$  is a function of temperature only. Along an isotherm,  $T$

is constant by definition. Therefore, the internal energy of the gas does not change.

**21.3** The area under each curve represents the number of molecules in that particular velocity range. The  $T = 900 \text{ K}$  curve has many more molecules moving between  $800 \text{ m/s}$  and  $1000 \text{ m/s}$  than does the  $T = 300 \text{ K}$  curve.

## Chapter Outline

- 22.1** Heat Engines and the Second Law of Thermodynamics
- 22.2** Reversible and Irreversible Processes
- 22.3** The Carnot Engine
- 22.4** Gasoline and Diesel Engines
- 22.5** Heat Pumps and Refrigerators
- 22.6** Entropy
- 22.7** Entropy Changes in Irreversible Processes
- 22.8** *(Optional)* Entropy on a Microscopic Scale

The first law of thermodynamics, which we studied in Chapter 20, is a statement of conservation of energy, generalized to include internal energy. This law states that a change in internal energy in a system can occur as a result of energy transfer by heat or by work, or by both. As was stated in Chapter 20, the law makes no distinction between the results of heat and the results of work—either heat or work can cause a change in internal energy. However, an important distinction between the two is not evident from the first law. One manifestation of this distinction is that it is impossible to convert internal energy completely to mechanical energy by taking a substance through a thermodynamic cycle such as in a *heat engine*, a device we study in this chapter.

Although the first law of thermodynamics is very important, it makes no distinction between processes that occur spontaneously and those that do not. However, we find that only certain types of energy-conversion and energy-transfer processes actually take place. The *second law of thermodynamics*, which we study in this chapter, establishes which processes do and which do not occur in nature. The following are examples of processes that proceed in only one direction, governed by the second law:

- When two objects at different temperatures are placed in thermal contact with each other, energy always flows by heat from the warmer to the cooler, never from the cooler to the warmer.
- A rubber ball dropped to the ground bounces several times and eventually comes to rest, but a ball lying on the ground never begins bouncing on its own.
- An oscillating pendulum eventually comes to rest because of collisions with air molecules and friction at the point of suspension. The mechanical energy of the system is converted to internal energy in the air, the pendulum, and the suspension; the reverse conversion of energy never occurs.

All these processes are *irreversible*—that is, they are processes that occur naturally in one direction only. No irreversible process has ever been observed to run backward—if it were to do so, it would violate the second law of thermodynamics.<sup>1</sup>

From an engineering standpoint, perhaps the most important implication of the second law is the limited efficiency of heat engines. The second law states that a machine capable of continuously converting internal energy completely to other forms of energy in a cyclic process cannot be constructed.

## 22.1 HEAT ENGINES AND THE SECOND LAW OF THERMODYNAMICS

 **A heat engine** is a device that converts internal energy to mechanical energy. For instance, in a typical process by which a power plant produces electricity, coal or some other fuel is burned, and the high-temperature gases produced are used to convert liquid water to steam. This steam is directed at the blades of a turbine, setting it into rotation. The mechanical energy associated with this rotation is used to drive an electric generator. Another heat engine—the internal combustion engine in an automobile—uses energy from a burning fuel to perform work that results in the motion of the automobile.

<sup>1</sup> Although we have never *observed* a process occurring in the time-reversed sense, it is *possible* for it to occur. As we shall see later in the chapter, however, such a process is highly improbable. From this viewpoint, we say that processes occur with a vastly greater probability in one direction than in the opposite direction.

**Figure 22.1** This steam-driven locomotive runs from Durango to Silverton, Colorado. It obtains its energy by burning wood or coal. The generated energy vaporizes water into steam, which powers the locomotive. (This locomotive must take on water from tanks located along the route to replace steam lost through the funnel.) Modern locomotives use diesel fuel instead of wood or coal. Whether old-fashioned or modern, such locomotives are heat engines, which extract energy from a burning fuel and convert a fraction of it to mechanical energy.

A heat engine carries some working substance through a cyclic process during which (1) the working substance absorbs energy from a high-temperature energy reservoir, (2) work is done by the engine, and (3) energy is expelled by the engine to a lower-temperature reservoir. As an example, consider the operation of a steam engine (Fig. 22.1), in which the working substance is water. The water in a boiler absorbs energy from burning fuel and evaporates to steam, which then does work by expanding against a piston. After the steam cools and condenses, the liquid water produced returns to the boiler and the cycle repeats.

It is useful to represent a heat engine schematically as in Figure 22.2. The engine absorbs a quantity of energy  $Q_h$  from the hot reservoir, does work  $W$ , and then gives up a quantity of energy  $Q_c$  to the cold reservoir. Because the working substance goes through a cycle, its initial and final internal energies are equal, and so  $\Delta E_{\text{int}} = 0$ . Hence, from the first law of thermodynamics,  $\Delta E_{\text{int}} = Q - W$ , and with no change in internal energy, **the net work  $W$  done by a heat engine is equal to the net energy  $Q_{\text{net}}$  flowing through it.** As we can see from Figure 22.2,  $Q_{\text{net}} = Q_h - Q_c$ ; therefore,

$$W = Q_h - Q_c \quad (22.1)$$

In this expression and in many others throughout this chapter, to be consistent with traditional treatments of heat engines, we take both  $Q_h$  and  $Q_c$  to be positive quantities, even though  $Q_c$  represents energy leaving the engine. In discussions of heat engines, we shall describe energy leaving a system with an explicit minus sign,

**Lord Kelvin** British physicist and mathematician (1824–1907) Born William Thomson in Belfast, Kelvin was the first to propose the use of an absolute scale of temperature. The Kelvin temperature scale is named in his honor. Kelvin's work in thermodynamics led to the idea that energy cannot pass spontaneously from a colder body to a hotter body. (J. L. Charmet/SPL/Photo Researchers, Inc.)

**Figure 22.2** Schematic representation of a heat engine. The engine absorbs energy  $Q_h$  from the hot reservoir, expels energy  $Q_c$  to the cold reservoir, and does work  $W$ .

**Figure 22.3** *PV* diagram for an arbitrary cyclic process. The value of the net work done equals the area enclosed by the curve.

as in Equation 22.1. Also note that we model the energy input and output for the heat engine as heat, as it often is; however, the energy transfer could occur by another mechanism.

**The net work done in a cyclic process is the area enclosed by the curve representing the process on a *PV* diagram.** This is shown for an arbitrary cyclic process in Figure 22.3.

The **thermal efficiency**  $e$  of a heat engine is defined as the ratio of the net work done by the engine during one cycle to the energy absorbed at the higher temperature during the cycle:

$$e = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h} \quad (22.2)$$

We can think of the efficiency as the ratio of what you get (mechanical work) to what you give (energy transfer at the higher temperature). In practice, we find that all heat engines expel only a fraction of the absorbed energy as mechanical work and that consequently the efficiency is less than 100%. For example, a good automobile engine has an efficiency of about 20%, and diesel engines have efficiencies ranging from 35% to 40%.

Equation 22.2 shows that a heat engine has 100% efficiency ( $e = 1$ ) only if  $Q_c = 0$ —that is, if no energy is expelled to the cold reservoir. In other words, a heat engine with perfect efficiency would have to expel all of the absorbed energy as mechanical work. On the basis of the fact that efficiencies of real engines are well below 100%, the **Kelvin–Planck** form of the **second law of thermodynamics** states the following:

Kelvin–Planck statement of the second law of thermodynamics

It is impossible to construct a heat engine that, operating in a cycle, produces no effect other than the absorption of energy from a reservoir and the performance of an equal amount of work.

This statement of the second law means that, during the operation of a heat engine,  $W$  can never be equal to  $Q_h$ , or, alternatively, that some energy  $Q_c$  must be

**Figure 22.4** Schematic diagram of a heat engine that absorbs energy  $Q_h$  from a hot reservoir and does an equivalent amount of work. It is impossible to construct such a perfect engine.

rejected to the environment. Figure 22.4 is a schematic diagram of the impossible “perfect” heat engine.

The first and second laws of thermodynamics can be summarized as follows: The first law specifies that **we cannot get more energy out of a cyclic process by work than the amount of energy we put in**, and the second law states that **we cannot break even because we must put more energy in, at the higher temperature, than the net amount of energy we get out by work**.

### EXAMPLE 22.1 The Efficiency of an Engine

Find the efficiency of a heat engine that absorbs 2 000 J of energy from a hot reservoir and exhausts 1 500 J to a cold reservoir.

Equation 22.2:

$$e = 1 - \frac{Q_c}{Q_h} = 1 - \frac{1\,500\text{ J}}{2\,000\text{ J}} = 0.25, \text{ or } 25\%$$

**Solution** To calculate the efficiency of the engine, we use

## Refrigerators and Heat Pumps

**Refrigerators** and **heat pumps** are heat engines running in reverse. Here, we introduce them briefly for the purposes of developing an alternate statement of the second law; we shall discuss them more fully in Section 22.5.

In a refrigerator or heat pump, the engine absorbs energy  $Q_c$  from a cold reservoir and expels energy  $Q_h$  to a hot reservoir (Fig. 22.5). This can be accomplished only if work is done *on* the engine. From the first law, we know that the energy given up to the hot reservoir must equal the sum of the work done and the energy absorbed from the cold reservoir. Therefore, the refrigerator or heat pump transfers energy from a colder body (for example, the contents of a kitchen refrigerator or the winter air outside a building) to a hotter body (the air in the kitchen or a room in the building). In practice, it is desirable to carry out this process with a minimum of work. If it could be accomplished without doing any work, then the refrigerator or heat pump would be “perfect” (Fig. 22.6). Again, the existence of

**Figure 22.5** Schematic diagram of a refrigerator, which absorbs energy  $Q_c$  from a cold reservoir and expels energy  $Q_h$  to a hot reservoir. Work  $W$  is done *on* the refrigerator. A heat pump, which can be used to heat or cool a building, works the same way.

**Figure 22.6** Schematic diagram of an impossible refrigerator or heat pump—that is, one that absorbs energy  $Q_c$  from a cold reservoir and expels an equivalent amount of energy to a hot reservoir with  $W = 0$ .

Clausius statement of the second law of thermodynamics

such a device would be in violation of the second law of thermodynamics, which in the form of the **Clausius statement**<sup>2</sup> states:

It is impossible to construct a cyclical machine whose sole effect is the continuous transfer of energy from one object to another object at a higher temperature without the input of energy by work.

In simpler terms, **energy does not flow spontaneously from a cold object to a hot object.** For example, we cool homes in summer using heat pumps called *air conditioners*. The air conditioner pumps energy from the cool room in the home to the warm air outside. This direction of energy transfer requires an input of energy to the air conditioner, which is supplied by the electric power company.

The Clausius and Kelvin–Planck statements of the second law of thermodynamics appear, at first sight, to be unrelated, but in fact they are equivalent in all respects. Although we do not prove so here, if either statement is false, then so is the other.<sup>3</sup>

## 22.2 REVERSIBLE AND IRREVERSIBLE PROCESSES

**Figure 22.7** Adiabatic free expansion of a gas.

In the next section we discuss a theoretical heat engine that is the most efficient possible. To understand its nature, we must first examine the meaning of reversible and irreversible processes. In a **reversible** process, the system undergoing the process can be returned to its initial conditions along the same path shown on a  $PV$  diagram, and every point along this path is an equilibrium state. A process that does not satisfy these requirements is **irreversible**.

All natural processes are known to be irreversible. From the endless number of examples that could be selected, let us examine the adiabatic free expansion of a gas, which was already discussed in Section 20.6, and show that it cannot be reversible. The system that we consider is a gas in a thermally insulated container, as shown in Figure 22.7. A membrane separates the gas from a vacuum. When the membrane is punctured, the gas expands freely into the vacuum. As a result of the puncture, the system has changed because it occupies a greater volume after the expansion. Because the gas does not exert a force through a distance on the surroundings, it does no work on the surroundings as it expands. In addition, no energy is transferred to or from the gas by heat because the container is insulated from its surroundings. Thus, in this adiabatic process, the system has changed but the surroundings have not.

For this process to be reversible, we need to be able to return the gas to its original volume and temperature without changing the surroundings. Imagine that we try to reverse the process by compressing the gas to its original volume. To do so, we fit the container with a piston and use an engine to force the piston inward. During this process, the surroundings change because work is being done by an outside agent on the system. In addition, the system changes because the compression increases the temperature of the gas. We can lower the temperature of the gas by allowing it to come into contact with an external energy reservoir. Although this step returns the gas to its original conditions, the surroundings are

<sup>2</sup> First expressed by Rudolf Clausius (1822–1888).

<sup>3</sup> See, for example, R. P. Bauman, *Modern Thermodynamics and Statistical Mechanics*, New York, Macmillan Publishing Co., 1992.

again affected because energy is being added to the surroundings from the gas. If this energy could somehow be used to drive the engine that we have used to compress the gas, then the net energy transfer to the surroundings would be zero. In this way, the system and its surroundings could be returned to their initial conditions, and we could identify the process as reversible. However, the Kelvin–Planck statement of the second law specifies that the energy removed from the gas to return the temperature to its original value cannot be completely converted to mechanical energy in the form of the work done by the engine in compressing the gas. Thus, we must conclude that the process is irreversible.

We could also argue that the adiabatic free expansion is irreversible by relying on the portion of the definition of a reversible process that refers to equilibrium states. For example, during the expansion, significant variations in pressure occur throughout the gas. Thus, there is no well-defined value of the pressure for the entire system at any time between the initial and final states. In fact, the process cannot even be represented as a path on a  $PV$  diagram. The  $PV$  diagram for an adiabatic free expansion would show the initial and final conditions as points, but these points would not be connected by a path. Thus, because the intermediate conditions between the initial and final states are not equilibrium states, the process is irreversible.

Although all real processes are always irreversible, some are almost reversible. If a real process occurs very slowly such that the system is always very nearly in an equilibrium state, then the process can be approximated as reversible. For example, let us imagine that we compress a gas very slowly by dropping some grains of sand onto a frictionless piston, as shown in Figure 22.8. We make the process isothermal by placing the gas in thermal contact with an energy reservoir, and we transfer just enough energy from the gas to the reservoir during the process to keep the temperature constant. The pressure, volume, and temperature of the gas are all well defined during the isothermal compression, so each state during the process is an equilibrium state. Each time we add a grain of sand to the piston, the volume of the gas decreases slightly while the pressure increases slightly. Each grain we add represents a change to a new equilibrium state. We can reverse the process by slowly removing grains from the piston.

A general characteristic of a reversible process is that no dissipative effects (such as turbulence or friction) that convert mechanical energy to internal energy can be present. Such effects can be impossible to eliminate completely. Hence, it is not surprising that real processes in nature are irreversible.

## 22.3 THE CARNOT ENGINE

**10.9** In 1824 a French engineer named Sadi Carnot described a theoretical engine, now called a **Carnot engine**, that is of great importance from both practical and theoretical viewpoints. He showed that a heat engine operating in an ideal, reversible cycle—called a **Carnot cycle**—between two energy reservoirs is the most efficient engine possible. Such an ideal engine establishes an upper limit on the efficiencies of all other engines. That is, the net work done by a working substance taken through the Carnot cycle is the greatest amount of work possible for a given amount of energy supplied to the substance at the upper temperature. **Carnot's theorem** can be stated as follows:

No real heat engine operating between two energy reservoirs can be more efficient than a Carnot engine operating between the same two reservoirs.

**Figure 22.8** A gas in thermal contact with an energy reservoir is compressed slowly as individual grains of sand drop onto the piston. The compression is isothermal and reversible.

**Sadi Carnot** French physicist (1796–1832) Carnot was the first to show the quantitative relationship between work and heat. In 1824 he published his only work—*Reflections on the Motive Power of Heat*—which reviewed the industrial, political, and economic importance of the steam engine. In it, he defined work as “weight lifted through a height.” (FPG)

To argue the validity of this theorem, let us imagine two heat engines operating between the *same* energy reservoirs. One is a Carnot engine with efficiency  $e_C$ , and the other is an engine with efficiency  $e$ , which is greater than  $e_C$ . We use the more efficient engine to drive the Carnot engine as a Carnot refrigerator. Thus, the output by work of the more efficient engine is matched to the input by work of the

**Figure 22.9** The Carnot cycle. In process  $A \rightarrow B$ , the gas expands isothermally while in contact with a reservoir at  $T_h$ . In process  $B \rightarrow C$ , the gas expands adiabatically ( $Q = 0$ ). In process  $C \rightarrow D$ , the gas is compressed isothermally while in contact with a reservoir at  $T_c < T_h$ . In process  $D \rightarrow A$ , the gas is compressed adiabatically. The upward arrows on the piston indicate that weights are being removed during the expansions, and the downward arrows indicate that weights are being added during the compressions.

Carnot refrigerator. For the *combination* of the engine and refrigerator, then, no exchange by work with the surroundings occurs. Because we have assumed that the engine is more efficient than the refrigerator, the net result of the combination is a transfer of energy from the cold to the hot reservoir without work being done on the combination. According to the Clausius statement of the second law, this is impossible. Hence, the assumption that  $e > e_C$  must be false. **All real engines are less efficient than the Carnot engine because they do not operate through a reversible cycle.** The efficiency of a real engine is further reduced by such practical difficulties as friction and energy losses by conduction.

To describe the Carnot cycle taking place between temperatures  $T_c$  and  $T_h$ , we assume that the working substance is an ideal gas contained in a cylinder fitted with a movable piston at one end. The cylinder's walls and the piston are thermally nonconducting. Four stages of the Carnot cycle are shown in Figure 22.9, and the  $PV$  diagram for the cycle is shown in Figure 22.10. The Carnot cycle consists of two adiabatic processes and two isothermal processes, all reversible:

1. Process  $A \rightarrow B$  (Fig. 22.9a) is an isothermal expansion at temperature  $T_h$ . The gas is placed in thermal contact with an energy reservoir at temperature  $T_h$ . During the expansion, the gas absorbs energy  $Q_h$  from the reservoir through the base of the cylinder and does work  $W_{AB}$  in raising the piston.
2. In process  $B \rightarrow C$  (Fig. 22.9b), the base of the cylinder is replaced by a thermally nonconducting wall, and the gas expands adiabatically—that is, no energy enters or leaves the system. During the expansion, the temperature of the gas decreases from  $T_h$  to  $T_c$  and the gas does work  $W_{BC}$  in raising the piston.
3. In process  $C \rightarrow D$  (Fig. 22.9c), the gas is placed in thermal contact with an energy reservoir at temperature  $T_c$  and is compressed isothermally at temperature  $T_c$ . During this time, the gas expels energy  $Q_c$  to the reservoir, and the work done by the piston on the gas is  $W_{CD}$ .
4. In the final process  $D \rightarrow A$  (Fig. 22.9d), the base of the cylinder is replaced by a nonconducting wall, and the gas is compressed adiabatically. The temperature of the gas increases to  $T_h$ , and the work done by the piston on the gas is  $W_{DA}$ .

The net work done in this reversible, cyclic process is equal to the area enclosed by the path  $ABCD$  in Figure 22.10. As we demonstrated in Section 22.1, because the change in internal energy is zero, the net work  $W$  done in one cycle equals the net energy transferred into the system,  $Q_h - Q_c$ . The thermal efficiency of the engine is given by Equation 22.2:

$$e = \frac{W}{Q_h} = \frac{Q_h - Q_c}{Q_h} = 1 - \frac{Q_c}{Q_h}$$

In Example 22.2, we show that for a Carnot cycle

$$\frac{Q_c}{Q_h} = \frac{T_c}{T_h} \quad (22.3)$$

Hence, the thermal efficiency of a Carnot engine is

$$e_C = 1 - \frac{T_c}{T_h} \quad (22.4)$$

This result indicates that **all Carnot engines operating between the same two temperatures have the same efficiency.**

**Figure 22.10**  $PV$  diagram for the Carnot cycle. The net work done,  $W$ , equals the net energy received in one cycle,  $Q_h - Q_c$ . Note that  $\Delta E_{\text{int}} = 0$  for the cycle.

Ratio of energies for a Carnot cycle

Efficiency of a Carnot engine

Equation 22.4 can be applied to any working substance operating in a Carnot cycle between two energy reservoirs. According to this equation, the efficiency is zero if  $T_c = T_h$ , as one would expect. The efficiency increases as  $T_c$  is lowered and as  $T_h$  is raised. However, the efficiency can be unity (100%) only if  $T_c = 0$  K. Such reservoirs are not available; thus, the maximum efficiency is always less than 100%. In most practical cases,  $T_c$  is near room temperature, which is about 300 K. Therefore, one usually strives to increase the efficiency by raising  $T_h$ .

### EXAMPLE 22.2 Efficiency of the Carnot Engine

Show that the efficiency of a heat engine operating in a Carnot cycle using an ideal gas is given by Equation 22.4.

**Solution** During the isothermal expansion (process  $A \rightarrow B$  in Figure 22.9), the temperature does not change. Thus, the internal energy remains constant. The work done by a gas during an isothermal expansion is given by Equation 20.13. According to the first law, this work is equal to  $Q_h$ , the energy absorbed, so that

$$Q_h = W_{AB} = nRT_h \ln \frac{V_B}{V_A}$$

In a similar manner, the energy transferred to the cold reservoir during the isothermal compression  $C \rightarrow D$  is

$$Q_c = |W_{CD}| = nRT_c \ln \frac{V_C}{V_D}$$

We take the absolute value of the work because we are defining all values of  $Q$  for a heat engine as positive, as mentioned earlier. Dividing the second expression by the first, we find that

$$(1) \quad \frac{Q_c}{Q_h} = \frac{T_c}{T_h} \frac{\ln(V_C/V_D)}{\ln(V_B/V_A)}$$

We now show that the ratio of the logarithmic quantities is unity by establishing a relationship between the ratio of volumes. For any quasi-static, adiabatic process, the pressure and volume are related by Equation 21.18:

$$(2) \quad PV^\gamma = \text{constant}$$

During any reversible, quasi-static process, the ideal gas must also obey the equation of state,  $PV = nRT$ . Solving this ex-

pression for  $P$  and substituting into (2), we obtain

$$\frac{nRT}{V} V^\gamma = \text{constant}$$

which we can write as

$$TV^{\gamma-1} = \text{constant}$$

where we have absorbed  $nR$  into the constant right-hand side. Applying this result to the adiabatic processes  $B \rightarrow C$  and  $D \rightarrow A$ , we obtain

$$T_h V_B^{\gamma-1} = T_c V_C^{\gamma-1}$$

$$T_h V_A^{\gamma-1} = T_c V_D^{\gamma-1}$$

Dividing the first equation by the second, we obtain

$$(V_B/V_A)^{\gamma-1} = (V_C/V_D)^{\gamma-1}$$

$$(3) \quad \frac{V_B}{V_A} = \frac{V_C}{V_D}$$

Substituting (3) into (1), we find that the logarithmic terms cancel, and we obtain the relationship

$$\frac{Q_c}{Q_h} = \frac{T_c}{T_h}$$

Using this result and Equation 22.2, we see that the thermal efficiency of the Carnot engine is

$$e_C = 1 - \frac{Q_c}{Q_h} = 1 - \frac{T_c}{T_h}$$

which is Equation 22.4, the one we set out to prove.

### EXAMPLE 22.3 The Steam Engine

A steam engine has a boiler that operates at 500 K. The energy from the burning fuel changes water to steam, and this steam then drives a piston. The cold reservoir's temperature is that of the outside air, approximately 300 K. What is the maximum thermal efficiency of this steam engine?

**Solution** Using Equation 22.4, we find that the maximum thermal efficiency for any engine operating between these temperatures is

$$e_C = 1 - \frac{T_c}{T_h} = 1 - \frac{300 \text{ K}}{500 \text{ K}} = 0.4, \text{ or } 40\%$$

You should note that this is the highest *theoretical* efficiency of the engine. In practice, the efficiency is considerably lower.

can perform in each cycle if it absorbs 200 J of energy from the hot reservoir during each cycle.

**Exercise** Determine the maximum work that the engine **Answer** 80 J.

### EXAMPLE 22.4 The Carnot Efficiency

The highest theoretical efficiency of a certain engine is 30%. If this engine uses the atmosphere, which has a temperature of 300 K, as its cold reservoir, what is the temperature of its hot reservoir?

**Solution** We use the Carnot efficiency to find  $T_h$ :

$$e_C = 1 - \frac{T_c}{T_h}$$

$$T_h = \frac{T_c}{1 - e_C} = \frac{300 \text{ K}}{1 - 0.30} = 430 \text{ K}$$

## 22.4 GASOLINE AND DIESEL ENGINES

In a gasoline engine, six processes occur in each cycle; five of these are illustrated in Figure 22.11. In this discussion, we consider the interior of the cylinder above the piston to be the system that is taken through repeated cycles in the operation of the engine. For a given cycle, the piston moves up and down twice. This represents a four-stroke cycle consisting of two upstrokes and two downstrokes. The processes in the cycle can be approximated by the **Otto cycle**, a  $PV$  diagram of which is illustrated in Figure 22.12:

1. During the *intake stroke*  $O \rightarrow A$  (Fig. 22.11a), the piston moves downward, and a gaseous mixture of air and fuel is drawn into the cylinder at atmospheric pressure. In this process, the volume increases from  $V_2$  to  $V_1$ . This is the energy input part of the cycle, as energy enters the system (the interior of the cylinder) as internal energy stored in the fuel. This is energy transfer by *mass transfer*—that is, the energy is carried with a substance. It is similar to convection, which we studied in Chapter 20.
2. During the *compression stroke*  $A \rightarrow B$  (Fig. 22.11b), the piston moves upward, the air–fuel mixture is compressed adiabatically from volume  $V_1$  to volume  $V_2$ , and the temperature increases from  $T_A$  to  $T_B$ . The work done by the gas is negative, and its value is equal to the area under the curve  $AB$  in Figure 22.12.
3. In process  $B \rightarrow C$ , combustion occurs when the spark plug fires (Fig. 22.11c). This is not one of the strokes of the cycle because it occurs in a very short period of time while the piston is at its highest position. The combustion represents a rapid transformation from internal energy stored in chemical bonds in the fuel to internal energy associated with molecular motion, which is related to temperature. During this time, the pressure and temperature in the cylinder increase rapidly, with the temperature rising from  $T_B$  to  $T_C$ . The volume, however, remains approximately constant because of the short time interval. As a result, approximately no work is done by the gas. We can model this process in the  $PV$  diagram (Fig. 22.12) as that process in which the energy  $Q_h$  enters the system. However, in reality this process is a transformation of energy already in the cylinder (from process  $O \rightarrow A$ ) rather than a transfer.
4. In the *power stroke*  $C \rightarrow D$  (Fig. 22.11d), the gas expands adiabatically from  $V_2$  to

**Figure 22.11** The four-stroke cycle of a conventional gasoline engine. (a) In the intake stroke, air is mixed with fuel. (b) The intake valve is then closed, and the air–fuel mixture is compressed by the piston. (c) The mixture is ignited by the spark plug, with the result that the temperature of the mixture increases. (d) In the power stroke, the gas expands against the piston. (e) Finally, the residual gases are expelled, and the cycle repeats.

**Figure 22.12**  $PV$  diagram for the Otto cycle, which approximately represents the processes occurring in an internal combustion engine.

$V_1$ . This expansion causes the temperature to drop from  $T_C$  to  $T_D$ . Work is done by the gas in pushing the piston downward, and the value of this work is equal to the area under the curve  $CD$ .

- In the process  $D \rightarrow A$  (not shown in Fig. 22.11), an exhaust valve is opened as the piston reaches the bottom of its travel, and the pressure suddenly drops for a short time interval. During this interval, the piston is almost stationary and the volume is approximately constant. Energy is expelled from the interior of the cylinder and continues to be expelled during the next process.
- In the final process, the *exhaust stroke*  $A \rightarrow O$  (Fig. 22.11e), the piston moves upward while the exhaust valve remains open. Residual gases are exhausted at atmospheric pressure, and the volume decreases from  $V_1$  to  $V_2$ . The cycle then repeats.

If the air–fuel mixture is assumed to be an ideal gas, then the efficiency of the Otto cycle is

$$e = 1 - \frac{1}{(V_1/V_2)^{\gamma-1}} \quad (22.5)$$

where  $\gamma$  is the ratio of the molar specific heats  $C_P/C_V$  for the fuel–air mixture and  $V_1/V_2$  is the **compression ratio**. Equation 22.5, which we derive in Example 22.5, shows that the efficiency increases as the compression ratio increases. For a typical compression ratio of 8 and with  $\gamma = 1.4$ , we predict a theoretical efficiency of 56% for an engine operating in the idealized Otto cycle. This value is much greater than that achieved in real engines (15% to 20%) because of such effects as friction, energy transfer by conduction through the cylinder walls, and incomplete combustion of the air–fuel mixture.

Diesel engines operate on a cycle similar to the Otto cycle but do not employ a spark plug. The compression ratio for a diesel engine is much greater than that

for a gasoline engine. Air in the cylinder is compressed to a very small volume, and, as a consequence, the cylinder temperature at the end of the compression stroke is very high. At this point, fuel is injected into the cylinder. The temperature is high enough for the fuel–air mixture to ignite without the assistance of a spark plug. Diesel engines are more efficient than gasoline engines because of their greater compression ratios and resulting higher combustion temperatures.

### EXAMPLE 22.5 Efficiency of the Otto Cycle

Show that the thermal efficiency of an engine operating in an idealized Otto cycle (see Figs. 22.11 and 22.12) is given by Equation 22.5. Treat the working substance as an ideal gas.

**Solution** First, let us calculate the work done by the gas during each cycle. No work is done during processes  $B \rightarrow C$  and  $D \rightarrow A$ . The work done by the gas during the adiabatic compression  $A \rightarrow B$  is negative, and the work done by the gas during the adiabatic expansion  $C \rightarrow D$  is positive. The value of the net work done equals the area of the shaded region bounded by the closed curve in Figure 22.12. Because the change in internal energy for one cycle is zero, we see from the first law that the net work done during one cycle equals the net energy flow through the system:

$$W = Q_h - Q_c$$

Because processes  $B \rightarrow C$  and  $D \rightarrow A$  take place at constant volume, and because the gas is ideal, we find from the definition of molar specific heat (Eq. 21.8) that

$$Q_h = nC_V(T_C - T_B) \quad \text{and} \quad Q_c = nC_V(T_D - T_A)$$

Using these expressions together with Equation 22.2, we obtain for the thermal efficiency

$$(1) \quad e = \frac{W}{Q_h} = 1 - \frac{Q_c}{Q_h} = 1 - \frac{T_D - T_A}{T_C - T_B}$$

We can simplify this expression by noting that processes  $A \rightarrow B$  and  $C \rightarrow D$  are adiabatic and hence obey the relationship  $TV^{\gamma-1} = \text{constant}$ , which we obtained in Example 22.2. For the two adiabatic processes, then,

$$A \rightarrow B: \quad T_A V_A^{\gamma-1} = T_B V_B^{\gamma-1}$$

$$C \rightarrow D: \quad T_C V_C^{\gamma-1} = T_D V_D^{\gamma-1}$$

Using these equations and relying on the fact that

$V_A = V_D = V_1$  and  $V_B = V_C = V_2$ , we find that

$$(2) \quad T_A V_1^{\gamma-1} = T_B V_2^{\gamma-1} \quad T_A = T_B \left( \frac{V_2}{V_1} \right)^{\gamma-1}$$

$$(3) \quad T_D V_1^{\gamma-1} = T_C V_2^{\gamma-1} \quad T_D = T_C \left( \frac{V_2}{V_1} \right)^{\gamma-1}$$

Subtracting (2) from (3) and rearranging, we find that

$$(4) \quad \frac{T_D - T_A}{T_C - T_B} = \left( \frac{V_2}{V_1} \right)^{\gamma-1}$$

Substituting (4) into (1), we obtain for the thermal efficiency

$$(5) \quad e = 1 - \frac{1}{(V_1/V_2)^{\gamma-1}}$$

which is Equation 22.5.

We can also express this efficiency in terms of temperatures by noting from (2) and (3) that

$$\left( \frac{V_2}{V_1} \right)^{\gamma-1} = \frac{T_A}{T_B} = \frac{T_D}{T_C}$$

Therefore, (5) becomes

$$(6) \quad e = 1 - \frac{T_A}{T_B} = 1 - \frac{T_D}{T_C}$$

During the Otto cycle, the lowest temperature is  $T_A$  and the highest temperature is  $T_C$ . Therefore, the efficiency of a Carnot engine operating between reservoirs at these two temperatures, which is given by the expression  $e_C = 1 - (T_A/T_C)$ , is *greater* than the efficiency of the Otto cycle given by (6), as expected.

### APPLICATION Models of Gasoline and Diesel Engines

We can use the thermodynamic principles discussed in this and earlier chapters to model the performance of gasoline and diesel engines. In both types of engine, a gas is first compressed in the cylinders of the engine and then the fuel–air mixture is ignited. Work is done on the gas during compression, but significantly more work is done on the piston by the

mixture as the products of combustion expand in the cylinder. The power of the engine is transferred from the piston to the crankshaft by the connecting rod.

Two important quantities of either engine are the **displacement volume**, which is the volume displaced by the piston as it moves from the bottom to the top of the cylinder, and the com-

**Figure 22.13** PV diagram for an ideal diesel engine.

pression ratio  $r$ , which is the ratio of the maximum and minimum volumes of the cylinder (see p. 680). In our notation,  $r = V_A/V_B$ , or  $V_1/V_2$  in Eq. 22.5. Most gasoline and diesel engines operate with a four-cycle process (intake, compression, power, exhaust), in which the net work of the intake and exhaust cycles can be considered negligible. Therefore, power is developed only once for every two revolutions of the crankshaft.

In a diesel engine, only air (and no fuel) is present in the cylinder at the beginning of the compression. In the idealized diesel cycle of Figure 22.13, air in the cylinder undergoes an adiabatic compression from  $A$  to  $B$ . Starting at  $B$ , fuel is injected into the cylinder in such a way that the fuel–air mixture undergoes a constant-pressure expansion to an intermediate volume  $V_C$  ( $B \rightarrow C$ ). The high temperature of the mixture causes combustion, and the power stroke is an adiabatic expansion back to  $V_D = V_A$  ( $C \rightarrow D$ ). The exhaust valve is opened, and a constant-volume output of energy occurs ( $D \rightarrow A$ ) as the cylinder empties.

To simplify our calculations, we assume that the mixture in the cylinder is air modeled as an ideal gas. We use specific heats  $c$  instead of molar specific heats  $C$  and assume constant values for air at 300 K. We express the specific heats and the universal gas constant in terms of unit masses rather than moles. Thus,  $c_V = 0.718 \text{ kJ/kg} \cdot \text{K}$ ,  $c_P = 1.005 \text{ kJ/kg} \cdot \text{K}$ ,  $\gamma = c_P/c_V = 1.40$ , and  $R = c_P - c_V = 0.287 \text{ kJ/kg} \cdot \text{K} = 0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K}$ .

### A 3.00-L Gasoline Engine

Let us calculate the power delivered by a six-cylinder gasoline engine that has a displacement volume of 3.00 L operating at 4 000 rpm and having a compression ratio of  $r = 9.50$ . The air–fuel mixture enters a cylinder at atmospheric pressure and an ambient temperature of  $27^\circ\text{C}$ . During combustion, the mixture reaches a temperature of  $1\,350^\circ\text{C}$ .

First, let us calculate the work done by an individual cylinder. Using the initial pressure  $P_A = 100 \text{ kPa}$  and the initial temperature  $T_A = 300 \text{ K}$ , we calculate the initial volume and the mass of the air–fuel mixture. We know that the ratio of the initial and final volumes is the compression ratio,

$$\frac{V_A}{V_B} = r = 9.50$$

We also know that the difference in volumes is the displacement volume. The 3.00-L rating of the engine is the total displacement volume for all six cylinders. Thus, for one cylinder,

$$V_A - V_B = \frac{3.00 \text{ L}}{6} = \frac{3.00 \times 10^{-3} \text{ m}^3}{6} = 0.500 \times 10^{-3} \text{ m}^3$$

Solving these two equations simultaneously, we find the initial and final volumes:

$$V_A = 0.559 \times 10^{-3} \text{ m}^3 \quad V_B = 0.588 \times 10^{-4} \text{ m}^3$$

Using the ideal gas law (in the form  $PV = mRT$ , because we are using the universal gas constant in terms of mass rather than moles), we can find the mass of the air–fuel mixture:

$$\begin{aligned} m &= \frac{P_A V_A}{RT_A} = \frac{(100 \text{ kPa})(0.559 \times 10^{-3} \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})} \\ &= 6.49 \times 10^{-4} \text{ kg} \end{aligned}$$

Process  $A \rightarrow B$  (see Fig. 22.12) is an adiabatic compression, and this means that  $PV^\gamma = \text{constant}$ ; hence,

$$\begin{aligned} P_B V_B^\gamma &= P_A V_A^\gamma \\ P_B &= P_A \left( \frac{V_A}{V_B} \right)^\gamma = P_A (r)^\gamma = (100 \text{ kPa})(9.50)^{1.40} \\ &= 2.34 \times 10^3 \text{ kPa} \end{aligned}$$

Using the ideal gas law, we find that the temperature after the compression is

$$\begin{aligned} T_B &= \frac{P_B V_B}{mR} = \frac{(2.34 \times 10^3 \text{ kPa})(0.588 \times 10^{-4} \text{ m}^3)}{(6.49 \times 10^{-4} \text{ kg})(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} \\ &= 739 \text{ K} \end{aligned}$$

In process  $B \rightarrow C$ , the combustion that transforms the internal energy in chemical bonds into internal energy of molecular motion occurs at constant volume; thus,  $V_C = V_B$ . Combustion causes the temperature to increase to  $T_C = 1\,350^\circ\text{C} = 1\,623 \text{ K}$ . Using this value and the ideal gas law, we can calculate  $P_C$ :

$$\begin{aligned} P_C &= \frac{mRT_C}{V_C} \\ &= \frac{(6.49 \times 10^{-4} \text{ kg})(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(1\,623 \text{ K})}{(0.588 \times 10^{-4} \text{ m}^3)} \\ &= 5.14 \times 10^3 \text{ kPa} \end{aligned}$$

Process  $C \rightarrow D$  is an adiabatic expansion; the pressure after the expansion is

$$\begin{aligned} P_D &= P_C \left( \frac{V_C}{V_D} \right)^\gamma = P_C \left( \frac{V_B}{V_A} \right)^\gamma = P_C \left( \frac{1}{r} \right)^\gamma \\ &= (5.14 \times 10^3 \text{ kPa}) \left( \frac{1}{9.50} \right)^{1.40} = 220 \text{ kPa} \end{aligned}$$

Using the ideal gas law again, we find the final temperature:

$$T_D = \frac{P_D V_D}{mR} = \frac{(220 \text{ kPa})(0.559 \times 10^{-3} \text{ m}^3)}{(6.49 \times 10^{-4} \text{ kg})(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} = 660 \text{ K}$$

Now that we have the temperatures at the beginning and end of each process of the cycle, we can calculate the net energy transfer and net work done by each cylinder every two cycles. From Equation 21.8, we can state

$$\begin{aligned} Q_h = Q_{\text{in}} &= mc_V(T_C - T_B) \\ &= (6.49 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(1623 \text{ K} - 739 \text{ K}) \\ &= 0.412 \text{ kJ} \end{aligned}$$

$$\begin{aligned} Q_c = Q_{\text{out}} &= mc_V(T_D - T_A) \\ &= (6.49 \times 10^{-4} \text{ kg})(0.718 \text{ kJ/kg} \cdot \text{K})(660 \text{ K} - 300 \text{ K}) \\ &= 0.168 \text{ kJ} \end{aligned}$$

$$W_{\text{net}} = Q_{\text{in}} - Q_{\text{out}} = 0.244 \text{ kJ}$$

From Equation 22.2, the efficiency is  $e = W_{\text{net}}/Q_{\text{in}} = 59\%$ . (We can also use Equation 22.5 to calculate the efficiency directly from the compression ratio.)

Recalling that power is delivered every other revolution of the crankshaft, we find that the net power for the six-cylinder engine operating at 4 000 rpm is

$$\begin{aligned} \mathcal{P}_{\text{net}} &= 6 \left( \frac{1}{2 \text{ rev}} \right) (4000 \text{ rev/min}) (1 \text{ min}/60 \text{ s}) (0.244 \text{ kJ}) \\ &= 49 \text{ kW} = 66 \text{ hp} \end{aligned}$$

### A 2.00-L Diesel Engine

Let us calculate the power delivered by a four-cylinder diesel engine that has a displacement volume of 2.00 L and is operating at 3 000 rpm. The compression ratio is  $r = V_A/V_B = 22.0$ , and the **cutoff ratio**, which is the ratio of the volume change during the constant-pressure process  $B \rightarrow C$  in Figure 22.13, is  $r_c = V_C/V_B = 2.00$ . The air enters each cylinder at the beginning of the compression cycle at atmospheric pressure and at an ambient temperature of 27°C.

Our model of the diesel engine is similar to our model of the gasoline engine except that now the fuel is injected at point  $B$  and the mixture self-ignites near the end of the compression cycle  $A \rightarrow B$ , when the temperature reaches the ignition temperature. We assume that the energy input occurs in the constant-pressure process  $B \rightarrow C$ , and that the expansion process continues from  $C$  to  $D$  with no further energy transfer by heat.

Let us calculate the work done by an individual cylinder that has an initial volume of  $V_A = (2.00 \times 10^{-3} \text{ m}^3)/4 = 0.500 \times 10^{-3} \text{ m}^3$ . Because the compression ratio is quite high, we approximate the maximum cylinder volume to be the displacement volume. Using the initial pressure  $P_A = 100 \text{ kPa}$  and initial temperature  $T_A = 300 \text{ K}$ , we can calculate the mass of the air in the cylinder using the ideal gas law:

$$m = \frac{P_A V_A}{RT_A} = \frac{(100 \text{ kPa})(0.500 \times 10^{-3} \text{ m}^3)}{(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})(300 \text{ K})} = 5.81 \times 10^{-4} \text{ kg}$$

Process  $A \rightarrow B$  is an adiabatic compression, so  $PV^\gamma = \text{constant}$ ; thus,

$$\begin{aligned} P_B V_B^\gamma &= P_A V_A^\gamma \\ P_B &= P_A \left( \frac{V_A}{V_B} \right)^\gamma = (100 \text{ kPa})(22.0)^{1.40} = 7.57 \times 10^3 \text{ kPa} \end{aligned}$$

Using the ideal gas law, we find that the temperature of the air after the compression is

$$\begin{aligned} T_B &= \frac{P_B V_B}{mR} = \frac{(7.57 \times 10^3 \text{ kPa})(0.500 \times 10^{-3} \text{ m}^3)}{(5.81 \times 10^{-4} \text{ kg})(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} \left( \frac{1}{22.0} \right) \\ &= 1.03 \times 10^3 \text{ K} \end{aligned}$$

Process  $B \rightarrow C$  is a constant-pressure expansion; thus,  $P_C = P_B$ . We know from the cutoff ratio of 2.00 that the volume doubles in this process. According to the ideal gas law, a doubling of volume in an isobaric process results in a doubling of the temperature, so

$$T_C = 2T_B = 2.06 \times 10^3 \text{ K}$$

Process  $C \rightarrow D$  is an adiabatic expansion; therefore,

$$\begin{aligned} P_D &= P_C \left( \frac{V_C}{V_D} \right)^\gamma = P_C \left( \frac{V_C}{V_B} \frac{V_B}{V_D} \right)^\gamma = P_C \left( r_c \frac{1}{r} \right)^\gamma \\ &= (7.57 \times 10^3 \text{ kPa}) \left( \frac{2.00}{22.0} \right)^{1.40} = 264 \text{ kPa} \end{aligned}$$

We find the temperature at  $D$  from the ideal gas law:

$$\begin{aligned} T_D &= \frac{P_D V_D}{mR} = \frac{(264 \text{ kPa})(0.500 \times 10^{-3} \text{ m}^3)}{(5.81 \times 10^{-4} \text{ kg})(0.287 \text{ kPa} \cdot \text{m}^3/\text{kg} \cdot \text{K})} \\ &= 792 \text{ K} \end{aligned}$$

Now that we have the temperatures at the beginning and the end of each process, we can calculate the net energy transfer by heat and the net work done by each cylinder every two cycles:

$$\begin{aligned} Q_h = Q_{\text{in}} &= mc_P(T_C - T_B) = 0.601 \text{ kJ} \\ Q_c = Q_{\text{out}} &= mc_V(T_D - T_A) = 0.205 \text{ kJ} \\ W_{\text{net}} &= Q_{\text{in}} - Q_{\text{out}} = 0.396 \text{ kJ} \end{aligned}$$

The efficiency is  $e = W_{\text{net}}/Q_{\text{in}} = 66\%$ .

The net power for the four-cylinder engine operating at 3 000 rpm is

$$\begin{aligned} \mathcal{P}_{\text{net}} &= 4 \left( \frac{1}{2 \text{ rev}} \right) (3000 \text{ rev/min}) (1 \text{ min}/60 \text{ s}) (0.396 \text{ kJ}) \\ &= 39.6 \text{ kW} = 53 \text{ hp} \end{aligned}$$

Of course, modern engine design goes beyond this simple thermodynamic treatment, which uses idealized cycles.

## 22.5 HEAT PUMPS AND REFRIGERATORS

In Section 22.1 we introduced a heat pump as a mechanical device that moves energy from a region at lower temperature to a region at higher temperature. Heat pumps have long been used for cooling homes and buildings, and they are now becoming increasingly popular for heating them as well. The heat pump contains two sets of metal coils that can exchange energy by heat with the surroundings: one set on the outside of the building, in contact with the air or buried in the ground; and the other set in the interior of the building. In the heating mode, a circulating fluid flowing through the coils absorbs energy from the outside and releases it to the interior of the building from the interior coils. The fluid is cold and at low pressure when it is in the external coils, where it absorbs energy by heat from either the air or the ground. The resulting warm fluid is then compressed and enters the interior coils as a hot, high-pressure fluid, where it releases its stored energy to the interior air.

An air conditioner is simply a heat pump operating in the cooling mode, with its exterior and interior coils interchanged. Energy is absorbed into the circulating fluid in the interior coils; then, after the fluid is compressed, energy leaves the fluid through the external coils. The air conditioner must have a way to release energy to the outside. Otherwise, the work done on the air conditioner would represent energy added to the air inside the house, and the temperature would increase. In the same manner, a refrigerator cannot cool the kitchen if the refrigerator door is left open. The amount of energy leaving the external coils (Fig. 22.14) behind or underneath the refrigerator is greater than the amount of energy removed from the food or from the air in the kitchen if the door is left open. The difference between the energy out and the energy in is the work done by the electricity supplied to the refrigerator.

Figure 22.15 is a schematic representation of a heat pump. The cold temperature is  $T_c$ , the hot temperature is  $T_h$ , and the energy absorbed by the circulating fluid is  $Q_c$ . The heat pump does work  $W$  on the fluid, and the energy transferred from the pump to the building in the heating mode is  $Q_h$ .

The effectiveness of a heat pump is described in terms of a number called the **coefficient of performance** (COP). In the heating mode, the COP is defined as the ratio of the energy transferred to the hot reservoir to the work required to transfer that energy:

$$\text{COP (heating mode)} \equiv \frac{\text{Energy transferred at high temperature}}{\text{Work done by pump}} = \frac{Q_h}{W} \quad (22.6)$$

Note that the COP is similar to the thermal efficiency for a heat engine in that it is a ratio of what you get (energy delivered to the interior of the building) to what you give (work input). Because  $Q_h$  is generally greater than  $W$ , typical values for the COP are greater than unity. It is desirable for the COP to be as high as possible, just as it is desirable for the thermal efficiency of an engine to be as high as possible.

If the outside temperature is 25°F or higher, then the COP for a heat pump is about 4. That is, the amount of energy transferred to the building is about four times greater than the work done by the motor in the heat pump. However, as the outside temperature decreases, it becomes more difficult for the heat pump to extract sufficient energy from the air, and so the COP decreases. In fact, the COP can fall below unity for temperatures below the midteens. Thus, the use of heat pumps that extract energy from the air, while satisfactory in moderate climates, is not appropriate in areas where winter temperatures are very low. It is possible to

**Figure 22.14** The coils on the back of a refrigerator transfer energy by heat to the air. The second law of thermodynamics states that this amount of energy must be greater than the amount of energy removed from the contents of the refrigerator (or from the air in the kitchen, if the refrigerator door is left open).

use heat pumps in colder areas by burying the external coils deep in the ground. In this case, the energy is extracted from the ground, which tends to be warmer than the air in the winter.

### Quick Quiz 22.1

In an electric heater, electrical energy can be converted to internal energy with an efficiency of 100%. By what percentage does the cost of heating your home change when you replace your electric heating system with a heat pump that has a COP of 4? Assume that the motor running the heat pump is 100% efficient.

Theoretically, a Carnot-cycle heat engine run in reverse constitutes the most effective heat pump possible, and it determines the maximum COP for a given combination of hot and cold reservoir temperatures. Using Equations 22.1 and 22.3, we see that the maximum COP for a heat pump in its heating mode is

$$\begin{aligned} \text{COP}_C(\text{heating mode}) &= \frac{Q_h}{W} \\ &= \frac{Q_h}{Q_h - Q_c} = \frac{1}{1 - \frac{Q_c}{Q_h}} = \frac{1}{1 - \frac{T_c}{T_h}} = \frac{T_h}{T_h - T_c} \end{aligned}$$

For a heat pump operating in the cooling mode, “what you get” is energy removed from the cold reservoir. The most effective refrigerator or air conditioner is one that removes the greatest amount of energy from the cold reservoir in exchange for the least amount of work. Thus, for these devices we define the COP in terms of  $Q_c$ :

$$\text{COP (cooling mode)} = \frac{Q_c}{W} \quad (22.7)$$

A good refrigerator should have a high COP, typically 5 or 6.

The greatest possible COP for a heat pump in the cooling mode is that of a heat pump whose working substance is carried through a Carnot cycle in reverse:

$$\text{COP}_C(\text{cooling mode}) = \frac{T_c}{T_h - T_c}$$

As the difference between the temperatures of the two reservoirs approaches zero in this expression, the theoretical COP approaches infinity. In practice, the low temperature of the cooling coils and the high temperature at the compressor limit the COP to values below 10.

**Figure 22.15** Schematic diagram of a heat pump, which absorbs energy  $Q_c$  from a cold reservoir and expels energy  $Q_h$  to a hot reservoir. Note that this diagram is the same as that for the refrigerator shown in Figure 22.5.

### QuickLab

Estimate the COP of your refrigerator by making rough temperature measurements of the stored food and of the exhaust coils (found either on the back of the unit or behind a panel on the bottom). Use just your hand if no thermometer is available.

## 22.6 ENTROPY

The zeroth law of thermodynamics involves the concept of temperature, and the first law involves the concept of internal energy. Temperature and internal energy are both state functions—that is, they can be used to describe the thermodynamic state of a system. Another state function—this one related to the second law of thermodynamics—is **entropy**  $S$ . In this section we define entropy on a macroscopic scale as it was first expressed by Clausius in 1865.

Consider any infinitesimal process in which a system changes from one equilibrium state to another. If  $dQ_r$  is the amount of energy transferred by heat when the system follows a reversible path between the states, then the change in entropy  $dS$  is equal to this amount of energy for the reversible process divided by the absolute temperature of the system:

Clausius definition of change in entropy

$$dS = \frac{dQ_r}{T} \quad (22.8)$$

We have assumed that the temperature is constant because the process is infinitesimal. Since we have claimed that entropy is a state function, **the change in entropy during a process depends only on the end points and therefore is independent of the actual path followed.**

The subscript  $r$  on the quantity  $dQ_r$  is a reminder that the transferred energy is to be measured along a reversible path, even though the system may actually have followed some irreversible path. When energy is absorbed by the system,  $dQ_r$  is positive and the entropy of the system increases. When energy is expelled by the system,  $dQ_r$  is negative and the entropy of the system decreases. Note that Equation 22.8 defines not entropy but rather the *change* in entropy. Hence, the meaningful quantity in describing a process is the *change* in entropy.

Entropy was originally formulated as a useful concept in thermodynamics; however, its importance grew tremendously as the field of statistical mechanics developed because the analytical techniques of statistical mechanics provide an alternative means of interpreting entropy. In statistical mechanics, the behavior of a substance is described in terms of the statistical behavior of its atoms and molecules. One of the main results of this treatment is that **isolated systems tend toward disorder and that entropy is a measure of this disorder.** For example, consider the molecules of a gas in the air in your room. If half of the gas molecules had velocity vectors of equal magnitude directed toward the left and the other half had velocity vectors of the same magnitude directed toward the right, the situation would be very ordered. However, such a situation is extremely unlikely. If you could actually view the molecules, you would see that they move haphazardly in all directions, bumping into one another, changing speed upon collision, some going fast and others going slowly. This situation is highly disordered.

The cause of the tendency of an isolated system toward disorder is easily explained. To do so, we distinguish between *microstates* and *macrostates* of a system. A **microstate** is a particular description of the properties of the individual molecules of the system. For example, the description we just gave of the velocity vectors of the air molecules in your room being very ordered refers to a particular microstate, and the more likely haphazard motion is another microstate—one that represents disorder. A **macrostate** is a description of the conditions of the system from a macroscopic point of view and makes use of macroscopic variables such as pressure, density, and temperature. For example, in both of the microstates described for the air molecules in your room, the air molecules are distributed uniformly throughout the volume of the room; this uniform density distribution is a macrostate. We could not distinguish between our two microstates by making a macroscopic measurement—both microstates would appear to be the same macroscopically, and the two macrostates corresponding to these microstates are equivalent.

For any given macrostate of the system, a number of microstates are possible, or *accessible*. Among these microstates, it is assumed that all are equally probable. However, when all possible microstates are examined, it is found that far more of them are disordered than are ordered. Because all of the microstates are equally

probable, it is highly likely that the actual macrostate is one resulting from one of the highly disordered microstates, simply because there are many more of them. Similarly, the probability of a macrostate's forming from disordered microstates is greater than the probability of a macrostate's forming from ordered microstates.

All physical processes that take place in a system tend to cause the system and its surroundings to move toward more probable macrostates. The more probable macrostate is always one of greater disorder. If we consider a system and its surroundings to include the entire Universe, then the Universe is always moving toward a macrostate corresponding to greater disorder. Because entropy is a measure of disorder, an alternative way of stating this is **the entropy of the Universe increases in all real processes**. This is yet another statement of the second law of thermodynamics that can be shown to be equivalent to the Kelvin–Planck and Clausius statements.

To calculate the change in entropy for a finite process, we must recognize that  $T$  is generally not constant. If  $dQ_r$  is the energy transferred by heat when the system is at a temperature  $T$ , then the change in entropy in an arbitrary reversible process between an initial state and a final state is

$$\Delta S = \int_i^f dS = \int_i^f \frac{dQ_r}{T} \quad (\text{reversible path}) \quad (22.9)$$

As with an infinitesimal process, the change in entropy  $\Delta S$  of a system going from one state to another has the same value for *all* paths connecting the two states. That is, the finite change in entropy  $\Delta S$  of a system depends only on the properties of the initial and final equilibrium states. Thus, we are free to choose a particular reversible path over which to evaluate the entropy in place of the actual path, as long as the initial and final states are the same for both paths.

In real processes, the disorder of the Universe increases

Change in entropy for a finite process

### Quick Quiz 22.2

Which of the following is true for the entropy change of a system that undergoes a reversible, adiabatic process? (a)  $\Delta S < 0$ . (b)  $\Delta S = 0$ . (c)  $\Delta S > 0$ .

Let us consider the changes in entropy that occur in a Carnot heat engine operating between the temperatures  $T_c$  and  $T_h$ . In one cycle, the engine absorbs energy  $Q_h$  from the hot reservoir and expels energy  $Q_c$  to the cold reservoir. These energy transfers occur only during the isothermal portions of the Carnot cycle; thus, the constant temperature can be brought out in front of the integral sign in Equation 22.9. The integral then simply has the value of the total amount of energy transferred by heat. Thus, the total change in entropy for one cycle is

$$\Delta S = \frac{Q_h}{T_h} - \frac{Q_c}{T_c}$$

where the negative sign represents the fact that energy  $Q_c$  is expelled by the system, since we continue to define  $Q_c$  as a positive quantity when referring to heat engines. In Example 22.2 we showed that, for a Carnot engine,

$$\frac{Q_c}{Q_h} = \frac{T_c}{T_h}$$

Using this result in the previous expression for  $\Delta S$ , we find that the total change in

The change in entropy for a Carnot cycle is zero

entropy for a Carnot engine operating in a cycle is *zero*:

$$\Delta S = 0$$

Now let us consider a system taken through an arbitrary (non-Carnot) reversible cycle. Because entropy is a state function—and hence depends only on the properties of a given equilibrium state—we conclude that  $\Delta S = 0$  for *any* reversible cycle. In general, we can write this condition in the mathematical form

$\Delta S = 0$  for any reversible cycle

$$\oint \frac{dQ_r}{T} = 0 \quad (22.10)$$

where the symbol  $\oint$  indicates that the integration is over a closed path.

### Quasi-Static, Reversible Process for an Ideal Gas

Let us suppose that an ideal gas undergoes a quasi-static, reversible process from an initial state having temperature  $T_i$  and volume  $V_i$  to a final state described by  $T_f$  and  $V_f$ . Let us calculate the change in entropy of the gas for this process.

Writing the first law of thermodynamics in differential form and rearranging the terms, we have  $dQ_r = dE_{\text{int}} + dW$ , where  $dW = P dV$ . For an ideal gas, recall that  $dE_{\text{int}} = nC_V dT$  (Eq. 21.12), and from the ideal gas law, we have  $P = nRT/V$ . Therefore, we can express the energy transferred by heat in the process as

$$dQ_r = dE_{\text{int}} + P dV = nC_V dT + nRT \frac{dV}{V}$$

We cannot integrate this expression as it stands because the last term contains two variables,  $T$  and  $V$ . However, if we divide all terms by  $T$ , each of the terms on the right-hand side depends on only one variable:

$$\frac{dQ_r}{T} = nC_V \frac{dT}{T} + nR \frac{dV}{V} \quad (22.11)$$

Assuming that  $C_V$  is constant over the interval in question, and integrating Equation 22.11 from the initial state to the final state, we obtain

$$\Delta S = \int_i^f \frac{dQ_r}{T} = nC_V \ln \frac{T_f}{T_i} + nR \ln \frac{V_f}{V_i} \quad (22.12)$$

This expression demonstrates mathematically what we argued earlier—that  $\Delta S$  depends only on the initial and final states and is independent of the path between the states. Also, note in Equation 22.12 that  $\Delta S$  can be positive or negative, depending on the values of the initial and final volumes and temperatures. Finally, for a cyclic process ( $T_i = T_f$  and  $V_i = V_f$ ), we see from Equation 22.12 that  $\Delta S = 0$ . This is evidence that entropy is a state function.

### EXAMPLE 22.6 Change in Entropy—Melting

A solid that has a latent heat of fusion  $L_f$  melts at a temperature  $T_m$ . (a) Calculate the change in entropy of this substance when a mass  $m$  of the substance melts.

**Solution** Let us assume that the melting occurs so slowly that it can be considered a reversible process. In this case the temperature can be regarded as constant and equal to  $T_m$ .

Making use of Equations 22.9 and that for the latent heat of fusion  $Q = mL_f$  (Eq. 20.6), we find that

$$\Delta S = \int \frac{dQ_r}{T} = \frac{1}{T_m} \int dQ = \frac{Q}{T_m} = \frac{mL_f}{T_m}$$

Note that we are able to remove  $T_m$  from the integral because the process is isothermal. Note also that  $\Delta S$  is positive. This means that when a solid melts, its entropy increases because the molecules are much more disordered in the liquid state than they are in the solid state. The positive value for  $\Delta S$  also means that the substance in its liquid state does not spontaneously transfer energy from itself to the surroundings and freeze because to do so would involve a spontaneous decrease in entropy.

(b) Estimate the value of the change in entropy of an ice cube when it melts.

**Solution** Let us assume an ice tray makes cubes that are about 3 cm on a side. The volume per cube is then (very roughly)  $30 \text{ cm}^3$ . This much liquid water has a mass of 30 g. From Table 20.2 we find that the latent heat of fusion of ice is  $3.33 \times 10^5 \text{ J/kg}$ . Substituting these values into our answer for part (a), we find that

$$\Delta S = \frac{mL_f}{T_m} = \frac{(0.03 \text{ kg})(3.33 \times 10^5 \text{ J/kg})}{273 \text{ K}} = 4 \times 10^1 \text{ J/K}$$

We retain only one significant figure, in keeping with the nature of our estimations.

## 22.7 ENTROPY CHANGES IN IRREVERSIBLE PROCESSES

By definition, calculation of the change in entropy requires information about a reversible path connecting the initial and final equilibrium states. To calculate changes in entropy for real (irreversible) processes, we must remember that entropy (like internal energy) depends only on the *state* of the system. That is, entropy is a state function. Hence, the change in entropy when a system moves between any two equilibrium states depends only on the initial and final states. We can show that if this were not the case, the second law of thermodynamics would be violated.

We now calculate the entropy change in some irreversible process between two equilibrium states by devising a reversible process (or series of reversible processes) between the same two states and computing  $\Delta S = \int dQ_r/T$  for the reversible process. In irreversible processes, it is critically important that we distinguish between  $Q$ , the actual energy transfer in the process, and  $Q_r$ , the energy that would have been transferred by heat along a reversible path. Only  $Q_r$  is the correct value to be used in calculating the entropy change.

As we shall see in the following examples, the change in entropy for a system and its surroundings is always positive for an irreversible process. In general, the total entropy—and therefore the disorder—always increase in an irreversible process. Keeping these considerations in mind, we can state the second law of thermodynamics as follows:

The total entropy of an isolated system that undergoes a change can never decrease.

Furthermore, **if the process is irreversible, then the total entropy of an isolated system always increases. In a reversible process, the total entropy of an isolated system remains constant.**

When dealing with a system that is not isolated from its surroundings, remember that the increase in entropy described in the second law is that of the system *and* its surroundings. When a system and its surroundings interact in an irreversible process, the increase in entropy of one is greater than the decrease in entropy of the other. Hence, we conclude that **the change in entropy of the Universe must be greater than zero for an irreversible process and equal to zero for a reversible process.** Ultimately, the entropy of the Universe should reach a maximum value. At this value, the Universe will be in a state of uniform temperature and density. All physical, chemical, and biological processes will cease because a state of perfect disorder implies that no energy is available for doing work. This gloomy state of affairs is sometimes referred to as the heat death of the Universe.

**Quick Quiz 22.3**

In the presence of sunlight, a tree rearranges an unorganized collection of carbon dioxide and water molecules into the highly ordered collection of molecules we see as leaves and branches. True or false: This reduction of entropy in the tree is a violation of the second law of thermodynamics. Explain your response.

**Entropy Change in Thermal Conduction**

Let us now consider a system consisting of a hot reservoir and a cold reservoir in thermal contact with each other and isolated from the rest of the Universe. A process occurs during which energy  $Q$  is transferred by heat from the hot reservoir at temperature  $T_h$  to the cold reservoir at temperature  $T_c$ . Because the cold reservoir absorbs energy  $Q$ , its entropy increases by  $Q/T_c$ . At the same time, the hot reservoir loses energy  $Q$ , and so its entropy change is  $-Q/T_h$ . Because  $T_h > T_c$ , the increase in entropy of the cold reservoir is greater than the decrease in entropy of the hot reservoir. Therefore, the change in entropy of the system (and of the Universe) is greater than zero:

$$\Delta S_U = \frac{Q}{T_c} + \frac{-Q}{T_h} > 0$$

**EXAMPLE 22.7** Which Way Does the Energy Flow?

A large, cold object is at 273 K, and a large, hot object is at 373 K. Show that it is impossible for a small amount of energy—for example, 8.00 J—to be transferred spontaneously from the cold object to the hot one without a decrease in the entropy of the Universe and therefore a violation of the second law.

**Solution** We assume that, during the energy transfer, the two objects do not undergo a temperature change. This is not a necessary assumption; we make it only to avoid using integral calculus in our calculations. The process as described is irreversible, and so we must find an equivalent reversible process. It is sufficient to assume that the objects are connected by a poor thermal conductor whose temperature spans the range from 273 K to 373 K. This conductor transfers energy slowly, and its state does not change during the process. Under this assumption, the energy transfer to or from each object is reversible, and we may set  $Q = Q_r$ . The entropy change of the hot object is

$$\Delta S_h = \frac{Q_r}{T_h} = \frac{8.00 \text{ J}}{373 \text{ K}} = 0.0214 \text{ J/K}$$

The cold object loses energy, and its entropy change is

$$\Delta S_c = \frac{Q_r}{T_c} = \frac{-8.00 \text{ J}}{273 \text{ K}} = -0.0293 \text{ J/K}$$

We consider the two objects to be isolated from the rest of the Universe. Thus, the entropy change of the Universe is just

that of our two-object system, which is

$$\Delta S_U = \Delta S_c + \Delta S_h = -0.0079 \text{ J/K}$$

This decrease in entropy of the Universe is in violation of the second law. That is, **the spontaneous transfer of energy from a cold to a hot object cannot occur.**

In terms of disorder, let us consider the violation of the second law if energy were to continue to transfer spontaneously from a cold object to a hot object. Before the transfer, a certain degree of order is associated with the different temperatures of the objects. The hot object's molecules have a higher average energy than the cold object's molecules. If energy spontaneously flows from the cold object to the hot object, then, over a period of time, the cold object will become colder and the hot object will become hotter. The difference in average molecular energy will become even greater; this would represent an increase in order for the system and a violation of the second law.

In comparison, the process that does occur naturally is the flow of energy from the hot object to the cold object. In this process, the difference in average molecular energy decreases; this represents a more random distribution of energy and an increase in disorder.

**Exercise** Suppose that 8.00 J of energy is transferred from a hot object to a cold one. What is the net entropy change of the Universe?

**Answer** +0.0079 J/K.

## Entropy Change in a Free Expansion

Let us again consider the adiabatic free expansion of a gas occupying an initial volume  $V_i$  (Fig. 22.16). A membrane separating the gas from an evacuated region is broken, and the gas expands (irreversibly) to a volume  $V_f$ . Let us find the changes in entropy of the gas and of the Universe during this process.

The process is clearly neither reversible nor quasi-static. The work done by the gas against the vacuum is zero, and because the walls are insulating, no energy is transferred by heat during the expansion. That is,  $W = 0$  and  $Q = 0$ . Using the first law, we see that the change in internal energy is zero. Because the gas is ideal,  $E_{\text{int}}$  depends on temperature only, and we conclude that  $\Delta T = 0$  or  $T_i = T_f$ .

To apply Equation 22.9, we cannot use  $Q = 0$ , the value for the irreversible process, but must instead find  $Q_r$ ; that is, we must find an equivalent reversible process that shares the same initial and final states. A simple choice is an isothermal, reversible expansion in which the gas pushes slowly against a piston while energy enters the gas by heat from a reservoir to hold the temperature constant. Because  $T$  is constant in this process, Equation 22.9 gives

$$\Delta S = \int_i^f \frac{dQ_r}{T} = \frac{1}{T} \int_i^f dQ_r$$

For an isothermal process, the first law of thermodynamics specifies that  $\int_i^f dQ_r$  is equal to the work done by the gas during the expansion from  $V_i$  to  $V_f$ , which is given by Equation 20.13. Using this result, we find that the entropy change for the gas is

$$\Delta S = nR \ln \frac{V_f}{V_i} \quad (22.13)$$

Because  $V_f > V_i$ , we conclude that  $\Delta S$  is positive. This positive result indicates that both the entropy and the disorder of the gas increase as a result of the irreversible, adiabatic expansion.

Because the free expansion takes place in an insulated container, no energy is transferred by heat from the surroundings. (Remember that the isothermal, reversible expansion is only a *replacement* process that we use to calculate the entropy change for the gas; it is not the *actual* process.) Thus, the free expansion has no effect on the surroundings, and the entropy change of the surroundings is zero. Thus, the entropy change for the Universe is positive; this is consistent with the second law.

**Figure 22.16** Adiabatic free expansion of a gas. When the membrane separating the gas from the evacuated region is ruptured, the gas expands freely and irreversibly. As a result, it occupies a greater final volume. The container is thermally insulated from its surroundings; thus,  $Q = 0$ .

### EXAMPLE 22.8 Free Expansion of a Gas

Calculate the change in entropy for a process in which 2.00 mol of an ideal gas undergoes a free expansion to three times its initial volume.

**Solution** Using Equation 22.13 with  $n = 2.00$  mol and  $V_f = 3V_i$ , we find that

$$\Delta S = nR \ln \frac{V_f}{V_i} = (2.00 \text{ mol})(8.31 \text{ J/mol} \cdot \text{K})(\ln 3)$$

$$= 18.3 \text{ J/K}$$

It is easy to see that the gas is more disordered after the expansion. Instead of being concentrated in a relatively small space, the molecules are scattered over a larger region.

## Entropy Change in Calorimetric Processes

A substance of mass  $m_1$ , specific heat  $c_1$ , and initial temperature  $T_1$  is placed in thermal contact with a second substance of mass  $m_2$ , specific heat  $c_2$ , and initial

temperature  $T_2 > T_1$ . The two substances are contained in a calorimeter so that no energy is lost to the surroundings. The system of the two substances is allowed to reach thermal equilibrium. What is the total entropy change for the system?

First, let us calculate the final equilibrium temperature  $T_f$ . Using the techniques of Section 20.2—namely, Equation 20.5,  $Q_{\text{cold}} = -Q_{\text{hot}}$ , and Equation 20.4,  $Q = mc\Delta T$ , we obtain

$$\begin{aligned} m_1c_1\Delta T_1 &= -m_2c_2\Delta T_2 \\ m_1c_1(T_f - T_1) &= -m_2c_2(T_f - T_2) \end{aligned}$$

Solving for  $T_f$ , we have

$$T_f = \frac{m_1c_1T_1 + m_2c_2T_2}{m_1c_1 + m_2c_2} \quad (22.14)$$

The process is irreversible because the system goes through a series of non-equilibrium states. During such a transformation, the temperature of the system at any time is not well defined because different parts of the system have different temperatures. However, we can imagine that the hot substance at the initial temperature  $T_2$  is slowly cooled to the temperature  $T_f$  as it comes into contact with a series of reservoirs differing infinitesimally in temperature, the first reservoir being at  $T_2$  and the last being at  $T_f$ . Such a series of very small changes in temperature would approximate a reversible process. We imagine doing the same thing for the cold substance. Applying Equation 22.9 and noting that  $dQ = mc\,dT$  for an infinitesimal change, we have

$$\Delta S = \int_1 \frac{dQ_{\text{cold}}}{T} + \int_2 \frac{dQ_{\text{hot}}}{T} = m_1c_1 \int_{T_1}^{T_f} \frac{dT}{T} + m_2c_2 \int_{T_2}^{T_f} \frac{dT}{T}$$

where we have assumed that the specific heats remain constant. Integrating, we find that

$$\Delta S = m_1c_1 \ln \frac{T_f}{T_1} + m_2c_2 \ln \frac{T_f}{T_2} \quad (22.15)$$

where  $T_f$  is given by Equation 22.14. If Equation 22.14 is substituted into Equation 22.15, we can show that one of the terms in Equation 22.15 is always positive and the other is always negative. (You may want to verify this for yourself.) The positive term is always greater than the negative term, and this results in a positive value for  $\Delta S$ . Thus, we conclude that the entropy of the Universe increases in this irreversible process.

Finally, you should note that Equation 22.15 is valid only when no mixing of different substances occurs, because a further entropy increase is associated with the increase in disorder during the mixing. If the substances are liquids or gases and mixing occurs, the result applies only if the two fluids are identical, as in the following example.

Change in entropy for a calorimetric process

### EXAMPLE 22.9 Calculating $\Delta S$ for a Calorimetric Process

Suppose that 1.00 kg of water at 0.00°C is mixed with an equal mass of water at 100°C. After equilibrium is reached, the mixture has a uniform temperature of 50.0°C. What is the change in entropy of the system?

**Solution** We can calculate the change in entropy from Equation 22.15 using the values  $m_1 = m_2 = 1.00$  kg,  $c_1 = c_2 = 4186$  J/kg·K,  $T_1 = 273$  K,  $T_2 = 373$  K, and  $T_f = 323$  K:

$$\begin{aligned}\Delta S &= m_1 c_1 \ln \frac{T_f}{T_1} + m_2 c_2 \ln \frac{T_f}{T_2} &= 704 \text{ J/K} - 602 \text{ J/K} &= 102 \text{ J/K} \\ &= (1.00 \text{ kg})(4186 \text{ J/kg}\cdot\text{K}) \ln \left( \frac{323 \text{ K}}{273 \text{ K}} \right) && \text{That is, as a result of this irreversible process, the increase in} \\ &+ (1.00 \text{ kg})(4186 \text{ J/kg}\cdot\text{K}) \ln \left( \frac{323 \text{ K}}{373 \text{ K}} \right) && \text{entropy of the cold water is greater than the decrease in en-} \\ &&& \text{tropy of the warm water. Consequently, the increase in en-} \\ &&& \text{tropy of the system is } 102 \text{ J/K.}\end{aligned}$$

### Optional Section

## 22.8 ENTROPY ON A MICROSCOPIC SCALE<sup>4</sup>

As we have seen, we can approach entropy by relying on macroscopic concepts and using parameters such as pressure and temperature. We can also treat entropy from a microscopic viewpoint through statistical analysis of molecular motions. We now use a microscopic model to investigate once again the free expansion of an ideal gas, which was discussed from a macroscopic point of view in the preceding section.

In the kinetic theory of gases, gas molecules are represented as particles moving randomly. Let us suppose that the gas is initially confined to a volume  $V_i$ , as shown in Figure 22.17a. When the partition separating  $V_i$  from a larger container is removed, the molecules eventually are distributed throughout the greater volume  $V_f$  (Fig. 22.17b). For a given uniform distribution of gas in the volume, there are a large number of equivalent microstates, and we can relate the entropy of the gas to the number of microstates corresponding to a given macrostate.

We count the number of microstates by considering the variety of molecular locations involved in the free expansion. The instant after the partition is removed (and before the molecules have had a chance to rush into the other half of the container), all the molecules are in the initial volume. We assume that each molecule occupies some microscopic volume  $V_m$ . The total number of possible locations of a single molecule in a macroscopic initial volume  $V_i$  is the ratio  $w_i = V_i/V_m$ , which is a huge number. We use  $w_i$  here to represent the number of ways that the molecule can be placed in the volume, or the number of microstates, which is equivalent to the number of available locations. We assume that the molecule's occupying each of these locations is equally probable.

As more molecules are added to the system, the number of possible ways that the molecules can be positioned in the volume multiplies. For example, in considering two molecules, for every possible placement of the first, all possible placements of the second are available. Thus, there are  $w_1$  ways of locating the first molecule, and for each of these, there are  $w_2$  ways of locating the second molecule. The total number of ways of locating the two molecules is  $w_1 w_2$ .

Neglecting the very small probability of having two molecules occupy the same location, each molecule may go into any of the  $V_i/V_m$  locations, and so the number of ways of locating  $N$  molecules in the volume becomes  $W_i = w_i^N = (V_i/V_m)^N$ . ( $W_i$  is not to be confused with work.) Similarly, when the volume is increased to  $V_f$ , the number of ways of locating  $N$  molecules increases to  $W_f = w_f^N = (V_f/V_m)^N$ . The ratio of the number of ways of placing the molecules in the volume for the

**Figure 22.17** In a free expansion, the gas is allowed to expand into a region that was previously a vacuum.

<sup>4</sup> This section was adapted from A. Hudson and R. Nelson, *University Physics*, Philadelphia, Saunders College Publishing, 1990.

initial and final configurations is

$$\frac{W_f}{W_i} = \frac{(V_f/V_m)^N}{(V_i/V_m)^N} = \left(\frac{V_f}{V_i}\right)^N$$

If we now take the natural logarithm of this equation and multiply by Boltzmann's constant, we find that

$$k_B \ln\left(\frac{W_f}{W_i}\right) = nN_A k_B \ln\left(\frac{V_f}{V_i}\right)$$

where we have used the equality  $N = nN_A$ . We know from Equation 19.11 that  $N_A k_B$  is the universal gas constant  $R$ ; thus, we can write this equation as

$$k_B \ln W_f - k_B \ln W_i = nR \ln\left(\frac{V_f}{V_i}\right) \quad (22.16)$$

From Equation 22.13 we know that when  $n$  mol of a gas undergoes a free expansion from  $V_i$  to  $V_f$ , the change in entropy is

$$S_f - S_i = nR \ln\left(\frac{V_f}{V_i}\right) \quad (22.17)$$

Note that the right-hand sides of Equations 22.16 and 22.17 are identical. Thus, we make the following important connection between entropy and the number of microstates for a given macrostate:

$$S \equiv k_B \ln W \quad (22.18)$$

Entropy (microscopic definition)

The more microstates there are that correspond to a given macrostate, the greater is the entropy of that macrostate. As we have discussed previously, there are many more disordered microstates than ordered microstates. Thus, Equation 22.18 indicates mathematically that **entropy is a measure of microscopic disorder**. Although in our discussion we used the specific example of the free expansion of an ideal gas, a more rigorous development of the statistical interpretation of entropy would lead us to the same conclusion.

Imagine the container of gas depicted in Figure 22.18a as having all of its molecules traveling at speeds greater than the mean value on the left side and all of its molecules traveling at speeds less than the mean value on the right side (an ordered microstate). Compare this with the uniform mixture of fast- and slow-mov-

**Figure 22.18** A container of gas in two equally probable states of molecular motion. (a) An ordered arrangement, which is one of a few and therefore a collectively unlikely set. (b) A disordered arrangement, which is one of many and therefore a collectively likely set.

**Figure 22.19** By tossing a coin into a jar, the carnival-goer can win the fish in the jar. It is more likely that the coin will land in a jar containing a goldfish than in the one containing the black fish.

ing molecules in Figure 22.18b (a disordered microstate). You might expect the ordered microstate to be very unlikely because random motions tend to mix the slow- and fast-moving molecules uniformly. Yet *individually* each of these microstates is equally probable. However, there are far more disordered microstates than ordered microstates, and so a macrostate corresponding to a large number of equivalent disordered microstates is much more probable than a macrostate corresponding to a small number of equivalent ordered microstates.

Figure 22.19 shows a real-world example of this concept. There are two possible macrostates for the carnival game—winning a goldfish and winning a black fish. Because only one jar in the array of jars contains a black fish, only one possible microstate corresponds to the macrostate of winning a black fish. A large number of microstates are described by the coin's falling into a jar containing a goldfish. Thus, for the macrostate of winning a goldfish, there are many equivalent microstates. As a result, the probability of winning a goldfish is much greater than the probability of winning a black fish. If there are 24 goldfish and 1 black fish, the probability of winning the black fish is 1 in 25. This assumes that all microstates have the same probability, a situation that may not be quite true for the situation shown in Figure 22.19. If you are an accurate coin tosser and you are aiming for the edge of the array of jars, then the probability of the coin's landing in a jar near the edge is likely to be greater than the probability of its landing in a jar near the center.

Let us consider a similar type of probability problem for 100 molecules in a container. At any given moment, the probability of one molecule's being in the left part of the container shown in Figure 22.20a as a result of random motion is  $\frac{1}{2}$ . If there are two molecules, as shown in Figure 22.20b, the probability of both being in the left part is  $(\frac{1}{2})^2$  or 1 in 4. If there are three molecules (Fig. 22.20c), the probability of all of them being in the left portion at the same moment is  $(\frac{1}{2})^3$ , or 1 in 8. For 100 independently moving molecules, the probability that the 50 fastest ones will be found in the left part at any moment is  $(\frac{1}{2})^{50}$ . Likewise, the probability that the remaining 50 slower molecules will be found in the right part at any moment is  $(\frac{1}{2})^{50}$ . Therefore, the probability of finding this fast-slow separation as a result of random motion is the product  $(\frac{1}{2})^{50}(\frac{1}{2})^{50} = (\frac{1}{2})^{100}$ , which corresponds to about 1 in  $10^{30}$ . When this calculation is extrapolated from 100 molecules to the number in 1 mol of gas ( $6.02 \times 10^{23}$ ), the ordered arrangement is found to be *extremely* improbable!

### QuickLab

Roll a pair of dice 100 times and record the total number of spots appearing on the dice for each throw. Which total comes up most frequently? Is this expected?

**Figure 22.20** (a) One molecule in a two-sided container has a 1-in-2 chance of being on the left side. (b) Two molecules have a 1-in-4 chance of being on the left side at the same time. (c) Three molecules have a 1-in-8 chance of being on the left side at the same time.

### EXAMPLE 22.10 Adiabatic Free Expansion—One Last Time

Let us verify that the macroscopic and microscopic approaches to the calculation of entropy lead to the same conclusion for the adiabatic free expansion of an ideal gas. Suppose that 1 mol of gas expands to four times its initial volume. As we have seen for this process, the initial and final temperatures are the same. (a) Using a macroscopic approach, calculate the entropy change for the gas. (b) Using statistical considerations, calculate the change in entropy for the gas and show that it agrees with the answer you obtained in part (a).

**Solution** (a) Using Equation 22.13, we have

$$\Delta S = nR \ln \left( \frac{V_f}{V_i} \right) = (1)R \ln \left( \frac{4V_i}{V_i} \right) = R \ln 4$$

(b) The number of microstates available to a single molecule in the initial volume  $V_i$  is  $w_i = V_i/V_m$ . For 1 mol ( $N_A$  molecules), the number of available microstates is

$$W_i = w_i^{N_A} = \left( \frac{V_i}{V_m} \right)^{N_A}$$

The number of microstates for all  $N_A$  molecules in the final volume  $V_f = 4V_i$  is

$$W_f = \left( \frac{V_f}{V_m} \right)^{N_A} = \left( \frac{4V_i}{V_m} \right)^{N_A}$$

Thus, the ratio of the number of final microstates to initial microstates is

$$\frac{W_f}{W_i} = 4^{N_A}$$

Using Equation 22.18, we obtain

$$\begin{aligned} \Delta S &= k_B \ln W_f - k_B \ln W_i = k_B \ln \left( \frac{W_f}{W_i} \right) \\ &= k_B \ln (4^{N_A}) = N_A k_B \ln 4 = R \ln 4 \end{aligned}$$

The answer is the same as that for part (a), which dealt with macroscopic parameters.

### CONCEPTUAL EXAMPLE 22.11 Let's Play Marbles!

Suppose you have a bag of 100 marbles. Fifty of the marbles are red, and 50 are green. You are allowed to draw four marbles from the bag according to the following rules: Draw one marble, record its color, and return it to the bag. Then draw another marble. Continue this process until you have drawn and returned four marbles. What are the possible

macrostates for this set of events? What is the most likely macrostate? What is the least likely macrostate?

**Solution** Because each marble is returned to the bag before the next one is drawn, the probability of drawing a red marble is always the same as the probability of drawing a

green one. All the possible microstates and macrostates are shown in Table 22.1. As this table indicates, there is only one way to draw four red marbles, and so there is only one microstate. However, there are four possible microstates that correspond to the macrostate of one green marble and three red marbles; six microstates that correspond to two green marbles and two red marbles; four microstates that corre-

spond to three green marbles and one red marble; and one microstate that corresponds to four green marbles. The most likely macrostate—two red marbles and two green marbles—corresponds to the most disordered microstates. The least likely macrostates—four red marbles or four green marbles—correspond to the most ordered microstates.

**TABLE 22.1** Possible Results of Drawing Four Marbles from a Bag

All G	GGGG	1

## SUMMARY

A **heat engine** is a device that converts internal energy to other useful forms of energy. The net work done by a heat engine in carrying a working substance through a cyclic process ( $\Delta E_{\text{int}} = 0$ ) is

$$W = Q_h - Q_c \quad (22.1)$$

where  $Q_h$  is the energy absorbed from a hot reservoir and  $Q_c$  is the energy expelled to a cold reservoir.

The **thermal efficiency**  $e$  of a heat engine is

$$e = \frac{W}{Q_h} = 1 - \frac{Q_c}{Q_h} \quad (22.2)$$

The **second law of thermodynamics** can be stated in the following two ways:

- It is impossible to construct a heat engine that, operating in a cycle, produces no effect other than the absorption of energy from a reservoir and the performance of an equal amount of work (the Kelvin–Planck statement).
- It is impossible to construct a cyclic machine whose sole effect is the continuous transfer of energy from one object to another object at a higher temperature without the input of energy by work (the Clausius statement).

In a **reversible** process, the system can be returned to its initial conditions along the same path shown on a  $PV$  diagram, and every point along this path is an equilibrium state. A process that does not satisfy these requirements is **irreversible**. **Carnot's theorem** states that no real heat engine operating (irreversibly) between the temperatures  $T_c$  and  $T_h$  can be more efficient than an engine operating reversibly in a Carnot cycle between the same two temperatures.

The **thermal efficiency** of a heat engine operating in the Carnot cycle is

$$e_C = 1 - \frac{T_c}{T_h} \quad (22.4)$$

You should be able to use this equation (or an equivalent form involving a ratio of heats) to determine the maximum possible efficiency of any heat engine.

The second law of thermodynamics states that when real (irreversible) processes occur, the degree of disorder in the system plus the surroundings increases. When a process occurs in an isolated system, the state of the system becomes more disordered. The measure of disorder in a system is called **entropy**  $S$ . Thus, another way in which the second law can be stated is

- The entropy of the Universe increases in all real processes.

The **change in entropy**  $dS$  of a system during a process between two infinitesimally separated equilibrium states is

$$dS = \frac{dQ_r}{T} \quad (22.8)$$

where  $dQ_r$  is the energy transfer by heat for a reversible process that connects the initial and final states. The change in entropy of a system during an arbitrary process between an initial state and a final state is

$$\Delta S = \int_i^f \frac{dQ_r}{T} \quad (22.9)$$

The value of  $\Delta S$  for the system is the same for all paths connecting the initial and final states. The change in entropy for a system undergoing any reversible, cyclic process is zero, and when such a process occurs, the entropy of the Universe remains constant.

From a microscopic viewpoint, entropy is defined as

$$S \equiv k_B \ln W \quad (22.18)$$

where  $k_B$  is Boltzmann's constant and  $W$  is the number of microstates available to the system for the existing macrostate. Because of the statistical tendency of systems to proceed toward states of greater probability and greater disorder, all natural processes are irreversible, and entropy increases. Thus, entropy is a measure of microscopic disorder.

## QUESTIONS

1. Is it possible to convert internal energy to mechanical energy? Describe a process in which such a conversion occurs.
2. What are some factors that affect the efficiency of automobile engines?
3. In practical heat engines, which are we able to control more: the temperature of the hot reservoir, or the temperature of the cold reservoir? Explain.
4. A steam-driven turbine is one major component of an electric power plant. Why is it advantageous to have the temperature of the steam as high as possible?
5. Is it possible to construct a heat engine that creates no thermal pollution? What does this tell us about environmental considerations for an industrialized society?
6. Discuss three common examples of natural processes that involve an increase in entropy. Be sure to account for all parts of each system under consideration.
7. Discuss the change in entropy of a gas that expands (a) at constant temperature and (b) adiabatically.
8. In solar ponds constructed in Israel, the Sun's energy is concentrated near the bottom of a salty pond. With the proper layering of salt in the water, convection is prevented, and temperatures of  $100^\circ\text{C}$  may be reached. Can you estimate the maximum efficiency with which useful energy can be extracted from the pond?
9. The vortex tube (Fig. Q22.9) is a T-shaped device that takes in compressed air at 20 atm and  $20^\circ\text{C}$  and gives off air at  $-20^\circ\text{C}$  from one flared end and air at  $60^\circ\text{C}$  from the other flared end. Does the operation of this device vi-

Figure Q22.9

olate the second law of thermodynamics? If not, explain why not.

10. Why does your automobile burn more gas in winter than in summer?
11. Can a heat pump have a coefficient of performance (COP) less than unity? Explain.
12. Give some examples of irreversible processes that occur in nature.
13. Give an example of a process in nature that is nearly reversible.
14. A thermodynamic process occurs in which the entropy of a system changes by  $-8.0 \text{ J/K}$ . According to the second law of thermodynamics, what can you conclude about the entropy change of the environment?
15. If a supersaturated sugar solution is allowed to evaporate slowly, sugar crystals form in the container. Hence, sugar molecules go from a disordered form (in solution) to a highly ordered crystalline form. Does this process violate the second law of thermodynamics? Explain.

16. How could you increase the entropy of 1 mol of a metal that is at room temperature? How could you decrease its entropy?
17. A heat pump is to be installed in a region where the average outdoor temperature in the winter months is  $-20^\circ\text{C}$ . In view of this, why would it be advisable to place the outdoor compressor unit deep in the ground? Why are heat pumps not commonly used for heating in cold climates?
18. Suppose your roommate is “Mr. Clean” and tidies up your messy room after a big party. That is, your roommate is increasing order in the room. Does this represent a violation of the second law of thermodynamics?
19. Discuss the entropy changes that occur when you (a) bake a loaf of bread and (b) consume the bread.
20. The device shown in Figure Q22.20, which is called a thermoelectric converter, uses a series of semiconductor cells to convert internal energy to electrical energy. In the photograph on the left, both legs of the device are at the same temperature and no electrical energy is produced. However, when one leg is at a higher temperature than the other, as shown in the photograph on the right, electrical energy is produced as the device extracts energy from the hot reservoir and drives a small electric motor. (a) Why does the temperature differential produce electrical energy in this demonstration? (b) In what sense does this intriguing experiment demonstrate the second law of thermodynamics?
21. A classmate tells you that it is just as likely for all the air molecules in the room you are both in to be concentrated in one corner (with the rest of the room being a vacuum) as it is for the air molecules to be distributed uniformly about the room in their current state. Is this true? Why doesn't the situation he describes actually happen?

### Section 22.1 Heat Engines and the Second Law of Thermodynamics

#### Section 22.2 Reversible and Irreversible Processes

- A heat engine absorbs 360 J of energy and performs 25.0 J of work in each cycle. Find (a) the efficiency of the engine and (b) the energy expelled to the cold reservoir in each cycle.
- The energy absorbed by an engine is three times greater than the work it performs. (a) What is its thermal efficiency? (b) What fraction of the energy absorbed is expelled to the cold reservoir?
-  A particular engine has a power output of 5.00 kW and an efficiency of 25.0%. Assuming that the engine expels 8 000 J of energy in each cycle, find (a) the energy absorbed in each cycle and (b) the time for each cycle.
- A heat engine performs 200 J of work in each cycle and has an efficiency of 30.0%. For each cycle, how much energy is (a) absorbed and (b) expelled?
- An ideal gas is compressed to half its original volume while its temperature is held constant. (a) If 1 000 J of energy is removed from the gas during the compression, how much work is done on the gas? (b) What is the change in the internal energy of the gas during the compression?
- Suppose that a heat engine is connected to two energy reservoirs, one a pool of molten aluminum (660°C) and the other a block of solid mercury (−38.9°C). The engine runs by freezing 1.00 g of aluminum and melting 15.0 g of mercury during each cycle. The heat of fusion of aluminum is  $3.97 \times 10^5$  J/kg; the heat of fusion of mercury is  $1.18 \times 10^4$  J/kg. What is the efficiency of this engine?

### Section 22.3 The Carnot Engine

-  One of the most efficient engines ever built (actual efficiency 42.0%) operates between 430°C and 1 870°C. (a) What is its maximum theoretical efficiency? (b) How much power does the engine deliver if it absorbs  $1.40 \times 10^5$  J of energy each second from the hot reservoir?
- A heat engine operating between 80.0°C and 200°C achieves 20.0% of the maximum possible efficiency. What energy input will enable the engine to perform 10.0 kJ of work?
- A Carnot engine has a power output of 150 kW. The engine operates between two reservoirs at 20.0°C and 500°C. (a) How much energy does it absorb per hour? (b) How much energy is lost per hour in its exhaust?
- A steam engine is operated in a cold climate where the exhaust temperature is 0°C. (a) Calculate the theoretical maximum efficiency of the engine, using an intake steam temperature of 100°C. (b) If superheated steam at 200°C were used instead, what would be the maximum possible efficiency?
-   An ideal gas is taken through a Carnot cycle. The isothermal expansion occurs at 250°C, and the isothermal compression takes place at 50.0°C. Assuming that the gas absorbs 1 200 J of energy from the hot reservoir during the isothermal expansion, find (a) the energy expelled to the cold reservoir in each cycle and (b) the net work done by the gas in each cycle.
- The exhaust temperature of a Carnot heat engine is 300°C. What is the intake temperature if the efficiency of the engine is 30.0%?
- A power plant operates at 32.0% efficiency during the summer when the sea water for cooling is at 20.0°C. The plant uses 350°C steam to drive turbines. Assuming that the plant's efficiency changes in the same proportion as the ideal efficiency, what would be the plant's efficiency in the winter, when the sea water is at 10.0°C?
- Argon enters a turbine at a rate of 80.0 kg/min, a temperature of 800°C, and a pressure of 1.50 MPa. It expands adiabatically as it pushes on the turbine blades and exits at a pressure of 300 kPa. (a) Calculate its temperature at the time of exit. (b) Calculate the (maximum) power output of the turning turbine. (c) The turbine is one component of a model closed-cycle gas turbine engine. Calculate the maximum efficiency of the engine.
- A power plant that would make use of the temperature gradient in the ocean has been proposed. The system is to operate between 5.00°C (water temperature at a depth of about 1 km) and 20.0°C (surface water temperature). (a) What is the maximum efficiency of such a system? (b) If the power output of the plant is 75.0 MW, how much energy is absorbed per hour? (c) In view of your answer to part (a), do you think such a system is worthwhile (considering that there is no charge for fuel)?
- A 20.0%-efficient real engine is used to speed up a train from rest to 5.00 m/s. It is known that an ideal (Carnot) engine having the same cold and hot reservoirs would accelerate the same train from rest to a speed of 6.50 m/s using the same amount of fuel. Assuming that the engines use air at 300 K as a cold reservoir, find the temperature of the steam serving as the hot reservoir.
- A firebox is at 750 K, and the ambient temperature is 300 K. The efficiency of a Carnot engine doing 150 J of work as it transports energy between these constant-temperature baths is 60.0%. The Carnot engine must absorb energy  $150 \text{ J} / 0.600 = 250 \text{ J}$  from the hot reser-

voir and release 100 J of energy into the environment. To follow Carnot's reasoning, suppose that some other heat engine S could have an efficiency of 70.0%.

(a) Find the energy input and energy output of engine S as it does 150 J of work. (b) Let engine S operate as in part (a) and run the Carnot engine in reverse. Find the total energy the firebox puts out as both engines operate together and the total energy absorbed by the environment. Show that the Clausius statement of the second law of thermodynamics is violated. (c) Find the energy input and work output of engine S as it exhausts 100 J of energy. (d) Let engine S operate as in (c) and contribute 150 J of its work output to running the Carnot engine in reverse. Find the total energy that the firebox puts out as both engines operate together, the total work output, and the total energy absorbed by the environment. Show that the Kelvin–Planck statement of the second law is violated. Thus, our assumption about the efficiency of engine S must be false. (e) Let the engines operate together through one cycle as in part (d). Find the change in entropy of the Universe. Show that the entropy statement of the second law is violated.

18. At point *A* in a Carnot cycle, 2.34 mol of a monatomic ideal gas has a pressure of 1 400 kPa, a volume of 10.0 L, and a temperature of 720 K. It expands isothermally to point *B*, and then expands adiabatically to point *C*, where its volume is 24.0 L. An isothermal compression brings it to point *D*, where its new volume is 15.0 L. An adiabatic process returns the gas to point *A*.
- (a) Determine all the unknown pressures, volumes, and temperatures as you fill in the following table:

	<i>P</i>	<i>V</i>	<i>T</i>
<i>A</i>	1 400 kPa	10.0 L	720 K
<i>B</i>			
<i>C</i>		24.0 L	
<i>D</i>		15.0 L	

(b) Find the energy added by heat, the work done, and the change in internal energy for each of the following steps:  $A \rightarrow B$ ,  $B \rightarrow C$ ,  $C \rightarrow D$ , and  $D \rightarrow A$ . (c) Show that  $W_{\text{net}}/Q_{\text{in}} = 1 - T_C/T_A$ , the Carnot efficiency.

### Section 22.4 Gasoline and Diesel Engines

19. In a cylinder of an automobile engine just after combustion, the gas is confined to a volume of 50.0 cm<sup>3</sup> and has an initial pressure of  $3.00 \times 10^6$  Pa. The piston moves outward to a final volume of 300 cm<sup>3</sup>, and the gas expands without energy loss by heat. (a) If  $\gamma = 1.40$  for the gas, what is the final pressure? (b) How much work is done by the gas in expanding?
20. A gasoline engine has a compression ratio of 6.00 and uses a gas for which  $\gamma = 1.40$ . (a) What is the efficiency of the engine if it operates in an idealized Otto cycle?

(b) If the actual efficiency is 15.0%, what fraction of the fuel is wasted as a result of friction and energy losses by heat that could be avoided in a reversible engine? (Assume complete combustion of the air–fuel mixture.)

21. A 1.60-L gasoline engine with a compression ratio of 6.20 has a power output of 102 hp. Assuming that the engine operates in an idealized Otto cycle, find the energy absorbed and exhausted each second. Assume that the fuel–air mixture behaves like an ideal gas, with  $\gamma = 1.40$ .
22. The compression ratio of an Otto cycle, as shown in Figure 22.12, is  $V_A/V_B = 8.00$ . At the beginning *A* of the compression process, 500 cm<sup>3</sup> of gas is at 100 kPa and 20.0°C. At the beginning of the adiabatic expansion, the temperature is  $T_C = 750^\circ\text{C}$ . Model the working fluid as an ideal gas, with  $E_{\text{int}} = nC_V T = 2.50nRT$  and  $\gamma = 1.40$ . (a) Fill in the following table to track the states of the gas:

	<i>T</i> (K)	<i>P</i> (kPa)	<i>V</i> (cm <sup>3</sup> )	<i>E</i> <sub>int</sub>
<i>A</i>	293	100	500	
<i>B</i>				
<i>C</i>	1 023			
<i>D</i>				
<i>A</i>				

(b) Fill in the following table to track the processes:

	<i>Q</i>	<i>W</i>	$\Delta E_{\text{int}}$
$A \rightarrow B$			
$B \rightarrow C$			
$C \rightarrow D$			
$D \rightarrow A$			
<i>ABCD</i> <i>A</i>			

(c) Identify the energy input  $Q_h$ , the energy exhaust  $Q_c$ , and the net output work  $W$ . (d) Calculate the thermal efficiency. (e) Find the number of revolutions per minute that the crankshaft must complete for a one-cylinder engine to have an output power of 1.00 kW = 1.34 hp. (*Hint:* The thermodynamic cycle involves four piston strokes.)

### Section 22.5 Heat Pumps and Refrigerators

23. What is the coefficient of performance of a refrigerator that operates with Carnot efficiency between the temperatures  $-3.00^\circ\text{C}$  and  $+27.0^\circ\text{C}$ ?
24. What is the maximum possible coefficient of performance of a heat pump that brings energy from outdoors at  $-3.00^\circ\text{C}$  into a  $22.0^\circ\text{C}$  house? (*Hint:* The heat pump does work  $W$ , which is also available to warm up the house.)

25. An ideal refrigerator or ideal heat pump is equivalent to a Carnot engine running in reverse. That is, energy  $Q_c$  is absorbed from a cold reservoir, and energy  $Q_h$  is rejected to a hot reservoir. (a) Show that the work that must be supplied to run the refrigerator or heat pump is

$$W = \frac{T_h - T_c}{T_c} Q_c$$

(b) Show that the coefficient of performance (COP) of the ideal refrigerator is

$$\text{COP} = \frac{T_c}{T_h - T_c}$$

26. A heat pump (Fig. P22.26) is essentially a heat engine run backward. It extracts energy from colder air outside and deposits it in a warmer room. Suppose that the ratio of the actual energy entering the room to the work done by the device's motor is 10.0% of the theoretical maximum ratio. Determine the energy entering the room per joule of work done by the motor when the inside temperature is  $20.0^\circ\text{C}$  and the outside temperature is  $-5.00^\circ\text{C}$ .

Figure P22.26

- WEB 27. How much work does an ideal Carnot refrigerator require to remove 1.00 J of energy from helium at 4.00 K and reject this energy to a room-temperature ( $293\text{-K}$ ) environment?
28. How much work does an ideal Carnot refrigerator require to remove energy  $Q$  from helium at  $T_c$  and reject this energy to a room-temperature environment at  $T_h$ ?
29. A refrigerator has a coefficient of performance equal to 5.00. Assuming that the refrigerator absorbs 120 J of energy from a cold reservoir in each cycle, find (a) the work required in each cycle and (b) the energy expelled to the hot reservoir.
30. A refrigerator maintains a temperature of  $0^\circ\text{C}$  in the cold compartment with a room temperature of  $25.0^\circ\text{C}$ . It removes energy from the cold compartment at the rate  $8\,000\text{ kJ/h}$ . (a) What minimum power is required

to operate the refrigerator? (b) At what rate does the refrigerator exhaust energy into the room?

### Section 22.6 Entropy

31. An ice tray contains 500 g of water at  $0^\circ\text{C}$ . Calculate the change in entropy of the water as it freezes slowly and completely at  $0^\circ\text{C}$ .
32. At a pressure of 1 atm, liquid helium boils at 4.20 K. The latent heat of vaporization is 20.5 kJ/kg. Determine the entropy change (per kilogram) of the helium resulting from vaporization.
33. Calculate the change in entropy of 250 g of water heated slowly from  $20.0^\circ\text{C}$  to  $80.0^\circ\text{C}$ . (Hint: Note that  $dQ = mc\,dT$ .)
34. An airtight freezer holds 2.50 mol of air at  $25.0^\circ\text{C}$  and 1.00 atm. The air is then cooled to  $-18.0^\circ\text{C}$ . (a) What is the change in entropy of the air if the volume is held constant? (b) What would the change be if the pressure were maintained at 1 atm during the cooling?

### Section 22.7 Entropy Changes in Irreversible Processes

35. The temperature at the surface of the Sun is approximately 5 700 K, and the temperature at the surface of the Earth is approximately 290 K. What entropy change occurs when 1 000 J of energy is transferred by radiation from the Sun to the Earth?
36. A 1.00-kg iron horseshoe is taken from a furnace at  $900^\circ\text{C}$  and dropped into 4.00 kg of water at  $10.0^\circ\text{C}$ . Assuming that no energy is lost by heat to the surroundings, determine the total entropy change of the system (horseshoe and water).
- WEB 37. A 1 500-kg car is moving at 20.0 m/s. The driver brakes to a stop. The brakes cool off to the temperature of the surrounding air, which is nearly constant at  $20.0^\circ\text{C}$ . What is the total entropy change?
38. How fast are you personally making the entropy of the Universe increase right now? Make an order-of-magnitude estimate, stating what quantities you take as data and the values you measure or estimate for them.
39. One mole of  $\text{H}_2$  gas is contained in the left-hand side of the container shown in Figure P22.39, which has equal volumes left and right. The right-hand side is evacuated. When the valve is opened, the gas streams into the right-hand side. What is the final entropy change of the gas? Does the temperature of the gas change?

Figure P22.39

40. A rigid tank of small mass contains 40.0 g of argon, initially at  $200^\circ\text{C}$  and 100 kPa. The tank is placed into a reservoir at  $0^\circ\text{C}$  and is allowed to cool to thermal equi-

librium. Calculate (a) the volume of the tank, (b) the change in internal energy of the argon, (c) the energy transferred by heat, (d) the change in entropy of the argon, and (e) the change in entropy of the constant-temperature bath.

41. A 2.00-L container has a center partition that divides it into two equal parts, as shown in Figure P22.41. The left-hand side contains  $\text{H}_2$  gas, and the right-hand side contains  $\text{O}_2$  gas. Both gases are at room temperature and at atmospheric pressure. The partition is removed, and the gases are allowed to mix. What is the entropy increase of the system?

Figure P22.41

42. A 100 000-kg iceberg at  $-5.00^\circ\text{C}$  breaks away from the polar ice shelf and floats away into the ocean, at  $5.00^\circ\text{C}$ . What is the final change in the entropy of the system after the iceberg has completely melted? (The specific heat of ice is  $2100 \text{ J/kg} \cdot ^\circ\text{C}$ .)
43. One mole of an ideal monatomic gas, initially at a pressure of 1.00 atm and a volume of  $0.0250 \text{ m}^3$ , is heated to a final state with a pressure of 2.00 atm and a volume of  $0.0400 \text{ m}^3$ . Determine the change in entropy of the gas for this process.
44. One mole of a diatomic ideal gas, initially having pressure  $P$  and volume  $V$ , expands so as to have pressure  $2P$  and volume  $2V$ . Determine the entropy change of the gas in the process.

(Optional)

### Section 22.8 Entropy on a Microscopic Scale

45. If you toss two dice, what is the total number of ways in which you can obtain (a) a 12 and (b) a 7?
46. Prepare a table like Table 22.1 for the following occurrence. You toss four coins into the air simultaneously and then record the results of your tosses in terms of the numbers of heads and tails that result. For example, HHTH and HTHH are two possible ways in which three heads and one tail can be achieved. (a) On the basis of your table, what is the most probable result of a toss? In terms of entropy, (b) what is the most ordered state, and (c) what is the most disordered?
47. Repeat the procedure used to construct Table 22.1 (a) for the case in which you draw three marbles from your bag rather than four and (b) for the case in which you draw five rather than four.

### ADDITIONAL PROBLEMS

48. Every second at Niagara Falls, some  $5000 \text{ m}^3$  of water falls a distance of 50.0 m (Fig. P22.48). What is the increase in entropy per second due to the falling water? (Assume that the mass of the surroundings is so great that its temperature and that of the water stay nearly constant at  $20.0^\circ\text{C}$ . Suppose that a negligible amount of water evaporates.)

Figure P22.48 Niagara Falls. (Jan Kopec/Tony Stone Images)

49. If a 35.0%-efficient Carnot heat engine is run in reverse so that it functions as a refrigerator, what would be the engine's (that is, the refrigerator's) coefficient of performance (COP)?
50. How much work does an ideal Carnot refrigerator use to change 0.500 kg of tap water at  $10.0^\circ\text{C}$  into ice at  $-20.0^\circ\text{C}$ ? Assume that the freezer compartment is held at  $-20.0^\circ\text{C}$  and that the refrigerator exhausts energy into a room at  $20.0^\circ\text{C}$ .
- WEB 51. A house loses energy through the exterior walls and roof at a rate of  $5000 \text{ J/s} = 5.00 \text{ kW}$  when the interior temperature is  $22.0^\circ\text{C}$  and the outside temperature is  $-5.00^\circ\text{C}$ . Calculate the electric power required to maintain the interior temperature at  $22.0^\circ\text{C}$  for the following two cases: (a) The electric power is used in electric resistance heaters (which convert all of the electricity supplied into internal energy). (b) The electric power is used to drive an electric motor that operates the compressor of a heat pump (which has a coefficient of performance [COP] equal to 60.0% of the Carnot-cycle value).
52. A heat engine operates between two reservoirs at  $T_2 = 600 \text{ K}$  and  $T_1 = 350 \text{ K}$ . It absorbs  $1000 \text{ J}$  of energy from the higher-temperature reservoir and performs  $250 \text{ J}$  of work. Find (a) the entropy change of the Universe  $\Delta S_U$  for this process and (b) the work  $W$  that could have been done by an ideal Carnot engine operating between these two reservoirs. (c) Show that the difference between the work done in parts (a) and (b) is  $T_1 \Delta S_U$ .
- WEB 53. Figure P22.53 represents  $n$  mol of an ideal monatomic gas being taken through a cycle that consists of two isothermal processes at temperatures  $3T_i$  and  $T_i$  and two constant-volume processes. For each cycle, determine,

Figure P22.53

in terms of  $n$ ,  $R$ , and  $T_i$ , (a) the net energy transferred by heat to the gas and (b) the efficiency of an engine operating in this cycle.

54. A refrigerator has a coefficient of performance (COP) of 3.00. The ice tray compartment is at  $-20.0^\circ\text{C}$ , and the room temperature is  $22.0^\circ\text{C}$ . The refrigerator can convert 30.0 g of water at  $22.0^\circ\text{C}$  to 30.0 g of ice at  $-20.0^\circ\text{C}$  each minute. What input power is required? Give your answer in watts.
55. An ideal (Carnot) freezer in a kitchen has a constant temperature of 260 K, while the air in the kitchen has a constant temperature of 300 K. Suppose that the insulation for the freezer is not perfect, such that some energy flows into the freezer at a rate of 0.150 W. Determine the average power that the freezer's motor needs to maintain the constant temperature in the freezer.
56. An electric power plant has an overall efficiency of 15.0%. The plant is to deliver 150 MW of power to a city, and its turbines use coal as the fuel. The burning coal produces steam, which drives the turbines. The steam is then condensed to water at  $25.0^\circ\text{C}$  as it passes through cooling coils in contact with river water. (a) How many metric tons of coal does the plant consume each day (1 metric ton =  $10^3$  kg)? (b) What is the total cost of the fuel per year if the delivered price is  $\$8.00/\text{metric ton}$ ? (c) If the river water is delivered at  $20.0^\circ\text{C}$ , at what minimum rate must it flow over the cooling coils in order that its temperature not exceed  $25.0^\circ\text{C}$ ? (Note: The heat of combustion of coal is  $33.0$  kJ/g.)
57. A power plant, having a Carnot efficiency, produces 1 000 MW of electrical power from turbines that take in steam at 500 K and reject water at 300 K into a flowing river. Assuming that the water downstream is 6.00 K warmer due to the output of the power plant, determine the flow rate of the river.
58. A power plant, having a Carnot efficiency, produces electric power  $\mathcal{P}$  from turbines that take in energy from steam at temperature  $T_h$  and discharge energy at temperature  $T_c$  through a heat exchanger into a flowing river. Assuming that the water downstream is warmer by  $\Delta T$  due to the output of the power plant, determine the flow rate of the river.

59. An athlete whose mass is 70.0 kg drinks 16 oz (453.6 g) of refrigerated water. The water is at a temperature of  $35.0^\circ\text{F}$ . (a) Neglecting the temperature change of her body that results from the water intake (that is, the body is regarded as a reservoir that is always at  $98.6^\circ\text{F}$ ), find the entropy increase of the entire system. (b) Assume that the entire body is cooled by the drink and that the average specific heat of a human is equal to the specific heat of liquid water. Neglecting any other energy transfers by heat and any metabolic energy release, find the athlete's temperature after she drinks the cold water, given an initial body temperature of  $98.6^\circ\text{F}$ . Under these assumptions, what is the entropy increase of the entire system? Compare this result with the one you obtained in part (a).
60. One mole of an ideal monatomic gas is taken through the cycle shown in Figure P22.60. The process  $A \rightarrow B$  is a reversible isothermal expansion. Calculate (a) the net work done by the gas, (b) the energy added to the gas, (c) the energy expelled by the gas, and (d) the efficiency of the cycle.

Figure P22.60

61. Calculate the increase in entropy of the Universe when you add 20.0 g of  $5.00^\circ\text{C}$  cream to 200 g of  $60.0^\circ\text{C}$  coffee. Assume that the specific heats of cream and coffee are both  $4.20$  J/g  $\cdot$   $^\circ\text{C}$ .
62. In 1993 the federal government instituted a requirement that all room air conditioners sold in the United States must have an energy efficiency ratio (EER) of 10 or higher. The EER is defined as the ratio of the cooling capacity of the air conditioner, measured in Btu/h, to its electrical power requirement in watts. (a) Convert the EER of 10.0 to dimensionless form, using the conversion  $1$  Btu =  $1\,055$  J. (b) What is the appropriate name for this dimensionless quantity? (c) In the 1970s it was common to find room air conditioners with EERs of 5 or lower. Compare the operating costs for 10 000-Btu/h air conditioners with EERs of 5.00 and 10.0 if each air conditioner were to operate for 1 500 h during the summer in a city where electricity costs 10.0¢ per kilowatt-hour.

63. One mole of a monatomic ideal gas is taken through the cycle shown in Figure P22.63. At point A, the pressure, volume, and temperature are  $P_i$ ,  $V_i$ , and  $T_i$ , respectively. In terms of  $R$  and  $T_i$ , find (a) the total energy entering the system by heat per cycle, (b) the total energy leaving the system by heat per cycle, (c) the efficiency of an engine operating in this cycle, and (d) the efficiency of an engine operating in a Carnot cycle between the same temperature extremes.

Figure P22.63

64. One mole of an ideal gas expands isothermally. (a) If the gas doubles its volume, show that the work of expansion is  $W = RT \ln 2$ . (b) Because the internal energy  $E_{\text{int}}$  of an ideal gas depends solely on its temperature, no change in  $E_{\text{int}}$  occurs during the expansion. It follows from the first law that the heat input to the gas during the expansion is equal to the energy output by work. Why does this conversion *not* violate the second law?
65. A system consisting of  $n$  mol of an ideal gas undergoes a reversible, *isobaric* process from a volume  $V_i$  to a volume  $3V_i$ . Calculate the change in entropy of the gas. (*Hint*: Imagine that the system goes from the initial state to the final state first along an isotherm and then along an adiabatic path—no change in entropy occurs along the adiabatic path.)
66. Suppose you are working in a patent office, and an inventor comes to you with the claim that her heat engine, which employs water as a working substance, has a

thermodynamic efficiency of 0.61. She explains that it operates between energy reservoirs at  $4^\circ\text{C}$  and  $0^\circ\text{C}$ . It is a very complicated device, with many pistons, gears, and pulleys, and the cycle involves freezing and melting. Does her claim that  $e = 0.61$  warrant serious consideration? Explain.

67. An idealized diesel engine operates in a cycle known as the *air-standard diesel cycle*, as shown in Figure 22.13. Fuel is sprayed into the cylinder at the point of maximum compression  $B$ . Combustion occurs during the expansion  $B \rightarrow C$ , which is approximated as an isobaric process. Show that the efficiency of an engine operating in this idealized diesel cycle is

$$e = 1 - \frac{1}{\gamma} \left( \frac{T_D - T_A}{T_C - T_B} \right)$$

68. One mole of an ideal gas ( $\gamma = 1.40$ ) is carried through the Carnot cycle described in Figure 22.10. At point A, the pressure is 25.0 atm and the temperature is 600 K. At point C, the pressure is 1.00 atm and the temperature is 400 K. (a) Determine the pressures and volumes at points A, B, C, and D. (b) Calculate the net work done per cycle. (c) Determine the efficiency of an engine operating in this cycle.
69. A typical human has a mass of 70.0 kg and produces about 2 000 kcal ( $2.00 \times 10^6$  cal) of metabolic energy per day. (a) Find the rate of metabolic energy production in watts and in calories per hour. (b) If none of the metabolic energy were transferred out of the body, and the specific heat of the human body is  $1.00 \text{ cal/g} \cdot ^\circ\text{C}$ , what is the rate at which body temperature would rise? Give your answer in degrees Celsius per hour and in degrees Fahrenheit per hour.
70. Suppose that 1.00 kg of water at  $10.0^\circ\text{C}$  is mixed with 1.00 kg of water at  $30.0^\circ\text{C}$  at constant pressure. When the mixture has reached equilibrium, (a) what is the final temperature? (b) Take  $c_p = 4.19 \text{ kJ/kg} \cdot \text{K}$  for water. Show that the entropy of the system increases by

$$\Delta S = 4.19 \ln \left[ \left( \frac{293}{283} \right) \left( \frac{293}{303} \right) \right] \text{ kJ/K}$$

(c) Verify numerically that  $\Delta S > 0$ . (d) Is the mixing an irreversible process?

## ANSWERS TO QUICK QUIZZES

- 22.1 The cost of heating your home decreases to 25% of the original cost. With electric heating, you receive the same amount of energy for heating your home as enters it by electricity. The COP of 4 for the heat pump means that you are receiving four times as much energy as the energy entering by electricity. With four times as much energy per unit of energy from electricity, you need only one-fourth as much electricity.
- 22.2 (b) Because the process is reversible and adiabatic,  $Q_r = 0$ ; therefore,  $\Delta S = 0$ .

- 22.3 False. The second law states that the entropy of the *Universe* increases in real processes. Although the organization of molecules into ordered leaves and branches represents a decrease in entropy *of the tree*, this organization takes place because of a number of processes in which the tree interacts with its surroundings. If we include the entropy changes associated with all these processes, the entropy change of the Universe during the growth of a tree is still positive.

## # PUZZLER

Soft contact lenses are comfortable to wear because they attract the proteins in the wearer's tears, incorporating the complex molecules right into the lenses. They become, in a sense, part of the wearer. Some types of makeup exploit this same attractive force to adhere to the skin. What is the nature of this force?

*(Charles D. Winters)*

## Electric Fields

### Chapter Outline

**23.1** Properties of Electric Charges

**23.2** Insulators and Conductors

**23.3** Coulomb's Law

**23.4** The Electric Field

**23.5** Electric Field of a Continuous Charge Distribution

**23.6** Electric Field Lines

**23.7** Motion of Charged Particles in a Uniform Electric Field

The electromagnetic force between charged particles is one of the fundamental forces of nature. We begin this chapter by describing some of the basic properties of electric forces. We then discuss Coulomb's law, which is the fundamental law governing the force between any two charged particles. Next, we introduce the concept of an electric field associated with a charge distribution and describe its effect on other charged particles. We then show how to use Coulomb's law to calculate the electric field for a given charge distribution. We conclude the chapter with a discussion of the motion of a charged particle in a uniform electric field.

## 23.1 PROPERTIES OF ELECTRIC CHARGES

 A number of simple experiments demonstrate the existence of electric forces and charges. For example, after running a comb through your hair on a dry day, you will find that the comb attracts bits of paper. The attractive force is often strong enough to suspend the paper. The same effect occurs when materials such as glass or rubber are rubbed with silk or fur.

Another simple experiment is to rub an inflated balloon with wool. The balloon then adheres to a wall, often for hours. When materials behave in this way, they are said to be *electrified*, or to have become **electrically charged**. You can easily electrify your body by vigorously rubbing your shoes on a wool rug. The electric charge on your body can be felt and removed by lightly touching (and startling) a friend. Under the right conditions, you will see a spark when you touch, and both of you will feel a slight tingle. (Experiments such as these work best on a dry day because an excessive amount of moisture in the air can cause any charge you build up to “leak” from your body to the Earth.)

In a series of simple experiments, it is found that there are two kinds of electric charges, which were given the names **positive** and **negative** by Benjamin Franklin (1706–1790). To verify that this is true, consider a hard rubber rod that has been rubbed with fur and then suspended by a nonmetallic thread, as shown in Figure 23.1. When a glass rod that has been rubbed with silk is brought near the rubber rod, the two attract each other (Fig. 23.1a). On the other hand, if two charged rubber rods (or two charged glass rods) are brought near each other, as shown in Figure 23.1b, the two repel each other. This observation shows that the rubber and glass are in two different states of electrification. On the basis of these observations, we conclude that **like charges repel one another and unlike charges attract one another**.

Using the convention suggested by Franklin, the electric charge on the glass rod is called positive and that on the rubber rod is called negative. Therefore, any charged object attracted to a charged rubber rod (or repelled by a charged glass rod) must have a positive charge, and any charged object repelled by a charged rubber rod (or attracted to a charged glass rod) must have a negative charge.

 Attractive electric forces are responsible for the behavior of a wide variety of commercial products. For example, the plastic in many contact lenses, *etafilcon*, is made up of molecules that electrically attract the protein molecules in human tears. These protein molecules are absorbed and held by the plastic so that the lens ends up being primarily composed of the wearer's tears. Because of this, the wearer's eye does not treat the lens as a foreign object, and it can be worn comfortably. Many cosmetics also take advantage of electric forces by incorporating materials that are electrically attracted to skin or hair, causing the pigments or other chemicals to stay put once they are applied.

### QuickLab

Rub an inflated balloon against your hair and then hold the balloon near a thin stream of water running from a faucet. What happens? (A rubbed plastic pen or comb will also work.)

**Figure 23.1** (a) A negatively charged rubber rod suspended by a thread is attracted to a positively charged glass rod. (b) A negatively charged rubber rod is repelled by another negatively charged rubber rod.

Charge is conserved

**Figure 23.2** Rubbing a balloon against your hair on a dry day causes the balloon and your hair to become charged.

Charge is quantized

Another important aspect of Franklin's model of electricity is the implication that **electric charge is always conserved**. That is, when one object is rubbed against another, charge is not created in the process. The electrified state is due to a *transfer* of charge from one object to the other. One object gains some amount of negative charge while the other gains an equal amount of positive charge. For example, when a glass rod is rubbed with silk, the silk obtains a negative charge that is equal in magnitude to the positive charge on the glass rod. We now know from our understanding of atomic structure that negatively charged electrons are transferred from the glass to the silk in the rubbing process. Similarly, when rubber is rubbed with fur, electrons are transferred from the fur to the rubber, giving the rubber a net negative charge and the fur a net positive charge. This process is consistent with the fact that neutral, uncharged matter contains as many positive charges (protons within atomic nuclei) as negative charges (electrons).

### Quick Quiz 23.1

If you rub an inflated balloon against your hair, the two materials attract each other, as shown in Figure 23.2. Is the amount of charge present in the balloon and your hair after rubbing (a) less than, (b) the same as, or (c) more than the amount of charge present before rubbing?

In 1909, Robert Millikan (1868–1953) discovered that electric charge always occurs as some integral multiple of a fundamental amount of charge  $e$ . In modern terms, the electric charge  $q$  is said to be **quantized**, where  $q$  is the standard symbol used for charge. That is, electric charge exists as discrete “packets,” and we can write  $q = Ne$ , where  $N$  is some integer. Other experiments in the same period showed that the electron has a charge  $-e$  and the proton has a charge of equal magnitude but opposite sign  $+e$ . Some particles, such as the neutron, have no charge. A neutral atom must contain as many protons as electrons.

Because charge is a conserved quantity, the net charge in a closed region remains the same. If charged particles are created in some process, they are always created in pairs whose members have equal-magnitude charges of opposite sign.

From our discussion thus far, we conclude that electric charge has the following important properties:

- Two kinds of charges occur in nature, with the property that unlike charges attract one another and like charges repel one another.
- Charge is conserved.
- Charge is quantized.

Properties of electric charge

## 23.2 INSULATORS AND CONDUCTORS

 It is convenient to classify substances in terms of their ability to conduct electric charge:

11.3

Electrical **conductors** are materials in which electric charges move freely, whereas electrical **insulators** are materials in which electric charges cannot move freely.

Materials such as glass, rubber, and wood fall into the category of electrical insulators. When such materials are charged by rubbing, only the area rubbed becomes charged, and the charge is unable to move to other regions of the material.

In contrast, materials such as copper, aluminum, and silver are good electrical conductors. When such materials are charged in some small region, the charge readily distributes itself over the entire surface of the material. If you hold a copper rod in your hand and rub it with wool or fur, it will not attract a small piece of paper. This might suggest that a metal cannot be charged. However, if you attach a wooden handle to the rod and then hold it by that handle as you rub the rod, the rod will remain charged and attract the piece of paper. The explanation for this is as follows: Without the insulating wood, the electric charges produced by rubbing readily move from the copper through your body and into the Earth. The insulating wooden handle prevents the flow of charge into your hand.

**Semiconductors** are a third class of materials, and their electrical properties are somewhere between those of insulators and those of conductors. Silicon and germanium are well-known examples of semiconductors commonly used in the fabrication of a variety of electronic devices, such as transistors and light-emitting diodes. The electrical properties of semiconductors can be changed over many orders of magnitude by the addition of controlled amounts of certain atoms to the materials.

When a conductor is connected to the Earth by means of a conducting wire or pipe, it is said to be **grounded**. The Earth can then be considered an infinite “sink” to which electric charges can easily migrate. With this in mind, we can understand how to charge a conductor by a process known as **induction**.

To understand induction, consider a neutral (uncharged) conducting sphere insulated from ground, as shown in Figure 23.3a. When a negatively charged rubber rod is brought near the sphere, the region of the sphere nearest the rod obtains an excess of positive charge while the region farthest from the rod obtains an equal excess of negative charge, as shown in Figure 23.3b. (That is, electrons in the region nearest the rod migrate to the opposite side of the sphere. This occurs even if the rod never actually touches the sphere.) If the same experiment is performed with a conducting wire connected from the sphere to ground (Fig. 23.3c), some of the electrons in the conductor are so strongly repelled by the presence of

Metals are good conductors

Charging by induction

**Figure 23.3** Charging a metallic object by *induction* (that is, the two objects never touch each other). (a) A neutral metallic sphere, with equal numbers of positive and negative charges. (b) The charge on the neutral sphere is redistributed when a charged rubber rod is placed near the sphere. (c) When the sphere is grounded, some of its electrons leave through the ground wire. (d) When the ground connection is removed, the sphere has excess positive charge that is nonuniformly distributed. (e) When the rod is removed, the excess positive charge becomes uniformly distributed over the surface of the sphere.

**Figure 23.4** (a) The charged object on the left induces charges on the surface of an insulator. (b) A charged comb attracts bits of paper because charges are displaced in the paper.

the negative charge in the rod that they move out of the sphere through the ground wire and into the Earth. If the wire to ground is then removed (Fig. 23.3d), the conducting sphere contains an excess of *induced* positive charge. When the rubber rod is removed from the vicinity of the sphere (Fig. 23.3e), this induced positive charge remains on the ungrounded sphere. Note that the charge remaining on the sphere is uniformly distributed over its surface because of the repulsive forces among the like charges. Also note that the rubber rod loses none of its negative charge during this process.

Charging an object by induction requires no contact with the body inducing the charge. This is in contrast to charging an object by rubbing (that is, by *conduction*), which does require contact between the two objects.

A process similar to induction in conductors takes place in insulators. In most neutral molecules, the center of positive charge coincides with the center of negative charge. However, in the presence of a charged object, these centers inside each molecule in an insulator may shift slightly, resulting in more positive charge on one side of the molecule than on the other. This realignment of charge within individual molecules produces an induced charge on the surface of the insulator, as shown in Figure 23.4. Knowing about induction in insulators, you should be able to explain why a comb that has been rubbed through hair attracts bits of electrically neutral paper and why a balloon that has been rubbed against your clothing is able to stick to an electrically neutral wall.

### Quick Quiz 23.2

Object A is attracted to object B. If object B is known to be positively charged, what can we say about object A? (a) It is positively charged. (b) It is negatively charged. (c) It is electrically neutral. (d) Not enough information to answer.

## 23.3 COULOMB'S LAW

**11.4** Charles Coulomb (1736–1806) measured the magnitudes of the electric forces between charged objects using the torsion balance, which he invented (Fig. 23.5).

### QuickLab

Tear some paper into very small pieces. Comb your hair and then bring the comb close to the paper pieces. Notice that they are accelerated toward the comb. How does the magnitude of the electric force compare with the magnitude of the gravitational force exerted on the paper? Keep watching and you might see a few pieces jump away from the comb. They don't just fall away; they are repelled. What causes this?

#### Charles Coulomb (1736–1806)

Coulomb's major contribution to science was in the field of electrostatics and magnetism. During his lifetime, he also investigated the strengths of materials and determined the forces that affect objects on beams, thereby contributing to the field of structural mechanics. In the field of ergonomics, his research provided a fundamental understanding of the ways in which people and animals can best do work. (Photo courtesy of AIP Niels Bohr Library/E. Scott Barr Collection)

**Figure 23.5** Coulomb's torsion balance, used to establish the inverse-square law for the electric force between two charges.

Coulomb confirmed that the electric force between two small charged spheres is proportional to the inverse square of their separation distance  $r$ —that is,  $F_e \propto 1/r^2$ . The operating principle of the torsion balance is the same as that of the apparatus used by Cavendish to measure the gravitational constant (see Section 14.2), with the electrically neutral spheres replaced by charged ones. The electric force between charged spheres A and B in Figure 23.5 causes the spheres to either attract or repel each other, and the resulting motion causes the suspended fiber to twist. Because the restoring torque of the twisted fiber is proportional to the angle through which the fiber rotates, a measurement of this angle provides a quantitative measure of the electric force of attraction or repulsion. Once the spheres are charged by rubbing, the electric force between them is very large compared with the gravitational attraction, and so the gravitational force can be neglected.

Coulomb's experiments showed that the **electric force** between two stationary charged particles

- is inversely proportional to the square of the separation  $r$  between the particles and directed along the line joining them;
- is proportional to the product of the charges  $q_1$  and  $q_2$  on the two particles;
- is attractive if the charges are of opposite sign and repulsive if the charges have the same sign.

From these observations, we can express **Coulomb's law** as an equation giving the magnitude of the electric force (sometimes called the *Coulomb force*) between two point charges:

$$F_e = k_e \frac{|q_1||q_2|}{r^2} \quad (23.1)$$

where  $k_e$  is a constant called the **Coulomb constant**. In his experiments, Coulomb was able to show that the value of the exponent of  $r$  was 2 to within an uncertainty of a few percent. Modern experiments have shown that the exponent is 2 to within an uncertainty of a few parts in  $10^{16}$ .

The value of the Coulomb constant depends on the choice of units. The SI unit of charge is the **coulomb** (C). The Coulomb constant  $k_e$  in SI units has the value

$$k_e = 8.9875 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2$$

This constant is also written in the form

$$k_e = \frac{1}{4\pi\epsilon_0}$$

where the constant  $\epsilon_0$  (lowercase Greek epsilon) is known as the *permittivity of free space* and has the value  $8.8542 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2$ .

The smallest unit of charge known in nature is the charge on an electron or proton,<sup>1</sup> which has an absolute value of

$$|e| = 1.60219 \times 10^{-19} \text{ C}$$

Therefore, 1 C of charge is approximately equal to the charge of  $6.24 \times 10^{18}$  electrons or protons. This number is very small when compared with the number of

<sup>1</sup> No unit of charge smaller than  $e$  has been detected as a free charge; however, recent theories propose the existence of particles called *quarks* having charges  $e/3$  and  $2e/3$ . Although there is considerable experimental evidence for such particles inside nuclear matter, *free* quarks have never been detected. We discuss other properties of quarks in Chapter 46 of the extended version of this text.

Coulomb constant

Charge on an electron or proton

**TABLE 23.1** Charge and Mass of the Electron, Proton, and Neutron

Particle	Charge (C)	Mass (kg)
Electron (e)	$-1.602\,191\,7 \times 10^{-19}$	$9.109\,5 \times 10^{-31}$
Proton (p)	$+1.602\,191\,7 \times 10^{-19}$	$1.672\,61 \times 10^{-27}$
Neutron (n)	0	$1.674\,92 \times 10^{-27}$

free electrons<sup>2</sup> in  $1\text{ cm}^3$  of copper, which is of the order of  $10^{23}$ . Still, 1 C is a substantial amount of charge. In typical experiments in which a rubber or glass rod is charged by friction, a net charge of the order of  $10^{-6}$  C is obtained. In other words, only a very small fraction of the total available charge is transferred between the rod and the rubbing material.

The charges and masses of the electron, proton, and neutron are given in Table 23.1.

### EXAMPLE 23.1 The Hydrogen Atom

The electron and proton of a hydrogen atom are separated (on the average) by a distance of approximately  $5.3 \times 10^{-11}$  m. Find the magnitudes of the electric force and the gravitational force between the two particles.

**Solution** From Coulomb's law, we find that the attractive electric force has the magnitude

$$F_e = k_e \frac{|e|^2}{r^2} = \left( 8.99 \times 10^9 \frac{\text{N} \cdot \text{m}^2}{\text{C}^2} \right) \frac{(1.60 \times 10^{-19} \text{ C})^2}{(5.3 \times 10^{-11} \text{ m})^2}$$

$$= 8.2 \times 10^{-8} \text{ N}$$

Using Newton's law of gravitation and Table 23.1 for the particle masses, we find that the gravitational force has the magnitude

$$F_g = G \frac{m_e m_p}{r^2}$$

$$= \left( 6.7 \times 10^{-11} \frac{\text{N} \cdot \text{m}^2}{\text{kg}^2} \right)$$

$$= \times \frac{(9.11 \times 10^{-31} \text{ kg})(1.67 \times 10^{-27} \text{ kg})}{(5.3 \times 10^{-11} \text{ m})^2}$$

$$= 3.6 \times 10^{-47} \text{ N}$$

The ratio  $F_e/F_g \approx 2 \times 10^{39}$ . Thus, the gravitational force between charged atomic particles is negligible when compared with the electric force. Note the similarity of form of Newton's law of gravitation and Coulomb's law of electric forces. Other than magnitude, what is a fundamental difference between the two forces?

When dealing with Coulomb's law, you must remember that force is a vector quantity and must be treated accordingly. Thus, the law expressed in vector form for the electric force exerted by a charge  $q_1$  on a second charge  $q_2$ , written  $\mathbf{F}_{12}$ , is

$$\mathbf{F}_{12} = k_e \frac{q_1 q_2}{r^2} \hat{\mathbf{r}} \quad (23.2)$$

where  $\hat{\mathbf{r}}$  is a unit vector directed from  $q_1$  to  $q_2$ , as shown in Figure 23.6a. Because the electric force obeys Newton's third law, the electric force exerted by  $q_2$  on  $q_1$  is

<sup>2</sup> A metal atom, such as copper, contains one or more outer electrons, which are weakly bound to the nucleus. When many atoms combine to form a metal, the so-called *free electrons* are these outer electrons, which are not bound to any one atom. These electrons move about the metal in a manner similar to that of gas molecules moving in a container.

**Figure 23.6** Two point charges separated by a distance  $r$  exert a force on each other that is given by Coulomb's law. The force  $\mathbf{F}_{21}$  exerted by  $q_2$  on  $q_1$  is equal in magnitude and opposite in direction to the force  $\mathbf{F}_{12}$  exerted by  $q_1$  on  $q_2$ . (a) When the charges are of the same sign, the force is repulsive. (b) When the charges are of opposite signs, the force is attractive.

equal in magnitude to the force exerted by  $q_1$  on  $q_2$  and in the opposite direction; that is,  $\mathbf{F}_{21} = -\mathbf{F}_{12}$ . Finally, from Equation 23.2, we see that if  $q_1$  and  $q_2$  have the same sign, as in Figure 23.6a, the product  $q_1q_2$  is positive and the force is repulsive. If  $q_1$  and  $q_2$  are of opposite sign, as shown in Figure 23.6b, the product  $q_1q_2$  is negative and the force is attractive. Noting the sign of the product  $q_1q_2$  is an easy way of determining the direction of forces acting on the charges.

### Quick Quiz 23.3

Object A has a charge of  $+2 \mu\text{C}$ , and object B has a charge of  $+6 \mu\text{C}$ . Which statement is true?

- (a)  $\mathbf{F}_{AB} = -3\mathbf{F}_{BA}$ .    (b)  $\mathbf{F}_{AB} = -\mathbf{F}_{BA}$ .    (c)  $3\mathbf{F}_{AB} = -\mathbf{F}_{BA}$ .

When more than two charges are present, the force between any pair of them is given by Equation 23.2. Therefore, the resultant force on any one of them equals the vector sum of the forces exerted by the various individual charges. For example, if four charges are present, then the resultant force exerted by particles 2, 3, and 4 on particle 1 is

$$\mathbf{F}_1 = \mathbf{F}_{21} + \mathbf{F}_{31} + \mathbf{F}_{41}$$

### EXAMPLE 23.2 Find the Resultant Force

Consider three point charges located at the corners of a right triangle as shown in Figure 23.7, where  $q_1 = q_3 = 5.0 \mu\text{C}$ ,  $q_2 = -2.0 \mu\text{C}$ , and  $a = 0.10 \text{ m}$ . Find the resultant force exerted on  $q_3$ .

**Solution** First, note the direction of the individual forces exerted by  $q_1$  and  $q_2$  on  $q_3$ . The force  $F_{23}$  exerted by  $q_2$  on  $q_3$  is attractive because  $q_2$  and  $q_3$  have opposite signs. The force  $F_{13}$  exerted by  $q_1$  on  $q_3$  is repulsive because both charges are positive.

The magnitude of  $\mathbf{F}_{23}$  is

$$\begin{aligned} F_{23} &= k_e \frac{|q_2||q_3|}{a^2} \\ &= \left(8.99 \times 10^9 \frac{\text{N} \cdot \text{m}^2}{\text{C}^2}\right) \frac{(2.0 \times 10^{-6} \text{ C})(5.0 \times 10^{-6} \text{ C})}{(0.10 \text{ m})^2} \\ &= 9.0 \text{ N} \end{aligned}$$

Note that because  $q_3$  and  $q_2$  have opposite signs,  $\mathbf{F}_{23}$  is to the left, as shown in Figure 23.7.

**Figure 23.7** The force exerted by  $q_1$  on  $q_3$  is  $\mathbf{F}_{13}$ . The force exerted by  $q_2$  on  $q_3$  is  $\mathbf{F}_{23}$ . The resultant force  $\mathbf{F}_3$  exerted on  $q_3$  is the vector sum  $\mathbf{F}_{13} + \mathbf{F}_{23}$ .

The magnitude of the force exerted by  $q_1$  on  $q_3$  is

$$F_{13} = k_e \frac{|q_1||q_3|}{(\sqrt{2}a)^2}$$

$$= \left(8.99 \times 10^9 \frac{\text{N} \cdot \text{m}^2}{\text{C}^2}\right) \frac{(5.0 \times 10^{-6} \text{ C})(5.0 \times 10^{-6} \text{ C})}{2(0.10 \text{ m})^2}$$

$$= 11 \text{ N}$$

The force  $\mathbf{F}_{13}$  is repulsive and makes an angle of  $45^\circ$  with the  $x$  axis. Therefore, the  $x$  and  $y$  components of  $\mathbf{F}_{13}$  are equal, with magnitude given by  $F_{13} \cos 45^\circ = 7.9 \text{ N}$ .

The force  $\mathbf{F}_{23}$  is in the negative  $x$  direction. Hence, the  $x$  and  $y$  components of the resultant force acting on  $q_3$  are

$$F_{3x} = F_{13x} + F_{23} = 7.9 \text{ N} - 9.0 \text{ N} = -1.1 \text{ N}$$

$$F_{3y} = F_{13y} = 7.9 \text{ N}$$

We can also express the resultant force acting on  $q_3$  in unit-vector form as

$$\mathbf{F}_3 = (-1.1\mathbf{i} + 7.9\mathbf{j}) \text{ N}$$

**Exercise** Find the magnitude and direction of the resultant force  $\mathbf{F}_3$ .

**Answer** 8.0 N at an angle of  $98^\circ$  with the  $x$  axis.

### EXAMPLE 23.3 Where Is the Resultant Force Zero?

Three point charges lie along the  $x$  axis as shown in Figure 23.8. The positive charge  $q_1 = 15.0 \mu\text{C}$  is at  $x = 2.00 \text{ m}$ , the positive charge  $q_2 = 6.00 \mu\text{C}$  is at the origin, and the resultant force acting on  $q_3$  is zero. What is the  $x$  coordinate of  $q_3$ ?

**Solution** Because  $q_3$  is negative and  $q_1$  and  $q_2$  are positive, the forces  $\mathbf{F}_{13}$  and  $\mathbf{F}_{23}$  are both attractive, as indicated in Figure 23.8. From Coulomb's law,  $\mathbf{F}_{13}$  and  $\mathbf{F}_{23}$  have magnitudes

$$F_{13} = k_e \frac{|q_1||q_3|}{(2.00 - x)^2} \quad F_{23} = k_e \frac{|q_2||q_3|}{x^2}$$

For the resultant force on  $q_3$  to be zero,  $\mathbf{F}_{23}$  must be equal in magnitude and opposite in direction to  $\mathbf{F}_{13}$ , or

$$k_e \frac{|q_2||q_3|}{x^2} = k_e \frac{|q_1||q_3|}{(2.00 - x)^2}$$

Noting that  $k_e$  and  $q_3$  are common to both sides and so can be dropped, we solve for  $x$  and find that

$$(2.00 - x)^2 |q_2| = x^2 |q_1|$$

$$(4.00 - 4.00x + x^2)(6.00 \times 10^{-6} \text{ C}) = x^2(15.0 \times 10^{-6} \text{ C})$$

Solving this quadratic equation for  $x$ , we find that

$$x = 0.775 \text{ m.} \quad \text{Why is the negative root not acceptable?}$$

**Figure 23.8** Three point charges are placed along the  $x$  axis. If the net force acting on  $q_3$  is zero, then the force  $\mathbf{F}_{13}$  exerted by  $q_1$  on  $q_3$  must be equal in magnitude and opposite in direction to the force  $\mathbf{F}_{23}$  exerted by  $q_2$  on  $q_3$ .

### EXAMPLE 23.4 Find the Charge on the Spheres

Two identical small charged spheres, each having a mass of  $3.0 \times 10^{-2} \text{ kg}$ , hang in equilibrium as shown in Figure 23.9a. The length of each string is  $0.15 \text{ m}$ , and the angle  $\theta$  is  $5.0^\circ$ . Find the magnitude of the charge on each sphere.

**Solution** From the right triangle shown in Figure 23.9a,

we see that  $\sin \theta = a/L$ . Therefore,

$$a = L \sin \theta = (0.15 \text{ m}) \sin 5.0^\circ = 0.013 \text{ m}$$

The separation of the spheres is  $2a = 0.026 \text{ m}$ .

The forces acting on the left sphere are shown in Figure 23.9b. Because the sphere is in equilibrium, the forces in the

horizontal and vertical directions must separately add up to zero:

$$(1) \quad \sum F_x = T \sin \theta - F_e = 0$$

$$(2) \quad \sum F_y = T \cos \theta - mg = 0$$

From Equation (2), we see that  $T = mg / \cos \theta$ ; thus,  $T$  can be

**Figure 23.9** (a) Two identical spheres, each carrying the same charge  $q$ , suspended in equilibrium. (b) The free-body diagram for the sphere on the left.

eliminated from Equation (1) if we make this substitution. This gives a value for the magnitude of the electric force  $F_e$ :

$$(3) \quad F_e = mg \tan \theta \\ = (3.0 \times 10^{-2} \text{ kg})(9.80 \text{ m/s}^2) \tan 5.0^\circ \\ = 2.6 \times 10^{-2} \text{ N}$$

From Coulomb's law (Eq. 23.1), the magnitude of the electric force is

$$F_e = k_e \frac{|q|^2}{r^2}$$

where  $r = 2a = 0.026 \text{ m}$  and  $|q|$  is the magnitude of the charge on each sphere. (Note that the term  $|q|^2$  arises here because the charge is the same on both spheres.) This equation can be solved for  $|q|^2$  to give

$$|q|^2 = \frac{F_e r^2}{k_e} = \frac{(2.6 \times 10^{-2} \text{ N})(0.026 \text{ m})^2}{8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2}$$

$$|q| = 4.4 \times 10^{-8} \text{ C}$$

**Exercise** If the charge on the spheres were negative, how many electrons would have to be added to them to yield a net charge of  $-4.4 \times 10^{-8} \text{ C}$ ?

**Answer**  $2.7 \times 10^{11}$  electrons.

### QuickLab

For this experiment you need two 20-cm strips of transparent tape (mass of each  $\approx 65 \text{ mg}$ ). Fold about 1 cm of tape over at one end of each strip to create a handle. Press both pieces of tape side by side onto a table top, rubbing your finger back and forth across the strips. Quickly pull the strips off the surface so that they become charged. Hold the tape handles together and the strips will repel each other, forming an inverted "V" shape. Measure the angle between the pieces, and estimate the excess charge on each strip. Assume that the charges act as if they were located at the center of mass of each strip.

## 23.4 THE ELECTRIC FIELD

Two field forces have been introduced into our discussions so far—the gravitational force and the electric force. As pointed out earlier, field forces can act through space, producing an effect even when no physical contact between the objects occurs. The gravitational field  $\mathbf{g}$  at a point in space was defined in Section 14.6 to be equal to the gravitational force  $\mathbf{F}_g$  acting on a test particle of mass  $m$  divided by that mass:  $\mathbf{g} \equiv \mathbf{F}_g/m$ . A similar approach to electric forces was developed by Michael Faraday and is of such practical value that we shall devote much attention to it in the next several chapters. In this approach, an **electric field** is said to exist in the region of space around a charged object. When another charged object enters this electric field, an electric force acts on it. As an example, consider Figure 23.10, which shows a small positive test charge  $q_0$  placed near a second object carrying a much greater positive charge  $Q$ . We define the strength (in other words, the magnitude) of the electric field at the location of the test charge to be the electric force *per unit charge*, or to be more specific

**Figure 23.10** A small positive test charge  $q_0$  placed near an object carrying a much larger positive charge  $Q$  experiences an electric field  $\mathbf{E}$  directed as shown.

**the electric field  $\mathbf{E}$**  at a point in space is defined as the electric force  $\mathbf{F}_e$  acting on a positive test charge  $q_0$  placed at that point divided by the magnitude of the test charge:

$$\mathbf{E} \equiv \frac{\mathbf{F}_e}{q_0} \quad (23.3)$$

Definition of electric field

Note that  $\mathbf{E}$  is the field produced by some charge *external* to the test charge—it is not the field produced by the test charge itself. Also, note that the existence of an electric field is a property of its source. For example, every electron comes with its own electric field.

The vector  $\mathbf{E}$  has the SI units of newtons per coulomb (N/C), and, as Figure 23.10 shows, its direction is the direction of the force a positive test charge experiences when placed in the field. We say that **an electric field exists at a point if a test charge at rest at that point experiences an electric force**. Once the magnitude and direction of the electric field are known at some point, the electric force exerted on *any* charged particle placed at that point can be calculated from

This dramatic photograph captures a lightning bolt striking a tree near some rural homes.

**TABLE 23.2** Typical Electric Field Values

Source	$E$ (N/C)
Fluorescent lighting tube	10
Atmosphere (fair weather)	100
Balloon rubbed on hair	1 000
Atmosphere (under thundercloud)	10 000
Photocopier	100 000
Spark in air	$> 3\,000\,000$
Near electron in hydrogen atom	$5 \times 10^{11}$

**Figure 23.11** (a) For a small enough test charge  $q_0$ , the charge distribution on the sphere is undisturbed. (b) When the test charge  $q'_0$  is greater, the charge distribution on the sphere is disturbed as the result of the proximity of  $q'_0$ .

Equation 23.3. Furthermore, the electric field is said to exist at some point (even empty space) **regardless of whether a test charge is located at that point.** (This is analogous to the gravitational field set up by any object, which is said to exist at a given point regardless of whether some other object is present at that point to “feel” the field.) The electric field magnitudes for various field sources are given in Table 23.2.

When using Equation 23.3, we must assume that the test charge  $q_0$  is small enough that it does not disturb the charge distribution responsible for the electric field. If a vanishingly small test charge  $q_0$  is placed near a uniformly charged metallic sphere, as shown in Figure 23.11a, the charge on the metallic sphere, which produces the electric field, remains uniformly distributed. If the test charge is great enough ( $q'_0 \gg q_0$ ), as shown in Figure 23.11b, the charge on the metallic sphere is redistributed and the ratio of the force to the test charge is different: ( $F'_e/q'_0 \neq F_e/q_0$ ). That is, because of this redistribution of charge on the metallic sphere, the electric field it sets up is different from the field it sets up in the presence of the much smaller  $q_0$ .

To determine the direction of an electric field, consider a point charge  $q$  located a distance  $r$  from a test charge  $q_0$  located at a point  $P$ , as shown in Figure 23.12. According to Coulomb’s law, the force exerted by  $q$  on the test charge is

$$\mathbf{F}_e = k_e \frac{qq_0}{r^2} \hat{\mathbf{r}}$$

where  $\hat{\mathbf{r}}$  is a unit vector directed from  $q$  toward  $q_0$ . Because the electric field at  $P$ , the position of the test charge, is defined by  $\mathbf{E} = \mathbf{F}_e/q_0$ , we find that at  $P$ , the electric field created by  $q$  is

$$\mathbf{E} = k_e \frac{q}{r^2} \hat{\mathbf{r}} \quad (23.4)$$

If  $q$  is positive, as it is in Figure 23.12a, the electric field is directed radially outward from it. If  $q$  is negative, as it is in Figure 23.12b, the field is directed toward it.

To calculate the electric field at a point  $P$  due to a group of point charges, we first calculate the electric field vectors at  $P$  individually using Equation 23.4 and then add them vectorially. In other words,

at any point  $P$ , the total electric field due to a group of charges equals the vector sum of the electric fields of the individual charges.

This superposition principle applied to fields follows directly from the superposition property of electric forces. Thus, the electric field of a group of charges can

**Figure 23.12** A test charge  $q_0$  at point  $P$  is a distance  $r$  from a point charge  $q$ . (a) If  $q$  is positive, then the electric field at  $P$  points radially outward from  $q$ . (b) If  $q$  is negative, then the electric field at  $P$  points radially inward toward  $q$ .

This metallic sphere is charged by a generator so that it carries a net electric charge. The high concentration of charge on the sphere creates a strong electric field around the sphere. The charges then leak through the gas surrounding the sphere, producing a pink glow.

be expressed as

$$\mathbf{E} = k_e \sum_i \frac{q_i}{r_i^2} \hat{\mathbf{r}}_i \quad (23.5)$$

where  $r_i$  is the distance from the  $i$ th charge  $q_i$  to the point  $P$  (the location of the test charge) and  $\hat{\mathbf{r}}_i$  is a unit vector directed from  $q_i$  toward  $P$ .

### Quick Quiz 23.4

A charge of  $+3 \mu\text{C}$  is at a point  $P$  where the electric field is directed to the right and has a magnitude of  $4 \times 10^6 \text{ N/C}$ . If the charge is replaced with a  $-3\text{-}\mu\text{C}$  charge, what happens to the electric field at  $P$ ?

### EXAMPLE 23.5 Electric Field Due to Two Charges

A charge  $q_1 = 7.0 \mu\text{C}$  is located at the origin, and a second charge  $q_2 = -5.0 \mu\text{C}$  is located on the  $x$  axis,  $0.30 \text{ m}$  from the origin (Fig. 23.13). Find the electric field at the point  $P$ , which has coordinates  $(0, 0.40) \text{ m}$ .

**Solution** First, let us find the magnitude of the electric field at  $P$  due to each charge. The fields  $\mathbf{E}_1$  due to the  $7.0\text{-}\mu\text{C}$  charge and  $\mathbf{E}_2$  due to the  $-5.0\text{-}\mu\text{C}$  charge are shown in Figure 23.13. Their magnitudes are

$$\begin{aligned} E_1 &= k_e \frac{|q_1|}{r_1^2} = \left( 8.99 \times 10^9 \frac{\text{N}\cdot\text{m}^2}{\text{C}^2} \right) \frac{(7.0 \times 10^{-6} \text{ C})}{(0.40 \text{ m})^2} \\ &= 3.9 \times 10^5 \text{ N/C} \end{aligned}$$

$$\begin{aligned} E_2 &= k_e \frac{|q_2|}{r_2^2} = \left( 8.99 \times 10^9 \frac{\text{N}\cdot\text{m}^2}{\text{C}^2} \right) \frac{(5.0 \times 10^{-6} \text{ C})}{(0.50 \text{ m})^2} \\ &= 1.8 \times 10^5 \text{ N/C} \end{aligned}$$

The vector  $\mathbf{E}_1$  has only a  $y$  component. The vector  $\mathbf{E}_2$  has an  $x$  component given by  $E_2 \cos \theta = \frac{3}{5}E_2$  and a negative  $y$  component given by  $-E_2 \sin \theta = -\frac{4}{5}E_2$ . Hence, we can express the vectors as

**Figure 23.13** The total electric field  $\mathbf{E}$  at  $P$  equals the vector sum  $\mathbf{E}_1 + \mathbf{E}_2$ , where  $\mathbf{E}_1$  is the field due to the positive charge  $q_1$  and  $\mathbf{E}_2$  is the field due to the negative charge  $q_2$ .

$$\mathbf{E}_1 = 3.9 \times 10^5 \mathbf{j} \text{ N/C}$$

$$\mathbf{E}_2 = (1.1 \times 10^5 \mathbf{i} - 1.4 \times 10^5 \mathbf{j}) \text{ N/C}$$

The resultant field  $\mathbf{E}$  at  $P$  is the superposition of  $\mathbf{E}_1$  and  $\mathbf{E}_2$ :

$$\mathbf{E} = \mathbf{E}_1 + \mathbf{E}_2 = (1.1 \times 10^5 \mathbf{i} + 2.5 \times 10^5 \mathbf{j}) \text{ N/C}$$

From this result, we find that  $\mathbf{E}$  has a magnitude of  $2.7 \times 10^5 \text{ N/C}$  and makes an angle  $\phi$  of  $66^\circ$  with the positive  $x$  axis.

**Exercise** Find the electric force exerted on a charge of  $2.0 \times 10^{-8} \text{ C}$  located at  $P$ .

**Answer**  $5.4 \times 10^{-3} \text{ N}$  in the same direction as  $\mathbf{E}$ .

### EXAMPLE 23.6 Electric Field of a Dipole

An **electric dipole** is defined as a positive charge  $q$  and a negative charge  $-q$  separated by some distance. For the dipole shown in Figure 23.14, find the electric field  $\mathbf{E}$  at  $P$  due to the charges, where  $P$  is a distance  $y \gg a$  from the origin.

**Solution** At  $P$ , the fields  $\mathbf{E}_1$  and  $\mathbf{E}_2$  due to the two charges are equal in magnitude because  $P$  is equidistant from the charges. The total field is  $\mathbf{E} = \mathbf{E}_1 + \mathbf{E}_2$ , where

$$E_1 = E_2 = k_e \frac{q}{r^2} = k_e \frac{q}{y^2 + a^2}$$

The  $y$  components of  $\mathbf{E}_1$  and  $\mathbf{E}_2$  cancel each other, and the  $x$  components add because they are both in the positive  $x$  direction. Therefore,  $\mathbf{E}$  is parallel to the  $x$  axis and has a magnitude equal to  $2E_1 \cos \theta$ . From Figure 23.14 we see that  $\cos \theta = a/r = a/(y^2 + a^2)^{1/2}$ . Therefore,

$$\begin{aligned} E &= 2E_1 \cos \theta = 2k_e \frac{q}{(y^2 + a^2)} \frac{a}{(y^2 + a^2)^{1/2}} \\ &= k_e \frac{2qa}{(y^2 + a^2)^{3/2}} \end{aligned}$$

Because  $y \gg a$ , we can neglect  $a^2$  and write

$$E \approx k_e \frac{2qa}{y^3}$$

Thus, we see that, at distances far from a dipole but along the perpendicular bisector of the line joining the two charges, the magnitude of the electric field created by the dipole varies as  $1/r^3$ , whereas the more slowly varying field of a point charge varies as  $1/r^2$  (see Eq. 23.4). This is because at distant points, the fields of the two charges of equal magnitude and opposite sign almost cancel each other. The  $1/r^3$

variation in  $E$  for the dipole also is obtained for a distant point along the  $x$  axis (see Problem 21) and for any general distant point.

The electric dipole is a good model of many molecules, such as hydrochloric acid (HCl). As we shall see in later chapters, neutral atoms and molecules behave as dipoles when placed in an external electric field. Furthermore, many molecules, such as HCl, are permanent dipoles. The effect of such dipoles on the behavior of materials subjected to electric fields is discussed in Chapter 26.

**Figure 23.14** The total electric field  $\mathbf{E}$  at  $P$  due to two charges of equal magnitude and opposite sign (an electric dipole) equals the vector sum  $\mathbf{E}_1 + \mathbf{E}_2$ . The field  $\mathbf{E}_1$  is due to the positive charge  $q$ , and  $\mathbf{E}_2$  is the field due to the negative charge  $-q$ .

## 23.5 ELECTRIC FIELD OF A CONTINUOUS CHARGE DISTRIBUTION

Very often the distances between charges in a group of charges are much smaller than the distance from the group to some point of interest (for example, a point where the electric field is to be calculated). In such situations, the system of

charges is smeared out, or *continuous*. That is, the system of closely spaced charges is equivalent to a total charge that is continuously distributed along some line, over some surface, or throughout some volume.

To evaluate the electric field created by a continuous charge distribution, we use the following procedure: First, we divide the charge distribution into small elements, each of which contains a small charge  $\Delta q$ , as shown in Figure 23.15. Next, we use Equation 23.4 to calculate the electric field due to one of these elements at a point  $P$ . Finally, we evaluate the total field at  $P$  due to the charge distribution by summing the contributions of all the charge elements (that is, by applying the superposition principle).

The electric field at  $P$  due to one element carrying charge  $\Delta q$  is

$$\Delta \mathbf{E} = k_e \frac{\Delta q}{r^2} \hat{\mathbf{r}}$$

where  $r$  is the distance from the element to point  $P$  and  $\hat{\mathbf{r}}$  is a unit vector directed from the charge element toward  $P$ . The total electric field at  $P$  due to all elements in the charge distribution is approximately

$$\mathbf{E} \approx k_e \sum_i \frac{\Delta q_i}{r_i^2} \hat{\mathbf{r}}_i$$

where the index  $i$  refers to the  $i$ th element in the distribution. Because the charge distribution is approximately continuous, the total field at  $P$  in the limit  $\Delta q_i \rightarrow 0$  is

$$\mathbf{E} = k_e \lim_{\Delta q_i \rightarrow 0} \sum_i \frac{\Delta q_i}{r_i^2} \hat{\mathbf{r}}_i = k_e \int \frac{dq}{r^2} \hat{\mathbf{r}} \quad (23.6)$$

where the integration is over the entire charge distribution. This is a vector operation and must be treated appropriately.

We illustrate this type of calculation with several examples, in which we assume the charge is uniformly distributed on a line, on a surface, or throughout a volume. When performing such calculations, it is convenient to use the concept of a charge density along with the following notations:

- If a charge  $Q$  is uniformly distributed throughout a volume  $V$ , the **volume charge density**  $\rho$  is defined by

$$\rho \equiv \frac{Q}{V}$$

where  $\rho$  has units of coulombs per cubic meter ( $\text{C}/\text{m}^3$ ).

- If a charge  $Q$  is uniformly distributed on a surface of area  $A$ , the **surface charge density**  $\sigma$  (lowercase Greek sigma) is defined by

$$\sigma \equiv \frac{Q}{A}$$

where  $\sigma$  has units of coulombs per square meter ( $\text{C}/\text{m}^2$ ).

- If a charge  $Q$  is uniformly distributed along a line of length  $\ell$ , the **linear charge density**  $\lambda$  is defined by

$$\lambda \equiv \frac{Q}{\ell}$$

where  $\lambda$  has units of coulombs per meter ( $\text{C}/\text{m}$ ).

A continuous charge distribution

**Figure 23.15** The electric field at  $P$  due to a continuous charge distribution is the vector sum of the fields  $\Delta \mathbf{E}$  due to all the elements  $\Delta q$  of the charge distribution.

Electric field of a continuous charge distribution

Volume charge density

Surface charge density

Linear charge density

- If the charge is nonuniformly distributed over a volume, surface, or line, we have to express the charge densities as

$$\rho = \frac{dQ}{dV} \quad \sigma = \frac{dQ}{dA} \quad \lambda = \frac{dQ}{d\ell}$$

where  $dQ$  is the amount of charge in a small volume, surface, or length element.

### EXAMPLE 23.7 The Electric Field Due to a Charged Rod

A rod of length  $\ell$  has a uniform positive charge per unit length  $\lambda$  and a total charge  $Q$ . Calculate the electric field at a point  $P$  that is located along the long axis of the rod and a distance  $a$  from one end (Fig. 23.16).

**Solution** Let us assume that the rod is lying along the  $x$  axis, that  $dx$  is the length of one small segment, and that  $dq$  is the charge on that segment. Because the rod has a charge per unit length  $\lambda$ , the charge  $dq$  on the small segment is  $dq = \lambda dx$ .

The field  $d\mathbf{E}$  due to this segment at  $P$  is in the negative  $x$  direction (because the source of the field carries a positive charge  $Q$ ), and its magnitude is

$$dE = k_e \frac{dq}{x^2} = k_e \lambda \frac{dx}{x^2}$$

Because every other element also produces a field in the negative  $x$  direction, the problem of summing their contributions is particularly simple in this case. The total field at  $P$  due to all segments of the rod, which are at different distances from  $P$ , is given by Equation 23.6, which in this case becomes<sup>3</sup>

$$E = \int_a^{\ell+a} k_e \lambda \frac{dx}{x^2}$$

where the limits on the integral extend from one end of the rod ( $x = a$ ) to the other ( $x = \ell + a$ ). The constants  $k_e$  and  $\lambda$  can be removed from the integral to yield

$$\begin{aligned} E &= k_e \lambda \int_a^{\ell+a} \frac{dx}{x^2} = k_e \lambda \left[ -\frac{1}{x} \right]_a^{\ell+a} \\ &= k_e \lambda \left( \frac{1}{a} - \frac{1}{\ell + a} \right) = \frac{k_e Q}{a(\ell + a)} \end{aligned}$$

where we have used the fact that the total charge  $Q = \lambda \ell$ .

If  $P$  is far from the rod ( $a \gg \ell$ ), then the  $\ell$  in the denominator can be neglected, and  $E \approx k_e Q/a^2$ . This is just the form you would expect for a point charge. Therefore, at large values of  $a/\ell$ , the charge distribution appears to be a point charge of magnitude  $Q$ . The use of the limiting technique ( $a/\ell \rightarrow \infty$ ) often is a good method for checking a theoretical formula.

**Figure 23.16** The electric field at  $P$  due to a uniformly charged rod lying along the  $x$  axis. The magnitude of the field at  $P$  due to the segment of charge  $dq$  is  $k_e dq/x^2$ . The total field at  $P$  is the vector sum over all segments of the rod.

### EXAMPLE 23.8 The Electric Field of a Uniform Ring of Charge

A ring of radius  $a$  carries a uniformly distributed positive total charge  $Q$ . Calculate the electric field due to the ring at a point  $P$  lying a distance  $x$  from its center along the central axis perpendicular to the plane of the ring (Fig. 23.17a).

**Solution** The magnitude of the electric field at  $P$  due to the segment of charge  $dq$  is

$$dE = k_e \frac{dq}{r^2}$$

This field has an  $x$  component  $dE_x = dE \cos \theta$  along the axis and a component  $dE_\perp$  perpendicular to the axis. As we see in Figure 23.17b, however, the resultant field at  $P$  must lie along the  $x$  axis because the perpendicular components of all the

<sup>3</sup> It is important that you understand how to carry out integrations such as this. First, express the charge element  $dq$  in terms of the other variables in the integral (in this example, there is one variable,  $x$ , and so we made the change  $dq = \lambda dx$ ). The integral must be over scalar quantities; therefore, you must express the electric field in terms of components, if necessary. (In this example the field has only an  $x$  component, so we do not bother with this detail.) Then, reduce your expression to an integral over a single variable (or to multiple integrals, each over a single variable). In examples that have spherical or cylindrical symmetry, the single variable will be a radial coordinate.

various charge segments sum to zero. That is, the perpendicular component of the field created by any charge element is canceled by the perpendicular component created by an element on the opposite side of the ring. Because  $r = (x^2 + a^2)^{1/2}$  and  $\cos \theta = x/r$ , we find that

$$dE_x = dE \cos \theta = \left( k_e \frac{dq}{r^2} \right) \frac{x}{r} = \frac{k_e x}{(x^2 + a^2)^{3/2}} dq$$

All segments of the ring make the same contribution to the field at  $P$  because they are all equidistant from this point. Thus, we can integrate to obtain the total field at  $P$ :

**Figure 23.17** A uniformly charged ring of radius  $a$ . (a) The field at  $P$  on the  $x$  axis due to an element of charge  $dq$ . (b) The total electric field at  $P$  is along the  $x$  axis. The perpendicular component of the field at  $P$  due to segment 1 is canceled by the perpendicular component due to segment 2.

$$\begin{aligned} E_x &= \int \frac{k_e x}{(x^2 + a^2)^{3/2}} dq = \frac{k_e x}{(x^2 + a^2)^{3/2}} \int dq \\ &= \frac{k_e x}{(x^2 + a^2)^{3/2}} Q \end{aligned}$$

This result shows that the field is zero at  $x = 0$ . Does this finding surprise you?

**Exercise** Show that at great distances from the ring ( $x \gg a$ ) the electric field along the axis shown in Figure 23.17 approaches that of a point charge of magnitude  $Q$ .

### EXAMPLE 23.9 The Electric Field of a Uniformly Charged Disk

A disk of radius  $R$  has a uniform surface charge density  $\sigma$ . Calculate the electric field at a point  $P$  that lies along the central perpendicular axis of the disk and a distance  $x$  from the center of the disk (Fig. 23.18).

**Solution** If we consider the disk as a set of concentric rings, we can use our result from Example 23.8—which gives the field created by a ring of radius  $a$ —and sum the contri-

butions of all rings making up the disk. By symmetry, the field at an axial point must be along the central axis.

The ring of radius  $r$  and width  $dr$  shown in Figure 23.18 has a surface area equal to  $2\pi r dr$ . The charge  $dq$  on this ring is equal to the area of the ring multiplied by the surface charge density:  $dq = 2\pi r \sigma dr$ . Using this result in the equation given for  $E_x$  in Example 23.8 (with  $a$  replaced by  $r$ ), we have for the field due to the ring

$$dE = \frac{k_e x}{(x^2 + r^2)^{3/2}} (2\pi r \sigma dr)$$

To obtain the total field at  $P$ , we integrate this expression over the limits  $r = 0$  to  $r = R$ , noting that  $x$  is a constant. This gives

**Figure 23.18** A uniformly charged disk of radius  $R$ . The electric field at an axial point  $P$  is directed along the central axis, perpendicular to the plane of the disk.

$$\begin{aligned} E &= k_e x \pi \sigma \int_0^R \frac{2r dr}{(x^2 + r^2)^{3/2}} \\ &= k_e x \pi \sigma \int_0^R (x^2 + r^2)^{-3/2} d(r^2) \\ &= k_e x \pi \sigma \left[ \frac{(x^2 + r^2)^{-1/2}}{-1/2} \right]_0^R \\ &= 2\pi k_e \sigma \left( \frac{x}{|x|} - \frac{x}{(x^2 + R^2)^{1/2}} \right) \end{aligned}$$

This result is valid for all values of  $x$ . We can calculate the field close to the disk along the axis by assuming that  $R \gg x$ ; thus, the expression in parentheses reduces to unity:

$$E \approx 2\pi k_e \sigma = \frac{\sigma}{2\epsilon_0}$$

where  $\epsilon_0 = 1/(4\pi k_e)$  is the permittivity of free space. As we shall find in the next chapter, we obtain the same result for the field created by a uniformly charged infinite sheet.

## 23.6 ELECTRIC FIELD LINES

**11.5** A convenient way of visualizing electric field patterns is to draw lines that follow the same direction as the electric field vector at any point. These lines, called **electric field lines**, are related to the electric field in any region of space in the following manner:

- The electric field vector  $\mathbf{E}$  is tangent to the electric field line at each point.
- The number of lines per unit area through a surface perpendicular to the lines is proportional to the magnitude of the electric field in that region. Thus,  $E$  is great when the field lines are close together and small when they are far apart.

**Figure 23.19** Electric field lines penetrating two surfaces. The magnitude of the field is greater on surface A than on surface B.

These properties are illustrated in Figure 23.19. The density of lines through surface A is greater than the density of lines through surface B. Therefore, the electric field is more intense on surface A than on surface B. Furthermore, the fact that the lines at different locations point in different directions indicates that the field is nonuniform.

Representative electric field lines for the field due to a single positive point charge are shown in Figure 23.20a. Note that in this two-dimensional drawing we show only the field lines that lie in the plane containing the point charge. The lines are actually directed radially outward from the charge in all directions; thus, instead of the flat “wheel” of lines shown, you should picture an entire sphere of lines. Because a positive test charge placed in this field would be repelled by the positive point charge, the lines are directed radially away from the positive point

**Figure 23.20** The electric field lines for a point charge. (a) For a positive point charge, the lines are directed radially outward. (b) For a negative point charge, the lines are directed radially inward. Note that the figures show only those field lines that lie in the plane containing the charge. (c) The dark areas are small pieces of thread suspended in oil, which align with the electric field produced by a small charged conductor at the center.

charge. The electric field lines representing the field due to a single negative point charge are directed toward the charge (Fig. 23.20b). In either case, the lines are along the radial direction and extend all the way to infinity. Note that the lines become closer together as they approach the charge; this indicates that the strength of the field increases as we move toward the source charge.

The rules for drawing electric field lines are as follows:

- The lines must begin on a positive charge and terminate on a negative charge.
- The number of lines drawn leaving a positive charge or approaching a negative charge is proportional to the magnitude of the charge.
- No two field lines can cross.

Is this visualization of the electric field in terms of field lines consistent with Equation 23.4, the expression we obtained for  $E$  using Coulomb's law? To answer this question, consider an imaginary spherical surface of radius  $r$  concentric with a point charge. From symmetry, we see that the magnitude of the electric field is the same everywhere on the surface of the sphere. The number of lines  $N$  that emerge from the charge is equal to the number that penetrate the spherical surface. Hence, the number of lines per unit area on the sphere is  $N/4\pi r^2$  (where the surface area of the sphere is  $4\pi r^2$ ). Because  $E$  is proportional to the number of lines per unit area, we see that  $E$  varies as  $1/r^2$ ; this finding is consistent with Equation 23.4.

As we have seen, we use electric field lines to qualitatively describe the electric field. One problem with this model is that we always draw a finite number of lines from (or to) each charge. Thus, it appears as if the field acts only in certain directions; this is not true. Instead, the field is *continuous*—that is, it exists at every point. Another problem associated with this model is the danger of gaining the wrong impression from a two-dimensional drawing of field lines being used to describe a three-dimensional situation. Be aware of these shortcomings every time you either draw or look at a diagram showing electric field lines.

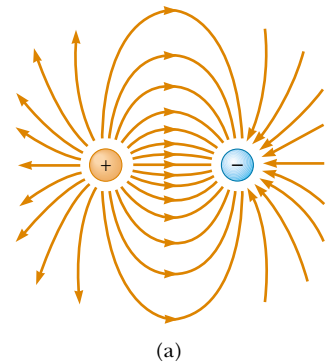

We choose the number of field lines starting from any positively charged object to be  $C'q$  and the number of lines ending on any negatively charged object to be  $C'|q|$ , where  $C'$  is an arbitrary proportionality constant. Once  $C'$  is chosen, the number of lines is fixed. For example, if object 1 has charge  $Q_1$  and object 2 has charge  $Q_2$ , then the ratio of number of lines is  $N_2/N_1 = Q_2/Q_1$ .

The electric field lines for two point charges of equal magnitude but opposite signs (an electric dipole) are shown in Figure 23.21. Because the charges are of equal magnitude, the number of lines that begin at the positive charge must equal the number that terminate at the negative charge. At points very near the charges, the lines are nearly radial. The high density of lines between the charges indicates a region of strong electric field.

Figure 23.22 shows the electric field lines in the vicinity of two equal positive point charges. Again, the lines are nearly radial at points close to either charge, and the same number of lines emerge from each charge because the charges are equal in magnitude. At great distances from the charges, the field is approximately equal to that of a single point charge of magnitude  $2q$ .

Finally, in Figure 23.23 we sketch the electric field lines associated with a positive charge  $+2q$  and a negative charge  $-q$ . In this case, the number of lines leaving  $+2q$  is twice the number terminating at  $-q$ . Hence, only half of the lines that leave the positive charge reach the negative charge. The remaining half terminate

#### Rules for drawing electric field lines

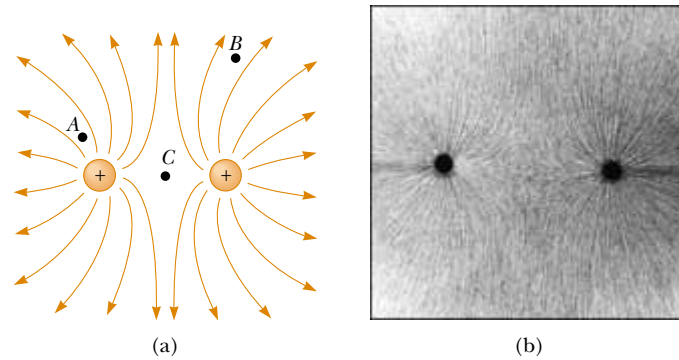

(a)

(b)

**Figure 23.21** (a) The electric field lines for two point charges of equal magnitude and opposite sign (an electric dipole). The number of lines leaving the positive charge equals the number terminating at the negative charge. (b) The dark lines are small pieces of thread suspended in oil, which align with the electric field of a dipole.

**Figure 23.22** (a) The electric field lines for two positive point charges. (The locations  $A$ ,  $B$ , and  $C$  are discussed in Quick Quiz 23.5.) (b) Pieces of thread suspended in oil, which align with the electric field created by two equal-magnitude positive charges.

**Figure 23.23** The electric field lines for a point charge  $+2q$  and a second point charge  $-q$ . Note that two lines leave  $+2q$  for every one that terminates on  $-q$ .

### Quick Quiz 23.5

Rank the magnitude of the electric field at points  $A$ ,  $B$ , and  $C$  shown in Figure 23.22a (greatest magnitude first).

## 23.7 MOTION OF CHARGED PARTICLES IN A UNIFORM ELECTRIC FIELD

When a particle of charge  $q$  and mass  $m$  is placed in an electric field  $\mathbf{E}$ , the electric force exerted on the charge is  $q\mathbf{E}$ . If this is the only force exerted on the particle, it must be the net force and so must cause the particle to accelerate. In this case, Newton's second law applied to the particle gives

$$\mathbf{F}_e = q\mathbf{E} = m\mathbf{a}$$

The acceleration of the particle is therefore

$$\mathbf{a} = \frac{q\mathbf{E}}{m} \quad (23.7)$$

If  $\mathbf{E}$  is uniform (that is, constant in magnitude and direction), then the acceleration is constant. If the particle has a positive charge, then its acceleration is in the direction of the electric field. If the particle has a negative charge, then its acceleration is in the direction opposite the electric field.

### EXAMPLE 23.10 An Accelerating Positive Charge

A positive point charge  $q$  of mass  $m$  is released from rest in a uniform electric field  $\mathbf{E}$  directed along the  $x$  axis, as shown in Figure 23.24. Describe its motion.

**Solution** The acceleration is constant and is given by  $q\mathbf{E}/m$ . The motion is simple linear motion along the  $x$  axis. Therefore, we can apply the equations of kinematics in one

dimension (see Chapter 2):

$$\begin{aligned}x_f &= x_i + v_{xi}t + \frac{1}{2}a_x t^2 \\v_{xf} &= v_{xi} + a_x t \\v_{xf}^2 &= v_{xi}^2 + 2a_x(x_f - x_i)\end{aligned}$$

Taking  $x_i = 0$  and  $v_{xi} = 0$ , we have

$$\begin{aligned}x_f &= \frac{1}{2}a_x t^2 = \frac{qE}{2m} t^2 \\v_{xf} &= a_x t = \frac{qE}{m} t \\v_{xf}^2 &= 2a_x x_f = \left(\frac{2qE}{m}\right)x_f\end{aligned}$$

The kinetic energy of the charge after it has moved a distance  $x = x_f - x_i$  is

$$K = \frac{1}{2}mv^2 = \frac{1}{2}m\left(\frac{2qE}{m}\right)x = qEx$$

We can also obtain this result from the work–kinetic energy

theorem because the work done by the electric force is  $F_e x = qEx$  and  $W = \Delta K$ .

**Figure 23.24** A positive point charge  $q$  in a uniform electric field  $\mathbf{E}$  undergoes constant acceleration in the direction of the field.

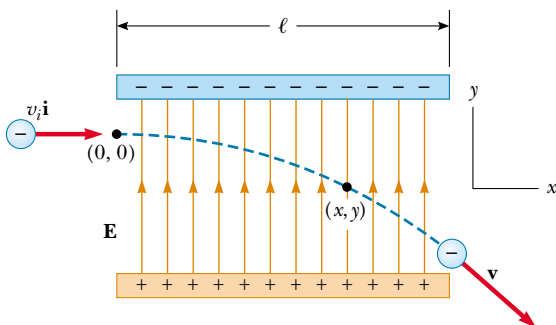

The electric field in the region between two oppositely charged flat metallic plates is approximately uniform (Fig. 23.25). Suppose an electron of charge  $-e$  is projected horizontally into this field with an initial velocity  $v_i \mathbf{i}$ . Because the electric field  $\mathbf{E}$  in Figure 23.25 is in the positive  $y$  direction, the acceleration of the electron is in the negative  $y$  direction. That is,

$$\mathbf{a} = -\frac{eE}{m} \mathbf{j} \quad (23.8)$$

Because the acceleration is constant, we can apply the equations of kinematics in two dimensions (see Chapter 4) with  $v_{xi} = v_i$  and  $v_{yi} = 0$ . After the electron has been in the electric field for a time  $t$ , the components of its velocity are

$$v_x = v_i = \text{constant} \quad (23.9)$$

$$v_y = a_y t = -\frac{eE}{m} t \quad (23.10)$$

**Figure 23.25** An electron is projected horizontally into a uniform electric field produced by two charged plates. The electron undergoes a downward acceleration (opposite  $\mathbf{E}$ ), and its motion is parabolic while it is between the plates.

Its coordinates after a time  $t$  in the field are

$$x = v_i t \quad (23.11)$$

$$y = \frac{1}{2} a_y t^2 = -\frac{1}{2} \frac{eE}{m} t^2 \quad (23.12)$$

Substituting the value  $t = x/v_i$  from Equation 23.11 into Equation 23.12, we see that  $y$  is proportional to  $x^2$ . Hence, the trajectory is a parabola. After the electron leaves the field, it continues to move in a straight line in the direction of  $\mathbf{v}$  in Figure 23.25, obeying Newton's first law, with a speed  $v > v_i$ .

Note that we have neglected the gravitational force acting on the electron. This is a good approximation when we are dealing with atomic particles. For an electric field of  $10^4$  N/C, the ratio of the magnitude of the electric force  $eE$  to the magnitude of the gravitational force  $mg$  is of the order of  $10^{14}$  for an electron and of the order of  $10^{11}$  for a proton.

### EXAMPLE 23.11 An Accelerated Electron

An electron enters the region of a uniform electric field as shown in Figure 23.25, with  $v_i = 3.00 \times 10^6$  m/s and  $E = 200$  N/C. The horizontal length of the plates is  $\ell = 0.100$  m. (a) Find the acceleration of the electron while it is in the electric field.

**Solution** The charge on the electron has an absolute value of  $1.60 \times 10^{-19}$  C, and  $m = 9.11 \times 10^{-31}$  kg. Therefore, Equation 23.8 gives

$$\begin{aligned} \mathbf{a} &= -\frac{eE}{m} \mathbf{j} = -\frac{(1.60 \times 10^{-19} \text{ C})(200 \text{ N/C})}{9.11 \times 10^{-31} \text{ kg}} \mathbf{j} \\ &= -3.51 \times 10^{13} \mathbf{j} \text{ m/s}^2 \end{aligned}$$

(b) Find the time it takes the electron to travel through the field.

**Solution** The horizontal distance across the field is  $\ell = 0.100$  m. Using Equation 23.11 with  $x = \ell$ , we find that the time spent in the electric field is

$$t = \frac{\ell}{v_i} = \frac{0.100 \text{ m}}{3.00 \times 10^6 \text{ m/s}} = 3.33 \times 10^{-8} \text{ s}$$

(c) What is the vertical displacement  $y$  of the electron while it is in the field?

**Solution** Using Equation 23.12 and the results from parts (a) and (b), we find that

$$\begin{aligned} y &= \frac{1}{2} a_y t^2 = \frac{1}{2} (-3.51 \times 10^{13} \text{ m/s}^2) (3.33 \times 10^{-8} \text{ s})^2 \\ &= -0.0195 \text{ m} = -1.95 \text{ cm} \end{aligned}$$

If the separation between the plates is less than this, the electron will strike the positive plate.

**Exercise** Find the speed of the electron as it emerges from the field.

**Answer**  $3.22 \times 10^6$  m/s.

## The Cathode Ray Tube

The example we just worked describes a portion of a cathode ray tube (CRT). This tube, illustrated in Figure 23.26, is commonly used to obtain a visual display of electronic information in oscilloscopes, radar systems, television receivers, and computer monitors. The CRT is a vacuum tube in which a beam of electrons is accelerated and deflected under the influence of electric or magnetic fields. The electron beam is produced by an assembly called an *electron gun* located in the neck of the tube. These electrons, if left undisturbed, travel in a straight-line path until they strike the front of the CRT, the "screen," which is coated with a material that emits visible light when bombarded with electrons.

In an oscilloscope, the electrons are deflected in various directions by two sets of plates placed at right angles to each other in the neck of the tube. (A television

**Figure 23.26** Schematic diagram of a cathode ray tube. Electrons leaving the hot cathode C are accelerated to the anode A. In addition to accelerating electrons, the electron gun is also used to focus the beam of electrons, and the plates deflect the beam.

CRT steers the beam with a magnetic field, as discussed in Chapter 29.) An external electric circuit is used to control the amount of charge present on the plates. The placing of positive charge on one horizontal plate and negative charge on the other creates an electric field between the plates and allows the beam to be steered from side to side. The vertical deflection plates act in the same way, except that changing the charge on them deflects the beam vertically.

## SUMMARY

**Electric charges** have the following important properties:

- Unlike charges attract one another, and like charges repel one another.
- Charge is conserved.
- Charge is quantized—that is, it exists in discrete packets that are some integral multiple of the electronic charge.

**Conductors** are materials in which charges move freely. **Insulators** are materials in which charges do not move freely.

**Coulomb's law** states that the electric force exerted by a charge  $q_1$  on a second charge  $q_2$  is

$$\mathbf{F}_{12} = k_e \frac{q_1 q_2}{r^2} \hat{\mathbf{r}} \quad (23.2)$$

where  $r$  is the distance between the two charges and  $\hat{\mathbf{r}}$  is a unit vector directed from  $q_1$  to  $q_2$ . The constant  $k_e$ , called the Coulomb constant, has the value  $k_e = 8.99 \times 10^9 \text{ N} \cdot \text{m}^2/\text{C}^2$ .

The smallest unit of charge known to exist in nature is the charge on an electron or proton,  $|e| = 1.602 \, 19 \times 10^{-19} \text{ C}$ .

The electric field  $\mathbf{E}$  at some point in space is defined as the electric force  $\mathbf{F}_e$  that acts on a small positive test charge placed at that point divided by the magnitude of the test charge  $q_0$ :

$$\mathbf{E} \equiv \frac{\mathbf{F}_e}{q_0} \quad (23.3)$$

At a distance  $r$  from a point charge  $q$ , the electric field due to the charge is given by

$$\mathbf{E} = k_e \frac{q}{r^2} \hat{\mathbf{r}} \quad (23.4)$$

where  $\hat{\mathbf{r}}$  is a unit vector directed from the charge to the point in question. The

electric field is directed radially outward from a positive charge and radially inward toward a negative charge.

The electric field due to a group of point charges can be obtained by using the superposition principle. That is, the total electric field at some point equals the vector sum of the electric fields of all the charges:

$$\mathbf{E} = k_e \sum_i \frac{q_i}{r_i^2} \hat{\mathbf{r}}_i \quad (23.5)$$

The electric field at some point of a continuous charge distribution is

$$\mathbf{E} = k_e \int \frac{dq}{r^2} \hat{\mathbf{r}} \quad (23.6)$$

where  $dq$  is the charge on one element of the charge distribution and  $r$  is the distance from the element to the point in question.

**Electric field lines** describe an electric field in any region of space. The number of lines per unit area through a surface perpendicular to the lines is proportional to the magnitude of  $\mathbf{E}$  in that region.

A charged particle of mass  $m$  and charge  $q$  moving in an electric field  $\mathbf{E}$  has an acceleration

$$\mathbf{a} = \frac{q\mathbf{E}}{m} \quad (23.7)$$

### Problem-Solving Hints

#### Finding the Electric Field

- **Units:** In calculations using the Coulomb constant  $k_e (= 1/4\pi\epsilon_0)$ , charges must be expressed in coulombs and distances in meters.
- **Calculating the electric field of point charges:** To find the total electric field at a given point, first calculate the electric field at the point due to each individual charge. The resultant field at the point is the vector sum of the fields due to the individual charges.
- **Continuous charge distributions:** When you are confronted with problems that involve a continuous distribution of charge, the vector sums for evaluating the total electric field at some point must be replaced by vector integrals. Divide the charge distribution into infinitesimal pieces, and calculate the vector sum by integrating over the entire charge distribution. You should review Examples 23.7 through 23.9.
- **Symmetry:** With both distributions of point charges and continuous charge distributions, take advantage of any symmetry in the system to simplify your calculations.

### QUESTIONS

1. Sparks are often observed (or heard) on a dry day when clothes are removed in the dark. Explain.
2. Explain from an atomic viewpoint why charge is usually transferred by electrons.
3. A balloon is negatively charged by rubbing and then clings to a wall. Does this mean that the wall is positively charged? Why does the balloon eventually fall?
4. A light, uncharged metallic sphere suspended from a thread is attracted to a charged rubber rod. After touching the rod, the sphere is repelled by the rod. Explain.

5. Explain what is meant by the term “a neutral atom.”
6. Why do some clothes cling together and to your body after they are removed from a dryer?
7. A large metallic sphere insulated from ground is charged with an electrostatic generator while a person standing on an insulating stool holds the sphere. Why is it safe to do this? Why wouldn't it be safe for another person to touch the sphere after it has been charged?
8. What are the similarities and differences between Newton's law of gravitation,  $F_g = Gm_1m_2/r^2$ , and Coulomb's law,  $F_e = k_e q_1q_2/r^2$ ?
9. Assume that someone proposes a theory that states that people are bound to the Earth by electric forces rather than by gravity. How could you prove this theory wrong?
10. How would you experimentally distinguish an electric field from a gravitational field?
11. Would life be different if the electron were positively charged and the proton were negatively charged? Does the choice of signs have any bearing on physical and chemical interactions? Explain.
12. When defining the electric field, why is it necessary to specify that the magnitude of the test charge be very small (that is, why is it necessary to take the limit of  $\mathbf{F}_e/q$  as  $q \rightarrow 0$ )?
13. Two charged conducting spheres, each of radius  $a$ , are separated by a distance  $r > 2a$ . Is the force on either sphere given by Coulomb's law? Explain. (*Hint*: Refer to Chapter 14 on gravitation.)
14. When is it valid to approximate a charge distribution by a point charge?
15. Is it possible for an electric field to exist in empty space? Explain.
16. Explain why electric field lines never cross. (*Hint*:  $\mathbf{E}$  must have a unique direction at all points.)
17. A free electron and free proton are placed in an identical electric field. Compare the electric forces on each particle. Compare their accelerations.
18. Explain what happens to the magnitude of the electric field of a point charge as  $r$  approaches zero.
19. A negative charge is placed in a region of space where the electric field is directed vertically upward. What is the direction of the electric force experienced by this charge?
20. A charge  $4q$  is a distance  $r$  from a charge  $-q$ . Compare the number of electric field lines leaving the charge  $4q$  with the number entering the charge  $-q$ .
21. In Figure 23.23, where do the extra lines leaving the charge  $+2q$  end?
22. Consider two equal point charges separated by some distance  $d$ . At what point (other than  $\infty$ ) would a third test charge experience no net force?
23. A negative point charge  $-q$  is placed at the point  $P$  near the positively charged ring shown in Figure 23.17. If  $x \ll a$ , describe the motion of the point charge if it is released from rest.
24. Explain the differences between linear, surface, and volume charge densities, and give examples of when each would be used.
25. If the electron in Figure 23.25 is projected into the electric field with an arbitrary velocity  $\mathbf{v}_i$  (at an angle to  $\mathbf{E}$ ), will its trajectory still be parabolic? Explain.
26. It has been reported that in some instances people near where a lightning bolt strikes the Earth have had their clothes thrown off. Explain why this might happen.
27. Why should a ground wire be connected to the metallic support rod for a television antenna?
28. A light strip of aluminum foil is draped over a wooden rod. When a rod carrying a positive charge is brought close to the foil, the two parts of the foil stand apart. Why? What kind of charge is on the foil?
29. Why is it more difficult to charge an object by rubbing on a humid day than on a dry day?

## PROBLEMS

1, 2, 3 = straightforward, intermediate, challenging □ = full solution available in the *Student Solutions Manual and Study Guide*

 = paired numerical/symbolic problems

### Section 23.1 Properties of Electric Charges

### Section 23.2 Insulators and Conductors

### Section 23.3 Coulomb's Law

1. (a) Calculate the number of electrons in a small, electrically neutral silver pin that has a mass of 10.0 g. Silver has 47 electrons per atom, and its molar mass is 107.87 g/mol. (b) Electrons are added to the pin until the net negative charge is 1.00 mC. How many electrons are added for every  $10^9$  electrons already present?
2. (a) Two protons in a molecule are separated by a distance of  $3.80 \times 10^{-10}$  m. Find the electric force exerted by one proton on the other. (b) How does the magnitude of this

force compare with the magnitude of the gravitational force between the two protons? (c) What must be the charge-to-mass ratio of a particle if the magnitude of the gravitational force between two of these particles equals the magnitude of the electric force between them?

- WEB 3. Richard Feynman once said that if two persons stood at arm's length from each other and each person had 1% more electrons than protons, the force of repulsion between them would be enough to lift a “weight” equal to that of the entire Earth. Carry out an order-of-magnitude calculation to substantiate this assertion.
4. Two small silver spheres, each with a mass of 10.0 g, are separated by 1.00 m. Calculate the fraction of the elec-

trons in one sphere that must be transferred to the other to produce an attractive force of  $1.00 \times 10^4$  N (about 1 ton) between the spheres. (The number of electrons per atom of silver is 47, and the number of atoms per gram is Avogadro's number divided by the molar mass of silver, 107.87 g/mol.)

- Suppose that 1.00 g of hydrogen is separated into electrons and protons. Suppose also that the protons are placed at the Earth's north pole and the electrons are placed at the south pole. What is the resulting compressional force on the Earth?
- Two identical conducting small spheres are placed with their centers 0.300 m apart. One is given a charge of 12.0 nC, and the other is given a charge of  $-18.0$  nC. (a) Find the electric force exerted on one sphere by the other. (b) The spheres are connected by a conducting wire. Find the electric force between the two after equilibrium has occurred.
- Three point charges are located at the corners of an equilateral triangle, as shown in Figure P23.7. Calculate the net electric force on the  $7.00\text{-}\mu\text{C}$  charge.

Figure P23.7 Problems 7 and 15.

- Two small beads having positive charges  $3q$  and  $q$  are fixed at the opposite ends of a horizontal insulating rod extending from the origin to the point  $x = d$ . As shown in Figure P23.8, a third small charged bead is free to slide on the rod. At what position is the third bead in equilibrium? Can it be in stable equilibrium?

Figure P23.8

- Review Problem.** In the Bohr theory of the hydrogen atom, an electron moves in a circular orbit about a proton, where the radius of the orbit is  $0.529 \times 10^{-10}$  m. (a) Find the electric force between the two. (b) If this force causes the centripetal acceleration of the electron, what is the speed of the electron?

- Review Problem.** Two identical point charges each having charge  $+q$  are fixed in space and separated by a distance  $d$ . A third point charge  $-Q$  of mass  $m$  is free to move and lies initially at rest on a perpendicular bisector of the two fixed charges a distance  $x$  from the midpoint of the two fixed charges (Fig. P23.10). (a) Show that if  $x$  is small compared with  $d$ , the motion of  $-Q$  is simple harmonic along the perpendicular bisector. Determine the period of that motion. (b) How fast will the charge  $-Q$  be moving when it is at the midpoint between the two fixed charges, if initially it is released at a distance  $x = a \ll d$  from the midpoint?

Figure P23.10

### Section 23.4 The Electric Field

- What are the magnitude and direction of the electric field that will balance the weight of (a) an electron and (b) a proton? (Use the data in Table 23.1.)
- An object having a net charge of  $24.0 \mu\text{C}$  is placed in a uniform electric field of  $610$  N/C that is directed vertically. What is the mass of this object if it "floats" in the field?
- In Figure P23.13, determine the point (other than infinity) at which the electric field is zero.

Figure P23.13

- An airplane is flying through a thundercloud at a height of 2 000 m. (This is a very dangerous thing to do because of updrafts, turbulence, and the possibility of electric discharge.) If there are charge concentrations of  $+40.0$  C at a height of 3 000 m within the cloud and of  $-40.0$  C at a height of 1 000 m, what is the electric field  $E$  at the aircraft?

15. Three charges are at the corners of an equilateral triangle, as shown in Figure P23.7. (a) Calculate the electric field at the position of the  $2.00\text{-}\mu\text{C}$  charge due to the  $7.00\text{-}\mu\text{C}$  and  $-4.00\text{-}\mu\text{C}$  charges. (b) Use your answer to part (a) to determine the force on the  $2.00\text{-}\mu\text{C}$  charge.
16. Three point charges are arranged as shown in Figure P23.16. (a) Find the vector electric field that the  $6.00\text{-nC}$  and  $-3.00\text{-nC}$  charges together create at the origin. (b) Find the vector force on the  $5.00\text{-nC}$  charge.

Figure P23.16

- WEB 17. Three equal positive charges  $q$  are at the corners of an equilateral triangle of side  $a$ , as shown in Figure P23.17. (a) Assume that the three charges together create an electric field. Find the location of a point (other than  $\infty$ ) where the electric field is zero. (*Hint:* Sketch the field lines in the plane of the charges.) (b) What are the magnitude and direction of the electric field at  $P$  due to the two charges at the base?

Figure P23.17

18. Two  $2.00\text{-}\mu\text{C}$  point charges are located on the  $x$  axis. One is at  $x = 1.00\text{ m}$ , and the other is at  $x = -1.00\text{ m}$ . (a) Determine the electric field on the  $y$  axis at  $y = 0.500\text{ m}$ . (b) Calculate the electric force on a  $-3.00\text{-}\mu\text{C}$  charge placed on the  $y$  axis at  $y = 0.500\text{ m}$ .
19. Four point charges are at the corners of a square of side  $a$ , as shown in Figure P23.19. (a) Determine the magnitude and direction of the electric field at the location of charge  $q$ . (b) What is the resultant force on  $q$ ?
20. A point particle having charge  $q$  is located at point  $(x_0, y_0)$  in the  $xy$  plane. Show that the  $x$  and  $y$  components

Figure P23.19

nents of the electric field at point  $(x, y)$  due to this charge  $q$  are

$$E_x = \frac{k_e q (x - x_0)}{[(x - x_0)^2 + (y - y_0)^2]^{3/2}}$$

$$E_y = \frac{k_e q (y - y_0)}{[(x - x_0)^2 + (y - y_0)^2]^{3/2}}$$

21. Consider the electric dipole shown in Figure P23.21. Show that the electric field at a distant point along the  $x$  axis is  $E_x \cong 4k_e qa/x^3$ .

Figure P23.21

22. Consider  $n$  equal positive point charges each of magnitude  $Q/n$  placed symmetrically around a circle of radius  $R$ . (a) Calculate the magnitude of the electric field  $E$  at a point a distance  $x$  on the line passing through the center of the circle and perpendicular to the plane of the circle. (b) Explain why this result is identical to the one obtained in Example 23.8.
23. Consider an infinite number of identical charges (each of charge  $q$ ) placed along the  $x$  axis at distances  $a, 2a, 3a, 4a, \dots$  from the origin. What is the electric field at the origin due to this distribution? *Hint:* Use the fact that

$$1 + \frac{1}{2^2} + \frac{1}{3^2} + \frac{1}{4^2} + \dots = \frac{\pi^2}{6}$$

### Section 23.5 Electric Field of a Continuous Charge Distribution

24. A rod  $14.0\text{ cm}$  long is uniformly charged and has a total charge of  $-22.0\text{ }\mu\text{C}$ . Determine the magnitude and direction of the electric field along the axis of the rod at a point  $36.0\text{ cm}$  from its center.

25. A continuous line of charge lies along the  $x$  axis, extending from  $x = +x_0$  to positive infinity. The line carries a uniform linear charge density  $\lambda_0$ . What are the magnitude and direction of the electric field at the origin?
26. A line of charge starts at  $x = +x_0$  and extends to positive infinity. If the linear charge density is  $\lambda = \lambda_0 x_0/x$ , determine the electric field at the origin.
27. A uniformly charged ring of radius 10.0 cm has a total charge of  $75.0 \mu\text{C}$ . Find the electric field on the axis of the ring at (a) 1.00 cm, (b) 5.00 cm, (c) 30.0 cm, and (d) 100 cm from the center of the ring.
28. Show that the maximum field strength  $E_{\text{max}}$  along the axis of a uniformly charged ring occurs at  $x = a/\sqrt{2}$  (see Fig. 23.17) and has the value  $Q/(6\sqrt{3}\pi\epsilon_0 a^2)$ .
29. A uniformly charged disk of radius 35.0 cm carries a charge density of  $7.90 \times 10^{-3} \text{ C/m}^2$ . Calculate the electric field on the axis of the disk at (a) 5.00 cm, (b) 10.0 cm, (c) 50.0 cm, and (d) 200 cm from the center of the disk.
30. Example 23.9 derives the exact expression for the electric field at a point on the axis of a uniformly charged disk. Consider a disk of radius  $R = 3.00 \text{ cm}$  having a uniformly distributed charge of  $+5.20 \mu\text{C}$ . (a) Using the result of Example 23.9, compute the electric field at a point on the axis and 3.00 mm from the center. Compare this answer with the field computed from the near-field approximation  $E = \sigma/2\epsilon_0$ . (b) Using the result of Example 23.9, compute the electric field at a point on the axis and 30.0 cm from the center of the disk. Compare this result with the electric field obtained by treating the disk as a  $+5.20\text{-}\mu\text{C}$  point charge at a distance of 30.0 cm.
31. The electric field along the axis of a uniformly charged disk of radius  $R$  and total charge  $Q$  was calculated in Example 23.9. Show that the electric field at distances  $x$  that are great compared with  $R$  approaches that of a point charge  $Q = \sigma\pi R^2$ . (Hint: First show that  $x/(x^2 + R^2)^{1/2} = (1 + R^2/x^2)^{-1/2}$ , and use the binomial expansion  $(1 + \delta)^n \approx 1 + n\delta$  when  $\delta \ll 1$ .)
32. A piece of Styrofoam having a mass  $m$  carries a net charge of  $-q$  and floats above the center of a very large horizontal sheet of plastic that has a uniform charge density on its surface. What is the charge per unit area on the plastic sheet?
- WEB 33. A uniformly charged insulating rod of length 14.0 cm is bent into the shape of a semicircle, as shown in Figure P23.33. The rod has a total charge of  $-7.50 \mu\text{C}$ . Find the magnitude and direction of the electric field at  $O$ , the center of the semicircle.
34. (a) Consider a uniformly charged right circular cylindrical shell having total charge  $Q$ , radius  $R$ , and height  $h$ . Determine the electric field at a point a distance  $d$  from the right side of the cylinder, as shown in Figure P23.34. (Hint: Use the result of Example 23.8 and treat the cylinder as a collection of ring charges.) (b) Consider now a solid cylinder with the same dimensions and

Figure P23.33

Figure P23.34

carrying the same charge, which is uniformly distributed through its volume. Use the result of Example 23.9 to find the field it creates at the same point.

35. A thin rod of length  $\ell$  and uniform charge per unit length  $\lambda$  lies along the  $x$  axis, as shown in Figure P23.35. (a) Show that the electric field at  $P$ , a distance  $y$  from the rod, along the perpendicular bisector has no  $x$  component and is given by  $E = 2k_e\lambda \sin \theta_0/y$ . (b) Using your result to part (a), show that the field of a rod of infinite length is  $E = 2k_e\lambda/y$ . (Hint: First calculate the field at  $P$  due to an element of length  $dx$ , which has a charge  $\lambda dx$ . Then change variables from  $x$  to  $\theta$ , using the facts that  $x = y \tan \theta$  and  $dx = y \sec^2 \theta d\theta$ , and integrate over  $\theta$ .)

Figure P23.35

36. Three solid plastic cylinders all have a radius of 2.50 cm and a length of 6.00 cm. One (a) carries charge with

uniform density  $15.0 \text{ nC/m}^2$  everywhere on its surface. Another (b) carries charge with the same uniform density on its curved lateral surface only. The third (c) carries charge with uniform density  $500 \text{ nC/m}^3$  throughout the plastic. Find the charge of each cylinder.

37. Eight solid plastic cubes, each  $3.00 \text{ cm}$  on each edge, are glued together to form each one of the objects (i, ii, iii, and iv) shown in Figure P23.37. (a) If each object carries charge with a uniform density of  $400 \text{ nC/m}^3$  throughout its volume, what is the charge of each object? (b) If each object is given charge with a uniform density of  $15.0 \text{ nC/m}^2$  everywhere on its exposed surface, what is the charge on each object? (c) If charge is placed only on the edges where perpendicular surfaces meet, with a uniform density of  $80.0 \text{ pC/m}$ , what is the charge of each object?

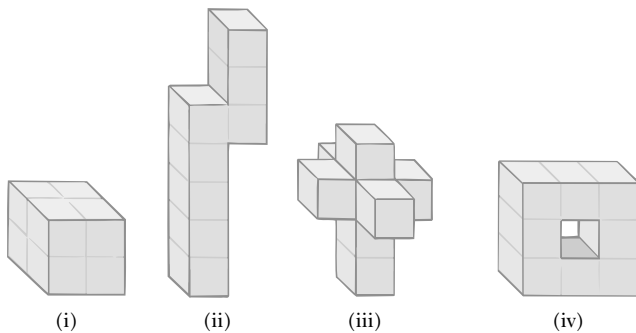

Figure P23.37

### Section 23.6 Electric Field Lines

38. A positively charged disk has a uniform charge per unit area as described in Example 23.9. Sketch the electric field lines in a plane perpendicular to the plane of the disk passing through its center.
39. A negatively charged rod of finite length has a uniform charge per unit length. Sketch the electric field lines in a plane containing the rod.
40. Figure P23.40 shows the electric field lines for two point charges separated by a small distance. (a) Determine the ratio  $q_1/q_2$ . (b) What are the signs of  $q_1$  and  $q_2$ ?

Figure P23.40

### Section 23.7 Motion of Charged Particles in a Uniform Electric Field

41. An electron and a proton are each placed at rest in an electric field of  $520 \text{ N/C}$ . Calculate the speed of each particle  $48.0 \text{ ns}$  after being released.
42. A proton is projected in the positive  $x$  direction into a region of uniform electric field  $\mathbf{E} = -6.00 \times 10^5 \mathbf{i} \text{ N/C}$ . The proton travels  $7.00 \text{ cm}$  before coming to rest. Determine (a) the acceleration of the proton, (b) its initial speed, and (c) the time it takes the proton to come to rest.
43. A proton accelerates from rest in a uniform electric field of  $640 \text{ N/C}$ . At some later time, its speed has reached  $1.20 \times 10^6 \text{ m/s}$  (nonrelativistic, since  $v$  is much less than the speed of light). (a) Find the acceleration of the proton. (b) How long does it take the proton to reach this speed? (c) How far has it moved in this time? (d) What is its kinetic energy at this time?
44. The electrons in a particle beam each have a kinetic energy of  $1.60 \times 10^{-17} \text{ J}$ . What are the magnitude and direction of the electric field that stops these electrons in a distance of  $10.0 \text{ cm}$ ?
- WEB 45. The electrons in a particle beam each have a kinetic energy  $K$ . What are the magnitude and direction of the electric field that stops these electrons in a distance  $d$ ?
46. A positively charged bead having a mass of  $1.00 \text{ g}$  falls from rest in a vacuum from a height of  $5.00 \text{ m}$  in a uniform vertical electric field with a magnitude of  $1.00 \times 10^4 \text{ N/C}$ . The bead hits the ground at a speed of  $21.0 \text{ m/s}$ . Determine (a) the direction of the electric field (up or down) and (b) the charge on the bead.
47. A proton moves at  $4.50 \times 10^5 \text{ m/s}$  in the horizontal direction. It enters a uniform vertical electric field with a magnitude of  $9.60 \times 10^3 \text{ N/C}$ . Ignoring any gravitational effects, find (a) the time it takes the proton to travel  $5.00 \text{ cm}$  horizontally, (b) its vertical displacement after it has traveled  $5.00 \text{ cm}$  horizontally, and (c) the horizontal and vertical components of its velocity after it has traveled  $5.00 \text{ cm}$  horizontally.
48. An electron is projected at an angle of  $30.0^\circ$  above the horizontal at a speed of  $8.20 \times 10^5 \text{ m/s}$  in a region where the electric field is  $\mathbf{E} = 390 \mathbf{j} \text{ N/C}$ . Neglecting the effects of gravity, find (a) the time it takes the electron to return to its initial height, (b) the maximum height it reaches, and (c) its horizontal displacement when it reaches its maximum height.
49. Protons are projected with an initial speed  $v_i = 9.55 \times 10^3 \text{ m/s}$  into a region where a uniform electric field  $\mathbf{E} = (-720 \mathbf{j}) \text{ N/C}$  is present, as shown in Figure P23.49. The protons are to hit a target that lies at a horizontal distance of  $1.27 \text{ mm}$  from the point where the protons are launched. Find (a) the two projection angles  $\theta$  that result in a hit and (b) the total time of flight for each trajectory.

Figure P23.49

## ADDITIONAL PROBLEMS

50. Three point charges are aligned along the  $x$  axis as shown in Figure P23.50. Find the electric field at (a) the position  $(2.00, 0)$  and (b) the position  $(0, 2.00)$ .

Figure P23.50

51. A uniform electric field of magnitude  $640 \text{ N/C}$  exists between two parallel plates that are  $4.00 \text{ cm}$  apart. A proton is released from the positive plate at the same instant that an electron is released from the negative plate. (a) Determine the distance from the positive plate at which the two pass each other. (Ignore the electrical attraction between the proton and electron.) (b) Repeat part (a) for a sodium ion ( $\text{Na}^+$ ) and a chlorine ion ( $\text{Cl}^-$ ).

52. A small,  $2.00\text{-g}$  plastic ball is suspended by a  $20.0\text{-cm}$ -long string in a uniform electric field, as shown in Figure P23.52. If the ball is in equilibrium when the string

Figure P23.52

makes a  $15.0^\circ$  angle with the vertical, what is the net charge on the ball?

- WEB 53. A charged cork ball of mass  $1.00 \text{ g}$  is suspended on a light string in the presence of a uniform electric field, as shown in Figure P23.53. When  $\mathbf{E} = (3.00\mathbf{i} + 5.00\mathbf{j}) \times 10^5 \text{ N/C}$ , the ball is in equilibrium at  $\theta = 37.0^\circ$ . Find (a) the charge on the ball and (b) the tension in the string.
54. A charged cork ball of mass  $m$  is suspended on a light string in the presence of a uniform electric field, as shown in Figure P23.53. When  $\mathbf{E} = (A\mathbf{i} + B\mathbf{j}) \text{ N/C}$ , where  $A$  and  $B$  are positive numbers, the ball is in equilibrium at the angle  $\theta$ . Find (a) the charge on the ball and (b) the tension in the string.

Figure P23.53 Problems 53 and 54.

55. Four identical point charges ( $q = +10.0 \mu\text{C}$ ) are located on the corners of a rectangle, as shown in Figure P23.55. The dimensions of the rectangle are  $L = 60.0 \text{ cm}$  and  $W = 15.0 \text{ cm}$ . Calculate the magnitude and direction of the net electric force exerted on the charge at the lower left corner by the other three charges.

Figure P23.55

56. Three identical small Styrofoam balls ( $m = 2.00 \text{ g}$ ) are suspended from a fixed point by three nonconducting threads, each with a length of  $50.0 \text{ cm}$  and with negli-

ble mass. At equilibrium the three balls form an equilateral triangle with sides of 30.0 cm. What is the common charge  $q$  carried by each ball?

57. Two identical metallic blocks resting on a frictionless horizontal surface are connected by a light metallic spring having the spring constant  $k = 100 \text{ N/m}$  and an unstretched length of 0.300 m, as shown in Figure P23.57a. A total charge of  $Q$  is slowly placed on the system, causing the spring to stretch to an equilibrium length of 0.400 m, as shown in Figure P23.57b. Determine the value of  $Q$ , assuming that all the charge resides on the blocks and that the blocks are like point charges.
58. Two identical metallic blocks resting on a frictionless horizontal surface are connected by a light metallic spring having a spring constant  $k$  and an unstretched length  $L_i$ , as shown in Figure P23.57a. A total charge of  $Q$  is slowly placed on the system, causing the spring to stretch to an equilibrium length  $L$ , as shown in Figure P23.57b. Determine the value of  $Q$ , assuming that all the charge resides on the blocks and that the blocks are like point charges.

Figure P23.57 Problems 57 and 58.

59. Identical thin rods of length  $2a$  carry equal charges,  $+Q$ , uniformly distributed along their lengths. The rods lie along the  $x$  axis with their centers separated by a distance of  $b > 2a$  (Fig. P23.59). Show that the magnitude of the force exerted by the left rod on the right one is given by

$$F = \left( \frac{k_e Q^2}{4a^2} \right) \ln \left( \frac{b^2}{b^2 - 4a^2} \right)$$

60. A particle is said to be nonrelativistic as long as its speed is less than one-tenth the speed of light, or less than  $3.00 \times 10^7 \text{ m/s}$ . (a) How long will an electron remain nonrelativistic if it starts from rest in a region of an electric field of  $1.00 \text{ N/C}$ ? (b) How long will a proton remain nonrelativistic in the same electric field? (c) Electric fields are commonly much larger than

Figure P23.59

$1 \text{ N/C}$ . Will the charged particle remain nonrelativistic for a shorter or a longer time in a much larger electric field?

61. A line of positive charge is formed into a semicircle of radius  $R = 60.0 \text{ cm}$ , as shown in Figure P23.61. The charge per unit length along the semicircle is described by the expression  $\lambda = \lambda_0 \cos \theta$ . The total charge on the semicircle is  $12.0 \mu\text{C}$ . Calculate the total force on a charge of  $3.00 \mu\text{C}$  placed at the center of curvature.

Figure P23.61

62. Two small spheres, each of mass 2.00 g, are suspended by light strings 10.0 cm in length (Fig. P23.62). A uniform electric field is applied in the  $x$  direction. The spheres have charges equal to  $-5.00 \times 10^{-8} \text{ C}$  and  $+5.00 \times 10^{-8} \text{ C}$ . Determine the electric field that enables the spheres to be in equilibrium at an angle of  $\theta = 10.0^\circ$ .

Figure P23.62

- 63.** Two small spheres of mass  $m$  are suspended from strings of length  $\ell$  that are connected at a common point. One sphere has charge  $Q$ ; the other has charge  $2Q$ . Assume that the angles  $\theta_1$  and  $\theta_2$  that the strings make with the vertical are small. (a) How are  $\theta_1$  and  $\theta_2$  related? (b) Show that the distance  $r$  between the spheres is

$$r \cong \left( \frac{4k_e Q^2 \ell}{mg} \right)^{1/3}$$

- 64.** Three charges of equal magnitude  $q$  are fixed in position at the vertices of an equilateral triangle (Fig. P23.64). A fourth charge  $Q$  is free to move along the positive  $x$  axis under the influence of the forces exerted by the three fixed charges. Find a value for  $s$  for which  $Q$  is in equilibrium. You will need to solve a transcendental equation.

Figure P23.64

- 65. Review Problem.** Four identical point charges, each having charge  $+q$ , are fixed at the corners of a square of side  $L$ . A fifth point charge  $-Q$  lies a distance  $z$  along the line perpendicular to the plane of the square and passing through the center of the square (Fig. P23.65). (a) Show that the force exerted on  $-Q$  by the other four charges is

$$\mathbf{F} = -\frac{4k_e q Q z}{\left( z^2 + \frac{L^2}{2} \right)^{3/2}} \mathbf{k}$$

Note that this force is directed toward the center of the square whether  $z$  is positive ( $-Q$  above the square) or negative ( $-Q$  below the square). (b) If  $z$  is small compared with  $L$ , the above expression reduces to  $\mathbf{F} \approx -(\text{constant})z\mathbf{k}$ . Why does this imply that the motion of  $-Q$  is simple harmonic, and what would be the period of this motion if the mass of  $-Q$  were  $m$ ?

Figure P23.65

- 66. Review Problem.** A 1.00-g cork ball with a charge of  $2.00 \mu\text{C}$  is suspended vertically on a 0.500-m-long light string in the presence of a uniform, downward-directed electric field of magnitude  $E = 1.00 \times 10^5 \text{ N/C}$ . If the ball is displaced slightly from the vertical, it oscillates like a simple pendulum. (a) Determine the period of this oscillation. (b) Should gravity be included in the calculation for part (a)? Explain.
- 67.** Three charges of equal magnitude  $q$  reside at the corners of an equilateral triangle of side length  $a$  (Fig. P23.67). (a) Find the magnitude and direction of the electric field at point  $P$ , midway between the negative charges, in terms of  $k_e$ ,  $q$ , and  $a$ . (b) Where must a  $-4q$  charge be placed so that any charge located at  $P$  experiences no net electric force? In part (b), let  $P$  be the origin and let the distance between the  $+q$  charge and  $P$  be 1.00 m.

Figure P23.67

- 68.** Two identical beads each have a mass  $m$  and charge  $q$ . When placed in a hemispherical bowl of radius  $R$  with frictionless, nonconducting walls, the beads move, and at equilibrium they are a distance  $R$  apart (Fig. P23.68). Determine the charge on each bead.

Figure P23.68

69. Eight point charges, each of magnitude  $q$ , are located on the corners of a cube of side  $s$ , as shown in Figure P23.69. (a) Determine the  $x$ ,  $y$ , and  $z$  components of the resultant force exerted on the charge located at point  $A$  by the other charges. (b) What are the magnitude and direction of this resultant force?

Figure P23.69 Problems 69 and 70.

70. Consider the charge distribution shown in Figure P23.69. (a) Show that the magnitude of the electric field at the center of any face of the cube has a value of  $2.18k_e q/s^2$ . (b) What is the direction of the electric field at the center of the top face of the cube?
71. A line of charge with a uniform density of  $35.0 \text{ nC/m}$  lies along the line  $y = -15.0 \text{ cm}$ , between the points with coordinates  $x = 0$  and  $x = 40.0 \text{ cm}$ . Find the electric field it creates at the origin.
72. Three point charges  $q$ ,  $-2q$ , and  $q$  are located along the  $x$  axis, as shown in Figure P23.72. Show that the electric field at  $P$  ( $y \gg a$ ) along the  $y$  axis is

$$\mathbf{E} = -k_e \frac{3qa^2}{y^4} \mathbf{j}$$

Figure P23.72

This charge distribution, which is essentially that of two electric dipoles, is called an *electric quadrupole*. Note that  $\mathbf{E}$  varies as  $r^{-4}$  for the quadrupole, compared with variations of  $r^{-3}$  for the dipole and  $r^{-2}$  for the monopole (a single charge).

73. **Review Problem.** A negatively charged particle  $-q$  is placed at the center of a uniformly charged ring, where the ring has a total positive charge  $Q$ , as shown in Example 23.8. The particle, confined to move along the  $x$  axis, is displaced a *small* distance  $x$  along the axis (where  $x \ll a$ ) and released. Show that the particle oscillates with simple harmonic motion with a frequency

$$f = \frac{1}{2\pi} \left( \frac{k_e q Q}{ma^3} \right)^{1/2}$$

74. **Review Problem.** An electric dipole in a uniform electric field is displaced slightly from its equilibrium position, as shown in Figure P23.74, where  $\theta$  is small and the charges are separated by a distance  $2a$ . The moment of inertia of the dipole is  $I$ . If the dipole is released from this position, show that its angular orientation exhibits simple harmonic motion with a frequency

$$f = \frac{1}{2\pi} \sqrt{\frac{2qaE}{I}}$$

Figure P23.74

### ANSWERS TO QUICK QUIZZES

**23.1** (b). The amount of charge present after rubbing is the same as that before; it is just distributed differently.

**23.2** (d). Object A might be negatively charged, but it also might be electrically neutral with an induced charge separation, as shown in the following figure:

**23.3** (b). From Newton's third law, the electric force exerted by object B on object A is equal in magnitude to the force exerted by object A on object B and in the opposite direction—that is,  $\mathbf{F}_{AB} = -\mathbf{F}_{BA}$ .

**23.4** Nothing, if we assume that the source charge producing the field is not disturbed by our actions. Remember that the electric field is created not by the  $+3\text{-}\mu\text{C}$  charge or by the  $-3\text{-}\mu\text{C}$  charge but by the source charge (unseen in this case).

**23.5** A, B, and C. The field is greatest at point A because this is where the field lines are closest together. The absence of lines at point C indicates that the electric field there is zero.

## PUZZLER\*

Some railway companies are planning to coat the windows of their commuter trains with a very thin layer of metal. (The coating is so thin you can see through it.) They are doing this in response to rider complaints about other passengers' talking loudly on cellular telephones. How can a metallic coating that is only a few hundred nanometers thick overcome this problem? (Arthur Tilley/FPG International)

# Gauss's Law

### Chapter Outline

- 24.1** Electric Flux
- 24.2** Gauss's Law
- 24.3** Application of Gauss's Law to Charged Insulators
- 24.4** Conductors in Electrostatic Equilibrium
- 24.5** (Optional) Experimental Verification of Gauss's Law and Coulomb's Law
- 24.6** (Optional) Formal Derivation of Gauss's Law

**Figure 24.1** Field lines representing a uniform electric field penetrating a plane of area  $A$  perpendicular to the field. The electric flux  $\Phi_E$  through this area is equal to  $EA$ .

In the preceding chapter we showed how to use Coulomb's law to calculate the electric field generated by a given charge distribution. In this chapter, we describe *Gauss's law* and an alternative procedure for calculating electric fields. The law is based on the fact that the fundamental electrostatic force between point charges exhibits an inverse-square behavior. Although a consequence of Coulomb's law, Gauss's law is more convenient for calculating the electric fields of highly symmetric charge distributions and makes possible useful qualitative reasoning when we are dealing with complicated problems.

## 24.1 ELECTRIC FLUX

**11.6** The concept of electric field lines is described qualitatively in Chapter 23. We now use the concept of electric flux to treat electric field lines in a more quantitative way.

Consider an electric field that is uniform in both magnitude and direction, as shown in Figure 24.1. The field lines penetrate a rectangular surface of area  $A$ , which is perpendicular to the field. Recall from Section 23.6 that the number of lines per unit area (in other words, the *line density*) is proportional to the magnitude of the electric field. Therefore, the total number of lines penetrating the surface is proportional to the product  $EA$ . This product of the magnitude of the electric field  $E$  and surface area  $A$  perpendicular to the field is called the **electric flux**  $\Phi_E$  (uppercase Greek phi):

$$\Phi_E = EA \quad (24.1)$$

From the SI units of  $E$  and  $A$ , we see that  $\Phi_E$  has units of newton–meters squared per coulomb ( $\text{N}\cdot\text{m}^2/\text{C}$ ). **Electric flux is proportional to the number of electric field lines penetrating some surface.**

### EXAMPLE 24.1 Flux Through a Sphere

What is the electric flux through a sphere that has a radius of 1.00 m and carries a charge of  $+1.00 \mu\text{C}$  at its center?

**Solution** The magnitude of the electric field 1.00 m from this charge is given by Equation 23.4,

$$\begin{aligned} E &= k_e \frac{q}{r^2} = (8.99 \times 10^9 \text{ N}\cdot\text{m}^2/\text{C}^2) \frac{1.00 \times 10^{-6} \text{ C}}{(1.00 \text{ m})^2} \\ &= 8.99 \times 10^3 \text{ N/C} \end{aligned}$$

The field points radially outward and is therefore everywhere

perpendicular to the surface of the sphere. The flux through the sphere (whose surface area  $A = 4\pi r^2 = 12.6 \text{ m}^2$ ) is thus

$$\begin{aligned} \Phi_E &= EA = (8.99 \times 10^3 \text{ N/C})(12.6 \text{ m}^2) \\ &= 1.13 \times 10^5 \text{ N}\cdot\text{m}^2/\text{C} \end{aligned}$$

**Exercise** What would be the (a) electric field and (b) flux through the sphere if it had a radius of 0.500 m?

**Answer** (a)  $3.60 \times 10^4 \text{ N/C}$ ; (b)  $1.13 \times 10^5 \text{ N}\cdot\text{m}^2/\text{C}$ .

If the surface under consideration is not perpendicular to the field, the flux through it must be less than that given by Equation 24.1. We can understand this by considering Figure 24.2, in which the normal to the surface of area  $A$  is at an angle  $\theta$  to the uniform electric field. Note that the number of lines that cross this area  $A$  is equal to the number that cross the area  $A'$ , which is a projection of area  $A$  aligned perpendicular to the field. From Figure 24.2 we see that the two areas are related by  $A' = A \cos \theta$ . Because the flux through  $A$  equals the flux through  $A'$ , we

**Figure 24.2** Field lines representing a uniform electric field penetrating an area  $A$  that is at an angle  $\theta$  to the field. Because the number of lines that go through the area  $A'$  is the same as the number that go through  $A$ , the flux through  $A'$  is equal to the flux through  $A$  and is given by  $\Phi_E = EA \cos \theta$ .

conclude that the flux through  $A$  is

$$\Phi_E = EA' = EA \cos \theta \quad (24.2)$$

From this result, we see that the flux through a surface of fixed area  $A$  has a maximum value  $EA$  when the surface is perpendicular to the field (in other words, when the normal to the surface is parallel to the field, that is,  $\theta = 0^\circ$  in Figure 24.2); the flux is zero when the surface is parallel to the field (in other words, when the normal to the surface is perpendicular to the field, that is,  $\theta = 90^\circ$ ).

We assumed a uniform electric field in the preceding discussion. In more general situations, the electric field may vary over a surface. Therefore, our definition of flux given by Equation 24.2 has meaning only over a small element of area. Consider a general surface divided up into a large number of small elements, each of area  $\Delta A$ . The variation in the electric field over one element can be neglected if the element is sufficiently small. It is convenient to define a vector  $\Delta \mathbf{A}_i$  whose magnitude represents the area of the  $i$ th element of the surface and whose direction is defined to be perpendicular to the surface element, as shown in Figure 24.3. The electric flux  $\Delta \Phi_E$  through this element is

$$\Delta \Phi_E = E_i \Delta A_i \cos \theta = \mathbf{E}_i \cdot \Delta \mathbf{A}_i$$

where we have used the definition of the scalar product of two vectors ( $\mathbf{A} \cdot \mathbf{B} = AB \cos \theta$ ). By summing the contributions of all elements, we obtain the total flux through the surface.<sup>1</sup> If we let the area of each element approach zero, then the number of elements approaches infinity and the sum is replaced by an integral. Therefore, the general definition of electric flux is

$$\Phi_E = \lim_{\Delta A_i \rightarrow 0} \sum \mathbf{E}_i \cdot \Delta \mathbf{A}_i = \int_{\text{surface}} \mathbf{E} \cdot d\mathbf{A} \quad (24.3)$$

Equation 24.3 is a *surface integral*, which means it must be evaluated over the surface in question. In general, the value of  $\Phi_E$  depends both on the field pattern and on the surface.

We are often interested in evaluating the flux through a *closed surface*, which is defined as one that divides space into an inside and an outside region, so that one cannot move from one region to the other without crossing the surface. The surface of a sphere, for example, is a closed surface.

Consider the closed surface in Figure 24.4. The vectors  $\Delta \mathbf{A}_i$  point in different directions for the various surface elements, but at each point they are normal to

<sup>1</sup> It is important to note that drawings with field lines have their inaccuracies because a small area element (depending on its location) may happen to have too many or too few field lines penetrating it. We stress that the basic definition of electric flux is  $\int \mathbf{E} \cdot d\mathbf{A}$ . The use of lines is only an aid for visualizing the concept.

## QuickLab

Shine a desk lamp onto a playing card and notice how the size of the shadow on your desk depends on the orientation of the card with respect to the beam of light. Could a formula like Equation 24.2 be used to describe how much light was being blocked by the card?

**Figure 24.3** A small element of surface area  $\Delta A_i$ . The electric field makes an angle  $\theta$  with the vector  $\Delta \mathbf{A}_i$ , defined as being normal to the surface element, and the flux through the element is equal to  $E_i \Delta A_i \cos \theta$ .

Definition of electric flux

**Figure 24.4** A closed surface in an electric field. The area vectors  $\Delta\mathbf{A}_i$  are, by convention, normal to the surface and point outward. The flux through an area element can be positive (element ①), zero (element ②), or negative (element ③).

**Karl Friedrich Gauss** German mathematician and astronomer (1777–1855)

the surface and, by convention, always point outward. At the element labeled ①, the field lines are crossing the surface from the inside to the outside and  $\theta < 90^\circ$ ; hence, the flux  $\Delta\Phi_E = \mathbf{E} \cdot \Delta\mathbf{A}_i$  through this element is positive. For element ②, the field lines graze the surface (perpendicular to the vector  $\Delta\mathbf{A}_i$ ); thus,  $\theta = 90^\circ$  and the flux is zero. For elements such as ③, where the field lines are crossing the surface from outside to inside,  $180^\circ > \theta > 90^\circ$  and the flux is negative because  $\cos \theta$  is negative. The *net* flux through the surface is proportional to the net number of lines leaving the surface, where the net number means *the number leaving the surface minus the number entering the surface*. If more lines are leaving than entering, the net flux is positive. If more lines are entering than leaving, the net flux is negative. Using the symbol  $\oint$  to represent an integral over a closed surface, we can write the net flux  $\Phi_E$  through a closed surface as

$$\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = \oint E_n dA \quad (24.4)$$

where  $E_n$  represents the component of the electric field normal to the surface. Evaluating the net flux through a closed surface can be very cumbersome. However, if the field is normal to the surface at each point and constant in magnitude, the calculation is straightforward, as it was in Example 24.1. The next example also illustrates this point.

### EXAMPLE 24.2 Flux Through a Cube

Consider a uniform electric field  $\mathbf{E}$  oriented in the  $x$  direction. Find the net electric flux through the surface of a cube of edges  $\ell$ , oriented as shown in Figure 24.5.

**Solution** The net flux is the sum of the fluxes through all faces of the cube. First, note that the flux through four of the

faces (③, ④, and the unnumbered ones) is zero because  $\mathbf{E}$  is perpendicular to  $d\mathbf{A}$  on these faces.

The net flux through faces ① and ② is

$$\Phi_E = \int_1 \mathbf{E} \cdot d\mathbf{A} + \int_2 \mathbf{E} \cdot d\mathbf{A}$$

**Figure 24.5** A closed surface in the shape of a cube in a uniform electric field oriented parallel to the  $x$  axis. The net flux through the closed surface is zero. Side ④ is the bottom of the cube, and side ① is opposite side ②.

For ①,  $\mathbf{E}$  is constant and directed inward but  $d\mathbf{A}_1$  is directed outward ( $\theta = 180^\circ$ ); thus, the flux through this face is

$$\int_1 \mathbf{E} \cdot d\mathbf{A} = \int_1 E(\cos 180^\circ) dA = -E \int_1 dA = -EA = -E\ell^2$$

because the area of each face is  $A = \ell^2$ .

For ②,  $\mathbf{E}$  is constant and outward and in the same direction as  $d\mathbf{A}_2$  ( $\theta = 0^\circ$ ); hence, the flux through this face is

$$\int_2 \mathbf{E} \cdot d\mathbf{A} = \int_2 E(\cos 0^\circ) dA = E \int_2 dA = +EA = E\ell^2$$

Therefore, the net flux over all six faces is

$$\Phi_E = -E\ell^2 + E\ell^2 + 0 + 0 + 0 + 0 = 0$$

## 24.2 GAUSS'S LAW

**11.6** In this section we describe a general relationship between the net electric flux through a closed surface (often called a *Gaussian surface*) and the charge enclosed by the surface. This relationship, known as *Gauss's law*, is of fundamental importance in the study of electric fields.

Let us again consider a positive point charge  $q$  located at the center of a sphere of radius  $r$ , as shown in Figure 24.6. From Equation 23.4 we know that the magnitude of the electric field everywhere on the surface of the sphere is  $E = k_e q/r^2$ . As noted in Example 24.1, the field lines are directed radially outward and hence perpendicular to the surface at every point on the surface. That is, at each surface point,  $\mathbf{E}$  is parallel to the vector  $\Delta\mathbf{A}_i$  representing a local element of area  $\Delta A_i$  surrounding the surface point. Therefore,

$$\mathbf{E} \cdot \Delta\mathbf{A}_i = E \Delta A_i$$

and from Equation 24.4 we find that the net flux through the gaussian surface is

$$\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = \oint E dA = E \oint dA$$

where we have moved  $E$  outside of the integral because, by symmetry,  $E$  is constant over the surface and given by  $E = k_e q/r^2$ . Furthermore, because the surface is spherical,  $\oint dA = A = 4\pi r^2$ . Hence, the net flux through the gaussian surface is

$$\Phi_E = \frac{k_e q}{r^2} (4\pi r^2) = 4\pi k_e q$$

Recalling from Section 23.3 that  $k_e = 1/(4\pi\epsilon_0)$ , we can write this equation in the form

$$\Phi_E = \frac{q}{\epsilon_0} \quad (24.5)$$

We can verify that this expression for the net flux gives the same result as Example 24.1:  $\Phi_E = (1.00 \times 10^{-6} \text{ C}) / (8.85 \times 10^{-12} \text{ C}^2/\text{N}\cdot\text{m}^2) = 1.13 \times 10^5 \text{ N}\cdot\text{m}^2/\text{C}$ .

**Figure 24.6** A spherical gaussian surface of radius  $r$  surrounding a point charge  $q$ . When the charge is at the center of the sphere, the electric field is everywhere normal to the surface and constant in magnitude.

**Figure 24.7** Closed surfaces of various shapes surrounding a charge  $q$ . The net electric flux is the same through all surfaces.

**Figure 24.8** A point charge located *outside* a closed surface. The number of lines entering the surface equals the number leaving the surface.

The net electric flux through a closed surface is zero if there is no charge inside

Note from Equation 24.5 that the net flux through the spherical surface is proportional to the charge inside. The flux is independent of the radius  $r$  because the area of the spherical surface is proportional to  $r^2$ , whereas the electric field is proportional to  $1/r^2$ . Thus, in the product of area and electric field, the dependence on  $r$  cancels.

Now consider several closed surfaces surrounding a charge  $q$ , as shown in Figure 24.7. Surface  $S_1$  is spherical, but surfaces  $S_2$  and  $S_3$  are not. From Equation 24.5, the flux that passes through  $S_1$  has the value  $q/\epsilon_0$ . As we discussed in the previous section, flux is proportional to the number of electric field lines passing through a surface. The construction shown in Figure 24.7 shows that the number of lines through  $S_1$  is equal to the number of lines through the nonspherical surfaces  $S_2$  and  $S_3$ . Therefore, we conclude that the net flux through *any* closed surface is independent of the shape of that surface. **The net flux through any closed surface surrounding a point charge  $q$  is given by  $q/\epsilon_0$ .**

Now consider a point charge located *outside* a closed surface of arbitrary shape, as shown in Figure 24.8. As you can see from this construction, any electric field line that enters the surface leaves the surface at another point. The number of electric field lines entering the surface equals the number leaving the surface. Therefore, we conclude that **the net electric flux through a closed surface that surrounds no charge is zero.** If we apply this result to Example 24.2, we can easily see that the net flux through the cube is zero because there is no charge inside the cube.

### Quick Quiz 24.1

Suppose that the charge in Example 24.1 is just outside the sphere, 1.01 m from its center. What is the total flux through the sphere?

Let us extend these arguments to two generalized cases: (1) that of many point charges and (2) that of a continuous distribution of charge. We once again use the superposition principle, which states that **the electric field due to many charges is the vector sum of the electric fields produced by the individual charges.** Therefore, we can express the flux through any closed surface as

$$\oint \mathbf{E} \cdot d\mathbf{A} = \oint (\mathbf{E}_1 + \mathbf{E}_2 + \cdots) \cdot d\mathbf{A}$$

where  $\mathbf{E}$  is the total electric field at any point on the surface produced by the vector addition of the electric fields at that point due to the individual charges.

Consider the system of charges shown in Figure 24.9. The surface  $S$  surrounds only one charge,  $q_1$ ; hence, the net flux through  $S$  is  $q_1/\epsilon_0$ . The flux through  $S$  due to charges  $q_2$  and  $q_3$  outside it is zero because each electric field line that enters  $S$  at one point leaves it at another. The surface  $S'$  surrounds charges  $q_2$  and  $q_3$ ; hence, the net flux through it is  $(q_2 + q_3)/\epsilon_0$ . Finally, the net flux through surface  $S''$  is zero because there is no charge inside this surface. That is, *all* the electric field lines that enter  $S''$  at one point leave at another.

**Gauss's law**, which is a generalization of what we have just described, states that the net flux through *any* closed surface is

$$\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = \frac{q_{\text{in}}}{\epsilon_0} \quad (24.6)$$

where  $q_{\text{in}}$  represents the net charge inside the surface and  $\mathbf{E}$  represents the electric field at any point on the surface.

A formal proof of Gauss's law is presented in Section 24.6. When using Equation 24.6, you should note that although the charge  $q_{\text{in}}$  is the net charge inside the gaussian surface,  $\mathbf{E}$  represents the *total electric field*, which includes contributions from charges both inside and outside the surface.

In principle, Gauss's law can be solved for  $\mathbf{E}$  to determine the electric field due to a system of charges or a continuous distribution of charge. In practice, however, this type of solution is applicable only in a limited number of highly symmetric situations. As we shall see in the next section, Gauss's law can be used to evaluate the electric field for charge distributions that have spherical, cylindrical, or planar symmetry. If one chooses the gaussian surface surrounding the charge distribution carefully, the integral in Equation 24.6 can be simplified. You should also note that a gaussian surface is a mathematical construction and need not coincide with any real physical surface.

### Quick Quiz 24.2

For a gaussian surface through which the net flux is zero, the following four statements *could be true*. Which of the statements *must be true*? (a) There are no charges inside the surface. (b) The net charge inside the surface is zero. (c) The electric field is zero everywhere on the surface. (d) The number of electric field lines entering the surface equals the number leaving the surface.

### CONCEPTUAL EXAMPLE 24.3

A spherical gaussian surface surrounds a point charge  $q$ . Describe what happens to the total flux through the surface if (a) the charge is tripled, (b) the radius of the sphere is doubled, (c) the surface is changed to a cube, and (d) the charge is moved to another location inside the surface.

**Solution** (a) The flux through the surface is tripled because flux is proportional to the amount of charge inside the surface.

(b) The flux does not change because all electric field

lines from the charge pass through the sphere, regardless of its radius.

(c) The flux does not change when the shape of the gaussian surface changes because all electric field lines from the charge pass through the surface, regardless of its shape.

(d) The flux does not change when the charge is moved to another location inside that surface because Gauss's law refers to the total charge enclosed, regardless of where the charge is located inside the surface.

Gauss's law

Gauss's law is useful for evaluating  $E$  when the charge distribution has high symmetry

**Figure 24.9** The net electric flux through any closed surface depends only on the charge *inside* that surface. The net flux through surface  $S$  is  $q_1/\epsilon_0$ , the net flux through surface  $S'$  is  $(q_2 + q_3)/\epsilon_0$ , and the net flux through surface  $S''$  is zero.

### 24.3 APPLICATION OF GAUSS'S LAW TO CHARGED INSULATORS

As mentioned earlier, Gauss's law is useful in determining electric fields when the charge distribution is characterized by a high degree of symmetry. The following examples demonstrate ways of choosing the gaussian surface over which the surface integral given by Equation 24.6 can be simplified and the electric field determined. In choosing the surface, we should always take advantage of the symmetry of the charge distribution so that we can remove  $E$  from the integral and solve for it. The goal in this type of calculation is to determine a surface that satisfies one or more of the following conditions:

1. The value of the electric field can be argued by symmetry to be constant over the surface.
2. The dot product in Equation 24.6 can be expressed as a simple algebraic product  $E dA$  because  $\mathbf{E}$  and  $d\mathbf{A}$  are parallel.
3. The dot product in Equation 24.6 is zero because  $\mathbf{E}$  and  $d\mathbf{A}$  are perpendicular.
4. The field can be argued to be zero over the surface.

All four of these conditions are used in examples throughout the remainder of this chapter.

#### EXAMPLE 24.4 The Electric Field Due to a Point Charge

Starting with Gauss's law, calculate the electric field due to an isolated point charge  $q$ .

**Solution** A single charge represents the simplest possible charge distribution, and we use this familiar case to show how to solve for the electric field with Gauss's law. We choose a spherical gaussian surface of radius  $r$  centered on the point charge, as shown in Figure 24.10. The electric field due to a positive point charge is directed radially outward by symmetry and is therefore normal to the surface at every point. Thus, as in condition (2),  $\mathbf{E}$  is parallel to  $d\mathbf{A}$  at each point. Therefore,  $\mathbf{E} \cdot d\mathbf{A} = E dA$  and Gauss's law gives

$$\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = \oint E dA = \frac{q}{\epsilon_0}$$

By symmetry,  $E$  is constant everywhere on the surface, which satisfies condition (1), so it can be removed from the integral. Therefore,

$$\oint E dA = E \oint dA = E(4\pi r^2) = \frac{q}{\epsilon_0}$$

where we have used the fact that the surface area of a sphere is  $4\pi r^2$ . Now, we solve for the electric field:

$$E = \frac{q}{4\pi\epsilon_0 r^2} = k_e \frac{q}{r^2}$$

This is the familiar electric field due to a point charge that we developed from Coulomb's law in Chapter 23.

**Figure 24.10** The point charge  $q$  is at the center of the spherical gaussian surface, and  $\mathbf{E}$  is parallel to  $d\mathbf{A}$  at every point on the surface.

#### EXAMPLE 24.5 A Spherically Symmetric Charge Distribution

An insulating solid sphere of radius  $a$  has a uniform volume charge density  $\rho$  and carries a total positive charge  $Q$  (Fig. 24.11). (a) Calculate the magnitude of the electric field at a point outside the sphere.

**Solution** Because the charge distribution is spherically symmetric, we again select a spherical gaussian surface of radius  $r$ , concentric with the sphere, as shown in Figure 24.11a. For this choice, conditions (1) and (2) are satisfied, as they

were for the point charge in Example 24.4. Following the line of reasoning given in Example 24.4, we find that

$$E = k_e \frac{Q}{r^2} \quad (\text{for } r > a)$$

Note that this result is identical to the one we obtained for a point charge. Therefore, we conclude that, for a uniformly charged sphere, the field in the region external to the sphere is *equivalent* to that of a point charge located at the center of the sphere.

(b) Find the magnitude of the electric field at a point inside the sphere.

**Solution** In this case we select a spherical gaussian surface having radius  $r < a$ , concentric with the insulated sphere (Fig. 24.11b). Let us denote the volume of this smaller sphere by  $V'$ . To apply Gauss's law in this situation, it is important to recognize that the charge  $q_{\text{in}}$  within the gaussian surface of volume  $V'$  is less than  $Q$ . To calculate  $q_{\text{in}}$ , we use the fact that  $q_{\text{in}} = \rho V'$ :

$$q_{\text{in}} = \rho V' = \rho \left( \frac{4}{3} \pi r^3 \right)$$

By symmetry, the magnitude of the electric field is constant everywhere on the spherical gaussian surface and is normal

**Figure 24.11** A uniformly charged insulating sphere of radius  $a$  and total charge  $Q$ . (a) The magnitude of the electric field at a point exterior to the sphere is  $k_e Q/r^2$ . (b) The magnitude of the electric field inside the insulating sphere is due only to the charge *within* the gaussian sphere defined by the dashed circle and is  $k_e Qr/a^3$ .

to the surface at each point—both conditions (1) and (2) are satisfied. Therefore, Gauss's law in the region  $r < a$  gives

$$\oint E \, dA = E \oint dA = E(4\pi r^2) = \frac{q_{\text{in}}}{\epsilon_0}$$

Solving for  $E$  gives

$$E = \frac{q_{\text{in}}}{4\pi\epsilon_0 r^2} = \frac{\rho \frac{4}{3} \pi r^3}{4\pi\epsilon_0 r^2} = \frac{\rho}{3\epsilon_0} r$$

Because  $\rho = Q/\frac{4}{3}\pi a^3$  by definition and since  $k_e = 1/(4\pi\epsilon_0)$ , this expression for  $E$  can be written as

$$E = \frac{Qr}{4\pi\epsilon_0 a^3} = \frac{k_e Q}{a^3} r \quad (\text{for } r < a)$$

Note that this result for  $E$  differs from the one we obtained in part (a). It shows that  $E \rightarrow 0$  as  $r \rightarrow 0$ . Therefore, the result eliminates the problem that would exist at  $r = 0$  if  $E$  varied as  $1/r^2$  inside the sphere as it does outside the sphere. That is, if  $E \propto 1/r^2$  for  $r < a$ , the field would be infinite at  $r = 0$ , which is physically impossible. Note also that the expressions for parts (a) and (b) match when  $r = a$ .

A plot of  $E$  versus  $r$  is shown in Figure 24.12.

**Figure 24.12** A plot of  $E$  versus  $r$  for a uniformly charged insulating sphere. The electric field inside the sphere ( $r < a$ ) varies linearly with  $r$ . The field outside the sphere ( $r > a$ ) is the same as that of a point charge  $Q$  located at  $r = 0$ .

### EXAMPLE 24.6 The Electric Field Due to a Thin Spherical Shell

A thin spherical shell of radius  $a$  has a total charge  $Q$  distributed uniformly over its surface (Fig. 24.13a). Find the electric field at points (a) outside and (b) inside the shell.

**Solution** (a) The calculation for the field outside the shell is identical to that for the solid sphere shown in Example 24.5a. If we construct a spherical gaussian surface of radius  $r > a$  concentric with the shell (Fig. 24.13b), the charge inside this surface is  $Q$ . Therefore, the field at a point outside

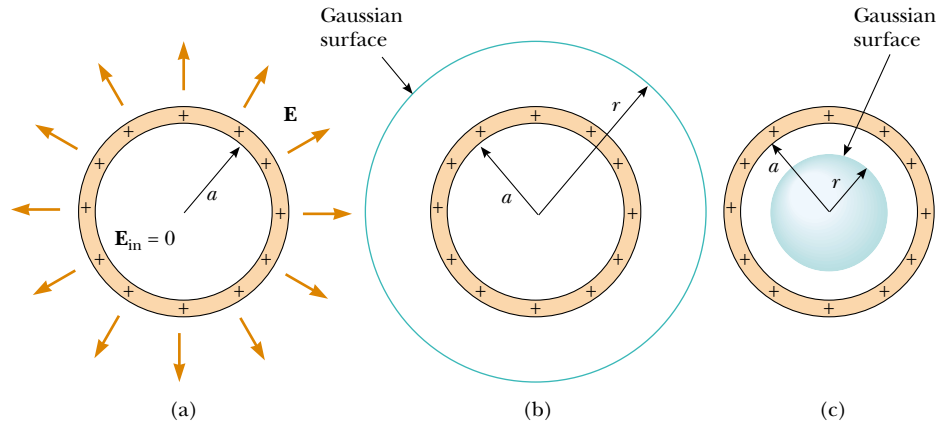

the shell is equivalent to that due to a point charge  $Q$  located at the center:

$$E = k_e \frac{Q}{r^2} \quad (\text{for } r > a)$$

(b) The electric field inside the spherical shell is zero. This follows from Gauss's law applied to a spherical surface of radius  $r < a$  concentric with the shell (Fig. 24.13c). Because

of the spherical symmetry of the charge distribution and because the net charge inside the surface is zero—satisfaction of conditions (1) and (2) again—application of Gauss's law shows that  $E = 0$  in the region  $r < a$ .

We obtain the same results using Equation 23.6 and integrating over the charge distribution. This calculation is rather complicated. Gauss's law allows us to determine these results in a much simpler way.

**Figure 24.13** (a) The electric field inside a uniformly charged spherical shell is zero. The field outside is the same as that due to a point charge  $Q$  located at the center of the shell. (b) Gaussian surface for  $r > a$ . (c) Gaussian surface for  $r < a$ .

### EXAMPLE 24.7 A Cylindrically Symmetric Charge Distribution

Find the electric field a distance  $r$  from a line of positive charge of infinite length and constant charge per unit length  $\lambda$  (Fig. 24.14a).

**Solution** The symmetry of the charge distribution requires that  $\mathbf{E}$  be perpendicular to the line charge and directed outward, as shown in Figure 24.14a and b. To reflect the symmetry of the charge distribution, we select a cylindrical gaussian surface of radius  $r$  and length  $\ell$  that is coaxial with the line charge. For the curved part of this surface,  $\mathbf{E}$  is constant in magnitude and perpendicular to the surface at each point—satisfaction of conditions (1) and (2). Furthermore, the flux through the ends of the gaussian cylinder is zero because  $\mathbf{E}$  is parallel to these surfaces—the first application we have seen of condition (3).

We take the surface integral in Gauss's law over the entire gaussian surface. Because of the zero value of  $\mathbf{E} \cdot d\mathbf{A}$  for the ends of the cylinder, however, we can restrict our attention to only the curved surface of the cylinder.

The total charge inside our gaussian surface is  $\lambda\ell$ . Applying Gauss's law and conditions (1) and (2), we find that for the curved surface

$$\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = E \oint dA = EA = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\lambda\ell}{\epsilon_0}$$

**Figure 24.14** (a) An infinite line of charge surrounded by a cylindrical gaussian surface concentric with the line. (b) An end view shows that the electric field at the cylindrical surface is constant in magnitude and perpendicular to the surface.

The area of the curved surface is  $A = 2\pi r\ell$ ; therefore,

$$E(2\pi r\ell) = \frac{\lambda\ell}{\epsilon_0}$$

$$E = \frac{\lambda}{2\pi\epsilon_0 r} = 2k_e \frac{\lambda}{r} \quad (24.7)$$

Thus, we see that the electric field due to a cylindrically symmetric charge distribution varies as  $1/r$ , whereas the field external to a spherically symmetric charge distribution varies as  $1/r^2$ . Equation 24.7 was also derived in Chapter 23 (see Problem 35[b]), by integration of the field of a point charge.

If the line charge in this example were of finite length, the result for  $E$  would not be that given by Equation 24.7. A finite line charge does not possess sufficient symmetry for us to make use of Gauss's law. This is because the magnitude of

the electric field is no longer constant over the surface of the gaussian cylinder—the field near the ends of the line would be different from that far from the ends. Thus, condition (1) would not be satisfied in this situation. Furthermore,  $\mathbf{E}$  is not perpendicular to the cylindrical surface at all points—the field vectors near the ends would have a component parallel to the line. Thus, condition (2) would not be satisfied. When there is insufficient symmetry in the charge distribution, as in this situation, it is necessary to use Equation 23.6 to calculate  $\mathbf{E}$ .

For points close to a finite line charge and far from the ends, Equation 24.7 gives a good approximation of the value of the field.

It is left for you to show (see Problem 29) that the electric field inside a uniformly charged rod of finite radius and infinite length is proportional to  $r$ .

### EXAMPLE 24.8 A Nonconducting Plane of Charge

Find the electric field due to a nonconducting, infinite plane of positive charge with uniform surface charge density  $\sigma$ .

**Solution** By symmetry,  $\mathbf{E}$  must be perpendicular to the plane and must have the same magnitude at all points equidistant from the plane. The fact that the direction of  $\mathbf{E}$  is away from positive charges indicates that the direction of  $\mathbf{E}$  on one side of the plane must be opposite its direction on the other side, as shown in Figure 24.15. A gaussian surface that reflects the symmetry is a small cylinder whose axis is perpendicular to the plane and whose ends each have an area  $A$  and are equidistant from the plane. Because  $\mathbf{E}$  is parallel to the curved surface—and, therefore, perpendicular to  $d\mathbf{A}$  everywhere on the surface—condition (3) is satisfied and there is no contribution to the surface integral from this surface. For the flat ends of the cylinder, conditions (1) and (2) are satisfied. The flux through each end of the cylinder is  $EA$ ; hence, the total flux through the entire gaussian surface is just that through the ends,  $\Phi_E = 2EA$ .

Noting that the total charge inside the surface is  $q_{\text{in}} = \sigma A$ , we use Gauss's law and find that

$$\Phi_E = 2EA = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\sigma A}{\epsilon_0}$$

$$E = \frac{\sigma}{2\epsilon_0} \quad (24.8)$$

Because the distance from each flat end of the cylinder to the plane does not appear in Equation 24.8, we conclude that  $E = \sigma/2\epsilon_0$  at any distance from the plane. That is, the field is uniform everywhere.

An important charge configuration related to this example consists of two parallel planes, one positively charged and the other negatively charged, and each with a surface charge density  $\sigma$  (see Problem 58). In this situation, the electric fields due to the two planes add in the region between the planes, resulting in a field of magnitude  $\sigma/\epsilon_0$ , and cancel elsewhere to give a field of zero.

**Figure 24.15** A cylindrical gaussian surface penetrating an infinite plane of charge. The flux is  $EA$  through each end of the gaussian surface and zero through its curved surface.

### CONCEPTUAL EXAMPLE 24.9

Explain why Gauss's law cannot be used to calculate the electric field near an electric dipole, a charged disk, or a triangle with a point charge at each corner.

**Solution** The charge distributions of all these configurations do not have sufficient symmetry to make the use of Gauss's law practical. We cannot find a closed surface surrounding any of these distributions that satisfies one or more of conditions (1) through (4) listed at the beginning of this section.

## 24.4 CONDUCTORS IN ELECTROSTATIC EQUILIBRIUM

As we learned in Section 23.2, a good electrical conductor contains charges (electrons) that are not bound to any atom and therefore are free to move about within the material. When there is no net motion of charge within a conductor, the conductor is in **electrostatic equilibrium**. As we shall see, a conductor in electrostatic equilibrium has the following properties:

1. The electric field is zero everywhere inside the conductor.
2. If an isolated conductor carries a charge, the charge resides on its surface.
3. The electric field just outside a charged conductor is perpendicular to the surface of the conductor and has a magnitude  $\sigma/\epsilon_0$ , where  $\sigma$  is the surface charge density at that point.
4. On an irregularly shaped conductor, the surface charge density is greatest at locations where the radius of curvature of the surface is smallest.

We verify the first three properties in the discussion that follows. The fourth property is presented here without further discussion so that we have a complete list of properties for conductors in electrostatic equilibrium.

We can understand the first property by considering a conducting slab placed in an external field  $\mathbf{E}$  (Fig. 24.16). We can argue that the electric field inside the conductor *must* be zero under the assumption that we have electrostatic equilibrium. If the field were not zero, free charges in the conductor would accelerate under the action of the field. This motion of electrons, however, would mean that the conductor is not in electrostatic equilibrium. Thus, the existence of electrostatic equilibrium is consistent only with a zero field in the conductor.

Let us investigate how this zero field is accomplished. Before the external field is applied, free electrons are uniformly distributed throughout the conductor. When the external field is applied, the free electrons accelerate to the left in Figure 24.16, causing a plane of negative charge to be present on the left surface. The movement of electrons to the left results in a plane of positive charge on the right surface. These planes of charge create an additional electric field inside the conductor that opposes the external field. As the electrons move, the surface charge density increases until the magnitude of the internal field equals that of the external field, and the net result is a net field of zero inside the conductor. The time it takes a good conductor to reach equilibrium is of the order of  $10^{-16}$  s, which for most purposes can be considered instantaneous.

We can use Gauss's law to verify the second property of a conductor in electrostatic equilibrium. Figure 24.17 shows an arbitrarily shaped conductor. A gaussian surface is drawn inside the conductor and can be as close to the conductor's surface as we wish. As we have just shown, the electric field everywhere inside the conductor is zero when it is in electrostatic equilibrium. Therefore, the electric field must be zero at every point on the gaussian surface, in accordance with condition (4) in Section 24.3. Thus, the net flux through this gaussian surface is zero. From this result and Gauss's law, we conclude that the net charge inside the gaussian sur-

Properties of a conductor in electrostatic equilibrium

**Figure 24.16** A conducting slab in an external electric field  $\mathbf{E}$ . The charges induced on the two surfaces of the slab produce an electric field that opposes the external field, giving a resultant field of zero inside the slab.

**Figure 24.17** A conductor of arbitrary shape. The broken line represents a gaussian surface just inside the conductor.

Electric field pattern surrounding a charged conducting plate placed near an oppositely charged conducting cylinder. Small pieces of thread suspended in oil align with the electric field lines. Note that (1) the field lines are perpendicular to both conductors and (2) there are no lines inside the cylinder ( $E = 0$ ).

face is zero. Because there can be no net charge inside the gaussian surface (which is arbitrarily close to the conductor's surface), **any net charge on the conductor must reside on its surface**. Gauss's law does not indicate how this excess charge is distributed on the conductor's surface.

We can also use Gauss's law to verify the third property. We draw a gaussian surface in the shape of a small cylinder whose end faces are parallel to the surface of the conductor (Fig. 24.18). Part of the cylinder is just outside the conductor, and part is inside. The field is normal to the conductor's surface from the condition of electrostatic equilibrium. (If  $\mathbf{E}$  had a component parallel to the conductor's surface, the free charges would move along the surface; in such a case, the conductor would not be in equilibrium.) Thus, we satisfy condition (3) in Section 24.3 for the curved part of the cylindrical gaussian surface—there is no flux through this part of the gaussian surface because  $\mathbf{E}$  is parallel to the surface. There is no flux through the flat face of the cylinder inside the conductor because here  $\mathbf{E} = 0$ —satisfaction of condition (4). Hence, the net flux through the gaussian surface is that through only the flat face outside the conductor, where the field is perpendicular to the gaussian surface. Using conditions (1) and (2) for this face, the flux is  $EA$ , where  $E$  is the electric field just outside the conductor and  $A$  is the area of the cylinder's face. Applying Gauss's law to this surface, we obtain

$$\Phi_E = \oint E \, dA = EA = \frac{q_{\text{in}}}{\epsilon_0} = \frac{\sigma A}{\epsilon_0}$$

where we have used the fact that  $q_{\text{in}} = \sigma A$ . Solving for  $E$  gives

$$E = \frac{\sigma}{\epsilon_0} \quad (24.9)$$

**Figure 24.18** A gaussian surface in the shape of a small cylinder is used to calculate the electric field just outside a charged conductor. The flux through the gaussian surface is  $E_n A$ . Remember that  $\mathbf{E}$  is zero inside the conductor.

Electric field just outside a charged conductor

### EXAMPLE 24.10 A Sphere Inside a Spherical Shell

A solid conducting sphere of radius  $a$  carries a net positive charge  $2Q$ . A conducting spherical shell of inner radius  $b$  and outer radius  $c$  is concentric with the solid sphere and carries a net charge  $-Q$ . Using Gauss's law, find the electric field in the regions labeled ①, ②, ③, and ④ in Figure 24.19 and the charge distribution on the shell when the entire system is in electrostatic equilibrium.

**Solution** First note that the charge distributions on both the sphere and the shell are characterized by spherical symmetry around their common center. To determine the electric field at various distances  $r$  from this center, we construct a spherical gaussian surface for each of the four regions of interest. Such a surface for region ② is shown in Figure 24.19.

To find  $E$  inside the solid sphere (region ①), consider a

**Figure 24.19** A solid conducting sphere of radius  $a$  and carrying a charge  $2Q$  surrounded by a conducting spherical shell carrying a charge  $-Q$ .

gaussian surface of radius  $r < a$ . Because there can be no charge inside a conductor in electrostatic equilibrium, we see that  $q_{\text{in}} = 0$ ; thus, on the basis of Gauss's law and symmetry,  $E_1 = 0$  for  $r < a$ .

In region ②—between the surface of the solid sphere and the inner surface of the shell—we construct a spherical gaussian surface of radius  $r$  where  $a < r < b$  and note that the charge inside this surface is  $+2Q$  (the charge on the solid sphere). Because of the spherical symmetry, the electric field

lines must be directed radially outward and be constant in magnitude on the gaussian surface. Following Example 24.4 and using Gauss's law, we find that

$$E_2 A = E_2 (4\pi r^2) = \frac{q_{\text{in}}}{\epsilon_0} = \frac{2Q}{\epsilon_0}$$

$$E_2 = \frac{2Q}{4\pi\epsilon_0 r^2} = \frac{2k_e Q}{r^2} \quad (\text{for } a < r < b)$$

In region ④, where  $r > c$ , the spherical gaussian surface we construct surrounds a total charge of  $q_{\text{in}} = 2Q + (-Q) = Q$ . Therefore, application of Gauss's law to this surface gives

$$E_4 = \frac{k_e Q}{r^2} \quad (\text{for } r > c)$$

In region ③, the electric field must be zero because the spherical shell is also a conductor in equilibrium. If we construct a gaussian surface of radius  $r$  where  $b < r < c$ , we see that  $q_{\text{in}}$  must be zero because  $E_3 = 0$ . From this argument, we conclude that the charge on the inner surface of the spherical shell must be  $-2Q$  to cancel the charge  $+2Q$  on the solid sphere. Because the net charge on the shell is  $-Q$ , we conclude that its outer surface must carry a charge  $+Q$ .

### Quick Quiz 24.3

How would the electric flux through a gaussian surface surrounding the shell in Example 24.10 change if the solid sphere were off-center but still inside the shell?

### Optional Section

## 24.5 EXPERIMENTAL VERIFICATION OF GAUSS'S LAW AND COULOMB'S LAW

When a net charge is placed on a conductor, the charge distributes itself on the surface in such a way that the electric field inside the conductor is zero. Gauss's law shows that there can be no net charge inside the conductor in this situation. In this section, we investigate an experimental verification of the absence of this charge.

We have seen that Gauss's law is equivalent to Equation 23.6, the expression for the electric field of a distribution of charge. Because this equation arises from Coulomb's law, we can claim theoretically that Gauss's law and Coulomb's law are equivalent. Hence, it is possible to test the validity of both laws by attempting to detect a net charge inside a conductor or, equivalently, a nonzero electric field inside the conductor. If a nonzero field is detected within the conductor, Gauss's law and Coulomb's law are invalid. Many experiments, including

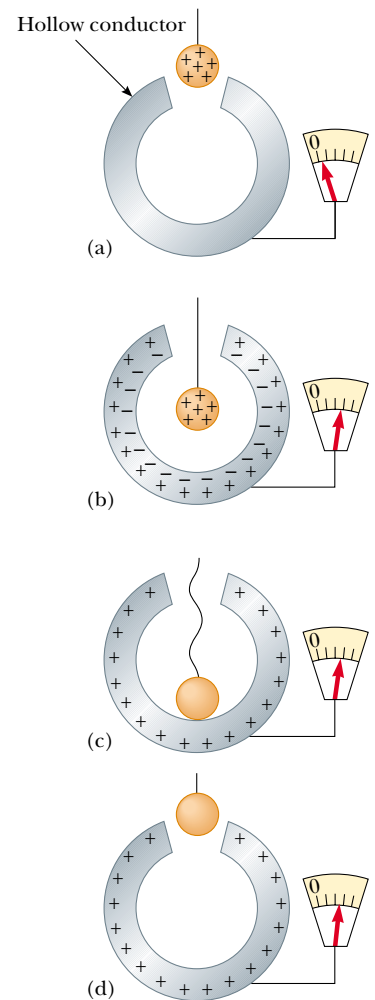

early work by Faraday, Cavendish, and Maxwell, have been performed to detect the field inside a conductor. In all reported cases, no electric field could be detected inside a conductor.

Here is one of the experiments that can be performed.<sup>2</sup> A positively charged metal ball at the end of a silk thread is lowered through a small opening into an uncharged hollow conductor that is insulated from ground (Fig. 24.20a). The positively charged ball induces a negative charge on the inner wall of the hollow conductor, leaving an equal positive charge on the outer wall (Fig. 24.20b). The presence of positive charge on the outer wall is indicated by the deflection of the needle of an electrometer (a device used to measure charge and that measures charge only on the outer surface of the conductor). The ball is then lowered and allowed to touch the inner surface of the hollow conductor (Fig. 24.20c). Charge is transferred between the ball and the inner surface so that neither is charged after contact is made. The needle deflection remains unchanged while this happens, indicating that the charge on the outer surface is unaffected. When the ball is removed, the electrometer reading remains the same (Fig. 24.20d). Furthermore, the ball is found to be uncharged; this verifies that charge was transferred between the ball and the inner surface of the hollow conductor. The overall effect is that the charge that was originally on the ball now appears on the hollow conductor. The fact that the deflection of the needle on the electrometer measuring the charge on the outer surface remained unchanged regardless of what was happening inside the hollow conductor indicates that the net charge on the system always resided on the outer surface of the conductor.

If we now apply another positive charge to the metal ball and place it near the outside of the conductor, it is repelled by the conductor. This demonstrates that  $\mathbf{E} \neq 0$  outside the conductor, a finding consistent with the fact that the conductor carries a net charge. If the charged metal ball is now lowered into the interior of the charged hollow conductor, it exhibits no evidence of an electric force. This shows that  $\mathbf{E} = 0$  inside the hollow conductor.

This experiment verifies the predictions of Gauss's law and therefore verifies Coulomb's law. The equivalence of Gauss's law and Coulomb's law is due to the inverse-square behavior of the electric force. Thus, we can interpret this experiment as verifying the exponent of 2 in the  $1/r^2$  behavior of the electric force. Experiments by Williams, Faller, and Hill in 1971 showed that the exponent of  $r$  in Coulomb's law is  $(2 + \delta)$ , where  $\delta = (2.7 \pm 3.1) \times 10^{-16}$ !

In the experiment we have described, the charged ball hanging in the hollow conductor would show no deflection even in the case in which an external electric field is applied to the entire system. The field inside the conductor is still zero. This ability of conductors to “block” external electric fields is utilized in many places, from electromagnetic shielding for computer components to thin metal coatings on the glass in airport control towers to keep radar originating outside the tower from disrupting the electronics inside. Cellular telephone users riding trains like the one pictured at the beginning of the chapter have to speak loudly to be heard above the noise of the train. In response to complaints from other passengers, the train companies are considering coating the windows with a thin metallic conductor. This coating, combined with the metal frame of the train car, blocks cellular telephone transmissions into and out of the train.

**Figure 24.20** An experiment showing that any charge transferred to a conductor resides on its surface in electrostatic equilibrium. The hollow conductor is insulated from ground, and the small metal ball is supported by an insulating thread.

### QuickLab

Wrap a radio or cordless telephone in aluminum foil and see if it still works. Does it matter if the foil touches the antenna?

<sup>2</sup> The experiment is often referred to as *Faraday's ice-pail experiment* because Faraday, the first to perform it, used an ice pail for the hollow conductor.

## Optional Section

## 24.6 FORMAL DERIVATION OF GAUSS'S LAW

One way of deriving Gauss's law involves *solid angles*. Consider a spherical surface of radius  $r$  containing an area element  $\Delta A$ . The solid angle  $\Delta\Omega$  (uppercase Greek omega) subtended at the center of the sphere by this element is defined to be

$$\Delta\Omega \equiv \frac{\Delta A}{r^2}$$

From this equation, we see that  $\Delta\Omega$  has no dimensions because  $\Delta A$  and  $r^2$  both have dimensions  $L^2$ . The dimensionless unit of a solid angle is the **steradian**. (You may want to compare this equation to Equation 10.1b, the definition of the radian.) Because the surface area of a sphere is  $4\pi r^2$ , the total solid angle subtended by the sphere is

$$\Omega = \frac{4\pi r^2}{r^2} = 4\pi \text{ steradians}$$

Now consider a point charge  $q$  surrounded by a closed surface of arbitrary shape (Fig. 24.21). The total electric flux through this surface can be obtained by evaluating  $\mathbf{E} \cdot \Delta\mathbf{A}$  for each small area element  $\Delta A$  and summing over all elements. The flux through each element is

$$\Delta\Phi_E = \mathbf{E} \cdot \Delta\mathbf{A} = E \Delta A \cos \theta = k_e q \frac{\Delta A \cos \theta}{r^2}$$

where  $r$  is the distance from the charge to the area element,  $\theta$  is the angle between the electric field  $\mathbf{E}$  and  $\Delta\mathbf{A}$  for the element, and  $E = k_e q/r^2$  for a point charge. In Figure 24.22, we see that the projection of the area element perpendicular to the radius vector is  $\Delta A \cos \theta$ . Thus, the quantity  $\Delta A \cos \theta/r^2$  is equal to the solid angle  $\Delta\Omega$  that the surface element  $\Delta A$  subtends at the charge  $q$ . We also see that  $\Delta\Omega$  is equal to the solid angle subtended by the area element of a spherical surface of radius  $r$ . Because the total solid angle at a point is  $4\pi$  steradians, the total flux

**Figure 24.21** A closed surface of arbitrary shape surrounds a point charge  $q$ . The net electric flux through the surface is independent of the shape of the surface.

**Figure 24.22** The area element  $\Delta A$  subtends a solid angle  $\Delta\Omega = (\Delta A \cos \theta)/r^2$  at the charge  $q$ .

through the closed surface is

$$\Phi_E = k_e q \oint \frac{dA \cos \theta}{r^2} = k_e q \oint d\Omega = 4\pi k_e q = \frac{q}{\epsilon_0}$$

Thus we have derived Gauss's law, Equation 24.6. Note that this result is independent of the shape of the closed surface and independent of the position of the charge within the surface.

## SUMMARY

**Electric flux** is proportional to the number of electric field lines that penetrate a surface. If the electric field is uniform and makes an angle  $\theta$  with the normal to a surface of area  $A$ , the electric flux through the surface is

$$\Phi_E = EA \cos \theta \quad (24.2)$$

In general, the electric flux through a surface is

$$\Phi_E = \int_{\text{surface}} \mathbf{E} \cdot d\mathbf{A} \quad (24.3)$$

You need to be able to apply Equations 24.2 and 24.3 in a variety of situations, particularly those in which symmetry simplifies the calculation.

**Gauss's law** says that the net electric flux  $\Phi_E$  through any closed gaussian surface is equal to the *net* charge inside the surface divided by  $\epsilon_0$ :

$$\Phi_E = \oint \mathbf{E} \cdot d\mathbf{A} = \frac{q_{\text{in}}}{\epsilon_0} \quad (24.6)$$

Using Gauss's law, you can calculate the electric field due to various symmetric charge distributions. Table 24.1 lists some typical results.

**TABLE 24.1** Typical Electric Field Calculations Using Gauss's Law

Charge Distribution	Electric Field	Location
Insulating sphere of radius $R$ , uniform charge density, and total charge $Q$	$\begin{cases} k_e \frac{Q}{r^2} \\ k_e \frac{Q}{R^3} r \end{cases}$	$r > R$  $r < R$
Thin spherical shell of radius $R$ and total charge $Q$	$\begin{cases} k_e \frac{Q}{r^2} \\ 0 \end{cases}$	$r > R$  $r < R$
Line charge of infinite length and charge per unit length $\lambda$	$2k_e \frac{\lambda}{r}$	Outside the line
Nonconducting, infinite charged plane having surface charge density $\sigma$	$\frac{\sigma}{2\epsilon_0}$	Everywhere outside the plane
Conductor having surface charge density $\sigma$	$\begin{cases} \frac{\sigma}{\epsilon_0} \\ 0 \end{cases}$	Just outside the conductor Inside the conductor

A conductor in **electrostatic equilibrium** has the following properties:

1. The electric field is zero everywhere inside the conductor.
2. Any net charge on the conductor resides entirely on its surface.
3. The electric field just outside the conductor is perpendicular to its surface and has a magnitude  $\sigma/\epsilon_0$ , where  $\sigma$  is the surface charge density at that point.
4. On an irregularly shaped conductor, the surface charge density is greatest where the radius of curvature of the surface is the smallest.

### Problem-Solving Hints

Gauss's law, as we have seen, is very powerful in solving problems involving highly symmetric charge distributions. In this chapter, you encountered three kinds of symmetry: planar, cylindrical, and spherical. It is important to review Examples 24.4 through 24.10 and to adhere to the following procedure when using Gauss's law:

- Select a gaussian surface that has a symmetry to match that of the charge distribution and satisfies one or more of the conditions listed in Section 24.3. For point charges or spherically symmetric charge distributions, the gaussian surface should be a sphere centered on the charge as in Examples 24.4, 24.5, 24.6, and 24.10. For uniform line charges or uniformly charged cylinders, your gaussian surface should be a cylindrical surface that is coaxial with the line charge or cylinder as in Example 24.7. For planes of charge, a useful choice is a cylindrical gaussian surface that straddles the plane, as shown in Example 24.8. These choices enable you to simplify the surface integral that appears in Gauss's law and represents the total electric flux through that surface.
- Evaluate the  $q_{\text{in}}/\epsilon_0$  term in Gauss's law, which amounts to calculating the total electric charge  $q_{\text{in}}$  inside the gaussian surface. If the charge density is uniform (that is, if  $\lambda$ ,  $\sigma$ , or  $\rho$  is constant), simply multiply that charge density by the length, area, or volume enclosed by the gaussian surface. If the charge distribution is *nonuniform*, integrate the charge density over the region enclosed by the gaussian surface. For example, if the charge is distributed along a line, integrate the expression  $dq = \lambda dx$ , where  $dq$  is the charge on an infinitesimal length element  $dx$ . For a plane of charge, integrate  $dq = \sigma dA$ , where  $dA$  is an infinitesimal element of area. For a volume of charge, integrate  $dq = \rho dV$ , where  $dV$  is an infinitesimal element of volume.
- Once the terms in Gauss's law have been evaluated, solve for the electric field on the gaussian surface if the charge distribution is given in the problem. Conversely, if the electric field is known, calculate the charge distribution that produces the field.

## QUESTIONS

1. The Sun is lower in the sky during the winter than it is in the summer. How does this change the flux of sunlight hitting a given area on the surface of the Earth? How does this affect the weather?
2. If the electric field in a region of space is zero, can you conclude no electric charges are in that region? Explain.
3. If more electric field lines are leaving a gaussian surface than entering, what can you conclude about the net charge enclosed by that surface?
4. A uniform electric field exists in a region of space in which there are no charges. What can you conclude about the net electric flux through a gaussian surface placed in this region of space?

5. If the total charge inside a closed surface is known but the distribution of the charge is unspecified, can you use Gauss's law to find the electric field? Explain.
6. Explain why the electric flux through a closed surface with a given enclosed charge is independent of the size or shape of the surface.
7. Consider the electric field due to a nonconducting infinite plane having a uniform charge density. Explain why the electric field does not depend on the distance from the plane in terms of the spacing of the electric field lines.
8. Use Gauss's law to explain why electric field lines must begin or end on electric charges. (*Hint:* Change the size of the gaussian surface.)
9. On the basis of the repulsive nature of the force between like charges and the freedom of motion of charge within the conductor, explain why excess charge on an isolated conductor must reside on its surface.
10. A person is placed in a large, hollow metallic sphere that is insulated from ground. If a large charge is placed on the sphere, will the person be harmed upon touching the inside of the sphere? Explain what will happen if the person also has an initial charge whose sign is opposite that of the charge on the sphere.
11. How would the observations described in Figure 24.20 differ if the hollow conductor were grounded? How would they differ if the small charged ball were an insulator rather than a conductor?
12. What other experiment might be performed on the ball in Figure 24.20 to show that its charge was transferred to the hollow conductor?
13. What would happen to the electrometer reading if the charged ball in Figure 24.20 touched the inner wall of the conductor? the outer wall?
14. You may have heard that one of the safer places to be during a lightning storm is inside a car. Why would this be the case?
15. Two solid spheres, both of radius  $R$ , carry identical total charges  $Q$ . One sphere is a good conductor, while the other is an insulator. If the charge on the insulating sphere is uniformly distributed throughout its interior volume, how do the electric fields outside these two spheres compare? Are the fields identical inside the two spheres?

### Section 24.1 Electric Flux

1. An electric field with a magnitude of  $3.50 \text{ kN/C}$  is applied along the  $x$  axis. Calculate the electric flux through a rectangular plane  $0.350 \text{ m}$  wide and  $0.700 \text{ m}$  long if (a) the plane is parallel to the  $yz$  plane; (b) the plane is parallel to the  $xy$  plane; and (c) the plane contains the  $y$  axis, and its normal makes an angle of  $40.0^\circ$  with the  $x$  axis.
2. A vertical electric field of magnitude  $2.00 \times 10^4 \text{ N/C}$  exists above the Earth's surface on a day when a thunderstorm is brewing. A car with a rectangular size of approximately  $6.00 \text{ m}$  by  $3.00 \text{ m}$  is traveling along a roadway sloping downward at  $10.0^\circ$ . Determine the electric flux through the bottom of the car.
3. A  $40.0\text{-cm}$ -diameter loop is rotated in a uniform electric field until the position of maximum electric flux is found. The flux in this position is measured to be  $5.20 \times 10^5 \text{ N}\cdot\text{m}^2/\text{C}$ . What is the magnitude of the electric field?
4. A spherical shell is placed in a uniform electric field. Find the total electric flux through the shell.
5. Consider a closed triangular box resting within a horizontal electric field of magnitude  $E = 7.80 \times 10^4 \text{ N/C}$ , as shown in Figure P24.5. Calculate the electric flux through (a) the vertical rectangular surface, (b) the slanted surface, and (c) the entire surface of the box.

Figure P24.5

6. A uniform electric field  $a\mathbf{i} + b\mathbf{j}$  intersects a surface of area  $A$ . What is the flux through this area if the surface lies (a) in the  $yz$  plane? (b) in the  $xz$  plane? (c) in the  $xy$  plane?
7. A point charge  $q$  is located at the center of a uniform ring having linear charge density  $\lambda$  and radius  $a$ , as shown in Figure P24.7. Determine the total electric flux

Figure P24.7

through a sphere centered at the point charge and having radius  $R$ , where  $R < a$ .

- A pyramid with a 6.00-m-square base and height of 4.00 m is placed in a vertical electric field of 52.0 N/C. Calculate the total electric flux through the pyramid's four slanted surfaces.
- A cone with base radius  $R$  and height  $h$  is located on a horizontal table. A horizontal uniform field  $E$  penetrates the cone, as shown in Figure P24.9. Determine the electric flux that enters the left-hand side of the cone.

Figure P24.9

- located a *very small* distance from the center of a *very large* square on the line perpendicular to the square and going through its center. Determine the approximate electric flux through the square due to the point charge. (c) Explain why the answers to parts (a) and (b) are identical.
- Calculate the total electric flux through the paraboloidal surface due to a constant electric field of magnitude  $E_0$  in the direction shown in Figure P24.14.

Figure P24.14

### Section 24.2 Gauss's Law

- The electric field everywhere on the surface of a thin spherical shell of radius 0.750 m is measured to be equal to 890 N/C and points radially toward the center of the sphere. (a) What is the net charge within the sphere's surface? (b) What can you conclude about the nature and distribution of the charge inside the spherical shell?
- The following charges are located inside a submarine:  $5.00 \mu\text{C}$ ,  $-9.00 \mu\text{C}$ ,  $27.0 \mu\text{C}$ , and  $-84.0 \mu\text{C}$ . (a) Calculate the net electric flux through the submarine. (b) Is the number of electric field lines leaving the submarine greater than, equal to, or less than the number entering it?
- Four closed surfaces,  $S_1$  through  $S_4$ , together with the charges  $-2Q$ ,  $Q$ , and  $-Q$  are sketched in Figure P24.12. Find the electric flux through each surface.

Figure P24.12

- (a) A point charge  $q$  is located a distance  $d$  from an infinite plane. Determine the electric flux through the plane due to the point charge. (b) A point charge  $q$  is

- WEB 15. A point charge  $Q$  is located just above the center of the flat face of a hemisphere of radius  $R$ , as shown in Figure P24.15. What is the electric flux (a) through the curved surface and (b) through the flat face?

Figure P24.15

- A point charge of  $12.0 \mu\text{C}$  is placed at the center of a spherical shell of radius 22.0 cm. What is the total electric flux through (a) the surface of the shell and (b) any hemispherical surface of the shell? (c) Do the results depend on the radius? Explain.
- A point charge of  $0.046 \mu\text{C}$  is inside a pyramid. Determine the total electric flux through the surface of the pyramid.
- An infinitely long line charge having a uniform charge per unit length  $\lambda$  lies a distance  $d$  from point  $O$ , as shown in Figure P24.18. Determine the total electric flux through the surface of a sphere of radius  $R$  centered at  $O$  resulting from this line charge. (*Hint:* Consider both cases: when  $R < d$ , and when  $R > d$ .)

Figure P24.18

19. A point charge  $Q = 5.00 \mu\text{C}$  is located at the center of a cube of side  $L = 0.100 \text{ m}$ . In addition, six other identical point charges having  $q = -1.00 \mu\text{C}$  are positioned symmetrically around  $Q$ , as shown in Figure P24.19. Determine the electric flux through one face of the cube.
20. A point charge  $Q$  is located at the center of a cube of side  $L$ . In addition, six other identical negative point charges are positioned symmetrically around  $Q$ , as shown in Figure P24.19. Determine the electric flux through one face of the cube.

Figure P24.19 Problems 19 and 20.

21. Consider an infinitely long line charge having uniform charge per unit length  $\lambda$ . Determine the total electric flux through a closed right circular cylinder of length  $L$  and radius  $R$  that is parallel to the line charge, if the distance between the axis of the cylinder and the line charge is  $d$ . (Hint: Consider both cases: when  $R < d$ , and when  $R > d$ .)
22. A  $10.0\text{-}\mu\text{C}$  charge located at the origin of a cartesian coordinate system is surrounded by a nonconducting hollow sphere of radius  $10.0 \text{ cm}$ . A drill with a radius of  $1.00 \text{ mm}$  is aligned along the  $z$  axis, and a hole is drilled in the sphere. Calculate the electric flux through the hole.

23. A charge of  $170 \mu\text{C}$  is at the center of a cube of side  $80.0 \text{ cm}$ . (a) Find the total flux through each face of the cube. (b) Find the flux through the whole surface of the cube. (c) Would your answers to parts (a) or (b) change if the charge were not at the center? Explain.
24. The total electric flux through a closed surface in the shape of a cylinder is  $8.60 \times 10^4 \text{ N}\cdot\text{m}^2/\text{C}$ . (a) What is the net charge within the cylinder? (b) From the information given, what can you say about the charge within the cylinder? (c) How would your answers to parts (a) and (b) change if the net flux were  $-8.60 \times 10^4 \text{ N}\cdot\text{m}^2/\text{C}$ ?
25. The line  $ag$  is a diagonal of a cube (Fig. P24.25). A point charge  $q$  is located on the extension of line  $ag$ , very close to vertex  $a$  of the cube. Determine the electric flux through each of the sides of the cube that meet at the point  $a$ .

Figure P24.25

### Section 24.3 Application of Gauss's Law to Charged Insulators

26. Determine the magnitude of the electric field at the surface of a lead-208 nucleus, which contains 82 protons and 126 neutrons. Assume that the lead nucleus has a volume 208 times that of one proton, and consider a proton to be a sphere of radius  $1.20 \times 10^{-15} \text{ m}$ .
27. A solid sphere of radius  $40.0 \text{ cm}$  has a total positive charge of  $26.0 \mu\text{C}$  uniformly distributed throughout its volume. Calculate the magnitude of the electric field (a)  $0 \text{ cm}$ , (b)  $10.0 \text{ cm}$ , (c)  $40.0 \text{ cm}$ , and (d)  $60.0 \text{ cm}$  from the center of the sphere.
28. A cylindrical shell of radius  $7.00 \text{ cm}$  and length  $240 \text{ cm}$  has its charge uniformly distributed on its curved surface. The magnitude of the electric field at a point  $19.0 \text{ cm}$  radially outward from its axis (measured from the midpoint of the shell) is  $36.0 \text{ kN/C}$ . Use approximate relationships to find (a) the net charge on the shell and (b) the electric field at a point  $4.00 \text{ cm}$  from the axis, measured radially outward from the midpoint of the shell.
- WEB 29. Consider a long cylindrical charge distribution of radius  $R$  with a uniform charge density  $\rho$ . Find the electric field at distance  $r$  from the axis where  $r < R$ .

30. A nonconducting wall carries a uniform charge density of  $8.60 \mu\text{C}/\text{cm}^2$ . What is the electric field  $7.00 \text{ cm}$  in front of the wall? Does your result change as the distance from the wall is varied?
31. Consider a thin spherical shell of radius  $14.0 \text{ cm}$  with a total charge of  $32.0 \mu\text{C}$  distributed uniformly on its surface. Find the electric field (a)  $10.0 \text{ cm}$  and (b)  $20.0 \text{ cm}$  from the center of the charge distribution.
32. In nuclear fission, a nucleus of uranium-238, which contains 92 protons, divides into two smaller spheres, each having 46 protons and a radius of  $5.90 \times 10^{-15} \text{ m}$ . What is the magnitude of the repulsive electric force pushing the two spheres apart?
33. Fill two rubber balloons with air. Suspend both of them from the same point on strings of equal length. Rub each with wool or your hair, so that they hang apart with a noticeable separation between them. Make order-of-magnitude estimates of (a) the force on each, (b) the charge on each, (c) the field each creates at the center of the other, and (d) the total flux of electric field created by each balloon. In your solution, state the quantities you take as data and the values you measure or estimate for them.
34. An insulating sphere is  $8.00 \text{ cm}$  in diameter and carries a  $5.70\text{-}\mu\text{C}$  charge uniformly distributed throughout its interior volume. Calculate the charge enclosed by a concentric spherical surface with radius (a)  $r = 2.00 \text{ cm}$  and (b)  $r = 6.00 \text{ cm}$ .
35. A uniformly charged, straight filament  $7.00 \text{ m}$  in length has a total positive charge of  $2.00 \mu\text{C}$ . An uncharged cardboard cylinder  $2.00 \text{ cm}$  in length and  $10.0 \text{ cm}$  in radius surrounds the filament at its center, with the filament as the axis of the cylinder. Using reasonable approximations, find (a) the electric field at the surface of the cylinder and (b) the total electric flux through the cylinder.
36. The charge per unit length on a long, straight filament is  $-90.0 \mu\text{C}/\text{m}$ . Find the electric field (a)  $10.0 \text{ cm}$ , (b)  $20.0 \text{ cm}$ , and (c)  $100 \text{ cm}$  from the filament, where distances are measured perpendicular to the length of the filament.
37. A large flat sheet of charge has a charge per unit area of  $9.00 \mu\text{C}/\text{m}^2$ . Find the electric field just above the surface of the sheet, measured from its midpoint.
- the same charge is spread uniformly over the *upper* surface of an otherwise identical glass plate, compare the electric fields just above the center of the upper surface of each plate.
41. A square plate of copper with  $50.0\text{-cm}$  sides has no net charge and is placed in a region of uniform electric field of  $80.0 \text{ kN/C}$  directed perpendicularly to the plate. Find (a) the charge density of each face of the plate and (b) the total charge on each face.
42. A hollow conducting sphere is surrounded by a larger concentric, spherical, conducting shell. The inner sphere has a charge  $-Q$ , and the outer sphere has a charge  $3Q$ . The charges are in electrostatic equilibrium. Using Gauss's law, find the charges and the electric fields everywhere.
43. Two identical conducting spheres each having a radius of  $0.500 \text{ cm}$  are connected by a light  $2.00\text{-m}$ -long conducting wire. Determine the tension in the wire if  $60.0 \mu\text{C}$  is placed on one of the conductors. (*Hint:* Assume that the surface distribution of charge on each sphere is uniform.)
44. The electric field on the surface of an irregularly shaped conductor varies from  $56.0 \text{ kN/C}$  to  $28.0 \text{ kN/C}$ . Calculate the local surface charge density at the point on the surface where the radius of curvature of the surface is (a) greatest and (b) smallest.
45. A long, straight wire is surrounded by a hollow metal cylinder whose axis coincides with that of the wire. The wire has a charge per unit length of  $\lambda$ , and the cylinder has a net charge per unit length of  $2\lambda$ . From this information, use Gauss's law to find (a) the charge per unit length on the inner and outer surfaces of the cylinder and (b) the electric field outside the cylinder, a distance  $r$  from the axis.
46. A conducting spherical shell of radius  $15.0 \text{ cm}$  carries a net charge of  $-6.40 \mu\text{C}$  uniformly distributed on its surface. Find the electric field at points (a) just outside the shell and (b) inside the shell.
- WEB 47. A thin conducting plate  $50.0 \text{ cm}$  on a side lies in the  $xy$  plane. If a total charge of  $4.00 \times 10^{-8} \text{ C}$  is placed on the plate, find (a) the charge density on the plate, (b) the electric field just above the plate, and (c) the electric field just below the plate.
48. A conducting spherical shell having an inner radius of  $a$  and an outer radius of  $b$  carries a net charge  $Q$ . If a point charge  $q$  is placed at the center of this shell, determine the surface charge density on (a) the inner surface of the shell and (b) the outer surface of the shell.
49. A solid conducting sphere of radius  $2.00 \text{ cm}$  has a charge  $8.00 \mu\text{C}$ . A conducting spherical shell of inner radius  $4.00 \text{ cm}$  and outer radius  $5.00 \text{ cm}$  is concentric with the solid sphere and has a charge  $-4.00 \mu\text{C}$ . Find the electric field at (a)  $r = 1.00 \text{ cm}$ , (b)  $r = 3.00 \text{ cm}$ , (c)  $r = 4.50 \text{ cm}$ , and (d)  $r = 7.00 \text{ cm}$  from the center of this charge configuration.

#### Section 24.4 Conductors in Electrostatic Equilibrium

38. On a clear, sunny day, a vertical electrical field of about  $130 \text{ N/C}$  points down over flat ground. What is the surface charge density on the ground for these conditions?
39. A long, straight metal rod has a radius of  $5.00 \text{ cm}$  and a charge per unit length of  $30.0 \text{ nC}/\text{m}$ . Find the electric field (a)  $3.00 \text{ cm}$ , (b)  $10.0 \text{ cm}$ , and (c)  $100 \text{ cm}$  from the axis of the rod, where distances are measured perpendicular to the rod.
40. A very large, thin, flat plate of aluminum of area  $A$  has a total charge  $Q$  uniformly distributed over its surfaces. If

50. A positive point charge is at a distance of  $R/2$  from the center of an uncharged thin conducting spherical shell of radius  $R$ . Sketch the electric field lines set up by this arrangement both inside and outside the shell.

(Optional)

### Section 24.6 Formal Derivation of Gauss's Law

51. A sphere of radius  $R$  surrounds a point charge  $Q$ , located at its center. (a) Show that the electric flux through a circular cap of half-angle  $\theta$  (Fig. P24.51) is

$$\Phi_E = \frac{Q}{2\epsilon_0} (1 - \cos \theta)$$

What is the flux for (b)  $\theta = 90^\circ$  and (c)  $\theta = 180^\circ$ ?

Figure P24.51

### ADDITIONAL PROBLEMS

52. A nonuniform electric field is given by the expression  $\mathbf{E} = ay\mathbf{i} + bz\mathbf{j} + cx\mathbf{k}$ , where  $a$ ,  $b$ , and  $c$  are constants. Determine the electric flux through a rectangular surface in the  $xy$  plane, extending from  $x = 0$  to  $x = w$  and from  $y = 0$  to  $y = h$ .
53. A solid insulating sphere of radius  $a$  carries a net positive charge  $3Q$ , uniformly distributed throughout its volume. Concentric with this sphere is a conducting spherical shell with inner radius  $b$  and outer radius  $c$ , and having a net charge  $-Q$ , as shown in Figure P24.53.
- Construct a spherical gaussian surface of radius  $r > c$  and find the net charge enclosed by this surface.
  - What is the direction of the electric field at  $r > c$ ?
  - Find the electric field at  $r > c$ .
  - Find the electric field in the region with radius  $r$  where  $c > r > b$ .
  - Construct a spherical gaussian surface of radius  $r$ , where  $c > r > b$ , and find the net charge enclosed by this surface.
  - Construct a spherical gaussian surface of radius  $r$ , where  $b > r > a$ , and find the net charge enclosed by this surface.
  - Find the electric field in the region  $b > r > a$ .
  - Construct a spherical gaussian surface of radius  $r < a$ , and find an expression for the

Figure P24.53

net charge enclosed by this surface, as a function of  $r$ . Note that the charge inside this surface is less than  $3Q$ .

- Find the electric field in the region  $r < a$ .
- Determine the charge on the inner surface of the conducting shell.
- Determine the charge on the outer surface of the conducting shell.
- Make a plot of the magnitude of the electric field versus  $r$ .

54. Consider two identical conducting spheres whose surfaces are separated by a small distance. One sphere is given a large net positive charge, while the other is given a small net positive charge. It is found that the force between them is attractive even though both spheres have net charges of the same sign. Explain how this is possible.

- WEB 55. A solid, insulating sphere of radius  $a$  has a uniform charge density  $\rho$  and a total charge  $Q$ . Concentric with this sphere is an uncharged, conducting hollow sphere whose inner and outer radii are  $b$  and  $c$ , as shown in Figure P24.55. (a) Find the magnitude of the electric field in the regions  $r < a$ ,  $a < r < b$ ,  $b < r < c$ , and  $r > c$ . (b) Determine the induced charge per unit area on the inner and outer surfaces of the hollow sphere.

Figure P24.55 Problems 55 and 56.

56. For the configuration shown in Figure P24.55, suppose that  $a = 5.00$  cm,  $b = 20.0$  cm, and  $c = 25.0$  cm. Furthermore, suppose that the electric field at a point 10.0 cm from the center is  $3.60 \times 10^3$  N/C radially inward, while the electric field at a point 50.0 cm from the center is  $2.00 \times 10^2$  N/C radially outward. From this information, find (a) the charge on the insulating sphere,

(b) the net charge on the hollow conducting sphere, and (c) the total charge on the inner and outer surfaces of the hollow conducting sphere.

57. An infinitely long cylindrical insulating shell of inner radius  $a$  and outer radius  $b$  has a uniform volume charge density  $\rho$  (C/m<sup>3</sup>). A line of charge density  $\lambda$  (C/m) is placed along the axis of the shell. Determine the electric field intensity everywhere.
58. Two infinite, nonconducting sheets of charge are parallel to each other, as shown in Figure P24.58. The sheet on the left has a uniform surface charge density  $\sigma$ , and the one on the right has a uniform charge density  $-\sigma$ . Calculate the value of the electric field at points (a) to the left of, (b) in between, and (c) to the right of the two sheets. (*Hint:* See Example 24.8.)

Figure P24.58

- WEB 59. Repeat the calculations for Problem 58 when both sheets have *positive* uniform surface charge densities of value  $\sigma$ .
60. A sphere of radius  $2a$  is made of a nonconducting material that has a uniform volume charge density  $\rho$ . (Assume that the material does not affect the electric field.) A spherical cavity of radius  $a$  is now removed from the sphere, as shown in Figure P24.60. Show that the electric field within the cavity is uniform and is given by  $E_x = 0$  and  $E_y = \rho a / 3\epsilon_0$ . (*Hint:* The field within the cavity is the superposition of the field due to the original uncut sphere, plus the field due to a sphere

Figure P24.60

the size of the cavity with a uniform negative charge density  $-\rho$ .)

61. **Review Problem.** An early (incorrect) model of the hydrogen atom, suggested by J. J. Thomson, proposed that a positive cloud of charge  $+e$  was uniformly distributed throughout the volume of a sphere of radius  $R$ , with the electron an equal-magnitude negative point charge  $-e$  at the center. (a) Using Gauss's law, show that the electron would be in equilibrium at the center and, if displaced from the center a distance  $r < R$ , would experience a restoring force of the form  $F = -Kr$ , where  $K$  is a constant. (b) Show that  $K = k_e e^2 / R^3$ . (c) Find an expression for the frequency  $f$  of simple harmonic oscillations that an electron of mass  $m_e$  would undergo if displaced a short distance ( $< R$ ) from the center and released. (d) Calculate a numerical value for  $R$  that would result in a frequency of electron vibration of  $2.47 \times 10^{15}$  Hz, the frequency of the light in the most intense line in the hydrogen spectrum.
62. A closed surface with dimensions  $a = b = 0.400$  m and  $c = 0.600$  m is located as shown in Figure P24.62. The electric field throughout the region is nonuniform and given by  $\mathbf{E} = (3.0 + 2.0x^2) \mathbf{i}$  N/C, where  $x$  is in meters. Calculate the net electric flux leaving the closed surface. What net charge is enclosed by the surface?

Figure P24.62

63. A solid insulating sphere of radius  $R$  has a nonuniform charge density that varies with  $r$  according to the expression  $\rho = Ar^2$ , where  $A$  is a constant and  $r < R$  is measured from the center of the sphere. (a) Show that the electric field outside ( $r > R$ ) the sphere is  $E = AR^5 / 5\epsilon_0 r^2$ . (b) Show that the electric field inside ( $r < R$ ) the sphere is  $E = Ar^3 / 5\epsilon_0$ . (*Hint:* Note that the total charge  $Q$  on the sphere is equal to the integral of  $\rho dV$ , where  $r$  extends from 0 to  $R$ ; also note that the charge  $q$  within a radius  $r < R$  is less than  $Q$ . To evaluate the integrals, note that the volume element  $dV$  for a spherical shell of radius  $r$  and thickness  $dr$  is equal to  $4\pi r^2 dr$ .)
64. A point charge  $Q$  is located on the axis of a disk of radius  $R$  at a distance  $b$  from the plane of the disk (Fig. P24.64). Show that if one fourth of the electric flux from the charge passes through the disk, then  $R = \sqrt{3}b$ .

Figure P24.64

65. A spherically symmetric charge distribution has a charge density given by  $\rho = a/r$ , where  $a$  is constant. Find the electric field as a function of  $r$ . (*Hint:* Note that the charge within a sphere of radius  $R$  is equal to the integral of  $\rho dV$ , where  $r$  extends from 0 to  $R$ . To evaluate the integral, note that the volume element  $dV$  for a spherical shell of radius  $r$  and thickness  $dr$  is equal to  $4\pi r^2 dr$ .)
66. An infinitely long insulating cylinder of radius  $R$  has a volume charge density that varies with the radius as

$$\rho = \rho_0 \left( a - \frac{r}{b} \right)$$

where  $\rho_0$ ,  $a$ , and  $b$  are positive constants and  $r$  is the distance from the axis of the cylinder. Use Gauss's law to determine the magnitude of the electric field at radial distances (a)  $r < R$  and (b)  $r > R$ .

67. **Review Problem.** A slab of insulating material (infinite in two of its three dimensions) has a uniform positive charge density  $\rho$ . An edge view of the slab is shown in Figure P24.67. (a) Show that the magnitude of the electric field a distance  $x$  from its center and inside the slab is  $E = \rho x / \epsilon_0$ . (b) Suppose that an electron of charge  $-e$  and mass  $m_e$  is placed inside the slab. If it is released from rest at a distance  $x$  from the center, show that the electron exhibits simple harmonic motion with

a frequency described by the expression

$$f = \frac{1}{2\pi} \sqrt{\frac{\rho e}{m_e \epsilon_0}}$$

Figure P24.67 Problems 67 and 68.

68. A slab of insulating material has a nonuniform positive charge density  $\rho = Cx^2$ , where  $x$  is measured from the center of the slab, as shown in Figure P24.67, and  $C$  is a constant. The slab is infinite in the  $y$  and  $z$  directions. Derive expressions for the electric field in (a) the exterior regions and (b) the interior region of the slab ( $-d/2 < x < d/2$ ).
69. (a) Using the mathematical similarity between Coulomb's law and Newton's law of universal gravitation, show that Gauss's law for gravitation can be written as

$$\oint \mathbf{g} \cdot d\mathbf{A} = -4\pi G m_{\text{in}}$$

where  $m_{\text{in}}$  is the mass inside the gaussian surface and  $\mathbf{g} = \mathbf{F}_g/m$  represents the gravitational field at any point on the gaussian surface. (b) Determine the gravitational field at a distance  $r$  from the center of the Earth where  $r < R_E$ , assuming that the Earth's mass density is uniform.

## ANSWERS TO QUICK QUIZZES

- 24.1 Zero, because there is no net charge within the surface.
- 24.2 (b) and (d). Statement (a) is not necessarily true because an equal number of positive and negative charges could be present inside the surface. Statement (c) is not necessarily true, as can be seen from Figure 24.8: A nonzero electric field exists everywhere on the surface, but the charge is not enclosed within the surface; thus, the net flux is zero.

- 24.3 Any gaussian surface surrounding the system encloses the same amount of charge, regardless of how the components of the system are moved. Thus, the flux through the gaussian surface would be the same as it is when the sphere and shell are concentric.

## # PUZZLER

Jennifer is holding on to an electrically charged sphere that reaches an electric potential of about 100 000 V. The device that generates this high electric potential is called a *Van de Graaff generator*. What causes Jennifer's hair to stand on end like the needles of a porcupine? Why is she safe in this situation in view of the fact that 110 V from a wall outlet can kill you? (Henry Leap and Jim Lehman)

## Electric Potential

### Chapter Outline

- 25.1** Potential Difference and Electric Potential
- 25.2** Potential Differences in a Uniform Electric Field
- 25.3** Electric Potential and Potential Energy Due to Point Charges
- 25.4** Obtaining the Value of the Electric Field from the Electric Potential
- 25.5** Electric Potential Due to Continuous Charge Distributions
- 25.6** Electric Potential Due to a Charged Conductor
- 25.7** (Optional) The Millikan Oil-Drop Experiment
- 25.8** (Optional) Applications of Electrostatics

The concept of potential energy was introduced in Chapter 8 in connection with such conservative forces as the force of gravity and the elastic force exerted by a spring. By using the law of conservation of energy, we were able to avoid working directly with forces when solving various problems in mechanics. In this chapter we see that the concept of potential energy is also of great value in the study of electricity. Because the electrostatic force given by Coulomb's law is conservative, electrostatic phenomena can be conveniently described in terms of an electric potential energy. This idea enables us to define a scalar quantity known as *electric potential*. Because the electric potential at any point in an electric field is a scalar function, we can use it to describe electrostatic phenomena more simply than if we were to rely only on the concepts of the electric field and electric forces. In later chapters we shall see that the concept of electric potential is of great practical value.

## 25.1 POTENTIAL DIFFERENCE AND ELECTRIC POTENTIAL

11.8 When a test charge  $q_0$  is placed in an electric field  $\mathbf{E}$  created by some other charged object, the electric force acting on the test charge is  $q_0\mathbf{E}$ . (If the field is produced by more than one charged object, this force acting on the test charge is the vector sum of the individual forces exerted on it by the various other charged objects.) The force  $q_0\mathbf{E}$  is conservative because the individual forces described by Coulomb's law are conservative. When the test charge is moved in the field by some external agent, the work done by the field on the charge is equal to the negative of the work done by the external agent causing the displacement. For an infinitesimal displacement  $d\mathbf{s}$ , the work done by the electric field on the charge is  $\mathbf{F} \cdot d\mathbf{s} = q_0\mathbf{E} \cdot d\mathbf{s}$ . As this amount of work is done by the field, the potential energy of the charge-field system is decreased by an amount  $dU = -q_0\mathbf{E} \cdot d\mathbf{s}$ . For a finite displacement of the charge from a point  $A$  to a point  $B$ , the change in potential energy of the system  $\Delta U = U_B - U_A$  is

$$\Delta U = -q_0 \int_A^B \mathbf{E} \cdot d\mathbf{s} \quad (25.1)$$

Change in potential energy

The integration is performed along the path that  $q_0$  follows as it moves from  $A$  to  $B$ , and the integral is called either a *path integral* or a *line integral* (the two terms are synonymous). Because the force  $q_0\mathbf{E}$  is conservative, **this line integral does not depend on the path taken from  $A$  to  $B$ .**

### Quick Quiz 25.1

If the path between  $A$  and  $B$  does not make any difference in Equation 25.1, why don't we just use the expression  $\Delta U = -q_0Ed$ , where  $d$  is the straight-line distance between  $A$  and  $B$ ?

The potential energy per unit charge  $U/q_0$  is independent of the value of  $q_0$  and has a unique value at every point in an electric field. This quantity  $U/q_0$  is called the **electric potential** (or simply the **potential**)  $V$ . Thus, the electric potential at any point in an electric field is

$$V = \frac{U}{q_0} \quad (25.2)$$

The fact that potential energy is a scalar quantity means that electric potential also is a scalar quantity.

The **potential difference**  $\Delta V = V_B - V_A$  between any two points  $A$  and  $B$  in an electric field is defined as the change in potential energy of the system divided by the test charge  $q_0$ :

Potential difference

$$\Delta V = \frac{\Delta U}{q_0} = - \int_A^B \mathbf{E} \cdot d\mathbf{s} \quad (25.3)$$

Potential difference should not be confused with difference in potential energy. The potential difference is proportional to the change in potential energy, and we see from Equation 25.3 that the two are related by  $\Delta U = q_0 \Delta V$ .

**Electric potential is a scalar characteristic of an electric field, independent of the charges that may be placed in the field. However, when we speak of potential energy, we are referring to the charge–field system.** Because we are usually interested in knowing the electric potential at the location of a charge and the potential energy resulting from the interaction of the charge with the field, we follow the common convention of speaking of the potential energy as if it belonged to the charge.

Because the change in potential energy of a charge is the negative of the work done by the electric field on the charge (as noted in Equation 25.1), the potential difference  $\Delta V$  between points  $A$  and  $B$  equals the work per unit charge that an external agent must perform to move a test charge from  $A$  to  $B$  without changing the kinetic energy of the test charge.

Just as with potential energy, only *differences* in electric potential are meaningful. To avoid having to work with potential differences, however, we often take the value of the electric potential to be zero at some convenient point in an electric field. This is what we do here: arbitrarily establish the electric potential to be zero at a point that is infinitely remote from the charges producing the field. Having made this choice, we can state that the **electric potential at an arbitrary point in an electric field equals the work required per unit charge to bring a positive test charge from infinity to that point.** Thus, if we take point  $A$  in Equation 25.3 to be at infinity, the electric potential at any point  $P$  is

$$V_P = - \int_{\infty}^P \mathbf{E} \cdot d\mathbf{s} \quad (25.4)$$

In reality,  $V_P$  represents the potential difference  $\Delta V$  between the point  $P$  and a point at infinity. (Eq. 25.4 is a special case of Eq. 25.3.)

Because electric potential is a measure of potential energy per unit charge, the SI unit of both electric potential and potential difference is joules per coulomb, which is defined as a **volt** (V):

Definition of volt

$$1 \text{ V} \equiv 1 \frac{\text{J}}{\text{C}}$$

That is, 1 J of work must be done to move a 1-C charge through a potential difference of 1 V.

Equation 25.3 shows that potential difference also has units of electric field times distance. From this, it follows that the SI unit of electric field (N/C) can also be expressed in volts per meter:

$$1 \frac{\text{N}}{\text{C}} = 1 \frac{\text{V}}{\text{m}}$$

A unit of energy commonly used in atomic and nuclear physics is the **electron volt (eV)**, which is defined as **the energy an electron (or proton) gains or loses by moving through a potential difference of 1 V**. Because  $1 \text{ V} = 1 \text{ J/C}$  and because the fundamental charge is approximately  $1.60 \times 10^{-19} \text{ C}$ , the electron volt is related to the joule as follows:

$$1 \text{ eV} = 1.60 \times 10^{-19} \text{ C} \cdot \text{V} = 1.60 \times 10^{-19} \text{ J} \quad (25.5)$$

For instance, an electron in the beam of a typical television picture tube may have a speed of  $3.5 \times 10^7 \text{ m/s}$ . This corresponds to a kinetic energy of  $5.6 \times 10^{-16} \text{ J}$ , which is equivalent to  $3.5 \times 10^3 \text{ eV}$ . Such an electron has to be accelerated from rest through a potential difference of 3.5 kV to reach this speed.

The electron volt

## 25.2 POTENTIAL DIFFERENCES IN A UNIFORM ELECTRIC FIELD

Equations 25.1 and 25.3 hold in all electric fields, whether uniform or varying, but they can be simplified for a uniform field. First, consider a uniform electric field directed along the negative  $y$  axis, as shown in Figure 25.1a. Let us calculate the potential difference between two points  $A$  and  $B$  separated by a distance  $d$ , where  $d$  is measured parallel to the field lines. Equation 25.3 gives

$$V_B - V_A = \Delta V = - \int_A^B \mathbf{E} \cdot d\mathbf{s} = - \int_A^B E \cos 0^\circ ds = - \int_A^B E ds$$

Because  $E$  is constant, we can remove it from the integral sign; this gives

$$\Delta V = -E \int_A^B ds = -Ed \quad (25.6)$$

Potential difference in a uniform electric field

The minus sign indicates that point  $B$  is at a lower electric potential than point  $A$ ; that is,  $V_B < V_A$ . **Electric field lines always point in the direction of decreasing electric potential**, as shown in Figure 25.1a.

Now suppose that a test charge  $q_0$  moves from  $A$  to  $B$ . We can calculate the change in its potential energy from Equations 25.3 and 25.6:

$$\Delta U = q_0 \Delta V = -q_0 Ed \quad (25.7)$$

**Figure 25.1** (a) When the electric field  $\mathbf{E}$  is directed downward, point  $B$  is at a lower electric potential than point  $A$ . A positive test charge that moves from point  $A$  to point  $B$  loses electric potential energy. (b) A mass  $m$  moving downward in the direction of the gravitational field  $\mathbf{g}$  loses gravitational potential energy.

### QuickLab

It takes an electric field of about 30 000 V/cm to cause a spark in dry air. Shuffle across a rug and reach toward a doorknob. By estimating the length of the spark, determine the electric potential difference between your finger and the doorknob after shuffling your feet but before touching the knob. (If it is very humid on the day you attempt this, it may not work. Why?)

**Figure 25.2** A uniform electric field directed along the positive  $x$  axis. Point  $B$  is at a lower electric potential than point  $A$ . Points  $B$  and  $C$  are at the *same* electric potential.

An equipotential surface

From this result, we see that if  $q_0$  is positive, then  $\Delta U$  is negative. We conclude that **a positive charge loses electric potential energy when it moves in the direction of the electric field.** This means that an electric field does work on a positive charge when the charge moves in the direction of the electric field. (This is analogous to the work done by the gravitational field on a falling mass, as shown in Figure 25.1b.) If a positive test charge is released from rest in this electric field, it experiences an electric force  $q_0\mathbf{E}$  in the direction of  $\mathbf{E}$  (downward in Fig. 25.1a). Therefore, it accelerates downward, gaining kinetic energy. **As the charged particle gains kinetic energy, it loses an equal amount of potential energy.**

If  $q_0$  is negative, then  $\Delta U$  is positive and the situation is reversed: **A negative charge gains electric potential energy when it moves in the direction of the electric field.** If a negative charge is released from rest in the field  $\mathbf{E}$ , it accelerates in a direction opposite the direction of the field.

Now consider the more general case of a charged particle that is free to move between any two points in a uniform electric field directed along the  $x$  axis, as shown in Figure 25.2. (In this situation, the charge is not being moved by an external agent as before.) If  $\mathbf{s}$  represents the displacement vector between points  $A$  and  $B$ , Equation 25.3 gives

$$\Delta V = - \int_A^B \mathbf{E} \cdot d\mathbf{s} = - \mathbf{E} \cdot \int_A^B d\mathbf{s} = - \mathbf{E} \cdot \mathbf{s} \quad (25.8)$$

where again we are able to remove  $\mathbf{E}$  from the integral because it is constant. The change in potential energy of the charge is

$$\Delta U = q_0 \Delta V = -q_0 \mathbf{E} \cdot \mathbf{s} \quad (25.9)$$

11.9

Finally, we conclude from Equation 25.8 that all points in a plane perpendicular to a uniform electric field are at the same electric potential. We can see this in Figure 25.2, where the potential difference  $V_B - V_A$  is equal to the potential difference  $V_C - V_A$ . (Prove this to yourself by working out the dot product  $\mathbf{E} \cdot \mathbf{s}$  for  $\mathbf{s}_{A \rightarrow B}$ , where the angle  $\theta$  between  $\mathbf{E}$  and  $\mathbf{s}$  is arbitrary as shown in Figure 25.2, and the dot product for  $\mathbf{s}_{A \rightarrow C}$ , where  $\theta = 0$ .) Therefore,  $V_B = V_C$ . **The name equipotential surface is given to any surface consisting of a continuous distribution of points having the same electric potential.**

Note that because  $\Delta U = q_0 \Delta V$ , no work is done in moving a test charge between any two points on an equipotential surface. The equipotential surfaces of a uniform electric field consist of a family of planes that are all perpendicular to the field. Equipotential surfaces for fields with other symmetries are described in later sections.

### Quick Quiz 25.2

The labeled points in Figure 25.3 are on a series of equipotential surfaces associated with an electric field. Rank (from greatest to least) the work done by the electric field on a positively charged particle that moves from  $A$  to  $B$ ; from  $B$  to  $C$ ; from  $C$  to  $D$ ; from  $D$  to  $E$ .

**Figure 25.3** Four equipotential surfaces.

**EXAMPLE 25.1** The Electric Field Between Two Parallel Plates of Opposite Charge

A battery produces a specified potential difference between conductors attached to the battery terminals. A 12-V battery is connected between two parallel plates, as shown in Figure 25.4. The separation between the plates is  $d = 0.30$  cm, and we assume the electric field between the plates to be uniform.

**Figure 25.4** A 12-V battery connected to two parallel plates. The electric field between the plates has a magnitude given by the potential difference  $\Delta V$  divided by the plate separation  $d$ .

(This assumption is reasonable if the plate separation is small relative to the plate dimensions and if we do not consider points near the plate edges.) Find the magnitude of the electric field between the plates.

**Solution** The electric field is directed from the positive plate ( $A$ ) to the negative one ( $B$ ), and the positive plate is at a higher electric potential than the negative plate is. The potential difference between the plates must equal the potential difference between the battery terminals. We can understand this by noting that all points on a conductor in equilibrium are at the same electric potential<sup>1</sup>; no potential difference exists between a terminal and any portion of the plate to which it is connected. Therefore, the magnitude of the electric field between the plates is, from Equation 25.6,

$$E = \frac{|V_B - V_A|}{d} = \frac{12 \text{ V}}{0.30 \times 10^{-2} \text{ m}} = 4.0 \times 10^3 \text{ V/m}$$

This configuration, which is shown in Figure 25.4 and called a *parallel-plate capacitor*, is examined in greater detail in Chapter 26.

**EXAMPLE 25.2** Motion of a Proton in a Uniform Electric Field

A proton is released from rest in a uniform electric field that has a magnitude of  $8.0 \times 10^4$  V/m and is directed along the positive  $x$  axis (Fig. 25.5). The proton undergoes a displacement of 0.50 m in the direction of  $\mathbf{E}$ . (a) Find the change in electric potential between points  $A$  and  $B$ .

**Solution** Because the proton (which, as you remember, carries a positive charge) moves in the direction of the field, we expect it to move to a position of lower electric potential.

**Figure 25.5** A proton accelerates from  $A$  to  $B$  in the direction of the electric field.

From Equation 25.6, we have

$$\begin{aligned} \Delta V &= -Ed = -(8.0 \times 10^4 \text{ V/m})(0.50 \text{ m}) \\ &= -4.0 \times 10^4 \text{ V} \end{aligned}$$

(b) Find the change in potential energy of the proton for this displacement.

**Solution**

$$\begin{aligned} \Delta U &= q_0 \Delta V = e \Delta V \\ &= (1.6 \times 10^{-19} \text{ C})(-4.0 \times 10^4 \text{ V}) \\ &= -6.4 \times 10^{-15} \text{ J} \end{aligned}$$

The negative sign means the potential energy of the proton decreases as it moves in the direction of the electric field. As the proton accelerates in the direction of the field, it gains kinetic energy and at the same time loses electric potential energy (because energy is conserved).

**Exercise** Use the concept of conservation of energy to find the speed of the proton at point  $B$ .

**Answer**  $2.77 \times 10^6$  m/s.

<sup>1</sup> The electric field vanishes within a conductor in electrostatic equilibrium; thus, the path integral  $\int \mathbf{E} \cdot d\mathbf{s}$  between any two points in the conductor must be zero. A more complete discussion of this point is given in Section 25.6.

### 25.3 ELECTRIC POTENTIAL AND POTENTIAL ENERGY DUE TO POINT CHARGES

Consider an isolated positive point charge  $q$ . Recall that such a charge produces an electric field that is directed radially outward from the charge. To find the electric potential at a point located a distance  $r$  from the charge, we begin with the general expression for potential difference:

$$V_B - V_A = - \int_A^B \mathbf{E} \cdot d\mathbf{s}$$

where  $A$  and  $B$  are the two arbitrary points shown in Figure 25.6. At any field point, the electric field due to the point charge is  $\mathbf{E} = k_e q \hat{\mathbf{r}}/r^2$  (Eq. 23.4), where  $\hat{\mathbf{r}}$  is a unit vector directed from the charge toward the field point. The quantity  $\mathbf{E} \cdot d\mathbf{s}$  can be expressed as

$$\mathbf{E} \cdot d\mathbf{s} = k_e \frac{q}{r^2} \hat{\mathbf{r}} \cdot d\mathbf{s}$$

Because the magnitude of  $\hat{\mathbf{r}}$  is 1, the dot product  $\hat{\mathbf{r}} \cdot d\mathbf{s} = ds \cos \theta$ , where  $\theta$  is the angle between  $\hat{\mathbf{r}}$  and  $d\mathbf{s}$ . Furthermore,  $ds \cos \theta$  is the projection of  $d\mathbf{s}$  onto  $\mathbf{r}$ ; thus,  $ds \cos \theta = dr$ . That is, any displacement  $d\mathbf{s}$  along the path from point  $A$  to point  $B$  produces a change  $dr$  in the magnitude of  $\mathbf{r}$ , the radial distance to the charge creating the field. Making these substitutions, we find that  $\mathbf{E} \cdot d\mathbf{s} = (k_e q/r^2) dr$ ; hence, the expression for the potential difference becomes

$$\begin{aligned} V_B - V_A &= - \int_{r_A}^{r_B} E_r dr = - k_e q \int_{r_A}^{r_B} \frac{dr}{r^2} = \frac{k_e q}{r} \Big|_{r_A}^{r_B} \\ V_B - V_A &= k_e q \left[ \frac{1}{r_B} - \frac{1}{r_A} \right] \end{aligned} \quad (25.10)$$

The integral of  $\mathbf{E} \cdot d\mathbf{s}$  is *independent* of the path between points  $A$  and  $B$ —as it must be because the electric field of a point charge is conservative. Furthermore, Equation 25.10 expresses the important result that the potential difference between any two points  $A$  and  $B$  in a field created by a point charge depends only on the radial coordinates  $r_A$  and  $r_B$ . It is customary to choose the reference of electric potential to be zero at  $r_A = \infty$ . With this reference, the electric potential created by a point charge at any distance  $r$  from the charge is

$$V = k_e \frac{q}{r} \quad (25.11)$$

Electric potential is graphed in Figure 25.7 as a function of  $r$ , the radial distance from a positive charge in the  $xy$  plane. Consider the following analogy to gravitational potential: Imagine trying to roll a marble toward the top of a hill shaped like Figure 25.7a. The gravitational force experienced by the marble is analogous to the repulsive force experienced by a positively charged object as it approaches another positively charged object. Similarly, the electric potential graph of the region surrounding a negative charge is analogous to a “hole” with respect to any approaching positively charged objects. A charged object must be infinitely distant from another charge before the surface is “flat” and has an electric potential of zero.

**Figure 25.6** The potential difference between points  $A$  and  $B$  due to a point charge  $q$  depends *only* on the initial and final radial coordinates  $r_A$  and  $r_B$ . The two dashed circles represent cross-sections of spherical equipotential surfaces.

Electric potential created by a point charge

(a)

(b)

**Figure 25.7** (a) The electric potential in the plane around a single positive charge is plotted on the vertical axis. (The electric potential function for a negative charge would look like a hole instead of a hill.) The red line shows the  $1/r$  nature of the electric potential, as given by Equation 25.11. (b) View looking straight down the vertical axis of the graph in part (a), showing concentric circles where the electric potential is constant. These circles are cross sections of equipotential spheres having the charge at the center.

### Quick Quiz 25.3

A spherical balloon contains a positively charged object at its center. As the balloon is inflated to a greater volume while the charged object remains at the center, does the electric potential at the surface of the balloon increase, decrease, or remain the same? How about the magnitude of the electric field? The electric flux?

We obtain the electric potential resulting from two or more point charges by applying the superposition principle. That is, the total electric potential at some point  $P$  due to several point charges is the sum of the potentials due to the individual charges. For a group of point charges, we can write the total electric potential at  $P$  in the form

Electric potential due to several point charges

$$V = k_e \sum_i \frac{q_i}{r_i} \quad (25.12)$$

where the potential is again taken to be zero at infinity and  $r_i$  is the distance from the point  $P$  to the charge  $q_i$ . Note that the sum in Equation 25.12 is an algebraic sum of scalars rather than a vector sum (which we use to calculate the electric field of a group of charges). Thus, it is often much easier to evaluate  $V$  than to evaluate  $\mathbf{E}$ . The electric potential around a dipole is illustrated in Figure 25.8.

We now consider the potential energy of a system of two charged particles. If  $V_1$  is the electric potential at a point  $P$  due to charge  $q_1$ , then the work an external agent must do to bring a second charge  $q_2$  from infinity to  $P$  without acceleration is  $q_2 V_1$ . By definition, this work equals the potential energy  $U$  of the two-particle system when the particles are separated by a distance  $r_{12}$  (Fig. 25.9). Therefore, we can express the potential energy as<sup>2</sup>

Electric potential energy due to two charges

$$U = k_e \frac{q_1 q_2}{r_{12}} \quad (25.13)$$

Note that if the charges are of the same sign,  $U$  is positive. This is consistent with the fact that positive work must be done by an external agent on the system to bring the two charges near one another (because like charges repel). If the charges are of opposite sign,  $U$  is negative; this means that negative work must be done against the attractive force between the unlike charges for them to be brought near each other.

If more than two charged particles are in the system, we can obtain the total potential energy by calculating  $U$  for every pair of charges and summing the terms algebraically. As an example, the total potential energy of the system of three charges shown in Figure 25.10 is

$$U = k_e \left( \frac{q_1 q_2}{r_{12}} + \frac{q_1 q_3}{r_{13}} + \frac{q_2 q_3}{r_{23}} \right) \quad (25.14)$$

Physically, we can interpret this as follows: Imagine that  $q_1$  is fixed at the position shown in Figure 25.10 but that  $q_2$  and  $q_3$  are at infinity. The work an external agent must do to bring  $q_2$  from infinity to its position near  $q_1$  is  $k_e q_1 q_2 / r_{12}$ , which is the first term in Equation 25.14. The last two terms represent the work required to bring  $q_3$  from infinity to its position near  $q_1$  and  $q_2$ . (The result is independent of the order in which the charges are transported.)

<sup>2</sup> The expression for the electric potential energy of a system made up of two point charges, Equation 25.13, is of the *same* form as the equation for the gravitational potential energy of a system made up of two point masses,  $Gm_1 m_2 / r$  (see Chapter 14). The similarity is not surprising in view of the fact that both expressions are derived from an inverse-square force law.

(a)

(b)

**Figure 25.8** (a) The electric potential in the plane containing a dipole. (b) Top view of the function graphed in part (a).

**Figure 25.9** If two point charges are separated by a distance  $r_{12}$ , the potential energy of the pair of charges is given by  $k_e q_1 q_2 / r_{12}$ .

**Figure 25.10** Three point charges are fixed at the positions shown. The potential energy of this system of charges is given by Equation 25.14.

**EXAMPLE 25.3** The Electric Potential Due to Two Point Charges

A charge  $q_1 = 2.00 \mu\text{C}$  is located at the origin, and a charge  $q_2 = -6.00 \mu\text{C}$  is located at  $(0, 3.00)$  m, as shown in Figure 25.11a. (a) Find the total electric potential due to these charges at the point  $P$ , whose coordinates are  $(4.00, 0)$  m.

**Solution** For two charges, the sum in Equation 25.12 gives

$$\begin{aligned} V_P &= k_e \left( \frac{q_1}{r_1} + \frac{q_2}{r_2} \right) \\ &= 8.99 \times 10^9 \frac{\text{N} \cdot \text{m}^2}{\text{C}^2} \left( \frac{2.00 \times 10^{-6} \text{ C}}{4.00 \text{ m}} + \frac{-6.00 \times 10^{-6} \text{ C}}{5.00 \text{ m}} \right) \\ &= -6.29 \times 10^3 \text{ V} \end{aligned}$$

(b) Find the change in potential energy of a  $3.00\text{-}\mu\text{C}$  charge as it moves from infinity to point  $P$  (Fig. 25.11b).

**Solution** When the charge is at infinity,  $U_i = 0$ , and when the charge is at  $P$ ,  $U_f = q_3 V_P$ ; therefore,

$$\begin{aligned} \Delta U &= q_3 V_P - 0 = (3.00 \times 10^{-6} \text{ C})(-6.29 \times 10^3 \text{ V}) \\ &= -18.9 \times 10^{-3} \text{ J} \end{aligned}$$

Therefore, because  $W = -\Delta U$ , positive work would have to be done by an external agent to remove the charge from point  $P$  back to infinity.

**Exercise** Find the total potential energy of the system illustrated in Figure 25.11b.

**Answer**  $-5.48 \times 10^{-2} \text{ J}$ .

**Figure 25.11** (a) The electric potential at  $P$  due to the two charges is the algebraic sum of the potentials due to the individual charges. (b) What is the potential energy of the three-charge system?

## 25.4 OBTAINING THE VALUE OF THE ELECTRIC FIELD FROM THE ELECTRIC POTENTIAL

The electric field  $\mathbf{E}$  and the electric potential  $V$  are related as shown in Equation 25.3. We now show how to calculate the value of the electric field if the electric potential is known in a certain region.

From Equation 25.3 we can express the potential difference  $dV$  between two points a distance  $ds$  apart as

$$dV = -\mathbf{E} \cdot d\mathbf{s} \quad (25.15)$$

If the electric field has only one component  $E_x$ , then  $\mathbf{E} \cdot d\mathbf{s} = E_x dx$ . Therefore, Equation 25.15 becomes  $dV = -E_x dx$ , or

$$E_x = -\frac{dV}{dx} \quad (25.16)$$

That is, the magnitude of the electric field in the direction of some coordinate is equal to the negative of the derivative of the electric potential with respect to that coordinate. Recall from the discussion following Equation 25.8 that the electric potential does not change for any displacement perpendicular to an electric field. This is consistent with the notion, developed in Section 25.2, that equipotential surfaces are perpendicular to the field, as shown in Figure 25.12. A small positive charge placed at rest on an electric field line begins to move along the direction of  $\mathbf{E}$  because that is the direction of the force exerted on the charge by the charge distribution creating the electric field (and hence is the direction of  $\mathbf{a}$ ). Because the charge starts with zero velocity, it moves in the direction of the change in velocity—that is, in the direction of  $\mathbf{a}$ . In Figures 25.12a and 25.12b, a charge placed at rest in the field will move in a straight line because its acceleration vector is always parallel to its velocity vector. The magnitude of  $\mathbf{v}$  increases, but its direction does not change. The situation is different in Figure 25.12c. A positive charge placed at some point near the dipole first moves in a direction parallel to  $\mathbf{E}$  at that point. Because the direction of the electric field is different at different locations, however, the force acting on the charge changes direction, and  $\mathbf{a}$  is no longer parallel to  $\mathbf{v}$ . This causes the moving charge to change direction and speed, but it does not necessarily follow the electric field lines. Recall that it is not the velocity vector but rather the acceleration vector that is proportional to force.

If the charge distribution creating an electric field has spherical symmetry such that the volume charge density depends only on the radial distance  $r$ , then the electric field is radial. In this case,  $\mathbf{E} \cdot d\mathbf{s} = E_r dr$ , and thus we can express  $dV$  in the form  $dV = -E_r dr$ . Therefore,

$$E_r = -\frac{dV}{dr} \quad (25.17)$$

For example, the electric potential of a point charge is  $V = k_e q/r$ . Because  $V$  is a function of  $r$  only, the potential function has spherical symmetry. Applying Equation 25.17, we find that the electric field due to the point charge is  $E_r = k_e q/r^2$ , a familiar result. Note that the potential changes only in the radial direction, not in

**Figure 25.12** Equipotential surfaces (dashed blue lines) and electric field lines (red lines) for (a) a uniform electric field produced by an infinite sheet of charge, (b) a point charge, and (c) an electric dipole. In all cases, the equipotential surfaces are *perpendicular* to the electric field lines at every point. Compare these drawings with Figures 25.2, 25.7b, and 25.8b.

Equipotential surfaces are perpendicular to the electric field lines

any direction perpendicular to  $r$ . Thus,  $V$  (like  $E_r$ ) is a function only of  $r$ . Again, this is consistent with the idea that **equipotential surfaces are perpendicular to field lines**. In this case the equipotential surfaces are a family of spheres concentric with the spherically symmetric charge distribution (Fig. 25.12b).

The equipotential surfaces for an electric dipole are sketched in Figure 25.12c. When a test charge undergoes a displacement  $d\mathbf{s}$  along an equipotential surface, then  $dV = 0$  because the potential is constant along an equipotential surface. From Equation 25.15, then,  $dV = -\mathbf{E} \cdot d\mathbf{s} = 0$ ; thus,  $\mathbf{E}$  must be perpendicular to the displacement along the equipotential surface. This shows that the equipotential surfaces must *always* be *perpendicular* to the electric field lines.

In general, the electric potential is a function of all three spatial coordinates. If  $V(r)$  is given in terms of the cartesian coordinates, the electric field components  $E_x$ ,  $E_y$ , and  $E_z$  can readily be found from  $V(x, y, z)$  as the partial derivatives<sup>3</sup>

$$E_x = -\frac{\partial V}{\partial x} \quad E_y = -\frac{\partial V}{\partial y} \quad E_z = -\frac{\partial V}{\partial z}$$

For example, if  $V = 3x^2y + y^2 + yz$ , then

$$\frac{\partial V}{\partial x} = \frac{\partial}{\partial x} (3x^2y + y^2 + yz) = \frac{\partial}{\partial x} (3x^2y) = 3y \frac{d}{dx} (x^2) = 6xy$$

### EXAMPLE 25.4 The Electric Potential Due to a Dipole

An electric dipole consists of two charges of equal magnitude and opposite sign separated by a distance  $2a$ , as shown in Figure 25.13. The dipole is along the  $x$  axis and is centered at the origin. (a) Calculate the electric potential at point  $P$ .

**Solution** For point  $P$  in Figure 25.13,

$$V = k_e \sum \frac{q_i}{r_i} = k_e \left( \frac{q}{x-a} - \frac{q}{x+a} \right) = \frac{2k_e qa}{x^2 - a^2}$$

Figure 25.13 An electric dipole located on the  $x$  axis.

(How would this result change if point  $P$  happened to be located to the left of the negative charge?)

(b) Calculate  $V$  and  $E_x$  at a point far from the dipole.

**Solution** If point  $P$  is far from the dipole, such that  $x \gg a$ , then  $a^2$  can be neglected in the term  $x^2 - a^2$ , and  $V$  becomes

$$V \approx \frac{2k_e qa}{x^2} \quad (x \gg a)$$

Using Equation 25.16 and this result, we can calculate the electric field at a point far from the dipole:

$$E_x = -\frac{dV}{dx} = \frac{4k_e qa}{x^3} \quad (x \gg a)$$

(c) Calculate  $V$  and  $E_x$  if point  $P$  is located anywhere between the two charges.

**Solution**

$$V = k_e \sum \frac{q_i}{r_i} = k_e \left( \frac{q}{a-x} - \frac{q}{x+a} \right) = -\frac{2k_e qx}{x^2 - a^2}$$

$$E_x = -\frac{dV}{dx} = -\frac{d}{dx} \left( -\frac{2k_e qx}{x^2 - a^2} \right) = 2k_e q \left( \frac{-x^2 - a^2}{(x^2 - a^2)^2} \right)$$

<sup>3</sup> In vector notation,  $\mathbf{E}$  is often written

$$\mathbf{E} = -\nabla V = -\left( \mathbf{i} \frac{\partial}{\partial x} + \mathbf{j} \frac{\partial}{\partial y} + \mathbf{k} \frac{\partial}{\partial z} \right) V$$

where  $\nabla$  is called the *gradient operator*.

We can check these results by considering the situation at the center of the dipole, where  $x = 0$ ,  $V = 0$ , and  $E_x = -2k_e q/a^2$ .

**Exercise** Verify the electric field result in part (c) by calculating the sum of the individual electric field vectors at the origin due to the two charges.

## 25.5 ELECTRIC POTENTIAL DUE TO CONTINUOUS CHARGE DISTRIBUTIONS

We can calculate the electric potential due to a continuous charge distribution in two ways. If the charge distribution is known, we can start with Equation 25.11 for the electric potential of a point charge. We then consider the potential due to a small charge element  $dq$ , treating this element as a point charge (Fig. 25.14). The electric potential  $dV$  at some point  $P$  due to the charge element  $dq$  is

$$dV = k_e \frac{dq}{r} \quad (25.18)$$

where  $r$  is the distance from the charge element to point  $P$ . To obtain the total potential at point  $P$ , we integrate Equation 25.18 to include contributions from all elements of the charge distribution. Because each element is, in general, a different distance from point  $P$  and because  $k_e$  is constant, we can express  $V$  as

$$V = k_e \int \frac{dq}{r} \quad (25.19)$$

In effect, we have replaced the sum in Equation 25.12 with an integral. Note that this expression for  $V$  uses a particular reference: The electric potential is taken to be zero when point  $P$  is infinitely far from the charge distribution.

If the electric field is already known from other considerations, such as Gauss's law, we can calculate the electric potential due to a continuous charge distribution using Equation 25.3. If the charge distribution is highly symmetric, we first evaluate  $\mathbf{E}$  at any point using Gauss's law and then substitute the value obtained into Equation 25.3 to determine the potential difference  $\Delta V$  between any two points. We then choose the electric potential  $V$  to be zero at some convenient point.

We illustrate both methods with several examples.

### EXAMPLE 25.5 Electric Potential Due to a Uniformly Charged Ring

(a) Find an expression for the electric potential at a point  $P$  located on the perpendicular central axis of a uniformly charged ring of radius  $a$  and total charge  $Q$ .

**Solution** Let us orient the ring so that its plane is perpendicular to an  $x$  axis and its center is at the origin. We can then take point  $P$  to be at a distance  $x$  from the center of the ring, as shown in Figure 25.15. The charge element  $dq$  is at a distance  $\sqrt{x^2 + a^2}$  from point  $P$ . Hence, we can express  $V$  as

$$V = k_e \int \frac{dq}{r} = k_e \int \frac{dq}{\sqrt{x^2 + a^2}}$$

Because each element  $dq$  is at the same distance from point  $P$ ,

we can remove  $\sqrt{x^2 + a^2}$  from the integral, and  $V$  reduces to

$$V = \frac{k_e}{\sqrt{x^2 + a^2}} \int dq = \frac{k_e Q}{\sqrt{x^2 + a^2}} \quad (25.20)$$

The only variable in this expression for  $V$  is  $x$ . This is not surprising because our calculation is valid only for points along the  $x$  axis, where  $y$  and  $z$  are both zero.

(b) Find an expression for the magnitude of the electric field at point  $P$ .

**Solution** From symmetry, we see that along the  $x$  axis  $\mathbf{E}$  can have only an  $x$  component. Therefore, we can use Equa-

**Figure 25.14** The electric potential at the point  $P$  due to a continuous charge distribution can be calculated by dividing the charged body into segments of charge  $dq$  and summing the electric potential contributions over all segments.

tion 25.16:

$$\begin{aligned} E_x &= -\frac{dV}{dx} = -k_e Q \frac{d}{dx} (x^2 + a^2)^{-1/2} \\ &= -k_e Q \left(-\frac{1}{2}\right) (x^2 + a^2)^{-3/2} (2x) \\ &= \frac{k_e Q x}{(x^2 + a^2)^{3/2}} \end{aligned} \quad (25.21)$$

This result agrees with that obtained by direct integration (see Example 23.8). Note that  $E_x = 0$  at  $x = 0$  (the center of the ring). Could you have guessed this from Coulomb's law?

**Exercise** What is the electric potential at the center of the ring? What does the value of the field at the center tell you about the value of  $V$  at the center?

**Answer**  $V = k_e Q/a$ . Because  $E_x = -dV/dx = 0$  at the cen-

ter,  $V$  has either a maximum or minimum value; it is, in fact, a maximum.

**Figure 25.15** A uniformly charged ring of radius  $a$  lies in a plane perpendicular to the  $x$  axis. All segments  $dq$  of the ring are the same distance from any point  $P$  lying on the  $x$  axis.

### EXAMPLE 25.6 Electric Potential Due to a Uniformly Charged Disk

Find (a) the electric potential and (b) the magnitude of the electric field along the perpendicular central axis of a uniformly charged disk of radius  $a$  and surface charge density  $\sigma$ .

**Solution** (a) Again, we choose the point  $P$  to be at a distance  $x$  from the center of the disk and take the plane of the disk to be perpendicular to the  $x$  axis. We can simplify the problem by dividing the disk into a series of charged rings. The electric potential of each ring is given by Equation 25.20. Consider one such ring of radius  $r$  and width  $dr$ , as indicated in Figure 25.16. The surface area of the ring is  $dA = 2\pi r dr$ ;

**Figure 25.16** A uniformly charged disk of radius  $a$  lies in a plane perpendicular to the  $x$  axis. The calculation of the electric potential at any point  $P$  on the  $x$  axis is simplified by dividing the disk into many rings each of area  $2\pi r dr$ .

from the definition of surface charge density (see Section 23.5), we know that the charge on the ring is  $dq = \sigma dA = \sigma 2\pi r dr$ . Hence, the potential at the point  $P$  due to this ring is

$$dV = \frac{k_e dq}{\sqrt{r^2 + x^2}} = \frac{k_e \sigma 2\pi r dr}{\sqrt{r^2 + x^2}}$$

To find the *total* electric potential at  $P$ , we sum over all rings making up the disk. That is, we integrate  $dV$  from  $r = 0$  to  $r = a$ :

$$V = \pi k_e \sigma \int_0^a \frac{2r dr}{\sqrt{r^2 + x^2}} = \pi k_e \sigma \int_0^a (r^2 + x^2)^{-1/2} 2r dr$$

This integral is of the form  $u^n du$  and has the value  $u^{n+1}/(n+1)$ , where  $n = -\frac{1}{2}$  and  $u = r^2 + x^2$ . This gives

$$V = 2\pi k_e \sigma [(x^2 + a^2)^{1/2} - x] \quad (25.22)$$

(b) As in Example 25.5, we can find the electric field at any axial point from

$$E_x = -\frac{dV}{dx} = 2\pi k_e \sigma \left(1 - \frac{x}{\sqrt{x^2 + a^2}}\right) \quad (25.23)$$

The calculation of  $V$  and  $\mathbf{E}$  for an arbitrary point off the axis is more difficult to perform, and we do not treat this situation in this text.

**EXAMPLE 25.7** Electric Potential Due to a Finite Line of Charge

A rod of length  $\ell$  located along the  $x$  axis has a total charge  $Q$  and a uniform linear charge density  $\lambda = Q/\ell$ . Find the electric potential at a point  $P$  located on the  $y$  axis a distance  $a$  from the origin (Fig. 25.17).

**Solution** The length element  $dx$  has a charge  $dq = \lambda dx$ . Because this element is a distance  $r = \sqrt{x^2 + a^2}$  from point  $P$ , we can express the potential at point  $P$  due to this element as

$$dV = k_e \frac{dq}{r} = k_e \frac{\lambda dx}{\sqrt{x^2 + a^2}}$$

To obtain the total potential at  $P$ , we integrate this expression over the limits  $x = 0$  to  $x = \ell$ . Noting that  $k_e$  and  $\lambda$  are constants, we find that

$$V = k_e \lambda \int_0^\ell \frac{dx}{\sqrt{x^2 + a^2}} = k_e \frac{Q}{\ell} \int_0^\ell \frac{dx}{\sqrt{x^2 + a^2}}$$

This integral has the following value (see Appendix B):

$$\int \frac{dx}{\sqrt{x^2 + a^2}} = \ln(x + \sqrt{x^2 + a^2})$$

Evaluating  $V$ , we find that

$$V = \frac{k_e Q}{\ell} \ln\left(\frac{\ell + \sqrt{\ell^2 + a^2}}{a}\right) \quad (25.24)$$

**Figure 25.17** A uniform line charge of length  $\ell$  located along the  $x$  axis. To calculate the electric potential at  $P$ , the line charge is divided into segments each of length  $dx$  and each carrying a charge  $dq = \lambda dx$ .

**EXAMPLE 25.8** Electric Potential Due to a Uniformly Charged Sphere

An insulating solid sphere of radius  $R$  has a uniform positive volume charge density and total charge  $Q$ . (a) Find the electric potential at a point outside the sphere, that is, for  $r > R$ . Take the potential to be zero at  $r = \infty$ .

**Solution** In Example 24.5, we found that the magnitude of the electric field outside a uniformly charged sphere of radius  $R$  is

$$E_r = k_e \frac{Q}{r^2} \quad (\text{for } r > R)$$

where the field is directed radially outward when  $Q$  is positive. In this case, to obtain the electric potential at an exterior point, such as  $B$  in Figure 25.18, we use Equation 25.4 and the expression for  $E_r$  given above:

$$V_B = - \int_\infty^r E_r dr = -k_e Q \int_\infty^r \frac{dr}{r^2}$$

$$V_B = k_e \frac{Q}{r} \quad (\text{for } r > R)$$

Note that the result is identical to the expression for the electric potential due to a point charge (Eq. 25.11).

Because the potential must be continuous at  $r = R$ , we can use this expression to obtain the potential at the surface of the sphere. That is, the potential at a point such as  $C$  shown in Figure 25.18 is

$$V_C = k_e \frac{Q}{R} \quad (\text{for } r = R)$$

(b) Find the potential at a point inside the sphere, that is, for  $r < R$ .

**Figure 25.18** A uniformly charged insulating sphere of radius  $R$  and total charge  $Q$ . The electric potentials at points  $B$  and  $C$  are equivalent to those produced by a point charge  $Q$  located at the center of the sphere, but this is not true for point  $D$ .

**Solution** In Example 24.5 we found that the electric field inside an insulating uniformly charged sphere is

$$E_r = \frac{k_e Q}{R^3} r \quad (\text{for } r < R)$$

We can use this result and Equation 25.3 to evaluate the potential difference  $V_D - V_C$  at some interior point  $D$ :

$$V_D - V_C = - \int_R^r E_r dr = - \frac{k_e Q}{R^3} \int_R^r r dr = \frac{k_e Q}{2R^3} (R^2 - r^2)$$

Substituting  $V_C = k_e Q/R$  into this expression and solving for  $V_D$ , we obtain

$$V_D = \frac{k_e Q}{2R} \left( 3 - \frac{r^2}{R^2} \right) \quad (\text{for } r < R) \quad (25.25)$$

At  $r = R$ , this expression gives a result that agrees with that for the potential at the surface, that is,  $V_C$ . A plot of  $V$  versus  $r$  for this charge distribution is given in Figure 25.19.

**Exercise** What are the magnitude of the electric field and the electric potential at the center of the sphere?

**Answer**  $E = 0$ ;  $V_0 = 3k_e Q/2R$ .

**Figure 25.19** A plot of electric potential  $V$  versus distance  $r$  from the center of a uniformly charged insulating sphere of radius  $R$ . The curve for  $V_D$  inside the sphere is parabolic and joins smoothly with the curve for  $V_B$  outside the sphere, which is a hyperbola. The potential has a maximum value  $V_0$  at the center of the sphere. We could make this graph three dimensional (similar to Figures 25.7a and 25.8a) by spinning it around the vertical axis.

## 25.6 ELECTRIC POTENTIAL DUE TO A CHARGED CONDUCTOR

In Section 24.4 we found that when a solid conductor in equilibrium carries a net charge, the charge resides on the outer surface of the conductor. Furthermore, we showed that the electric field just outside the conductor is perpendicular to the surface and that the field inside is zero.

We now show that **every point on the surface of a charged conductor in equilibrium is at the same electric potential**. Consider two points  $A$  and  $B$  on the surface of a charged conductor, as shown in Figure 25.20. Along a surface path connecting these points,  $\mathbf{E}$  is always perpendicular to the displacement  $d\mathbf{s}$ ; there-

**Figure 25.20** An arbitrarily shaped conductor carrying a positive charge. When the conductor is in electrostatic equilibrium, all of the charge resides at the surface,  $\mathbf{E} = 0$  inside the conductor, and the direction of  $\mathbf{E}$  just outside the conductor is perpendicular to the surface. The electric potential is constant inside the conductor and is equal to the potential at the surface. Note from the spacing of the plus signs that the surface charge density is nonuniform.

fore  $\mathbf{E} \cdot d\mathbf{s} = 0$ . Using this result and Equation 25.3, we conclude that the potential difference between  $A$  and  $B$  is necessarily zero:

$$V_B - V_A = - \int_A^B \mathbf{E} \cdot d\mathbf{s} = 0$$

This result applies to any two points on the surface. Therefore,  $V$  is constant everywhere on the surface of a charged conductor in equilibrium. That is,

the surface of any charged conductor in electrostatic equilibrium is an equipotential surface. Furthermore, because the electric field is zero inside the conductor, we conclude from the relationship  $E_r = -dV/dr$  that the electric potential is constant everywhere inside the conductor and equal to its value at the surface.

Because this is true about the electric potential, no work is required to move a test charge from the interior of a charged conductor to its surface.

Consider a solid metal conducting sphere of radius  $R$  and total positive charge  $Q$ , as shown in Figure 25.21a. The electric field outside the sphere is  $k_e Q/r^2$  and points radially outward. From Example 25.8, we know that the electric potential at the interior and surface of the sphere must be  $k_e Q/R$  relative to infinity. The potential outside the sphere is  $k_e Q/r$ . Figure 25.21b is a plot of the electric potential as a function of  $r$ , and Figure 25.21c shows how the electric field varies with  $r$ .

When a net charge is placed on a spherical conductor, the surface charge density is uniform, as indicated in Figure 25.21a. However, if the conductor is non-spherical, as in Figure 25.20, the surface charge density is high where the radius of curvature is small and the surface is convex (as noted in Section 24.4), and it is low where the radius of curvature is small and the surface is concave. Because the electric field just outside the conductor is proportional to the surface charge density, we see that **the electric field is large near convex points having small radii of curvature and reaches very high values at sharp points.**

Figure 25.22 shows the electric field lines around two spherical conductors: one carrying a net charge  $Q$ , and a larger one carrying zero net charge. In this case, the surface charge density is not uniform on either conductor. The sphere having zero net charge has negative charges induced on its side that faces the

The surface of a charged conductor is an equipotential surface

**Figure 25.21** (a) The excess charge on a conducting sphere of radius  $R$  is uniformly distributed on its surface. (b) Electric potential versus distance  $r$  from the center of the charged conducting sphere. (c) Electric field magnitude versus distance  $r$  from the center of the charged conducting sphere.

Electric field pattern of a charged conducting plate placed near an oppositely charged pointed conductor. Small pieces of thread suspended in oil align with the electric field lines. The field surrounding the pointed conductor is most intense near the pointed end and at other places where the radius of curvature is small.

**Figure 25.22** The electric field lines (in red) around two spherical conductors. The smaller sphere has a net charge  $Q$ , and the larger one has zero net charge. The blue curves are cross-sections of equipotential surfaces.

charged sphere and positive charges induced on its side opposite the charged sphere. The blue curves in the figure represent the cross-sections of the equipotential surfaces for this charge configuration. As usual, the field lines are perpendicular to the conducting surfaces at all points, and the equipotential surfaces are perpendicular to the field lines everywhere. Trying to move a positive charge in the region of these conductors would be like moving a marble on a hill that is flat on top (representing the conductor on the left) and has another flat area partway down the side of the hill (representing the conductor on the right).

### EXAMPLE 25.9 Two Connected Charged Spheres

Two spherical conductors of radii  $r_1$  and  $r_2$  are separated by a distance much greater than the radius of either sphere. The spheres are connected by a conducting wire, as shown in Figure 25.23. The charges on the spheres in equilibrium are  $q_1$  and  $q_2$ , respectively, and they are uniformly charged. Find the ratio of the magnitudes of the electric fields at the surfaces of the spheres.

**Solution** Because the spheres are connected by a conducting wire, they must both be at the same electric potential:

$$V = k_e \frac{q_1}{r_1} = k_e \frac{q_2}{r_2}$$

Therefore, the ratio of charges is

**Figure 25.23** Two charged spherical conductors connected by a conducting wire. The spheres are at the same electric potential  $V$ .

$$(1) \quad \frac{q_1}{q_2} = \frac{r_1}{r_2}$$

Because the spheres are very far apart and their surfaces uniformly charged, we can express the magnitude of the electric fields at their surfaces as

$$E_1 = k_e \frac{q_1}{r_1^2} \quad \text{and} \quad E_2 = k_e \frac{q_2}{r_2^2}$$

Taking the ratio of these two fields and making use of Equation (1), we find that

$$\frac{E_1}{E_2} = \frac{r_2}{r_1}$$

Hence, the field is more intense in the vicinity of the smaller sphere even though the electric potentials of both spheres are the same.

### A Cavity Within a Conductor

Now consider a conductor of arbitrary shape containing a cavity as shown in Figure 25.24. Let us assume that no charges are inside the cavity. **In this case, the electric field inside the cavity must be zero** regardless of the charge distribution on the outside surface of the conductor. Furthermore, the field in the cavity is zero even if an electric field exists outside the conductor.

To prove this point, we use the fact that every point on the conductor is at the same electric potential, and therefore any two points  $A$  and  $B$  on the surface of the cavity must be at the same potential. Now imagine that a field  $\mathbf{E}$  exists in the cavity and evaluate the potential difference  $V_B - V_A$  defined by Equation 25.3:

$$V_B - V_A = - \int_A^B \mathbf{E} \cdot d\mathbf{s}$$

If  $\mathbf{E}$  is nonzero, we can always find a path between  $A$  and  $B$  for which  $\mathbf{E} \cdot d\mathbf{s}$  is a positive number; thus, the integral must be positive. However, because  $V_B - V_A = 0$ , the integral of  $\mathbf{E} \cdot d\mathbf{s}$  must be zero for all paths between any two points on the conductor, which implies that  $\mathbf{E}$  is zero everywhere. This contradiction can be reconciled only if  $\mathbf{E}$  is zero inside the cavity. Thus, we conclude that a cavity surrounded by conducting walls is a field-free region as long as no charges are inside the cavity.

### Corona Discharge

A phenomenon known as **corona discharge** is often observed near a conductor such as a high-voltage power line. When the electric field in the vicinity of the conductor is sufficiently strong, electrons are stripped from air molecules. This causes the molecules to be ionized, thereby increasing the air's ability to conduct. The observed glow (or corona discharge) results from the recombination of free electrons with the ionized air molecules. If a conductor has an irregular shape, the electric field can be very high near sharp points or edges of the conductor; consequently, the ionization process and corona discharge are most likely to occur around such points.

**Figure 25.24** A conductor in electrostatic equilibrium containing a cavity. The electric field in the cavity is zero, regardless of the charge on the conductor.

### Quick Quiz 25.4

(a) Is it possible for the magnitude of the electric field to be zero at a location where the electric potential is not zero? (b) Can the electric potential be zero where the electric field is nonzero?

## 25.7 THE MILLIKAN OIL-DROP EXPERIMENT

During the period from 1909 to 1913, Robert Millikan performed a brilliant set of experiments in which he measured  $e$ , the elementary charge on an electron, and demonstrated the quantized nature of this charge. His apparatus, diagrammed in Figure 25.25, contains two parallel metallic plates. Charged oil droplets from an atomizer are allowed to pass through a small hole in the upper plate. A horizontally directed light beam (not shown in the diagram) is used to illuminate the oil droplets, which are viewed through a telescope whose long axis is at right angles to the light beam. When the droplets are viewed in this manner, they appear as shining stars against a dark background, and the rate at which individual drops fall can be determined.<sup>4</sup>

Let us assume that a single drop having a mass  $m$  and carrying a charge  $q$  is being viewed and that its charge is negative. If no electric field is present between the plates, the two forces acting on the charge are the force of gravity  $m\mathbf{g}$  acting downward and a viscous drag force  $\mathbf{F}_D$  acting upward as indicated in Figure 25.26a. The drag force is proportional to the drop's speed. When the drop reaches its terminal speed  $v$ , the two forces balance each other ( $mg = F_D$ ).

Now suppose that a battery connected to the plates sets up an electric field between the plates such that the upper plate is at the higher electric potential. In this case, a third force  $q\mathbf{E}$  acts on the charged drop. Because  $q$  is negative and  $\mathbf{E}$  is directed downward, this electric force is directed upward, as shown in Figure 25.26b. If this force is sufficiently great, the drop moves upward and the drag force  $\mathbf{F}'_D$  acts downward. When the upward electric force  $q\mathbf{E}$  balances the sum of the gravitational force and the downward drag force  $\mathbf{F}'_D$ , the drop reaches a new terminal speed  $v'$  in the upward direction.

With the field turned on, a drop moves slowly upward, typically at rates of hundredths of a centimeter per second. The rate of fall in the absence of a field is comparable. Hence, one can follow a single droplet for hours, alternately rising and falling, by simply turning the electric field on and off.

(a) Field off

(b) Field on

**Figure 25.25** Schematic drawing of the Millikan oil-drop apparatus.

**Figure 25.26** The forces acting on a negatively charged oil droplet in the Millikan experiment.

<sup>4</sup> At one time, the oil droplets were termed “Millikan’s Shining Stars.” Perhaps this description has lost its popularity because of the generations of physics students who have experienced hallucinations, near blindness, migraine headaches, and so forth, while repeating Millikan’s experiment!

After recording measurements on thousands of droplets, Millikan and his co-workers found that all droplets, to within about 1% precision, had a charge equal to some integer multiple of the elementary charge  $e$ :

$$q = ne \quad n = 0, -1, -2, -3, \dots$$

where  $e = 1.60 \times 10^{-19}$  C. Millikan's experiment yields conclusive evidence that charge is quantized. For this work, he was awarded the Nobel Prize in Physics in 1923.

## 25.8 APPLICATIONS OF ELECTROSTATICS

The practical application of electrostatics is represented by such devices as lightning rods and electrostatic precipitators and by such processes as xerography and the painting of automobiles. Scientific devices based on the principles of electrostatics include electrostatic generators, the field-ion microscope, and ion-drive rocket engines.

### The Van de Graaff Generator

11.10

In Section 24.5 we described an experiment that demonstrates a method for transferring charge to a hollow conductor (the Faraday ice-pail experiment). When a charged conductor is placed in contact with the inside of a hollow conductor, all of the charge of the charged conductor is transferred to the hollow conductor. In principle, the charge on the hollow conductor and its electric potential can be increased without limit by repetition of the process.

In 1929 Robert J. Van de Graaff (1901–1967) used this principle to design and build an electrostatic generator. This type of generator is used extensively in nuclear physics research. A schematic representation of the generator is given in Figure 25.27. Charge is delivered continuously to a high-potential electrode by means of a moving belt of insulating material. The high-voltage electrode is a hollow conductor mounted on an insulating column. The belt is charged at point A by means of a corona discharge between comb-like metallic needles and a grounded grid. The needles are maintained at a positive electric potential of typically  $10^4$  V. The positive charge on the moving belt is transferred to the hollow conductor by a second comb of needles at point B. Because the electric field inside the hollow conductor is negligible, the positive charge on the belt is easily transferred to the conductor regardless of its potential. In practice, it is possible to increase the electric potential of the hollow conductor until electrical discharge occurs through the air. Because the “breakdown” electric field in air is about  $3 \times 10^6$  V/m, a sphere 1 m in radius can be raised to a maximum potential of  $3 \times 10^6$  V. The potential can be increased further by increasing the radius of the hollow conductor and by placing the entire system in a container filled with high-pressure gas.

Van de Graaff generators can produce potential differences as large as 20 million volts. Protons accelerated through such large potential differences receive enough energy to initiate nuclear reactions between themselves and various target nuclei. Smaller generators are often seen in science classrooms and museums. If a person insulated from the ground touches the sphere of a Van de Graaff generator, his or her body can be brought to a high electric potential. The hair acquires a net positive charge, and each strand is repelled by all the others. The result is a

**Figure 25.27** Schematic diagram of a Van de Graaff generator. Charge is transferred to the hollow conductor at the top by means of a moving belt. The charge is deposited on the belt at point A and transferred to the hollow conductor at point B.

scene such as that depicted in the photograph at the beginning of this chapter. In addition to being insulated from ground, the person holding the sphere is safe in this demonstration because the total charge on the sphere is very small (on the order of  $1 \mu\text{C}$ ). If this amount of charge accidentally passed from the sphere through the person to ground, the corresponding current would do no harm.

### QuickLab

Sprinkle some salt and pepper on an open dish and mix the two together. Now pull a comb through your hair several times and bring the comb to within 1 cm of the salt and pepper. What happens? How is what happens here related to the operation of an electrostatic precipitator?

## The Electrostatic Precipitator

One important application of electrical discharge in gases is the *electrostatic precipitator*. This device removes particulate matter from combustion gases, thereby reducing air pollution. Precipitators are especially useful in coal-burning power plants and in industrial operations that generate large quantities of smoke. Current systems are able to eliminate more than 99% of the ash from smoke.

Figure 25.28a shows a schematic diagram of an electrostatic precipitator. A high potential difference (typically 40 to 100 kV) is maintained between a wire running down the center of a duct and the walls of the duct, which are grounded. The wire is maintained at a negative electric potential with respect to the walls, so the electric field is directed toward the wire. The values of the field near the wire become high enough to cause a corona discharge around the wire; the discharge ionizes some air molecules to form positive ions, electrons, and such negative ions as  $\text{O}_2^-$ . The air to be cleaned enters the duct and moves near the wire. As the electrons and negative ions created by the discharge are accelerated toward the outer wall by the electric field, the dirt particles in the air become charged by collisions and ion capture. Because most of the charged dirt particles are negative, they too are drawn to the duct walls by the electric field. When the duct is periodically shaken, the particles break loose and are collected at the bottom.

(a)

(b)

(c)

**Figure 25.28** (a) Schematic diagram of an electrostatic precipitator. The high negative electric potential maintained on the central coiled wire creates an electrical discharge in the vicinity of the wire. Compare the air pollution when the electrostatic precipitator is (b) operating and (c) turned off.

In addition to reducing the level of particulate matter in the atmosphere (compare Figs. 25.28b and c), the electrostatic precipitator recovers valuable materials in the form of metal oxides.

### Xerography and Laser Printers

The basic idea of xerography<sup>5</sup> was developed by Chester Carlson, who was granted a patent for the xerographic process in 1940. The one feature of this process that makes it unique is the use of a photoconductive material to form an image. (A *photoconductor* is a material that is a poor electrical conductor in the dark but that becomes a good electrical conductor when exposed to light.)

The xerographic process is illustrated in Figure 25.29a to d. First, the surface of a plate or drum that has been coated with a thin film of photoconductive material (usually selenium or some compound of selenium) is given a positive electrostatic charge in the dark. An image of the page to be copied is then focused by a lens onto the charged surface. The photoconducting surface becomes conducting only in areas where light strikes it. In these areas, the light produces charge carriers in the photoconductor that move the positive charge off the drum. However, positive

**Figure 25.29** The xerographic process: (a) The photoconductive surface of the drum is positively charged. (b) Through the use of a light source and lens, an image is formed on the surface in the form of positive charges. (c) The surface containing the image is covered with a negatively charged powder, which adheres only to the image area. (d) A piece of paper is placed over the surface and given a positive charge. This transfers the image to the paper as the negatively charged powder particles migrate to the paper. The paper is then heat-treated to “fix” the powder. (e) A laser printer operates similarly except the image is produced by turning a laser beam on and off as it sweeps across the selenium-coated drum.

<sup>5</sup> The prefix *xero-* is from the Greek word meaning “dry.” Note that no liquid ink is used anywhere in xerography.

charges remain on those areas of the photoconductor not exposed to light, leaving a latent image of the object in the form of a positive surface charge distribution.

Next, a negatively charged powder called a *toner* is dusted onto the photoconducting surface. The charged powder adheres only to those areas of the surface that contain the positively charged image. At this point, the image becomes visible. The toner (and hence the image) are then transferred to the surface of a sheet of positively charged paper.

Finally, the toner is “fixed” to the surface of the paper as the toner melts while passing through high-temperature rollers. This results in a permanent copy of the original.

A laser printer (Fig. 25.29e) operates by the same principle, with the exception that a computer-directed laser beam is used to illuminate the photoconductor instead of a lens.

---

### SUMMARY

When a positive test charge  $q_0$  is moved between points  $A$  and  $B$  in an electric field  $\mathbf{E}$ , the **change in the potential energy** is

$$\Delta U = -q_0 \int_A^B \mathbf{E} \cdot d\mathbf{s} \quad (25.1)$$

The **electric potential**  $V = U/q_0$  is a scalar quantity and has units of joules per coulomb (J/C), where  $1 \text{ J/C} \equiv 1 \text{ V}$ .

The **potential difference**  $\Delta V$  between points  $A$  and  $B$  in an electric field  $\mathbf{E}$  is defined as

$$\Delta V = \frac{\Delta U}{q_0} = - \int_A^B \mathbf{E} \cdot d\mathbf{s} \quad (25.3)$$

The potential difference between two points  $A$  and  $B$  in a uniform electric field  $\mathbf{E}$  is

$$\Delta V = -Ed \quad (25.6)$$

where  $d$  is the magnitude of the displacement in the direction parallel to  $\mathbf{E}$ .

An **equipotential surface** is one on which all points are at the same electric potential. Equipotential surfaces are perpendicular to electric field lines.

If we define  $V = 0$  at  $r_A = \infty$ , the electric potential due to a point charge at any distance  $r$  from the charge is

$$V = k_e \frac{q}{r} \quad (25.11)$$

We can obtain the electric potential associated with a group of point charges by summing the potentials due to the individual charges.

The **potential energy associated with a pair of point charges** separated by a distance  $r_{12}$  is

$$U = k_e \frac{q_1 q_2}{r_{12}} \quad (25.13)$$

This energy represents the work required to bring the charges from an infinite separation to the separation  $r_{12}$ . We obtain the potential energy of a distribution of point charges by summing terms like Equation 25.13 over all pairs of particles.

**TABLE 25.1** Electric Potential Due to Various Charge Distributions

Charge Distribution	Electric Potential	Location
Uniformly charged ring of radius $a$	$V = k_e \frac{Q}{\sqrt{x^2 + a^2}}$	Along perpendicular central axis of ring, distance $x$ from ring center
Uniformly charged disk of radius $a$	$V = 2\pi k_e \sigma [(x^2 + a^2)^{1/2} - x]$	Along perpendicular central axis of disk, distance $x$ from disk center
Uniformly charged, insulating solid sphere of radius $R$ and total charge $Q$	$V = k_e \frac{Q}{r}$	$r \geq R$
	$V = \frac{k_e Q}{2R} \left( 3 - \frac{r^2}{R^2} \right)$	$r < R$
Isolated conducting sphere of radius $R$ and total charge $Q$	$V = k_e \frac{Q}{r}$	$r > R$
	$V = k_e \frac{Q}{R}$	$r \leq R$

If we know the electric potential as a function of coordinates  $x$ ,  $y$ ,  $z$ , we can obtain the components of the electric field by taking the negative derivative of the electric potential with respect to the coordinates. For example, the  $x$  component of the electric field is

$$E_x = -\frac{dV}{dx} \quad (25.16)$$

The **electric potential due to a continuous charge distribution** is

$$V = k_e \int \frac{dq}{r} \quad (25.19)$$

Every point on the surface of a charged conductor in electrostatic equilibrium is at the same electric potential. The potential is constant everywhere inside the conductor and equal to its value at the surface.

Table 25.1 lists electric potentials due to several charge distributions.

## Problem-Solving Hints

### Calculating Electric Potential

- Remember that electric potential is a scalar quantity, so components need not be considered. Therefore, when using the superposition principle to evaluate the electric potential at a point due to a system of point charges, simply take the algebraic sum of the potentials due to the various charges. However, you must keep track of signs. The potential is positive for positive charges, and it is negative for negative charges.
- Just as with gravitational potential energy in mechanics, only *changes* in electric potential are significant; hence, the point where you choose the poten-

tial to be zero is arbitrary. When dealing with point charges or a charge distribution of finite size, we usually define  $V = 0$  to be at a point infinitely far from the charges.

- You can evaluate the electric potential at some point  $P$  due to a continuous distribution of charge by dividing the charge distribution into infinitesimal elements of charge  $dq$  located at a distance  $r$  from  $P$ . Then, treat one charge element as a point charge, such that the potential at  $P$  due to the element is  $dV = k_e dq/r$ . Obtain the total potential at  $P$  by integrating  $dV$  over the entire charge distribution. In performing the integration for most problems, you must express  $dq$  and  $r$  in terms of a single variable. To simplify the integration, consider the geometry involved in the problem carefully. Review Examples 25.5 through 25.7 for guidance.
- Another method that you can use to obtain the electric potential due to a finite continuous charge distribution is to start with the definition of potential difference given by Equation 25.3. If you know or can easily obtain  $\mathbf{E}$  (from Gauss's law), then you can evaluate the line integral of  $\mathbf{E} \cdot d\mathbf{s}$ . An example of this method is given in Example 25.8.
- Once you know the electric potential at a point, you can obtain the electric field at that point by remembering that the electric field component in a specified direction is equal to the negative of the derivative of the electric potential in that direction. Example 25.4 illustrates this procedure.

## QUESTIONS

1. Distinguish between electric potential and electric potential energy.
2. A negative charge moves in the direction of a uniform electric field. Does the potential energy of the charge increase or decrease? Does it move to a position of higher or lower potential?
3. Give a physical explanation of the fact that the potential energy of a pair of like charges is positive whereas the potential energy of a pair of unlike charges is negative.
4. A uniform electric field is parallel to the  $x$  axis. In what direction can a charge be displaced in this field without any external work being done on the charge?
5. Explain why equipotential surfaces are always perpendicular to electric field lines.
6. Describe the equipotential surfaces for (a) an infinite line of charge and (b) a uniformly charged sphere.
7. Explain why, under static conditions, all points in a conductor must be at the same electric potential.
8. The electric field inside a hollow, uniformly charged sphere is zero. Does this imply that the potential is zero inside the sphere? Explain.
9. The potential of a point charge is defined to be zero at an infinite distance. Why can we not define the potential of an infinite line of charge to be zero at  $r = \infty$ ?
10. Two charged conducting spheres of different radii are connected by a conducting wire, as shown in Figure 25.23. Which sphere has the greater charge density?
11. What determines the maximum potential to which the dome of a Van de Graaff generator can be raised?
12. Explain the origin of the glow sometimes observed around the cables of a high-voltage power line.
13. Why is it important to avoid sharp edges or points on conductors used in high-voltage equipment?
14. How would you shield an electronic circuit or laboratory from stray electric fields? Why does this work?
15. Why is it relatively safe to stay in an automobile with a metal body during a severe thunderstorm?
16. Walking across a carpet and then touching someone can result in a shock. Explain why this occurs.

### Section 25.1 Potential Difference and Electric Potential

- How much work is done (by a battery, generator, or some other source of electrical energy) in moving Avogadro's number of electrons from an initial point where the electric potential is 9.00 V to a point where the potential is  $-5.00$  V? (The potential in each case is measured relative to a common reference point.)
- An ion accelerated through a potential difference of 115 V experiences an increase in kinetic energy of  $7.37 \times 10^{-17}$  J. Calculate the charge on the ion.
- (a) Calculate the speed of a proton that is accelerated from rest through a potential difference of 120 V. (b) Calculate the speed of an electron that is accelerated through the same potential difference.
- Review Problem.** Through what potential difference would an electron need to be accelerated for it to achieve a speed of 40.0% of the speed of light, starting from rest? The speed of light is  $c = 3.00 \times 10^8$  m/s; review Section 7.7.
- What potential difference is needed to stop an electron having an initial speed of  $4.20 \times 10^5$  m/s?

### Section 25.2 Potential Differences in a Uniform Electric Field

- A uniform electric field of magnitude 250 V/m is directed in the positive  $x$  direction. A  $+12.0\text{-}\mu\text{C}$  charge moves from the origin to the point  $(x, y) = (20.0\text{ cm}, 50.0\text{ cm})$ . (a) What was the change in the potential energy of this charge? (b) Through what potential difference did the charge move?
- The difference in potential between the accelerating plates of a TV set is about 25 000 V. If the distance between these plates is 1.50 cm, find the magnitude of the uniform electric field in this region.
- Suppose an electron is released from rest in a uniform electric field whose magnitude is  $5.90 \times 10^3$  V/m. (a) Through what potential difference will it have passed after moving 1.00 cm? (b) How fast will the electron be moving after it has traveled 1.00 cm?
- WEB An electron moving parallel to the  $x$  axis has an initial speed of  $3.70 \times 10^6$  m/s at the origin. Its speed is reduced to  $1.40 \times 10^5$  m/s at the point  $x = 2.00$  cm. Calculate the potential difference between the origin and that point. Which point is at the higher potential?
- A uniform electric field of magnitude 325 V/m is directed in the *negative*  $y$  direction as shown in Figure P25.10. The coordinates of point A are  $(-0.200, -0.300)$  m, and those of point B are  $(0.400, 0.500)$  m. Calculate the potential difference  $V_B - V_A$ , using the blue path.

Figure P25.10

- A 4.00-kg block carrying a charge  $Q = 50.0\ \mu\text{C}$  is connected to a spring for which  $k = 100$  N/m. The block lies on a frictionless horizontal track, and the system is immersed in a uniform electric field of magnitude  $E = 5.00 \times 10^5$  V/m, directed as shown in Figure P25.11. If the block is released from rest when the spring is unstretched (at  $x = 0$ ), (a) by what maximum amount does the spring expand? (b) What is the equilibrium position of the block? (c) Show that the block's motion is simple harmonic, and determine its period. (d) Repeat part (a) if the coefficient of kinetic friction between block and surface is 0.200.
- A block having mass  $m$  and charge  $Q$  is connected to a spring having constant  $k$ . The block lies on a frictionless horizontal track, and the system is immersed in a uniform electric field of magnitude  $E$ , directed as shown in Figure P25.11. If the block is released from rest when the spring is unstretched (at  $x = 0$ ), (a) by what maximum amount does the spring expand? (b) What is the equilibrium position of the block? (c) Show that the block's motion is simple harmonic, and determine its period. (d) Repeat part (a) if the coefficient of kinetic friction between block and surface is  $\mu_k$ .

Figure P25.11 Problems 11 and 12.

13. On planet Tehar, the acceleration due to gravity is the same as that on Earth but there is also a strong downward electric field with the field being uniform close to the planet's surface. A 2.00-kg ball having a charge of  $5.00 \mu\text{C}$  is thrown upward at a speed of 20.1 m/s and it hits the ground after an interval of 4.10 s. What is the potential difference between the starting point and the top point of the trajectory?
14. An insulating rod having linear charge density  $\lambda = 40.0 \mu\text{C}/\text{m}$  and linear mass density  $\mu = 0.100 \text{ kg}/\text{m}$  is released from rest in a uniform electric field  $E = 100 \text{ V}/\text{m}$  directed perpendicular to the rod (Fig. P25.14). (a) Determine the speed of the rod after it has traveled 2.00 m. (b) How does your answer to part (a) change if the electric field is not perpendicular to the rod? Explain.

Figure P25.14

15. A particle having charge  $q = +2.00 \mu\text{C}$  and mass  $m = 0.0100 \text{ kg}$  is connected to a string that is  $L = 1.50 \text{ m}$  long and is tied to the pivot point  $P$  in Figure P25.15. The particle, string, and pivot point all lie on a horizontal table. The particle is released from rest when the

Figure P25.15

string makes an angle  $\theta = 60.0^\circ$  with a uniform electric field of magnitude  $E = 300 \text{ V}/\text{m}$ . Determine the speed of the particle when the string is parallel to the electric field (point  $a$  in Fig. P25.15).

### Section 25.3 Electric Potential and Potential Energy Due to Point Charges

Note: Unless stated otherwise, assume a reference level of potential  $V = 0$  at  $r = \infty$ .

16. (a) Find the potential at a distance of 1.00 cm from a proton. (b) What is the potential difference between two points that are 1.00 cm and 2.00 cm from a proton? (c) Repeat parts (a) and (b) for an electron.
17. Given two  $2.00\text{-}\mu\text{C}$  charges, as shown in Figure P25.17, and a positive test charge  $q = 1.28 \times 10^{-18} \text{ C}$  at the origin, (a) what is the net force exerted on  $q$  by the two  $2.00\text{-}\mu\text{C}$  charges? (b) What is the electric field at the origin due to the two  $2.00\text{-}\mu\text{C}$  charges? (c) What is the electric potential at the origin due to the two  $2.00\text{-}\mu\text{C}$  charges?

Figure P25.17

18. A charge  $+q$  is at the origin. A charge  $-2q$  is at  $x = 2.00 \text{ m}$  on the  $x$  axis. For what finite value(s) of  $x$  is (a) the electric field zero? (b) the electric potential zero?
19. The Bohr model of the hydrogen atom states that the single electron can exist only in certain allowed orbits around the proton. The radius of each Bohr orbit is  $r = n^2 (0.0529 \text{ nm})$  where  $n = 1, 2, 3, \dots$ . Calculate the electric potential energy of a hydrogen atom when the electron is in the (a) first allowed orbit,  $n = 1$ ; (b) second allowed orbit,  $n = 2$ ; and (c) when the electron has escaped from the atom ( $r = \infty$ ). Express your answers in electron volts.
20. Two point charges  $Q_1 = +5.00 \text{ nC}$  and  $Q_2 = -3.00 \text{ nC}$  are separated by 35.0 cm. (a) What is the potential energy of the pair? What is the significance of the algebraic sign of your answer? (b) What is the electric potential at a point midway between the charges?
21. The three charges in Figure P25.21 are at the vertices of an isosceles triangle. Calculate the electric potential at the midpoint of the base, taking  $q = 7.00 \mu\text{C}$ .
22. Compare this problem with Problem 55 in Chapter 23. Four identical point charges ( $q = +10.0 \mu\text{C}$ ) are located on the corners of a rectangle, as shown in Figure P23.55. The dimensions of the rectangle are  $L = 60.0 \text{ cm}$  and  $W = 15.0 \text{ cm}$ . Calculate the electric potential energy of the charge at the lower left corner due to the other three charges.

Figure P25.21

- WEB 23.** Show that the amount of work required to assemble four identical point charges of magnitude  $Q$  at the corners of a square of side  $s$  is  $5.41 k_e Q^2 / s$ .
- 24.** Compare this problem with Problem 18 in Chapter 23. Two point charges each of magnitude  $2.00 \mu\text{C}$  are located on the  $x$  axis. One is at  $x = 1.00 \text{ m}$ , and the other is at  $x = -1.00 \text{ m}$ . (a) Determine the electric potential on the  $y$  axis at  $y = 0.500 \text{ m}$ . (b) Calculate the electric potential energy of a third charge, of  $-3.00 \mu\text{C}$ , placed on the  $y$  axis at  $y = 0.500 \text{ m}$ .
- 25.** Compare this problem with Problem 22 in Chapter 23. Five equal negative point charges  $-q$  are placed symmetrically around a circle of radius  $R$ . Calculate the electric potential at the center of the circle.
- 26.** Compare this problem with Problem 17 in Chapter 23. Three equal positive charges  $q$  are at the corners of an equilateral triangle of side  $a$ , as shown in Figure P23.17. (a) At what point, if any, in the plane of the charges is the electric potential zero? (b) What is the electric potential at the point  $P$  due to the two charges at the base of the triangle?
- 27. Review Problem.** Two insulating spheres having radii  $0.300 \text{ cm}$  and  $0.500 \text{ cm}$ , masses  $0.100 \text{ kg}$  and  $0.700 \text{ kg}$ , and charges  $-2.00 \mu\text{C}$  and  $3.00 \mu\text{C}$  are released from rest when their centers are separated by  $1.00 \text{ m}$ . (a) How fast will each be moving when they collide? (*Hint:* Consider conservation of energy and linear momentum.) (b) If the spheres were conductors would the speeds be larger or smaller than those calculated in part (a)? Explain.
- 28. Review Problem.** Two insulating spheres having radii  $r_1$  and  $r_2$ , masses  $m_1$  and  $m_2$ , and charges  $-q_1$  and  $q_2$  are released from rest when their centers are separated by a distance  $d$ . (a) How fast is each moving when they

collide? (*Hint:* Consider conservation of energy and conservation of linear momentum.) (b) If the spheres were conductors, would the speeds be greater or less than those calculated in part (a)?

- 29.** A small spherical object carries a charge of  $8.00 \text{ nC}$ . At what distance from the center of the object is the potential equal to  $100 \text{ V}$ ?  $50.0 \text{ V}$ ?  $25.0 \text{ V}$ ? Is the spacing of the equipotentials proportional to the change in potential?
- 30.** Two point charges of equal magnitude are located along the  $y$  axis equal distances above and below the  $x$  axis, as shown in Figure P25.30. (a) Plot a graph of the potential at points along the  $x$  axis over the interval  $-3a < x < 3a$ . You should plot the potential in units of  $k_e Q/a$ . (b) Let the charge located at  $-a$  be negative and plot the potential along the  $y$  axis over the interval  $-4a < y < 4a$ .

Figure P25.30

- 31.** In Rutherford's famous scattering experiments that led to the planetary model of the atom, alpha particles (charge  $+2e$ , mass  $= 6.64 \times 10^{-27} \text{ kg}$ ) were fired at a gold nucleus (charge  $+79e$ ). An alpha particle, initially very far from the gold nucleus, is fired with a velocity of  $2.00 \times 10^7 \text{ m/s}$  directly toward the center of the nucleus. How close does the alpha particle get to this center before turning around? Assume the gold nucleus remains stationary.
- 32.** An electron starts from rest  $3.00 \text{ cm}$  from the center of a uniformly charged insulating sphere of radius  $2.00 \text{ cm}$  and total charge  $1.00 \text{ nC}$ . What is the speed of the electron when it reaches the surface of the sphere?
- 33.** Calculate the energy required to assemble the array of charges shown in Figure P25.33, where  $a = 0.200 \text{ m}$ ,  $b = 0.400 \text{ m}$ , and  $q = 6.00 \mu\text{C}$ .
- 34.** Four identical particles each have charge  $q$  and mass  $m$ . They are released from rest at the vertices of a square of side  $L$ . How fast is each charge moving when their distance from the center of the square doubles?

Figure P25.33

35. How much work is required to assemble eight identical point charges, each of magnitude  $q$ , at the corners of a cube of side  $s$ ?

### Section 25.4 Obtaining the Value of the Electric Field from the Electric Potential

36. The potential in a region between  $x = 0$  and  $x = 6.00$  m is  $V = a + bx$  where  $a = 10.0$  V and  $b = -7.00$  V/m. Determine (a) the potential at  $x = 0$ , 3.00 m, and 6.00 m and (b) the magnitude and direction of the electric field at  $x = 0$ , 3.00 m, and 6.00 m.
- WEB 37. Over a certain region of space, the electric potential is  $V = 5x - 3x^2y + 2yz^2$ . Find the expressions for the  $x$ ,  $y$ , and  $z$  components of the electric field over this region. What is the magnitude of the field at the point  $P$ , which has coordinates  $(1, 0, -2)$  m?
38. The electric potential inside a charged spherical conductor of radius  $R$  is given by  $V = k_e Q/R$  and outside the conductor is given by  $V = k_e Q/r$ . Using  $E_r = -dV/dr$ , derive the electric field (a) inside and (b) outside this charge distribution.
39. It is shown in Example 25.7 that the potential at a point  $P$  a distance  $a$  above one end of a uniformly charged rod of length  $\ell$  lying along the  $x$  axis is

$$V = \frac{k_e Q}{\ell} \ln\left(\frac{\ell + \sqrt{\ell^2 + a^2}}{a}\right)$$

Use this result to derive an expression for the  $y$  component of the electric field at  $P$ . (*Hint*: Replace  $a$  with  $y$ .)

40. When an uncharged conducting sphere of radius  $a$  is placed at the origin of an  $xyz$  coordinate system that lies in an initially uniform electric field  $\mathbf{E} = E_0 \mathbf{k}$ , the resulting electric potential is

$$V(x, y, z) = V_0 - E_0 z + \frac{E_0 a^3 z}{(x^2 + y^2 + z^2)^{3/2}}$$

for points outside the sphere, where  $V_0$  is the (constant) electric potential on the conductor. Use this equation to determine the  $x$ ,  $y$ , and  $z$  components of the resulting electric field.

### Section 25.5 Electric Potential Due to Continuous Charge Distributions

41. Consider a ring of radius  $R$  with the total charge  $Q$  spread uniformly over its perimeter. What is the potential difference between the point at the center of the ring and a point on its axis a distance  $2R$  from the center?
42. Compare this problem with Problem 33 in Chapter 23. A uniformly charged insulating rod of length 14.0 cm is bent into the shape of a semicircle, as shown in Figure P23.33. If the rod has a total charge of  $-7.50 \mu\text{C}$ , find the electric potential at  $O$ , the center of the semicircle.
43. A rod of length  $L$  (Fig. P25.43) lies along the  $x$  axis with its left end at the origin and has a nonuniform charge density  $\lambda = \alpha x$  (where  $\alpha$  is a positive constant). (a) What are the units of  $\alpha$ ? (b) Calculate the electric potential at  $A$ .

Figure P25.43 Problems 43 and 44.

44. For the arrangement described in the previous problem, calculate the electric potential at point  $B$  that lies on the perpendicular bisector of the rod a distance  $b$  above the  $x$  axis.
45. Calculate the electric potential at point  $P$  on the axis of the annulus shown in Figure P25.45, which has a uniform charge density  $\sigma$ .

Figure P25.45

46. A wire of finite length that has a uniform linear charge density  $\lambda$  is bent into the shape shown in Figure P25.46. Find the electric potential at point  $O$ .

Figure P25.46

### Section 25.6 Electric Potential Due to a Charged Conductor

47. How many electrons should be removed from an initially uncharged spherical conductor of radius 0.300 m to produce a potential of 7.50 kV at the surface?
48. Two charged spherical conductors are connected by a long conducting wire, and a charge of  $20.0 \mu\text{C}$  is placed on the combination. (a) If one sphere has a radius of 4.00 cm and the other has a radius of 6.00 cm, what is the electric field near the surface of each sphere? (b) What is the electric potential of each sphere?
- WEB 49. A spherical conductor has a radius of 14.0 cm and charge of  $26.0 \mu\text{C}$ . Calculate the electric field and the electric potential at (a)  $r = 10.0$  cm, (b)  $r = 20.0$  cm, and (c)  $r = 14.0$  cm from the center.
50. Two concentric spherical conducting shells of radii  $a = 0.400$  m and  $b = 0.500$  m are connected by a thin wire, as shown in Figure P25.50. If a total charge  $Q = 10.0 \mu\text{C}$  is placed on the system, how much charge settles on each sphere?

Figure P25.50

(Optional)

### Section 25.7 The Millikan Oil-Drop Experiment

(Optional)

### Section 25.8 Applications of Electrostatics

51. Consider a Van de Graaff generator with a 30.0-cm-diameter dome operating in dry air. (a) What is the maximum potential of the dome? (b) What is the maximum charge on the dome?
52. The spherical dome of a Van de Graaff generator can be raised to a maximum potential of 600 kV; then additional charge leaks off in sparks, by producing breakdown of the surrounding dry air. Determine (a) the charge on the dome and (b) the radius of the dome.

### ADDITIONAL PROBLEMS

53. The liquid-drop model of the nucleus suggests that high-energy oscillations of certain nuclei can split the nucleus into two unequal fragments plus a few neutrons. The fragments acquire kinetic energy from their mutual Coulomb repulsion. Calculate the electric potential energy (in electron volts) of two spherical fragments from a uranium nucleus having the following charges and radii:  $38e$  and  $5.50 \times 10^{-15}$  m;  $54e$  and  $6.20 \times 10^{-15}$  m. Assume that the charge is distributed uniformly throughout the volume of each spherical fragment and that their surfaces are initially in contact at rest. (The electrons surrounding the nucleus can be neglected.)
54. On a dry winter day you scuff your leather-soled shoes across a carpet and get a shock when you extend the tip of one finger toward a metal doorknob. In a dark room you see a spark perhaps 5 mm long. Make order-of-magnitude estimates of (a) your electric potential and (b) the charge on your body before you touch the doorknob. Explain your reasoning.
55. The charge distribution shown in Figure P25.55 is referred to as a linear quadrupole. (a) Show that the potential at a point on the  $x$  axis where  $x > a$  is

$$V = \frac{2k_e Q a^2}{x^3 - x a^2}$$

- (b) Show that the expression obtained in part (a) when  $x \gg a$  reduces to

$$V = \frac{2k_e Q a^2}{x^3}$$

Quadrupole

Figure P25.55

56. (a) Use the exact result from Problem 55 to find the electric field at any point along the axis of the linear quadrupole for  $x > a$ . (b) Evaluate  $E$  at  $x = 3a$  if  $a = 2.00$  mm and  $Q = 3.00 \mu\text{C}$ .
57. At a certain distance from a point charge, the magnitude of the electric field is 500 V/m and the electric potential is  $-3.00$  kV. (a) What is the distance to the charge? (b) What is the magnitude of the charge?
58. An electron is released from rest on the axis of a uniform positively charged ring, 0.100 m from the ring's

center. If the linear charge density of the ring is  $+0.100 \mu\text{C}/\text{m}$  and the radius of the ring is  $0.200 \text{ m}$ , how fast will the electron be moving when it reaches the center of the ring?

59. (a) Consider a uniformly charged cylindrical shell having total charge  $Q$ , radius  $R$ , and height  $h$ . Determine the electrostatic potential at a point a distance  $d$  from the right side of the cylinder, as shown in Figure P25.59. (*Hint:* Use the result of Example 25.5 by treating the cylinder as a collection of ring charges.) (b) Use the result of Example 25.6 to solve the same problem for a solid cylinder.

Figure P25.59

60. Two parallel plates having charges of equal magnitude but opposite sign are separated by  $12.0 \text{ cm}$ . Each plate has a surface charge density of  $36.0 \text{ nC}/\text{m}^2$ . A proton is released from rest at the positive plate. Determine (a) the potential difference between the plates, (b) the energy of the proton when it reaches the negative plate, (c) the speed of the proton just before it strikes the negative plate, (d) the acceleration of the proton, and (e) the force on the proton. (f) From the force, find the magnitude of the electric field and show that it is equal to that found from the charge densities on the plates.

61. Calculate the work that must be done to charge a spherical shell of radius  $R$  to a total charge  $Q$ .

62. A Geiger–Müller counter is a radiation detector that essentially consists of a hollow cylinder (the cathode) of inner radius  $r_a$  and a coaxial cylindrical wire (the anode) of radius  $r_b$  (Fig. P25.62). The charge per unit length on the anode is  $\lambda$ , while the charge per unit length on the cathode is  $-\lambda$ . (a) Show that the magnitude of the potential difference between the wire and the cylinder in the sensitive region of the detector is

$$\Delta V = 2k_e \lambda \ln\left(\frac{r_a}{r_b}\right)$$

(b) Show that the magnitude of the electric field over that region is given by

$$E = \frac{\Delta V}{\ln(r_a/r_b)} \left(\frac{1}{r}\right)$$

where  $r$  is the distance from the center of the anode to the point where the field is to be calculated.

Figure P25.62

- WEB 63. From Gauss's law, the electric field set up by a uniform line of charge is

$$\mathbf{E} = \left(\frac{\lambda}{2\pi\epsilon_0 r}\right) \hat{\mathbf{r}}$$

where  $\hat{\mathbf{r}}$  is a unit vector pointing radially away from the line and  $\lambda$  is the charge per unit length along the line. Derive an expression for the potential difference between  $r = r_1$  and  $r = r_2$ .

64. A point charge  $q$  is located at  $x = -R$ , and a point charge  $-2q$  is located at the origin. Prove that the equipotential surface that has zero potential is a sphere centered at  $(-4R/3, 0, 0)$  and having a radius  $r = 2R/3$ .
65. Consider two thin, conducting, spherical shells as shown in cross-section in Figure P25.65. The inner shell has a radius  $r_1 = 15.0 \text{ cm}$  and a charge of  $10.0 \text{ nC}$ . The outer shell has a radius  $r_2 = 30.0 \text{ cm}$  and a charge of  $-15.0 \text{ nC}$ . Find (a) the electric field  $\mathbf{E}$  and (b) the electric potential  $V$  in regions A, B, and C, with  $V = 0$  at  $r = \infty$ .

Figure P25.65

66. The  $x$  axis is the symmetry axis of a uniformly charged ring of radius  $R$  and charge  $Q$  (Fig. P25.66). A point charge  $Q$  of mass  $M$  is located at the center of the ring. When it is displaced slightly, the point charge accelerates

ates along the  $x$  axis to infinity. Show that the ultimate speed of the point charge is

$$v = \left( \frac{2k_e Q^2}{MR} \right)^{1/2}$$

Figure P25.66

67. An infinite sheet of charge that has a surface charge density of  $25.0 \text{ nC/m}^2$  lies in the  $yz$  plane, passes through the origin, and is at a potential of  $1.00 \text{ kV}$  at the point  $y = 0, z = 0$ . A long wire having a linear charge density of  $80.0 \text{ nC/m}$  lies parallel to the  $y$  axis and intersects the  $x$  axis at  $x = 3.00 \text{ m}$ . (a) Determine, as a function of  $x$ , the potential along the  $x$  axis between wire and sheet. (b) What is the potential energy of a  $2.00\text{-nC}$  charge placed at  $x = 0.800 \text{ m}$ ?
68. The thin, uniformly charged rod shown in Figure P25.68 has a linear charge density  $\lambda$ . Find an expression for the electric potential at  $P$ .

Figure P25.68

69. A dipole is located along the  $y$  axis as shown in Figure P25.69. (a) At a point  $P$ , which is far from the dipole ( $r \gg a$ ), the electric potential is

$$V = k_e \frac{p \cos \theta}{r^2}$$

where  $p = 2qa$ . Calculate the radial component  $E_r$  and the perpendicular component  $E_\theta$  of the associated electric field. Note that  $E_\theta = -(1/r)(\partial V/\partial \theta)$ . Do these results seem reasonable for  $\theta = 90^\circ$  and  $0^\circ$ ? for  $r = 0$ ?

Figure P25.69

- (b) For the dipole arrangement shown, express  $V$  in terms of cartesian coordinates using  $r = (x^2 + y^2)^{1/2}$  and

$$\cos \theta = \frac{y}{(x^2 + y^2)^{1/2}}$$

Using these results and taking  $r \gg a$ , calculate the field components  $E_x$  and  $E_y$ .

70. Figure P25.70 shows several equipotential lines each labeled by its potential in volts. The distance between the lines of the square grid represents  $1.00 \text{ cm}$ . (a) Is the magnitude of the field bigger at  $A$  or at  $B$ ? Why? (b) What is  $\mathbf{E}$  at  $B$ ? (c) Represent what the field looks like by drawing at least eight field lines.

Figure P25.70

71. A disk of radius  $R$  has a nonuniform surface charge density  $\sigma = Cr$ , where  $C$  is a constant and  $r$  is measured from the center of the disk (Fig. P25.71). Find (by direct integration) the potential at  $P$ .

Figure P25.71

72. A solid sphere of radius  $R$  has a uniform charge density  $\rho$  and total charge  $Q$ . Derive an expression for its total

electric potential energy. (*Hint:* Imagine that the sphere is constructed by adding successive layers of concentric shells of charge  $dq = (4\pi r^2 dr)\rho$  and use  $dU = V dq$ .)

73. The results of Problem 62 apply also to an electrostatic precipitator (see Figs. 25.28a and P25.62). An applied voltage  $\Delta V = V_a - V_b = 50.0$  kV is to produce an electric field of magnitude  $5.50$  MV/m at the surface of the central wire. The outer cylindrical wall has uniform radius  $r_a = 0.850$  m. (a) What should be the radius  $r_b$  of the central wire? You will need to solve a transcendental equation. (b) What is the magnitude of the electric field at the outer wall?

## ANSWERS TO QUICK QUIZZES

- 25.1 We do if the electric field is uniform. (This is precisely what we do in the next section.) In general, however, an electric field changes from one place to another.
- 25.2  $B \rightarrow C$ ,  $C \rightarrow D$ ,  $A \rightarrow B$ ,  $D \rightarrow E$ . Moving from  $B$  to  $C$  decreases the electric potential by 2 V, so the electric field performs 2 J of work on each coulomb of charge that moves. Moving from  $C$  to  $D$  decreases the electric potential by 1 V, so 1 J of work is done by the field. It takes no work to move the charge from  $A$  to  $B$  because the electric potential does not change. Moving from  $D$  to  $E$  increases the electric potential by 1 V, and thus the field does  $-1$  J of work, just as raising a mass to a higher elevation causes the gravitational field to do negative work on the mass.
- 25.3 The electric potential decreases in inverse proportion to the radius (see Eq. 25.11). The electric field magnitude decreases as the reciprocal of the radius squared (see Eq. 23.4). Because the surface area increases as  $r^2$  while the electric field magnitude decreases as  $1/r^2$ , the electric flux through the surface remains constant (see Eq. 24.1).
- 25.4 (a) Yes. Consider four equal charges placed at the corners of a square. The electric potential graph for this situation is shown in the figure. At the center of the square, the electric field is zero because the individual fields from the four charges cancel, but the potential is not zero. This is also the situation inside a charged conductor. (b) Yes again. In Figure 25.8, for instance, the

electric potential is zero at the center of the dipole, but the magnitude of the field at that point is not zero. (The two charges in a dipole are by definition of opposite sign; thus, the electric field lines created by the two charges extend from the positive to the negative charge and do not cancel anywhere.) This is the situation we presented in Example 25.4c, in which the equations we obtained give  $V = 0$  and  $E_x \neq 0$ .

| <b>26.4</b> Energy Stored in a Charged Capacitor |   |

In this chapter, we discuss *capacitors*—devices that store electric charge. Capacitors are commonly used in a variety of electric circuits. For instance, they are used to tune the frequency of radio receivers, as filters in power supplies, to eliminate sparking in automobile ignition systems, and as energy-storing devices in electronic flash units.

A capacitor consists of two conductors separated by an insulator. We shall see that the capacitance of a given capacitor depends on its geometry and on the material—called a *dielectric*—that separates the conductors.

## 26.1 DEFINITION OF CAPACITANCE

13.5 Consider two conductors carrying charges of equal magnitude but of opposite sign, as shown in Figure 26.1. Such a combination of two conductors is called a **capacitor**. The conductors are called *plates*. A potential difference  $\Delta V$  exists between the conductors due to the presence of the charges. Because the unit of potential difference is the volt, a potential difference is often called a **voltage**. We shall use this term to describe the potential difference across a circuit element or between two points in space.

What determines how much charge is on the plates of a capacitor for a given voltage? In other words, what is the *capacity* of the device for storing charge at a particular value of  $\Delta V$ ? Experiments show that the quantity of charge  $Q$  on a capacitor<sup>1</sup> is linearly proportional to the potential difference between the conductors; that is,  $Q \propto \Delta V$ . The proportionality constant depends on the shape and separation of the conductors.<sup>2</sup> We can write this relationship as  $Q = C \Delta V$  if we define capacitance as follows:

Definition of capacitance

The **capacitance**  $C$  of a capacitor is the ratio of the magnitude of the charge on either conductor to the magnitude of the potential difference between them:

$$C \equiv \frac{Q}{\Delta V} \quad (26.1)$$

Note that by definition *capacitance is always a positive quantity*. Furthermore, the potential difference  $\Delta V$  is always expressed in Equation 26.1 as a positive quantity. Because the potential difference increases linearly with the stored charge, the ratio  $Q/\Delta V$  is constant for a given capacitor. Therefore, capacitance is a measure of a capacitor's ability to store charge and electric potential energy.

From Equation 26.1, we see that capacitance has SI units of coulombs per volt. The SI unit of capacitance is the **farad** (F), which was named in honor of Michael Faraday:

$$1 \text{ F} = 1 \text{ C/V}$$

The farad is a very large unit of capacitance. In practice, typical devices have capacitances ranging from microfarads ( $10^{-6}$  F) to picofarads ( $10^{-12}$  F). For practical purposes, capacitors often are labeled “mF” for microfarads and “mmF” for microfarads or, equivalently, “pF” for picofarads.

**Figure 26.1** A capacitor consists of two conductors carrying charges of equal magnitude but opposite sign.

<sup>1</sup> Although the total charge on the capacitor is zero (because there is as much excess positive charge on one conductor as there is excess negative charge on the other), it is common practice to refer to the magnitude of the charge on either conductor as “the charge on the capacitor.”

<sup>2</sup> The proportionality between  $\Delta V$  and  $Q$  can be proved from Coulomb's law or by experiment.

A collection of capacitors used in a variety of applications.

**Figure 26.2** A parallel-plate capacitor consists of two parallel conducting plates, each of area  $A$ , separated by a distance  $d$ . When the capacitor is charged, the plates carry equal amounts of charge. One plate carries positive charge, and the other carries negative charge.

Let us consider a capacitor formed from a pair of parallel plates, as shown in Figure 26.2. Each plate is connected to one terminal of a battery (not shown in Fig. 26.2), which acts as a source of potential difference. If the capacitor is initially uncharged, the battery establishes an electric field in the connecting wires when the connections are made. Let us focus on the plate connected to the negative terminal of the battery. The electric field applies a force on electrons in the wire just outside this plate; this force causes the electrons to move onto the plate. This movement continues until the plate, the wire, and the terminal are all at the same electric potential. Once this equilibrium point is attained, a potential difference no longer exists between the terminal and the plate, and as a result no electric field is present in the wire, and the movement of electrons stops. The plate now carries a negative charge. A similar process occurs at the other capacitor plate, with electrons moving from the plate to the wire, leaving the plate positively charged. In this final configuration, the potential difference across the capacitor plates is the same as that between the terminals of the battery.

Suppose that we have a capacitor rated at 4 pF. This rating means that the capacitor can store 4 pC of charge for each volt of potential difference between the two conductors. If a 9-V battery is connected across this capacitor, one of the conductors ends up with a net charge of  $-36$  pC and the other ends up with a net charge of  $+36$  pC.

## 26.2 CALCULATING CAPACITANCE

We can calculate the capacitance of a pair of oppositely charged conductors in the following manner: We assume a charge of magnitude  $Q$ , and we calculate the potential difference using the techniques described in the preceding chapter. We then use the expression  $C = Q/\Delta V$  to evaluate the capacitance. As we might expect, we can perform this calculation relatively easily if the geometry of the capacitor is simple.

We can calculate the capacitance of an isolated spherical conductor of radius  $R$  and charge  $Q$  if we assume that the second conductor making up the capacitor is a concentric hollow sphere of infinite radius. The electric potential of the sphere of radius  $R$  is simply  $k_e Q/R$ , and setting  $V = 0$  at infinity as usual, we have

$$C = \frac{Q}{\Delta V} = \frac{Q}{k_e Q/R} = \frac{R}{k_e} = 4\pi\epsilon_0 R \quad (26.2)$$

This expression shows that the capacitance of an isolated charged sphere is proportional to its radius and is independent of both the charge on the sphere and the potential difference.

### QuickLab

Roll some socks into balls and stuff them into a shoebox. What determines how many socks fit in the box? Relate how hard you push on the socks to  $\Delta V$  for a capacitor. How does the size of the box influence its “sock capacity”?

The capacitance of a pair of conductors depends on the geometry of the conductors. Let us illustrate this with three familiar geometries, namely, parallel plates, concentric cylinders, and concentric spheres. In these examples, we assume that the charged conductors are separated by a vacuum. The effect of a dielectric material placed between the conductors is treated in Section 26.5.

### Parallel-Plate Capacitors

Two parallel metallic plates of equal area  $A$  are separated by a distance  $d$ , as shown in Figure 26.2. One plate carries a charge  $Q$ , and the other carries a charge  $-Q$ . Let us consider how the geometry of these conductors influences the capacity of the combination to store charge. Recall that charges of like sign repel one another. As a capacitor is being charged by a battery, electrons flow into the negative plate and out of the positive plate. If the capacitor plates are large, the accumulated charges are able to distribute themselves over a substantial area, and the amount of charge that can be stored on a plate for a given potential difference increases as the plate area is increased. Thus, we expect the capacitance to be proportional to the plate area  $A$ .

Now let us consider the region that separates the plates. If the battery has a constant potential difference between its terminals, then the electric field between the plates must increase as  $d$  is decreased. Let us imagine that we move the plates closer together and consider the situation before any charges have had a chance to move in response to this change. Because no charges have moved, the electric field between the plates has the same value but extends over a shorter distance. Thus, the magnitude of the potential difference between the plates  $\Delta V = Ed$  (Eq. 25.6) is now smaller. The difference between this new capacitor voltage and the terminal voltage of the battery now exists as a potential difference across the wires connecting the battery to the capacitor. This potential difference results in an electric field in the wires that drives more charge onto the plates, increasing the potential difference between the plates. When the potential difference between the plates again matches that of the battery, the potential difference across the wires falls back to zero, and the flow of charge stops. Thus, moving the plates closer together causes the charge on the capacitor to increase. If  $d$  is increased, the charge decreases. As a result, we expect the device's capacitance to be inversely proportional to  $d$ .

**Figure 26.3** (a) The electric field between the plates of a parallel-plate capacitor is uniform near the center but nonuniform near the edges. (b) Electric field pattern of two oppositely charged conducting parallel plates. Small pieces of thread on an oil surface align with the electric field.

We can verify these physical arguments with the following derivation. The surface charge density on either plate is  $\sigma = Q/A$ . If the plates are very close together (in comparison with their length and width), we can assume that the electric field is uniform between the plates and is zero elsewhere. According to the last paragraph of Example 24.8, the value of the electric field between the plates is

$$E = \frac{\sigma}{\epsilon_0} = \frac{Q}{\epsilon_0 A}$$

Because the field between the plates is uniform, the magnitude of the potential difference between the plates equals  $Ed$  (see Eq. 25.6); therefore,

$$\Delta V = Ed = \frac{Qd}{\epsilon_0 A}$$

Substituting this result into Equation 26.1, we find that the capacitance is

$$C = \frac{Q}{\Delta V} = \frac{Q}{Qd/\epsilon_0 A}$$

$$C = \frac{\epsilon_0 A}{d} \quad (26.3)$$

That is, **the capacitance of a parallel-plate capacitor is proportional to the area of its plates and inversely proportional to the plate separation**, just as we expect from our conceptual argument.

A careful inspection of the electric field lines for a parallel-plate capacitor reveals that the field is uniform in the central region between the plates, as shown in Figure 26.3a. However, the field is nonuniform at the edges of the plates. Figure 26.3b is a photograph of the electric field pattern of a parallel-plate capacitor. Note the nonuniform nature of the electric field at the ends of the plates. Such end effects can be neglected if the plate separation is small compared with the length of the plates.

### Quick Quiz 26.1

Many computer keyboard buttons are constructed of capacitors, as shown in Figure 26.4. When a key is pushed down, the soft insulator between the movable plate and the fixed plate is compressed. When the key is pressed, the capacitance (a) increases, (b) decreases, or (c) changes in a way that we cannot determine because the complicated electric circuit connected to the keyboard button may cause a change in  $\Delta V$ .

**Figure 26.4** One type of computer keyboard button.

### EXAMPLE 26.1 Parallel-Plate Capacitor

A parallel-plate capacitor has an area  $A = 2.00 \times 10^{-4} \text{ m}^2$  and a plate separation  $d = 1.00 \text{ mm}$ . Find its capacitance.

**Solution** From Equation 26.3, we find that

$$C = \epsilon_0 \frac{A}{d} = (8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2) \left( \frac{2.00 \times 10^{-4} \text{ m}^2}{1.00 \times 10^{-3} \text{ m}} \right)$$

$$= 1.77 \times 10^{-12} \text{ F} = 1.77 \text{ pF}$$

**Exercise** What is the capacitance for a plate separation of 3.00 mm?

**Answer** 0.590 pF.

## Cylindrical and Spherical Capacitors

From the definition of capacitance, we can, in principle, find the capacitance of any geometric arrangement of conductors. The following examples demonstrate the use of this definition to calculate the capacitance of the other familiar geometries that we mentioned: cylinders and spheres.

### EXAMPLE 26.2 The Cylindrical Capacitor

A solid cylindrical conductor of radius  $a$  and charge  $Q$  is coaxial with a cylindrical shell of negligible thickness, radius  $b > a$ , and charge  $-Q$  (Fig. 26.5a). Find the capacitance of this cylindrical capacitor if its length is  $\ell$ .

**Solution** It is difficult to apply physical arguments to this configuration, although we can reasonably expect the capacitance to be proportional to the cylinder length  $\ell$  for the same reason that parallel-plate capacitance is proportional to plate area: Stored charges have more room in which to be distributed. If we assume that  $\ell$  is much greater than  $a$  and  $b$ , we can neglect end effects. In this case, the electric field is perpendicular to the long axis of the cylinders and is confined to the region between them (Fig. 26.5b). We must first calculate the potential difference between the two cylinders, which is given in general by

$$V_b - V_a = - \int_a^b \mathbf{E} \cdot d\mathbf{s}$$

where  $\mathbf{E}$  is the electric field in the region  $a < r < b$ . In Chapter 24, we showed using Gauss's law that the magnitude of the electric field of a cylindrical charge distribution having linear charge density  $\lambda$  is  $E_r = 2k_e\lambda/r$  (Eq. 24.7). The same result applies here because, according to Gauss's law, the charge on the outer cylinder does not contribute to the electric field inside it. Using this result and noting from Figure 26.5b that  $\mathbf{E}$  is along  $r$ , we find that

$$V_b - V_a = - \int_a^b E_r dr = -2k_e\lambda \int_a^b \frac{dr}{r} = -2k_e\lambda \ln\left(\frac{b}{a}\right)$$

Substituting this result into Equation 26.1 and using the fact that  $\lambda = Q/\ell$ , we obtain

$$C = \frac{Q}{\Delta V} = \frac{Q}{\frac{2k_e Q}{\ell} \ln\left(\frac{b}{a}\right)} = \frac{\ell}{2k_e \ln\left(\frac{b}{a}\right)} \quad (26.4)$$

where  $\Delta V$  is the magnitude of the potential difference, given

by  $\Delta V = |V_b - V_a| = 2k_e\lambda \ln(b/a)$ , a positive quantity. As predicted, the capacitance is proportional to the length of the cylinders. As we might expect, the capacitance also depends on the radii of the two cylindrical conductors. From Equation 26.4, we see that the capacitance per unit length of a combination of concentric cylindrical conductors is

$$\frac{C}{\ell} = \frac{1}{2k_e \ln\left(\frac{b}{a}\right)} \quad (26.5)$$

An example of this type of geometric arrangement is a *coaxial cable*, which consists of two concentric cylindrical conductors separated by an insulator. The cable carries electrical signals in the inner and outer conductors. Such a geometry is especially useful for shielding the signals from any possible external influences.

**Figure 26.5** (a) A cylindrical capacitor consists of a solid cylindrical conductor of radius  $a$  and length  $\ell$  surrounded by a coaxial cylindrical shell of radius  $b$ . (b) End view. The dashed line represents the end of the cylindrical gaussian surface of radius  $r$  and length  $\ell$ .

### EXAMPLE 26.3 The Spherical Capacitor

A spherical capacitor consists of a spherical conducting shell of radius  $b$  and charge  $-Q$  concentric with a smaller conducting sphere of radius  $a$  and charge  $Q$  (Fig. 26.6). Find the capacitance of this device.

**Solution** As we showed in Chapter 24, the field outside a spherically symmetric charge distribution is radial and given by the expression  $k_e Q/r^2$ . In this case, this result applies to the field between the spheres ( $a < r < b$ ). From

Gauss's law we see that only the inner sphere contributes to this field. Thus, the potential difference between the spheres is

$$\begin{aligned} V_b - V_a &= - \int_a^b E_r dr = -k_e Q \int_a^b \frac{dr}{r^2} = k_e Q \left[ \frac{1}{r} \right]_a^b \\ &= k_e Q \left( \frac{1}{b} - \frac{1}{a} \right) \end{aligned}$$

The magnitude of the potential difference is

$$\Delta V = |V_b - V_a| = k_e Q \frac{(b - a)}{ab}$$

Substituting this value for  $\Delta V$  into Equation 26.1, we obtain

$$C = \frac{Q}{\Delta V} = \frac{ab}{k_e(b - a)} \quad (26.6)$$

**Figure 26.6** A spherical capacitor consists of an inner sphere of radius  $a$  surrounded by a concentric spherical shell of radius  $b$ . The electric field between the spheres is directed radially outward when the inner sphere is positively charged.

**Exercise** Show that as the radius  $b$  of the outer sphere approaches infinity, the capacitance approaches the value  $a/k_e = 4\pi\epsilon_0 a$ .

### Quick Quiz 26.2

What is the magnitude of the electric field in the region outside the spherical capacitor described in Example 26.3?

## 26.3 COMBINATIONS OF CAPACITORS

**13.5** Two or more capacitors often are combined in electric circuits. We can calculate the equivalent capacitance of certain combinations using methods described in this section. The circuit symbols for capacitors and batteries, as well as the color codes used for them in this text, are given in Figure 26.7. The symbol for the capacitor reflects the geometry of the most common model for a capacitor—a pair of parallel plates. The positive terminal of the battery is at the higher potential and is represented in the circuit symbol by the longer vertical line.

### Parallel Combination

Two capacitors connected as shown in Figure 26.8a are known as a *parallel combination* of capacitors. Figure 26.8b shows a circuit diagram for this combination of capacitors. The left plates of the capacitors are connected by a conducting wire to the positive terminal of the battery and are therefore both at the same electric potential as the positive terminal. Likewise, the right plates are connected to the negative terminal and are therefore both at the same potential as the negative terminal. Thus, **the individual potential differences across capacitors connected in parallel are all the same and are equal to the potential difference applied across the combination.**

In a circuit such as that shown in Figure 26.8, the voltage applied across the combination is the terminal voltage of the battery. Situations can occur in which

**Figure 26.7** Circuit symbols for capacitors, batteries, and switches. Note that capacitors are in blue and batteries and switches are in red.

**Figure 26.8** (a) A parallel combination of two capacitors in an electric circuit in which the potential difference across the battery terminals is  $\Delta V$ . (b) The circuit diagram for the parallel combination. (c) The equivalent capacitance is  $C_{eq} = C_1 + C_2$ .

the parallel combination is in a circuit with other circuit elements; in such situations, we must determine the potential difference across the combination by analyzing the entire circuit.

When the capacitors are first connected in the circuit shown in Figure 26.8, electrons are transferred between the wires and the plates; this transfer leaves the left plates positively charged and the right plates negatively charged. The energy source for this charge transfer is the internal chemical energy stored in the battery, which is converted to electric potential energy associated with the charge separation. The flow of charge ceases when the voltage across the capacitors is equal to that across the battery terminals. The capacitors reach their maximum charge when the flow of charge ceases. Let us call the maximum charges on the two capacitors  $Q_1$  and  $Q_2$ . The *total charge*  $Q$  stored by the two capacitors is

$$Q = Q_1 + Q_2 \quad (26.7)$$

That is, **the total charge on capacitors connected in parallel is the sum of the charges on the individual capacitors.** Because the voltages across the capacitors are the same, the charges that they carry are

$$Q_1 = C_1 \Delta V \quad Q_2 = C_2 \Delta V$$

Suppose that we wish to replace these two capacitors by one *equivalent capacitor* having a capacitance  $C_{eq}$ , as shown in Figure 26.8c. The effect this equivalent capacitor has on the circuit must be exactly the same as the effect of the combination of the two individual capacitors. That is, the equivalent capacitor must store  $Q$  units of charge when connected to the battery. We can see from Figure 26.8c that the voltage across the equivalent capacitor also is  $\Delta V$  because the equivalent capac-

itor is connected directly across the battery terminals. Thus, for the equivalent capacitor,

$$Q = C_{\text{eq}} \Delta V$$

Substituting these three relationships for charge into Equation 26.7, we have

$$C_{\text{eq}} \Delta V = C_1 \Delta V + C_2 \Delta V$$

$$C_{\text{eq}} = C_1 + C_2 \quad \left( \begin{array}{l} \text{parallel} \\ \text{combination} \end{array} \right)$$

If we extend this treatment to three or more capacitors connected in parallel, we find the equivalent capacitance to be

$$C_{\text{eq}} = C_1 + C_2 + C_3 + \cdots \quad (\text{parallel combination}) \quad (26.8)$$

Thus, **the equivalent capacitance of a parallel combination of capacitors is greater than any of the individual capacitances.** This makes sense because we are essentially combining the areas of all the capacitor plates when we connect them with conducting wire.

### Series Combination

Two capacitors connected as shown in Figure 26.9a are known as a *series combination* of capacitors. The left plate of capacitor 1 and the right plate of capacitor 2 are connected to the terminals of a battery. The other two plates are connected to each other and to nothing else; hence, they form an isolated conductor that is initially uncharged and must continue to have zero net charge. To analyze this combination, let us begin by considering the uncharged capacitors and follow what happens just after a battery is connected to the circuit. When the battery is con-

**Figure 26.9** (a) A series combination of two capacitors. The charges on the two capacitors are the same. (b) The capacitors replaced by a single equivalent capacitor. The equivalent capacitance can be calculated from the relationship

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2}$$

nected, electrons are transferred out of the left plate of  $C_1$  and into the right plate of  $C_2$ . As this negative charge accumulates on the right plate of  $C_2$ , an equivalent amount of negative charge is forced off the left plate of  $C_2$ , and this left plate therefore has an excess positive charge. The negative charge leaving the left plate of  $C_2$  travels through the connecting wire and accumulates on the right plate of  $C_1$ . As a result, all the right plates end up with a charge  $-Q$ , and all the left plates end up with a charge  $+Q$ . Thus, **the charges on capacitors connected in series are the same.**

From Figure 26.9a, we see that the voltage  $\Delta V$  across the battery terminals is split between the two capacitors:

$$\Delta V = \Delta V_1 + \Delta V_2 \quad (26.9)$$

where  $\Delta V_1$  and  $\Delta V_2$  are the potential differences across capacitors  $C_1$  and  $C_2$ , respectively. In general, **the total potential difference across any number of capacitors connected in series is the sum of the potential differences across the individual capacitors.**

Suppose that an equivalent capacitor has the same effect on the circuit as the series combination. After it is fully charged, the equivalent capacitor must have a charge of  $-Q$  on its right plate and a charge of  $+Q$  on its left plate. Applying the definition of capacitance to the circuit in Figure 26.9b, we have

$$\Delta V = \frac{Q}{C_{\text{eq}}}$$

Because we can apply the expression  $Q = C\Delta V$  to each capacitor shown in Figure 26.9a, the potential difference across each is

$$\Delta V_1 = \frac{Q}{C_1} \quad \Delta V_2 = \frac{Q}{C_2}$$

Substituting these expressions into Equation 26.9 and noting that  $\Delta V = Q/C_{\text{eq}}$ , we have

$$\frac{Q}{C_{\text{eq}}} = \frac{Q}{C_1} + \frac{Q}{C_2}$$

Canceling  $Q$ , we arrive at the relationship

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} \quad \left( \begin{array}{l} \text{series} \\ \text{combination} \end{array} \right)$$

When this analysis is applied to three or more capacitors connected in series, the relationship for the equivalent capacitance is

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \dots \quad \left( \begin{array}{l} \text{series} \\ \text{combination} \end{array} \right) \quad (26.10)$$

This demonstrates that **the equivalent capacitance of a series combination is always less than any individual capacitance in the combination.**

### EXAMPLE 26.4 Equivalent Capacitance

Find the equivalent capacitance between  $a$  and  $b$  for the combination of capacitors shown in Figure 26.10a. All capacitances are in microfarads.

**Solution** Using Equations 26.8 and 26.10, we reduce the combination step by step as indicated in the figure. The  $1.0\text{-}\mu\text{F}$  and  $3.0\text{-}\mu\text{F}$  capacitors are in parallel and combine ac-

According to the expression  $C_{\text{eq}} = C_1 + C_2 = 4.0 \mu\text{F}$ . The  $2.0\text{-}\mu\text{F}$  and  $6.0\text{-}\mu\text{F}$  capacitors also are in parallel and have an equivalent capacitance of  $8.0 \mu\text{F}$ . Thus, the upper branch in Figure 26.10b consists of two  $4.0\text{-}\mu\text{F}$  capacitors in series, which combine as follows:

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{4.0 \mu\text{F}} + \frac{1}{4.0 \mu\text{F}} = \frac{1}{2.0 \mu\text{F}}$$

$$C_{\text{eq}} = \frac{1}{1/2.0 \mu\text{F}} = 2.0 \mu\text{F}$$

The lower branch in Figure 26.10b consists of two  $8.0\text{-}\mu\text{F}$  capacitors in series, which combine to yield an equivalent capacitance of  $4.0 \mu\text{F}$ . Finally, the  $2.0\text{-}\mu\text{F}$  and  $4.0\text{-}\mu\text{F}$  capacitors in Figure 26.10c are in parallel and thus have an equivalent capacitance of  $6.0 \mu\text{F}$ .

**Exercise** Consider three capacitors having capacitances of  $3.0 \mu\text{F}$ ,  $6.0 \mu\text{F}$ , and  $12 \mu\text{F}$ . Find their equivalent capacitance when they are connected (a) in parallel and (b) in series.

**Answer** (a)  $21 \mu\text{F}$ ; (b)  $1.7 \mu\text{F}$ .

**Figure 26.10** To find the equivalent capacitance of the capacitors in part (a), we reduce the various combinations in steps as indicated in parts (b), (c), and (d), using the series and parallel rules described in the text.

## 26.4 ENERGY STORED IN A CHARGED CAPACITOR

Almost everyone who works with electronic equipment has at some time verified that a capacitor can store energy. If the plates of a charged capacitor are connected by a conductor, such as a wire, charge moves between the plates and the connecting wire until the capacitor is uncharged. The discharge can often be observed as a visible spark. If you should accidentally touch the opposite plates of a charged capacitor, your fingers act as a pathway for discharge, and the result is an electric shock. The degree of shock you receive depends on the capacitance and on the voltage applied to the capacitor. Such a shock could be fatal if high voltages are present, such as in the power supply of a television set. Because the charges can be stored in a capacitor even when the set is turned off, unplugging the television does not make it safe to open the case and touch the components inside.

Consider a parallel-plate capacitor that is initially uncharged, such that the initial potential difference across the plates is zero. Now imagine that the capacitor is connected to a battery and develops a maximum charge  $Q$ . (We assume that the capacitor is charged slowly so that the problem can be considered as an electrostatic system.) When the capacitor is connected to the battery, electrons in the wire just outside the plate connected to the negative terminal move into the plate to give it a negative charge. Electrons in the plate connected to the positive terminal move out of the plate into the wire to give the plate a positive charge. Thus, charges move only a small distance in the wires.

To calculate the energy of the capacitor, we shall assume a different process—one that does not actually occur but gives the same final result. We can make this

### QuickLab

Here's how to find out whether your calculator has a capacitor to protect values or programs during battery changes: Store a number in your calculator's memory, remove the calculator battery for a moment, and then quickly replace it. Was the number that you stored preserved while the battery was out of the calculator? (You may want to write down any critical numbers or programs that are stored in the calculator before trying this!)

assumption because the energy in the final configuration does not depend on the actual charge-transfer process. We imagine that we reach in and grab a small amount of positive charge on the plate connected to the negative terminal and apply a force that causes this positive charge to move over to the plate connected to the positive terminal. Thus, we do work on the charge as we transfer it from one plate to the other. At first, no work is required to transfer a small amount of charge  $dq$  from one plate to the other.<sup>3</sup> However, once this charge has been transferred, a small potential difference exists between the plates. Therefore, work must be done to move additional charge through this potential difference. As more and more charge is transferred from one plate to the other, the potential difference increases in proportion, and more work is required.

Suppose that  $q$  is the charge on the capacitor at some instant during the charging process. At the same instant, the potential difference across the capacitor is  $\Delta V = q/C$ . From Section 25.2, we know that the work necessary to transfer an increment of charge  $dq$  from the plate carrying charge  $-q$  to the plate carrying charge  $q$  (which is at the higher electric potential) is

$$dW = \Delta V dq = \frac{q}{C} dq$$

This is illustrated in Figure 26.11. The total work required to charge the capacitor from  $q = 0$  to some final charge  $q = Q$  is

$$W = \int_0^Q \frac{q}{C} dq = \frac{1}{C} \int_0^Q q dq = \frac{Q^2}{2C}$$

The work done in charging the capacitor appears as electric potential energy  $U$  stored in the capacitor. Therefore, we can express the potential energy stored in a charged capacitor in the following forms:

$$U = \frac{Q^2}{2C} = \frac{1}{2}Q\Delta V = \frac{1}{2}C(\Delta V)^2 \quad (26.11)$$

This result applies to any capacitor, regardless of its geometry. We see that for a given capacitance, the stored energy increases as the charge increases and as the potential difference increases. In practice, there is a limit to the maximum energy

Energy stored in a charged capacitor

**Figure 26.11** A plot of potential difference versus charge for a capacitor is a straight line having a slope  $1/C$ . The work required to move charge  $dq$  through the potential difference  $\Delta V$  across the capacitor plates is given by the area of the shaded rectangle. The total work required to charge the capacitor to a final charge  $Q$  is the triangular area under the straight line,  $W = \frac{1}{2}Q\Delta V$ . (Don't forget that  $1 \text{ V} = 1 \text{ J/C}$ ; hence, the unit for the area is the joule.)

<sup>3</sup> We shall use lowercase  $q$  for the varying charge on the capacitor while it is charging, to distinguish it from uppercase  $Q$ , which is the total charge on the capacitor after it is completely charged.

(or charge) that can be stored because, at a sufficiently great value of  $\Delta V$ , discharge ultimately occurs between the plates. For this reason, capacitors are usually labeled with a maximum operating voltage.

### Quick Quiz 26.3

You have three capacitors and a battery. How should you combine the capacitors and the battery in one circuit so that the capacitors will store the maximum possible energy?

We can consider the energy stored in a capacitor as being stored in the electric field created between the plates as the capacitor is charged. This description is reasonable in view of the fact that the electric field is proportional to the charge on the capacitor. For a parallel-plate capacitor, the potential difference is related to the electric field through the relationship  $\Delta V = Ed$ . Furthermore, its capacitance is  $C = \epsilon_0 A/d$  (Eq. 26.3). Substituting these expressions into Equation 26.11, we obtain

$$U = \frac{1}{2} \frac{\epsilon_0 A}{d} (E^2 d^2) = \frac{1}{2} (\epsilon_0 A d) E^2 \quad (26.12)$$

Because the volume  $V$  (volume, not voltage!) occupied by the electric field is  $Ad$ , the *energy per unit volume*  $u_E = U/V = U/Ad$ , known as the *energy density*, is

$$u_E = \frac{1}{2} \epsilon_0 E^2 \quad (26.13)$$

Although Equation 26.13 was derived for a parallel-plate capacitor, the expression is generally valid. That is, the **energy density in any electric field is proportional to the square of the magnitude of the electric field at a given point.**

Energy stored in a parallel-plate capacitor

Energy density in an electric field

This bank of capacitors stores electrical energy for use in the particle accelerator at FermiLab, located outside Chicago. Because the electric utility company cannot provide a large enough burst of energy to operate the equipment, these capacitors are slowly charged up, and then the energy is rapidly “dumped” into the accelerator. In this sense, the setup is much like a fire-protection water tank on top of a building. The tank collects water and stores it for situations in which a lot of water is needed in a short time.

**EXAMPLE 26.5** Rewiring Two Charged Capacitors

Two capacitors  $C_1$  and  $C_2$  (where  $C_1 > C_2$ ) are charged to the same initial potential difference  $\Delta V_i$ , but with opposite polarity. The charged capacitors are removed from the battery, and their plates are connected as shown in Figure 26.12a. The switches  $S_1$  and  $S_2$  are then closed, as shown in Figure 26.12b. (a) Find the final potential difference  $\Delta V_f$  between  $a$  and  $b$  after the switches are closed.

**Solution** Let us identify the left-hand plates of the capacitors as an isolated system because they are not connected to the right-hand plates by conductors. The charges on the left-hand plates before the switches are closed are

$$Q_{1i} = C_1 \Delta V_i \quad \text{and} \quad Q_{2i} = -C_2 \Delta V_i$$

The negative sign for  $Q_{2i}$  is necessary because the charge on the left plate of capacitor  $C_2$  is negative. The total charge  $Q$  in the system is

$$(1) \quad Q = Q_{1i} + Q_{2i} = (C_1 - C_2) \Delta V_i$$

After the switches are closed, the total charge in the system remains the same:

$$(2) \quad Q = Q_{1f} + Q_{2f}$$

The charges redistribute until the entire system is at the same potential  $\Delta V_f$ . Thus, the final potential difference across  $C_1$  must be the same as the final potential difference across  $C_2$ . To satisfy this requirement, the charges on the capacitors after the switches are closed are

$$Q_{1f} = C_1 \Delta V_f \quad \text{and} \quad Q_{2f} = C_2 \Delta V_f$$

Dividing the first equation by the second, we have

$$\frac{Q_{1f}}{Q_{2f}} = \frac{C_1 \Delta V_f}{C_2 \Delta V_f} = \frac{C_1}{C_2}$$

$$(3) \quad Q_{1f} = \frac{C_1}{C_2} Q_{2f}$$

Combining Equations (2) and (3), we obtain

$$Q = Q_{1f} + Q_{2f} = \frac{C_1}{C_2} Q_{2f} + Q_{2f} = Q_{2f} \left( 1 + \frac{C_1}{C_2} \right)$$

$$Q_{2f} = Q \left( \frac{C_2}{C_1 + C_2} \right)$$

Using Equation (3) to find  $Q_{1f}$  in terms of  $Q$ , we have

$$Q_{1f} = \frac{C_1}{C_2} Q_{2f} = \frac{C_1}{C_2} Q \left( \frac{C_2}{C_1 + C_2} \right) = Q \left( \frac{C_1}{C_1 + C_2} \right)$$

Finally, using Equation 26.1 to find the voltage across each capacitor, we find that

$$\Delta V_{1f} = \frac{Q_{1f}}{C_1} = \frac{Q \left( \frac{C_1}{C_1 + C_2} \right)}{C_1} = \frac{Q}{C_1 + C_2}$$

**Figure 26.12**

$$\Delta V_{2f} = \frac{Q_{2f}}{C_2} = \frac{Q \left( \frac{C_2}{C_1 + C_2} \right)}{C_2} = \frac{Q}{C_1 + C_2}$$

As noted earlier,  $\Delta V_{1f} = \Delta V_{2f} = \Delta V_f$ .

To express  $\Delta V_f$  in terms of the given quantities  $C_1$ ,  $C_2$ , and  $\Delta V_i$ , we substitute the value of  $Q$  from Equation (1) to obtain

$$\Delta V_f = \left( \frac{C_1 - C_2}{C_1 + C_2} \right) \Delta V_i$$

(b) Find the total energy stored in the capacitors before and after the switches are closed and the ratio of the final energy to the initial energy.

**Solution** Before the switches are closed, the total energy stored in the capacitors is

$$U_i = \frac{1}{2} C_1 (\Delta V_i)^2 + \frac{1}{2} C_2 (\Delta V_i)^2 = \frac{1}{2} (C_1 + C_2) (\Delta V_i)^2$$

After the switches are closed, the total energy stored in the capacitors is

$$U_f = \frac{1}{2} C_1 (\Delta V_f)^2 + \frac{1}{2} C_2 (\Delta V_f)^2 = \frac{1}{2} (C_1 + C_2) (\Delta V_f)^2$$

$$= \frac{1}{2} (C_1 + C_2) \left( \frac{Q}{C_1 + C_2} \right)^2 = \frac{1}{2} \frac{Q^2}{C_1 + C_2}$$

Using Equation (1), we can express this as

$$U_f = \frac{1}{2} \frac{Q^2}{(C_1 + C_2)} = \frac{1}{2} \frac{(C_1 - C_2)^2 (\Delta V_i)^2}{(C_1 + C_2)}$$

Therefore, the ratio of the final energy stored to the initial energy stored is

$$\frac{U_f}{U_i} = \frac{\frac{1}{2} \frac{(C_1 - C_2)^2 (\Delta V_i)^2}{(C_1 + C_2)}}{\frac{1}{2} (C_1 + C_2) (\Delta V_i)^2} = \left( \frac{C_1 - C_2}{C_1 + C_2} \right)^2$$

This ratio is less than unity, indicating that the final energy is less than the initial energy. At first, you might think that the law of energy conservation has been violated, but this is not the case. The “missing” energy is radiated away in the form of electromagnetic waves, as we shall see in Chapter 34.

### Quick Quiz 26.4

You charge a parallel-plate capacitor, remove it from the battery, and prevent the wires connected to the plates from touching each other. When you pull the plates apart, do the following quantities increase, decrease, or stay the same? (a)  $C$ ; (b)  $Q$ ; (c)  $E$  between the plates; (d)  $\Delta V$ ; (e) energy stored in the capacitor.

### Quick Quiz 26.5

Repeat Quick Quiz 26.4, but this time answer the questions for the situation in which the battery remains connected to the capacitor while you pull the plates apart.

One device in which capacitors have an important role is the *defibrillator* (Fig. 26.13). Up to 360 J is stored in the electric field of a large capacitor in a defibrillator when it is fully charged. The defibrillator can deliver all this energy to a patient in about 2 ms. (This is roughly equivalent to 3 000 times the power output of a 60-W lightbulb!) The sudden electric shock stops the fibrillation (random contractions) of the heart that often accompanies heart attacks and helps to restore the correct rhythm.

A camera’s flash unit also uses a capacitor, although the total amount of energy stored is much less than that stored in a defibrillator. After the flash unit’s capacitor is charged, tripping the camera’s shutter causes the stored energy to be sent through a special lightbulb that briefly illuminates the subject being photographed.

#### web

To learn more about defibrillators, visit  
[www.physiocontrol.com](http://www.physiocontrol.com)

**Figure 26.13** In a hospital or at an emergency scene, you might see a patient being revived with a defibrillator. The defibrillator’s paddles are applied to the patient’s chest, and an electric shock is sent through the chest cavity. The aim of this technique is to restore the heart’s normal rhythm pattern.

## 26.5 CAPACITORS WITH DIELECTRICS

A **dielectric** is a nonconducting material, such as rubber, glass, or waxed paper. When a dielectric is inserted between the plates of a capacitor, the capacitance increases. If the dielectric completely fills the space between the plates, the capacitance increases by a dimensionless factor  $\kappa$ , which is called the **dielectric constant**. The dielectric constant is a property of a material and varies from one material to another. In this section, we analyze this change in capacitance in terms of electrical parameters such as electric charge, electric field, and potential difference; in Section 26.7, we shall discuss the microscopic origin of these changes.

We can perform the following experiment to illustrate the effect of a dielectric in a capacitor: Consider a parallel-plate capacitor that without a dielectric has a charge  $Q_0$  and a capacitance  $C_0$ . The potential difference across the capacitor is  $\Delta V_0 = Q_0/C_0$ . Figure 26.14a illustrates this situation. The potential difference is measured by a *voltmeter*, which we shall study in greater detail in Chapter 28. Note that no battery is shown in the figure; also, we must assume that no charge can flow through an ideal voltmeter, as we shall learn in Section 28.5. Hence, there is no path by which charge can flow and alter the charge on the capacitor. If a dielectric is now inserted between the plates, as shown in Figure 26.14b, the voltmeter indicates that the voltage between the plates decreases to a value  $\Delta V$ . The voltages with and without the dielectric are related by the factor  $\kappa$  as follows:

$$\Delta V = \frac{\Delta V_0}{\kappa}$$

Because  $\Delta V < \Delta V_0$ , we see that  $\kappa > 1$ .

Because the charge  $Q_0$  on the capacitor does not change, we conclude that the capacitance must change to the value

$$C = \frac{Q_0}{\Delta V} = \frac{Q_0}{\Delta V_0/\kappa} = \kappa \frac{Q_0}{\Delta V_0}$$

$$C = \kappa C_0 \quad (26.14)$$

The capacitance of a filled capacitor is greater than that of an empty one by a factor  $\kappa$ .

That is, the capacitance *increases* by the factor  $\kappa$  when the dielectric completely fills the region between the plates.<sup>4</sup> For a parallel-plate capacitor, where  $C_0 = \epsilon_0 A/d$  (Eq. 26.3), we can express the capacitance when the capacitor is filled with a dielectric as

$$C = \kappa \frac{\epsilon_0 A}{d} \quad (26.15)$$

From Equations 26.3 and 26.15, it would appear that we could make the capacitance very large by decreasing  $d$ , the distance between the plates. In practice, the lowest value of  $d$  is limited by the electric discharge that could occur through the dielectric medium separating the plates. For any given separation  $d$ , the maximum voltage that can be applied to a capacitor without causing a discharge depends on the **dielectric strength** (maximum electric field) of the dielectric. If the magnitude of the electric field in the dielectric exceeds the dielectric strength, then the insulating properties break down and the dielectric begins to conduct. Insulating materials have values of  $\kappa$  greater than unity and dielectric strengths

<sup>4</sup> If the dielectric is introduced while the potential difference is being maintained constant by a battery, the charge increases to a value  $Q = \kappa Q_0$ . The additional charge is supplied by the battery, and the capacitance again increases by the factor  $\kappa$ .

**Figure 26.14** A charged capacitor (a) before and (b) after insertion of a dielectric between the plates. The charge on the plates remains unchanged, but the potential difference decreases from  $\Delta V_0$  to  $\Delta V = \Delta V_0/\kappa$ . Thus, the capacitance *increases* from  $C_0$  to  $\kappa C_0$ .

greater than that of air, as Table 26.1 indicates. Thus, we see that a dielectric provides the following advantages:

- Increase in capacitance
- Increase in maximum operating voltage
- Possible mechanical support between the plates, which allows the plates to be close together without touching, thereby decreasing  $d$  and increasing  $C$

**TABLE 26.1** Dielectric Constants and Dielectric Strengths of Various Materials at Room Temperature

Material	Dielectric Constant $\kappa$	Dielectric Strength <sup>a</sup> (V/m)
Air (dry)	1.000 59	$3 \times 10^6$
Bakelite	4.9	$24 \times 10^6$
Fused quartz	3.78	$8 \times 10^6$
Neoprene rubber	6.7	$12 \times 10^6$
Nylon	3.4	$14 \times 10^6$
Paper	3.7	$16 \times 10^6$
Polystyrene	2.56	$24 \times 10^6$
Polyvinyl chloride	3.4	$40 \times 10^6$
Porcelain	6	$12 \times 10^6$
Pyrex glass	5.6	$14 \times 10^6$
Silicone oil	2.5	$15 \times 10^6$
Strontium titanate	233	$8 \times 10^6$
Teflon	2.1	$60 \times 10^6$
Vacuum	1.000 00	—
Water	80	—

<sup>a</sup> The dielectric strength equals the maximum electric field that can exist in a dielectric without electrical breakdown. Note that these values depend strongly on the presence of impurities and flaws in the materials.

(a) Kirlan photograph created by dropping a steel ball into a high-energy electric field. Kirlan photography is also known as *electrophotography*. (b) Sparks from static electricity discharge between a fork and four electrodes. Many sparks were used to create this image because only one spark forms for a given discharge. Note that the bottom prong discharges to both electrodes at the bottom right. The light of each spark is created by the excitation of gas atoms along its path.

### Types of Capacitors

Commercial capacitors are often made from metallic foil interlaced with thin sheets of either paraffin-impregnated paper or Mylar as the dielectric material. These alternate layers of metallic foil and dielectric are rolled into a cylinder to form a small package (Fig. 26.15a). High-voltage capacitors commonly consist of a number of interwoven metallic plates immersed in silicone oil (Fig. 26.15b). Small capacitors are often constructed from ceramic materials. Variable capacitors (typically 10 to 500 pF) usually consist of two interwoven sets of metallic plates, one fixed and the other movable, and contain air as the dielectric.

Often, an *electrolytic capacitor* is used to store large amounts of charge at relatively low voltages. This device, shown in Figure 26.15c, consists of a metallic foil in contact with an *electrolyte*—a solution that conducts electricity by virtue of the motion of ions contained in the solution. When a voltage is applied between the foil and the electrolyte, a thin layer of metal oxide (an insulator) is formed on the foil,

**Figure 26.15** Three commercial capacitor designs. (a) A tubular capacitor, whose plates are separated by paper and then rolled into a cylinder. (b) A high-voltage capacitor consisting of many parallel plates separated by insulating oil. (c) An electrolytic capacitor.

and this layer serves as the dielectric. Very large values of capacitance can be obtained in an electrolytic capacitor because the dielectric layer is very thin, and thus the plate separation is very small.

Electrolytic capacitors are not reversible as are many other capacitors—they have a polarity, which is indicated by positive and negative signs marked on the device. When electrolytic capacitors are used in circuits, the polarity must be aligned properly. If the polarity of the applied voltage is opposite that which is intended, the oxide layer is removed and the capacitor conducts electricity instead of storing charge.

### Quick Quiz 26.6

If you have ever tried to hang a picture, you know it can be difficult to locate a wooden stud in which to anchor your nail or screw. A carpenter's stud-finder is basically a capacitor with its plates arranged side by side instead of facing one another, as shown in Figure 26.16. When the device is moved over a stud, does the capacitance increase or decrease?

**Figure 26.16** A stud-finder. (a) The materials between the plates of the capacitor are the wallboard and air. (b) When the capacitor moves across a stud in the wall, the materials between the plates are the wallboard and the wood. The change in the dielectric constant causes a signal light to illuminate.

### EXAMPLE 26.6 A Paper-Filled Capacitor

A parallel-plate capacitor has plates of dimensions 2.0 cm by 3.0 cm separated by a 1.0-mm thickness of paper. (a) Find its capacitance.

**Solution** Because  $\kappa = 3.7$  for paper (see Table 26.1), we have

$$C = \kappa \frac{\epsilon_0 A}{d} = 3.7(8.85 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2) \left( \frac{6.0 \times 10^{-4} \text{ m}^2}{1.0 \times 10^{-3} \text{ m}} \right) \\ = 20 \times 10^{-12} \text{ F} = 20 \text{ pF}$$

(b) What is the maximum charge that can be placed on the capacitor?

**Solution** From Table 26.1 we see that the dielectric strength of paper is  $16 \times 10^6 \text{ V/m}$ . Because the thickness of

the paper is 1.0 mm, the maximum voltage that can be applied before breakdown is

$$\Delta V_{\text{max}} = E_{\text{max}} d = (16 \times 10^6 \text{ V/m})(1.0 \times 10^{-3} \text{ m}) \\ = 16 \times 10^3 \text{ V}$$

Hence, the maximum charge is

$$Q_{\text{max}} = C \Delta V_{\text{max}} = (20 \times 10^{-12} \text{ F})(16 \times 10^3 \text{ V}) = 0.32 \mu\text{C}$$

**Exercise** What is the maximum energy that can be stored in the capacitor?

**Answer**  $2.6 \times 10^{-3} \text{ J}$ .

**EXAMPLE 26.7** Energy Stored Before and After

A parallel-plate capacitor is charged with a battery to a charge  $Q_0$ , as shown in Figure 26.17a. The battery is then removed, and a slab of material that has a dielectric constant  $\kappa$  is inserted between the plates, as shown in Figure 26.17b. Find the energy stored in the capacitor before and after the dielectric is inserted.

**Solution** The energy stored in the absence of the dielectric is (see Eq. 26.11):

$$U_0 = \frac{Q_0^2}{2C_0}$$

After the battery is removed and the dielectric inserted, the charge on the capacitor remains the same. Hence, the energy stored in the presence of the dielectric is

$$U = \frac{Q_0^2}{2C}$$

But the capacitance in the presence of the dielectric is  $C = \kappa C_0$ , so  $U$  becomes

$$U = \frac{Q_0^2}{2\kappa C_0} = \frac{U_0}{\kappa}$$

Because  $\kappa > 1$ , the final energy is less than the initial energy. We can account for the “missing” energy by noting that the dielectric, when inserted, gets pulled into the device (see the following discussion and Figure 26.18). An external agent must do negative work to keep the dielectric from accelerating. This work is simply the difference  $U - U_0$ . (Alternatively, the positive work done by the system on the external agent is  $U_0 - U$ .)

**Exercise** Suppose that the capacitance in the absence of a dielectric is 8.50 pF and that the capacitor is charged to a potential difference of 12.0 V. If the battery is disconnected and a slab of polystyrene is inserted between the plates, what is  $U_0 - U$ ?

**Answer** 373 pJ.

(a)

(b)

**Figure 26.17**

As we have seen, the energy of a capacitor not connected to a battery is lowered when a dielectric is inserted between the plates; this means that negative work is done on the dielectric by the external agent inserting the dielectric into the capacitor. This, in turn, implies that a force that draws it into the capacitor must be acting on the dielectric. This force originates from the nonuniform nature of the electric field of the capacitor near its edges, as indicated in Figure 26.18. The horizontal component of this *fringe field* acts on the induced charges on the surface of the dielectric, producing a net horizontal force directed into the space between the capacitor plates.

**Quick Quiz 26.7**

A fully charged parallel-plate capacitor remains connected to a battery while you slide a dielectric between the plates. Do the following quantities increase, decrease, or stay the same? (a)  $C$ ; (b)  $Q$ ; (c)  $E$  between the plates; (d)  $\Delta V$ ; (e) energy stored in the capacitor.

**Figure 26.18** The nonuniform electric field near the edges of a parallel-plate capacitor causes a dielectric to be pulled into the capacitor. Note that the field acts on the induced surface charges on the dielectric, which are nonuniformly distributed.

### Optional Section

## 26.6 ELECTRIC DIPOLE IN AN ELECTRIC FIELD

We have discussed the effect on the capacitance of placing a dielectric between the plates of a capacitor. In Section 26.7, we shall describe the microscopic origin of this effect. Before we can do so, however, we need to expand upon the discussion of the electric dipole that we began in Section 23.4 (see Example 23.6). The electric dipole consists of two charges of equal magnitude but opposite sign separated by a distance  $2a$ , as shown in Figure 26.19. The **electric dipole moment** of this configuration is defined as the vector  $\mathbf{p}$  directed from  $-q$  to  $+q$  along the line joining the charges and having magnitude  $2aq$ :

$$p \equiv 2aq \quad (26.16)$$

Now suppose that an electric dipole is placed in a uniform electric field  $\mathbf{E}$ , as shown in Figure 26.20. We identify  $\mathbf{E}$  as the field *external* to the dipole, distinguishing it from the field *due to* the dipole, which we discussed in Section 23.4. The field  $\mathbf{E}$  is established by some other charge distribution, and we place the dipole into this field. Let us imagine that the dipole moment makes an angle  $\theta$  with the field.

The electric forces acting on the two charges are equal in magnitude but opposite in direction as shown in Figure 26.20 (each has a magnitude  $F = qE$ ). Thus, the net force on the dipole is zero. However, the two forces produce a net torque on the dipole; as a result, the dipole rotates in the direction that brings the dipole moment vector into greater alignment with the field. The torque due to the force on the positive charge about an axis through  $O$  in Figure 26.20 is  $Fa \sin \theta$ , where  $a \sin \theta$  is the moment arm of  $F$  about  $O$ . This force tends to produce a clockwise rotation. The torque about  $O$  on the negative charge also is  $Fa \sin \theta$ ; here again, the force tends to produce a clockwise rotation. Thus, the net torque about  $O$  is

$$\tau = 2Fa \sin \theta$$

Because  $F = qE$  and  $p = 2aq$ , we can express  $\tau$  as

$$\tau = 2aqE \sin \theta = pE \sin \theta \quad (26.17)$$

**Figure 26.19** An electric dipole consists of two charges of equal magnitude but opposite sign separated by a distance of  $2a$ . The electric dipole moment  $\mathbf{p}$  is directed from  $-q$  to  $+q$ .

**Figure 26.20** An electric dipole in a uniform external electric field. The dipole moment  $\mathbf{p}$  is at an angle  $\theta$  to the field, causing the dipole to experience a torque.

It is convenient to express the torque in vector form as the cross product of the vectors  $\mathbf{p}$  and  $\mathbf{E}$ :

Torque on an electric dipole in an external electric field

$$\boldsymbol{\tau} = \mathbf{p} \times \mathbf{E} \quad (26.18)$$

We can determine the potential energy of the system of an electric dipole in an external electric field as a function of the orientation of the dipole with respect to the field. To do this, we recognize that work must be done by an external agent to rotate the dipole through an angle so as to cause the dipole moment vector to become less aligned with the field. The work done is then stored as potential energy in the system of the dipole and the external field. The work  $dW$  required to rotate the dipole through an angle  $d\theta$  is  $dW = \tau d\theta$  (Eq. 10.22). Because  $\tau = pE \sin \theta$  and because the work is transformed into potential energy  $U$ , we find that, for a rotation from  $\theta_i$  to  $\theta_f$ , the change in potential energy is

$$\begin{aligned} U_f - U_i &= \int_{\theta_i}^{\theta_f} \tau d\theta = \int_{\theta_i}^{\theta_f} pE \sin \theta d\theta = pE \int_{\theta_i}^{\theta_f} \sin \theta d\theta \\ &= pE \left[ -\cos \theta \right]_{\theta_i}^{\theta_f} = pE(\cos \theta_i - \cos \theta_f) \end{aligned}$$

The term that contains  $\cos \theta_i$  is a constant that depends on the initial orientation of the dipole. It is convenient for us to choose  $\theta_i = 90^\circ$ , so that  $\cos \theta_i = \cos 90^\circ = 0$ . Furthermore, let us choose  $U_i = 0$  at  $\theta_i = 90^\circ$  as our reference of potential energy. Hence, we can express a general value of  $U = U_f$  as

$$U = -pE \cos \theta \quad (26.19)$$

We can write this expression for the potential energy of a dipole in an electric field as the dot product of the vectors  $\mathbf{p}$  and  $\mathbf{E}$ :

Potential energy of a dipole in an electric field

$$U = -\mathbf{p} \cdot \mathbf{E} \quad (26.20)$$

To develop a conceptual understanding of Equation 26.19, let us compare this expression with the expression for the potential energy of an object in the gravitational field of the Earth,  $U = mgh$  (see Chapter 8). The gravitational expression includes a parameter associated with the object we place in the field—its mass  $m$ . Likewise, Equation 26.19 includes a parameter of the object in the electric field—its dipole moment  $p$ . The gravitational expression includes the magnitude of the gravitational field  $g$ . Similarly, Equation 26.19 includes the magnitude of the electric field  $E$ . So far, these two contributions to the potential energy expressions appear analogous. However, the final contribution is somewhat different in the two cases. In the gravitational expression, the potential energy depends on how high we lift the object, measured by  $h$ . In Equation 26.19, the potential energy depends on the angle  $\theta$  through which we rotate the dipole. In both cases, we are making a change in the system. In the gravitational case, the change involves moving an object in a *translational* sense, whereas in the electrical case, the change involves moving an object in a *rotational* sense. In both cases, however, once the change is made, the system tends to return to the original configuration when the object is released: the object of mass  $m$  falls back to the ground, and the dipole begins to rotate back toward the configuration in which it was aligned with the field. Thus, apart from the type of motion, the expressions for potential energy in these two cases are similar.

Molecules are said to be *polarized* when a separation exists between the average position of the negative charges and the average position of the positive charges in the molecule. In some molecules, such as water, this condition is always present—such molecules are called **polar molecules**. Molecules that do not possess a permanent polarization are called **nonpolar molecules**.

We can understand the permanent polarization of water by inspecting the geometry of the water molecule. In the water molecule, the oxygen atom is bonded to the hydrogen atoms such that an angle of  $105^\circ$  is formed between the two bonds (Fig. 26.21). The center of the negative charge distribution is near the oxygen atom, and the center of the positive charge distribution lies at a point midway along the line joining the hydrogen atoms (the point labeled  $\times$  in Fig. 26.21). We can model the water molecule and other polar molecules as dipoles because the average positions of the positive and negative charges act as point charges. As a result, we can apply our discussion of dipoles to the behavior of polar molecules.

Microwave ovens take advantage of the polar nature of the water molecule. When in operation, microwave ovens generate a rapidly changing electric field that causes the polar molecules to swing back and forth, absorbing energy from the field in the process. Because the jostling molecules collide with each other, the energy they absorb from the field is converted to internal energy, which corresponds to an increase in temperature of the food.

Another household scenario in which the dipole structure of water is exploited is washing with soap and water. Grease and oil are made up of nonpolar molecules, which are generally not attracted to water. Plain water is not very useful for removing this type of grime. Soap contains long molecules called *surfactants*. In a long molecule, the polarity characteristics of one end of the molecule can be different from those at the other end. In a surfactant molecule, one end acts like a nonpolar molecule and the other acts like a polar molecule. The nonpolar end can attach to a grease or oil molecule, and the polar end can attach to a water molecule. Thus, the soap serves as a chain, linking the dirt and water molecules together. When the water is rinsed away, the grease and oil go with it.

A symmetric molecule (Fig. 26.22a) has no permanent polarization, but polarization can be induced by placing the molecule in an electric field. A field directed to the left, as shown in Figure 26.22b, would cause the center of the positive charge distribution to shift to the left from its initial position and the center of the negative charge distribution to shift to the right. This *induced polarization* is the effect that predominates in most materials used as dielectrics in capacitors.

**Figure 26.21** The water molecule,  $\text{H}_2\text{O}$ , has a permanent polarization resulting from its bent geometry. The center of the positive charge distribution is at the point  $\times$ .

**Figure 26.22** (a) A symmetric molecule has no permanent polarization. (b) An external electric field induces a polarization in the molecule.

### EXAMPLE 26.8 The $\text{H}_2\text{O}$ Molecule

The water ( $\text{H}_2\text{O}$ ) molecule has an electric dipole moment of  $6.3 \times 10^{-30} \text{ C}\cdot\text{m}$ . A sample contains  $10^{21}$  water molecules, with the dipole moments all oriented in the direction of an electric field of magnitude  $2.5 \times 10^5 \text{ N/C}$ . How much work is required to rotate the dipoles from this orientation ( $\theta = 0^\circ$ ) to one in which all the dipole moments are perpendicular to the field ( $\theta = 90^\circ$ )?

**Solution** The work required to rotate one molecule  $90^\circ$  is equal to the difference in potential energy between the  $90^\circ$  orientation and the  $0^\circ$  orientation. Using Equation 26.19, we

obtain

$$\begin{aligned} W &= U_{90} - U_0 = (-pE \cos 90^\circ) - (-pE \cos 0^\circ) \\ &= pE = (6.3 \times 10^{-30} \text{ C}\cdot\text{m})(2.5 \times 10^5 \text{ N/C}) \\ &= 1.6 \times 10^{-24} \text{ J} \end{aligned}$$

Because there are  $10^{21}$  molecules in the sample, the *total* work required is

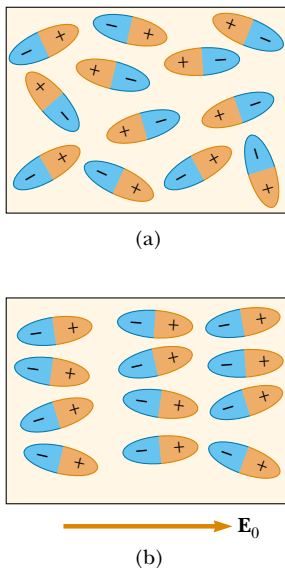

$$W_{\text{total}} = (10^{21})(1.6 \times 10^{-24} \text{ J}) = 1.6 \times 10^{-3} \text{ J}$$

## Optional Section

## 26.7 AN ATOMIC DESCRIPTION OF DIELECTRICS

In Section 26.5 we found that the potential difference  $\Delta V_0$  between the plates of a capacitor is reduced to  $\Delta V_0/\kappa$  when a dielectric is introduced. Because the potential difference between the plates equals the product of the electric field and the separation  $d$ , the electric field is also reduced. Thus, if  $\mathbf{E}_0$  is the electric field without the dielectric, the field in the presence of a dielectric is

$$\mathbf{E} = \frac{\mathbf{E}_0}{\kappa} \quad (26.21)$$

**Figure 26.23** (a) Polar molecules are randomly oriented in the absence of an external electric field. (b) When an external field is applied, the molecules partially align with the field.

Let us first consider a dielectric made up of polar molecules placed in the electric field between the plates of a capacitor. The dipoles (that is, the polar molecules making up the dielectric) are randomly oriented in the absence of an electric field, as shown in Figure 26.23a. When an external field  $\mathbf{E}_0$  due to charges on the capacitor plates is applied, a torque is exerted on the dipoles, causing them to partially align with the field, as shown in Figure 26.23b. We can now describe the dielectric as being polarized. The degree of alignment of the molecules with the electric field depends on temperature and on the magnitude of the field. In general, the alignment increases with decreasing temperature and with increasing electric field.

If the molecules of the dielectric are nonpolar, then the electric field due to the plates produces some charge separation and an *induced dipole moment*. These induced dipole moments tend to align with the external field, and the dielectric is polarized. Thus, we can polarize a dielectric with an external field regardless of whether the molecules are polar or nonpolar.

With these ideas in mind, consider a slab of dielectric material placed between the plates of a capacitor so that it is in a uniform electric field  $\mathbf{E}_0$ , as shown in Figure 26.24a. The electric field due to the plates is directed to the right and polarizes the dielectric. The net effect on the dielectric is the formation of an *induced positive surface charge density*  $\sigma_{\text{ind}}$  on the right face and an equal negative surface charge density  $-\sigma_{\text{ind}}$  on the left face, as shown in Figure 26.24b. These induced surface charges on the dielectric give rise to an induced electric field  $\mathbf{E}_{\text{ind}}$  in the direction opposite the external field  $\mathbf{E}_0$ . Therefore, the net electric field  $\mathbf{E}$  in the

**Figure 26.24** (a) When a dielectric is polarized, the dipole moments of the molecules in the dielectric are partially aligned with the external field  $\mathbf{E}_0$ . (b) This polarization causes an induced negative surface charge on one side of the dielectric and an equal induced positive surface charge on the opposite side. This separation of charge results in a reduction in the net electric field within the dielectric.

dielectric has a magnitude

$$E = E_0 - E_{\text{ind}} \tag{26.22}$$

In the parallel-plate capacitor shown in Figure 26.25, the external field  $E_0$  is related to the charge density  $\sigma$  on the plates through the relationship  $E_0 = \sigma/\epsilon_0$ . The induced electric field in the dielectric is related to the induced charge density  $\sigma_{\text{ind}}$  through the relationship  $E_{\text{ind}} = \sigma_{\text{ind}}/\epsilon_0$ . Because  $E = E_0/\kappa = \sigma/\kappa\epsilon_0$ , substitution into Equation 26.22 gives

$$\begin{aligned} \frac{\sigma}{\kappa\epsilon_0} &= \frac{\sigma}{\epsilon_0} - \frac{\sigma_{\text{ind}}}{\epsilon_0} \\ \sigma_{\text{ind}} &= \left(\frac{\kappa - 1}{\kappa}\right)\sigma \end{aligned} \tag{26.23}$$

Because  $\kappa > 1$ , this expression shows that the charge density  $\sigma_{\text{ind}}$  induced on the dielectric is less than the charge density  $\sigma$  on the plates. For instance, if  $\kappa = 3$ , we see that the induced charge density is two-thirds the charge density on the plates. If no dielectric is present, then  $\kappa = 1$  and  $\sigma_{\text{ind}} = 0$  as expected. However, if the dielectric is replaced by an electrical conductor, for which  $E = 0$ , then Equation 26.22 indicates that  $E_0 = E_{\text{ind}}$ ; this corresponds to  $\sigma_{\text{ind}} = \sigma$ . That is, the surface charge induced on the conductor is equal in magnitude but opposite in sign to that on the plates, resulting in a net electric field of zero in the conductor.

**Figure 26.25** Induced charge on a dielectric placed between the plates of a charged capacitor. Note that the induced charge density on the dielectric is less than the charge density on the plates.

**EXAMPLE 26.9** Effect of a Metallic Slab

A parallel-plate capacitor has a plate separation  $d$  and plate area  $A$ . An uncharged metallic slab of thickness  $a$  is inserted midway between the plates. (a) Find the capacitance of the device.

**Solution** We can solve this problem by noting that any charge that appears on one plate of the capacitor must induce a charge of equal magnitude but opposite sign on the near side of the slab, as shown in Figure 26.26a. Consequently, the net charge on the slab remains zero, and the electric field inside the slab is zero. Hence, the capacitor is equivalent to two capacitors in series, each having a plate separation  $(d - a)/2$ , as shown in Figure 26.26b.

Using the rule for adding two capacitors in series (Eq. 26.10), we obtain

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{\frac{\epsilon_0 A}{(d - a)/2}} + \frac{1}{\frac{\epsilon_0 A}{(d - a)/2}}$$

$$C = \frac{\epsilon_0 A}{d - a}$$

Note that  $C$  approaches infinity as  $a$  approaches  $d$ . Why?

(b) Show that the capacitance is unaffected if the metallic slab is infinitesimally thin.

**Solution** In the result for part (a), we let  $a \rightarrow 0$ :

$$C = \lim_{a \rightarrow 0} \frac{\epsilon_0 A}{d - a} = \frac{\epsilon_0 A}{d}$$

which is the original capacitance.

**Figure 26.26** (a) A parallel-plate capacitor of plate separation  $d$  partially filled with a metallic slab of thickness  $a$ . (b) The equivalent circuit of the device in part (a) consists of two capacitors in series, each having a plate separation  $(d - a)/2$ .

(c) Show that the answer to part (a) does not depend on where the slab is inserted.

**Solution** Let us imagine that the slab in Figure 26.26a is moved upward so that the distance between the upper edge of the slab and the upper plate is  $b$ . Then, the distance between the lower edge of the slab and the lower plate is  $d - b - a$ . As in part (a), we find the total capacitance of the series combination:

$$\begin{aligned} \frac{1}{C} &= \frac{1}{C_1} + \frac{1}{C_2} = \frac{1}{\frac{\epsilon_0 A}{b}} + \frac{1}{\frac{\epsilon_0 A}{d - b - a}} \\ &= \frac{b}{\epsilon_0 A} + \frac{d - b - a}{\epsilon_0 A} = \frac{d - a}{\epsilon_0 A} \\ C &= \frac{\epsilon_0 A}{d - a} \end{aligned}$$

This is the same result as in part (a). It is independent of the value of  $b$ , so it does not matter where the slab is located.

### EXAMPLE 26.10 A Partially Filled Capacitor

A parallel-plate capacitor with a plate separation  $d$  has a capacitance  $C_0$  in the absence of a dielectric. What is the capacitance when a slab of dielectric material of dielectric constant  $\kappa$  and thickness  $\frac{1}{3}d$  is inserted between the plates (Fig. 26.27a)?

**Figure 26.27** (a) A parallel-plate capacitor of plate separation  $d$  partially filled with a dielectric of thickness  $d/3$ . (b) The equivalent circuit of the capacitor consists of two capacitors connected in series.

**Solution** In Example 26.9, we found that we could insert a metallic slab between the plates of a capacitor and consider the combination as two capacitors in series. The resulting capacitance was independent of the location of the slab. Furthermore, if the thickness of the slab approaches zero, then the capacitance of the system approaches the capacitance when the slab is absent. From this, we conclude that we can insert an infinitesimally thin metallic slab anywhere between the plates of a capacitor without affecting the capacitance. Thus, let us imagine sliding an infinitesimally thin metallic slab along the bottom face of the dielectric shown in Figure 26.27a. We can then consider this system to be the series combination of the two capacitors shown in Figure 26.27b: one having a plate separation  $d/3$  and filled with a dielectric, and the other having a plate separation  $2d/3$  and air between its plates.

From Equations 26.15 and 26.3, the two capacitances are

$$C_1 = \frac{\kappa\epsilon_0 A}{d/3} \quad \text{and} \quad C_2 = \frac{\epsilon_0 A}{2d/3}$$

Using Equation 26.10 for two capacitors combined in series, we have

$$\begin{aligned} \frac{1}{C} &= \frac{1}{C_1} + \frac{1}{C_2} = \frac{d/3}{\kappa\epsilon_0 A} + \frac{2d/3}{\epsilon_0 A} \\ &= \frac{d}{3\epsilon_0 A} \left( \frac{1}{\kappa} + 2 \right) = \frac{d}{3\epsilon_0 A} \left( \frac{1 + 2\kappa}{\kappa} \right) \\ C &= \left( \frac{3\kappa}{2\kappa + 1} \right) \frac{\epsilon_0 A}{d} \end{aligned}$$

Because the capacitance without the dielectric is  $C_0 = \epsilon_0 A/d$ , we see that

$$C = \left( \frac{3\kappa}{2\kappa + 1} \right) C_0$$

## SUMMARY

A **capacitor** consists of two conductors carrying charges of equal magnitude but opposite sign. The **capacitance**  $C$  of any capacitor is the ratio of the charge  $Q$  on either conductor to the potential difference  $\Delta V$  between them:

$$C \equiv \frac{Q}{\Delta V} \quad (26.1)$$

This relationship can be used in situations in which any two of the three variables are known. It is important to remember that this ratio is constant for a given configuration of conductors because the capacitance depends only on the geometry of the conductors and not on an external source of charge or potential difference.

The SI unit of capacitance is coulombs per volt, or the **farad** (F), and  $1 \text{ F} = 1 \text{ C/V}$ .

Capacitance expressions for various geometries are summarized in Table 26.2.

If two or more capacitors are connected in parallel, then the potential difference is the same across all of them. The equivalent capacitance of a parallel combination of capacitors is

$$C_{\text{eq}} = C_1 + C_2 + C_3 + \cdots \quad (26.8)$$

If two or more capacitors are connected in series, the charge is the same on all of them, and the equivalent capacitance of the series combination is given by

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots \quad (26.10)$$

These two equations enable you to simplify many electric circuits by replacing multiple capacitors with a single equivalent capacitance.

Work is required to charge a capacitor because the charging process is equivalent to the transfer of charges from one conductor at a lower electric potential to another conductor at a higher potential. The work done in charging the capacitor to a charge  $Q$  equals the electric potential energy  $U$  stored in the capacitor, where

$$U = \frac{Q^2}{2C} = \frac{1}{2}Q\Delta V = \frac{1}{2}C(\Delta V)^2 \quad (26.11)$$

**TABLE 26.2** Capacitance and Geometry

Geometry	Capacitance	Equation
Isolated charged sphere of radius $R$ (second charged conductor assumed at infinity)	$C = 4\pi\epsilon_0 R$	26.2
Parallel-plate capacitor of plate area $A$ and plate separation $d$	$C = \epsilon_0 \frac{A}{d}$	26.3
Cylindrical capacitor of length $\ell$ and inner and outer radii $a$ and $b$ , respectively	$C = \frac{\ell}{2k_e \ln\left(\frac{b}{a}\right)}$	26.4
Spherical capacitor with inner and outer radii $a$ and $b$ , respectively	$C = \frac{ab}{k_e (b - a)}$	26.6

When a dielectric material is inserted between the plates of a capacitor, the capacitance increases by a dimensionless factor  $\kappa$ , called the **dielectric constant**:

$$C = \kappa C_0 \quad (26.14)$$

where  $C_0$  is the capacitance in the absence of the dielectric. The increase in capacitance is due to a decrease in the magnitude of the electric field in the presence of the dielectric and to a corresponding decrease in the potential difference between the plates—if we assume that the charging battery is removed from the circuit before the dielectric is inserted. The decrease in the magnitude of  $\mathbf{E}$  arises from an internal electric field produced by aligned dipoles in the dielectric. This internal field produced by the dipoles opposes the applied field due to the capacitor plates, and the result is a reduction in the net electric field.

The **electric dipole moment**  $\mathbf{p}$  of an electric dipole has a magnitude

$$p \equiv 2aq \quad (26.16)$$

The direction of the electric dipole moment vector is from the negative charge toward the positive charge.

The torque acting on an electric dipole in a uniform electric field  $\mathbf{E}$  is

$$\boldsymbol{\tau} = \mathbf{p} \times \mathbf{E} \quad (26.18)$$

The potential energy of an electric dipole in a uniform external electric field  $\mathbf{E}$  is

$$U = -\mathbf{p} \cdot \mathbf{E} \quad (26.20)$$

### Problem-Solving Hints

#### Capacitors

- Be careful with units. When you calculate capacitance in farads, make sure that distances are expressed in meters and that you use the SI value of  $\epsilon_0$ . When checking consistency of units, remember that the unit for electric fields can be either N/C or V/m.
- When two or more capacitors are connected in parallel, the potential difference across each is the same. The charge on each capacitor is proportional to its capacitance; hence, the capacitances can be added directly to give the equivalent capacitance of the parallel combination. The equivalent capacitance is always larger than the individual capacitances.
- When two or more capacitors are connected in series, they carry the same charge, and the sum of the potential differences equals the total potential difference applied to the combination. The sum of the reciprocals of the capacitances equals the reciprocal of the equivalent capacitance, which is always less than the capacitance of the smallest individual capacitor.
- A dielectric increases the capacitance of a capacitor by a factor  $\kappa$  (the dielectric constant) over its capacitance when air is between the plates.
- For problems in which a battery is being connected or disconnected, note whether modifications to the capacitor are made while it is connected to the battery or after it has been disconnected. If the capacitor remains connected to the battery, the voltage across the capacitor remains unchanged (equal to the battery voltage), and the charge is proportional to the capaci-

tance, although it may be modified (for instance, by the insertion of a dielectric). If you disconnect the capacitor from the battery before making any modifications to the capacitor, then its charge remains fixed. In this case, as you vary the capacitance, the voltage across the plates changes according to the expression  $\Delta V = Q/C$ .

## QUESTIONS

- If you were asked to design a capacitor in a situation for which small size and large capacitance were required, what factors would be important in your design?
- The plates of a capacitor are connected to a battery. What happens to the charge on the plates if the connecting wires are removed from the battery? What happens to the charge if the wires are removed from the battery and connected to each other?
- A farad is a very large unit of capacitance. Calculate the length of one side of a square, air-filled capacitor that has a plate separation of 1 m. Assume that it has a capacitance of 1 F.
- A pair of capacitors are connected in parallel, while an identical pair are connected in series. Which pair would be more dangerous to handle after being connected to the same voltage source? Explain.
- If you are given three different capacitors  $C_1$ ,  $C_2$ ,  $C_3$ , how many different combinations of capacitance can you produce?
- What advantage might there be in using two identical capacitors in parallel connected in series with another identical parallel pair rather than a single capacitor?
- Is it always possible to reduce a combination of capacitors to one equivalent capacitor with the rules we have developed? Explain.
- Because the net charge in a capacitor is always zero, what does a capacitor store?
- Because the charges on the plates of a parallel-plate capacitor are of opposite sign, they attract each other. Hence, it would take positive work to increase the plate separation. What happens to the external work done in this process?
- Explain why the work needed to move a charge  $Q$  through a potential difference  $\Delta V$  is  $W = Q\Delta V$ , whereas the energy stored in a charged capacitor is  $U = \frac{1}{2}Q\Delta V$ . Where does the  $\frac{1}{2}$  factor come from?
- If the potential difference across a capacitor is doubled, by what factor does the stored energy change?
- Why is it dangerous to touch the terminals of a high-voltage capacitor even after the applied voltage has been turned off? What can be done to make the capacitor safe to handle after the voltage source has been removed?
- Describe how you can increase the maximum operating voltage of a parallel-plate capacitor for a fixed plate separation.
- An air-filled capacitor is charged, disconnected from the power supply, and, finally, connected to a voltmeter. Explain how and why the voltage reading changes when a dielectric is inserted between the plates of the capacitor.
- Using the polar molecule description of a dielectric, explain how a dielectric affects the electric field inside a capacitor.
- Explain why a dielectric increases the maximum operating voltage of a capacitor even though the physical size of the capacitor does not change.
- What is the difference between dielectric strength and the dielectric constant?
- Explain why a water molecule is permanently polarized. What type of molecule has no permanent polarization?
- If a dielectric-filled capacitor is heated, how does its capacitance change? (Neglect thermal expansion and assume that the dipole orientations are temperature dependent.)

### Section 26.1 Definition of Capacitance

- (a) How much charge is on each plate of a  $4.00\text{-}\mu\text{F}$  capacitor when it is connected to a  $12.0\text{-V}$  battery?  
 (b) If this same capacitor is connected to a  $1.50\text{-V}$  battery, what charge is stored?
- Two conductors having net charges of  $+10.0\ \mu\text{C}$  and  $-10.0\ \mu\text{C}$  have a potential difference of  $10.0\ \text{V}$ . Determine (a) the capacitance of the system and (b) the potential difference between the two conductors if the charges on each are increased to  $+100\ \mu\text{C}$  and  $-100\ \mu\text{C}$ .

### Section 26.2 Calculating Capacitance

3. An isolated charged conducting sphere of radius 12.0 cm creates an electric field of  $4.90 \times 10^4$  N/C at a distance 21.0 cm from its center. (a) What is its surface charge density? (b) What is its capacitance?
4. (a) If a drop of liquid has capacitance 1.00 pF, what is its radius? (b) If another drop has radius 2.00 mm, what is its capacitance? (c) What is the charge on the smaller drop if its potential is 100 V?
5. Two conducting spheres with diameters of 0.400 m and 1.00 m are separated by a distance that is large compared with the diameters. The spheres are connected by a thin wire and are charged to  $7.00 \mu\text{C}$ . (a) How is this total charge shared between the spheres? (Neglect any charge on the wire.) (b) What is the potential of the system of spheres when the reference potential is taken to be  $V = 0$  at  $r = \infty$ ?
6. Regarding the Earth and a cloud layer 800 m above the Earth as the “plates” of a capacitor, calculate the capacitance if the cloud layer has an area of  $1.00 \text{ km}^2$ . Assume that the air between the cloud and the ground is pure and dry. Assume that charge builds up on the cloud and on the ground until a uniform electric field with a magnitude of  $3.00 \times 10^6$  N/C throughout the space between them makes the air break down and conduct electricity as a lightning bolt. What is the maximum charge the cloud can hold?
- WEB 7. An air-filled capacitor consists of two parallel plates, each with an area of  $7.60 \text{ cm}^2$ , separated by a distance of 1.80 mm. If a 20.0-V potential difference is applied to these plates, calculate (a) the electric field between the plates, (b) the surface charge density, (c) the capacitance, and (d) the charge on each plate.
8. A 1-megabit computer memory chip contains many 60.0-fF capacitors. Each capacitor has a plate area of  $21.0 \times 10^{-12} \text{ m}^2$ . Determine the plate separation of such a capacitor (assume a parallel-plate configuration). The characteristic atomic diameter is  $10^{-10} \text{ m} = 0.100 \text{ nm}$ . Express the plate separation in nanometers.
9. When a potential difference of 150 V is applied to the plates of a parallel-plate capacitor, the plates carry a surface charge density of  $30.0 \text{ nC/cm}^2$ . What is the spacing between the plates?
10. A variable air capacitor used in tuning circuits is made of  $N$  semicircular plates each of radius  $R$  and positioned a distance  $d$  from each other. As shown in Figure P26.10, a second identical set of plates is enmeshed with its plates halfway between those of the first set. The second set can rotate as a unit. Determine the capacitance as a function of the angle of rotation  $\theta$ , where  $\theta = 0$  corresponds to the maximum capacitance.
- WEB 11. A 50.0-m length of coaxial cable has an inner conductor that has a diameter of 2.58 mm and carries a charge of  $8.10 \mu\text{C}$ . The surrounding conductor has an inner diameter of 7.27 mm and a charge of  $-8.10 \mu\text{C}$ . (a) What is the capacitance of this cable? (b) What is

Figure P26.10

- the potential difference between the two conductors? Assume the region between the conductors is air.
12. A  $20.0\text{-}\mu\text{F}$  spherical capacitor is composed of two metallic spheres, one having a radius twice as large as the other. If the region between the spheres is a vacuum, determine the volume of this region.
13. A small object with a mass of 350 mg carries a charge of  $30.0 \text{ nC}$  and is suspended by a thread between the vertical plates of a parallel-plate capacitor. The plates are separated by 4.00 cm. If the thread makes an angle of  $15.0^\circ$  with the vertical, what is the potential difference between the plates?
14. A small object of mass  $m$  carries a charge  $q$  and is suspended by a thread between the vertical plates of a parallel-plate capacitor. The plate separation is  $d$ . If the thread makes an angle  $\theta$  with the vertical, what is the potential difference between the plates?
15. An air-filled spherical capacitor is constructed with inner and outer shell radii of 7.00 and 14.0 cm, respectively. (a) Calculate the capacitance of the device. (b) What potential difference between the spheres results in a charge of  $4.00 \mu\text{C}$  on the capacitor?
16. Find the capacitance of the Earth. (*Hint:* The outer conductor of the “spherical capacitor” may be considered as a conducting sphere at infinity where  $V$  approaches zero.)

### Section 26.3 Combinations of Capacitors

17. Two capacitors  $C_1 = 5.00 \mu\text{F}$  and  $C_2 = 12.0 \mu\text{F}$  are connected in parallel, and the resulting combination is connected to a 9.00-V battery. (a) What is the value of the equivalent capacitance of the combination? What are (b) the potential difference across each capacitor and (c) the charge stored on each capacitor?
18. The two capacitors of Problem 17 are now connected in series and to a 9.00-V battery. Find (a) the value of the equivalent capacitance of the combination, (b) the voltage across each capacitor, and (c) the charge on each capacitor.
19. Two capacitors when connected in parallel give an equivalent capacitance of  $9.00 \text{ pF}$  and an equivalent ca-

capacitance of  $2.00 \text{ pF}$  when connected in series. What is the capacitance of each capacitor?

20. Two capacitors when connected in parallel give an equivalent capacitance of  $C_p$  and an equivalent capacitance of  $C_s$  when connected in series. What is the capacitance of each capacitor?

- WEB 21. Four capacitors are connected as shown in Figure P26.21. (a) Find the equivalent capacitance between points  $a$  and  $b$ . (b) Calculate the charge on each capacitor if  $\Delta V_{ab} = 15.0 \text{ V}$ .

Figure P26.21

22. Evaluate the equivalent capacitance of the configuration shown in Figure P26.22. All the capacitors are identical, and each has capacitance  $C$ .

Figure P26.22

23. Consider the circuit shown in Figure P26.23, where  $C_1 = 6.00 \text{ } \mu\text{F}$ ,  $C_2 = 3.00 \text{ } \mu\text{F}$ , and  $\Delta V = 20.0 \text{ V}$ . Capacitor  $C_1$  is first charged by the closing of switch  $S_1$ . Switch  $S_1$  is then opened, and the charged capacitor is connected to the uncharged capacitor by the closing of  $S_2$ . Calculate the initial charge acquired by  $C_1$  and the final charge on each.

Figure P26.23

24. According to its design specification, the timer circuit delaying the closing of an elevator door is to have a capacitance of  $32.0 \text{ } \mu\text{F}$  between two points  $A$  and  $B$ . (a) When one circuit is being constructed, the inexpensive capacitor installed between these two points is found to have capacitance  $34.8 \text{ } \mu\text{F}$ . To meet the specification, one additional capacitor can be placed between the two points. Should it be in series or in parallel with the  $34.8\text{-}\mu\text{F}$  capacitor? What should be its capacitance? (b) The next circuit comes down the assembly line with capacitance  $29.8 \text{ } \mu\text{F}$  between  $A$  and  $B$ . What additional capacitor should be installed in series or in parallel in that circuit, to meet the specification?
25. The circuit in Figure P26.25 consists of two identical parallel metallic plates connected by identical metallic springs to a  $100\text{-V}$  battery. With the switch open, the plates are uncharged, are separated by a distance  $d = 8.00 \text{ mm}$ , and have a capacitance  $C = 2.00 \text{ } \mu\text{F}$ . When the switch is closed, the distance between the plates decreases by a factor of  $0.500$ . (a) How much charge collects on each plate and (b) what is the spring constant for each spring? (*Hint*: Use the result of Problem 35.)

Figure P26.25

26. Figure P26.26 shows six concentric conducting spheres,  $A$ ,  $B$ ,  $C$ ,  $D$ ,  $E$ , and  $F$  having radii  $R$ ,  $2R$ ,  $3R$ ,  $4R$ ,  $5R$ , and  $6R$ , respectively. Spheres  $B$  and  $C$  are connected by a conducting wire, as are spheres  $D$  and  $E$ . Determine the equivalent capacitance of this system.
27. A group of identical capacitors is connected first in series and then in parallel. The combined capacitance in parallel is 100 times larger than for the series connection. How many capacitors are in the group?
28. Find the equivalent capacitance between points  $a$  and  $b$  for the group of capacitors connected as shown in Figure P26.28 if  $C_1 = 5.00 \text{ } \mu\text{F}$ ,  $C_2 = 10.0 \text{ } \mu\text{F}$ , and  $C_3 = 2.00 \text{ } \mu\text{F}$ .
29. For the network described in the previous problem if the potential difference between points  $a$  and  $b$  is  $60.0 \text{ V}$ , what charge is stored on  $C_3$ ?

Figure P26.26

Figure P26.28 Problems 28 and 29.

30. Find the equivalent capacitance between points  $a$  and  $b$  in the combination of capacitors shown in Figure P26.30.

Figure P26.30

### Section 26.4 Energy Stored in a Charged Capacitor

31. (a) A  $3.00\text{-}\mu\text{F}$  capacitor is connected to a  $12.0\text{-V}$  battery. How much energy is stored in the capacitor? (b) If the capacitor had been connected to a  $6.00\text{-V}$  battery, how much energy would have been stored?
32. Two capacitors  $C_1 = 25.0\ \mu\text{F}$  and  $C_2 = 5.00\ \mu\text{F}$  are connected in parallel and charged with a  $100\text{-V}$  power supply. (a) Draw a circuit diagram and calculate the total

energy stored in the two capacitors. (b) What potential difference would be required across the same two capacitors connected in series so that the combination stores the same energy as in part (a)? Draw a circuit diagram of this circuit.

33. A parallel-plate capacitor is charged and then disconnected from a battery. By what fraction does the stored energy change (increase or decrease) when the plate separation is doubled?
34. A uniform electric field  $E = 3\ 000\ \text{V/m}$  exists within a certain region. What volume of space contains an energy equal to  $1.00 \times 10^{-7}\ \text{J}$ ? Express your answer in cubic meters and in liters.
- WEB 35. A parallel-plate capacitor has a charge  $Q$  and plates of area  $A$ . Show that the force exerted on each plate by the other is  $F = Q^2/2\epsilon_0 A$ . (Hint: Let  $C = \epsilon_0 A/x$  for an arbitrary plate separation  $x$ ; then require that the work done in separating the two charged plates be  $W = \int F dx$ .)
36. Plate  $a$  of a parallel-plate, air-filled capacitor is connected to a spring having force constant  $k$ , and plate  $b$  is fixed. They rest on a table top as shown (top view) in Figure P26.36. If a charge  $+Q$  is placed on plate  $a$  and a charge  $-Q$  is placed on plate  $b$ , by how much does the spring expand?

Figure P26.36

37. **Review Problem.** A certain storm cloud has a potential difference of  $1.00 \times 10^8\ \text{V}$  relative to a tree. If, during a lightning storm,  $50.0\ \text{C}$  of charge is transferred through this potential difference and  $1.00\%$  of the energy is absorbed by the tree, how much water (sap in the tree) initially at  $30.0^\circ\text{C}$  can be boiled away? Water has a specific heat of  $4\ 186\ \text{J/kg}\cdot^\circ\text{C}$ , a boiling point of  $100^\circ\text{C}$ , and a heat of vaporization of  $2.26 \times 10^6\ \text{J/kg}$ .
38. Show that the energy associated with a conducting sphere of radius  $R$  and charge  $Q$  surrounded by a vacuum is  $U = k_e Q^2/2R$ .
39. Einstein said that energy is associated with mass according to the famous relationship  $E = mc^2$ . Estimate the radius of an electron, assuming that its charge is distributed uniformly over the surface of a sphere of radius  $R$  and that the mass-energy of the electron is equal to the total energy stored in the resulting nonzero electric field between  $R$  and infinity. (See Problem 38. Experimentally, an electron nevertheless appears to be a point particle. The electric field close to the electron must be described by quantum electrodynamics, rather than the classical electrodynamics that we study.)

### Section 26.5 Capacitors with Dielectrics

40. Find the capacitance of a parallel-plate capacitor that uses Bakelite as a dielectric, if each of the plates has an area of  $5.00 \text{ cm}^2$  and the plate separation is  $2.00 \text{ mm}$ .
41. Determine (a) the capacitance and (b) the maximum voltage that can be applied to a Teflon-filled parallel-plate capacitor having a plate area of  $1.75 \text{ cm}^2$  and plate separation of  $0.0400 \text{ mm}$ .
42. (a) How much charge can be placed on a capacitor with air between the plates before it breaks down, if the area of each of the plates is  $5.00 \text{ cm}^2$ ? (b) Find the maximum charge if polystyrene is used between the plates instead of air.
43. A commercial capacitor is constructed as shown in Figure 26.15a. This particular capacitor is rolled from two strips of aluminum separated by two strips of paraffin-coated paper. Each strip of foil and paper is  $7.00 \text{ cm}$  wide. The foil is  $0.00400 \text{ mm}$  thick, and the paper is  $0.0250 \text{ mm}$  thick and has a dielectric constant of  $3.70$ . What length should the strips be if a capacitance of  $9.50 \times 10^{-8} \text{ F}$  is desired? (Use the parallel-plate formula.)
44. The supermarket sells rolls of aluminum foil, plastic wrap, and waxed paper. Describe a capacitor made from supermarket materials. Compute order-of-magnitude estimates for its capacitance and its breakdown voltage.
45. A capacitor that has air between its plates is connected across a potential difference of  $12.0 \text{ V}$  and stores  $48.0 \text{ } \mu\text{C}$  of charge. It is then disconnected from the source while still charged. (a) Find the capacitance of the capacitor. (b) A piece of Teflon is inserted between the plates. Find its new capacitance. (c) Find the voltage and charge now on the capacitor.
46. A parallel-plate capacitor in air has a plate separation of  $1.50 \text{ cm}$  and a plate area of  $25.0 \text{ cm}^2$ . The plates are charged to a potential difference of  $250 \text{ V}$  and disconnected from the source. The capacitor is then immersed in distilled water. Determine (a) the charge on the plates before and after immersion, (b) the capacitance and voltage after immersion, and (c) the change in energy of the capacitor. Neglect the conductance of the liquid.
47. A conducting spherical shell has inner radius  $a$  and outer radius  $c$ . The space between these two surfaces is filled with a dielectric for which the dielectric constant is  $\kappa_1$  between  $a$  and  $b$ , and  $\kappa_2$  between  $b$  and  $c$  (Fig. P26.47). Determine the capacitance of this system.
48. A wafer of titanium dioxide ( $\kappa = 173$ ) has an area of  $1.00 \text{ cm}^2$  and a thickness of  $0.100 \text{ mm}$ . Aluminum is evaporated on the parallel faces to form a parallel-plate capacitor. (a) Calculate the capacitance. (b) When the capacitor is charged with a  $12.0\text{-V}$  battery, what is the magnitude of charge delivered to each plate? (c) For the situation in part (b), what are the free and induced surface charge densities? (d) What is the magnitude  $E$  of the electric field?

Figure P26.47

49. Each capacitor in the combination shown in Figure P26.49 has a breakdown voltage of  $15.0 \text{ V}$ . What is the breakdown voltage of the combination?

Figure P26.49

(Optional)

### Section 26.6 Electric Dipole in an Electric Field

50. A small rigid object carries positive and negative  $3.50\text{-nC}$  charges. It is oriented so that the positive charge is at the point  $(-1.20 \text{ mm}, 1.10 \text{ mm})$  and the negative charge is at the point  $(1.40 \text{ mm}, -1.30 \text{ mm})$ . (a) Find the electric dipole moment of the object. The object is placed in an electric field  $\mathbf{E} = (7800\mathbf{i} - 4900\mathbf{j}) \text{ N/C}$ . (b) Find the torque acting on the object. (c) Find the potential energy of the object in this orientation. (d) If the orientation of the object can change, find the difference between its maximum and its minimum potential energies.
51. A small object with electric dipole moment  $\mathbf{p}$  is placed in a nonuniform electric field  $\mathbf{E} = E(x)\mathbf{i}$ . That is, the field is in the  $x$  direction, and its magnitude depends on the coordinate  $x$ . Let  $\theta$  represent the angle between the dipole moment and the  $x$  direction. (a) Prove that the dipole experiences a net force  $F = p(dE/dx) \cos \theta$  in the direction toward which the field increases. (b) Consider the field created by a spherical balloon centered at the origin. The balloon has a radius of  $15.0 \text{ cm}$  and carries a charge of  $2.00 \text{ } \mu\text{C}$ . Evaluate  $dE/dx$  at the point  $(16 \text{ cm}, 0, 0)$ . Assume that a water droplet at this point has an induced dipole moment of  $(6.30\mathbf{i}) \text{ nC}\cdot\text{m}$ . Find the force on it.

(Optional)

### Section 26.7 An Atomic Description of Dielectrics

52. A detector of radiation called a Geiger–Muller counter consists of a closed, hollow, conducting cylinder with a

fine wire along its axis. Suppose that the internal diameter of the cylinder is 2.50 cm and that the wire along the axis has a diameter of 0.200 mm. If the dielectric strength of the gas between the central wire and the cylinder is  $1.20 \times 10^6$  V/m, calculate the maximum voltage that can be applied between the wire and the cylinder before breakdown occurs in the gas.

53. The general form of Gauss's law describes how a charge creates an electric field in a material, as well as in a vacuum. It is

$$\oint \mathbf{E} \cdot d\mathbf{A} = \frac{q}{\epsilon}$$

where  $\epsilon = \kappa\epsilon_0$  is the permittivity of the material.

(a) A sheet with charge  $Q$  uniformly distributed over its area  $A$  is surrounded by a dielectric. Show that the sheet creates a uniform electric field with magnitude  $E = Q/2A\epsilon$  at nearby points. (b) Two large sheets of area  $A$  carrying opposite charges of equal magnitude  $Q$  are a small distance  $d$  apart. Show that they create a uniform electric field of magnitude  $E = Q/A\epsilon$  between them. (c) Assume that the negative plate is at zero potential. Show that the positive plate is at a potential  $Qd/A\epsilon$ . (d) Show that the capacitance of the pair of plates is  $A\epsilon/d = \kappa A\epsilon_0/d$ .

### ADDITIONAL PROBLEMS

54. For the system of capacitors shown in Figure P26.54, find (a) the equivalent capacitance of the system, (b) the potential difference across each capacitor, (c) the charge on each capacitor, and (d) the total energy stored by the group.

Figure P26.54

55. Consider two long, parallel, and oppositely charged wires of radius  $d$  with their centers separated by a distance  $D$ . Assuming the charge is distributed uniformly on the surface of each wire, show that the capacitance per unit length of this pair of wires is

$$\frac{C}{\ell} = \frac{\pi\epsilon_0}{\ln\left(\frac{D-d}{d}\right)}$$

56. A 2.00-nF parallel-plate capacitor is charged to an initial potential difference  $\Delta V_i = 100$  V and then isolated. The dielectric material between the plates is mica ( $\kappa = 5.00$ ). (a) How much work is required to withdraw the mica sheet? (b) What is the potential difference of the capacitor after the mica is withdrawn?

- WEB 57. A parallel-plate capacitor is constructed using a dielectric material whose dielectric constant is 3.00 and whose dielectric strength is  $2.00 \times 10^8$  V/m. The desired capacitance is  $0.250 \mu\text{F}$ , and the capacitor must withstand a maximum potential difference of 4 000 V. Find the minimum area of the capacitor plates.

58. A parallel-plate capacitor is constructed using three dielectric materials, as shown in Figure P26.58. You may assume that  $\ell \gg d$ . (a) Find an expression for the capacitance of the device in terms of the plate area  $A$  and  $d$ ,  $\kappa_1$ ,  $\kappa_2$ , and  $\kappa_3$ . (b) Calculate the capacitance using the values  $A = 1.00 \text{ cm}^2$ ,  $d = 2.00 \text{ mm}$ ,  $\kappa_1 = 4.90$ ,  $\kappa_2 = 5.60$ , and  $\kappa_3 = 2.10$ .

Figure P26.58

59. A conducting slab of thickness  $d$  and area  $A$  is inserted into the space between the plates of a parallel-plate capacitor with spacing  $s$  and surface area  $A$ , as shown in Figure P26.59. The slab is not necessarily halfway between the capacitor plates. What is the capacitance of the system?

Figure P26.59

60. (a) Two spheres have radii  $a$  and  $b$  and their centers are a distance  $d$  apart. Show that the capacitance of this system is

$$C \approx \frac{4\pi\epsilon_0}{\frac{1}{a} + \frac{1}{b} - \frac{2}{d}}$$

provided that  $d$  is large compared with  $a$  and  $b$ . (Hint: Because the spheres are far apart, assume that the

charge on one sphere does not perturb the charge distribution on the other sphere. Thus, the potential of each sphere is expressed as that of a symmetric charge distribution,  $V = k_e Q/r$ , and the total potential at each sphere is the sum of the potentials due to each sphere. (b) Show that as  $d$  approaches infinity the above result reduces to that of two isolated spheres in series.

61. When a certain air-filled parallel-plate capacitor is connected across a battery, it acquires a charge (on each plate) of  $q_0$ . While the battery connection is maintained, a dielectric slab is inserted into and fills the region between the plates. This results in the accumulation of an *additional* charge  $q$  on each plate. What is the dielectric constant of the slab?
62. A capacitor is constructed from two square plates of sides  $\ell$  and separation  $d$ . A material of dielectric constant  $\kappa$  is inserted a distance  $x$  into the capacitor, as shown in Figure P26.62. (a) Find the equivalent capacitance of the device. (b) Calculate the energy stored in the capacitor if the potential difference is  $\Delta V$ . (c) Find the direction and magnitude of the force exerted on the dielectric, assuming a constant potential difference  $\Delta V$ . Neglect friction. (d) Obtain a numerical value for the force assuming that  $\ell = 5.00$  cm,  $\Delta V = 2\,000$  V,  $d = 2.00$  mm, and the dielectric is glass ( $\kappa = 4.50$ ). (*Hint:* The system can be considered as two capacitors connected in *parallel*.)

Figure P26.62 Problems 62 and 63.

63. A capacitor is constructed from two square plates of sides  $\ell$  and separation  $d$ , as suggested in Figure P26.62. You may assume that  $d$  is much less than  $\ell$ . The plates carry charges  $+Q_0$  and  $-Q_0$ . A block of metal has a width  $\ell$ , a length  $\ell$ , and a thickness slightly less than  $d$ . It is inserted a distance  $x$  into the capacitor. The charges on the plates are not disturbed as the block slides in. In a static situation, a metal prevents an electric field from penetrating it. The metal can be thought of as a perfect dielectric, with  $\kappa \rightarrow \infty$ . (a) Calculate the stored energy as a function of  $x$ . (b) Find the direction and magnitude of the force that acts on the metallic block. (c) The area of the advancing front face of the block is essentially equal to  $\ell d$ . Considering the force on the block as acting on this face, find the stress (force per area) on it. (d) For comparison, express the energy density in the electric field between the capacitor plates in terms of  $Q_0$ ,  $\ell$ ,  $d$ , and  $\epsilon_0$ .

64. When considering the energy supply for an automobile, the energy per unit mass of the energy source is an important parameter. Using the following data, compare the energy per unit mass (J/kg) for gasoline, lead–acid batteries, and capacitors. (The ampere A will be introduced in Chapter 27 and is the SI unit of electric current.  $1\text{ A} = 1\text{ C/s}$ .)

Gasoline: 126 000 Btu/gal; density =  $670\text{ kg/m}^3$   
 Lead–acid battery: 12.0 V; 100 A·h; mass = 16.0 kg  
 Capacitor: potential difference at full charge = 12.0 V; capacitance = 0.100 F; mass = 0.100 kg

65. An isolated capacitor of unknown capacitance has been charged to a potential difference of 100 V. When the charged capacitor is then connected in parallel to an uncharged  $10.0\text{-}\mu\text{F}$  capacitor, the voltage across the combination is 30.0 V. Calculate the unknown capacitance.
66. A certain electronic circuit calls for a capacitor having a capacitance of  $1.20\text{ pF}$  and a breakdown potential of 1 000 V. If you have a supply of  $6.00\text{-pF}$  capacitors, each having a breakdown potential of 200 V, how could you meet this circuit requirement?
67. In the arrangement shown in Figure P26.67, a potential difference  $\Delta V$  is applied, and  $C_1$  is adjusted so that the voltmeter between points  $b$  and  $d$  reads zero. This “balance” occurs when  $C_1 = 4.00\text{ }\mu\text{F}$ . If  $C_3 = 9.00\text{ }\mu\text{F}$  and  $C_4 = 12.0\text{ }\mu\text{F}$ , calculate the value of  $C_2$ .

Figure P26.67

68. It is possible to obtain large potential differences by first charging a group of capacitors connected in parallel and then activating a switch arrangement that in effect disconnects the capacitors from the charging source and from each other and reconnects them in a series arrangement. The group of charged capacitors is then discharged in series. What is the maximum potential difference that can be obtained in this manner by using ten capacitors each of  $500\text{ }\mu\text{F}$  and a charging source of 800 V?
69. A parallel-plate capacitor of plate separation  $d$  is charged to a potential difference  $\Delta V_0$ . A dielectric slab

of thickness  $d$  and dielectric constant  $\kappa$  is introduced between the plates *while the battery remains connected to the plates*. (a) Show that the ratio of energy stored after the dielectric is introduced to the energy stored in the empty capacitor is  $U/U_0 = \kappa$ . Give a physical explanation for this increase in stored energy. (b) What happens to the charge on the capacitor? (Note that this situation is not the same as Example 26.7, in which the battery was removed from the circuit before the dielectric was introduced.)

70. A parallel-plate capacitor with plates of area  $A$  and plate separation  $d$  has the region between the plates filled with two dielectric materials as in Figure P26.70. Assume that  $d \ll L$  and that  $d \ll W$ . (a) Determine the capacitance and (b) show that when  $\kappa_1 = \kappa_2 = \kappa$  your result becomes the same as that for a capacitor containing a single dielectric,  $C = \kappa\epsilon_0 A/d$ .

Figure P26.70

71. A vertical parallel-plate capacitor is half filled with a dielectric for which the dielectric constant is 2.00 (Fig. P26.71a). When this capacitor is positioned horizontally, what fraction of it should be filled with the same dielectric (Fig. P26.71b) so that the two capacitors have equal capacitance?

Figure P26.71

72. Capacitors  $C_1 = 6.00 \mu\text{F}$  and  $C_2 = 2.00 \mu\text{F}$  are charged as a parallel combination across a 250-V battery. The ca-

pacitors are disconnected from the battery and from each other. They are then connected positive plate to negative plate and negative plate to positive plate. Calculate the resulting charge on each capacitor.

73. The inner conductor of a coaxial cable has a radius of 0.800 mm, and the outer conductor's inside radius is 3.00 mm. The space between the conductors is filled with polyethylene, which has a dielectric constant of 2.30 and a dielectric strength of  $18.0 \times 10^6 \text{ V/m}$ . What is the maximum potential difference that this cable can withstand?
74. You are optimizing coaxial cable design for a major manufacturer. Show that for a given outer conductor radius  $b$ , maximum potential difference capability is attained when the radius of the inner conductor is  $a = b/e$  where  $e$  is the base of natural logarithms.
75. Calculate the equivalent capacitance between the points  $a$  and  $b$  in Figure P26.75. Note that this is not a simple series or parallel combination. (*Hint*: Assume a potential difference  $\Delta V$  between points  $a$  and  $b$ . Write expressions for  $\Delta V_{ab}$  in terms of the charges and capacitances for the various possible pathways from  $a$  to  $b$ , and require conservation of charge for those capacitor plates that are connected to each other.)

Figure P26.75

76. Determine the effective capacitance of the combination shown in Figure P26.76. (*Hint*: Consider the symmetry involved!)

Figure P26.76

---

**ANSWERS TO QUICK QUIZZES**

- 26.1** (a) because the plate separation is decreased. Capacitance depends only on how a capacitor is constructed and not on the external circuit.
- 26.2** Zero. If you construct a spherical gaussian surface outside and concentric with the capacitor, the net charge inside the surface is zero. Applying Gauss's law to this configuration, we find that  $E = 0$  at points outside the capacitor.
- 26.3** For a given voltage, the energy stored in a capacitor is proportional to  $C$ :  $U = C(\Delta V)^2/2$ . Thus, you want to maximize the equivalent capacitance. You do this by connecting the three capacitors in parallel, so that the capacitances add.
- 26.4** (a)  $C$  decreases (Eq. 26.3). (b)  $Q$  stays the same because there is no place for the charge to flow. (c)  $E$  remains constant (see Eq. 24.8 and the paragraph following it). (d)  $\Delta V$  increases because  $\Delta V = Q/C$ ,  $Q$  is constant (part b), and  $C$  decreases (part a). (e) The energy stored in the capacitor is proportional to both  $Q$  and  $\Delta V$  (Eq. 26.11) and thus increases. The additional energy comes from the work you do in pulling the two plates apart.
- 26.5** (a)  $C$  decreases (Eq. 26.3). (b)  $Q$  decreases. The battery supplies a constant potential difference  $\Delta V$ ; thus, charge must flow out of the capacitor if  $C = Q/\Delta V$  is to decrease. (c)  $E$  decreases because the charge density on the plates decreases. (d)  $\Delta V$  remains constant because of the presence of the battery. (e) The energy stored in the capacitor decreases (Eq. 26.11).
- 26.6** It increases. The dielectric constant of wood (and of all other insulating materials, for that matter) is greater than 1; therefore, the capacitance increases (Eq. 26.14). This increase is sensed by the stud-finder's special circuitry, which causes an indicator on the device to light up.
- 26.7** (a)  $C$  increases (Eq. 26.14). (b)  $Q$  increases. Because the battery maintains a constant  $\Delta V$ ,  $Q$  must increase if  $C (= Q/\Delta V)$  increases. (c)  $E$  between the plates remains constant because  $\Delta V = Ed$  and neither  $\Delta V$  nor  $d$  changes. The electric field due to the charges on the plates increases because more charge has flowed onto the plates. The induced surface charges on the dielectric create a field that opposes the increase in the field caused by the greater number of charges on the plates. (d) The battery maintains a constant  $\Delta V$ . (e) The energy stored in the capacitor increases (Eq. 26.11). You would have to push the dielectric into the capacitor, just as you would have to do positive work to raise a mass and increase its gravitational potential energy.

## PUZZLER

Electrical workers restoring power to the eastern Ontario town of St. Isidore, which was without power for several days in January 1998 because of a severe ice storm. It is very dangerous to touch fallen power transmission lines because of their high electric potential, which might be hundreds of thousands of volts relative to the ground. Why is such a high potential difference used in power transmission if it is so dangerous, and why aren't birds that perch on the wires electrocuted? (AP/Wide World Photos/Fred Chartrand)

## Current and Resistance

### Chapter Outline

- |   |   |
|---|---|
| <b>27.1</b> Electric Current                  | <b>27.4</b> Resistance and Temperature  |
| <b>27.2</b> Resistance and Ohm's Law          | <b>27.5</b> (Optional) Superconductors  |
| <b>27.3</b> A Model for Electrical Conduction | <b>27.6</b> Electrical Energy and Power |

Thus far our treatment of electrical phenomena has been confined to the study of charges at rest, or *electrostatics*. We now consider situations involving electric charges in motion. We use the term *electric current*, or simply *current*, to describe the rate of flow of charge through some region of space. Most practical applications of electricity deal with electric currents. For example, the battery in a flashlight supplies current to the filament of the bulb when the switch is turned on. A variety of home appliances operate on alternating current. In these common situations, the charges flow through a conductor, such as a copper wire. It also is possible for currents to exist outside a conductor. For instance, a beam of electrons in a television picture tube constitutes a current.

This chapter begins with the definitions of current and current density. A microscopic description of current is given, and some of the factors that contribute to the resistance to the flow of charge in conductors are discussed. A classical model is used to describe electrical conduction in metals, and some of the limitations of this model are cited.

## 27.1 ELECTRIC CURRENT

13.2

It is instructive to draw an analogy between water flow and current. In many localities it is common practice to install low-flow showerheads in homes as a water-conservation measure. We quantify the flow of water from these and similar devices by specifying the amount of water that emerges during a given time interval, which is often measured in liters per minute. On a grander scale, we can characterize a river current by describing the rate at which the water flows past a particular location. For example, the flow over the brink at Niagara Falls is maintained at rates between 1 400 m<sup>3</sup>/s and 2 800 m<sup>3</sup>/s.

Now consider a system of electric charges in motion. Whenever there is a net flow of charge through some region, a **current** is said to exist. To define current more precisely, suppose that the charges are moving perpendicular to a surface of area  $A$ , as shown in Figure 27.1. (This area could be the cross-sectional area of a wire, for example.) **The current is the rate at which charge flows through this surface.** If  $\Delta Q$  is the amount of charge that passes through this area in a time interval  $\Delta t$ , the **average current**  $I_{\text{av}}$  is equal to the charge that passes through  $A$  per unit time:

$$I_{\text{av}} = \frac{\Delta Q}{\Delta t} \quad (27.1)$$

If the rate at which charge flows varies in time, then the current varies in time; we define the **instantaneous current**  $I$  as the differential limit of average current:

$$I \equiv \frac{dQ}{dt} \quad (27.2)$$

The SI unit of current is the **ampere** (A):

$$1 \text{ A} = \frac{1 \text{ C}}{1 \text{ s}} \quad (27.3)$$

That is, 1 A of current is equivalent to 1 C of charge passing through the surface area in 1 s.

The charges passing through the surface in Figure 27.1 can be positive or negative, or both. **It is conventional to assign to the current the same direction as the flow of positive charge.** In electrical conductors, such as copper or alu-

**Figure 27.1** Charges in motion through an area  $A$ . The time rate at which charge flows through the area is defined as the current  $I$ . The direction of the current is the direction in which positive charges flow when free to do so.

Electric current

The direction of the current

minimum, the current is due to the motion of negatively charged electrons. Therefore, when we speak of current in an ordinary conductor, **the direction of the current is opposite the direction of flow of electrons.** However, if we are considering a beam of positively charged protons in an accelerator, the current is in the direction of motion of the protons. In some cases—such as those involving gases and electrolytes, for instance—the current is the result of the flow of both positive and negative charges.

If the ends of a conducting wire are connected to form a loop, all points on the loop are at the same electric potential, and hence the electric field is zero within and at the surface of the conductor. Because the electric field is zero, there is no net transport of charge through the wire, and therefore there is no current. The current in the conductor is zero even if the conductor has an excess of charge on it. However, if the ends of the conducting wire are connected to a battery, all points on the loop are not at the same potential. The battery sets up a potential difference between the ends of the loop, creating an electric field within the wire. The electric field exerts forces on the conduction electrons in the wire, causing them to move around the loop and thus creating a current.

It is common to refer to a moving charge (positive or negative) as a mobile **charge carrier.** For example, the mobile charge carriers in a metal are electrons.

**Figure 27.2** A section of a uniform conductor of cross-sectional area  $A$ . The mobile charge carriers move with a speed  $v_d$ , and the distance they travel in a time  $\Delta t$  is  $\Delta x = v_d \Delta t$ . The number of carriers in the section of length  $\Delta x$  is  $nA v_d \Delta t$ , where  $n$  is the number of carriers per unit volume.

Average current in a conductor

### Microscopic Model of Current

We can relate current to the motion of the charge carriers by describing a microscopic model of conduction in a metal. Consider the current in a conductor of cross-sectional area  $A$  (Fig. 27.2). The volume of a section of the conductor of length  $\Delta x$  (the gray region shown in Fig. 27.2) is  $A \Delta x$ . If  $n$  represents the number of mobile charge carriers per unit volume (in other words, the charge carrier density), the number of carriers in the gray section is  $nA \Delta x$ . Therefore, the charge  $\Delta Q$  in this section is

$$\Delta Q = \text{number of carriers in section} \times \text{charge per carrier} = (nA \Delta x)q$$

where  $q$  is the charge on each carrier. If the carriers move with a speed  $v_d$ , the distance they move in a time  $\Delta t$  is  $\Delta x = v_d \Delta t$ . Therefore, we can write  $\Delta Q$  in the form

$$\Delta Q = (nA v_d \Delta t)q$$

If we divide both sides of this equation by  $\Delta t$ , we see that the average current in the conductor is

$$I_{\text{av}} = \frac{\Delta Q}{\Delta t} = nq v_d A \quad (27.4)$$

The speed of the charge carriers  $v_d$  is an average speed called the **drift speed.** To understand the meaning of drift speed, consider a conductor in which the charge carriers are free electrons. If the conductor is isolated—that is, the potential difference across it is zero—then these electrons undergo random motion that is analogous to the motion of gas molecules. As we discussed earlier, when a potential difference is applied across the conductor (for example, by means of a battery), an electric field is set up in the conductor; this field exerts an electric force on the electrons, producing a current. However, the electrons do not move in straight lines along the conductor. Instead, they collide repeatedly with the metal atoms, and their resultant motion is complicated and zigzag (Fig. 27.3). Despite the collisions, the electrons move slowly along the conductor (in a direction opposite that of  $\mathbf{E}$ ) at the drift velocity  $\mathbf{v}_d$ .

**Figure 27.3** A schematic representation of the zigzag motion of an electron in a conductor. The changes in direction are the result of collisions between the electron and atoms in the conductor. Note that the net motion of the electron is opposite the direction of the electric field. Each section of the zigzag path is a parabolic segment.

We can think of the atom–electron collisions in a conductor as an effective internal friction (or drag force) similar to that experienced by the molecules of a liquid flowing through a pipe stuffed with steel wool. The energy transferred from the electrons to the metal atoms during collision causes an increase in the vibrational energy of the atoms and a corresponding increase in the temperature of the conductor.

### Quick Quiz 27.1

Consider positive and negative charges moving horizontally through the four regions shown in Figure 27.4. Rank the current in these four regions, from lowest to highest.

**Figure 27.4**

### EXAMPLE 27.1 Drift Speed in a Copper Wire

The 12-gauge copper wire in a typical residential building has a cross-sectional area of  $3.31 \times 10^{-6} \text{ m}^2$ . If it carries a current of 10.0 A, what is the drift speed of the electrons? Assume that each copper atom contributes one free electron to the current. The density of copper is  $8.95 \text{ g/cm}^3$ .

**Solution** From the periodic table of the elements in Appendix C, we find that the molar mass of copper is 63.5 g/mol. Recall that 1 mol of any substance contains Avogadro's number of atoms ( $6.02 \times 10^{23}$ ). Knowing the density of copper, we can calculate the volume occupied by 63.5 g (= 1 mol) of copper:

$$V = \frac{m}{\rho} = \frac{63.5 \text{ g}}{8.95 \text{ g/cm}^3} = 7.09 \text{ cm}^3$$

Because each copper atom contributes one free electron to the current, we have

$$\begin{aligned} n &= \frac{6.02 \times 10^{23} \text{ electrons}}{7.09 \text{ cm}^3} (1.00 \times 10^6 \text{ cm}^3/\text{m}^3) \\ &= 8.49 \times 10^{28} \text{ electrons/m}^3 \end{aligned}$$

From Equation 27.4, we find that the drift speed is

$$v_d = \frac{I}{nqA}$$

where  $q$  is the absolute value of the charge on each electron. Thus,

$$\begin{aligned} v_d &= \frac{I}{nqA} \\ &= \frac{10.0 \text{ C/s}}{(8.49 \times 10^{28} \text{ m}^{-3})(1.60 \times 10^{-19} \text{ C})(3.31 \times 10^{-6} \text{ m}^2)} \\ &= 2.22 \times 10^{-4} \text{ m/s} \end{aligned}$$

**Exercise** If a copper wire carries a current of 80.0 mA, how many electrons flow past a given cross-section of the wire in 10.0 min?

**Answer**  $3.0 \times 10^{20}$  electrons.

Example 27.1 shows that typical drift speeds are very low. For instance, electrons traveling with a speed of  $2.46 \times 10^{-4}$  m/s would take about 68 min to travel 1 m! In view of this, you might wonder why a light turns on almost instantaneously when a switch is thrown. In a conductor, the electric field that drives the free electrons travels through the conductor with a speed close to that of light. Thus, when you flip on a light switch, the message for the electrons to start moving through the wire (the electric field) reaches them at a speed on the order of  $10^8$  m/s.

## 27.2 RESISTANCE AND OHM'S LAW

 In Chapter 24 we found that no electric field can exist inside a conductor. However, this statement is true *only* if the conductor is in static equilibrium. The purpose of this section is to describe what happens when the charges in the conductor are allowed to move.

Charges moving in a conductor produce a current under the action of an electric field, which is maintained by the connection of a battery across the conductor. An electric field can exist in the conductor because the charges in this situation are in motion—that is, this is a *nonelectrostatic* situation.

Consider a conductor of cross-sectional area  $A$  carrying a current  $I$ . The **current density**  $J$  in the conductor is defined as the current per unit area. Because the current  $I = nqv_dA$ , the current density is

$$J \equiv \frac{I}{A} = nqv_d \quad (27.5)$$

where  $J$  has SI units of A/m<sup>2</sup>. This expression is valid only if the current density is uniform and only if the surface of cross-sectional area  $A$  is perpendicular to the direction of the current. In general, the current density is a vector quantity:

$$\mathbf{J} = nq\mathbf{v}_d \quad (27.6)$$

From this equation, we see that current density, like current, is in the direction of charge motion for positive charge carriers and opposite the direction of motion for negative charge carriers.

**A current density  $\mathbf{J}$  and an electric field  $\mathbf{E}$  are established in a conductor whenever a potential difference is maintained across the conductor.** If the potential difference is constant, then the current also is constant. In some materials, the current density is proportional to the electric field:

$$\mathbf{J} = \sigma\mathbf{E} \quad (27.7)$$

where the constant of proportionality  $\sigma$  is called the **conductivity** of the conductor.<sup>1</sup> Materials that obey Equation 27.7 are said to follow **Ohm's law**, named after Georg Simon Ohm (1787–1854). More specifically, Ohm's law states that

for many materials (including most metals), the ratio of the current density to the electric field is a constant  $\sigma$  that is independent of the electric field producing the current.

Materials that obey Ohm's law and hence demonstrate this simple relationship between  $\mathbf{E}$  and  $\mathbf{J}$  are said to be *ohmic*. Experimentally, it is found that not all materials have this property, however, and materials that do not obey Ohm's law are said to

<sup>1</sup> Do not confuse conductivity  $\sigma$  with surface charge density, for which the same symbol is used.

Current density

Ohm's law

be *nonohmic*. Ohm's law is not a fundamental law of nature but rather an empirical relationship valid only for certain materials.

### Quick Quiz 27.2

Suppose that a current-carrying ohmic metal wire has a cross-sectional area that gradually becomes smaller from one end of the wire to the other. How do drift velocity, current density, and electric field vary along the wire? Note that the current must have the same value everywhere in the wire so that charge does not accumulate at any one point.

We can obtain a form of Ohm's law useful in practical applications by considering a segment of straight wire of uniform cross-sectional area  $A$  and length  $\ell$ , as shown in Figure 27.5. A potential difference  $\Delta V = V_b - V_a$  is maintained across the wire, creating in the wire an electric field and a current. If the field is assumed to be uniform, the potential difference is related to the field through the relationship<sup>2</sup>

$$\Delta V = E\ell$$

Therefore, we can express the magnitude of the current density in the wire as

$$J = \sigma E = \sigma \frac{\Delta V}{\ell}$$

Because  $J = I/A$ , we can write the potential difference as

$$\Delta V = \frac{\ell}{\sigma} J = \left( \frac{\ell}{\sigma A} \right) I$$

The quantity  $\ell/\sigma A$  is called the **resistance**  $R$  of the conductor. We can define the resistance as the ratio of the potential difference across a conductor to the current through the conductor:

$$R \equiv \frac{\ell}{\sigma A} \equiv \frac{\Delta V}{I} \quad (27.8)$$

Resistance of a conductor

From this result we see that resistance has SI units of volts per ampere. One volt per ampere is defined to be 1 **ohm** ( $\Omega$ ):

$$1 \Omega \equiv \frac{1 \text{ V}}{1 \text{ A}} \quad (27.9)$$

**Figure 27.5** A uniform conductor of length  $\ell$  and cross-sectional area  $A$ . A potential difference  $\Delta V = V_b - V_a$  maintained across the conductor sets up an electric field  $\mathbf{E}$ , and this field produces a current  $I$  that is proportional to the potential difference.

<sup>2</sup> This result follows from the definition of potential difference:

$$V_b - V_a = - \int_a^b \mathbf{E} \cdot d\mathbf{s} = E \int_0^\ell dx = E\ell$$

An assortment of resistors used in electric circuits.

This expression shows that if a potential difference of 1 V across a conductor causes a current of 1 A, the resistance of the conductor is 1  $\Omega$ . For example, if an electrical appliance connected to a 120-V source of potential difference carries a current of 6 A, its resistance is 20  $\Omega$ .

Equation 27.8 solved for potential difference ( $\Delta V = I\ell/\sigma A$ ) explains part of the chapter-opening puzzler: How can a bird perch on a high-voltage power line without being electrocuted? Even though the potential difference between the ground and the wire might be hundreds of thousands of volts, that between the bird's feet (which is what determines how much current flows through the bird) is very small.

The inverse of conductivity is **resistivity**<sup>3</sup>  $\rho$ :

Resistivity

$$\rho \equiv \frac{1}{\sigma} \quad (27.10)$$

where  $\rho$  has the units ohm-meters ( $\Omega \cdot \text{m}$ ). We can use this definition and Equation 27.8 to express the resistance of a uniform block of material as

Resistance of a uniform conductor

$$R = \rho \frac{\ell}{A} \quad (27.11)$$

Every ohmic material has a characteristic resistivity that depends on the properties of the material and on temperature. Additionally, as you can see from Equation 27.11, the resistance of a sample depends on geometry as well as on resistivity. Table 27.1 gives the resistivities of a variety of materials at 20°C. Note the enormous range, from very low values for good conductors such as copper and silver, to very high values for good insulators such as glass and rubber. An ideal conductor would have zero resistivity, and an ideal insulator would have infinite resistivity.

Equation 27.11 shows that the resistance of a given cylindrical conductor is proportional to its length and inversely proportional to its cross-sectional area. If the length of a wire is doubled, then its resistance doubles. If its cross-sectional area is doubled, then its resistance decreases by one half. The situation is analogous to the flow of a liquid through a pipe. As the pipe's length is increased, the

<sup>3</sup> Do not confuse resistivity with mass density or charge density, for which the same symbol is used.

**TABLE 27.1** Resistivities and Temperature Coefficients of Resistivity for Various Materials

Material	Resistivity <sup>a</sup> ( $\Omega \cdot \text{m}$ )	Temperature Coefficient $\alpha[(^{\circ}\text{C})^{-1}]$
Silver	$1.59 \times 10^{-8}$	$3.8 \times 10^{-3}$
Copper	$1.7 \times 10^{-8}$	$3.9 \times 10^{-3}$
Gold	$2.44 \times 10^{-8}$	$3.4 \times 10^{-3}$
Aluminum	$2.82 \times 10^{-8}$	$3.9 \times 10^{-3}$
Tungsten	$5.6 \times 10^{-8}$	$4.5 \times 10^{-3}$
Iron	$10 \times 10^{-8}$	$5.0 \times 10^{-3}$
Platinum	$11 \times 10^{-8}$	$3.92 \times 10^{-3}$
Lead	$22 \times 10^{-8}$	$3.9 \times 10^{-3}$
Nichrome <sup>b</sup>	$1.50 \times 10^{-6}$	$0.4 \times 10^{-3}$
Carbon	$3.5 \times 10^{-5}$	$-0.5 \times 10^{-3}$
Germanium	0.46	$-48 \times 10^{-3}$
Silicon	640	$-75 \times 10^{-3}$
Glass	$10^{10}$ to $10^{14}$	
Hard rubber	$\approx 10^{13}$	
Sulfur	$10^{15}$	
Quartz (fused)	$75 \times 10^{16}$	

<sup>a</sup> All values at 20°C.

<sup>b</sup> A nickel–chromium alloy commonly used in heating elements.

resistance to flow increases. As the pipe's cross-sectional area is increased, more liquid crosses a given cross-section of the pipe per unit time. Thus, more liquid flows for the same pressure differential applied to the pipe, and the resistance to flow decreases.

Most electric circuits use devices called **resistors** to control the current level in the various parts of the circuit. Two common types of resistors are the *composition resistor*, which contains carbon, and the *wire-wound resistor*, which consists of a coil of wire. Resistors' values in ohms are normally indicated by color-coding, as shown in Figure 27.6 and Table 27.2.

Ohmic materials have a linear current–potential difference relationship over a broad range of applied potential differences (Fig. 27.7a). The slope of the  $I$ -versus- $\Delta V$  curve in the linear region yields a value for  $1/R$ . Nonohmic materials

**Figure 27.6** The colored bands on a resistor represent a code for determining resistance. The first two colors give the first two digits in the resistance value. The third color represents the power of ten for the multiplier of the resistance value. The last color is the tolerance of the resistance value. As an example, the four colors on the circled resistors are red (= 2), black (= 0), orange (=  $10^3$ ), and gold (= 5%), and so the resistance value is  $20 \times 10^3 \Omega = 20 \text{ k}\Omega$  with a tolerance value of 5% = 1 k $\Omega$ . (The values for the colors are from Table 27.2.)

**TABLE 27.2** Color Coding for Resistors

Color	Number	Multiplier	Tolerance
Black	0	1	
Brown	1	$10^1$	
Red	2	$10^2$	
Orange	3	$10^3$	
Yellow	4	$10^4$	
Green	5	$10^5$	
Blue	6	$10^6$	
Violet	7	$10^7$	
Gray	8	$10^8$	
White	9	$10^9$	
Gold		$10^{-1}$	5%
Silver		$10^{-2}$	10%
Colorless			20%

**Figure 27.7** (a) The current–potential difference curve for an ohmic material. The curve is linear, and the slope is equal to the inverse of the resistance of the conductor. (b) A nonlinear current–potential difference curve for a semiconducting diode. This device does not obey Ohm’s law.

have a nonlinear current–potential difference relationship. One common semiconducting device that has nonlinear  $I$ -versus- $\Delta V$  characteristics is the *junction diode* (Fig. 27.7b). The resistance of this device is low for currents in one direction (positive  $\Delta V$ ) and high for currents in the reverse direction (negative  $\Delta V$ ). In fact, most modern electronic devices, such as transistors, have nonlinear current–potential difference relationships; their proper operation depends on the particular way in which they violate Ohm’s law.

### Quick Quiz 27.3

What does the slope of the curved line in Figure 27.7b represent?

### Quick Quiz 27.4

Your boss asks you to design an automobile battery jumper cable that has a low resistance. In view of Equation 27.11, what factors would you consider in your design?

**EXAMPLE 27.2** The Resistance of a Conductor

Calculate the resistance of an aluminum cylinder that is 10.0 cm long and has a cross-sectional area of  $2.00 \times 10^{-4} \text{ m}^2$ . Repeat the calculation for a cylinder of the same dimensions and made of glass having a resistivity of  $3.0 \times 10^{10} \Omega \cdot \text{m}$ .

**Solution** From Equation 27.11 and Table 27.1, we can calculate the resistance of the aluminum cylinder as follows:

$$R = \rho \frac{\ell}{A} = (2.82 \times 10^{-8} \Omega \cdot \text{m}) \left( \frac{0.100 \text{ m}}{2.00 \times 10^{-4} \text{ m}^2} \right)$$

$$= 1.41 \times 10^{-5} \Omega$$

Similarly, for glass we find that

$$R = \rho \frac{\ell}{A} = (3.0 \times 10^{10} \Omega \cdot \text{m}) \left( \frac{0.100 \text{ m}}{2.00 \times 10^{-4} \text{ m}^2} \right)$$

$$= 1.5 \times 10^{13} \Omega$$

As you might guess from the large difference in resistivi-

ties, the resistance of identically shaped cylinders of aluminum and glass differ widely. The resistance of the glass cylinder is 18 orders of magnitude greater than that of the aluminum cylinder.

Electrical insulators on telephone poles are often made of glass because of its low electrical conductivity.

**EXAMPLE 27.3** The Resistance of Nichrome Wire

(a) Calculate the resistance per unit length of a 22-gauge Nichrome wire, which has a radius of 0.321 mm.

**Solution** The cross-sectional area of this wire is

$$A = \pi r^2 = \pi(0.321 \times 10^{-3} \text{ m})^2 = 3.24 \times 10^{-7} \text{ m}^2$$

The resistivity of Nichrome is  $1.5 \times 10^{-6} \Omega \cdot \text{m}$  (see Table 27.1). Thus, we can use Equation 27.11 to find the resistance per unit length:

$$\frac{R}{\ell} = \frac{\rho}{A} = \frac{1.5 \times 10^{-6} \Omega \cdot \text{m}}{3.24 \times 10^{-7} \text{ m}^2} = 4.6 \Omega/\text{m}$$

(b) If a potential difference of 10 V is maintained across a 1.0-m length of the Nichrome wire, what is the current in the wire?

**Solution** Because a 1.0-m length of this wire has a resistance of 4.6  $\Omega$ , Equation 27.8 gives

$$I = \frac{\Delta V}{R} = \frac{10 \text{ V}}{4.6 \Omega} = 2.2 \text{ A}$$

Note from Table 27.1 that the resistivity of Nichrome wire is about 100 times that of copper. A copper wire of the same radius would have a resistance per unit length of only 0.052  $\Omega/\text{m}$ . A 1.0-m length of copper wire of the same radius would carry the same current (2.2 A) with an applied potential difference of only 0.11 V.

Because of its high resistivity and its resistance to oxidation, Nichrome is often used for heating elements in toasters, irons, and electric heaters.

**Exercise** What is the resistance of a 6.0-m length of 22-gauge Nichrome wire? How much current does the wire carry when connected to a 120-V source of potential difference?

**Answer** 28  $\Omega$ ; 4.3 A.

**Exercise** Calculate the current density and electric field in the wire when it carries a current of 2.2 A.

**Answer**  $6.8 \times 10^6 \text{ A/m}^2$ ; 10 N/C.

**EXAMPLE 27.4** The Radial Resistance of a Coaxial Cable

Coaxial cables are used extensively for cable television and other electronic applications. A coaxial cable consists of two cylindrical conductors. The gap between the conductors is

completely filled with silicon, as shown in Figure 27.8a, and current leakage through the silicon is unwanted. (The cable is designed to conduct current along its length.) The radius

of the inner conductor is  $a = 0.500$  cm, the radius of the outer one is  $b = 1.75$  cm, and the length of the cable is  $L = 15.0$  cm. Calculate the resistance of the silicon between the two conductors.

**Solution** In this type of problem, we must divide the object whose resistance we are calculating into concentric elements of infinitesimal thickness  $dr$  (Fig. 27.8b). We start by using the differential form of Equation 27.11, replacing  $\ell$  with  $r$  for the distance variable:  $dR = \rho dr/A$ , where  $dR$  is the resistance of an element of silicon of thickness  $dr$  and surface area  $A$ . In this example, we take as our representative concentric element a hollow silicon cylinder of radius  $r$ , thickness  $dr$ , and length  $L$ , as shown in Figure 27.8. Any current that passes from the inner conductor to the outer one must pass radially through this concentric element, and the area through which this current passes is  $A = 2\pi rL$ . (This is the curved surface area—circumference multiplied by length—of our hollow silicon cylinder of thickness  $dr$ .) Hence, we can write the resistance of our hollow cylinder of silicon as

$$dR = \frac{\rho}{2\pi rL} dr$$

Because we wish to know the total resistance across the entire thickness of the silicon, we must integrate this expression from  $r = a$  to  $r = b$ :

$$R = \int_a^b dR = \frac{\rho}{2\pi L} \int_a^b \frac{dr}{r} = \frac{\rho}{2\pi L} \ln\left(\frac{b}{a}\right)$$

Substituting in the values given, and using  $\rho = 640 \Omega \cdot \text{m}$  for silicon, we obtain

$$R = \frac{640 \Omega \cdot \text{m}}{2\pi(0.150 \text{ m})} \ln\left(\frac{1.75 \text{ cm}}{0.500 \text{ cm}}\right) = 851 \Omega$$

**Exercise** If a potential difference of 12.0 V is applied between the inner and outer conductors, what is the value of the total current that passes between them?

**Answer** 14.1 mA.

**Figure 27.8** A coaxial cable. (a) Silicon fills the gap between the two conductors. (b) End view, showing current leakage.

### 27.3 A MODEL FOR ELECTRICAL CONDUCTION

In this section we describe a classical model of electrical conduction in metals that was first proposed by Paul Drude in 1900. This model leads to Ohm's law and shows that resistivity can be related to the motion of electrons in metals. Although the Drude model described here does have limitations, it nevertheless introduces concepts that are still applied in more elaborate treatments.

Consider a conductor as a regular array of atoms plus a collection of free electrons, which are sometimes called *conduction* electrons. The conduction electrons, although bound to their respective atoms when the atoms are not part of a solid, gain mobility when the free atoms condense into a solid. In the absence of an electric field, the conduction electrons move in random directions through the con-

ductor with average speeds of the order of  $10^6$  m/s. The situation is similar to the motion of gas molecules confined in a vessel. In fact, some scientists refer to conduction electrons in a metal as an *electron gas*. There is no current through the conductor in the absence of an electric field because the drift velocity of the free electrons is zero. That is, on the average, just as many electrons move in one direction as in the opposite direction, and so there is no net flow of charge.

This situation changes when an electric field is applied. Now, in addition to undergoing the random motion just described, the free electrons drift slowly in a direction opposite that of the electric field, with an average drift speed  $v_d$  that is much smaller (typically  $10^{-4}$  m/s) than their average speed between collisions (typically  $10^6$  m/s).

Figure 27.9 provides a crude description of the motion of free electrons in a conductor. In the absence of an electric field, there is no net displacement after many collisions (Fig. 27.9a). An electric field  $\mathbf{E}$  modifies the random motion and causes the electrons to drift in a direction opposite that of  $\mathbf{E}$  (Fig. 27.9b). The slight curvature in the paths shown in Figure 27.9b results from the acceleration of the electrons between collisions, which is caused by the applied field.

In our model, we assume that the motion of an electron after a collision is independent of its motion before the collision. We also assume that the excess energy acquired by the electrons in the electric field is lost to the atoms of the conductor when the electrons and atoms collide. The energy given up to the atoms increases their vibrational energy, and this causes the temperature of the conductor to increase. The temperature increase of a conductor due to resistance is utilized in electric toasters and other familiar appliances.

We are now in a position to derive an expression for the drift velocity. When a free electron of mass  $m_e$  and charge  $q (= -e)$  is subjected to an electric field  $\mathbf{E}$ , it experiences a force  $\mathbf{F} = q\mathbf{E}$ . Because  $\Sigma\mathbf{F} = m_e\mathbf{a}$ , we conclude that the acceleration of the electron is

$$\mathbf{a} = \frac{q\mathbf{E}}{m_e} \quad (27.12)$$

This acceleration, which occurs for only a short time between collisions, enables the electron to acquire a small drift velocity. If  $t$  is the time since the last collision and  $\mathbf{v}_i$  is the electron's initial velocity the instant after that collision, then the velocity of the electron after a time  $t$  is

$$\mathbf{v}_f = \mathbf{v}_i + \mathbf{a}t = \mathbf{v}_i + \frac{q\mathbf{E}}{m_e} t \quad (27.13)$$

We now take the average value of  $\mathbf{v}_f$  over all possible times  $t$  and all possible values of  $\mathbf{v}_i$ . If we assume that the initial velocities are randomly distributed over all possible values, we see that the average value of  $\mathbf{v}_i$  is zero. The term  $(q\mathbf{E}/m_e)t$  is the velocity added by the field during one trip between atoms. If the electron starts with zero velocity, then the average value of the second term of Equation 27.13 is  $(q\mathbf{E}/m_e)\tau$ , where  $\tau$  is the *average time interval between successive collisions*. Because the average value of  $\mathbf{v}_f$  is equal to the drift velocity,<sup>4</sup> we have

$$\bar{\mathbf{v}}_f = \mathbf{v}_d = \frac{q\mathbf{E}}{m_e} \tau \quad (27.14)$$

<sup>4</sup> Because the collision process is random, each collision event is *independent* of what happened earlier. This is analogous to the random process of throwing a die. The probability of rolling a particular number on one throw is independent of the result of the previous throw. On average, the particular number comes up every sixth throw, starting at any arbitrary time.

**Figure 27.9** (a) A schematic diagram of the random motion of two charge carriers in a conductor in the absence of an electric field. The drift velocity is zero. (b) The motion of the charge carriers in a conductor in the presence of an electric field. Note that the random motion is modified by the field, and the charge carriers have a drift velocity.

Drift velocity

We can relate this expression for drift velocity to the current in the conductor. Substituting Equation 27.14 into Equation 27.6, we find that the magnitude of the current density is

Current density

$$J = nqv_d = \frac{nq^2E}{m_e} \tau \quad (27.15)$$

where  $n$  is the number of charge carriers per unit volume. Comparing this expression with Ohm's law,  $J = \sigma E$ , we obtain the following relationships for conductivity and resistivity:

Conductivity

$$\sigma = \frac{nq^2\tau}{m_e} \quad (27.16)$$

Resistivity

$$\rho = \frac{1}{\sigma} = \frac{m_e}{nq^2\tau} \quad (27.17)$$

According to this classical model, conductivity and resistivity do not depend on the strength of the electric field. This feature is characteristic of a conductor obeying Ohm's law.

The average time between collisions  $\tau$  is related to the average distance between collisions  $\ell$  (that is, the *mean free path*; see Section 21.7) and the average speed  $\bar{v}$  through the expression

$$\tau = \frac{\ell}{\bar{v}} \quad (27.18)$$

### EXAMPLE 27.5 Electron Collisions in a Wire

(a) Using the data and results from Example 27.1 and the classical model of electron conduction, estimate the average time between collisions for electrons in household copper wiring.

**Solution** From Equation 27.17, we see that

$$\tau = \frac{m_e}{nq^2\rho}$$

where  $\rho = 1.7 \times 10^{-8} \Omega \cdot \text{m}$  for copper and the carrier density is  $n = 8.49 \times 10^{28}$  electrons/ $\text{m}^3$  for the wire described in Example 27.1. Substitution of these values into the expression above gives

$$\tau = \frac{(9.11 \times 10^{-31} \text{ kg})}{(8.49 \times 10^{28} \text{ m}^{-3})(1.6 \times 10^{-19} \text{ C})^2(1.7 \times 10^{-8} \Omega \cdot \text{m})}$$

$$= 2.5 \times 10^{-14} \text{ s}$$

(b) Assuming that the average speed for free electrons in copper is  $1.6 \times 10^6$  m/s and using the result from part (a), calculate the mean free path for electrons in copper.

**Solution**

$$\begin{aligned} \ell = \bar{v}\tau &= (1.6 \times 10^6 \text{ m/s})(2.5 \times 10^{-14} \text{ s}) \\ &= 4.0 \times 10^{-8} \text{ m} \end{aligned}$$

which is equivalent to 40 nm (compared with atomic spacings of about 0.2 nm). Thus, although the time between collisions is very short, an electron in the wire travels about 200 atomic spacings between collisions.

Although this classical model of conduction is consistent with Ohm's law, it is not satisfactory for explaining some important phenomena. For example, classical values for  $\bar{v}$  calculated on the basis of an ideal-gas model (see Section 21.6) are smaller than the true values by about a factor of ten. Furthermore, if we substitute  $\ell/\bar{v}$  for  $\tau$  in Equation 27.17 and rearrange terms so that  $\bar{v}$  appears in the numerator, we find that the resistivity  $\rho$  is proportional to  $\bar{v}$ . According to the ideal-gas model,  $\bar{v}$  is proportional to  $\sqrt{T}$ ; hence, it should also be true that  $\rho \propto \sqrt{T}$ . This is in disagreement with the fact that, for pure metals, resistivity depends linearly on temperature. We are able to account for the linear dependence only by using a quantum mechanical model, which we now describe briefly.

According to quantum mechanics, electrons have wave-like properties. If the array of atoms in a conductor is regularly spaced (that is, it is periodic), then the wave-like character of the electrons enables them to move freely through the conductor, and a collision with an atom is unlikely. For an idealized conductor, no collisions would occur, the mean free path would be infinite, and the resistivity would be zero. Electron waves are scattered only if the atomic arrangement is irregular (not periodic) as a result of, for example, structural defects or impurities. At low temperatures, the resistivity of metals is dominated by scattering caused by collisions between electrons and defects or impurities. At high temperatures, the resistivity is dominated by scattering caused by collisions between electrons and atoms of the conductor, which are continuously displaced from the regularly spaced array as a result of thermal agitation. The thermal motion of the atoms causes the structure to be irregular (compared with an atomic array at rest), thereby reducing the electron's mean free path.

## 27.4 RESISTANCE AND TEMPERATURE

Over a limited temperature range, the resistivity of a metal varies approximately linearly with temperature according to the expression

$$\rho = \rho_0[1 + \alpha(T - T_0)] \quad (27.19)$$

Variation of  $\rho$  with temperature

where  $\rho$  is the resistivity at some temperature  $T$  (in degrees Celsius),  $\rho_0$  is the resistivity at some reference temperature  $T_0$  (usually taken to be  $20^\circ\text{C}$ ), and  $\alpha$  is the **temperature coefficient of resistivity**. From Equation 27.19, we see that the temperature coefficient of resistivity can be expressed as

$$\alpha = \frac{1}{\rho_0} \frac{\Delta\rho}{\Delta T} \quad (27.20)$$

Temperature coefficient of resistivity

where  $\Delta\rho = \rho - \rho_0$  is the change in resistivity in the temperature interval  $\Delta T = T - T_0$ .

The temperature coefficients of resistivity for various materials are given in Table 27.1. Note that the unit for  $\alpha$  is degrees Celsius<sup>-1</sup> [ $(^\circ\text{C})^{-1}$ ]. Because resistance is proportional to resistivity (Eq. 27.11), we can write the variation of resistance as

$$R = R_0[1 + \alpha(T - T_0)] \quad (27.21)$$

Use of this property enables us to make precise temperature measurements, as shown in the following example.

### EXAMPLE 27.6 A Platinum Resistance Thermometer

A resistance thermometer, which measures temperature by measuring the change in resistance of a conductor, is made from platinum and has a resistance of  $50.0\ \Omega$  at  $20.0^\circ\text{C}$ . When immersed in a vessel containing melting indium, its resistance increases to  $76.8\ \Omega$ . Calculate the melting point of the indium.

**Solution** Solving Equation 27.21 for  $\Delta T$  and using the  $\alpha$

value for platinum given in Table 27.1, we obtain

$$\Delta T = \frac{R - R_0}{\alpha R_0} = \frac{76.8\ \Omega - 50.0\ \Omega}{[3.92 \times 10^{-3}\ (\text{C}^\circ)^{-1}](50.0\ \Omega)} = 137^\circ\text{C}$$

Because  $T_0 = 20.0^\circ\text{C}$ , we find that  $T$ , the temperature of the melting indium sample, is  $157^\circ\text{C}$ .

**Figure 27.10** Resistivity versus temperature for a metal such as copper. The curve is linear over a wide range of temperatures, and  $\rho$  increases with increasing temperature. As  $T$  approaches absolute zero (inset), the resistivity approaches a finite value  $\rho_0$ .

**Figure 27.11** Resistivity versus temperature for a pure semiconductor, such as silicon or germanium.

For metals like copper, resistivity is nearly proportional to temperature, as shown in Figure 27.10. However, a nonlinear region always exists at very low temperatures, and the resistivity usually approaches some finite value as the temperature nears absolute zero. This residual resistivity near absolute zero is caused primarily by the collision of electrons with impurities and imperfections in the metal. In contrast, high-temperature resistivity (the linear region) is predominantly characterized by collisions between electrons and metal atoms.

Notice that three of the  $\alpha$  values in Table 27.1 are negative; this indicates that the resistivity of these materials decreases with increasing temperature (Fig. 27.11). This behavior is due to an increase in the density of charge carriers at higher temperatures.

Because the charge carriers in a semiconductor are often associated with impurity atoms, the resistivity of these materials is very sensitive to the type and concentration of such impurities. We shall return to the study of semiconductors in Chapter 43 of the extended version of this text.

### Quick Quiz 27.5

When does a lightbulb carry more current—just after it is turned on and the glow of the metal filament is increasing, or after it has been on for a few milliseconds and the glow is steady?

### Optional Section

## 27.5 SUPERCONDUCTORS

There is a class of metals and compounds whose resistance decreases to zero when they are below a certain temperature  $T_c$ , known as the *critical temperature*. These materials are known as **superconductors**. The resistance–temperature graph for a superconductor follows that of a normal metal at temperatures above  $T_c$  (Fig. 27.12). When the temperature is at or below  $T_c$ , the resistivity drops suddenly to zero. This phenomenon was discovered in 1911 by the Dutch physicist Heike Kamerlingh-Onnes (1853–1926) as he worked with mercury, which is a superconductor below 4.2 K. Recent measurements have shown that the resistivities of superconductors below their  $T_c$  values are less than  $4 \times 10^{-25} \Omega \cdot \text{m}$ —around  $10^{17}$  times smaller than the resistivity of copper and in practice considered to be zero.

Today thousands of superconductors are known, and as Figure 27.13 illustrates, the critical temperatures of recently discovered superconductors are substantially higher than initially thought possible. Two kinds of superconductors are recognized. The more recently identified ones, such as  $\text{YBa}_2\text{Cu}_3\text{O}_7$ , are essentially ceramics with high critical temperatures, whereas superconducting materials such

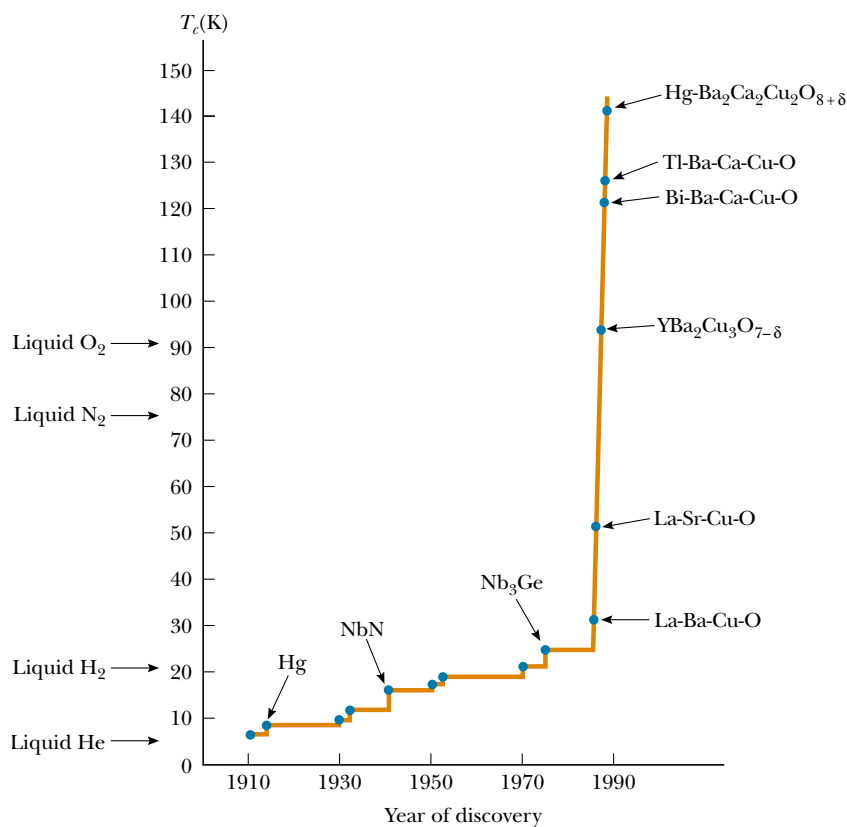

**Figure 27.12** Resistance versus temperature for a sample of mercury (Hg). The graph follows that of a normal metal above the critical temperature  $T_c$ . The resistance drops to zero at  $T_c$ , which is 4.2 K for mercury.

A small permanent magnet levitated above a disk of the superconductor  $\text{YBa}_2\text{Cu}_3\text{O}_7$ , which is at 77 K.

as those observed by Kamerlingh-Onnes are metals. If a room-temperature superconductor is ever identified, its impact on technology could be tremendous.

The value of  $T_c$  is sensitive to chemical composition, pressure, and molecular structure. It is interesting to note that copper, silver, and gold, which are excellent conductors, do not exhibit superconductivity.

**Figure 27.13** Evolution of the superconducting critical temperature since the discovery of the phenomenon.

One of the truly remarkable features of superconductors is that once a current is set up in them, it persists *without any applied potential difference* (because  $R = 0$ ). Steady currents have been observed to persist in superconducting loops for several years with no apparent decay!

An important and useful application of superconductivity is in the development of superconducting magnets, in which the magnitudes of the magnetic field are about ten times greater than those produced by the best normal electromagnets. Such superconducting magnets are being considered as a means of storing energy. Superconducting magnets are currently used in medical magnetic resonance imaging (MRI) units, which produce high-quality images of internal organs without the need for excessive exposure of patients to x-rays or other harmful radiation.

For further information on superconductivity, see Section 43.8.

## 27.6 ELECTRICAL ENERGY AND POWER

**13.3** If a battery is used to establish an electric current in a conductor, the chemical energy stored in the battery is continuously transformed into kinetic energy of the charge carriers. In the conductor, this kinetic energy is quickly lost as a result of collisions between the charge carriers and the atoms making up the conductor, and this leads to an increase in the temperature of the conductor. In other words, the chemical energy stored in the battery is continuously transformed to internal energy associated with the temperature of the conductor.

Consider a simple circuit consisting of a battery whose terminals are connected to a resistor, as shown in Figure 27.14. (Resistors are designated by the symbol  $\text{---}\text{---}\text{---}$ .) Now imagine following a positive quantity of charge  $\Delta Q$  that is moving clockwise around the circuit from point  $a$  through the battery and resistor back to point  $a$ . Points  $a$  and  $d$  are *grounded* (ground is designated by the symbol  $\text{---}\text{---}\text{---}$ ); that is, we take the electric potential at these two points to be zero. As the

charge moves from  $a$  to  $b$  through the battery, its electric potential energy  $U$  *increases* by an amount  $\Delta V \Delta Q$  (where  $\Delta V$  is the potential difference between  $b$  and  $a$ ), while the chemical potential energy in the battery *decreases* by the same amount. (Recall from Eq. 25.9 that  $\Delta U = q \Delta V$ .) However, as the charge moves from  $c$  to  $d$  through the resistor, it *loses* this electric potential energy as it collides with atoms in the resistor, thereby producing internal energy. If we neglect the resistance of the connecting wires, no loss in energy occurs for paths  $bc$  and  $da$ . When the charge arrives at point  $a$ , it must have the same electric potential energy (zero) that it had at the start.<sup>5</sup> Note that because charge cannot build up at any point, the current is the same everywhere in the circuit.

The rate at which the charge  $\Delta Q$  loses potential energy in going through the resistor is

$$\frac{\Delta U}{\Delta t} = \frac{\Delta Q}{\Delta t} \Delta V = I \Delta V$$

where  $I$  is the current in the circuit. In contrast, the charge regains this energy when it passes through the battery. Because the rate at which the charge loses energy equals the power  $\mathcal{P}$  delivered to the resistor (which appears as internal energy), we have

$$\mathcal{P} = I \Delta V \quad (27.22)$$

<sup>5</sup> Note that once the current reaches its steady-state value, there is *no* change in the kinetic energy of the charge carriers creating the current.

**Figure 27.14** A circuit consisting of a resistor of resistance  $R$  and a battery having a potential difference  $\Delta V$  across its terminals. Positive charge flows in the clockwise direction. Points  $a$  and  $d$  are grounded.

In this case, the power is supplied to a resistor by a battery. However, we can use Equation 27.22 to determine the power transferred to *any* device carrying a current  $I$  and having a potential difference  $\Delta V$  between its terminals.

Using Equation 27.22 and the fact that  $\Delta V = IR$  for a resistor, we can express the power delivered to the resistor in the alternative forms

$$\mathcal{P} = I^2R = \frac{(\Delta V)^2}{R} \quad (27.23)$$

When  $I$  is expressed in amperes,  $\Delta V$  in volts, and  $R$  in ohms, the SI unit of power is the watt, as it was in Chapter 7 in our discussion of mechanical power. The power lost as internal energy in a conductor of resistance  $R$  is called *joule heating*<sup>6</sup>; this transformation is also often referred to as an  $I^2R$  loss.

A battery, a device that supplies electrical energy, is called either a *source of electromotive force* or, more commonly, an *emf source*. The concept of emf is discussed in greater detail in Chapter 28. (The phrase *electromotive force* is an unfortunate choice because it describes not a force but rather a potential difference in volts.)

**When the internal resistance of the battery is neglected, the potential difference between points  $a$  and  $b$  in Figure 27.14 is equal to the emf  $\mathcal{E}$  of the battery**—that is,  $\Delta V = V_b - V_a = \mathcal{E}$ . This being true, we can state that the current in the circuit is  $I = \Delta V/R = \mathcal{E}/R$ . Because  $\Delta V = \mathcal{E}$ , the power supplied by the emf source can be expressed as  $\mathcal{P} = I\mathcal{E}$ , which equals the power delivered to the resistor,  $I^2R$ .

 When transporting electrical energy through power lines, such as those shown in Figure 27.15, utility companies seek to minimize the power transformed to internal energy in the lines and maximize the energy delivered to the consumer. Because  $\mathcal{P} = I\Delta V$ , the same amount of power can be transported either at high currents and low potential differences or at low currents and high potential differences. Utility companies choose to transport electrical energy at low currents and high potential differences primarily for economic reasons. Copper wire is very expensive, and so it is cheaper to use high-resistance wire (that is, wire having a small cross-sectional area; see Eq. 27.11). Thus, in the expression for the power delivered to a resistor,  $\mathcal{P} = I^2R$ , the resistance of the wire is fixed at a relatively high value for economic considerations. The  $I^2R$  loss can be reduced by keeping the current  $I$  as low as possible. In some instances, power is transported at potential differences as great as 765 kV. Once the electricity reaches your city, the potential difference is usually reduced to 4 kV by a device called a *transformer*. Another transformer drops the potential difference to 240 V before the electricity finally reaches your home. Of course, each time the potential difference decreases, the current increases by the same factor, and the power remains the same. We shall discuss transformers in greater detail in Chapter 33.

Power delivered to a resistor

**Figure 27.15** Power companies transfer electrical energy at high potential differences.

### Quick Quiz 27.6

The same potential difference is applied to the two lightbulbs shown in Figure 27.16. Which one of the following statements is true?

- The 30-W bulb carries the greater current and has the higher resistance.
- The 30-W bulb carries the greater current, but the 60-W bulb has the higher resistance.

### QuickLab

If you have access to an ohmmeter, verify your answer to Quick Quiz 27.6 by testing the resistance of a few lightbulbs.

<sup>6</sup> It is called *joule heating* even though the process of heat does not occur. This is another example of incorrect usage of the word *heat* that has become entrenched in our language.

**Figure 27.16** These lightbulbs operate at their rated power only when they are connected to a 120-V source.

- (c) The 30-W bulb has the higher resistance, but the 60-W bulb carries the greater current.  
 (d) The 60-W bulb carries the greater current and has the higher resistance.

### QuickLab

From the labels on household appliances such as hair dryers, televisions, and stereos, estimate the annual cost of operating them.

### Quick Quiz 27.7

For the two lightbulbs shown in Figure 27.17, rank the current values at points *a* through *f*, from greatest to least.

**Figure 27.17** Two lightbulbs connected across the same potential difference. The bulbs operate at their rated power only if they are connected to a 120-V battery.

### EXAMPLE 27.7 Power in an Electric Heater

An electric heater is constructed by applying a potential difference of 120 V to a Nichrome wire that has a total resistance of  $8.00 \Omega$ . Find the current carried by the wire and the power rating of the heater.

**Solution** Because  $\Delta V = IR$ , we have

$$I = \frac{\Delta V}{R} = \frac{120 \text{ V}}{8.00 \Omega} = 15.0 \text{ A}$$

We can find the power rating using the expression  $\mathcal{P} = I^2R$ :

$$\mathcal{P} = I^2R = (15.0 \text{ A})^2(8.00 \Omega) = 1.80 \text{ kW}$$

If we doubled the applied potential difference, the current would double but the power would quadruple because  $\mathcal{P} = (\Delta V)^2/R$ .

**EXAMPLE 27.8** The Cost of Making Dinner

Estimate the cost of cooking a turkey for 4 h in an oven that operates continuously at 20.0 A and 240 V.

**Solution** The power used by the oven is

$$\mathcal{P} = I\Delta V = (20.0 \text{ A})(240 \text{ V}) = 4800 \text{ W} = 4.80 \text{ kW}$$

Because the energy consumed equals power  $\times$  time, the amount of energy for which you must pay is

$$\text{Energy} = \mathcal{P}t = (4.80 \text{ kW})(4 \text{ h}) = 19.2 \text{ kWh}$$

If the energy is purchased at an estimated price of 8.00¢ per kilowatt hour, the cost is

$$\text{Cost} = (19.2 \text{ kWh})(\$0.080/\text{kWh}) = \boxed{\$1.54}$$

Demands on our dwindling energy supplies have made it necessary for us to be aware of the energy requirements of our electrical devices. Every electrical appliance carries a label that contains the information you need to calculate the appliance's power requirements. In many cases, the power consumption in watts is stated directly, as it is on a lightbulb. In other cases, the amount of current used by the device and the potential difference at which it operates are given. This information and Equation 27.22 are sufficient for calculating the operating cost of any electrical device.

**Exercise** What does it cost to operate a 100-W lightbulb for 24 h if the power company charges \$0.08/kWh?

**Answer** \$0.19.

**EXAMPLE 27.9** Current in an Electron Beam

In a certain particle accelerator, electrons emerge with an energy of 40.0 MeV (1 MeV =  $1.60 \times 10^{-13}$  J). The electrons emerge not in a steady stream but rather in pulses at the rate of 250 pulses/s. This corresponds to a time between pulses of 4.00 ms (Fig. 27.18). Each pulse has a duration of 200 ns, and the electrons in the pulse constitute a current of 250 mA. The current is zero between pulses. (a) How many electrons are delivered by the accelerator per pulse?

**Solution** We use Equation 27.2 in the form  $dQ = I dt$  and integrate to find the charge per pulse. While the pulse is on, the current is constant; thus,

$$\begin{aligned} Q_{\text{pulse}} &= I \int dt = I\Delta t = (250 \times 10^{-3} \text{ A})(200 \times 10^{-9} \text{ s}) \\ &= 5.00 \times 10^{-8} \text{ C} \end{aligned}$$

Dividing this quantity of charge per pulse by the electronic charge gives the number of electrons per pulse:

$$\begin{aligned} \text{Electrons per pulse} &= \frac{5.00 \times 10^{-8} \text{ C/pulse}}{1.60 \times 10^{-19} \text{ C/electron}} \\ &= \boxed{3.13 \times 10^{11} \text{ electrons/pulse}} \end{aligned}$$

(b) What is the average current per pulse delivered by the accelerator?

**Solution** Average current is given by Equation 27.1,  $I_{\text{av}} = \Delta Q / \Delta t$ . Because the time interval between pulses is 4.00 ms, and because we know the charge per pulse from part (a), we obtain

$$I_{\text{av}} = \frac{Q_{\text{pulse}}}{\Delta t} = \frac{5.00 \times 10^{-8} \text{ C}}{4.00 \times 10^{-3} \text{ s}} = \boxed{12.5 \mu\text{A}}$$

This represents only 0.005% of the peak current, which is 250 mA.

**Figure 27.18** Current versus time for a pulsed beam of electrons.

(c) What is the maximum power delivered by the electron beam?

**Solution** By definition, power is energy delivered per unit time. Thus, the maximum power is equal to the energy delivered by a pulse divided by the pulse duration:

$$\begin{aligned} \mathcal{P} &= \frac{E}{\Delta t} \\ &= \frac{(3.13 \times 10^{11} \text{ electrons/pulse})(40.0 \text{ MeV/electron})}{2.00 \times 10^{-7} \text{ s/pulse}} \end{aligned}$$

$$\begin{aligned} &= (6.26 \times 10^{19} \text{ MeV/s})(1.60 \times 10^{-13} \text{ J/MeV}) \\ &= 1.00 \times 10^7 \text{ W} = \boxed{10.0 \text{ MW}} \end{aligned}$$

We could also compute this power directly. We assume that each electron had zero energy before being accelerated. Thus, by definition, each electron must have gone through a potential difference of 40.0 MV to acquire a final energy of 40.0 MeV. Hence, we have

$$\mathcal{P} = I \Delta V = (250 \times 10^{-3} \text{ A})(40.0 \times 10^6 \text{ V}) = \boxed{10.0 \text{ MW}}$$

## SUMMARY

The **electric current**  $I$  in a conductor is defined as

$$I \equiv \frac{dQ}{dt} \quad (27.2)$$

where  $dQ$  is the charge that passes through a cross-section of the conductor in a time  $dt$ . The SI unit of current is the **ampere** (A), where 1 A = 1 C/s.

The average current in a conductor is related to the motion of the charge carriers through the relationship

$$I_{\text{av}} = nqv_d A \quad (27.4)$$

where  $n$  is the density of charge carriers,  $q$  is the charge on each carrier,  $v_d$  is the drift speed, and  $A$  is the cross-sectional area of the conductor.

The magnitude of the **current density**  $J$  in a conductor is the current per unit area:

$$J \equiv \frac{I}{A} = nqv_d \quad (27.5)$$

The current density in a conductor is proportional to the electric field according to the expression

$$\mathbf{J} = \sigma \mathbf{E} \quad (27.7)$$

The proportionality constant  $\sigma$  is called the **conductivity** of the material of which the conductor is made. The inverse of  $\sigma$  is known as **resistivity**  $\rho$  ( $\rho = 1/\sigma$ ). Equation 27.7 is known as **Ohm's law**, and a material is said to obey this law if the ratio of its current density  $\mathbf{J}$  to its applied electric field  $\mathbf{E}$  is a constant that is independent of the applied field.

The **resistance**  $R$  of a conductor is defined either in terms of the length of the conductor or in terms of the potential difference across it:

$$R \equiv \frac{\ell}{\sigma A} \equiv \frac{\Delta V}{I} \quad (27.8)$$

where  $\ell$  is the length of the conductor,  $\sigma$  is the conductivity of the material of which it is made,  $A$  is its cross-sectional area,  $\Delta V$  is the potential difference across it, and  $I$  is the current it carries.

The SI unit of resistance is volts per ampere, which is defined to be 1 **ohm** ( $\Omega$ ); that is,  $1 \Omega = 1 \text{ V/A}$ . If the resistance is independent of the applied potential difference, the conductor obeys Ohm's law.

In a classical model of electrical conduction in metals, the electrons are treated as molecules of a gas. In the absence of an electric field, the average velocity of the electrons is zero. When an electric field is applied, the electrons move (on the average) with a **drift velocity**  $\mathbf{v}_d$  that is opposite the electric field and given by the expression

$$\mathbf{v}_d = \frac{q\mathbf{E}}{m_e} \tau \quad (27.14)$$

where  $\tau$  is the average time between electron-atom collisions,  $m_e$  is the mass of the electron, and  $q$  is its charge. According to this model, the resistivity of the metal is

$$\rho = \frac{m_e}{nq^2\tau} \quad (27.17)$$

where  $n$  is the number of free electrons per unit volume.

The resistivity of a conductor varies approximately linearly with temperature according to the expression

$$\rho = \rho_0[1 + \alpha(T - T_0)] \quad (27.19)$$

where  $\alpha$  is the **temperature coefficient of resistivity** and  $\rho_0$  is the resistivity at some reference temperature  $T_0$ .

If a potential difference  $\Delta V$  is maintained across a resistor, the **power**, or rate at which energy is supplied to the resistor, is

$$\mathcal{P} = I\Delta V \quad (27.22)$$

Because the potential difference across a resistor is given by  $\Delta V = IR$ , we can express the power delivered to a resistor in the form

$$\mathcal{P} = I^2R = \frac{(\Delta V)^2}{R} \quad (27.23)$$

The electrical energy supplied to a resistor appears in the form of internal energy in the resistor.

## QUESTIONS

- Newspaper articles often contain statements such as "10 000 volts of electricity surged through the victim's body." What is wrong with this statement?
- What is the difference between resistance and resistivity?
- Two wires A and B of circular cross-section are made of the same metal and have equal lengths, but the resistance of wire A is three times greater than that of wire B. What is the ratio of their cross-sectional areas? How do their radii compare?
- What is required in order to maintain a steady current in a conductor?
- Do all conductors obey Ohm's law? Give examples to justify your answer.
- When the voltage across a certain conductor is doubled, the current is observed to increase by a factor of three. What can you conclude about the conductor?
- In the water analogy of an electric circuit, what corresponds to the power supply, resistor, charge, and potential difference?
- Why might a "good" electrical conductor also be a "good" thermal conductor?
- On the basis of the atomic theory of matter, explain why the resistance of a material should increase as its temperature increases.
- How does the resistance for copper and silicon change with temperature? Why are the behaviors of these two materials different?
- Explain how a current can persist in a superconductor in the absence of any applied voltage.
- What single experimental requirement makes superconducting devices expensive to operate? In principle, can this limitation be overcome?

13. What would happen to the drift velocity of the electrons in a wire and to the current in the wire if the electrons could move freely without resistance through the wire?
14. If charges flow very slowly through a metal, why does it not require several hours for a light to turn on when you throw a switch?
15. In a conductor, the electric field that drives the electrons through the conductor propagates with a speed that is almost the same as the speed of light, even though the drift velocity of the electrons is very small. Explain how these can both be true. Does a given electron move from one end of the conductor to the other?
16. Two conductors of the same length and radius are connected across the same potential difference. One conductor has twice the resistance of the other. To which conductor is more power delivered?
17. Car batteries are often rated in ampere-hours. Does this designate the amount of current, power, energy, or charge that can be drawn from the battery?
18. If you were to design an electric heater using Nichrome wire as the heating element, what parameters of the wire could you vary to meet a specific power output, such as 1 000 W?
19. Consider the following typical monthly utility rate structure: \$2.00 for the first 16 kWh, 8.00¢/kWh for the next 34 kWh, 6.50¢/kWh for the next 50 kWh, 5.00¢/kWh for the next 100 kWh, 4.00¢/kWh for the next 200 kWh, and 3.50¢/kWh for all kilowatt-hours in excess of 400 kWh. On the basis of these rates, determine the amount charged for 327 kWh.

## PROBLEMS

 = paired numerical/symbolic problems

### Section 27.1 Electric Current

1. In a particular cathode ray tube, the measured beam current is  $30.0 \mu\text{A}$ . How many electrons strike the tube screen every 40.0 s?
2. A teapot with a surface area of  $700 \text{ cm}^2$  is to be silver plated. It is attached to the negative electrode of an electrolytic cell containing silver nitrate ( $\text{Ag}^+\text{NO}_3^-$ ). If the cell is powered by a 12.0-V battery and has a resistance of  $1.80 \Omega$ , how long does it take for a 0.133-mm layer of silver to build up on the teapot? (The density of silver is  $10.5 \times 10^3 \text{ kg/m}^3$ .)
3. Suppose that the current through a conductor decreases exponentially with time according to the expression  $I(t) = I_0 e^{-t/\tau}$ , where  $I_0$  is the initial current (at  $t = 0$ ) and  $\tau$  is a constant having dimensions of time. Consider a fixed observation point within the conductor. (a) How much charge passes this point between  $t = 0$  and  $t = \tau$ ? (b) How much charge passes this point between  $t = 0$  and  $t = 10\tau$ ? (c) How much charge passes this point between  $t = 0$  and  $t = \infty$ ?
4. In the Bohr model of the hydrogen atom, an electron in the lowest energy state follows a circular path at a distance of  $5.29 \times 10^{-11} \text{ m}$  from the proton. (a) Show that the speed of the electron is  $2.19 \times 10^6 \text{ m/s}$ . (b) What is the effective current associated with this orbiting electron?
5. A small sphere that carries a charge of  $8.00 \text{ nC}$  is whirled in a circle at the end of an insulating string. The angular frequency of rotation is  $100\pi \text{ rad/s}$ . What average current does this rotating charge represent?
6. A small sphere that carries a charge  $q$  is whirled in a circle at the end of an insulating string. The angular frequency of rotation is  $\omega$ . What average current does this rotating charge represent?
7. The quantity of charge  $q$  (in coulombs) passing through a surface of area  $2.00 \text{ cm}^2$  varies with time according to the equation  $q = 4.00t^3 + 5.00t + 6.00$ , where  $t$  is in seconds. (a) What is the instantaneous current through the surface at  $t = 1.00 \text{ s}$ ? (b) What is the value of the current density?
8. An electric current is given by the expression  $I(t) = 100 \sin(120\pi t)$ , where  $I$  is in amperes and  $t$  is in seconds. What is the total charge carried by the current from  $t = 0$  to  $t = 1/240 \text{ s}$ ?
9. Figure P27.9 represents a section of a circular conductor of nonuniform diameter carrying a current of 5.00 A. The radius of cross-section  $A_1$  is 0.400 cm. (a) What is the magnitude of the current density across  $A_1$ ? (b) If the current density across  $A_2$  is one-fourth the value across  $A_1$ , what is the radius of the conductor at  $A_2$ ?

Figure P27.9

10. A Van de Graaff generator produces a beam of 2.00-MeV *deuterons*, which are heavy hydrogen nuclei containing a proton and a neutron. (a) If the beam current is  $10.0 \mu\text{A}$ , how far apart are the deuterons? (b) Is their electrostatic repulsion a factor in beam stability? Explain.
11. The electron beam emerging from a certain high-energy electron accelerator has a circular cross-section of radius 1.00 mm. (a) If the beam current is  $8.00 \mu\text{A}$ , what is the current density in the beam, assuming that it is uniform throughout? (b) The speed of the electrons is so close to the speed of light that their speed can be taken as  $c = 3.00 \times 10^8 \text{ m/s}$  with negligible error. Find the electron density in the beam. (c) How long does it take for Avogadro's number of electrons to emerge from the accelerator?
12. An aluminum wire having a cross-sectional area of  $4.00 \times 10^{-6} \text{ m}^2$  carries a current of 5.00 A. Find the drift speed of the electrons in the wire. The density of aluminum is  $2.70 \text{ g/cm}^3$ . (Assume that one electron is supplied by each atom.)

### Section 27.2 Resistance and Ohm's Law

13. A lightbulb has a resistance of  $240 \Omega$  when operating at a voltage of 120 V. What is the current through the lightbulb?
14. A resistor is constructed of a carbon rod that has a uniform cross-sectional area of  $5.00 \text{ mm}^2$ . When a potential difference of 15.0 V is applied across the ends of the rod, there is a current of  $4.00 \times 10^{-3} \text{ A}$  in the rod. Find (a) the resistance of the rod and (b) the rod's length.
- WEB 15. A 0.900-V potential difference is maintained across a 1.50-m length of tungsten wire that has a cross-sectional area of  $0.600 \text{ mm}^2$ . What is the current in the wire?
16. A conductor of uniform radius 1.20 cm carries a current of 3.00 A produced by an electric field of 120 V/m. What is the resistivity of the material?
17. Suppose that you wish to fabricate a uniform wire out of 1.00 g of copper. If the wire is to have a resistance of  $R = 0.500 \Omega$ , and if all of the copper is to be used, what will be (a) the length and (b) the diameter of this wire?
18. (a) Make an order-of-magnitude estimate of the resistance between the ends of a rubber band. (b) Make an order-of-magnitude estimate of the resistance between the 'heads' and 'tails' sides of a penny. In each case, state what quantities you take as data and the values you measure or estimate for them. (c) What would be the order of magnitude of the current that each carries if it were connected across a 120-V power supply? (WARNING! Do not try this at home!)
19. A solid cube of silver (density =  $10.5 \text{ g/cm}^3$ ) has a mass of 90.0 g. (a) What is the resistance between opposite faces of the cube? (b) If there is one conduction electron for each silver atom, what is the average drift speed of electrons when a potential difference of  $1.00 \times 10^{-5} \text{ V}$  is applied to opposite faces? (The

atomic number of silver is 47, and its molar mass is  $107.87 \text{ g/mol}$ .)

20. A metal wire of resistance  $R$  is cut into three equal pieces that are then connected side by side to form a new wire whose length is equal to one-third the original length. What is the resistance of this new wire?
21. A wire with a resistance  $R$  is lengthened to 1.25 times its original length by being pulled through a small hole. Find the resistance of the wire after it has been stretched.
22. Aluminum and copper wires of equal length are found to have the same resistance. What is the ratio of their radii?
23. A current density of  $6.00 \times 10^{-13} \text{ A/m}^2$  exists in the atmosphere where the electric field (due to charged thunderclouds in the vicinity) is 100 V/m. Calculate the electrical conductivity of the Earth's atmosphere in this region.
24. The rod in Figure P27.24 (not drawn to scale) is made of two materials. Both have a square cross section of 3.00 mm on a side. The first material has a resistivity of  $4.00 \times 10^{-3} \Omega \cdot \text{m}$  and is 25.0 cm long, while the second material has a resistivity of  $6.00 \times 10^{-3} \Omega \cdot \text{m}$  and is 40.0 cm long. What is the resistance between the ends of the rod?

Figure P27.24

### Section 27.3 A Model for Electrical Conduction

- WEB 25. If the drift velocity of free electrons in a copper wire is  $7.84 \times 10^{-4} \text{ m/s}$ , what is the electric field in the conductor?
26. If the current carried by a conductor is doubled, what happens to the (a) charge carrier density? (b) current density? (c) electron drift velocity? (d) average time between collisions?
27. Use data from Example 27.1 to calculate the collision mean free path of electrons in copper, assuming that the average thermal speed of conduction electrons is  $8.60 \times 10^5 \text{ m/s}$ .

### Section 27.4 Resistance and Temperature

28. While taking photographs in Death Valley on a day when the temperature is  $58.0^\circ\text{C}$ , Bill Hiker finds that a certain voltage applied to a copper wire produces a current of 1.000 A. Bill then travels to Antarctica and applies the same voltage to the same wire. What current does he register there if the temperature is  $-88.0^\circ\text{C}$ ? Assume that no change occurs in the wire's shape and size.
29. A certain lightbulb has a tungsten filament with a resistance of  $19.0 \Omega$  when cold and of  $140 \Omega$  when hot. Assuming that Equation 27.21 can be used over the large

temperature range involved here, find the temperature of the filament when hot. (Assume an initial temperature of  $20.0^\circ\text{C}$ .)

30. A carbon wire and a Nichrome wire are connected in series. If the combination has a resistance of  $10.0\text{ k}\Omega$  at  $0^\circ\text{C}$ , what is the resistance of each wire at  $0^\circ\text{C}$  such that the resistance of the combination does not change with temperature? (Note that the equivalent resistance of two resistors in series is the sum of their resistances.)
31. An aluminum wire with a diameter of  $0.100\text{ mm}$  has a uniform electric field with a magnitude of  $0.200\text{ V/m}$  imposed along its entire length. The temperature of the wire is  $50.0^\circ\text{C}$ . Assume one free electron per atom.  
(a) Using the information given in Table 27.1, determine the resistivity. (b) What is the current density in the wire? (c) What is the total current in the wire? (d) What is the drift speed of the conduction electrons? (e) What potential difference must exist between the ends of a  $2.00\text{-m}$  length of the wire if the stated electric field is to be produced?
32. **Review Problem.** An aluminum rod has a resistance of  $1.234\ \Omega$  at  $20.0^\circ\text{C}$ . Calculate the resistance of the rod at  $120^\circ\text{C}$  by accounting for the changes in both the resistivity and the dimensions of the rod.
33. What is the fractional change in the resistance of an iron filament when its temperature changes from  $25.0^\circ\text{C}$  to  $50.0^\circ\text{C}$ ?
34. The resistance of a platinum wire is to be calibrated for low-temperature measurements. A platinum wire with a resistance of  $1.00\ \Omega$  at  $20.0^\circ\text{C}$  is immersed in liquid nitrogen at  $77\text{ K}$  ( $-196^\circ\text{C}$ ). If the temperature response of the platinum wire is linear, what is the expected resistance of the platinum wire at  $-196^\circ\text{C}$ ?  
( $\alpha_{\text{platinum}} = 3.92 \times 10^{-3}/^\circ\text{C}$ )
35. The temperature of a tungsten sample is raised while a copper sample is maintained at  $20^\circ\text{C}$ . At what temperature will the resistivity of the tungsten sample be four times that of the copper sample?
36. A segment of Nichrome wire is initially at  $20.0^\circ\text{C}$ . Using the data from Table 27.1, calculate the temperature to which the wire must be heated if its resistance is to be doubled.

### Section 27.6 Electrical Energy and Power

37. A toaster is rated at  $600\text{ W}$  when connected to a  $120\text{-V}$  source. What current does the toaster carry, and what is its resistance?
38. In a hydroelectric installation, a turbine delivers  $1\ 500\text{ hp}$  to a generator, which in turn converts  $80.0\%$  of the mechanical energy into electrical energy. Under these conditions, what current does the generator deliver at a terminal potential difference of  $2\ 000\text{ V}$ ?

- WEB 39. **Review Problem.** What is the required resistance of an immersion heater that increases the temperature of  $1.50\text{ kg}$  of water from  $10.0^\circ\text{C}$  to  $50.0^\circ\text{C}$  in  $10.0\text{ min}$  while operating at  $110\text{ V}$ ?

40. **Review Problem.** What is the required resistance of an immersion heater that increases the temperature of a mass  $m$  of liquid water from  $T_1$  to  $T_2$  in a time  $t$  while operating at a voltage  $\Delta V$ ?

41. Suppose that a voltage surge produces  $140\text{ V}$  for a moment. By what percentage does the power output of a  $120\text{-V}$ ,  $100\text{-W}$  lightbulb increase? (Assume that its resistance does not change.)
42. A  $500\text{-W}$  heating coil designed to operate from  $110\text{ V}$  is made of Nichrome wire  $0.500\text{ mm}$  in diameter. (a) Assuming that the resistivity of the Nichrome remains constant at its  $20.0^\circ\text{C}$  value, find the length of wire used. (b) Now consider the variation of resistivity with temperature. What power does the coil of part (a) actually deliver when it is heated to  $1\ 200^\circ\text{C}$ ?
43. A coil of Nichrome wire is  $25.0\text{ m}$  long. The wire has a diameter of  $0.400\text{ mm}$  and is at  $20.0^\circ\text{C}$ . If it carries a current of  $0.500\text{ A}$ , what are (a) the magnitude of the electric field in the wire and (b) the power delivered to it? (c) If the temperature is increased to  $340^\circ\text{C}$  and the potential difference across the wire remains constant, what is the power delivered?
44. Batteries are rated in terms of ampere-hours ( $\text{A}\cdot\text{h}$ ): For example, a battery that can produce a current of  $2.00\text{ A}$  for  $3.00\text{ h}$  is rated at  $6.00\text{ A}\cdot\text{h}$ . (a) What is the total energy, in kilowatt-hours, stored in a  $12.0\text{-V}$  battery rated at  $55.0\text{ A}\cdot\text{h}$ ? (b) At a rate of  $\$0.060\ 0$  per kilowatt-hour, what is the value of the electricity produced by this battery?
45. A  $10.0\text{-V}$  battery is connected to a  $120\text{-}\Omega$  resistor. Neglecting the internal resistance of the battery, calculate the power delivered to the resistor.
46. It is estimated that each person in the United States (population =  $270$  million) has one electric clock, and that each clock uses energy at a rate of  $2.50\text{ W}$ . To supply this energy, about how many metric tons of coal are burned per hour in coal-fired electricity generating plants that are, on average,  $25.0\%$  efficient? (The heat of combustion for coal is  $33.0\text{ MJ/kg}$ .)
47. Compute the cost per day of operating a lamp that draws  $1.70\text{ A}$  from a  $110\text{-V}$  line if the cost of electrical energy is  $\$0.060\ 0/\text{kWh}$ .
48. **Review Problem.** The heating element of a coffee-maker operates at  $120\text{ V}$  and carries a current of  $2.00\text{ A}$ . Assuming that all of the energy transferred from the heating element is absorbed by the water, calculate how long it takes to heat  $0.500\text{ kg}$  of water from room temperature ( $23.0^\circ\text{C}$ ) to the boiling point.
49. A certain toaster has a heating element made of Nichrome resistance wire. When the toaster is first connected to a  $120\text{-V}$  source of potential difference (and the wire is at a temperature of  $20.0^\circ\text{C}$ ), the initial current is  $1.80\text{ A}$ . However, the current begins to decrease as the resistive element warms up. When the toaster has reached its final operating temperature, the current has dropped to  $1.53\text{ A}$ . (a) Find the power the toaster con-

sumes when it is at its operating temperature. (b) What is the final temperature of the heating element?

50. To heat a room having ceilings 8.0 ft high, about 10.0 W of electric power are required per square foot. At a cost of \$0.080 0/kWh, how much does it cost per day to use electricity to heat a room measuring 10.0 ft  $\times$  15.0 ft?
51. Estimate the cost of one person's routine use of a hair dryer for 1 yr. If you do not use a blow dryer yourself, observe or interview someone who does. State the quantities you estimate and their values.

### ADDITIONAL PROBLEMS

52. One lightbulb is marked "25 W 120 V," and another "100 W 120 V"; this means that each bulb converts its respective power when plugged into a constant 120-V potential difference. (a) Find the resistance of each bulb. (b) How long does it take for 1.00 C to pass through the dim bulb? How is this charge different at the time of its exit compared with the time of its entry? (c) How long does it take for 1.00 J to pass through the dim bulb? How is this energy different at the time of its exit compared with the time of its entry? (d) Find the cost of running the dim bulb continuously for 30.0 days if the electric company sells its product at \$0.070 0 per kWh. What product *does* the electric company sell? What is its price for one SI unit of this quantity?
53. A high-voltage transmission line with a diameter of 2.00 cm and a length of 200 km carries a steady current of 1 000 A. If the conductor is copper wire with a free charge density of  $8.00 \times 10^{28}$  electrons/m<sup>3</sup>, how long does it take one electron to travel the full length of the cable?
54. A high-voltage transmission line carries 1 000 A starting at 700 kV for a distance of 100 mi. If the resistance in the wire is 0.500  $\Omega$ /mi, what is the power loss due to resistive losses?
55. A more general definition of the temperature coefficient of resistivity is

$$\alpha = \frac{1}{\rho} \frac{d\rho}{dT}$$

where  $\rho$  is the resistivity at temperature  $T$ . (a) Assuming that  $\alpha$  is constant, show that

$$\rho = \rho_0 e^{\alpha(T - T_0)}$$

where  $\rho_0$  is the resistivity at temperature  $T_0$ . (b) Using the series expansion ( $e^x \cong 1 + x$  for  $x \ll 1$ ), show that the resistivity is given approximately by the expression  $\rho = \rho_0[1 + \alpha(T - T_0)]$  for  $\alpha(T - T_0) \ll 1$ .

56. A copper cable is to be designed to carry a current of 300 A with a power loss of only 2.00 W/m. What is the required radius of the copper cable?
- WEB 57. An experiment is conducted to measure the electrical resistivity of Nichrome in the form of wires with different lengths and cross-sectional areas. For one set of

measurements, a student uses 30-gauge wire, which has a cross-sectional area of  $7.30 \times 10^{-8}$  m<sup>2</sup>. The student measures the potential difference across the wire and the current in the wire with a voltmeter and ammeter, respectively. For each of the measurements given in the table taken on wires of three different lengths, calculate the resistance of the wires and the corresponding values of the resistivity. What is the average value of the resistivity, and how does this value compare with the value given in Table 27.1?

$L$ (m)	$\Delta V$ (V)	$I$ (A)	$R$ ( $\Omega$ )	$\rho$ ( $\Omega \cdot \text{m}$ )
0.540	5.22	0.500		
1.028	5.82	0.276		
1.543	5.94	0.187		

58. An electric utility company supplies a customer's house from the main power lines (120 V) with two copper wires, each of which is 50.0 m long and has a resistance of 0.108  $\Omega$  per 300 m. (a) Find the voltage at the customer's house for a load current of 110 A. For this load current, find (b) the power that the customer is receiving and (c) the power lost in the copper wires.
59. A straight cylindrical wire lying along the  $x$  axis has a length of 0.500 m and a diameter of 0.200 mm. It is made of a material described by Ohm's law with a resistivity of  $\rho = 4.00 \times 10^{-8}$   $\Omega \cdot \text{m}$ . Assume that a potential of 4.00 V is maintained at  $x = 0$ , and that  $V = 0$  at  $x = 0.500$  m. Find (a) the electric field  $\mathbf{E}$  in the wire, (b) the resistance of the wire, (c) the electric current in the wire, and (d) the current density  $\mathbf{J}$  in the wire. Express vectors in vector notation. (e) Show that  $\mathbf{E} = \rho \mathbf{J}$ .
60. A straight cylindrical wire lying along the  $x$  axis has a length  $L$  and a diameter  $d$ . It is made of a material described by Ohm's law with a resistivity  $\rho$ . Assume that a potential  $V$  is maintained at  $x = 0$ , and that  $V = 0$  at  $x = L$ . In terms of  $L$ ,  $d$ ,  $V$ ,  $\rho$ , and physical constants, derive expressions for (a) the electric field in the wire, (b) the resistance of the wire, (c) the electric current in the wire, and (d) the current density in the wire. Express vectors in vector notation. (e) Show that  $\mathbf{E} = \rho \mathbf{J}$ .
61. The potential difference across the filament of a lamp is maintained at a constant level while equilibrium temperature is being reached. It is observed that the steady-state current in the lamp is only one tenth of the current drawn by the lamp when it is first turned on. If the temperature coefficient of resistivity for the lamp at 20.0°C is  $0.004\ 50$  ( $^{\circ}\text{C}$ )<sup>-1</sup>, and if the resistance increases linearly with increasing temperature, what is the final operating temperature of the filament?
62. The current in a resistor decreases by 3.00 A when the potential difference applied across the resistor decreases from 12.0 V to 6.00 V. Find the resistance of the resistor.

63. An electric car is designed to run off a bank of 12.0-V batteries with a total energy storage of  $2.00 \times 10^7$  J. (a) If the electric motor draws 8.00 kW, what is the current delivered to the motor? (b) If the electric motor draws 8.00 kW as the car moves at a steady speed of 20.0 m/s, how far will the car travel before it is “out of juice”?
64. **Review Problem.** When a straight wire is heated, its resistance is given by the expression  $R = R_0[1 + \alpha(T - T_0)]$  according to Equation 27.21, where  $\alpha$  is the temperature coefficient of resistivity. (a) Show that a more precise result, one that accounts for the fact that the length and area of the wire change when heated, is

$$R = \frac{R_0[1 + \alpha(T - T_0)][1 + \alpha'(T - T_0)]}{[1 + 2\alpha'(T - T_0)]}$$

where  $\alpha'$  is the coefficient of linear expansion (see Chapter 19). (b) Compare these two results for a 2.00-m-long copper wire of radius 0.100 mm, first at 20.0°C and then heated to 100.0°C.

65. The temperature coefficients of resistivity in Table 27.1 were determined at a temperature of 20°C. What would they be at 0°C? (*Hint:* The temperature coefficient of resistivity at 20°C satisfies the expression  $\rho = \rho_0[1 + \alpha(T - T_0)]$ , where  $\rho_0$  is the resistivity of the material at  $T_0 = 20^\circ\text{C}$ . The temperature coefficient of resistivity  $\alpha'$  at 0°C must satisfy the expression  $\rho = \rho'_0[1 + \alpha'T]$ , where  $\rho'_0$  is the resistivity of the material at 0°C.)
66. A resistor is constructed by shaping a material of resistivity  $\rho$  into a hollow cylinder of length  $L$  and with inner and outer radii  $r_a$  and  $r_b$ , respectively (Fig. P27.66). In use, the application of a potential difference between the ends of the cylinder produces a current parallel to the axis. (a) Find a general expression for the resistance of such a device in terms of  $L$ ,  $\rho$ ,  $r_a$ , and  $r_b$ . (b) Obtain a numerical value for  $R$  when  $L = 4.00$  cm,  $r_a = 0.500$  cm,  $r_b = 1.20$  cm, and  $\rho = 3.50 \times 10^5 \Omega \cdot \text{m}$ . (c) Now suppose that the potential difference is applied between the inner and outer surfaces so that the resulting current flows radially outward. Find a general expression for the resistance of the device in terms of  $L$ ,  $\rho$ ,

Figure P27.66

$r_a$ , and  $r_b$ . (d) Calculate the value of  $R$ , using the parameter values given in part (b).

67. In a certain stereo system, each speaker has a resistance of  $4.00 \Omega$ . The system is rated at 60.0 W in each channel, and each speaker circuit includes a fuse rated at 4.00 A. Is this system adequately protected against overload? Explain your reasoning.
68. A close analogy exists between the flow of energy due to a temperature difference (see Section 20.7) and the flow of electric charge due to a potential difference. The energy  $dQ$  and the electric charge  $dq$  are both transported by free electrons in the conducting material. Consequently, a good electrical conductor is usually a good thermal conductor as well. Consider a thin conducting slab of thickness  $dx$ , area  $A$ , and electrical conductivity  $\sigma$ , with a potential difference  $dV$  between opposite faces. Show that the current  $I = dq/dt$  is given by the equation on the left:

Charge conduction	Analogous thermal conduction (Eq. 20.14)
$\frac{dq}{dt} = \sigma A \left  \frac{dV}{dx} \right $	$\frac{dQ}{dt} = kA \left  \frac{dT}{dx} \right $

In the analogous thermal conduction equation on the right, the rate of energy flow  $dQ/dt$  (in SI units of joules per second) is due to a temperature gradient  $dT/dx$  in a material of thermal conductivity  $k$ . State analogous rules relating the direction of the electric current to the change in potential and relating the direction of energy flow to the change in temperature.

69. Material with uniform resistivity  $\rho$  is formed into a wedge, as shown in Figure P27.69. Show that the resistance between face A and face B of this wedge is

$$R = \rho \frac{L}{w(y_2 - y_1)} \ln\left(\frac{y_2}{y_1}\right)$$

Figure P27.69

70. A material of resistivity  $\rho$  is formed into the shape of a truncated cone of altitude  $h$ , as shown in Figure P27.70.

The bottom end has a radius  $b$ , and the top end has a radius  $a$ . Assuming that the current is distributed uniformly over any particular cross-section of the cone so that the current density is not a function of radial position (although it does vary with position along the axis

Figure P27.70

of the cone), show that the resistance between the two ends is given by the expression

$$R = \frac{\rho}{\pi} \left( \frac{h}{ab} \right)$$

71. The current–voltage characteristic curve for a semiconductor diode as a function of temperature  $T$  is given by the equation

$$I = I_0(e^{e\Delta V/k_B T} - 1)$$

Here, the first symbol  $e$  represents the base of the natural logarithm. The second  $e$  is the charge on the electron. The  $k_B$  is Boltzmann's constant, and  $T$  is the absolute temperature. Set up a spreadsheet to calculate  $I$  and  $R = (\Delta V)/I$  for  $\Delta V = 0.400$  V to  $0.600$  V in increments of  $0.005$  V. Assume that  $I_0 = 1.00$  nA. Plot  $R$  versus  $\Delta V$  for  $T = 280$  K,  $300$  K, and  $320$  K.

## ANSWERS TO QUICK QUIZZES

- 27.1 d,  $b = c$ , a. The current in part (d) is equivalent to two positive charges moving to the left. Parts (b) and (c) each represent four positive charges moving in the same direction because negative charges moving to the left are equivalent to positive charges moving to the right. The current in part (a) is equivalent to five positive charges moving to the right.
- 27.2 Every portion of the wire carries the same current even though the wire constricts. As the cross-sectional area decreases, the drift velocity must increase in order for the constant current to be maintained, in accordance with Equation 27.4. Equations 27.5 and 27.6 indicate that the current density also increases. An increasing electric field must be causing the increasing current density, as indicated by Equation 27.7. If you were to draw this situation, you would show the electric field lines being compressed into the smaller area, indicating increasing magnitude of the electric field.
- 27.3 The curvature of the line indicates that the device is nonohmic (that is, its resistance varies with potential difference). Being the definition of resistance, Equation 27.8 still applies, giving different values for  $R$  at different points on the curve. The slope of the tangent to the graph line at a point is the reciprocal of the “dynamic resistance” at that point. Note that the resistance of the device (as measured by an ohmmeter) is the reciprocal of the slope of a secant line joining the origin to a particular point on the curve.
- 27.4 The cable should be as short as possible but still able to reach from one vehicle to another (small  $\ell$ ), it should be quite thick (large  $A$ ), and it should be made of a material with a low resistivity  $\rho$ . Referring to Table 27.1, you should probably choose copper or aluminum because the only two materials in the table that have lower  $\rho$  values—silver and gold—are prohibitively expensive for your purposes.
- 27.5 Just after it is turned on. When the filament is at room temperature, its resistance is low, and hence the current is relatively large ( $I = \Delta V/R$ ). As the filament warms up, its resistance increases, and the current decreases. Older lightbulbs often fail just as they are turned on because this large initial current “spike” produces rapid temperature increase and stress on the filament.
- 27.6 (c). Because the potential difference  $\Delta V$  is the same across the two bulbs and because the power delivered to a conductor is  $\mathcal{P} = I\Delta V$ , the 60-W bulb, with its higher power rating, must carry the greater current. The 30-W bulb has the higher resistance because it draws less current at the same potential difference.
- 27.7  $I_a = I_b > I_c = I_d > I_e = I_f$ . The current  $I_a$  leaves the positive terminal of the battery and then splits to flow through the two bulbs; thus,  $I_a = I_c + I_e$ . From Quick Quiz 27.6, we know that the current in the 60-W bulb is greater than that in the 30-W bulb. (Note that all the current does not follow the “path of least resistance,” which in this case is through the 60-W bulb.) Because charge does not build up in the bulbs, we know that all the charge flowing into a bulb from the left must flow out on the right; consequently,  $I_c = I_d$  and  $I_e = I_f$ . The two currents leaving the bulbs recombine to form the current back into the battery,  $I_f + I_d = I_b$ .

## # PUZZLER

If all these appliances were operating at one time, a circuit breaker would probably be tripped, preventing a potentially dangerous situation. What causes a circuit breaker to trip when too many electrical devices are plugged into one circuit? (George Semple)

## Direct Current Circuits

### Chapter Outline

**28.1** Electromotive Force

**28.2** Resistors in Series and in Parallel

**28.3** Kirchhoff's Rules

**28.4** RC Circuits

**28.5** (Optional) Electrical Instruments

**28.6** (Optional) Household Wiring and Electrical Safety

This chapter is concerned with the analysis of some simple electric circuits that contain batteries, resistors, and capacitors in various combinations. The analysis of these circuits is simplified by the use of two rules known as *Kirchhoff's rules*, which follow from the laws of conservation of energy and conservation of electric charge. Most of the circuits analyzed are assumed to be in *steady state*, which means that the currents are constant in magnitude and direction. In Section 28.4 we discuss circuits in which the current varies with time. Finally, we describe a variety of common electrical devices and techniques for measuring current, potential difference, resistance, and emf.

## 28.1 ELECTROMOTIVE FORCE

In Section 27.6 we found that a constant current can be maintained in a closed circuit through the use of a source of *emf*, which is a device (such as a battery or generator) that produces an electric field and thus may cause charges to move around a circuit. One can think of a source of emf as a “charge pump.” When an electric potential difference exists between two points, the source moves charges “uphill” from the lower potential to the higher. The emf  $\mathcal{E}$  describes the work done per unit charge, and hence the SI unit of emf is the volt.

Consider the circuit shown in Figure 28.1, consisting of a battery connected to a resistor. We assume that the connecting wires have no resistance. The positive terminal of the battery is at a higher potential than the negative terminal. If we neglect the internal resistance of the battery, the potential difference across it (called the *terminal voltage*) equals its emf. However, because a real battery always has some internal resistance  $r$ , the terminal voltage is not equal to the emf for a battery in a circuit in which there is a current. To understand why this is so, consider the circuit diagram in Figure 28.2a, where the battery of Figure 28.1 is represented by the dashed rectangle containing an emf  $\mathcal{E}$  in series with an internal resistance  $r$ . Now imagine moving through the battery clockwise from  $a$  to  $b$  and measuring the electric potential at various locations. As we pass from the negative terminal to the positive terminal, the potential *increases* by an amount  $\mathcal{E}$ . However, as we move through the resistance  $r$ , the potential *decreases* by an amount  $Ir$ , where  $I$  is the current in the circuit. Thus, the terminal voltage of the battery  $\Delta V = V_b - V_a$  is<sup>1</sup>

**Figure 28.1** A circuit consisting of a resistor connected to the terminals of a battery.

<sup>1</sup> The terminal voltage in this case is less than the emf by an amount  $Ir$ . In some situations, the terminal voltage may *exceed* the emf by an amount  $Ir$ . This happens when the direction of the current is *opposite* that of the emf, as in the case of charging a battery with another source of emf.

**Figure 28.2** (a) Circuit diagram of a source of emf  $\mathcal{E}$  (in this case, a battery), of internal resistance  $r$ , connected to an external resistor of resistance  $R$ . (b) Graphical representation showing how the electric potential changes as the circuit in part (a) is traversed clockwise.

$$\Delta V = \mathcal{E} - Ir \quad (28.1)$$

From this expression, note that  $\mathcal{E}$  is equivalent to the **open-circuit voltage**—that is, the *terminal voltage when the current is zero*. The emf is the voltage labeled on a battery—for example, the emf of a D cell is 1.5 V. The actual potential difference between the terminals of the battery depends on the current through the battery, as described by Equation 28.1.

Figure 28.2b is a graphical representation of the changes in electric potential as the circuit is traversed in the clockwise direction. By inspecting Figure 28.2a, we see that the terminal voltage  $\Delta V$  must equal the potential difference across the external resistance  $R$ , often called the **load resistance**. The load resistor might be a simple resistive circuit element, as in Figure 28.1, or it could be the resistance of some electrical device (such as a toaster, an electric heater, or a lightbulb) connected to the battery (or, in the case of household devices, to the wall outlet). The resistor represents a *load* on the battery because the battery must supply energy to operate the device. The potential difference across the load resistance is  $\Delta V = IR$ . Combining this expression with Equation 28.1, we see that

$$\mathcal{E} = IR + Ir \quad (28.2)$$

Solving for the current gives

$$I = \frac{\mathcal{E}}{R + r} \quad (28.3)$$

This equation shows that the current in this simple circuit depends on both the load resistance  $R$  external to the battery and the internal resistance  $r$ . If  $R$  is much greater than  $r$ , as it is in many real-world circuits, we can neglect  $r$ .

If we multiply Equation 28.2 by the current  $I$ , we obtain

$$I\mathcal{E} = I^2R + I^2r \quad (28.4)$$

This equation indicates that, because power  $\mathcal{P} = I\Delta V$  (see Eq. 27.22), the total power output  $I\mathcal{E}$  of the battery is delivered to the external load resistance in the amount  $I^2R$  and to the internal resistance in the amount  $I^2r$ . Again, if  $r \ll R$ , then most of the power delivered by the battery is transferred to the load resistance.

### EXAMPLE 28.1 Terminal Voltage of a Battery

A battery has an emf of 12.0 V and an internal resistance of 0.05  $\Omega$ . Its terminals are connected to a load resistance of 3.00  $\Omega$ . (a) Find the current in the circuit and the terminal voltage of the battery.

**Solution** Using first Equation 28.3 and then Equation 28.1, we obtain

$$I = \frac{\mathcal{E}}{R + r} = \frac{12.0 \text{ V}}{3.05 \Omega} = 3.93 \text{ A}$$

$$\Delta V = \mathcal{E} - Ir = 12.0 \text{ V} - (3.93 \text{ A})(0.05 \Omega) = 11.8 \text{ V}$$

To check this result, we can calculate the voltage across the load resistance  $R$ :

$$\Delta V = IR = (3.93 \text{ A})(3.00 \Omega) = 11.8 \text{ V}$$

(b) Calculate the power delivered to the load resistor, the power delivered to the internal resistance of the battery, and the power delivered by the battery.

**Solution** The power delivered to the load resistor is

$$\mathcal{P}_R = I^2R = (3.93 \text{ A})^2 (3.00 \Omega) = 46.3 \text{ W}$$

The power delivered to the internal resistance is

$$\mathcal{P}_r = I^2r = (3.93 \text{ A})^2 (0.05 \Omega) = 0.772 \text{ W}$$

Hence, the power delivered by the battery is the sum of these quantities, or 47.1 W. You should check this result, using the expression  $\mathcal{P} = I\mathcal{E}$ .

**EXAMPLE 28.2** Matching the Load

Show that the maximum power delivered to the load resistance  $R$  in Figure 28.2a occurs when the load resistance matches the internal resistance—that is, when  $R = r$ .

**Solution** The power delivered to the load resistance is equal to  $I^2R$ , where  $I$  is given by Equation 28.3:

$$\mathcal{P} = I^2R = \frac{\mathcal{E}^2R}{(R + r)^2}$$

When  $\mathcal{P}$  is plotted versus  $R$  as in Figure 28.3, we find that  $\mathcal{P}$  reaches a maximum value of  $\mathcal{E}^2/4r$  at  $R = r$ . We can also prove this by differentiating  $\mathcal{P}$  with respect to  $R$ , setting the result equal to zero, and solving for  $R$ . The details are left as a problem for you to solve (Problem 57).

**Figure 28.3** Graph of the power  $\mathcal{P}$  delivered by a battery to a load resistor of resistance  $R$  as a function of  $R$ . The power delivered to the resistor is a maximum when the load resistance equals the internal resistance of the battery.

**28.2 RESISTORS IN SERIES AND IN PARALLEL**

Suppose that you and your friends are at a crowded basketball game in a sports arena and decide to leave early. You have two choices: (1) your whole group can exit through a single door and walk down a long hallway containing several concession stands, each surrounded by a large crowd of people waiting to buy food or souvenirs; or (2) each member of your group can exit through a separate door in the main hall of the arena, where each will have to push his or her way through a single group of people standing by the door. In which scenario will less time be required for your group to leave the arena?

It should be clear that your group will be able to leave faster through the separate doors than down the hallway where each of you has to push through several groups of people. We could describe the groups of people in the hallway as acting in *series*, because each of you must push your way through all of the groups. The groups of people around the doors in the arena can be described as acting in *parallel*. Each member of your group must push through only one group of people, and each member pushes through a *different* group of people. This simple analogy will help us understand the behavior of currents in electric circuits containing more than one resistor.

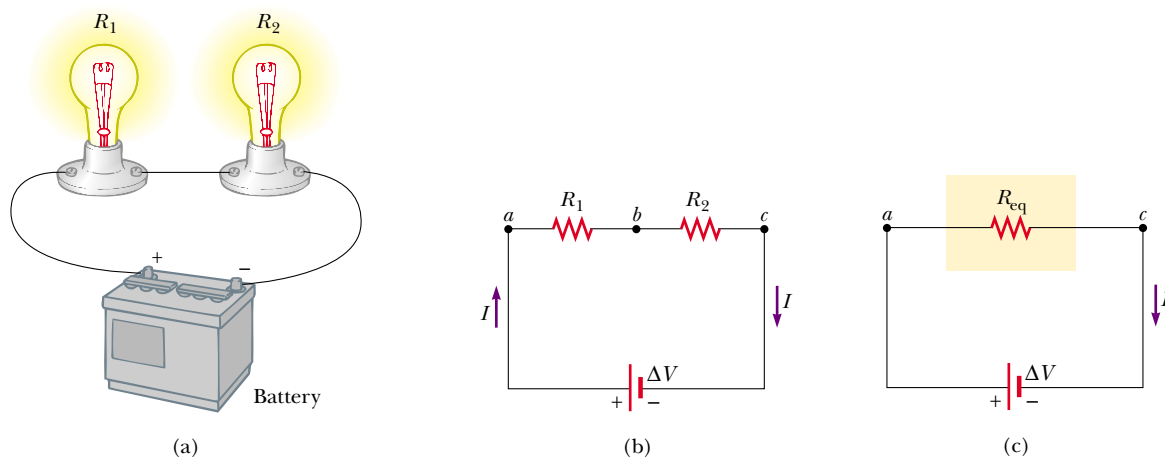

When two or more resistors are connected together as are the lightbulbs in Figure 28.4a, they are said to be in *series*. Figure 28.4b is the circuit diagram for the lightbulbs, which are shown as resistors, and the battery. In a series connection, all the charges moving through one resistor must also pass through the second resistor. (This is analogous to all members of your group pushing through the crowds in the single hallway of the sports arena.) Otherwise, charge would accumulate between the resistors. Thus,

for a series combination of resistors, the currents in the two resistors are the same because any charge that passes through  $R_1$  must also pass through  $R_2$ .

The potential difference applied across the series combination of resistors will divide between the resistors. In Figure 28.4b, because the voltage drop<sup>2</sup> from  $a$  to  $b$

<sup>2</sup> The term *voltage drop* is synonymous with a decrease in electric potential across a resistor and is used often by individuals working with electric circuits.

**Figure 28.4** (a) A series connection of two resistors  $R_1$  and  $R_2$ . The current in  $R_1$  is the same as that in  $R_2$ . (b) Circuit diagram for the two-resistor circuit. (c) The resistors replaced with a single resistor having an equivalent resistance  $R_{\text{eq}} = R_1 + R_2$ .

equals  $IR_1$  and the voltage drop from  $b$  to  $c$  equals  $IR_2$ , the voltage drop from  $a$  to  $c$  is

$$\Delta V = IR_1 + IR_2 = I(R_1 + R_2)$$

Therefore, we can replace the two resistors in series with a single resistor having an *equivalent resistance*  $R_{\text{eq}}$ , where

$$R_{\text{eq}} = R_1 + R_2 \quad (28.5)$$

The resistance  $R_{\text{eq}}$  is equivalent to the series combination  $R_1 + R_2$  in the sense that the circuit current is unchanged when  $R_{\text{eq}}$  replaces  $R_1 + R_2$ .

The equivalent resistance of three or more resistors connected in series is

$$R_{\text{eq}} = R_1 + R_2 + R_3 + \cdots \quad (28.6)$$

This relationship indicates that **the equivalent resistance of a series connection of resistors is always greater than any individual resistance.**

### Quick Quiz 28.1

If a piece of wire is used to connect points  $b$  and  $c$  in Figure 28.4b, does the brightness of bulb  $R_1$  increase, decrease, or stay the same? What happens to the brightness of bulb  $R_2$ ?

A series connection of three light-bulbs, all rated at 120 V but having power ratings of 60 W, 75 W, and 200 W. Why are the intensities of the bulbs different? Which bulb has the greatest resistance? How would their relative intensities differ if they were connected in parallel?

Now consider two resistors connected in *parallel*, as shown in Figure 28.5. When the current  $I$  reaches point  $a$  in Figure 28.5b, called a *junction*, it splits into two parts, with  $I_1$  going through  $R_1$  and  $I_2$  going through  $R_2$ . A **junction** is any point in a circuit where a current can split (just as your group might split up and leave the arena through several doors, as described earlier.) This split results in less current in each individual resistor than the current leaving the battery. Because charge must be conserved, the current  $I$  that enters point  $a$  must equal the total current leaving that point:

$$I = I_1 + I_2$$

**Figure 28.5** (a) A parallel connection of two resistors  $R_1$  and  $R_2$ . The potential difference across  $R_1$  is the same as that across  $R_2$ . (b) Circuit diagram for the two-resistor circuit. (c) The resistors replaced with a single resistor having an equivalent resistance  $R_{\text{eq}} = (R_1^{-1} + R_2^{-1})^{-1}$ .

As can be seen from Figure 28.5, both resistors are connected directly across the terminals of the battery. Thus,

when resistors are connected in parallel, the potential differences across them are the same.

Because the potential differences across the resistors are the same, the expression  $\Delta V = IR$  gives

$$I = I_1 + I_2 = \frac{\Delta V}{R_1} + \frac{\Delta V}{R_2} = \Delta V \left( \frac{1}{R_1} + \frac{1}{R_2} \right) = \frac{\Delta V}{R_{\text{eq}}}$$

From this result, we see that the equivalent resistance of two resistors in parallel is given by

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} \quad (28.7)$$

or

$$R_{\text{eq}} = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2}}$$

An extension of this analysis to three or more resistors in parallel gives

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \dots \quad (28.8)$$

### QuickLab

Tape one pair of drinking straws end to end, and tape a second pair side by side. Which pair is easier to blow through? What would happen if you were comparing three straws taped end to end with three taped side by side?

The equivalent resistance of several resistors in parallel

Three lightbulbs having power ratings of 25 W, 75 W, and 150 W, connected in parallel to a voltage source of about 100 V. All bulbs are rated at the same voltage. Why do the intensities differ? Which bulb draws the most current? Which has the least resistance?

We can see from this expression that **the equivalent resistance of two or more resistors connected in parallel is always less than the least resistance in the group.**

Household circuits are always wired such that the appliances are connected in parallel. Each device operates independently of the others so that if one is switched off, the others remain on. In addition, the devices operate on the same voltage.

### Quick Quiz 28.2

Assume that the battery of Figure 28.1 has zero internal resistance. If we add a second resistor in series with the first, does the current in the battery increase, decrease, or stay the same? How about the potential difference across the battery terminals? Would your answers change if the second resistor were connected in parallel to the first one?

### Quick Quiz 28.3

Are automobile headlights wired in series or in parallel? How can you tell?

### EXAMPLE 28.3 Find the Equivalent Resistance

Four resistors are connected as shown in Figure 28.6a. (a) Find the equivalent resistance between points  $a$  and  $c$ .

**Solution** The combination of resistors can be reduced in steps, as shown in Figure 28.6. The  $8.0\text{-}\Omega$  and  $4.0\text{-}\Omega$  resistors are in series; thus, the equivalent resistance between  $a$  and  $b$  is  $12\text{ }\Omega$  (see Eq. 28.5). The  $6.0\text{-}\Omega$  and  $3.0\text{-}\Omega$  resistors are in parallel, so from Equation 28.7 we find that the equivalent resistance from  $b$  to  $c$  is  $2.0\text{ }\Omega$ . Hence, the equivalent resistance from  $a$  to  $c$  is  $14\text{ }\Omega$ .

(b) What is the current in each resistor if a potential difference of 42 V is maintained between  $a$  and  $c$ ?

**Solution** The currents in the  $8.0\text{-}\Omega$  and  $4.0\text{-}\Omega$  resistors are the same because they are in series. In addition, this is the same as the current that would exist in the  $14\text{-}\Omega$  equivalent resistor subject to the 42-V potential difference. Therefore, using Equation 27.8 ( $R = \Delta V/I$ ) and the results from part (a), we obtain

$$I = \frac{\Delta V_{ac}}{R_{eq}} = \frac{42\text{ V}}{14\text{ }\Omega} = 3.0\text{ A}$$

This is the current in the  $8.0\text{-}\Omega$  and  $4.0\text{-}\Omega$  resistors. When this 3.0-A current enters the junction at  $b$ , however, it splits, with part passing through the  $6.0\text{-}\Omega$  resistor ( $I_1$ ) and part through the  $3.0\text{-}\Omega$  resistor ( $I_2$ ). Because the potential difference is  $\Delta V_{bc}$  across each of these resistors (since they are in parallel), we see that  $(6.0\text{ }\Omega)I_1 = (3.0\text{ }\Omega)I_2$ , or  $I_2 = 2I_1$ . Using this result and the fact that  $I_1 + I_2 = 3.0\text{ A}$ , we find that  $I_1 = 1.0\text{ A}$  and

$I_2 = 2.0\text{ A}$ . We could have guessed this at the start by noting that the current through the  $3.0\text{-}\Omega$  resistor has to be twice that through the  $6.0\text{-}\Omega$  resistor, in view of their relative resistances and the fact that the same voltage is applied to each of them.

As a final check of our results, note that  $\Delta V_{bc} = (6.0\text{ }\Omega)I_1 = (3.0\text{ }\Omega)I_2 = 6.0\text{ V}$  and  $\Delta V_{ab} = (12\text{ }\Omega)I = 36\text{ V}$ ; therefore,  $\Delta V_{ac} = \Delta V_{ab} + \Delta V_{bc} = 42\text{ V}$ , as it must.

Figure 28.6

**EXAMPLE 28.4** Three Resistors in Parallel

Three resistors are connected in parallel as shown in Figure 28.7. A potential difference of 18 V is maintained between points *a* and *b*. (a) Find the current in each resistor.

**Solution** The resistors are in parallel, and so the potential difference across each must be 18 V. Applying the relationship  $\Delta V = IR$  to each resistor gives

$$I_1 = \frac{\Delta V}{R_1} = \frac{18 \text{ V}}{3.0 \Omega} = 6.0 \text{ A}$$

$$I_2 = \frac{\Delta V}{R_2} = \frac{18 \text{ V}}{6.0 \Omega} = 3.0 \text{ A}$$

$$I_3 = \frac{\Delta V}{R_3} = \frac{18 \text{ V}}{9.0 \Omega} = 2.0 \text{ A}$$

(b) Calculate the power delivered to each resistor and the total power delivered to the combination of resistors.

**Solution** We apply the relationship  $\mathcal{P} = (\Delta V)^2/R$  to each resistor and obtain

$$\mathcal{P}_1 = \frac{\Delta V^2}{R_1} = \frac{(18 \text{ V})^2}{3.0 \Omega} = 110 \text{ W}$$

$$\mathcal{P}_2 = \frac{\Delta V^2}{R_2} = \frac{(18 \text{ V})^2}{6.0 \Omega} = 54 \text{ W}$$

$$\mathcal{P}_3 = \frac{\Delta V^2}{R_3} = \frac{(18 \text{ V})^2}{9.0 \Omega} = 36 \text{ W}$$

This shows that the smallest resistor receives the most power. Summing the three quantities gives a total power of 200 W.

(c) Calculate the equivalent resistance of the circuit.

**Solution** We can use Equation 28.8 to find  $R_{\text{eq}}$ :

$$\begin{aligned} \frac{1}{R_{\text{eq}}} &= \frac{1}{3.0 \Omega} + \frac{1}{6.0 \Omega} + \frac{1}{9.0 \Omega} \\ &= \frac{6}{18 \Omega} + \frac{3}{18 \Omega} + \frac{2}{18 \Omega} = \frac{11}{18 \Omega} \\ R_{\text{eq}} &= \frac{18 \Omega}{11} = 1.6 \Omega \end{aligned}$$

**Exercise** Use  $R_{\text{eq}}$  to calculate the total power delivered by the battery.

**Answer** 200 W.

**Figure 28.7** Three resistors connected in parallel. The voltage across each resistor is 18 V.

**EXAMPLE 28.5** Finding  $R_{\text{eq}}$  by Symmetry Arguments

Consider five resistors connected as shown in Figure 28.8a. Find the equivalent resistance between points *a* and *b*.

**Solution** In this type of problem, it is convenient to assume a current entering junction *a* and then apply symmetry

**Figure 28.8** Because of the symmetry in this circuit, the 5- $\Omega$  resistor does not contribute to the resistance between points *a* and *b* and therefore can be disregarded when we calculate the equivalent resistance.

arguments. Because of the symmetry in the circuit (all  $1\text{-}\Omega$  resistors in the outside loop), the currents in branches  $ac$  and  $ad$  must be equal; hence, the electric potentials at points  $c$  and  $d$  must be equal. This means that  $\Delta V_{cd} = 0$  and, as a result, points  $c$  and  $d$  may be connected together without affecting the circuit, as in Figure 28.8b. Thus, the  $5\text{-}\Omega$  resistor may

be removed from the circuit and the remaining circuit then reduced as in Figures 28.8c and d. From this reduction we see that the equivalent resistance of the combination is  $1\text{ }\Omega$ . Note that the result is  $1\text{ }\Omega$  regardless of the value of the resistor connected between  $c$  and  $d$ .

### CONCEPTUAL EXAMPLE 28.6 Operation of a Three-Way Lightbulb

Figure 28.9 illustrates how a three-way lightbulb is constructed to provide three levels of light intensity. The socket of the lamp is equipped with a three-way switch for selecting different light intensities. The bulb contains two filaments. When the lamp is connected to a  $120\text{-V}$  source, one filament receives  $100\text{ W}$  of power, and the other receives  $75\text{ W}$ . Explain how the two filaments are used to provide three different light intensities.

**Solution** The three light intensities are made possible by applying the  $120\text{ V}$  to one filament alone, to the other filament alone, or to the two filaments in parallel. When switch  $S_1$  is closed and switch  $S_2$  is opened, current passes only through the  $75\text{-W}$  filament. When switch  $S_1$  is open and switch  $S_2$  is closed, current passes only through the  $100\text{-W}$  filament. When both switches are closed, current passes through both filaments, and the total power is  $175\text{ W}$ .

If the filaments were connected in series and one of them were to break, no current could pass through the bulb, and the bulb would give no illumination, regardless of the switch position. However, with the filaments connected in parallel, if one of them (for example, the  $75\text{-W}$  filament) breaks, the bulb will still operate in two of the switch positions as current passes through the other ( $100\text{-W}$ ) filament.

**Exercise** Determine the resistances of the two filaments and their parallel equivalent resistance.

**Answer**  $144\text{ }\Omega$ ,  $192\text{ }\Omega$ ,  $82.3\text{ }\Omega$ .

Figure 28.9 A three-way lightbulb.

### APPLICATION Strings of Lights

Strings of lights are used for many ornamental purposes, such as decorating Christmas trees. Over the years, both parallel and series connections have been used for multilight strings powered by  $120\text{ V}$ .<sup>3</sup> Series-wired bulbs are safer than parallel-wired bulbs for indoor Christmas-tree use because series-wired bulbs operate with less light per bulb and at a lower temperature. However, if the filament of a single bulb fails (or if the bulb is removed from its socket), all the lights on the string are extinguished. The popularity of series-wired light strings diminished because troubleshooting a failed bulb was a tedious, time-consuming chore that involved trial-and-error substitution of a good bulb in each socket along the string until the defective bulb was found.

In a parallel-wired string, each bulb operates at  $120\text{ V}$ . By design, the bulbs are brighter and hotter than those on a series-wired string. As a result, these bulbs are inherently more dangerous (more likely to start a fire, for instance), but if one bulb in a parallel-wired string fails or is removed, the rest of the bulbs continue to glow. (A 25-bulb string of  $4\text{-W}$  bulbs results in a power of  $100\text{ W}$ ; the total power becomes substantial when several strings are used.)

A new design was developed for so-called “miniature” lights wired in series, to prevent the failure of one bulb from extinguishing the entire string. The solution is to create a connection (called a jumper) across the filament after it fails. (If an alternate connection existed across the filament before

<sup>3</sup> These and other household devices, such as the three-way lightbulb in Conceptual Example 28.6 and the kitchen appliances shown in this chapter’s Puzzler, actually operate on alternating current (ac), to be introduced in Chapter 33.

it failed, each bulb would represent a parallel circuit; in this circuit, the current would flow through the alternate connection, forming a short circuit, and the bulb would not glow.) When the filament breaks in one of these miniature lightbulbs, 120 V appears across the bulb because no current is present in the bulb and therefore no drop in potential occurs across the other bulbs. Inside the lightbulb, a small loop covered by an insulating material is wrapped around the filament leads. An arc burns the insulation and connects the filament leads when 120 V appears across the bulb—that is, when the filament fails. This “short” now completes the circuit through the bulb even though the filament is no longer active (Fig. 28.10).

Suppose that all the bulbs in a 50-bulb miniature-light string are operating. A 2.4-V potential drop occurs across each bulb because the bulbs are in series. The power input to this style of bulb is 0.34 W, so the total power supplied to the string is only 17 W. We calculate the filament resistance at the operating temperature to be  $(2.4 \text{ V})^2 / (0.34 \text{ W}) = 17 \Omega$ . When the bulb fails, the resistance across its terminals is reduced to zero because of the alternate jumper connection mentioned in the preceding paragraph. All the other bulbs not only stay on but glow more brightly because the total resistance of the string is reduced and consequently the current in each bulb increases.

Let us assume that the operating resistance of a bulb remains at  $17 \Omega$  even though its temperature rises as a result of the increased current. If one bulb fails, the potential drop across each of the remaining bulbs increases to 2.45 V, the current increases from 0.142 A to 0.145 A, and the power increases to 0.354 W. As more lights fail, the current keeps rising, the filament of each bulb operates at a higher temperature, and the lifetime of the bulb is reduced. It is therefore a good idea to check for failed (nonglowing) bulbs in such a series-wired string and replace them as soon as possible, in order to maximize the lifetimes of all the bulbs.

**Figure 28.10** (a) Schematic diagram of a modern “miniature” holiday lightbulb, with a jumper connection to provide a current path if the filament breaks. (b) A Christmas-tree lightbulb.

## 28.3 KIRCHHOFF'S RULES

**13.4** As we saw in the preceding section, we can analyze simple circuits using the expression  $\Delta V = IR$  and the rules for series and parallel combinations of resistors. Very often, however, it is not possible to reduce a circuit to a single loop. The procedure for analyzing more complex circuits is greatly simplified if we use two principles called **Kirchhoff's rules**:

1. The sum of the currents entering any junction in a circuit must equal the sum of the currents leaving that junction:

$$\sum I_{\text{in}} = \sum I_{\text{out}} \quad (28.9)$$

**Gustav Kirchhoff (1824–1887)**

Kirchhoff, a professor at Heidelberg, Germany, and Robert Bunsen invented the spectroscope and founded the science of spectroscopy, which we shall study in Chapter 40. They discovered the elements cesium and rubidium and invented astronomical spectroscopy. Kirchhoff formulated another Kirchhoff's rule, namely, "a cool substance will absorb light of the same wavelengths that it emits when hot." (AIP ESVA/W. F. Meggers Collection)

**QuickLab**

Draw an arbitrarily shaped closed loop that does not cross over itself. Label five points on the loop  $a$ ,  $b$ ,  $c$ ,  $d$ , and  $e$ , and assign a random number to each point. Now start at  $a$  and work your way around the loop, calculating the difference between each pair of adjacent numbers. Some of these differences will be positive, and some will be negative. Add the differences together, making sure you accurately keep track of the algebraic signs. What is the sum of the differences all the way around the loop?

2. The sum of the potential differences across all elements around any closed circuit loop must be zero:

$$\sum_{\text{closed loop}} \Delta V = 0 \quad (28.10)$$

Kirchhoff's first rule is a statement of conservation of electric charge. All current that enters a given point in a circuit must leave that point because charge cannot build up at a point. If we apply this rule to the junction shown in Figure 28.11a, we obtain

$$I_1 = I_2 + I_3$$

Figure 28.11b represents a mechanical analog of this situation, in which water flows through a branched pipe having no leaks. The flow rate into the pipe equals the total flow rate out of the two branches on the right.

Kirchhoff's second rule follows from the law of conservation of energy. Let us imagine moving a charge around the loop. When the charge returns to the starting point, the charge–circuit system must have the same energy as when the charge started from it. The sum of the increases in energy in some circuit elements must equal the sum of the decreases in energy in other elements. The potential energy decreases whenever the charge moves through a potential drop  $-IR$  across a resistor or whenever it moves in the reverse direction through a source of emf. The potential energy increases whenever the charge passes through a battery from the negative terminal to the positive terminal. Kirchhoff's second rule applies only for circuits in which an electric potential is defined at each point; this criterion may not be satisfied if changing electromagnetic fields are present, as we shall see in Chapter 31.

In justifying our claim that Kirchhoff's second rule is a statement of conservation of energy, we imagined carrying a charge around a loop. When applying this rule, we imagine *traveling* around the loop and consider changes in *electric potential*, rather than the changes in *potential energy* described in the previous paragraph. You should note the following sign conventions when using the second rule:

- Because charges move from the high-potential end of a resistor to the low-potential end, if a resistor is traversed in the direction of the current, the change in potential  $\Delta V$  across the resistor is  $-IR$  (Fig. 28.12a).
- If a resistor is traversed in the direction *opposite* the current, the change in potential  $\Delta V$  across the resistor is  $+IR$  (Fig. 28.12b).
- If a source of emf (assumed to have zero internal resistance) is traversed in the direction of the emf (from  $-$  to  $+$ ), the change in potential  $\Delta V$  is  $+\mathcal{E}$  (Fig. 28.12c). The emf of the battery increases the electric potential as we move through it in this direction.
- If a source of emf (assumed to have zero internal resistance) is traversed in the direction opposite the emf (from  $+$  to  $-$ ), the change in potential  $\Delta V$  is  $-\mathcal{E}$  (Fig. 28.12d). In this case the emf of the battery reduces the electric potential as we move through it.

Limitations exist on the numbers of times you can usefully apply Kirchhoff's rules in analyzing a given circuit. You can use the junction rule as often as you need, so long as each time you write an equation you include in it a current that has not been used in a preceding junction-rule equation. In general, the number of times you can use the junction rule is one fewer than the number of junction

**Figure 28.11** (a) Kirchhoff's junction rule. Conservation of charge requires that all current entering a junction must leave that junction. Therefore,  $I_1 = I_2 + I_3$ . (b) A mechanical analog of the junction rule: the amount of water flowing out of the branches on the right must equal the amount flowing into the single branch on the left.

**Figure 28.12** Rules for determining the potential changes across a resistor and a battery. (The battery is assumed to have no internal resistance.) Each circuit element is traversed from left to right.

points in the circuit. You can apply the loop rule as often as needed, so long as a new circuit element (resistor or battery) or a new current appears in each new equation. In general, **in order to solve a particular circuit problem, the number of independent equations you need to obtain from the two rules equals the number of unknown currents.**

Complex networks containing many loops and junctions generate great numbers of independent linear equations and a correspondingly great number of unknowns. Such situations can be handled formally through the use of matrix algebra. Computer programs can also be written to solve for the unknowns.

The following examples illustrate how to use Kirchhoff's rules. In all cases, it is assumed that the circuits have reached steady-state conditions—that is, the currents in the various branches are constant. Any capacitor **acts as an open circuit**; that is, the current in the branch containing the capacitor is zero under steady-state conditions.

## Problem-Solving Hints

### Kirchhoff's Rules

- Draw a circuit diagram, and label all the known and unknown quantities. You must assign a *direction* to the current in each branch of the circuit. Do not be alarmed if you guess the direction of a current incorrectly; your result will be negative, but *its magnitude will be correct*. Although the assignment of current directions is arbitrary, you must adhere rigorously to the assigned directions when applying Kirchhoff's rules.
- Apply the junction rule to any junctions in the circuit that provide new relationships among the various currents.

- Apply the loop rule to as many loops in the circuit as are needed to solve for the unknowns. To apply this rule, you must correctly identify the change in potential as you imagine crossing each element in traversing the closed loop (either clockwise or counterclockwise). Watch out for errors in sign!
- Solve the equations simultaneously for the unknown quantities.

### EXAMPLE 28.7 A Single-Loop Circuit

A single-loop circuit contains two resistors and two batteries, as shown in Figure 28.13. (Neglect the internal resistances of the batteries.) (a) Find the current in the circuit.

**Solution** We do not need Kirchhoff's rules to analyze this simple circuit, but let us use them anyway just to see how they are applied. There are no junctions in this single-loop circuit; thus, the current is the same in all elements. Let us assume that the current is clockwise, as shown in Figure 28.13. Traversing the circuit in the clockwise direction, starting at  $a$ , we see that  $a \rightarrow b$  represents a potential change of  $+\mathcal{E}_1$ ,  $b \rightarrow c$  represents a potential change of  $-IR_1$ ,  $c \rightarrow d$  represents a potential change of  $-\mathcal{E}_2$ , and  $d \rightarrow a$  represents a potential change of  $-IR_2$ . Applying Kirchhoff's loop rule gives

**Figure 28.13** A series circuit containing two batteries and two resistors, where the polarities of the batteries are in opposition.

$$\sum \Delta V = 0$$

$$\mathcal{E}_1 - IR_1 - \mathcal{E}_2 - IR_2 = 0$$

Solving for  $I$  and using the values given in Figure 28.13, we obtain

$$I = \frac{\mathcal{E}_1 - \mathcal{E}_2}{R_1 + R_2} = \frac{6.0 \text{ V} - 12 \text{ V}}{8.0 \Omega + 10 \Omega} = -0.33 \text{ A}$$

The negative sign for  $I$  indicates that the direction of the current is opposite the assumed direction.

(b) What power is delivered to each resistor? What power is delivered by the 12-V battery?

### Solution

$$\mathcal{P}_1 = I^2 R_1 = (0.33 \text{ A})^2 (8.0 \Omega) = 0.87 \text{ W}$$

$$\mathcal{P}_2 = I^2 R_2 = (0.33 \text{ A})^2 (10 \Omega) = 1.1 \text{ W}$$

Hence, the total power delivered to the resistors is  $\mathcal{P}_1 + \mathcal{P}_2 = 2.0 \text{ W}$ .

The 12-V battery delivers power  $I\mathcal{E}_2 = 4.0 \text{ W}$ . Half of this power is delivered to the two resistors, as we just calculated. The other half is delivered to the 6-V battery, which is being charged by the 12-V battery. If we had included the internal resistances of the batteries in our analysis, some of the power would appear as internal energy in the batteries; as a result, we would have found that less power was being delivered to the 6-V battery.

### EXAMPLE 28.8 Applying Kirchhoff's Rules

Find the currents  $I_1$ ,  $I_2$ , and  $I_3$  in the circuit shown in Figure 28.14.

**Solution** Notice that we cannot reduce this circuit to a simpler form by means of the rules of adding resistances in series and in parallel. We must use Kirchhoff's rules to analyze this circuit. We arbitrarily choose the directions of the currents as labeled in Figure 28.14. Applying Kirchhoff's junction rule to junction  $c$  gives

$$(1) \quad I_1 + I_2 = I_3$$

We now have one equation with three unknowns— $I_1$ ,  $I_2$ , and  $I_3$ . There are three loops in the circuit— $abcd$ ,  $befcb$ , and  $aefda$ . We therefore need only two loop equations to determine the unknown currents. (The third loop equation would give no new information.) Applying Kirchhoff's loop rule to loops  $abcd$  and  $befcb$  and traversing these loops clockwise, we obtain the expressions

$$(2) \quad abcd \quad 10 \text{ V} - (6 \Omega)I_1 - (2 \Omega)I_3 = 0$$

$$(3) \quad befcb \quad -14 \text{ V} + (6 \Omega)I_1 - 10 \text{ V} - (4 \Omega)I_2 = 0$$

Note that in loop *befcb* we obtain a positive value when traversing the  $6\text{-}\Omega$  resistor because our direction of travel is opposite the assumed direction of  $I_1$ .

Expressions (1), (2), and (3) represent three independent equations with three unknowns. Substituting Equation (1) into Equation (2) gives

$$10\text{ V} - (6\ \Omega)I_1 - (2\ \Omega)(I_1 + I_2) = 0$$

$$(4) \quad 10\text{ V} = (8\ \Omega)I_1 + (2\ \Omega)I_2$$

Dividing each term in Equation (3) by 2 and rearranging gives

**Figure 28.14** A circuit containing three loops.

$$(5) \quad -12\text{ V} = -(3\ \Omega)I_1 + (2\ \Omega)I_2$$

Subtracting Equation (5) from Equation (4) eliminates  $I_2$ , giving

$$22\text{ V} = (11\ \Omega)I_1$$

$$I_1 = 2\text{ A}$$

Using this value of  $I_1$  in Equation (5) gives a value for  $I_2$ :

$$(2\ \Omega)I_2 = (3\ \Omega)I_1 - 12\text{ V} = (3\ \Omega)(2\text{ A}) - 12\text{ V} = -6\text{ V}$$

$$I_2 = -3\text{ A}$$

Finally,

$$I_3 = I_1 + I_2 = -1\text{ A}$$

The fact that  $I_2$  and  $I_3$  are both negative indicates only that the currents are opposite the direction we chose for them. However, the numerical values are correct. What would have happened had we left the current directions as labeled in Figure 28.14 but traversed the loops in the opposite direction?

**Exercise** Find the potential difference between points *b* and *c*.

**Answer** 2 V.

### EXAMPLE 28.9 A Multiloop Circuit

(a) Under steady-state conditions, find the unknown currents  $I_1$ ,  $I_2$ , and  $I_3$  in the multiloop circuit shown in Figure 28.15.

**Solution** First note that because the capacitor represents an open circuit, there is no current between *g* and *b* along path *ghab* under steady-state conditions. Therefore, when the charges associated with  $I_1$  reach point *g*, they all go through the  $8.00\text{-V}$  battery to point *b*; hence,  $I_{gb} = I_1$ . Labeling the currents as shown in Figure 28.15 and applying Equation 28.9 to junction *c*, we obtain

$$(1) \quad I_1 + I_2 = I_3$$

Equation 28.10 applied to loops *defcd* and *cfghc*, traversed clockwise, gives

$$(2) \quad \text{defcd} \quad 4.00\text{ V} - (3.00\ \Omega)I_2 - (5.00\ \Omega)I_3 = 0$$

$$(3) \quad \text{cfghc} \quad (3.00\ \Omega)I_2 - (5.00\ \Omega)I_1 + 8.00\text{ V} = 0$$

From Equation (1) we see that  $I_1 = I_3 - I_2$ , which, when substituted into Equation (3), gives

$$(4) \quad (8.00\ \Omega)I_2 - (5.00\ \Omega)I_3 + 8.00\text{ V} = 0$$

Subtracting Equation (4) from Equation (2), we eliminate  $I_3$  and find that

$$I_2 = -\frac{4.00\text{ V}}{11.0\ \Omega} = -0.364\text{ A}$$

Because our value for  $I_2$  is negative, we conclude that the direction of  $I_2$  is from *c* to *f* through the  $3.00\text{-}\Omega$  resistor. Despite

**Figure 28.15** A multiloop circuit. Kirchoff's loop rule can be applied to any closed loop, including the one containing the capacitor.

this interpretation of the direction, however, we must continue to use this negative value for  $I_2$  in subsequent calculations because our equations were established with our original choice of direction.

Using  $I_2 = -0.364$  A in Equations (3) and (1) gives

$$I_1 = 1.38 \text{ A} \quad I_3 = 1.02 \text{ A}$$

(b) What is the charge on the capacitor?

**Solution** We can apply Kirchhoff's loop rule to loop *bghab* (or any other loop that contains the capacitor) to find the potential difference  $\Delta V_{\text{cap}}$  across the capacitor. We enter this potential difference in the equation without reference to a sign convention because the charge on the capacitor depends only on the magnitude of the potential difference. Moving clockwise around this loop, we obtain

$$\begin{aligned} -8.00 \text{ V} + \Delta V_{\text{cap}} - 3.00 \text{ V} &= 0 \\ \Delta V_{\text{cap}} &= 11.0 \text{ V} \end{aligned}$$

Because  $Q = C \Delta V_{\text{cap}}$  (see Eq. 26.1), the charge on the capacitor is

$$Q = (6.00 \mu\text{F})(11.0 \text{ V}) = 66.0 \mu\text{C}$$

Why is the left side of the capacitor positively charged?

**Exercise** Find the voltage across the capacitor by traversing any other loop.

**Answer** 11.0 V.

**Exercise** Reverse the direction of the 3.00-V battery and answer parts (a) and (b) again.

**Answer** (a)  $I_1 = 1.38$  A,  $I_2 = -0.364$  A,  $I_3 = 1.02$  A; (b) 30  $\mu\text{C}$ .

## 28.4 RC CIRCUITS

So far we have been analyzing steady-state circuits, in which the current is constant. In circuits containing capacitors, the current may vary in time. A circuit containing a series combination of a resistor and a capacitor is called an **RC circuit**.

### Charging a Capacitor

Let us assume that the capacitor in Figure 28.16 is initially uncharged. There is no current while switch S is open (Fig. 28.16b). If the switch is closed at  $t = 0$ , however, charge begins to flow, setting up a current in the circuit, and the capacitor begins to charge.<sup>4</sup> Note that during charging, charges do not jump across the capacitor plates because the gap between the plates represents an open circuit. Instead, charge is transferred between each plate and its connecting wire due to the electric field established in the wires by the battery, until the capacitor is fully charged. As the plates become charged, the potential difference across the capacitor increases. The value of the maximum charge depends on the voltage of the battery. Once the maximum charge is reached, the current in the circuit is zero because the potential difference across the capacitor matches that supplied by the battery.

To analyze this circuit quantitatively, let us apply Kirchhoff's loop rule to the circuit after the switch is closed. Traversing the loop clockwise gives

$$\mathcal{E} - \frac{q}{C} - IR = 0 \quad (28.11)$$

where  $q/C$  is the potential difference across the capacitor and  $IR$  is the potential

<sup>4</sup> In previous discussions of capacitors, we assumed a steady-state situation, in which no current was present in any branch of the circuit containing a capacitor. Now we are considering the case *before* the steady-state condition is realized; in this situation, charges are moving and a current exists in the wires connected to the capacitor.

**Figure 28.16** (a) A capacitor in series with a resistor, switch, and battery. (b) Circuit diagram representing this system at time  $t < 0$ , before the switch is closed. (c) Circuit diagram at time  $t > 0$ , after the switch has been closed.

difference across the resistor. We have used the sign conventions discussed earlier for the signs on  $\mathcal{E}$  and  $IR$ . For the capacitor, notice that we are traveling in the direction from the positive plate to the negative plate; this represents a decrease in potential. Thus, we use a negative sign for this voltage in Equation 28.11. Note that  $q$  and  $I$  are *instantaneous* values that depend on time (as opposed to steady-state values) as the capacitor is being charged.

We can use Equation 28.11 to find the initial current in the circuit and the maximum charge on the capacitor. At the instant the switch is closed ( $t = 0$ ), the charge on the capacitor is zero, and from Equation 28.11 we find that the initial current in the circuit  $I_0$  is a maximum and is equal to

$$I_0 = \frac{\mathcal{E}}{R} \quad (\text{current at } t = 0) \quad (28.12)$$

Maximum current

At this time, the potential difference from the battery terminals appears entirely across the resistor. Later, when the capacitor is charged to its maximum value  $Q$ , charges cease to flow, the current in the circuit is zero, and the potential difference from the battery terminals appears entirely across the capacitor. Substituting  $I = 0$  into Equation 28.11 gives the charge on the capacitor at this time:

$$Q = C\mathcal{E} \quad (\text{maximum charge}) \quad (28.13)$$

Maximum charge on the capacitor

To determine analytical expressions for the time dependence of the charge and current, we must solve Equation 28.11—a single equation containing two variables,  $q$  and  $I$ . The current in all parts of the series circuit must be the same. Thus, the current in the resistance  $R$  must be the same as the current flowing out of and into the capacitor plates. This current is equal to the time rate of change of the charge on the capacitor plates. Thus, we substitute  $I = dq/dt$  into Equation 28.11 and rearrange the equation:

$$\frac{dq}{dt} = \frac{\mathcal{E}}{R} - \frac{q}{RC}$$

To find an expression for  $q$ , we first combine the terms on the right-hand side:

$$\frac{dq}{dt} = \frac{C\mathcal{E}}{RC} - \frac{q}{RC} = -\frac{q - C\mathcal{E}}{RC}$$

Now we multiply by  $dt$  and divide by  $q - C\mathcal{E}$  to obtain

$$\frac{dq}{q - C\mathcal{E}} = -\frac{1}{RC} dt$$

Integrating this expression, using the fact that  $q = 0$  at  $t = 0$ , we obtain

$$\int_0^q \frac{dq}{q - C\mathcal{E}} = -\frac{1}{RC} \int_0^t dt$$

$$\ln\left(\frac{q - C\mathcal{E}}{-C\mathcal{E}}\right) = -\frac{t}{RC}$$

From the definition of the natural logarithm, we can write this expression as

Charge versus time for a capacitor being charged

$$q(t) = C\mathcal{E} (1 - e^{-t/RC}) = Q(1 - e^{-t/RC}) \quad (28.14)$$

where  $e$  is the base of the natural logarithm and we have made the substitution  $C\mathcal{E} = Q$  from Equation 28.13.

We can find an expression for the charging current by differentiating Equation 28.14 with respect to time. Using  $I = dq/dt$ , we find that

Current versus time for a charging capacitor

$$I(t) = \frac{\mathcal{E}}{R} e^{-t/RC} \quad (28.15)$$

Plots of capacitor charge and circuit current versus time are shown in Figure 28.17. Note that the charge is zero at  $t = 0$  and approaches the maximum value  $C\mathcal{E}$  as  $t \rightarrow \infty$ . The current has its maximum value  $I_0 = \mathcal{E}/R$  at  $t = 0$  and decays exponentially to zero as  $t \rightarrow \infty$ . The quantity  $RC$ , which appears in the exponents of Equations 28.14 and 28.15, is called the **time constant**  $\tau$  of the circuit. It represents the time it takes the current to decrease to  $1/e$  of its initial value; that is, in a time  $\tau$ ,  $I = e^{-1}I_0 = 0.368I_0$ . In a time  $2\tau$ ,  $I = e^{-2}I_0 = 0.135I_0$ , and so forth. Likewise, in a time  $\tau$ , the charge increases from zero to  $C\mathcal{E} (1 - e^{-1}) = 0.632C\mathcal{E}$ .

The following dimensional analysis shows that  $\tau$  has the units of time:

$$[\tau] = [RC] = \left[ \frac{\Delta V}{I} \times \frac{Q}{\Delta V} \right] = \left[ \frac{Q}{Q/\Delta t} \right] = [\Delta t] = \text{T}$$

**Figure 28.17** (a) Plot of capacitor charge versus time for the circuit shown in Figure 28.16. After a time interval equal to one time constant  $\tau$  has passed, the charge is 63.2% of the maximum value  $C\mathcal{E}$ . The charge approaches its maximum value as  $t$  approaches infinity. (b) Plot of current versus time for the circuit shown in Figure 28.16. The current has its maximum value  $I_0 = \mathcal{E}/R$  at  $t = 0$  and decays to zero exponentially as  $t$  approaches infinity. After a time interval equal to one time constant  $\tau$  has passed, the current is 36.8% of its initial value.

Because  $\tau = RC$  has units of time, the combination  $t/RC$  is dimensionless, as it must be in order to be an exponent of  $e$  in Equations 28.14 and 28.15.

The energy output of the battery as the capacitor is fully charged is  $Q\mathcal{E} = C\mathcal{E}^2$ . After the capacitor is fully charged, the energy stored in the capacitor is  $\frac{1}{2}Q\mathcal{E} = \frac{1}{2}C\mathcal{E}^2$ , which is just half the energy output of the battery. It is left as a problem (Problem 60) to show that the remaining half of the energy supplied by the battery appears as internal energy in the resistor.

### Discharging a Capacitor

Now let us consider the circuit shown in Figure 28.18, which consists of a capacitor carrying an initial charge  $Q$ , a resistor, and a switch. The *initial* charge  $Q$  is not the same as the *maximum* charge  $Q$  in the previous discussion, unless the discharge occurs after the capacitor is fully charged (as described earlier). When the switch is open, a potential difference  $Q/C$  exists across the capacitor and there is zero potential difference across the resistor because  $I = 0$ . If the switch is closed at  $t = 0$ , the capacitor begins to discharge through the resistor. At some time  $t$  during the discharge, the current in the circuit is  $I$  and the charge on the capacitor is  $q$  (Fig. 28.18b). The circuit in Figure 28.18 is the same as the circuit in Figure 28.16 except for the absence of the battery. Thus, we eliminate the emf  $\mathcal{E}$  from Equation 28.11 to obtain the appropriate loop equation for the circuit in Figure 28.18:

$$-\frac{q}{C} - IR = 0 \quad (28.16)$$

When we substitute  $I = dq/dt$  into this expression, it becomes

$$\begin{aligned} -R \frac{dq}{dt} &= \frac{q}{C} \\ \frac{dq}{q} &= -\frac{1}{RC} dt \end{aligned}$$

Integrating this expression, using the fact that  $q = Q$  at  $t = 0$ , gives

$$\begin{aligned} \int_Q^q \frac{dq}{q} &= -\frac{1}{RC} \int_0^t dt \\ \ln\left(\frac{q}{Q}\right) &= -\frac{t}{RC} \end{aligned}$$

$$q(t) = Qe^{-t/RC} \quad (28.17)$$

Differentiating this expression with respect to time gives the instantaneous current as a function of time:

$$I(t) = \frac{dq}{dt} = \frac{d}{dt} (Qe^{-t/RC}) = -\frac{Q}{RC} e^{-t/RC} \quad (28.18)$$

where  $Q/RC = I_0$  is the initial current. The negative sign indicates that the current direction now that the capacitor is discharging is opposite the current direction when the capacitor was being charged. (Compare the current directions in Figs. 28.16c and 28.18b.) We see that both the charge on the capacitor and the current decay exponentially at a rate characterized by the time constant  $\tau = RC$ .

**Figure 28.18** (a) A charged capacitor connected to a resistor and a switch, which is open at  $t < 0$ . (b) After the switch is closed, a current that decreases in magnitude with time is set up in the direction shown, and the charge on the capacitor decreases exponentially with time.

Charge versus time for a discharging capacitor

Current versus time for a discharging capacitor

**CONCEPTUAL EXAMPLE 28.10** Intermittent Windshield Wipers

Many automobiles are equipped with windshield wipers that can operate intermittently during a light rainfall. How does the operation of such wipers depend on the charging and discharging of a capacitor?

**Solution** The wipers are part of an  $RC$  circuit whose time constant can be varied by selecting different values of  $R$

through a multiposition switch. As it increases with time, the voltage across the capacitor reaches a point at which it triggers the wipers and discharges, ready to begin another charging cycle. The time interval between the individual sweeps of the wipers is determined by the value of the time constant.

**EXAMPLE 28.11** Charging a Capacitor in an  $RC$  Circuit

An uncharged capacitor and a resistor are connected in series to a battery, as shown in Figure 28.19. If  $\mathcal{E} = 12.0$  V,  $C = 5.00$   $\mu\text{F}$ , and  $R = 8.00 \times 10^5$   $\Omega$ , find the time constant of the circuit, the maximum charge on the capacitor, the maximum current in the circuit, and the charge and current as functions of time.

**Solution** The time constant of the circuit is  $\tau = RC = (8.00 \times 10^5 \Omega)(5.00 \times 10^{-6} \text{ F}) = 4.00$  s. The maximum charge on the capacitor is  $Q = C\mathcal{E} = (5.00 \mu\text{F})(12.0 \text{ V}) = 60.0$   $\mu\text{C}$ . The maximum current in the circuit is  $I_0 = \mathcal{E}/R = (12.0 \text{ V})/(8.00 \times 10^5 \Omega) = 15.0$   $\mu\text{A}$ . Using these values and Equations 28.14 and 28.15, we find that

$$q(t) = (60.0 \mu\text{C})(1 - e^{-t/4.00 \text{ s}})$$

$$I(t) = (15.0 \mu\text{A})e^{-t/4.00 \text{ s}}$$

Graphs of these functions are provided in Figure 28.20.

**Figure 28.19** The switch of this series  $RC$  circuit, open for times  $t < 0$ , is closed at  $t = 0$ .

**Exercise** Calculate the charge on the capacitor and the current in the circuit after one time constant has elapsed.

**Answer** 37.9  $\mu\text{C}$ , 5.52  $\mu\text{A}$ .

**Figure 28.20** Plots of (a) charge versus time and (b) current versus time for the  $RC$  circuit shown in Figure 28.19, with  $\mathcal{E} = 12.0$  V,  $R = 8.00 \times 10^5$   $\Omega$ , and  $C = 5.00$   $\mu\text{F}$ .

**EXAMPLE 28.12** Discharging a Capacitor in an  $RC$  Circuit

Consider a capacitor of capacitance  $C$  that is being discharged through a resistor of resistance  $R$ , as shown in Figure 28.18. (a) After how many time constants is the charge on the capacitor one-fourth its initial value?

**Solution** The charge on the capacitor varies with time according to Equation 28.17,  $q(t) = Qe^{-t/RC}$ . To find the time it takes  $q$  to drop to one-fourth its initial value, we substitute  $q(t) = Q/4$  into this expression and solve for  $t$ :

$$\frac{Q}{4} = Qe^{-t/RC}$$

$$\frac{1}{4} = e^{-t/RC}$$

Taking logarithms of both sides, we find

$$-\ln 4 = -\frac{t}{RC}$$

$$t = RC(\ln 4) = 1.39RC = 1.39\tau$$

(b) The energy stored in the capacitor decreases with time as the capacitor discharges. After how many time constants is this stored energy one-fourth its initial value?

**Solution** Using Equations 26.11 ( $U = Q^2/2C$ ) and 28.17, we can express the energy stored in the capacitor at any time  $t$  as

$$U = \frac{q^2}{2C} = \frac{(Qe^{-t/RC})^2}{2C} = \frac{Q^2}{2C} e^{-2t/RC} = U_0 e^{-2t/RC}$$

where  $U_0 = Q^2/2C$  is the initial energy stored in the capacitor. As in part (a), we now set  $U = U_0/4$  and solve for  $t$ :

$$\frac{U_0}{4} = U_0 e^{-2t/RC}$$

$$\frac{1}{4} = e^{-2t/RC}$$

Again, taking logarithms of both sides and solving for  $t$  gives

$$t = \frac{1}{2}RC(\ln 4) = 0.693RC = 0.693\tau$$

**Exercise** After how many time constants is the current in the circuit one-half its initial value?

**Answer**  $0.693RC = 0.693\tau$ .

### EXAMPLE 28.13 Energy Delivered to a Resistor

A  $5.00\text{-}\mu\text{F}$  capacitor is charged to a potential difference of  $800\text{ V}$  and then discharged through a  $25.0\text{-k}\Omega$  resistor. How much energy is delivered to the resistor in the time it takes to fully discharge the capacitor?

**Solution** We shall solve this problem in two ways. The first way is to note that the initial energy in the circuit equals the energy stored in the capacitor,  $C\mathcal{E}^2/2$  (see Eq. 26.11). Once the capacitor is fully discharged, the energy stored in it is zero. Because energy is conserved, the initial energy stored in the capacitor is transformed into internal energy in the resistor. Using the given values of  $C$  and  $\mathcal{E}$ , we find

$$\text{Energy} = \frac{1}{2}C\mathcal{E}^2 = \frac{1}{2}(5.00 \times 10^{-6}\text{ F})(800\text{ V})^2 = 1.60\text{ J}$$

The second way, which is more difficult but perhaps more instructive, is to note that as the capacitor discharges through the resistor, the rate at which energy is delivered to the resistor is given by  $I^2R$ , where  $I$  is the instantaneous current given by Equation 28.18. Because power is defined as the time rate of change of energy, we conclude that the energy delivered to the resistor must equal the time integral of  $I^2R dt$ :

$$\text{Energy} = \int_0^\infty I^2 R dt = \int_0^\infty (I_0 e^{-t/RC})^2 R dt$$

To evaluate this integral, we note that the initial current  $I_0$  is equal to  $\mathcal{E}/R$  and that all parameters except  $t$  are constant. Thus, we find

$$(1) \quad \text{Energy} = \frac{\mathcal{E}^2}{R} \int_0^\infty e^{-2t/RC} dt$$

This integral has a value of  $RC/2$ ; hence, we find

$$\text{Energy} = \frac{1}{2}C\mathcal{E}^2$$

which agrees with the result we obtained using the simpler approach, as it must. Note that we can use this second approach to find the total energy delivered to the resistor at any time after the switch is closed by simply replacing the upper limit in the integral with that specific value of  $t$ .

**Exercise** Show that the integral in Equation (1) has the value  $RC/2$ .

## 28.5 ELECTRICAL INSTRUMENTS

### The Ammeter

A device that measures current is called an **ammeter**. The current to be measured must pass directly through the ammeter, so the ammeter must be connected in se-

**Figure 28.21** Current can be measured with an ammeter connected in series with the resistor and battery of a circuit. An ideal ammeter has zero resistance.

**Figure 28.22** The potential difference across a resistor can be measured with a voltmeter connected in parallel with the resistor. An ideal voltmeter has infinite resistance.

ries with other elements in the circuit, as shown in Figure 28.21. When using an ammeter to measure direct currents, you must be sure to connect it so that current enters the instrument at the positive terminal and exits at the negative terminal.

**Ideally, an ammeter should have zero resistance so that the current being measured is not altered.** In the circuit shown in Figure 28.21, this condition requires that the resistance of the ammeter be much less than  $R_1 + R_2$ . Because any ammeter always has some internal resistance, the presence of the ammeter in the circuit slightly reduces the current from the value it would have in the meter's absence.

### The Voltmeter

A device that measures potential difference is called a **voltmeter**. The potential difference between any two points in a circuit can be measured by attaching the terminals of the voltmeter between these points without breaking the circuit, as shown in Figure 28.22. The potential difference across resistor  $R_2$  is measured by connecting the voltmeter in parallel with  $R_2$ . Again, it is necessary to observe the polarity of the instrument. The positive terminal of the voltmeter must be connected to the end of the resistor that is at the higher potential, and the negative terminal to the end of the resistor at the lower potential.

**An ideal voltmeter has infinite resistance so that no current passes through it.** In Figure 28.22, this condition requires that the voltmeter have a resistance much greater than  $R_2$ . In practice, if this condition is not met, corrections should be made for the known resistance of the voltmeter.

### The Galvanometer

The **galvanometer** is the main component in analog ammeters and voltmeters. Figure 28.23a illustrates the essential features of a common type called the *D'Arsonval galvanometer*. It consists of a coil of wire mounted so that it is free to rotate on a pivot in a magnetic field provided by a permanent magnet. The basic op-

**Figure 28.23** (a) The principal components of a D'Arsonval galvanometer. When the coil situated in a magnetic field carries a current, the magnetic torque causes the coil to twist. The angle through which the coil rotates is proportional to the current in the coil because of the counteracting torque of the spring. (b) A large-scale model of a galvanometer movement. Why does the coil rotate about the vertical axis after the switch is closed?

**Figure 28.24** (a) When a galvanometer is to be used as an ammeter, a shunt resistor  $R_p$  is connected in parallel with the galvanometer. (b) When the galvanometer is used as a voltmeter, a resistor  $R_s$  is connected in series with the galvanometer.

eration of the galvanometer makes use of the fact that a torque acts on a current loop in the presence of a magnetic field (Chapter 29). The torque experienced by the coil is proportional to the current through it: the larger the current, the greater the torque and the more the coil rotates before the spring tightens enough to stop the rotation. Hence, the deflection of a needle attached to the coil is proportional to the current. Once the instrument is properly calibrated, it can be used in conjunction with other circuit elements to measure either currents or potential differences.

A typical off-the-shelf galvanometer is often not suitable for use as an ammeter, primarily because it has a resistance of about  $60\ \Omega$ . An ammeter resistance this great considerably alters the current in a circuit. You can understand this by considering the following example: The current in a simple series circuit containing a 3-V battery and a  $3\text{-}\Omega$  resistor is 1 A. If you insert a  $60\text{-}\Omega$  galvanometer in this circuit to measure the current, the total resistance becomes  $63\ \Omega$  and the current is reduced to 0.048 A!

A second factor that limits the use of a galvanometer as an ammeter is the fact that a typical galvanometer gives a full-scale deflection for currents of the order of 1 mA or less. Consequently, such a galvanometer cannot be used directly to measure currents greater than this value. However, it can be converted to a useful ammeter by placing a shunt resistor  $R_p$  in parallel with the galvanometer, as shown in Figure 28.24a. The value of  $R_p$  must be much less than the galvanometer resistance so that most of the current to be measured passes through the shunt resistor.

A galvanometer can also be used as a voltmeter by adding an external resistor  $R_s$  in series with it, as shown in Figure 28.24b. In this case, the external resistor must have a value much greater than the resistance of the galvanometer to ensure that the galvanometer does not significantly alter the voltage being measured.

## The Wheatstone Bridge

An unknown resistance value can be accurately measured using a circuit known as a **Wheatstone bridge** (Fig. 28.25). This circuit consists of the unknown resistance  $R_x$ , three known resistances  $R_1$ ,  $R_2$ , and  $R_3$  (where  $R_1$  is a calibrated variable resistor), a galvanometer, and a battery. The known resistor  $R_1$  is varied until the galvanometer reading is zero—that is, until there is no current from  $a$  to  $b$ . Under this condition the bridge is said to be balanced. Because the electric potential at

**Figure 28.25** Circuit diagram for a Wheatstone bridge, an instrument used to measure an unknown resistance  $R_x$  in terms of known resistances  $R_1$ ,  $R_2$ , and  $R_3$ . When the bridge is balanced, no current is present in the galvanometer. The arrow superimposed on the circuit symbol for resistor  $R_1$  indicates that the value of this resistor can be varied by the person operating the bridge.

The strain gauge, a device used for experimental stress analysis, consists of a thin coiled wire bonded to a flexible plastic backing. The gauge measures stresses by detecting changes in the resistance of the coil as the strip bends. Resistance measurements are made with this device as one element of a Wheatstone bridge. Strain gauges are commonly used in modern electronic balances to measure the masses of objects.

**Figure 28.26** Voltages, currents, and resistances are frequently measured with digital multimeters like this one.

point  $a$  must equal the potential at point  $b$  when the bridge is balanced, the potential difference across  $R_1$  must equal the potential difference across  $R_2$ . Likewise, the potential difference across  $R_3$  must equal the potential difference across  $R_x$ . From these considerations we see that

$$(1) \quad I_1 R_1 = I_2 R_2$$

$$(2) \quad I_1 R_3 = I_2 R_x$$

Dividing Equation (1) by Equation (2) eliminates the currents, and solving for  $R_x$ , we find that

$$R_x = \frac{R_2 R_3}{R_1} \quad (28.19)$$

A number of similar devices also operate on the principle of null measurement (that is, adjustment of one circuit element to make the galvanometer read zero). One example is the capacitance bridge used to measure unknown capacitances. These devices do not require calibrated meters and can be used with any voltage source.

Wheatstone bridges are not useful for resistances above  $10^5 \Omega$ , but modern electronic instruments can measure resistances as high as  $10^{12} \Omega$ . Such instruments have an extremely high resistance between their input terminals. For example, input resistances of  $10^{10} \Omega$  are common in most digital multimeters, which are devices that are used to measure voltage, current, and resistance (Fig. 28.26).

### The Potentiometer

A **potentiometer** is a circuit that is used to measure an unknown emf  $\mathcal{E}_x$  by comparison with a known emf. In Figure 28.27, point  $d$  represents a sliding contact that is used to vary the resistance (and hence the potential difference) between points  $a$  and  $d$ . The other required components are a galvanometer, a battery of known emf  $\mathcal{E}_0$ , and a battery of unknown emf  $\mathcal{E}_x$ .

With the currents in the directions shown in Figure 28.27, we see from Kirchhoff's junction rule that the current in the resistor  $R_x$  is  $I - I_x$ , where  $I$  is the current in the left branch (through the battery of emf  $\mathcal{E}_0$ ) and  $I_x$  is the current in the right branch. Kirchhoff's loop rule applied to loop  $abcd$  traversed clockwise gives

$$-\mathcal{E}_x + (I - I_x)R_x = 0$$

Because current  $I_x$  passes through it, the galvanometer displays a nonzero reading. The sliding contact at  $d$  is now adjusted until the galvanometer reads zero (indicating a balanced circuit and that the potentiometer is another null-measurement device). Under this condition, the current in the galvanometer is zero, and the potential difference between  $a$  and  $d$  must equal the unknown emf  $\mathcal{E}_x$ :

$$\mathcal{E}_x = IR_x$$

Next, the battery of unknown emf is replaced by a standard battery of known emf  $\mathcal{E}_s$ , and the procedure is repeated. If  $R_s$  is the resistance between  $a$  and  $d$  when balance is achieved this time, then

$$\mathcal{E}_s = IR_s$$

where it is assumed that  $I$  remains the same. Combining this expression with the preceding one, we see that

$$\mathcal{E}_x = \frac{R_x}{R_s} \mathcal{E}_s \quad (28.20)$$

If the resistor is a wire of resistivity  $\rho$ , its resistance can be varied by using the sliding contact to vary the length  $L$ , indicating how much of the wire is part of the circuit. With the substitutions  $R_s = \rho L_s/A$  and  $R_x = \rho L_x/A$ , Equation 28.20 becomes

$$\mathcal{E}_x = \frac{L_x}{L_s} \mathcal{E}_s \quad (28.21)$$

where  $L_x$  is the resistor length when the battery of unknown emf  $\mathcal{E}_x$  is in the circuit and  $L_s$  is the resistor length when the standard battery is in the circuit.

The sliding-wire circuit of Figure 28.27 without the unknown emf and the galvanometer is sometimes called a *voltage divider*. This circuit makes it possible to tap into any desired smaller portion of the emf  $\mathcal{E}_0$  by adjusting the length of the resistor.

**Figure 28.27** Circuit diagram for a potentiometer. The circuit is used to measure an unknown emf  $\mathcal{E}_x$ .

### Optional Section

## 28.6 HOUSEHOLD WIRING AND ELECTRICAL SAFETY

Household circuits represent a practical application of some of the ideas presented in this chapter. In our world of electrical appliances, it is useful to understand the power requirements and limitations of conventional electrical systems and the safety measures that prevent accidents.

In a conventional installation, the utility company distributes electric power to individual homes by means of a pair of wires, with each home connected in parallel to these wires. One wire is called the *live wire*,<sup>5</sup> as illustrated in Figure 28.28, and the other is called the *neutral wire*. The potential difference between these two wires is about 120 V. This voltage alternates in time, with the neutral wire connected to ground and the potential of the live wire oscillating relative to ground. Much of what we have learned so far for the constant-emf situation (direct current) can also be applied to the alternating current that power companies supply to businesses and households. (Alternating voltage and current are discussed in Chapter 33.)

A meter is connected in series with the live wire entering the house to record the household's usage of electricity. After the meter, the wire splits so that there are several separate circuits in parallel distributed throughout the house. Each circuit contains a circuit breaker (or, in older installations, a fuse). The wire and circuit breaker for each circuit are carefully selected to meet the current demands for that circuit. If a circuit is to carry currents as large as 30 A, a heavy wire and an appropriate circuit breaker must be selected to handle this current. A circuit used to power only lamps and small appliances often requires only 15 A. Each circuit has its own circuit breaker to accommodate various load conditions.

As an example, consider a circuit in which a toaster oven, a microwave oven, and a coffee maker are connected (corresponding to  $R_1$ ,  $R_2$ , and  $R_3$  in Figure 28.28 and as shown in the chapter-opening photograph). We can calculate the current drawn by each appliance by using the expression  $\mathcal{P} = I\Delta V$ . The toaster oven, rated at 1 000 W, draws a current of  $1\,000\text{ W}/120\text{ V} = 8.33\text{ A}$ . The microwave oven, rated at 1 300 W, draws 10.8 A, and the coffee maker, rated at 800 W, draws 6.67 A. If the three appliances are operated simultaneously, they draw a total cur-

**Figure 28.28** Wiring diagram for a household circuit. The resistances represent appliances or other electrical devices that operate with an applied voltage of 120 V.

<sup>5</sup> *Live wire* is a common expression for a conductor whose electric potential is above or below ground potential.

**Figure 28.29** A power connection for a 240-V appliance.

rent of 25.8 A. Therefore, the circuit should be wired to handle at least this much current. If the rating of the circuit breaker protecting the circuit is too small—say, 20 A—the breaker will be tripped when the third appliance is turned on, preventing all three appliances from operating. To avoid this situation, the toaster oven and coffee maker can be operated on one 20-A circuit and the microwave oven on a separate 20-A circuit.

Many heavy-duty appliances, such as electric ranges and clothes dryers, require 240 V for their operation (Fig. 28.29). The power company supplies this voltage by providing a third wire that is 120 V below ground potential. The potential difference between this live wire and the other live wire (which is 120 V above ground potential) is 240 V. An appliance that operates from a 240-V line requires half the current of one operating from a 120-V line; therefore, smaller wires can be used in the higher-voltage circuit without overheating.

### Electrical Safety

When the live wire of an electrical outlet is connected directly to ground, the circuit is completed and a short-circuit condition exists. A *short circuit* occurs when almost zero resistance exists between two points at different potentials; this results in a very large current. When this happens accidentally, a properly operating circuit breaker opens the circuit and no damage is done. However, a person in contact with ground can be electrocuted by touching the live wire of a frayed cord or other exposed conductor. An exceptionally good (although very dangerous) ground contact is made when the person either touches a water pipe (normally at ground potential) or stands on the ground with wet feet. The latter situation represents a good ground because normal, nondistilled water is a conductor because it contains a large number of ions associated with impurities. This situation should be avoided at all cost.

Electric shock can result in fatal burns, or it can cause the muscles of vital organs, such as the heart, to malfunction. The degree of damage to the body depends on the magnitude of the current, the length of time it acts, the part of the body touched by the live wire, and the part of the body through which the current passes. Currents of 5 mA or less cause a sensation of shock but ordinarily do little or no damage. If the current is larger than about 10 mA, the muscles contract and the person may be unable to release the live wire. If a current of about 100 mA passes through the body for only a few seconds, the result can be fatal. Such a large current paralyzes the respiratory muscles and prevents breathing. In some cases, currents of about 1 A through the body can produce serious (and sometimes fatal) burns. In practice, no contact with live wires is regarded as safe whenever the voltage is greater than 24 V.

Many 120-V outlets are designed to accept a three-pronged power cord such as the one shown in Figure 28.30. (This feature is required in all new electrical installations.) One of these prongs is the live wire at a nominal potential of 120 V. The second, called the “neutral,” is nominally at 0 V and carries current to ground. The third, round prong is a safety ground wire that normally carries no current but is both grounded and connected directly to the casing of the appliance. If the live wire is accidentally shorted to the casing (which can occur if the wire insulation wears off), most of the current takes the low-resistance path through the appliance to ground. In contrast, if the casing of the appliance is not properly grounded and a short occurs, anyone in contact with the appliance experiences an electric shock because the body provides a low-resistance path to ground.

**Figure 28.30** A three-pronged power cord for a 120-V appliance.

Special power outlets called *ground-fault interrupters* (GFIs) are now being used in kitchens, bathrooms, basements, exterior outlets, and other hazardous areas of new homes. These devices are designed to protect persons from electric shock by sensing small currents ( $\approx 5$  mA) leaking to ground. (The principle of their operation is described in Chapter 31.) When an excessive leakage current is detected, the current is shut off in less than 1 ms.

### Quick Quiz 28.4

Is a circuit breaker wired in series or in parallel with the device it is protecting?

### SUMMARY

The **emf** of a battery is equal to the voltage across its terminals when the current is zero. That is, the emf is equivalent to the **open-circuit voltage** of the battery.

The **equivalent resistance** of a set of resistors connected in **series** is

$$R_{\text{eq}} = R_1 + R_2 + R_3 + \cdots \quad (28.6)$$

The **equivalent resistance** of a set of resistors connected in **parallel** is

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \cdots \quad (28.8)$$

If it is possible to combine resistors into series or parallel equivalents, the preceding two equations make it easy to determine how the resistors influence the rest of the circuit.

Circuits involving more than one loop are conveniently analyzed with the use of **Kirchhoff's rules**:

1. The sum of the currents entering any junction in an electric circuit must equal the sum of the currents leaving that junction:

$$\sum I_{\text{in}} = \sum I_{\text{out}} \quad (28.9)$$

2. The sum of the potential differences across all elements around any circuit loop must be zero:

$$\sum_{\text{closed loop}} \Delta V = 0 \quad (28.10)$$

The first rule is a statement of conservation of charge; the second is equivalent to a statement of conservation of energy.

When a resistor is traversed in the direction of the current, the change in potential  $\Delta V$  across the resistor is  $-IR$ . When a resistor is traversed in the direction opposite the current,  $\Delta V = +IR$ . When a source of emf is traversed in the direction of the emf (negative terminal to positive terminal), the change in potential is  $+\mathcal{E}$ . When a source of emf is traversed opposite the emf (positive to negative), the change in potential is  $-\mathcal{E}$ . The use of these rules together with Equations 28.9 and 28.10 allows you to analyze electric circuits.

If a capacitor is charged with a battery through a resistor of resistance  $R$ , the charge on the capacitor and the current in the circuit vary in time according to

the expressions

$$q(t) = Q(1 - e^{-t/RC}) \quad (28.14)$$

$$I(t) = \frac{\mathcal{E}}{R} e^{-t/RC} \quad (28.15)$$

where  $Q = C\mathcal{E}$  is the maximum charge on the capacitor. The product  $RC$  is called the **time constant**  $\tau$  of the circuit. If a charged capacitor is discharged through a resistor of resistance  $R$ , the charge and current decrease exponentially in time according to the expressions

$$q(t) = Qe^{-t/RC} \quad (28.17)$$

$$I(t) = -\frac{Q}{RC} e^{-t/RC} \quad (28.18)$$

where  $Q$  is the initial charge on the capacitor and  $Q/RC = I_0$  is the initial current in the circuit. Equations 28.14, 28.15, 28.17, and 28.18 permit you to analyze the current and potential differences in an  $RC$  circuit and the charge stored in the circuit's capacitor.

## QUESTIONS

1. Explain the difference between load resistance in a circuit and internal resistance in a battery.
2. Under what condition does the potential difference across the terminals of a battery equal its emf? Can the terminal voltage ever exceed the emf? Explain.
3. Is the direction of current through a battery always from the negative terminal to the positive one? Explain.
4. How would you connect resistors so that the equivalent resistance is greater than the greatest individual resistance? Give an example involving three resistors.
5. How would you connect resistors so that the equivalent resistance is less than the least individual resistance? Give an example involving three resistors.
6. Given three lightbulbs and a battery, sketch as many different electric circuits as you can.
7. Which of the following are the same for each resistor in a series connection—potential difference, current, power?
8. Which of the following are the same for each resistor in a parallel connection—potential difference, current, power?
9. What advantage might there be in using two identical resistors in parallel connected in series with another identical parallel pair, rather than just using a single resistor?
10. An incandescent lamp connected to a 120-V source with a short extension cord provides more illumination than the same lamp connected to the same source with a very long extension cord. Explain why.
11. When can the potential difference across a resistor be positive?
12. In Figure 28.15, suppose the wire between points  $g$  and  $h$  is replaced by a  $10\text{-}\Omega$  resistor. Explain why this change does not affect the currents calculated in Example 28.9.
13. Describe what happens to the lightbulb shown in Figure Q28.13 after the switch is closed. Assume that the capacitor has a large capacitance and is initially uncharged, and assume that the light illuminates when connected directly across the battery terminals.
14. What are the internal resistances of an ideal ammeter? of an ideal voltmeter? Do real meters ever attain these ideals?
15. Although the internal resistances of all sources of emf were neglected in the treatment of the potentiometer (Section 28.5), it is really not necessary to make this assumption. Explain why internal resistances play no role in the measurement of  $\mathcal{E}_x$ .

Figure Q28.13

16. Why is it dangerous to turn on a light when you are in the bathtub?
17. Suppose you fall from a building, and on your way down you grab a high-voltage wire. Assuming that you are hanging from the wire, will you be electrocuted? If the wire then breaks, should you continue to hold onto an end of the wire as you fall?
18. What advantage does 120-V operation offer over 240 V? What are its disadvantages compared with 240 V?
19. When electricians work with potentially live wires, they often use the backs of their hands or fingers to move the wires. Why do you suppose they employ this technique?
20. What procedure would you use to try to save a person who is “frozen” to a live high-voltage wire without endangering your own life?
21. If it is the current through the body that determines the seriousness of a shock, why do we see warnings of high voltage rather than high current near electrical equipment?
22. Suppose you are flying a kite when it strikes a high-voltage wire. What factors determine how great a shock you receive?
23. A series circuit consists of three identical lamps that are connected to a battery as shown in Figure Q28.23. When switch S is closed, what happens (a) to the intensities of lamps A and B, (b) to the intensity of lamp C, (c) to the current in the circuit, and (d) to the voltage across the three lamps? (e) Does the power delivered to the circuit increase, decrease, or remain the same?

Figure Q28.23

24. If your car's headlights are on when you start the ignition, why do they dim while the car is starting?
25. A ski resort consists of a few chair lifts and several interconnected downhill runs on the side of a mountain, with a lodge at the bottom. The lifts are analogous to batteries, and the runs are analogous to resistors. Describe how two runs can be in series. Describe how three runs can be in parallel. Sketch a junction of one lift and two runs. State Kirchhoff's junction rule for ski resorts. One of the skiers, who happens to be carrying an altimeter, stops to warm up her toes each time she passes the lodge. State Kirchhoff's loop rule for altitude.

## PROBLEMS

1, 2, 3 = straightforward, intermediate, challenging □ = full solution available in the *Student Solutions Manual and Study Guide*  
 WEB = solution posted at <http://www.saunderscollege.com/physics/> = Computer useful in solving problem = Interactive Physics  
 □ = paired numerical/symbolic problems

### Section 28.1 Electromotive Force

- WEB 1. A battery has an emf of 15.0 V. The terminal voltage of the battery is 11.6 V when it is delivering 20.0 W of power to an external load resistor  $R$ . (a) What is the value of  $R$ ? (b) What is the internal resistance of the battery?
2. (a) What is the current in a 5.60- $\Omega$  resistor connected to a battery that has a 0.200- $\Omega$  internal resistance if the terminal voltage of the battery is 10.0 V? (b) What is the emf of the battery?
3. Two 1.50-V batteries—with their positive terminals in the same direction—are inserted in series into the barrel of a flashlight. One battery has an internal resistance of 0.255  $\Omega$ , the other an internal resistance of 0.153  $\Omega$ . When the switch is closed, a current of 600 mA occurs in the lamp. (a) What is the lamp's resistance? (b) What percentage of the power from the batteries appears in the batteries themselves, as represented by an increase in temperature?

4. An automobile battery has an emf of 12.6 V and an internal resistance of 0.080  $\Omega$ . The headlights have a total resistance of 5.00  $\Omega$  (assumed constant). What is the potential difference across the headlight bulbs (a) when they are the only load on the battery and (b) when the starter motor, which takes an additional 35.0 A from the battery, is operated?

### Section 28.2 Resistors in Series and in Parallel

5. The current in a loop circuit that has a resistance of  $R_1$  is 2.00 A. The current is reduced to 1.60 A when an additional resistor  $R_2 = 3.00 \Omega$  is added in series with  $R_1$ . What is the value of  $R_1$ ?
6. (a) Find the equivalent resistance between points  $a$  and  $b$  in Figure P28.6. (b) Calculate the current in each resistor if a potential difference of 34.0 V is applied between points  $a$  and  $b$ .
7. A television repairman needs a 100- $\Omega$  resistor to repair a malfunctioning set. He is temporarily out of resistors

Figure P28.6

of this value. All he has in his toolbox are a 500- $\Omega$  resistor and two 250- $\Omega$  resistors. How can he obtain the desired resistance using the resistors he has on hand?

8. A lightbulb marked “75 W [at] 120 V” is screwed into a socket at one end of a long extension cord in which each of the two conductors has a resistance of 0.800  $\Omega$ . The other end of the extension cord is plugged into a 120-V outlet. Draw a circuit diagram, and find the actual power delivered to the bulb in this circuit.

- WEB 9. Consider the circuit shown in Figure P28.9. Find (a) the current in the 20.0- $\Omega$  resistor and (b) the potential difference between points *a* and *b*.

Figure P28.9

10. Four copper wires of equal length are connected in series. Their cross-sectional areas are 1.00 cm<sup>2</sup>, 2.00 cm<sup>2</sup>, 3.00 cm<sup>2</sup>, and 5.00 cm<sup>2</sup>. If a voltage of 120 V is applied to the arrangement, what is the voltage across the 2.00-cm<sup>2</sup> wire?
11. Three 100- $\Omega$  resistors are connected as shown in Figure P28.11. The maximum power that can safely be delivered to any one resistor is 25.0 W. (a) What is the maximum voltage that can be applied to the terminals *a* and *b*? (b) For the voltage determined in part (a), what is

Figure P28.11

the power delivered to each resistor? What is the total power delivered?

12. Using only three resistors—2.00  $\Omega$ , 3.00  $\Omega$ , and 4.00  $\Omega$ —find 17 resistance values that can be obtained with various combinations of one or more resistors. Tabulate the combinations in order of increasing resistance.
13. The current in a circuit is tripled by connecting a 500- $\Omega$  resistor in parallel with the resistance of the circuit. Determine the resistance of the circuit in the absence of the 500- $\Omega$  resistor.
14. The power delivered to the top part of the circuit shown in Figure P28.14 does not depend on whether the switch is opened or closed. If  $R = 1.00 \Omega$ , what is  $R'$ ? Neglect the internal resistance of the voltage source.

Figure P28.14

15. Calculate the power delivered to each resistor in the circuit shown in Figure P28.15.

Figure P28.15

16. Two resistors connected in series have an equivalent resistance of 690  $\Omega$ . When they are connected in parallel, their equivalent resistance is 150  $\Omega$ . Find the resistance of each resistor.
17. In Figures 28.4 and 28.5, let  $R_1 = 11.0 \Omega$ , let  $R_2 = 22.0 \Omega$ , and let the battery have a terminal voltage of 33.0 V. (a) In the parallel circuit shown in Figure 28.5, which resistor uses more power? (b) Verify that the sum of the power ( $I^2R$ ) used by each resistor equals the power supplied by the battery ( $I\Delta V$ ). (c) In the series circuit, which resistor uses more power? (d) Verify that the sum of the power ( $I^2R$ ) used by each resistor equals

the power supplied by the battery ( $\mathcal{P} = I\Delta V$ ).  
 (e) Which circuit configuration uses more power?

### Section 28.3 Kirchhoff's Rules

*Note:* The currents are not necessarily in the direction shown for some circuits.

18. The ammeter shown in Figure P28.18 reads 2.00 A. Find  $I_1$ ,  $I_2$ , and  $\mathcal{E}$ .

Figure P28.18

- WEB 19. Determine the current in each branch of the circuit shown in Figure P28.19.

Figure P28.19 Problems 19, 20, and 21.

20. In Figure P28.19, show how to add just enough ammeters to measure every different current that is flowing. Show how to add just enough voltmeters to measure the potential difference across each resistor and across each battery.  
 21. The circuit considered in Problem 19 and shown in Figure P28.19 is connected for 2.00 min. (a) Find the energy supplied by each battery. (b) Find the energy delivered to each resistor. (c) Find the total amount of energy converted from chemical energy in the battery to internal energy in the circuit resistance.

22. (a) Using Kirchhoff's rules, find the current in each resistor shown in Figure P28.22 and (b) find the potential difference between points  $c$  and  $f$ . Which point is at the higher potential?

Figure P28.22

23. If  $R = 1.00 \text{ k}\Omega$  and  $\mathcal{E} = 250 \text{ V}$  in Figure P28.23, determine the direction and magnitude of the current in the horizontal wire between  $a$  and  $e$ .

Figure P28.23

24. In the circuit of Figure P28.24, determine the current in each resistor and the voltage across the 200-Ω resistor.

Figure P28.24

25. A dead battery is charged by connecting it to the live battery of another car with jumper cables (Fig. P28.25). Determine the current in the starter and in the dead battery.

Figure P28.25

26. For the network shown in Figure P28.26, show that the resistance  $R_{ab} = \frac{27}{17} \Omega$ .

Figure P28.26

27. For the circuit shown in Figure P28.27, calculate (a) the current in the 2.00-Ω resistor and (b) the potential difference between points  $a$  and  $b$ .

Figure P28.27

28. Calculate the power delivered to each of the resistors shown in Figure P28.28.

Figure P28.28

### Section 28.4 RC Circuits

- WEB 29. Consider a series  $RC$  circuit (see Fig. 28.16) for which  $R = 1.00 \text{ M}\Omega$ ,  $C = 5.00 \mu\text{F}$ , and  $\mathcal{E} = 30.0 \text{ V}$ . Find (a) the time constant of the circuit and (b) the maximum charge on the capacitor after the switch is closed. (c) If the switch is closed at  $t = 0$ , find the current in the resistor 10.0 s later.
30. A 2.00-nF capacitor with an initial charge of  $5.10 \mu\text{C}$  is discharged through a 1.30-kΩ resistor. (a) Calculate the current through the resistor  $9.00 \mu\text{s}$  after the resistor is connected across the terminals of the capacitor. (b) What charge remains on the capacitor after  $8.00 \mu\text{s}$ ? (c) What is the maximum current in the resistor?
31. A fully charged capacitor stores energy  $U_0$ . How much energy remains when its charge has decreased to half its original value?
32. In the circuit of Figure P28.32, switch  $S$  has been open for a long time. It is then suddenly closed. Determine the time constant (a) before the switch is closed and (b) after the switch is closed. (c) If the switch is closed at  $t = 0$ , determine the current through it as a function of time.

Figure P28.32

33. The circuit shown in Figure P28.33 has been connected for a long time. (a) What is the voltage across the capacitor? (b) If the battery is disconnected, how long does it take the capacitor to discharge to one-tenth its initial voltage?

Figure P28.33

34. A 4.00-MΩ resistor and a 3.00-μF capacitor are connected in series with a 12.0-V power supply. (a) What is the time constant for the circuit? (b) Express the current in the circuit and the charge on the capacitor as functions of time.

35. Dielectric materials used in the manufacture of capacitors are characterized by conductivities that are small but not zero. Therefore, a charged capacitor slowly loses its charge by “leaking” across the dielectric. If a certain  $3.60\text{-}\mu\text{F}$  capacitor leaks charge such that the potential difference decreases to half its initial value in  $4.00\text{ s}$ , what is the equivalent resistance of the dielectric?
36. Dielectric materials used in the manufacture of capacitors are characterized by conductivities that are small but not zero. Therefore, a charged capacitor slowly loses its charge by “leaking” across the dielectric. If a capacitor having capacitance  $C$  leaks charge such that the potential difference decreases to half its initial value in a time  $t$ , what is the equivalent resistance of the dielectric?
37. A capacitor in an  $RC$  circuit is charged to  $60.0\%$  of its maximum value in  $0.900\text{ s}$ . What is the time constant of the circuit?

(Optional)

**Section 28.5 Electrical Instruments**

38. A typical galvanometer, which requires a current of  $1.50\text{ mA}$  for full-scale deflection and has a resistance of  $75.0\ \Omega$ , can be used to measure currents of much greater values. A relatively small shunt resistor is wired in parallel with the galvanometer (refer to Fig. 28.24a) so that an operator can measure large currents without causing damage to the galvanometer. Most of the current then flows through the shunt resistor. Calculate the value of the shunt resistor that enables the galvanometer to be used to measure a current of  $1.00\text{ A}$  at full-scale deflection. (*Hint:* Use Kirchhoff’s rules.)
39. The galvanometer described in the preceding problem can be used to measure voltages. In this case a large resistor is wired in series with the galvanometer in a way similar to that shown in Figure 28.24b. This arrangement, in effect, limits the current that flows through the galvanometer when large voltages are applied. Most of the potential drop occurs across the resistor placed in series. Calculate the value of the resistor that enables the galvanometer to measure an applied voltage of  $25.0\text{ V}$  at full-scale deflection.
40. A galvanometer with a full-scale sensitivity of  $1.00\text{ mA}$  requires a  $900\text{-}\Omega$  series resistor to make a voltmeter reading full scale when  $1.00\text{ V}$  is measured across the terminals. What series resistor is required to make the same galvanometer into a  $50.0\text{-V}$  (full-scale) voltmeter?
41. Assume that a galvanometer has an internal resistance of  $60.0\ \Omega$  and requires a current of  $0.500\text{ mA}$  to produce full-scale deflection. What resistance must be connected in parallel with the galvanometer if the combination is to serve as an ammeter that has a full-scale deflection for a current of  $0.100\text{ A}$ ?
42. A Wheatstone bridge of the type shown in Figure 28.25 is used to make a precise measurement of the resistance of a wire connector. If  $R_3 = 1.00\text{ k}\Omega$  and the bridge is balanced by adjusting  $R_1$  such that  $R_1 = 2.50R_2$ , what is  $R_x$ ?
43. Consider the case in which the Wheatstone bridge shown in Figure 28.25 is unbalanced. Calculate the current through the galvanometer when  $R_x = R_3 = 7.00\ \Omega$ ,  $R_2 = 21.0\ \Omega$ , and  $R_1 = 14.0\ \Omega$ . Assume that the voltage across the bridge is  $70.0\text{ V}$ , and neglect the galvanometer’s resistance.
44. **Review Problem.** A Wheatstone bridge can be used to measure the strain ( $\Delta L/L_i$ ) of a wire (see Section 12.4), where  $L_i$  is the length before stretching,  $L$  is the length after stretching, and  $\Delta L = L - L_i$ . Let  $\alpha = \Delta L/L_i$ . Show that the resistance is  $R = R_i(1 + 2\alpha + \alpha^2)$  for any length, where  $R_i = \rho L_i/A_i$ . Assume that the resistivity and volume of the wire stay constant.
45. Consider the potentiometer circuit shown in Figure 28.27. If a standard battery with an emf of  $1.0186\text{ V}$  is used in the circuit and the resistance between  $a$  and  $d$  is  $36.0\ \Omega$ , the galvanometer reads zero. If the standard battery is replaced by an unknown emf, the galvanometer reads zero when the resistance is adjusted to  $48.0\ \Omega$ . What is the value of the emf?
46. *Meter loading.* Work this problem to five-digit precision. Refer to Figure P28.46. (a) When a  $180.00\text{-}\Omega$  resistor is put across a battery with an emf of  $6.0000\text{ V}$  and an internal resistance of  $20.000\ \Omega$ , what current flows in the resistor? What will be the potential difference across it? (b) Suppose now that an ammeter with a resistance of  $0.50000\ \Omega$  and a voltmeter with a resistance of

**Figure P28.46**

$20\,000\ \Omega$  are added to the circuit, as shown in Figure P28.46b. Find the reading of each. (c) One terminal of one wire is moved, as shown in Figure P28.46c. Find the new meter readings.

(Optional)

### Section 28.6 Household Wiring and Electrical Safety

- WEB 47.** An electric heater is rated at  $1\,500\ \text{W}$ , a toaster at  $750\ \text{W}$ , and an electric grill at  $1\,000\ \text{W}$ . The three appliances are connected to a common  $120\text{-V}$  circuit.
- (a) How much current does each draw? (b) Is a  $25.0\text{-A}$  circuit breaker sufficient in this situation? Explain your answer.
- 48.** An  $8.00\text{-ft}$  extension cord has two  $18\text{-gauge}$  copper wires, each with a diameter of  $1.024\ \text{mm}$ . What is the  $I^2R$  loss in this cord when it carries a current of (a)  $1.00\ \text{A}$ ? (b)  $10.0\ \text{A}$ ?
- 49.** Sometimes aluminum wiring has been used instead of copper for economic reasons. According to the National Electrical Code, the maximum allowable current for  $12\text{-gauge}$  copper wire with rubber insulation is  $20\ \text{A}$ . What should be the maximum allowable current in a  $12\text{-gauge}$  aluminum wire if it is to have the same  $I^2R$  loss per unit length as the copper wire?
- 50.** Turn on your desk lamp. Pick up the cord with your thumb and index finger spanning its width. (a) Compute an order-of-magnitude estimate for the current that flows through your hand. You may assume that at a typical instant the conductor inside the lamp cord next to your thumb is at potential  $\sim 10^2\ \text{V}$  and that the conductor next to your index finger is at ground potential ( $0\ \text{V}$ ). The resistance of your hand depends strongly on the thickness and moisture content of the outer layers of your skin. Assume that the resistance of your hand between fingertip and thumb tip is  $\sim 10^4\ \Omega$ . You may model the cord as having rubber insulation. State the other quantities you measure or estimate and their values. Explain your reasoning. (b) Suppose that your body is isolated from any other charges or currents. In order-of-magnitude terms, describe the potential of your thumb where it contacts the cord and the potential of your finger where it touches the cord.

### ADDITIONAL PROBLEMS

- 51.** Four  $1.50\text{-V}$  AA batteries in series are used to power a transistor radio. If the batteries can provide a total charge of  $240\ \text{C}$ , how long will they last if the radio has a resistance of  $200\ \Omega$ ?
- 52.** A battery has an emf of  $9.20\ \text{V}$  and an internal resistance of  $1.20\ \Omega$ . (a) What resistance across the battery will extract from it a power of  $12.8\ \text{W}$ ? (b) a power of  $21.2\ \text{W}$ ?
- 53.** Calculate the potential difference between points  $a$  and  $b$  in Figure P28.53, and identify which point is at the higher potential.

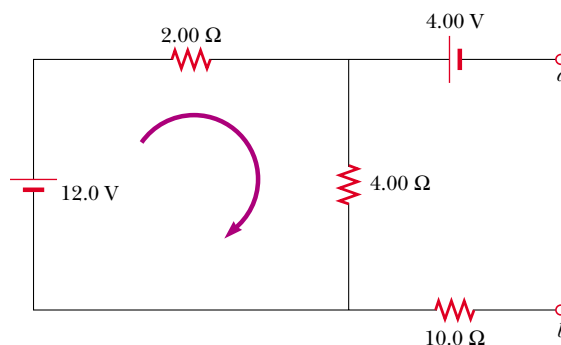

Figure P28.53

- 54.** A  $10.0\text{-}\mu\text{F}$  capacitor is charged by a  $10.0\text{-V}$  battery through a resistance  $R$ . The capacitor reaches a potential difference of  $4.00\ \text{V}$  at a time  $3.00\ \text{s}$  after charging begins. Find  $R$ .
- 55.** When two unknown resistors are connected in series with a battery,  $225\ \text{W}$  is delivered to the combination with a total current of  $5.00\ \text{A}$ . For the same total current,  $50.0\ \text{W}$  is delivered when the resistors are connected in parallel. Determine the values of the two resistors.
- 56.** When two unknown resistors are connected in series with a battery, a total power  $\mathcal{P}_s$  is delivered to the combination with a total current of  $I$ . For the same total current, a total power  $\mathcal{P}_p$  is delivered when the resistors are connected in parallel. Determine the values of the two resistors.
- 57.** A battery has an emf  $\mathcal{E}$  and internal resistance  $r$ . A variable resistor  $R$  is connected across the terminals of the battery. Determine the value of  $R$  such that (a) the potential difference across the terminals is a maximum, (b) the current in the circuit is a maximum, (c) the power delivered to the resistor is a maximum.
- 58.** A power supply has an open-circuit voltage of  $40.0\ \text{V}$  and an internal resistance of  $2.00\ \Omega$ . It is used to charge two storage batteries connected in series, each having an emf of  $6.00\ \text{V}$  and internal resistance of  $0.300\ \Omega$ . If the charging current is to be  $4.00\ \text{A}$ , (a) what additional resistance should be added in series? (b) Find the power delivered to the internal resistance of the supply, the  $I^2R$  loss in the batteries, and the power delivered to the added series resistance. (c) At what rate is the chemical energy in the batteries increasing?
- 59.** The value of a resistor  $R$  is to be determined using the ammeter-voltmeter setup shown in Figure P28.59. The ammeter has a resistance of  $0.500\ \Omega$ , and the voltmeter has a resistance of  $20\,000\ \Omega$ . Within what range of actual values of  $R$  will the measured values be correct, to within  $5.00\%$ , if the measurement is made using (a) the circuit shown in Figure P28.59a? (b) the circuit shown in Figure P28.59b?

Figure P28.59

60. A battery is used to charge a capacitor through a resistor, as shown in Figure 28.16. Show that half the energy supplied by the battery appears as internal energy in the resistor and that half is stored in the capacitor.

61. The values of the components in a simple series  $RC$  circuit containing a switch (Fig. 28.16) are  $C = 1.00 \mu\text{F}$ ,  $R = 2.00 \times 10^6 \Omega$ , and  $\mathcal{E} = 10.0 \text{ V}$ . At the instant  $10.0 \text{ s}$  after the switch is closed, calculate (a) the charge on the capacitor, (b) the current in the resistor, (c) the rate at which energy is being stored in the capacitor, and (d) the rate at which energy is being delivered by the battery.

62. The switch in Figure P28.62a closes when  $\Delta V_c > 2\Delta V/3$  and opens when  $\Delta V_c < \Delta V/3$ . The voltmeter reads a voltage as plotted in Figure P28.62b. What is the period  $T$  of the waveform in terms of  $R_A$ ,  $R_B$ , and  $C$ ?

Figure P28.62

63. Three  $60.0\text{-W}$ ,  $120\text{-V}$  lightbulbs are connected across a  $120\text{-V}$  power source, as shown in Figure P28.63. Find (a) the total power delivered to the three bulbs and (b) the voltage across each. Assume that the resistance of each bulb conforms to Ohm's law (even though in reality the resistance increases markedly with current).

Figure P28.63

64. Design a multirange voltmeter capable of full-scale deflection for  $20.0 \text{ V}$ ,  $50.0 \text{ V}$ , and  $100 \text{ V}$ . Assume that the meter movement is a galvanometer that has a resistance of  $60.0 \Omega$  and gives a full-scale deflection for a current of  $1.00 \text{ mA}$ .

65. Design a multirange ammeter capable of full-scale deflection for  $25.0 \text{ mA}$ ,  $50.0 \text{ mA}$ , and  $100 \text{ mA}$ . Assume that the meter movement is a galvanometer that has a resistance of  $25.0 \Omega$  and gives a full-scale deflection for  $1.00 \text{ mA}$ .

66. A particular galvanometer serves as a  $2.00\text{-V}$  full-scale voltmeter when a  $2500\text{-}\Omega$  resistor is connected in series with it. It serves as a  $0.500\text{-A}$  full-scale ammeter when a  $0.220\text{-}\Omega$  resistor is connected in parallel with it. Determine the internal resistance of the galvanometer and the current required to produce full-scale deflection.

67. In Figure P28.67, suppose that the switch has been closed for a length of time sufficiently long for the capacitor to become fully charged. (a) Find the steady-state current in each resistor. (b) Find the charge  $Q$  on the capacitor. (c) The switch is opened at  $t = 0$ . Write an equation for the current  $I_{R_2}$  in  $R_2$  as a function of time, and (d) find the time that it takes for the charge on the capacitor to fall to one-fifth its initial value.

Figure P28.67

68. The circuit shown in Figure P28.68 is set up in the laboratory to measure an unknown capacitance  $C$  with the use of a voltmeter of resistance  $R = 10.0 \text{ M}\Omega$  and a battery whose emf is  $6.19 \text{ V}$ . The data given in the table below are the measured voltages across the capacitor as a function of time, where  $t = 0$  represents the time at which the switch is opened. (a) Construct a graph of  $\ln(\mathcal{E}/\Delta V)$  versus  $t$ , and perform a linear least-squares fit to the data. (b) From the slope of your graph, obtain a value for the time constant of the circuit and a value for the capacitance.

$\Delta V$ (V)	$t$ (s)	$\ln(\mathcal{E}/\Delta V)$
6.19	0	
5.55	4.87	
4.93	11.1	
4.34	19.4	
3.72	30.8	
3.09	46.6	
2.47	67.3	
1.83	102.2	

Figure P28.68

69. (a) Using symmetry arguments, show that the current through any resistor in the configuration of Figure P28.69 is either  $I/3$  or  $I/6$ . All resistors have the same resistance  $r$ . (b) Show that the equivalent resistance between points  $a$  and  $b$  is  $(5/6)r$ .

Figure P28.69

70. The student engineer of a campus radio station wishes to verify the effectiveness of the lightning rod on the an-

tenna mast (Fig. P28.70). The unknown resistance  $R_x$  is between points  $C$  and  $E$ . Point  $E$  is a true ground but is inaccessible for direct measurement since this stratum is several meters below the Earth's surface. Two identical rods are driven into the ground at  $A$  and  $B$ , introducing an unknown resistance  $R_y$ . The procedure is as follows. Measure resistance  $R_1$  between points  $A$  and  $B$ , then connect  $A$  and  $B$  with a heavy conducting wire and measure resistance  $R_2$  between points  $A$  and  $C$ . (a) Derive a formula for  $R_x$  in terms of the observable resistances  $R_1$  and  $R_2$ . (b) A satisfactory ground resistance would be  $R_x < 2.00 \Omega$ . Is the grounding of the station adequate if measurements give  $R_1 = 13.0 \Omega$  and  $R_2 = 6.00 \Omega$ ?

Figure P28.70

71. Three  $2.00\text{-}\Omega$  resistors are connected as shown in Figure P28.71. Each can withstand a maximum power of  $32.0 \text{ W}$  without becoming excessively hot. Determine the maximum power that can be delivered to the combination of resistors.

Figure P28.71

72. The circuit in Figure P28.72 contains two resistors,  $R_1 = 2.00 \text{ k}\Omega$  and  $R_2 = 3.00 \text{ k}\Omega$ , and two capacitors,  $C_1 = 2.00 \mu\text{F}$  and  $C_2 = 3.00 \mu\text{F}$ , connected to a battery with emf  $\mathcal{E} = 120 \text{ V}$ . If no charges exist on the capacitors before switch  $S$  is closed, determine the charges  $q_1$  and  $q_2$  on capacitors  $C_1$  and  $C_2$ , respectively, after the switch is closed. (Hint: First reconstruct the circuit so that it becomes a simple  $RC$  circuit containing a single resistor and single capacitor in series, connected to the battery, and then determine the total charge  $q$  stored in the equivalent circuit.)

Figure P28.72

73. Assume that you have a battery of emf  $\mathcal{E}$  and three identical lightbulbs, each having constant resistance  $R$ . What is the total power from the battery if the bulbs are connected (a) in series? (b) in parallel? (c) For which connection do the bulbs shine the brightest?

## ANSWERS TO QUICK QUIZZES

- 28.1 Bulb  $R_1$  becomes brighter. Connecting  $b$  to  $c$  “shorts out” bulb  $R_2$  and changes the total resistance of the circuit from  $R_1 + R_2$  to just  $R_1$ . Because the resistance has decreased (and the potential difference supplied by the battery does not change), the current through the battery increases. This means that the current through bulb  $R_1$  increases, and bulb  $R_1$  glows more brightly. Bulb  $R_2$  goes out because the new piece of wire provides an almost resistance-free path for the current; hence, essentially zero current exists in bulb  $R_2$ .
- 28.2 Adding another series resistor increases the total resistance of the circuit and thus reduces the current in the battery. The potential difference across the battery terminals would increase because the reduced current results in a smaller voltage decrease across the internal resistance.

If the second resistor were connected in parallel, the total resistance of the circuit would decrease, and an increase in current through the battery would result. The potential difference across the terminals would decrease because the increased current results in a greater voltage decrease across the internal resistance.

- 28.3 They must be in parallel because if one burns out, the other continues to operate. If they were in series, one failed headlamp would interrupt the current throughout the entire circuit, including the other headlamp.
- 28.4 Because the circuit breaker trips and opens the circuit when the current in that circuit exceeds a certain preset value, it must be in series to sense the appropriate current (see Fig. 28.28).

## PUZZLER

Aurora Borealis, the Northern Lights, photographed near Fairbanks, Alaska. Such beautiful auroral displays are a common sight in far northern or southern latitudes, but they are quite rare in the middle latitudes. What causes these shimmering curtains of light, and why are they usually visible only near the Earth's North and South poles? (George Lepp/Tony Stone Images)

- 29.6** (Optional) The Hall Effect

**M**any historians of science believe that the compass, which uses a magnetic needle, was used in China as early as the 13th century B.C., its invention being of Arabic or Indian origin. The early Greeks knew about magnetism as early as 800 B.C. They discovered that the stone magnetite ( $\text{Fe}_3\text{O}_4$ ) attracts pieces of iron. Legend ascribes the name *magnetite* to the shepherd Magnes, the nails of whose shoes and the tip of whose staff stuck fast to chunks of magnetite while he pastured his flocks.

In 1269 a Frenchman named Pierre de Maricourt mapped out the directions taken by a needle placed at various points on the surface of a spherical natural magnet. He found that the directions formed lines that encircled the sphere and passed through two points diametrically opposite each other, which he called the *poles* of the magnet. Subsequent experiments showed that every magnet, regardless of its shape, has two poles, called *north* and *south* poles, that exert forces on other magnetic poles just as electric charges exert forces on one another. That is, like poles repel each other, and unlike poles attract each other.

The poles received their names because of the way a magnet behaves in the presence of the Earth's magnetic field. If a bar magnet is suspended from its mid-point and can swing freely in a horizontal plane, it will rotate until its north pole points to the Earth's geographic North Pole and its south pole points to the Earth's geographic South Pole.<sup>1</sup> (The same idea is used in the construction of a simple compass.)

In 1600 William Gilbert (1540–1603) extended de Maricourt's experiments to a variety of materials. Using the fact that a compass needle orients in preferred directions, he suggested that the Earth itself is a large permanent magnet. In 1750 experimenters used a torsion balance to show that magnetic poles exert attractive or repulsive forces on each other and that these forces vary as the inverse square of the distance between interacting poles. Although the force between two magnetic poles is similar to the force between two electric charges, there is an important difference. Electric charges can be isolated (witness the electron and proton), whereas **a single magnetic pole has never been isolated.** That is, **magnetic poles are always found in pairs.** All attempts thus far to detect an isolated magnetic pole have been unsuccessful. No matter how many times a permanent magnet is cut in two, each piece always has a north and a south pole. (There is some theoretical basis for speculating that magnetic *monopoles*—isolated north or south poles—may exist in nature, and attempts to detect them currently make up an active experimental field of investigation.)

The relationship between magnetism and electricity was discovered in 1819 when, during a lecture demonstration, the Danish scientist Hans Christian Oersted found that an electric current in a wire deflected a nearby compass needle.<sup>2</sup> Shortly thereafter, André Ampère (1775–1836) formulated quantitative laws for calculating the magnetic force exerted by one current-carrying electrical conductor on another. He also suggested that on the atomic level, electric current loops are responsible for *all* magnetic phenomena.

In the 1820s, further connections between electricity and magnetism were demonstrated by Faraday and independently by Joseph Henry (1797–1878). They

<sup>1</sup> Note that the Earth's geographic North Pole is magnetically a south pole, whereas its geographic South Pole is magnetically a north pole. Because *opposite* magnetic poles attract each other, the pole on a magnet that is attracted to the Earth's geographic North Pole is the magnet's *north* pole and the pole attracted to the Earth's geographic South Pole is the magnet's *south* pole.

<sup>2</sup> The same discovery was reported in 1802 by an Italian jurist, Gian Domenico Romagnosi, but was overlooked, probably because it was published in the newspaper *Gazetta de Trentino* rather than in a scholarly journal.

An electromagnet is used to move tons of scrap metal.

### QuickLab

If iron or steel is left in a weak magnetic field (such as that due to the Earth) long enough, it can become magnetized. Use a compass to see if you can detect a magnetic field near a steel file cabinet, cast iron radiator, or some other piece of ferrous metal that has been in one position for several years.

showed that an electric current can be produced in a circuit either by moving a magnet near the circuit or by changing the current in a nearby circuit. These observations demonstrate that a changing magnetic field creates an electric field. Years later, theoretical work by Maxwell showed that the reverse is also true: A changing electric field creates a magnetic field.

A similarity between electric and magnetic effects has provided methods of making permanent magnets. In Chapter 23 we learned that when rubber and wool are rubbed together, both become charged—one positively and the other negatively. In an analogous fashion, one can magnetize an unmagnetized piece of iron by stroking it with a magnet. Magnetism can also be induced in iron (and other materials) by other means. For example, if a piece of unmagnetized iron is placed near (but not touching) a strong magnet, the unmagnetized piece eventually becomes magnetized.

This chapter examines the forces that act on moving charges and on current-carrying wires in the presence of a magnetic field. The source of the magnetic field itself is described in Chapter 30.

## 29.1 THE MAGNETIC FIELD

In our study of electricity, we described the interactions between charged objects in terms of electric fields. Recall that an electric field surrounds any stationary or moving electric charge. In addition to an electric field, the region of space surrounding any *moving* electric charge also contains a magnetic field, as we shall see in Chapter 30. A magnetic field also surrounds any magnetic substance.

Historically, the symbol  $\mathbf{B}$  has been used to represent a magnetic field, and this is the notation we use in this text. The direction of the magnetic field  $\mathbf{B}$  at any location is the direction in which a compass needle points at that location. Figure 29.1 shows how the magnetic field of a bar magnet can be traced with the aid of a compass. Note that the magnetic field lines outside the magnet point away from north poles and toward south poles. One can display magnetic field patterns of a bar magnet using small iron filings, as shown in Figure 29.2.

We can define a magnetic field  $\mathbf{B}$  at some point in space in terms of the magnetic force  $\mathbf{F}_B$  that the field exerts on a test object, for which we use a charged particle moving with a velocity  $\mathbf{v}$ . For the time being, let us assume that no electric or gravitational fields are present at the location of the test object. Experiments on various charged particles moving in a magnetic field give the following results:

- The magnitude  $F_B$  of the magnetic force exerted on the particle is proportional to the charge  $q$  and to the speed  $v$  of the particle.

These refrigerator magnets are similar to a series of very short bar magnets placed end to end. If you slide the back of one refrigerator magnet in a circular path across the back of another one, you can feel a vibration as the two series of north and south poles move across each other.

**Figure 29.1** Compass needles can be used to trace the magnetic field lines of a bar magnet.

**Figure 29.2** (a) Magnetic field pattern surrounding a bar magnet as displayed with iron filings. (b) Magnetic field pattern between *unlike* poles of two bar magnets. (c) Magnetic field pattern between *like* poles of two bar magnets.

- The magnitude and direction of  $\mathbf{F}_B$  depend on the velocity of the particle and on the magnitude and direction of the magnetic field  $\mathbf{B}$ .
- When a charged particle moves parallel to the magnetic field vector, the magnetic force acting on the particle is zero.
- When the particle's velocity vector makes any angle  $\theta \neq 0$  with the magnetic field, the magnetic force acts in a direction perpendicular to both  $\mathbf{v}$  and  $\mathbf{B}$ ; that is,  $\mathbf{F}_B$  is perpendicular to the plane formed by  $\mathbf{v}$  and  $\mathbf{B}$  (Fig. 29.3a).

Properties of the magnetic force on a charge moving in a magnetic field  $\mathbf{B}$

**Figure 29.3** The direction of the magnetic force  $\mathbf{F}_B$  acting on a charged particle moving with a velocity  $\mathbf{v}$  in the presence of a magnetic field  $\mathbf{B}$ . (a) The magnetic force is perpendicular to both  $\mathbf{v}$  and  $\mathbf{B}$ . (b) Oppositely directed magnetic forces  $\mathbf{F}_B$  are exerted on two oppositely charged particles moving at the same velocity in a magnetic field.

The blue-white arc in this photograph indicates the circular path followed by an electron beam moving in a magnetic field. The vessel contains gas at very low pressure, and the beam is made visible as the electrons collide with the gas atoms, which then emit visible light. The magnetic field is produced by two coils (not shown). The apparatus can be used to measure the ratio  $e/m_e$  for the electron.

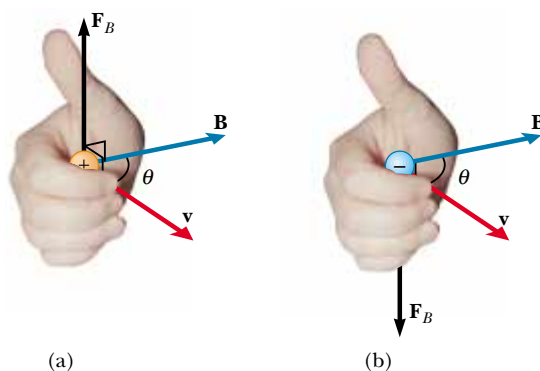

- The magnetic force exerted on a positive charge is in the direction opposite the direction of the magnetic force exerted on a negative charge moving in the same direction (Fig. 29.3b).
- The magnitude of the magnetic force exerted on the moving particle is proportional to  $\sin \theta$ , where  $\theta$  is the angle the particle's velocity vector makes with the direction of  $\mathbf{B}$ .

We can summarize these observations by writing the magnetic force in the form

$$\mathbf{F}_B = q\mathbf{v} \times \mathbf{B} \quad (29.1)$$

where the direction of  $\mathbf{F}_B$  is in the direction of  $\mathbf{v} \times \mathbf{B}$  if  $q$  is positive, which by definition of the cross product (see Section 11.2) is perpendicular to both  $\mathbf{v}$  and  $\mathbf{B}$ . We can regard this equation as an operational definition of the magnetic field at some point in space. That is, the magnetic field is defined in terms of the force acting on a moving charged particle.

Figure 29.4 reviews the right-hand rule for determining the direction of the cross product  $\mathbf{v} \times \mathbf{B}$ . You point the four fingers of your right hand along the direction of  $\mathbf{v}$  with the palm facing  $\mathbf{B}$  and curl them toward  $\mathbf{B}$ . The extended thumb, which is at a right angle to the fingers, points in the direction of  $\mathbf{v} \times \mathbf{B}$ . Because

**Figure 29.4** The right-hand rule for determining the direction of the magnetic force  $\mathbf{F}_B = q\mathbf{v} \times \mathbf{B}$  acting on a particle with charge  $q$  moving with a velocity  $\mathbf{v}$  in a magnetic field  $\mathbf{B}$ . The direction of  $\mathbf{v} \times \mathbf{B}$  is the direction in which the thumb points. (a) If  $q$  is positive,  $\mathbf{F}_B$  is upward. (b) If  $q$  is negative,  $\mathbf{F}_B$  is downward, antiparallel to the direction in which the thumb points.

$\mathbf{F}_B = q\mathbf{v} \times \mathbf{B}$ ,  $\mathbf{F}_B$  is in the direction of  $\mathbf{v} \times \mathbf{B}$  if  $q$  is positive (Fig. 29.4a) and opposite the direction of  $\mathbf{v} \times \mathbf{B}$  if  $q$  is negative (Fig. 29.4b). (If you need more help understanding the cross product, you should review pages 333 to 334, including Fig. 11.8.)

The magnitude of the magnetic force is

$$F_B = |q|vB \sin \theta \quad (29.2)$$

where  $\theta$  is the smaller angle between  $\mathbf{v}$  and  $\mathbf{B}$ . From this expression, we see that  $F$  is zero when  $\mathbf{v}$  is parallel or antiparallel to  $\mathbf{B}$  ( $\theta = 0$  or  $180^\circ$ ) and maximum ( $F_{B, \max} = |q|vB$ ) when  $\mathbf{v}$  is perpendicular to  $\mathbf{B}$  ( $\theta = 90^\circ$ ).

### Quick Quiz 29.1

What is the maximum work that a constant magnetic field  $\mathbf{B}$  can perform on a charge  $q$  moving through the field with velocity  $\mathbf{v}$ ?

There are several important differences between electric and magnetic forces:

- The electric force acts in the direction of the electric field, whereas the magnetic force acts perpendicular to the magnetic field.
- The electric force acts on a charged particle regardless of whether the particle is moving, whereas the magnetic force acts on a charged particle only when the particle is in motion.
- The electric force does work in displacing a charged particle, whereas the magnetic force associated with a steady magnetic field does no work when a particle is displaced.

From the last statement and on the basis of the work–kinetic energy theorem, we conclude that the kinetic energy of a charged particle moving through a magnetic field cannot be altered by the magnetic field alone. In other words,

when a charged particle moves with a velocity  $\mathbf{v}$  through a magnetic field, the field can alter the direction of the velocity vector but cannot change the speed or kinetic energy of the particle.

From Equation 29.2, we see that the SI unit of magnetic field is the newton per coulomb-meter per second, which is called the **tesla** (T):

$$1 \text{ T} = \frac{\text{N}}{\text{C} \cdot \text{m/s}}$$

Because a coulomb per second is defined to be an ampere, we see that

$$1 \text{ T} = 1 \frac{\text{N}}{\text{A} \cdot \text{m}}$$

A non-SI magnetic-field unit in common use, called the *gauss* (G), is related to the tesla through the conversion  $1 \text{ T} = 10^4 \text{ G}$ . Table 29.1 shows some typical values of magnetic fields.

### Quick Quiz 29.2

The north-pole end of a bar magnet is held near a positively charged piece of plastic. Is the plastic attracted, repelled, or unaffected by the magnet?

Magnitude of the magnetic force on a charged particle moving in a magnetic field

Differences between electric and magnetic forces

A magnetic field cannot change the speed of a particle

**TABLE 29.1** Some Approximate Magnetic Field Magnitudes

Source of Field	Field Magnitude (T)
Strong superconducting laboratory magnet	30
Strong conventional laboratory magnet	2
Medical MRI unit	1.5
Bar magnet	$10^{-2}$
Surface of the Sun	$10^{-2}$
Surface of the Earth	$0.5 \times 10^{-4}$
Inside human brain (due to nerve impulses)	$10^{-13}$

**EXAMPLE 29.1** An Electron Moving in a Magnetic Field

An electron in a television picture tube moves toward the front of the tube with a speed of  $8.0 \times 10^6$  m/s along the  $x$  axis (Fig. 29.5). Surrounding the neck of the tube are coils of wire that create a magnetic field of magnitude 0.025 T, directed at an angle of  $60^\circ$  to the  $x$  axis and lying in the  $xy$  plane. Calculate the magnetic force on and acceleration of the electron.

**Solution** Using Equation 29.2, we can find the magnitude of the magnetic force:

$$\begin{aligned} F_B &= |q|vB \sin \theta \\ &= (1.6 \times 10^{-19} \text{ C})(8.0 \times 10^6 \text{ m/s})(0.025 \text{ T})(\sin 60^\circ) \\ &= 2.8 \times 10^{-14} \text{ N} \end{aligned}$$

Because  $\mathbf{v} \times \mathbf{B}$  is in the positive  $z$  direction (from the right-hand rule) and the charge is negative,  $\mathbf{F}_B$  is in the negative  $z$  direction.

The mass of the electron is  $9.11 \times 10^{-31}$  kg, and so its acceleration is

$$a = \frac{F_B}{m_e} = \frac{2.8 \times 10^{-14} \text{ N}}{9.11 \times 10^{-31} \text{ kg}} = 3.1 \times 10^{16} \text{ m/s}^2$$

in the negative  $z$  direction.

**Figure 29.5** The magnetic force  $\mathbf{F}_B$  acting on the electron is in the negative  $z$  direction when  $\mathbf{v}$  and  $\mathbf{B}$  lie in the  $xy$  plane.

## 29.2 MAGNETIC FORCE ACTING ON A CURRENT-CARRYING CONDUCTOR

If a magnetic force is exerted on a single charged particle when the particle moves through a magnetic field, it should not surprise you that a current-carrying wire also experiences a force when placed in a magnetic field. This follows from the fact that the current is a collection of many charged particles in motion; hence, the resultant force exerted by the field on the wire is the vector sum of the individual forces exerted on all the charged particles making up the current. The force exerted on the particles is transmitted to the wire when the particles collide with the atoms making up the wire.

Before we continue our discussion, some explanation of the notation used in this book is in order. To indicate the direction of  $\mathbf{B}$  in illustrations, we sometimes present perspective views, such as those in Figures 29.5, 29.6a, and 29.7. In flat il-

**Figure 29.6** (a) A wire suspended vertically between the poles of a magnet. (b) The setup shown in part (a) as seen looking at the south pole of the magnet, so that the magnetic field (blue crosses) is directed into the page. When there is no current in the wire, it remains vertical. (c) When the current is upward, the wire deflects to the left. (d) When the current is downward, the wire deflects to the right.

illustrations, such as in Figure 29.6b to d, we depict a magnetic field directed into the page with blue crosses, which represent the tails of arrows shot perpendicularly and away from you. In this case, we call the field  $\mathbf{B}_{\text{in}}$ , where the subscript “in” indicates “into the page.” If  $\mathbf{B}$  is perpendicular and directed out of the page, we use a series of blue dots, which represent the tips of arrows coming toward you (see Fig. P29.56). In this case, we call the field  $\mathbf{B}_{\text{out}}$ . If  $\mathbf{B}$  lies in the plane of the page, we use a series of blue field lines with arrowheads, as shown in Figure 29.8.

One can demonstrate the magnetic force acting on a current-carrying conductor by hanging a wire between the poles of a magnet, as shown in Figure 29.6a. For ease in visualization, part of the horseshoe magnet in part (a) is removed to show the end face of the south pole in parts (b), (c), and (d) of Figure 29.6. The magnetic field is directed into the page and covers the region within the shaded circles. When the current in the wire is zero, the wire remains vertical, as shown in Figure 29.6b. However, when a current directed upward flows in the wire, as shown in Figure 29.6c, the wire deflects to the left. If we reverse the current, as shown in Figure 29.6d, the wire deflects to the right.

Let us quantify this discussion by considering a straight segment of wire of length  $L$  and cross-sectional area  $A$ , carrying a current  $I$  in a uniform magnetic field  $\mathbf{B}$ , as shown in Figure 29.7. The magnetic force exerted on a charge  $q$  moving with a drift velocity  $\mathbf{v}_d$  is  $q\mathbf{v}_d \times \mathbf{B}$ . To find the total force acting on the wire, we multiply the force  $q\mathbf{v}_d \times \mathbf{B}$  exerted on one charge by the number of charges in the segment. Because the volume of the segment is  $AL$ , the number of charges in the segment is  $nAL$ , where  $n$  is the number of charges per unit volume. Hence, the total magnetic force on the wire of length  $L$  is

$$\mathbf{F}_B = (q\mathbf{v}_d \times \mathbf{B})nAL$$

We can write this expression in a more convenient form by noting that, from Equation 27.4, the current in the wire is  $I = nqv_dA$ . Therefore,

$$\mathbf{F}_B = I\mathbf{L} \times \mathbf{B} \quad (29.3)$$

**Figure 29.7** A segment of a current-carrying wire located in a magnetic field  $\mathbf{B}$ . The magnetic force exerted on each charge making up the current is  $q\mathbf{v}_d \times \mathbf{B}$ , and the net force on the segment of length  $L$  is  $I\mathbf{L} \times \mathbf{B}$ .

Force on a segment of a wire in a uniform magnetic field

**Figure 29.8** A wire segment of arbitrary shape carrying a current  $I$  in a magnetic field  $\mathbf{B}$  experiences a magnetic force. The force on any segment  $d\mathbf{s}$  is  $I d\mathbf{s} \times \mathbf{B}$  and is directed out of the page. You should use the right-hand rule to confirm this force direction.

where  $\mathbf{L}$  is a vector that points in the direction of the current  $I$  and has a magnitude equal to the length  $L$  of the segment. Note that this expression applies only to a straight segment of wire in a uniform magnetic field.

Now let us consider an arbitrarily shaped wire segment of uniform cross-section in a magnetic field, as shown in Figure 29.8. It follows from Equation 29.3 that the magnetic force exerted on a small segment of vector length  $d\mathbf{s}$  in the presence of a field  $\mathbf{B}$  is

$$d\mathbf{F}_B = I d\mathbf{s} \times \mathbf{B} \quad (29.4)$$

where  $d\mathbf{F}_B$  is directed out of the page for the directions assumed in Figure 29.8. We can consider Equation 29.4 as an alternative definition of  $\mathbf{B}$ . That is, we can define the magnetic field  $\mathbf{B}$  in terms of a measurable force exerted on a current element, where the force is a maximum when  $\mathbf{B}$  is perpendicular to the element and zero when  $\mathbf{B}$  is parallel to the element.

To calculate the total force  $\mathbf{F}_B$  acting on the wire shown in Figure 29.8, we integrate Equation 29.4 over the length of the wire:

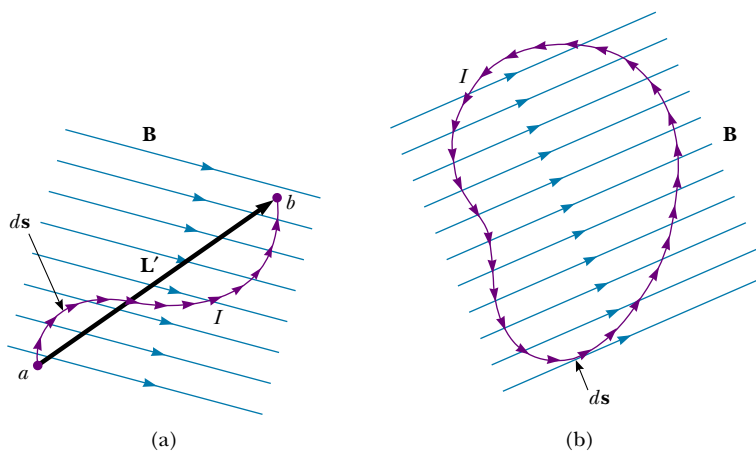

$$\mathbf{F}_B = I \int_a^b d\mathbf{s} \times \mathbf{B} \quad (29.5)$$

where  $a$  and  $b$  represent the end points of the wire. When this integration is carried out, the magnitude of the magnetic field and the direction the field makes with the vector  $d\mathbf{s}$  (in other words, with the orientation of the element) may differ at different points.

Now let us consider two special cases involving Equation 29.5. In both cases, the magnetic field is taken to be constant in magnitude and direction.

**Case 1** A curved wire carries a current  $I$  and is located in a uniform magnetic field  $\mathbf{B}$ , as shown in Figure 29.9a. Because the field is uniform, we can take  $\mathbf{B}$  outside the integral in Equation 29.5, and we obtain

$$\mathbf{F}_B = I \left( \int_a^b d\mathbf{s} \right) \times \mathbf{B} \quad (29.6)$$

**Figure 29.9** (a) A curved wire carrying a current  $I$  in a uniform magnetic field. The total magnetic force acting on the wire is equivalent to the force on a straight wire of length  $L'$  running between the ends of the curved wire. (b) A current-carrying loop of arbitrary shape in a uniform magnetic field. The net magnetic force on the loop is zero.

But the quantity  $\int_a^b ds$  represents the *vector sum* of all the length elements from  $a$  to  $b$ . From the law of vector addition, the sum equals the vector  $\mathbf{L}'$ , directed from  $a$  to  $b$ . Therefore, Equation 29.6 reduces to

$$\mathbf{F}_B = I\mathbf{L}' \times \mathbf{B} \quad (29.7)$$

**Case 2** An arbitrarily shaped closed loop carrying a current  $I$  is placed in a uniform magnetic field, as shown in Figure 29.9b. We can again express the force acting on the loop in the form of Equation 29.6, but this time we must take the vector sum of the length elements  $d\mathbf{s}$  over the entire loop:

$$\mathbf{F}_B = I\left(\oint d\mathbf{s}\right) \times \mathbf{B}$$

Because the set of length elements forms a closed polygon, the vector sum must be zero. This follows from the graphical procedure for adding vectors by the polygon method. Because  $\oint d\mathbf{s} = 0$ , we conclude that  $\mathbf{F}_B = 0$ :

The net magnetic force acting on any closed current loop in a uniform magnetic field is zero.

### EXAMPLE 29.2 Force on a Semicircular Conductor

A wire bent into a semicircle of radius  $R$  forms a closed circuit and carries a current  $I$ . The wire lies in the  $xy$  plane, and a uniform magnetic field is directed along the positive  $y$  axis, as shown in Figure 29.10. Find the magnitude and direction of the magnetic force acting on the straight portion of the wire and on the curved portion.

**Solution** The force  $\mathbf{F}_1$  acting on the straight portion has a magnitude  $F_1 = ILB = 2IRB$  because  $L = 2R$  and the wire is oriented perpendicular to  $\mathbf{B}$ . The direction of  $\mathbf{F}_1$  is out of the page because  $\mathbf{L} \times \mathbf{B}$  is along the positive  $z$  axis. (That is,  $\mathbf{L}$  is to the right, in the direction of the current; thus, according to the rule of cross products,  $\mathbf{L} \times \mathbf{B}$  is out of the page in Fig. 29.10.)

To find the force  $\mathbf{F}_2$  acting on the curved part, we first write an expression for the force  $d\mathbf{F}_2$  on the length element  $d\mathbf{s}$  shown in Figure 29.10. If  $\theta$  is the angle between  $\mathbf{B}$  and  $d\mathbf{s}$ , then the magnitude of  $d\mathbf{F}_2$  is

$$dF_2 = I |d\mathbf{s} \times \mathbf{B}| = IB \sin \theta ds$$

To integrate this expression, we must express  $ds$  in terms of  $\theta$ . Because  $s = R\theta$ , we have  $ds = R d\theta$ , and we can make this substitution for  $dF_2$ :

$$dF_2 = IRB \sin \theta d\theta$$

To obtain the total force  $F_2$  acting on the curved portion, we can integrate this expression to account for contributions from all elements  $ds$ . Note that the direction of the force on every element is the same: into the page (because  $d\mathbf{s} \times \mathbf{B}$  is into the page). Therefore, the resultant force  $\mathbf{F}_2$  on the

curved wire must also be into the page. Integrating our expression for  $dF_2$  over the limits  $\theta = 0$  to  $\theta = \pi$  (that is, the entire semicircle) gives

$$\begin{aligned} F_2 &= IRB \int_0^\pi \sin \theta d\theta = IRB [-\cos \theta]_0^\pi \\ &= -IRB(\cos \pi - \cos 0) = -IRB(-1 - 1) = 2IRB \end{aligned}$$

Because  $\mathbf{F}_2$ , with a magnitude of  $2IRB$ , is directed into the page and because  $\mathbf{F}_1$ , with a magnitude of  $2IRB$ , is directed out of the page, the net force on the closed loop is zero. This result is consistent with Case 2 described earlier.

**Figure 29.10** The net force acting on a closed current loop in a uniform magnetic field is zero. In the setup shown here, the force on the straight portion of the loop is  $2IRB$  and directed out of the page, and the force on the curved portion is  $2IRB$  directed into the page.

### Quick Quiz 29.3

The four wires shown in Figure 29.11 all carry the same current from point *A* to point *B* through the same magnetic field. Rank the wires according to the magnitude of the magnetic force exerted on them, from greatest to least.

**Figure 29.11** Which wire experiences the greatest magnetic force?

**Figure 29.12** (a) Overhead view of a rectangular current loop in a uniform magnetic field. No forces are acting on sides ① and ③ because these sides are parallel to  $\mathbf{B}$ . Forces are acting on sides ② and ④, however. (b) Edge view of the loop sighting down sides ② and ④ shows that the forces  $\mathbf{F}_2$  and  $\mathbf{F}_4$  exerted on these sides create a torque that tends to twist the loop clockwise. The purple dot in the left circle represents current in wire ② coming toward you; the purple cross in the right circle represents current in wire ④ moving away from you.

### 29.3 TORQUE ON A CURRENT LOOP IN A UNIFORM MAGNETIC FIELD

In the previous section, we showed how a force is exerted on a current-carrying conductor placed in a magnetic field. With this as a starting point, we now show that a torque is exerted on any current loop placed in a magnetic field. The results of this analysis will be of great value when we discuss motors in Chapter 31.

Consider a rectangular loop carrying a current  $I$  in the presence of a uniform magnetic field directed parallel to the plane of the loop, as shown in Figure 29.12a. No magnetic forces act on sides ① and ③ because these wires are parallel to the field; hence,  $\mathbf{L} \times \mathbf{B} = 0$  for these sides. However, magnetic forces do act on sides ② and ④ because these sides are oriented perpendicular to the field. The magnitude of these forces is, from Equation 29.3,

$$F_2 = F_4 = IaB$$

The direction of  $\mathbf{F}_2$ , the force exerted on wire ② is out of the page in the view shown in Figure 29.12a, and that of  $\mathbf{F}_4$ , the force exerted on wire ④, is into the page in the same view. If we view the loop from side ③ and sight along sides ② and ④, we see the view shown in Figure 29.12b, and the two forces  $\mathbf{F}_2$  and  $\mathbf{F}_4$  are directed as shown. Note that the two forces point in opposite directions but are *not* directed along the same line of action. If the loop is pivoted so that it can rotate about point  $O$ , these two forces produce about  $O$  a torque that rotates the loop clockwise. The magnitude of this torque  $\tau_{\max}$  is

$$\tau_{\max} = F_2 \frac{b}{2} + F_4 \frac{b}{2} = (IaB) \frac{b}{2} + (IaB) \frac{b}{2} = IabB$$

where the moment arm about  $O$  is  $b/2$  for each force. Because the area enclosed by the loop is  $A = ab$ , we can express the maximum torque as

$$\tau_{\max} = IAB \quad (29.8)$$

Remember that this maximum-torque result is valid only when the magnetic field is parallel to the plane of the loop. The sense of the rotation is clockwise when viewed from side ③, as indicated in Figure 29.12b. If the current direction were re-

versed, the force directions would also reverse, and the rotational tendency would be counterclockwise.

Now let us suppose that the uniform magnetic field makes an angle  $\theta < 90^\circ$  with a line perpendicular to the plane of the loop, as shown in Figure 29.13a. For convenience, we assume that  $\mathbf{B}$  is perpendicular to sides ① and ③. In this case, the magnetic forces  $\mathbf{F}_2$  and  $\mathbf{F}_4$  exerted on sides ② and ④ cancel each other and produce no torque because they pass through a common origin. However, the forces acting on sides ① and ③,  $\mathbf{F}_1$  and  $\mathbf{F}_3$ , form a couple and hence produce a torque about *any point*. Referring to the end view shown in Figure 29.13b, we note that the moment arm of  $\mathbf{F}_1$  about the point  $O$  is equal to  $(a/2) \sin \theta$ . Likewise, the moment arm of  $\mathbf{F}_3$  about  $O$  is also  $(a/2) \sin \theta$ . Because  $F_1 = F_3 = IbB$ , the net torque about  $O$  has the magnitude

$$\begin{aligned}\tau &= F_1 \frac{a}{2} \sin \theta + F_3 \frac{a}{2} \sin \theta \\ &= IbB \left( \frac{a}{2} \sin \theta \right) + IbB \left( \frac{a}{2} \sin \theta \right) = IabB \sin \theta \\ &= IAB \sin \theta\end{aligned}$$

where  $A = ab$  is the area of the loop. This result shows that the torque has its maximum value  $IAB$  when the field is perpendicular to the normal to the plane of the loop ( $\theta = 90^\circ$ ), as we saw when discussing Figure 29.12, and that it is zero when the field is parallel to the normal to the plane of the loop ( $\theta = 0$ ). As we see in Figure 29.13, the loop tends to rotate in the direction of decreasing values of  $\theta$  (that is, such that the area vector  $\mathbf{A}$  rotates toward the direction of the magnetic field).

**Figure 29.13** (a) A rectangular current loop in a uniform magnetic field. The area vector  $\mathbf{A}$  perpendicular to the plane of the loop makes an angle  $\theta$  with the field. The magnetic forces exerted on sides ② and ④ cancel, but the forces exerted on sides ① and ③ create a torque on the loop. (b) Edge view of the loop sighting down sides ① and ③.

### Quick Quiz 29.4

Describe the forces on the rectangular current loop shown in Figure 29.13 if the magnetic field is directed as shown but increases in magnitude going from left to right.

A convenient expression for the torque exerted on a loop placed in a uniform magnetic field  $\mathbf{B}$  is

$$\boldsymbol{\tau} = I\mathbf{A} \times \mathbf{B} \quad (29.9)$$

where  $\mathbf{A}$ , the vector shown in Figure 29.13, is perpendicular to the plane of the loop and has a magnitude equal to the area of the loop. We determine the direction of  $\mathbf{A}$  using the right-hand rule described in Figure 29.14. When you curl the fingers of your right hand in the direction of the current in the loop, your thumb points in the direction of  $\mathbf{A}$ . The product  $I\mathbf{A}$  is defined to be the **magnetic dipole moment**  $\boldsymbol{\mu}$  (often simply called the “magnetic moment”) of the loop:

$$\boldsymbol{\mu} = I\mathbf{A} \quad (29.10)$$

The SI unit of magnetic dipole moment is ampere-meter<sup>2</sup> ( $\text{A} \cdot \text{m}^2$ ). Using this definition, we can express the torque exerted on a current-carrying loop in a magnetic field  $\mathbf{B}$  as

$$\boldsymbol{\tau} = \boldsymbol{\mu} \times \mathbf{B} \quad (29.11)$$

Note that this result is analogous to Equation 26.18,  $\boldsymbol{\tau} = \mathbf{p} \times \mathbf{E}$ , for the torque exerted on an electric dipole in the presence of an electric field  $\mathbf{E}$ , where  $\mathbf{p}$  is the electric dipole moment.

Although we obtained the torque for a particular orientation of  $\mathbf{B}$  with respect to the loop, the equation  $\boldsymbol{\tau} = \boldsymbol{\mu} \times \mathbf{B}$  is valid for any orientation. Furthermore, although we derived the torque expression for a rectangular loop, the result is valid for a loop of any shape.

If a coil consists of  $N$  turns of wire, each carrying the same current and enclosing the same area, the total magnetic dipole moment of the coil is  $N$  times the magnetic dipole moment for one turn. The torque on an  $N$ -turn coil is  $N$  times that on a one-turn coil. Thus, we write  $\boldsymbol{\tau} = N\boldsymbol{\mu}_{\text{loop}} \times \mathbf{B} = \boldsymbol{\mu}_{\text{coil}} \times \mathbf{B}$ .

In Section 26.6, we found that the potential energy of an electric dipole in an electric field is given by  $U = -\mathbf{p} \cdot \mathbf{E}$ . This energy depends on the orientation of the dipole in the electric field. Likewise, the potential energy of a magnetic dipole in a magnetic field depends on the orientation of the dipole in the magnetic field and is given by

$$U = -\boldsymbol{\mu} \cdot \mathbf{B} \quad (29.12)$$

From this expression, we see that a magnetic dipole has its lowest energy  $U_{\text{min}} = -\boldsymbol{\mu}B$  when  $\boldsymbol{\mu}$  points in the same direction as  $\mathbf{B}$ . The dipole has its highest energy  $U_{\text{max}} = +\boldsymbol{\mu}B$  when  $\boldsymbol{\mu}$  points in the direction opposite  $\mathbf{B}$ .

### Quick Quiz 29.5

Rank the magnitude of the torques acting on the rectangular loops shown in Figure 29.15, from highest to lowest. All loops are identical and carry the same current.

Torque on a current loop

Magnetic dipole moment of a current loop

**Figure 29.14** Right-hand rule for determining the direction of the vector  $\mathbf{A}$ . The direction of the magnetic moment  $\boldsymbol{\mu}$  is the same as the direction of  $\mathbf{A}$ .

**Figure 29.15** Which current loop (seen edge-on) experiences the greatest torque?

### EXAMPLE 29.3 The Magnetic Dipole Moment of a Coil

A rectangular coil of dimensions  $5.40\text{ cm} \times 8.50\text{ cm}$  consists of 25 turns of wire and carries a current of  $15.0\text{ mA}$ . A  $0.350\text{-T}$  magnetic field is applied parallel to the plane of the loop. (a) Calculate the magnitude of its magnetic dipole moment.

**Solution** Because the coil has 25 turns, we modify Equation 29.10 to obtain

$$\begin{aligned}\mu_{\text{coil}} &= NIA = (25)(15.0 \times 10^{-3}\text{ A})(0.0540\text{ m})(0.0850\text{ m}) \\ &= 1.72 \times 10^{-3}\text{ A}\cdot\text{m}^2\end{aligned}$$

(b) What is the magnitude of the torque acting on the loop?

**Solution** Because  $\mathbf{B}$  is perpendicular to  $\boldsymbol{\mu}_{\text{coil}}$ , Equation 29.11 gives

$$\begin{aligned}\tau &= \mu_{\text{coil}}B = (1.72 \times 10^{-3}\text{ A}\cdot\text{m}^2)(0.350\text{ T}) \\ &= 6.02 \times 10^{-4}\text{ N}\cdot\text{m}\end{aligned}$$

**Exercise** Show that the units  $\text{A}\cdot\text{m}^2\cdot\text{T}$  reduce to the torque units  $\text{N}\cdot\text{m}$ .

**Exercise** Calculate the magnitude of the torque on the coil when the field makes an angle of (a)  $60^\circ$  and (b)  $0^\circ$  with  $\boldsymbol{\mu}$ .

**Answer** (a)  $5.21 \times 10^{-4}\text{ N}\cdot\text{m}$ ; (b) zero.

#### web

For more information on torquers, visit the Web site of a company that supplies these devices to NASA:  
<http://www.smad.com>

### EXAMPLE 29.4 Satellite Attitude Control

Many satellites use coils called *torquers* to adjust their orientation. These devices interact with the Earth's magnetic field to create a torque on the spacecraft in the  $x$ ,  $y$ , or  $z$  direction. The major advantage of this type of attitude-control system is that it uses solar-generated electricity and so does not consume any thruster fuel.

If a typical device has a magnetic dipole moment of  $250\text{ A}\cdot\text{m}^2$ , what is the maximum torque applied to a satellite when its torquer is turned on at an altitude where the magnitude of the Earth's magnetic field is  $3.0 \times 10^{-5}\text{ T}$ ?

**Solution** We once again apply Equation 29.11, recognizing that the maximum torque is obtained when the magnetic

dipole moment of the torquer is perpendicular to the Earth's magnetic field:

$$\begin{aligned}\tau_{\text{max}} &= \mu B = (250\text{ A}\cdot\text{m}^2)(3.0 \times 10^{-5}\text{ T}) \\ &= 7.5 \times 10^{-3}\text{ N}\cdot\text{m}\end{aligned}$$

**Exercise** If the torquer requires  $1.3\text{ W}$  of power at a potential difference of  $28\text{ V}$ , how much current does it draw when it operates?

**Answer**  $46\text{ mA}$ .

**EXAMPLE 29.5** The D'Arsonval Galvanometer

An end view of a D'Arsonval galvanometer (see Section 28.5) is shown in Figure 29.16. When the turns of wire making up the coil carry a current, the magnetic field created by the magnet exerts on the coil a torque that turns it (along with its attached pointer) against the spring. Let us show that the angle of deflection of the pointer is directly proportional to the current in the coil.

**Solution** We can use Equation 29.11 to find the torque  $\tau_m$  the magnetic field exerts on the coil. If we assume that the magnetic field through the coil is perpendicular to the normal to the plane of the coil, Equation 29.11 becomes

$$\tau_m = \mu B$$

(This is a reasonable assumption because the circular cross section of the magnet ensures radial magnetic field lines.) This magnetic torque is opposed by the torque due to the spring, which is given by the rotational version of Hooke's law,  $\tau_s = -\kappa\phi$ , where  $\kappa$  is the torsional spring constant and  $\phi$  is the angle through which the spring turns. Because the coil does not have an angular acceleration when the pointer is at rest, the sum of these torques must be zero:

$$(1) \quad \tau_m + \tau_s = \mu B - \kappa\phi = 0$$

Equation 29.10 allows us to relate the magnetic moment of the  $N$  turns of wire to the current through them:

$$\mu = NIA$$

We can substitute this expression for  $\mu$  in Equation (1) to obtain

$$(NIA)B - \kappa\phi = 0$$

$$\phi = \frac{NAB}{\kappa} I$$

Thus, the angle of deflection of the pointer is directly proportional to the current in the loop. The factor  $NAB/\kappa$  tells us that deflection also depends on the design of the meter.

**Figure 29.16** End view of a moving-coil galvanometer.

## 29.4 MOTION OF A CHARGED PARTICLE IN A UNIFORM MAGNETIC FIELD

### QuickLab

Move a bar magnet across the screen of a black-and-white television and watch what happens to the picture. The electrons are deflected by the magnetic field as they approach the screen, causing distortion. (WARNING: Do not attempt to do this with a *color* television or computer monitor. These devices typically contain a metallic plate that can become magnetized by the bar magnet. If this happens, a repair shop will need to “degauss” the screen.)

12.3

In Section 29.1 we found that the magnetic force acting on a charged particle moving in a magnetic field is perpendicular to the velocity of the particle and that consequently the work done on the particle by the magnetic force is zero. Let us now consider the special case of a positively charged particle moving in a uniform magnetic field with the initial velocity vector of the particle perpendicular to the field. Let us assume that the direction of the magnetic field is into the page. Figure 29.17 shows that the particle moves in a circle in a plane perpendicular to the magnetic field.

The particle moves in this way because the magnetic force  $\mathbf{F}_B$  is at right angles to  $\mathbf{v}$  and  $\mathbf{B}$  and has a constant magnitude  $qvB$ . As the force deflects the particle, the directions of  $\mathbf{v}$  and  $\mathbf{F}_B$  change continuously, as Figure 29.17 shows. Because  $\mathbf{F}_B$  always points toward the center of the circle, **it changes only the direction of  $\mathbf{v}$  and not its magnitude.** As Figure 29.17 illustrates, the rotation is counterclockwise for a positive charge. If  $q$  were negative, the rotation would be clockwise. We can use Equation 6.1 to equate this magnetic force to the radial force required to

keep the charge moving in a circle:

$$\begin{aligned}\sum F &= ma_r \\ F_B &= qvB = \frac{mv^2}{r} \\ r &= \frac{mv}{qB}\end{aligned}\quad (29.13)$$

That is, the radius of the path is proportional to the linear momentum  $mv$  of the particle and inversely proportional to the magnitude of the charge on the particle and to the magnitude of the magnetic field. The angular speed of the particle (from Eq. 10.10) is

$$\omega = \frac{v}{r} = \frac{qB}{m}\quad (29.14)$$

The period of the motion (the time that the particle takes to complete one revolution) is equal to the circumference of the circle divided by the linear speed of the particle:

$$T = \frac{2\pi r}{v} = \frac{2\pi}{\omega} = \frac{2\pi m}{qB}\quad (29.15)$$

These results show that the angular speed of the particle and the period of the circular motion do not depend on the linear speed of the particle or on the radius of the orbit. The angular speed  $\omega$  is often referred to as the **cyclotron frequency** because charged particles circulate at this angular speed in the type of accelerator called a *cyclotron*, which is discussed in Section 29.5.

If a charged particle moves in a uniform magnetic field with its velocity at some arbitrary angle with respect to  $\mathbf{B}$ , its path is a helix. For example, if the field is directed in the  $x$  direction, as shown in Figure 29.18, there is no component of force in the  $x$  direction. As a result,  $a_x = 0$ , and the  $x$  component of velocity remains constant. However, the magnetic force  $q\mathbf{v} \times \mathbf{B}$  causes the components  $v_y$  and  $v_z$  to change in time, and the resulting motion is a helix whose axis is parallel to the magnetic field. The projection of the path onto the  $yz$  plane (viewed along the  $x$  axis) is a circle. (The projections of the path onto the  $xy$  and  $xz$  planes are sinusoids!) Equations 29.13 to 29.15 still apply provided that  $v$  is replaced by  $v_{\perp} = \sqrt{v_y^2 + v_z^2}$ .

**Figure 29.17** When the velocity of a charged particle is perpendicular to a uniform magnetic field, the particle moves in a circular path in a plane perpendicular to  $\mathbf{B}$ . The magnetic force  $\mathbf{F}_B$  acting on the charge is always directed toward the center of the circle.

**Figure 29.18** A charged particle having a velocity vector that has a component parallel to a uniform magnetic field moves in a helical path.

### EXAMPLE 29.6 A Proton Moving Perpendicular to a Uniform Magnetic Field

A proton is moving in a circular orbit of radius 14 cm in a uniform 0.35-T magnetic field perpendicular to the velocity of the proton. Find the linear speed of the proton.

**Solution** From Equation 29.13, we have

$$\begin{aligned}v &= \frac{qBr}{m_p} = \frac{(1.60 \times 10^{-19} \text{ C})(0.35 \text{ T})(14 \times 10^{-2} \text{ m})}{1.67 \times 10^{-27} \text{ kg}} \\ &= 4.7 \times 10^6 \text{ m/s}\end{aligned}$$

**Exercise** If an electron moves in a direction perpendicular to the same magnetic field with this same linear speed, what is the radius of its circular orbit?

**Answer**  $7.6 \times 10^{-5} \text{ m}$ .

**EXAMPLE 29.7** Bending an Electron Beam

In an experiment designed to measure the magnitude of a uniform magnetic field, electrons are accelerated from rest through a potential difference of 350 V. The electrons travel along a curved path because of the magnetic force exerted on them, and the radius of the path is measured to be 7.5 cm. (Fig. 29.19 shows such a curved beam of electrons.) If the magnetic field is perpendicular to the beam, (a) what is the magnitude of the field?

**Solution** First we must calculate the speed of the electrons. We can use the fact that the increase in their kinetic energy must equal the decrease in their potential energy  $|e|\Delta V$  (because of conservation of energy). Then we can use Equation 29.13 to find the magnitude of the magnetic field. Because  $K_i = 0$  and  $K_f = m_e v^2/2$ , we have

$$\begin{aligned} \frac{1}{2}m_e v^2 &= |e|\Delta V \\ v &= \sqrt{\frac{2|e|\Delta V}{m_e}} = \sqrt{\frac{2(1.60 \times 10^{-19} \text{ C})(350 \text{ V})}{9.11 \times 10^{-31} \text{ kg}}} \\ &= 1.11 \times 10^7 \text{ m/s} \\ B &= \frac{m_e v}{|e|r} = \frac{(9.11 \times 10^{-31} \text{ kg})(1.11 \times 10^7 \text{ m/s})}{(1.60 \times 10^{-19} \text{ C})(0.075 \text{ m})} \\ &= 8.4 \times 10^{-4} \text{ T} \end{aligned}$$

(b) What is the angular speed of the electrons?

**Solution** Using Equation 29.14, we find that

$$\omega = \frac{v}{r} = \frac{1.11 \times 10^7 \text{ m/s}}{0.075 \text{ m}} = 1.5 \times 10^8 \text{ rad/s}$$

**Exercise** What is the period of revolution of the electrons?

**Answer** 43 ns.

**Figure 29.19** The bending of an electron beam in a magnetic field.

**Figure 29.20** A charged particle moving in a nonuniform magnetic field (a magnetic bottle) spirals about the field (red path) and oscillates between the end points. The magnetic force exerted on the particle near either end of the bottle has a component that causes the particle to spiral back toward the center.

When charged particles move in a nonuniform magnetic field, the motion is complex. For example, in a magnetic field that is strong at the ends and weak in the middle, such as that shown in Figure 29.20, the particles can oscillate back and forth between the end points. A charged particle starting at one end spirals along the field lines until it reaches the other end, where it reverses its path and spirals back. This configuration is known as a *magnetic bottle* because charged particles can be trapped within it. The magnetic bottle has been used to confine a *plasma*, a gas consisting of ions and electrons. Such a plasma-confinement scheme could fulfill a crucial role in the control of nuclear fusion, a process that could supply us with an almost endless source of energy. Unfortunately, the magnetic bottle has its problems. If a large number of particles are trapped, collisions between them cause the particles to eventually leak from the system.

The Van Allen radiation belts consist of charged particles (mostly electrons and protons) surrounding the Earth in doughnut-shaped regions (Fig. 29.21). The particles, trapped by the Earth's nonuniform magnetic field, spiral around the field lines from pole to pole, covering the distance in just a few seconds. These particles originate mainly from the Sun, but some come from stars and other heavenly objects. For this reason, the particles are called *cosmic rays*. Most cosmic rays are deflected by the Earth's magnetic field and never reach the atmosphere. However, some of the particles become trapped; it is these particles that make up the Van Allen belts. When the particles are located over the poles, they sometimes collide with atoms in the atmosphere, causing the atoms to emit visible light. Such collisions are the origin of the beautiful Aurora Borealis, or Northern Lights, in the northern hemisphere and the Aurora Australis in the southern hemisphere.

**Figure 29.21** The Van Allen belts are made up of charged particles trapped by the Earth's nonuniform magnetic field. The magnetic field lines are in blue and the particle paths in red.

Auroras are usually confined to the polar regions because it is here that the Van Allen belts are nearest the Earth's surface. Occasionally, though, solar activity causes larger numbers of charged particles to enter the belts and significantly distort the normal magnetic field lines associated with the Earth. In these situations an aurora can sometimes be seen at lower latitudes. 12.1  
&  
12.11

This color-enhanced photograph, taken at CERN, the particle physics laboratory outside Geneva, Switzerland, shows a collection of tracks left by subatomic particles in a bubble chamber. A bubble chamber is a container filled with liquid hydrogen that is superheated, that is, momentarily raised above its normal boiling point by a sudden drop in pressure in the container. Any charged particle passing through the liquid in this state leaves behind a trail of tiny bubbles as the liquid boils in its wake. These bubbles are seen as fine tracks, showing the characteristic paths of different types of particles. The paths are curved because there is an intense applied magnetic field. The tightly wound spiral tracks are due to electrons and positrons.

## Optional Section

## 29.5 APPLICATIONS INVOLVING CHARGED PARTICLES MOVING IN A MAGNETIC FIELD

A charge moving with a velocity  $\mathbf{v}$  in the presence of both an electric field  $\mathbf{E}$  and a magnetic field  $\mathbf{B}$  experiences both an electric force  $q\mathbf{E}$  and a magnetic force  $q\mathbf{v} \times \mathbf{B}$ . The total force (called the Lorentz force) acting on the charge is

Lorentz force

$$\sum \mathbf{F} = q\mathbf{E} + q\mathbf{v} \times \mathbf{B} \quad (29.16)$$

### Velocity Selector

In many experiments involving moving charged particles, it is important that the particles all move with essentially the same velocity. This can be achieved by applying a combination of an electric field and a magnetic field oriented as shown in Figure 29.22. A uniform electric field is directed vertically downward (in the plane of the page in Fig. 29.22a), and a uniform magnetic field is applied in the direction perpendicular to the electric field (into the page in Fig. 29.22a). For  $q$  positive, the magnetic force  $q\mathbf{v} \times \mathbf{B}$  is upward and the electric force  $q\mathbf{E}$  is downward. When the magnitudes of the two fields are chosen so that  $qE = qvB$ , the particle moves in a straight horizontal line through the region of the fields. From the expression  $qE = qvB$ , we find that

$$v = \frac{E}{B} \quad (29.17)$$

Only those particles having speed  $v$  pass undeflected through the mutually perpendicular electric and magnetic fields. The magnetic force exerted on particles moving at speeds greater than this is stronger than the electric force, and the particles are deflected upward. Those moving at speeds less than this are deflected downward.

### The Mass Spectrometer

A **mass spectrometer** separates ions according to their mass-to-charge ratio. In one version of this device, known as the *Bainbridge mass spectrometer*, a beam of ions first passes through a velocity selector and then enters a second uniform magnetic field  $\mathbf{B}_0$  that has the same direction as the magnetic field in the selector (Fig. 29.23). Upon entering the second magnetic field, the ions move in a semicircle of

**Figure 29.22** (a) A velocity selector. When a positively charged particle is in the presence of a magnetic field directed into the page and an electric field directed downward, it experiences a downward electric force  $q\mathbf{E}$  and an upward magnetic force  $q\mathbf{v} \times \mathbf{B}$ . (b) When these forces balance, the particle moves in a horizontal line through the fields.

**Figure 29.23** A mass spectrometer. Positively charged particles are sent first through a velocity selector and then into a region where the magnetic field  $\mathbf{B}_0$  causes the particles to move in a semicircular path and strike a photographic film at  $P$ .

radius  $r$  before striking a photographic plate at  $P$ . If the ions are positively charged, the beam deflects upward, as Figure 29.23 shows. If the ions are negatively charged, the beam would deflect downward. From Equation 29.13, we can express the ratio  $m/q$  as

$$\frac{m}{q} = \frac{rB_0}{v}$$

Using Equation 29.17, we find that

$$\frac{m}{q} = \frac{rB_0B}{E} \quad (29.18)$$

Therefore, we can determine  $m/q$  by measuring the radius of curvature and knowing the field magnitudes  $B$ ,  $B_0$ , and  $E$ . In practice, one usually measures the masses of various isotopes of a given ion, with the ions all carrying the same charge  $q$ . In this way, the mass ratios can be determined even if  $q$  is unknown.

A variation of this technique was used by J. J. Thomson (1856–1940) in 1897 to measure the ratio  $e/m_e$  for electrons. Figure 29.24a shows the basic apparatus he

(a)

(b)

**Figure 29.24** (a) Thomson's apparatus for measuring  $e/m_e$ . Electrons are accelerated from the cathode, pass through two slits, and are deflected by both an electric field and a magnetic field (directed perpendicular to the electric field). The beam of electrons then strikes a fluorescent screen. (b) J. J. Thomson (*left*) in the Cavendish Laboratory, University of Cambridge. It is interesting to note that the man on the right, Frank Baldwin Jewett, is a distant relative of John W. Jewett, Jr., contributing author of this text.

used. Electrons are accelerated from the cathode and pass through two slits. They then drift into a region of perpendicular electric and magnetic fields. The magnitudes of the two fields are first adjusted to produce an undeflected beam. When the magnetic field is turned off, the electric field produces a measurable beam deflection that is recorded on the fluorescent screen. From the size of the deflection and the measured values of  $E$  and  $B$ , the charge-to-mass ratio can be determined. The results of this crucial experiment represent the discovery of the electron as a fundamental particle of nature.

### Quick Quiz 29.6

When a photographic plate from a mass spectrometer like the one shown in Figure 29.23 is developed, the three patterns shown in Figure 29.25 are observed. Rank the particles that caused the patterns by speed and  $m/q$  ratio.

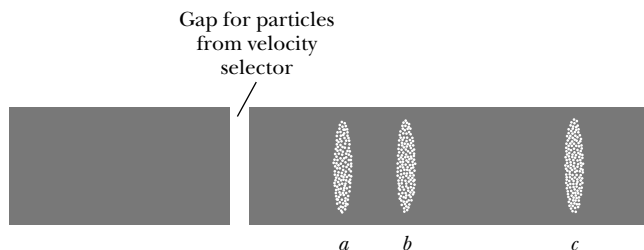

Figure 29.25

### The Cyclotron

A **cyclotron** can accelerate charged particles to very high speeds. Both electric and magnetic forces have a key role. The energetic particles produced are used to bombard atomic nuclei and thereby produce nuclear reactions of interest to researchers. A number of hospitals use cyclotron facilities to produce radioactive substances for diagnosis and treatment.

A schematic drawing of a cyclotron is shown in Figure 29.26. The charges move inside two semicircular containers  $D_1$  and  $D_2$ , referred to as *dees*. A high-frequency alternating potential difference is applied to the dees, and a uniform magnetic field is directed perpendicular to them. A positive ion released at  $P$  near the center of the magnet in one dee moves in a semicircular path (indicated by the dashed red line in the drawing) and arrives back at the gap in a time  $T/2$ , where  $T$  is the time needed to make one complete trip around the two dees, given by Equation 29.15. The frequency of the applied potential difference is adjusted so that the polarity of the dees is reversed in the same time it takes the ion to travel around one dee. If the applied potential difference is adjusted such that  $D_2$  is at a lower electric potential than  $D_1$  by an amount  $\Delta V$ , the ion accelerates across the gap to  $D_2$  and its kinetic energy increases by an amount  $q\Delta V$ . It then moves around  $D_2$  in a semicircular path of greater radius (because its speed has increased). After a time  $T/2$ , it again arrives at the gap between the dees. By this time, the polarity across the dees is again reversed, and the ion is given another “kick” across the gap. The motion continues so that for each half-circle trip around one dee, the ion gains additional kinetic energy equal to  $q\Delta V$ . When the radius of its path is nearly that of the dees, the energetic ion leaves the system through the exit slit. It is important to note that the operation of the cyclotron is

**Figure 29.26** (a) A cyclotron consists of an ion source at  $P$ , two dees  $D_1$  and  $D_2$  across which an alternating potential difference is applied, and a uniform magnetic field. (The south pole of the magnet is not shown.) The red dashed curved lines represent the path of the particles. (b) The first cyclotron, invented by E.O. Lawrence and M.S. Livingston in 1934.

based on the fact that  $T$  is independent of the speed of the ion and of the radius of the circular path.

We can obtain an expression for the kinetic energy of the ion when it exits the cyclotron in terms of the radius  $R$  of the dees. From Equation 29.13 we know that  $v = qBR/m$ . Hence, the kinetic energy is

$$K = \frac{1}{2}mv^2 = \frac{q^2B^2R^2}{2m} \quad (29.19)$$

When the energy of the ions in a cyclotron exceeds about 20 MeV, relativistic effects come into play. (Such effects are discussed in Chapter 39.) We observe that  $T$  increases and that the moving ions do not remain in phase with the applied potential difference. Some accelerators overcome this problem by modifying the period of the applied potential difference so that it remains in phase with the moving ions.

### Optional Section

## 29.6 THE HALL EFFECT

When a current-carrying conductor is placed in a magnetic field, a potential difference is generated in a direction perpendicular to both the current and the magnetic field. This phenomenon, first observed by Edwin Hall (1855–1938) in 1879, is known as the *Hall effect*. It arises from the deflection of charge carriers to one side of the conductor as a result of the magnetic force they experience. The Hall effect gives information regarding the sign of the charge carriers and their density; it can also be used to measure the magnitude of magnetic fields.

The arrangement for observing the Hall effect consists of a flat conductor carrying a current  $I$  in the  $x$  direction, as shown in Figure 29.27. A uniform magnetic field  $\mathbf{B}$  is applied in the  $y$  direction. If the charge carriers are electrons moving in the negative  $x$  direction with a drift velocity  $\mathbf{v}_d$ , they experience an upward mag-

### web

More information on these accelerators is available at

<http://www.fnal.gov> or  
<http://www.CERN.ch>

The CERN site also discusses the creation of the World Wide Web there by physicists in the mid-1990s.

**Figure 29.27** To observe the Hall effect, a magnetic field is applied to a current-carrying conductor. When  $I$  is in the  $x$  direction and  $\mathbf{B}$  in the  $y$  direction, both positive and negative charge carriers are deflected upward in the magnetic field. The Hall voltage is measured between points  $a$  and  $c$ .

netic force  $\mathbf{F}_B = q\mathbf{v}_d \times \mathbf{B}$ , are deflected upward, and accumulate at the upper edge of the flat conductor, leaving an excess of positive charge at the lower edge (Fig. 29.28a). This accumulation of charge at the edges increases until the electric force resulting from the charge separation balances the magnetic force acting on the carriers. When this equilibrium condition is reached, the electrons are no longer deflected upward. A sensitive voltmeter or potentiometer connected across the sample, as shown in Figure 29.28, can measure the potential difference—known as the **Hall voltage**  $\Delta V_H$ —generated across the conductor.

If the charge carriers are positive and hence move in the positive  $x$  direction, as shown in Figures 29.27 and 29.28b, they also experience an upward magnetic force  $q\mathbf{v}_d \times \mathbf{B}$ . This produces a buildup of positive charge on the upper edge and leaves an excess of negative charge on the lower edge. Hence, the sign of the Hall voltage generated in the sample is opposite the sign of the Hall voltage resulting from the deflection of electrons. The sign of the charge carriers can therefore be determined from a measurement of the polarity of the Hall voltage.

In deriving an expression for the Hall voltage, we first note that the magnetic force exerted on the carriers has magnitude  $qv_dB$ . In equilibrium, this force is balanced by the electric force  $qE_H$ , where  $E_H$  is the magnitude of the electric field due to the charge separation (sometimes referred to as the *Hall field*). Therefore,

$$qv_dB = qE_H$$

$$E_H = v_dB$$

**Figure 29.28** (a) When the charge carriers in a Hall effect apparatus are negative, the upper edge of the conductor becomes negatively charged, and  $c$  is at a lower electric potential than  $a$ . (b) When the charge carriers are positive, the upper edge becomes positively charged, and  $c$  is at a higher potential than  $a$ . In either case, the charge carriers are no longer deflected when the edges become fully charged, that is, when there is a balance between the electrostatic force  $qE_H$  and the magnetic deflection force  $qvB$ .

If  $d$  is the width of the conductor, the Hall voltage is

$$\Delta V_H = E_H d = v_d B d \quad (29.20)$$

Thus, the measured Hall voltage gives a value for the drift speed of the charge carriers if  $d$  and  $B$  are known.

We can obtain the charge carrier density  $n$  by measuring the current in the sample. From Equation 27.4, we can express the drift speed as

$$v_d = \frac{I}{nqA} \quad (29.21)$$

where  $A$  is the cross-sectional area of the conductor. Substituting Equation 29.21 into Equation 29.20, we obtain

$$\Delta V_H = \frac{IBd}{nqA} \quad (29.22)$$

Because  $A = td$ , where  $t$  is the thickness of the conductor, we can also express Equation 29.22 as

$$\Delta V_H = \frac{IB}{nqt} = \frac{R_H IB}{t} \quad (29.23)$$

where  $R_H = 1/nq$  is the **Hall coefficient**. This relationship shows that a properly calibrated conductor can be used to measure the magnitude of an unknown magnetic field.

Because all quantities in Equation 29.23 other than  $nq$  can be measured, a value for the Hall coefficient is readily obtainable. The sign and magnitude of  $R_H$  give the sign of the charge carriers and their number density. In most metals, the charge carriers are electrons, and the charge carrier density determined from Hall-effect measurements is in good agreement with calculated values for such metals as lithium (Li), sodium (Na), copper (Cu), and silver (Ag), whose atoms each give up one electron to act as a current carrier. In this case,  $n$  is approximately equal to the number of conducting electrons per unit volume. However, this classical model is not valid for metals such as iron (Fe), bismuth (Bi), and cadmium (Cd) or for semiconductors. These discrepancies can be explained only by using a model based on the quantum nature of solids.

The Hall voltage

#### web

In 1980, Klaus von Klitzing discovered that the Hall voltage is quantized. He won the Nobel Prize for this discovery in 1985. For a discussion of the quantum Hall effect and some of its consequences, visit our Web site at <http://www.saunderscollege.com/physics/>

### EXAMPLE 29.8 The Hall Effect for Copper

A rectangular copper strip 1.5 cm wide and 0.10 cm thick carries a current of 5.0 A. Find the Hall voltage for a 1.2-T magnetic field applied in a direction perpendicular to the strip.

**Solution** If we assume that one electron per atom is available for conduction, we can take the charge carrier density to be  $n = 8.49 \times 10^{28}$  electrons/m<sup>3</sup> (see Example 27.1). Substituting this value and the given data into Equation 29.23 gives

$$\begin{aligned} \Delta V_H &= \frac{IB}{nqt} \\ &= \frac{(5.0 \text{ A})(1.2 \text{ T})}{(8.49 \times 10^{28} \text{ m}^{-3})(1.6 \times 10^{-19} \text{ C})(0.0010 \text{ m})} \end{aligned}$$

$$\Delta V_H = 0.44 \mu\text{V}$$

Such an extremely small Hall voltage is expected in good conductors. (Note that the width of the conductor is not needed in this calculation.)

In semiconductors,  $n$  is much smaller than it is in metals that contribute one electron per atom to the current; hence, the Hall voltage is usually greater because it varies as the inverse of  $n$ . Currents of the order of 0.1 mA are generally used for such materials. Consider a piece of silicon that has the same dimensions as the copper strip in this example and whose value for  $n = 1.0 \times 10^{20}$  electrons/m<sup>3</sup>. Taking  $B = 1.2$  T and  $I = 0.10$  mA, we find that  $\Delta V_H = 7.5$  mV. A potential difference of this magnitude is readily measured.

### SUMMARY

The magnetic force that acts on a charge  $q$  moving with a velocity  $\mathbf{v}$  in a magnetic field  $\mathbf{B}$  is

$$\mathbf{F}_B = q\mathbf{v} \times \mathbf{B} \quad (29.1)$$

The direction of this magnetic force is perpendicular both to the velocity of the particle and to the magnetic field. The magnitude of this force is

$$F_B = |q|vB \sin \theta \quad (29.2)$$

where  $\theta$  is the smaller angle between  $\mathbf{v}$  and  $\mathbf{B}$ . The SI unit of  $\mathbf{B}$  is the **tesla** (T), where  $1 \text{ T} = 1 \text{ N/A} \cdot \text{m}$ .

When a charged particle moves in a magnetic field, the work done by the magnetic force on the particle is zero because the displacement is always perpendicular to the direction of the force. The magnetic field can alter the direction of the particle's velocity vector, but it cannot change its speed.

If a straight conductor of length  $L$  carries a current  $I$ , the force exerted on that conductor when it is placed in a uniform magnetic field  $\mathbf{B}$  is

$$\mathbf{F}_B = I\mathbf{L} \times \mathbf{B} \quad (29.3)$$

where the direction of  $\mathbf{L}$  is in the direction of the current and  $|\mathbf{L}| = L$ .

If an arbitrarily shaped wire carrying a current  $I$  is placed in a magnetic field, the magnetic force exerted on a very small segment  $d\mathbf{s}$  is

$$d\mathbf{F}_B = I d\mathbf{s} \times \mathbf{B} \quad (29.4)$$

To determine the total magnetic force on the wire, one must integrate Equation 29.4, keeping in mind that both  $\mathbf{B}$  and  $d\mathbf{s}$  may vary at each point. Integration gives for the force exerted on a current-carrying conductor of arbitrary shape in a uniform magnetic field

$$\mathbf{F}_B = I\mathbf{L}' \times \mathbf{B} \quad (29.7)$$

where  $\mathbf{L}'$  is a vector directed from one end of the conductor to the opposite end. Because integration of Equation 29.4 for a closed loop yields a zero result, the net magnetic force on any closed loop carrying a current in a uniform magnetic field is zero.

The **magnetic dipole moment**  $\boldsymbol{\mu}$  of a loop carrying a current  $I$  is

$$\boldsymbol{\mu} = I\mathbf{A} \quad (29.10)$$

where the area vector  $\mathbf{A}$  is perpendicular to the plane of the loop and  $|\mathbf{A}|$  is equal to the area of the loop. The SI unit of  $\boldsymbol{\mu}$  is  $\text{A} \cdot \text{m}^2$ .

The torque  $\boldsymbol{\tau}$  on a current loop placed in a uniform magnetic field  $\mathbf{B}$  is

$$\boldsymbol{\tau} = \boldsymbol{\mu} \times \mathbf{B} \quad (29.11)$$

and the potential energy of a magnetic dipole in a magnetic field is

$$U = -\boldsymbol{\mu} \cdot \mathbf{B} \quad (29.12)$$

If a charged particle moves in a uniform magnetic field so that its initial velocity is perpendicular to the field, the particle moves in a circle, the plane of which is perpendicular to the magnetic field. The radius of the circular path is

$$r = \frac{mv}{qB} \quad (29.13)$$

where  $m$  is the mass of the particle and  $q$  is its charge. The angular speed of the charged particle is

$$\omega = \frac{qB}{m} \quad (29.14)$$

### QUESTIONS

- At a given instant, a proton moves in the positive  $x$  direction in a region where a magnetic field is directed in the negative  $z$  direction. What is the direction of the magnetic force? Does the proton continue to move in the positive  $x$  direction? Explain.
- Two charged particles are projected into a region where a magnetic field is directed perpendicular to their velocities. If the charges are deflected in opposite directions, what can be said about them?
- If a charged particle moves in a straight line through some region of space, can one say that the magnetic field in that region is zero?
- Suppose an electron is chasing a proton up this page when suddenly a magnetic field directed perpendicular into the page is turned on. What happens to the particles?
- How can the motion of a moving charged particle be used to distinguish between a magnetic field and an electric field? Give a specific example to justify your argument.
- List several similarities and differences between electric and magnetic forces.
- Justify the following statement: "It is impossible for a constant (in other words, a time-independent) magnetic field to alter the speed of a charged particle."
- In view of the preceding statement, what is the role of a magnetic field in a cyclotron?
- A current-carrying conductor experiences no magnetic force when placed in a certain manner in a uniform magnetic field. Explain.
- Is it possible to orient a current loop in a uniform magnetic field such that the loop does not tend to rotate? Explain.
- How can a current loop be used to determine the presence of a magnetic field in a given region of space?
- What is the net force acting on a compass needle in a uniform magnetic field?
- What type of magnetic field is required to exert a resultant force on a magnetic dipole? What is the direction of the resultant force?
- A proton moving horizontally enters a region where a uniform magnetic field is directed perpendicular to the proton's velocity, as shown in Figure Q29.14. Describe the subsequent motion of the proton. How would an electron behave under the same circumstances?
- In a magnetic bottle, what causes the direction of the velocity of the confined charged particles to reverse? (*Hint*: Find the direction of the magnetic force acting on the particles in a region where the field lines converge.)
- In the cyclotron, why do particles of different velocities take the same amount of time to complete one half-circle trip around one dee?

Figure Q29.14

- The *bubble chamber* is a device used for observing tracks of particles that pass through the chamber, which is immersed in a magnetic field. If some of the tracks are spirals and others are straight lines, what can you say about the particles?
- Can a constant magnetic field set into motion an electron initially at rest? Explain your answer.
- You are designing a magnetic probe that uses the Hall effect to measure magnetic fields. Assume that you are restricted to using a given material and that you have already made the probe as thin as possible. What, if anything, can be done to increase the Hall voltage produced for a given magnetic field?
- The electron beam shown in Figure Q29.20 is projected to the right. The beam deflects downward in the presence of a magnetic field produced by a pair of current-carrying coils. (a) What is the direction of the magnetic field? (b) What would happen to the beam if the current in the coils were reversed?

## Section 29.1 The Magnetic Field

- WEB **1.** Determine the initial direction of the deflection of charged particles as they enter the magnetic fields, as shown in Figure P29.1.

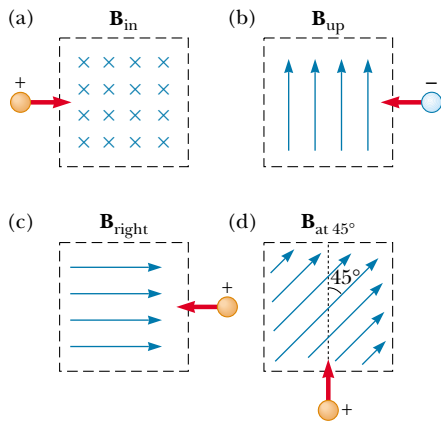

Figure P29.1

- Consider an electron near the Earth's equator. In which direction does it tend to deflect if its velocity is directed (a) downward, (b) northward, (c) westward, or (d) southeastward?
- An electron moving along the positive  $x$  axis perpendicular to a magnetic field experiences a magnetic deflection in the negative  $y$  direction. What is the direction of the magnetic field?
- A proton travels with a speed of  $3.00 \times 10^6$  m/s at an angle of  $37.0^\circ$  with the direction of a magnetic field of 0.300 T in the  $+y$  direction. What are (a) the magnitude of the magnetic force on the proton and (b) its acceleration?
- 5.** A proton moves in a direction perpendicular to a uniform magnetic field  $\mathbf{B}$  at  $1.00 \times 10^7$  m/s and experiences an acceleration of  $2.00 \times 10^{13}$  m/s<sup>2</sup> in the  $+x$  direction when its velocity is in the  $+z$  direction. Determine the magnitude and direction of the field.
- An electron is accelerated through 2 400 V from rest and then enters a region where there is a uniform 1.70-T magnetic field. What are (a) the maximum and (b) the minimum values of the magnetic force this charge can experience?
- At the equator, near the surface of the Earth, the magnetic field is approximately  $50.0 \mu\text{T}$  northward, and the electric field is about 100 N/C downward in fair weather. Find the gravitational, electric, and magnetic forces on an electron with an instantaneous velocity of

$6.00 \times 10^6$  m/s directed to the east in this environment.

- A 30.0-g metal ball having net charge  $Q = 5.00 \mu\text{C}$  is thrown out of a window horizontally at a speed  $v = 20.0$  m/s. The window is at a height  $h = 20.0$  m above the ground. A uniform horizontal magnetic field of magnitude  $B = 0.0100$  T is perpendicular to the plane of the ball's trajectory. Find the magnetic force acting on the ball just before it hits the ground.
- 9.** A proton moving at  $4.00 \times 10^6$  m/s through a magnetic field of 1.70 T experiences a magnetic force of magnitude  $8.20 \times 10^{-13}$  N. What is the angle between the proton's velocity and the field?
- An electron has a velocity of 1.20 km/s (in the positive  $x$  direction) and an acceleration of  $2.00 \times 10^{12}$  m/s<sup>2</sup> (in the positive  $z$  direction) in uniform electric and magnetic fields. If the electric field has a magnitude of 20.0 N/C (in the positive  $z$  direction), what can you determine about the magnetic field in the region? What can you not determine?
- 11.** A proton moves with a velocity of  $\mathbf{v} = (2\mathbf{i} - 4\mathbf{j} + \mathbf{k})$  m/s in a region in which the magnetic field is  $\mathbf{B} = (\mathbf{i} + 2\mathbf{j} - 3\mathbf{k})$  T. What is the magnitude of the magnetic force this charge experiences?
- An electron is projected into a uniform magnetic field  $\mathbf{B} = (1.40\mathbf{i} + 2.10\mathbf{j})$  T. Find the vector expression for the force on the electron when its velocity is  $\mathbf{v} = 3.70 \times 10^5 \mathbf{j}$  m/s.

## Section 29.2 Magnetic Force Acting on a Current-Carrying Conductor

- WEB **13.** A wire having a mass per unit length of 0.500 g/cm carries a 2.00-A current horizontally to the south. What are the direction and magnitude of the minimum magnetic field needed to lift this wire vertically upward?
- A wire carries a steady current of 2.40 A. A straight section of the wire is 0.750 m long and lies along the  $x$  axis within a uniform magnetic field of magnitude  $B = 1.60$  T in the positive  $z$  direction. If the current is in the  $+x$  direction, what is the magnetic force on the section of wire?
  - A wire 2.80 m in length carries a current of 5.00 A in a region where a uniform magnetic field has a magnitude of 0.390 T. Calculate the magnitude of the magnetic force on the wire if the angle between the magnetic field and the current is (a)  $60.0^\circ$ , (b)  $90.0^\circ$ , (c)  $120^\circ$ .
  - A conductor suspended by two flexible wires as shown in Figure P29.16 has a mass per unit length of 0.0400 kg/m. What current must exist in the conductor for the tension in the supporting wires to be zero when the magnetic

Figure P29.16

field is 3.60 T into the page? What is the required direction for the current?

17. Imagine a very long, uniform wire with a linear mass density of 1.00 g/m that encircles the Earth at its magnetic equator. Suppose that the planet's magnetic field is  $50.0 \mu\text{T}$  horizontally north throughout this region. What are the magnitude and direction of the current in the wire that keep it levitated just above the ground?
18. In Figure P29.18, the cube is 40.0 cm on each edge. Four straight segments of wire— $ab$ ,  $bc$ ,  $cd$ , and  $da$ —form a closed loop that carries a current  $I = 5.00 \text{ A}$ , in the direction shown. A uniform magnetic field of magnitude  $B = 0.020 \text{ T}$  is in the positive  $y$  direction. Determine the magnitude and direction of the magnetic force on each segment.

Figure P29.18

19. **Review Problem.** A rod with a mass of 0.720 kg and a radius of 6.00 cm rests on two parallel rails (Fig. P29.19) that are  $d = 12.0 \text{ cm}$  apart and  $L = 45.0 \text{ cm}$  long. The rod carries a current of  $I = 48.0 \text{ A}$  (in the direction shown) and rolls along the rails without slipping. If it starts from rest, what is the speed of the rod as it leaves the rails if a uniform magnetic field of magnitude 0.240 T is directed perpendicular to the rod and the rails?
20. **Review Problem.** A rod of mass  $m$  and radius  $R$  rests on two parallel rails (Fig. P29.19) that are a distance  $d$  apart and have a length  $L$ . The rod carries a current  $I$  (in the direction shown) and rolls along the rails without slipping. If it starts from rest, what is the speed of the rod as it leaves the rails if a uniform magnetic field  $\mathbf{B}$  is directed perpendicular to the rod and the rails?

Figure P29.19 Problems 19 and 20.

- WEB 21. A nonuniform magnetic field exerts a net force on a magnetic dipole. A strong magnet is placed under a horizontal conducting ring of radius  $r$  that carries current  $I$ , as shown in Figure P29.21. If the magnetic field  $\mathbf{B}$  makes an angle  $\theta$  with the vertical at the ring's location, what are the magnitude and direction of the resultant force on the ring?

Figure P29.21

22. Assume that in Atlanta, Georgia, the Earth's magnetic field is  $52.0 \mu\text{T}$  northward at  $60.0^\circ$  below the horizontal. A tube in a neon sign carries a current of 35.0 mA between two diagonally opposite corners of a shop window, which lies in a north-south vertical plane. The current enters the tube at the bottom south corner of the window. It exits at the opposite corner, which is 1.40 m farther north and 0.850 m higher up. Between these two points, the glowing tube spells out DONUTS. Use the theorem proved as "Case 1" in the text to determine the total vector magnetic force on the tube.

### Section 29.3 Torque on a Current Loop in a Uniform Magnetic Field

23. A current of 17.0 mA is maintained in a single circular loop with a circumference of 2.00 m. A magnetic field

- of 0.800 T is directed parallel to the plane of the loop.
- (a) Calculate the magnetic moment of the loop.
- (b) What is the magnitude of the torque exerted on the loop by the magnetic field?
24. A small bar magnet is suspended in a uniform 0.250-T magnetic field. The maximum torque experienced by the bar magnet is  $4.60 \times 10^{-3} \text{ N} \cdot \text{m}$ . Calculate the magnetic moment of the bar magnet.

**WEB** 25. A rectangular loop consists of  $N = 100$  closely wrapped turns and has dimensions  $a = 0.400 \text{ m}$  and  $b = 0.300 \text{ m}$ . The loop is hinged along the  $y$  axis, and its plane makes an angle  $\theta = 30.0^\circ$  with the  $x$  axis (Fig. P29.25). What is the magnitude of the torque exerted on the loop by a uniform magnetic field  $B = 0.800 \text{ T}$  directed along the  $x$  axis when the current is  $I = 1.20 \text{ A}$  in the direction shown? What is the expected direction of rotation of the loop?

Figure P29.25

26. A long piece of wire of mass 0.100 kg and total length of 4.00 m is used to make a square coil with a side of 0.100 m. The coil is hinged along a horizontal side, carries a 3.40-A current, and is placed in a vertical magnetic field with a magnitude of 0.010 0 T. (a) Determine the angle that the plane of the coil makes with the vertical when the coil is in equilibrium. (b) Find the torque acting on the coil due to the magnetic force at equilibrium.
27. A 40.0-cm length of wire carries a current of 20.0 A. It is bent into a loop and placed with its normal perpendicular to a magnetic field with a strength of 0.520 T. What is the torque on the loop if it is bent into (a) an equilateral triangle, (b) a square, (c) a circle? (d) Which torque is greatest?
28. A current loop with dipole moment  $\mu$  is placed in a uniform magnetic field  $\mathbf{B}$ . Prove that its potential energy is  $U = -\mu \cdot \mathbf{B}$ . You may imitate the discussion of the potential energy of an electric dipole in an electric field given in Chapter 26.
29. The needle of a magnetic compass has a magnetic moment of  $9.70 \text{ mA} \cdot \text{m}^2$ . At its location, the Earth's magnetic field is  $55.0 \mu\text{T}$  north at  $48.0^\circ$  below the horizontal. (a) Identify the orientations at which the compass

needle has minimum potential energy and maximum potential energy. (b) How much work must be done on the needle for it to move from the former to the latter orientation?

30. A wire is formed into a circle having a diameter of 10.0 cm and is placed in a uniform magnetic field of 3.00 mT. A current of 5.00 A passes through the wire. Find (a) the maximum torque on the wire and (b) the range of potential energy of the wire in the field for different orientations of the circle.

### Section 29.4 Motion of a Charged Particle in a Uniform Magnetic Field

31. The magnetic field of the Earth at a certain location is directed vertically downward and has a magnitude of  $50.0 \mu\text{T}$ . A proton is moving horizontally toward the west in this field with a speed of  $6.20 \times 10^6 \text{ m/s}$ .
- (a) What are the direction and magnitude of the magnetic force that the field exerts on this charge?
- (b) What is the radius of the circular arc followed by this proton?
32. A singly charged positive ion has a mass of  $3.20 \times 10^{-26} \text{ kg}$ . After being accelerated from rest through a potential difference of 833 V, the ion enters a magnetic field of 0.920 T along a direction perpendicular to the direction of the field. Calculate the radius of the path of the ion in the field.
33. **Review Problem.** One electron collides elastically with a second electron initially at rest. After the collision, the radii of their trajectories are 1.00 cm and 2.40 cm. The trajectories are perpendicular to a uniform magnetic field of magnitude 0.044 0 T. Determine the energy (in keV) of the incident electron.
34. A proton moving in a circular path perpendicular to a constant magnetic field takes  $1.00 \mu\text{s}$  to complete one revolution. Determine the magnitude of the magnetic field.
35. A proton (charge  $+e$ , mass  $m_p$ ), a deuteron (charge  $+e$ , mass  $2m_p$ ), and an alpha particle (charge  $+2e$ , mass  $4m_p$ ) are accelerated through a common potential difference  $\Delta V$ . The particles enter a uniform magnetic field  $\mathbf{B}$  with a velocity in a direction perpendicular to  $\mathbf{B}$ . The proton moves in a circular path of radius  $r_p$ . Determine the values of the radii of the circular orbits for the deuteron  $r_d$  and the alpha particle  $r_\alpha$  in terms of  $r_p$ .
36. **Review Problem.** An electron moves in a circular path perpendicular to a constant magnetic field with a magnitude of 1.00 mT. If the angular momentum of the electron about the center of the circle is  $4.00 \times 10^{-25} \text{ J} \cdot \text{s}$ , determine (a) the radius of the circular path and (b) the speed of the electron.
37. Calculate the cyclotron frequency of a proton in a magnetic field with a magnitude of 5.20 T.
38. A singly charged ion of mass  $m$  is accelerated from rest by a potential difference  $\Delta V$ . It is then deflected by a uniform magnetic field (perpendicular to the ion's velocity) into a semicircle of radius  $R$ . Now a doubly

charged ion of mass  $m'$  is accelerated through the same potential difference and deflected by the same magnetic field into a semicircle of radius  $R' = 2R$ . What is the ratio of the ions' masses?

39. A cosmic-ray proton in interstellar space has an energy of 10.0 MeV and executes a circular orbit having a radius equal to that of Mercury's orbit around the Sun ( $5.80 \times 10^{10}$  m). What is the magnetic field in that region of space?
40. A singly charged positive ion moving at  $4.60 \times 10^5$  m/s leaves a circular track of radius 7.94 mm along a direction perpendicular to the 1.80-T magnetic field of a bubble chamber. Compute the mass (in atomic mass units) of this ion, and identify it from that value.

(Optional)

### Section 29.5 Applications Involving Charged Particles Moving in a Magnetic Field

41. A velocity selector consists of magnetic and electric fields described by the expressions  $\mathbf{E} = E\mathbf{k}$  and  $\mathbf{B} = B\mathbf{j}$ . If  $B = 0.0150$  T, find the value of  $E$  such that a 750-eV electron moving along the positive  $x$  axis is undeflected.
42. (a) Singly charged uranium-238 ions are accelerated through a potential difference of 2.00 kV and enter a uniform magnetic field of 1.20 T directed perpendicular to their velocities. Determine the radius of their circular path. (b) Repeat for uranium-235 ions. How does the ratio of these path radii depend on the accelerating voltage and the magnetic field strength?
43. Consider the mass spectrometer shown schematically in Figure 29.23. The electric field between the plates of the velocity selector is 2500 V/m, and the magnetic field in both the velocity selector and the deflection chamber has a magnitude of 0.0350 T. Calculate the radius of the path for a singly charged ion having a mass  $m = 2.18 \times 10^{-26}$  kg.
44. What is the required radius of a cyclotron designed to accelerate protons to energies of 34.0 MeV using a magnetic field of 5.20 T?
45. A cyclotron designed to accelerate protons has a magnetic field with a magnitude of 0.450 T over a region of radius 1.20 m. What are (a) the cyclotron frequency and (b) the maximum speed acquired by the protons?
46. At the Fermilab accelerator in Batavia, Illinois, protons having momentum  $4.80 \times 10^{-16}$  kg·m/s are held in a circular orbit of radius 1.00 km by an upward magnetic field. What is the magnitude of this field?
47. The picture tube in a television uses magnetic deflection coils rather than electric deflection plates. Suppose an electron beam is accelerated through a 50.0-kV potential difference and then travels through a region of uniform magnetic field 1.00 cm wide. The screen is located 10.0 cm from the center of the coils and is 50.0 cm wide. When the field is turned off, the electron beam hits the center of the screen. What field magnitude is necessary to deflect the beam to the side of the screen? Ignore relativistic corrections.

(Optional)

### Section 29.6 The Hall Effect

48. A flat ribbon of silver having a thickness  $t = 0.200$  mm is used in a Hall-effect measurement of a uniform magnetic field perpendicular to the ribbon, as shown in Figure P29.48. The Hall coefficient for silver is  $R_H = 0.840 \times 10^{-10}$  m<sup>3</sup>/C. (a) What is the density of charge carriers in silver? (b) If a current  $I = 20.0$  A produces a Hall voltage  $\Delta V_H = 15.0$   $\mu$ V, what is the magnitude of the applied magnetic field?

Figure P29.48

49. A section of conductor 0.400 cm thick is used in a Hall-effect measurement. A Hall voltage of 35.0  $\mu$ V is measured for a current of 21.0 A in a magnetic field of 1.80 T. Calculate the Hall coefficient for the conductor.
50. A flat copper ribbon 0.330 mm thick carries a steady current of 50.0 A and is located in a uniform 1.30-T magnetic field directed perpendicular to the plane of the ribbon. If a Hall voltage of 9.60  $\mu$ V is measured across the ribbon, what is the charge density of the free electrons? What effective number of free electrons per atom does this result indicate?
51. In an experiment designed to measure the Earth's magnetic field using the Hall effect, a copper bar 0.500 cm thick is positioned along an east–west direction. If a current of 8.00 A in the conductor results in a Hall voltage of 5.10  $\mu$ V, what is the magnitude of the Earth's magnetic field? (Assume that  $n = 8.48 \times 10^{28}$  electrons/m<sup>3</sup> and that the plane of the bar is rotated to be perpendicular to the direction of  $\mathbf{B}$ .)
52. A Hall-effect probe operates with a 120-mA current. When the probe is placed in a uniform magnetic field with a magnitude of 0.0800 T, it produces a Hall voltage of 0.700  $\mu$ V. (a) When it is measuring an unknown magnetic field, the Hall voltage is 0.330  $\mu$ V. What is the unknown magnitude of the field? (b) If the thickness of the probe in the direction of  $\mathbf{B}$  is 2.00 mm, find the charge-carrier density (each of charge  $e$ ).

### ADDITIONAL PROBLEMS

53. An electron enters a region of magnetic field of magnitude 0.100 T, traveling perpendicular to the linear boundary of the region. The direction of the field is perpendicular to the velocity of the electron. (a) Determine the time it takes for the electron to leave the "field-filled" region, noting that its path is a semicircle. (b) Find the kinetic energy of the electron if the maximum depth of penetration in the field is 2.00 cm.

54. A 0.200-kg metal rod carrying a current of 10.0 A glides on two horizontal rails 0.500 m apart. What vertical magnetic field is required to keep the rod moving at a constant speed if the coefficient of kinetic friction between the rod and rails is 0.100?
55. Sodium melts at 99°C. Liquid sodium, an excellent thermal conductor, is used in some nuclear reactors to cool the reactor core. The liquid sodium is moved through pipes by pumps that exploit the force on a moving charge in a magnetic field. The principle is as follows: Assume that the liquid metal is in an electrically insulating pipe having a rectangular cross-section of width  $w$  and height  $h$ . A uniform magnetic field perpendicular to the pipe affects a section of length  $L$  (Fig. P29.55). An electric current directed perpendicular to the pipe and to the magnetic field produces a current density  $J$  in the liquid sodium. (a) Explain why this arrangement produces on the liquid a force that is directed along the length of the pipe. (b) Show that the section of liquid in the magnetic field experiences a pressure increase  $JLB$ .

Figure P29.55

56. Protons having a kinetic energy of 5.00 MeV are moving in the positive  $x$  direction and enter a magnetic field  $\mathbf{B} = (0.050\ 0\ \mathbf{k})$  T directed out of the plane of the page and extending from  $x = 0$  to  $x = 1.00$  m, as shown in Figure P29.56. (a) Calculate the  $y$  component of the protons' momentum as they leave the magnetic field. (b) Find the angle  $\alpha$  between the initial velocity vector of the proton beam and the velocity vector after the beam emerges from the field. (*Hint:* Neglect relativistic effects and note that  $1\ \text{eV} = 1.60 \times 10^{-19}\ \text{J}$ .)

Figure P29.56

57. (a) A proton moving in the  $+x$  direction with velocity  $\mathbf{v} = v_x\mathbf{i}$  experiences a magnetic force  $\mathbf{F} = F_y\mathbf{j}$ . Explain what you can and cannot infer about  $\mathbf{B}$  from this information. (b) In terms of  $F_y$ , what would be the force on a proton in the same field moving with velocity

$\mathbf{v} = -v_x\mathbf{i}$ ? (c) What would be the force on an electron in the same field moving with velocity  $\mathbf{v} = v_x\mathbf{i}$ ?

58. **Review Problem.** A wire having a linear mass density of 1.00 g/cm is placed on a horizontal surface that has a coefficient of friction of 0.200. The wire carries a current of 1.50 A toward the east and slides horizontally to the north. What are the magnitude and direction of the smallest magnetic field that enables the wire to move in this fashion?
59. A positive charge  $q = 3.20 \times 10^{-19}\ \text{C}$  moves with a velocity  $\mathbf{v} = (2\mathbf{i} + 3\mathbf{j} - 1\mathbf{k})\ \text{m/s}$  through a region where both a uniform magnetic field and a uniform electric field exist. (a) What is the total force on the moving charge (in unit-vector notation) if  $\mathbf{B} = (2\mathbf{i} + 4\mathbf{j} + 1\mathbf{k})\ \text{T}$  and  $\mathbf{E} = (4\mathbf{i} - 1\mathbf{j} - 2\mathbf{k})\ \text{V/m}$ ? (b) What angle does the force vector make with the positive  $x$  axis?
60. A cosmic-ray proton traveling at half the speed of light is heading directly toward the center of the Earth in the plane of the Earth's equator. Will it hit the Earth? Assume that the Earth's magnetic field is uniform over the planet's equatorial plane with a magnitude of  $50.0\ \mu\text{T}$ , extending out  $1.30 \times 10^7\ \text{m}$  from the surface of the Earth. Assume that the field is zero at greater distances. Calculate the radius of curvature of the proton's path in the magnetic field. Ignore relativistic effects.
61. The circuit in Figure P29.61 consists of wires at the top and bottom and identical metal springs as the left and right sides. The wire at the bottom has a mass of 10.0 g and is 5.00 cm long. The springs stretch 0.500 cm under the weight of the wire, and the circuit has a total resistance of  $12.0\ \Omega$ . When a magnetic field is turned on, directed out of the page, the springs stretch an additional 0.300 cm. What is the magnitude of the magnetic field? (The upper portion of the circuit is fixed.)

Figure P29.61

62. A hand-held electric mixer contains an electric motor. Model the motor as a single flat compact circular coil carrying electric current in a region where a magnetic field is produced by an external permanent magnet. You need consider only one instant in the operation of the motor. (We will consider motors again in Chapter 31.) The coil moves because the magnetic field exerts torque on the coil, as described in Section 29.3. Make

order-of-magnitude estimates of the magnetic field, the torque on the coil, the current in it, its area, and the number of turns in the coil, so that they are related according to Equation 29.11. Note that the input power to the motor is electric, given by  $\mathcal{P} = I\Delta V$ , and the useful output power is mechanical, given by  $\mathcal{P} = \tau\omega$ .

63. A metal rod having a mass per unit length of  $0.0100 \text{ kg/m}$  carries a current of  $I = 5.00 \text{ A}$ . The rod hangs from two wires in a uniform vertical magnetic field, as shown in Figure P29.63. If the wires make an angle  $\theta = 45.0^\circ$  with the vertical when in equilibrium, determine the magnitude of the magnetic field.
64. A metal rod having a mass per unit length  $\mu$  carries a current  $I$ . The rod hangs from two wires in a uniform vertical magnetic field, as shown in Figure P29.63. If the wires make an angle  $\theta$  with the vertical when in equilibrium, determine the magnitude of the magnetic field.

Figure P29.63 Problems 63 and 64.

65. A cyclotron is sometimes used for carbon dating, which we consider in Section 44.6. Carbon-14 and carbon-12 ions are obtained from a sample of the material to be dated and accelerated in the cyclotron. If the cyclotron has a magnetic field of magnitude  $2.40 \text{ T}$ , what is the difference in cyclotron frequencies for the two ions?
66. A uniform magnetic field of magnitude  $0.150 \text{ T}$  is directed along the positive  $x$  axis. A positron moving at  $5.00 \times 10^6 \text{ m/s}$  enters the field along a direction that makes an angle of  $85.0^\circ$  with the  $x$  axis (Fig. P29.66).

Figure P29.66

The motion of the particle is expected to be a helix, as described in Section 29.4. Calculate (a) the pitch  $p$  and (b) the radius  $r$  of the trajectory.

67. Consider an electron orbiting a proton and maintained in a fixed circular path of radius  $R = 5.29 \times 10^{-11} \text{ m}$  by the Coulomb force. Treating the orbiting charge as a current loop, calculate the resulting torque when the system is in a magnetic field of  $0.400 \text{ T}$  directed perpendicular to the magnetic moment of the electron.
68. A singly charged ion completes five revolutions in a uniform magnetic field of magnitude  $5.00 \times 10^{-2} \text{ T}$  in  $1.50 \text{ ms}$ . Calculate the mass of the ion in kilograms.
69. A proton moving in the plane of the page has a kinetic energy of  $6.00 \text{ MeV}$ . It enters a magnetic field of magnitude  $B = 1.00 \text{ T}$  directed into the page, moving at an angle of  $\theta = 45.0^\circ$  with the straight linear boundary of the field, as shown in Figure P29.69. (a) Find the distance  $x$  from the point of entry to where the proton leaves the field. (b) Determine the angle  $\theta'$  between the boundary and the proton's velocity vector as it leaves the field.

Figure P29.69

70. Table P29.70 shows measurements of a Hall voltage and corresponding magnetic field for a probe used to measure magnetic fields. (a) Plot these data, and deduce a relationship between the two variables. (b) If the mea-

measurements were taken with a current of 0.200 A and the sample is made from a material having a charge-carrier density of  $1.00 \times 10^{26}/\text{m}^3$ , what is the thickness of the sample?

71. A heart surgeon monitors the flow rate of blood through an artery using an electromagnetic flowmeter (Fig. P29.71). Electrodes *A* and *B* make contact with the outer surface of the blood vessel, which has interior diameter 3.00 mm. (a) For a magnetic field magnitude of 0.040 0 T, an emf of 160  $\mu\text{V}$  appears between the electrodes. Calculate the speed of the blood. (b) Verify

Figure P29.71

that electrode *A* is positive, as shown. Does the sign of the emf depend on whether the mobile ions in the blood are predominantly positively or negatively charged? Explain.

72. As illustrated in Figure P29.72, a particle of mass  $m$  having positive charge  $q$  is initially traveling upward with velocity  $v\mathbf{j}$ . At the origin of coordinates it enters a region between  $y = 0$  and  $y = h$  containing a uniform magnetic field  $B\mathbf{k}$  directed perpendicular out of the page. (a) What is the critical value of  $v$  such that the particle just reaches  $y = h$ ? Describe the path of the particle under this condition, and predict its final velocity. (b) Specify the path of the particle and its final velocity if  $v$  is less than the critical value. (c) Specify the path of the particle and its final velocity if  $v$  is greater than the critical value.

Figure P29.72

## ANSWERS TO QUICK QUIZZES

- 29.1 Zero. Because the magnetic force exerted by the field on the charge is always perpendicular to the velocity of the charge, the field can never do any work on the charge:  $W = \mathbf{F}_B \cdot d\mathbf{s} = (\mathbf{F}_B \cdot \mathbf{v}) dt = 0$ . Work requires a component of force along the direction of motion.
- 29.2 Unaffected. The magnetic force exerted by a magnetic field on a charge is proportional to the charge's velocity relative to the field. If the charge is stationary, as in this situation, there is no magnetic force.
- 29.3 (c), (b), (a), (d). As Example 29.2 shows, we need to be concerned only with the "effective length" of wire perpendicular to the magnetic field or, stated another way, the length of the "magnetic field shadow" cast by the wire. For (c), 4 m of wire is perpendicular to the field. The short vertical pieces experience no magnetic force because their currents are parallel to the field. When the wire in (b) is broken into many short vertical and horizontal segments alternately parallel and perpendicular to the field, we find a total of 3.5 m of horizontal segments perpendicular to the field and therefore experiencing a force. Next comes (a), with 3 m of wire effectively perpendicular to the field. Only 2 m of the wire in (d) experiences a force. The portion carrying current from 2 m to 4 m does experience a force directed out of the page, but this force is canceled by an oppositely directed force acting on the current as it moves from 4 m to 2 m.
- 29.4 Because it is in the region of the stronger magnetic field, side ③ experiences a greater force than side ①:  $F_3 > F_1$ . Therefore, in addition to the torque resulting from the two forces, a net force is exerted downward on the loop.
- 29.5 (c), (b), (a). Because all loops enclose the same area and carry the same current, the magnitude of  $\boldsymbol{\mu}$  is the same for all. For (c),  $\boldsymbol{\mu}$  points upward and is perpendicular to the magnetic field and  $\boldsymbol{\tau} = \boldsymbol{\mu} \times \mathbf{B}$ . This is the maximum torque possible. The next largest cross product of  $\boldsymbol{\mu}$  and  $\mathbf{B}$  is for (b), in which  $\boldsymbol{\mu}$  points toward the upper right (as illustrated in Fig. 29.13b). Finally,  $\boldsymbol{\mu}$  for the loop in (a) points along the direction of  $\mathbf{B}$ ; thus, the torque is zero.
- 29.6 The velocity selector ensures that all three types of particles have the same speed. We cannot determine individual masses or charges, but we can rank the particles by  $m/q$  ratio. Equation 29.18 indicates that those particles traveling through the circle of greatest radius have the greatest  $m/q$  ratio. Thus, the  $m/q$  ranking, from greatest to least value, is  $c, b, a$ .

## PUZZLER

All three of these commonplace items use magnetism to store information. The cassette can store more than an hour of music, the floppy disk can hold the equivalent of hundreds of pages of information, and many hours of television programming can be recorded on the videotape. How do these devices work?  
(George Semple)

## Sources of the Magnetic Field

### Chapter Outline

- 30.1** The Biot–Savart Law
- 30.2** The Magnetic Force Between Two Parallel Conductors
- 30.3** Ampère’s Law
- 30.4** The Magnetic Field of a Solenoid
- 30.5** Magnetic Flux
- 30.6** Gauss’s Law in Magnetism
- 30.7** Displacement Current and the General Form of Ampère’s Law
- 30.8** (Optional) Magnetism in Matter
- 30.9** (Optional) The Magnetic Field of the Earth

In the preceding chapter, we discussed the magnetic force exerted on a charged particle moving in a magnetic field. To complete the description of the magnetic interaction, this chapter deals with the origin of the magnetic field—moving charges. We begin by showing how to use the law of Biot and Savart to calculate the magnetic field produced at some point in space by a small current element. Using this formalism and the principle of superposition, we then calculate the total magnetic field due to various current distributions. Next, we show how to determine the force between two current-carrying conductors, which leads to the definition of the ampere. We also introduce Ampère’s law, which is useful in calculating the magnetic field of a highly symmetric configuration carrying a steady current.

This chapter is also concerned with the complex processes that occur in magnetic materials. All magnetic effects in matter can be explained on the basis of atomic magnetic moments, which arise both from the orbital motion of the electrons and from an intrinsic property of the electrons known as spin.

### 30.1 THE BIOT–SAVART LAW

Shortly after Oersted’s discovery in 1819 that a compass needle is deflected by a current-carrying conductor, Jean-Baptiste Biot (1774–1862) and Félix Savart (1791–1841) performed quantitative experiments on the force exerted by an electric current on a nearby magnet. From their experimental results, Biot and Savart arrived at a mathematical expression that gives the magnetic field at some point in space in terms of the current that produces the field. That expression is based on the following experimental observations for the magnetic field  $d\mathbf{B}$  at a point  $P$  associated with a length element  $d\mathbf{s}$  of a wire carrying a steady current  $I$  (Fig. 30.1):

Properties of the magnetic field created by an electric current

- The vector  $d\mathbf{B}$  is perpendicular both to  $d\mathbf{s}$  (which points in the direction of the current) and to the unit vector  $\hat{\mathbf{r}}$  directed from  $d\mathbf{s}$  to  $P$ .
- The magnitude of  $d\mathbf{B}$  is inversely proportional to  $r^2$ , where  $r$  is the distance from  $d\mathbf{s}$  to  $P$ .
- The magnitude of  $d\mathbf{B}$  is proportional to the current and to the magnitude  $ds$  of the length element  $d\mathbf{s}$ .
- The magnitude of  $d\mathbf{B}$  is proportional to  $\sin \theta$ , where  $\theta$  is the angle between the vectors  $d\mathbf{s}$  and  $\hat{\mathbf{r}}$ .

**Figure 30.1** (a) The magnetic field  $d\mathbf{B}$  at point  $P$  due to the current  $I$  through a length element  $d\mathbf{s}$  is given by the Biot–Savart law. The direction of the field is out of the page at  $P$  and into the page at  $P'$ . (b) The cross product  $d\mathbf{s} \times \hat{\mathbf{r}}$  points out of the page when  $\hat{\mathbf{r}}$  points toward  $P$ . (c) The cross product  $d\mathbf{s} \times \hat{\mathbf{r}}$  points into the page when  $\hat{\mathbf{r}}$  points toward  $P'$ .

These observations are summarized in the mathematical formula known today as the **Biot–Savart law**:

$$d\mathbf{B} = \frac{\mu_0}{4\pi} \frac{I d\mathbf{s} \times \hat{\mathbf{r}}}{r^2} \quad (30.1)$$

Biot–Savart law

where  $\mu_0$  is a constant called the **permeability of free space**:

$$\mu_0 = 4\pi \times 10^{-7} \text{ T}\cdot\text{m/A} \quad (30.2)$$

Permeability of free space

It is important to note that the field  $d\mathbf{B}$  in Equation 30.1 is the field created by the current in only a small length element  $d\mathbf{s}$  of the conductor. To find the total magnetic field  $\mathbf{B}$  created at some point by a current of finite size, we must sum up contributions from all current elements  $I d\mathbf{s}$  that make up the current. That is, we must evaluate  $\mathbf{B}$  by integrating Equation 30.1:

$$\mathbf{B} = \frac{\mu_0 I}{4\pi} \int \frac{d\mathbf{s} \times \hat{\mathbf{r}}}{r^2} \quad (30.3)$$

where the integral is taken over the entire current distribution. This expression must be handled with special care because the integrand is a cross product and therefore a vector quantity. We shall see one case of such an integration in Example 30.1.

Although we developed the Biot–Savart law for a current-carrying wire, it is also valid for a current consisting of charges flowing through space, such as the electron beam in a television set. In that case,  $d\mathbf{s}$  represents the length of a small segment of space in which the charges flow.

Interesting similarities exist between the Biot–Savart law for magnetism and Coulomb’s law for electrostatics. The current element produces a magnetic field, whereas a point charge produces an electric field. Furthermore, the magnitude of the magnetic field varies as the inverse square of the distance from the current element, as does the electric field due to a point charge. However, the directions of the two fields are quite different. The electric field created by a point charge is radial, but the magnetic field created by a current element is perpendicular to both the length element  $d\mathbf{s}$  and the unit vector  $\hat{\mathbf{r}}$ , as described by the cross product in Equation 30.1. Hence, if the conductor lies in the plane of the page, as shown in Figure 30.1,  $d\mathbf{B}$  points out of the page at  $P$  and into the page at  $P'$ .

Another difference between electric and magnetic fields is related to the source of the field. An electric field is established by an isolated electric charge. The Biot–Savart law gives the magnetic field of an isolated current element at some point, but such an isolated current element cannot exist the way an isolated electric charge can. A current element *must* be part of an extended current distribution because we must have a complete circuit in order for charges to flow. Thus, the Biot–Savart law is only the first step in a calculation of a magnetic field; it must be followed by an integration over the current distribution.

In the examples that follow, it is important to recognize that **the magnetic field determined in these calculations is the field created by a current-carrying conductor**. This field is not to be confused with any additional fields that may be present outside the conductor due to other sources, such as a bar magnet placed nearby.

**EXAMPLE 30.1** Magnetic Field Surrounding a Thin, Straight Conductor

Consider a thin, straight wire carrying a constant current  $I$  and placed along the  $x$  axis as shown in Figure 30.2. Determine the magnitude and direction of the magnetic field at point  $P$  due to this current.

**Solution** From the Biot–Savart law, we expect that the magnitude of the field is proportional to the current in the wire and decreases as the distance  $a$  from the wire to point  $P$  increases. We start by considering a length element  $d\mathbf{s}$  located a distance  $r$  from  $P$ . The direction of the magnetic field at point  $P$  due to the current in this element is out of the page because  $d\mathbf{s} \times \hat{\mathbf{r}}$  is out of the page. In fact, since *all* of the current elements  $I d\mathbf{s}$  lie in the plane of the page, they all produce a magnetic field directed out of the page at point  $P$ . Thus, we have the direction of the magnetic field at point  $P$ , and we need only find the magnitude.

Taking the origin at  $O$  and letting point  $P$  be along the positive  $y$  axis, with  $\mathbf{k}$  being a unit vector pointing out of the page, we see that

$$d\mathbf{s} \times \hat{\mathbf{r}} = \mathbf{k} |d\mathbf{s} \times \hat{\mathbf{r}}| = \mathbf{k}(dx \sin \theta)$$

where, from Chapter 3,  $|d\mathbf{s} \times \hat{\mathbf{r}}|$  represents the magnitude of  $d\mathbf{s} \times \hat{\mathbf{r}}$ . Because  $\hat{\mathbf{r}}$  is a unit vector, the unit of the cross product is simply the unit of  $d\mathbf{s}$ , which is length. Substitution into Equation 30.1 gives

$$d\mathbf{B} = (dB)\mathbf{k} = \frac{\mu_0 I}{4\pi} \frac{dx \sin \theta}{r^2} \mathbf{k}$$

Because all current elements produce a magnetic field in the  $\mathbf{k}$  direction, let us restrict our attention to the magnitude of the field due to one current element, which is

$$(1) \quad dB = \frac{\mu_0 I}{4\pi} \frac{dx \sin \theta}{r^2}$$

To integrate this expression, we must relate the variables  $\theta$ ,  $x$ , and  $r$ . One approach is to express  $x$  and  $r$  in terms of  $\theta$ . From the geometry in Figure 30.2a, we have

$$(2) \quad r = \frac{a}{\sin \theta} = a \csc \theta$$

Because  $\tan \theta = a/(-x)$  from the right triangle in Figure 30.2a (the negative sign is necessary because  $d\mathbf{s}$  is located at a negative value of  $x$ ), we have

$$x = -a \cot \theta$$

Taking the derivative of this expression gives

$$(3) \quad dx = a \csc^2 \theta d\theta$$

Substitution of Equations (2) and (3) into Equation (1) gives

$$(4) \quad dB = \frac{\mu_0 I}{4\pi} \frac{a \csc^2 \theta \sin \theta d\theta}{a^2 \csc^2 \theta} = \frac{\mu_0 I}{4\pi a} \sin \theta d\theta$$

an expression in which the only variable is  $\theta$ . We can now obtain the magnitude of the magnetic field at point  $P$  by integrating Equation (4) over all elements, subtending angles ranging from  $\theta_1$  to  $\theta_2$  as defined in Figure 30.2b:

$$B = \frac{\mu_0 I}{4\pi a} \int_{\theta_1}^{\theta_2} \sin \theta d\theta = \frac{\mu_0 I}{4\pi a} (\cos \theta_1 - \cos \theta_2) \quad (30.4)$$

We can use this result to find the magnetic field of any straight current-carrying wire if we know the geometry and hence the angles  $\theta_1$  and  $\theta_2$ . Consider the special case of an infinitely long, straight wire. If we let the wire in Figure 30.2b become infinitely long, we see that  $\theta_1 = 0$  and  $\theta_2 = \pi$  for length elements ranging between positions  $x = -\infty$  and  $x = +\infty$ . Because  $(\cos \theta_1 - \cos \theta_2) = (\cos 0 - \cos \pi) = 2$ , Equation 30.4 becomes

$$B = \frac{\mu_0 I}{2\pi a} \quad (30.5)$$

Equations 30.4 and 30.5 both show that the magnitude of

**Figure 30.2** (a) A thin, straight wire carrying a current  $I$ . The magnetic field at point  $P$  due to the current in each element  $d\mathbf{s}$  of the wire is out of the page, so the net field at point  $P$  is also out of the page. (b) The angles  $\theta_1$  and  $\theta_2$ , used for determining the net field. When the wire is infinitely long,  $\theta_1 = 0$  and  $\theta_2 = 180^\circ$ .

the magnetic field is proportional to the current and decreases with increasing distance from the wire, as we expected. Notice that Equation 30.5 has the same mathematical form as the expression for the magnitude of the electric field due to a long charged wire (see Eq. 24.7).

**Exercise** Calculate the magnitude of the magnetic field 4.0 cm from an infinitely long, straight wire carrying a current of 5.0 A.

**Answer**  $2.5 \times 10^{-5}$  T.

The result of Example 30.1 is important because a current in the form of a long, straight wire occurs often. Figure 30.3 is a three-dimensional view of the magnetic field surrounding a long, straight current-carrying wire. Because of the symmetry of the wire, the magnetic field lines are circles concentric with the wire and lie in planes perpendicular to the wire. The magnitude of  $\mathbf{B}$  is constant on any circle of radius  $a$  and is given by Equation 30.5. A convenient rule for determining the direction of  $\mathbf{B}$  is to grasp the wire with the right hand, positioning the thumb along the direction of the current. The four fingers wrap in the direction of the magnetic field.

**Figure 30.3** The right-hand rule for determining the direction of the magnetic field surrounding a long, straight wire carrying a current. Note that the magnetic field lines form circles around the wire.

### EXAMPLE 30.2 Magnetic Field Due to a Curved Wire Segment

Calculate the magnetic field at point  $O$  for the current-carrying wire segment shown in Figure 30.4. The wire consists of two straight portions and a circular arc of radius  $R$ , which subtends an angle  $\theta$ . The arrowheads on the wire indicate the direction of the current.

**Solution** The magnetic field at  $O$  due to the current in the straight segments  $AA'$  and  $CC'$  is zero because  $d\mathbf{s}$  is parallel to  $\hat{\mathbf{r}}$  along these paths; this means that  $d\mathbf{s} \times \hat{\mathbf{r}} = 0$ . Each length element  $d\mathbf{s}$  along path  $AC$  is at the same distance  $R$  from  $O$ , and the current in each contributes a field element  $d\mathbf{B}$  directed into the page at  $O$ . Furthermore, at every point on  $AC$ ,  $d\mathbf{s}$  is perpendicular to  $\hat{\mathbf{r}}$ ; hence,  $|d\mathbf{s} \times \hat{\mathbf{r}}| = ds$ . Using this information and Equation 30.1, we can find the magnitude of the field at  $O$  due to the current in an element of length  $ds$ :

$$dB = \frac{\mu_0 I}{4\pi} \frac{ds}{R^2}$$

**Figure 30.4** The magnetic field at  $O$  due to the current in the curved segment  $AC$  is into the page. The contribution to the field at  $O$  due to the current in the two straight segments is zero.

Because  $I$  and  $R$  are constants, we can easily integrate this expression over the curved path  $AC$ :

$$B = \frac{\mu_0 I}{4\pi R^2} \int ds = \frac{\mu_0 I}{4\pi R^2} s = \frac{\mu_0 I}{4\pi R} \theta \quad (30.6)$$

where we have used the fact that  $s = R\theta$  with  $\theta$  measured in

radians. The direction of  $\mathbf{B}$  is into the page at  $O$  because  $d\mathbf{s} \times \hat{\mathbf{r}}$  is into the page for every length element.

**Exercise** A circular wire loop of radius  $R$  carries a current  $I$ . What is the magnitude of the magnetic field at its center?

**Answer**  $\mu_0 I/2R$ .

### EXAMPLE 30.3 Magnetic Field on the Axis of a Circular Current Loop

Consider a circular wire loop of radius  $R$  located in the  $yz$  plane and carrying a steady current  $I$ , as shown in Figure 30.5. Calculate the magnetic field at an axial point  $P$  a distance  $x$  from the center of the loop.

**Solution** In this situation, note that every length element  $d\mathbf{s}$  is perpendicular to the vector  $\hat{\mathbf{r}}$  at the location of the element. Thus, for any element,  $d\mathbf{s} \times \hat{\mathbf{r}} = (ds)(1) \sin 90^\circ = ds$ . Furthermore, all length elements around the loop are at the same distance  $r$  from  $P$ , where  $r^2 = x^2 + R^2$ . Hence, the magnitude of  $d\mathbf{B}$  due to the current in any length element  $d\mathbf{s}$  is

$$dB = \frac{\mu_0 I}{4\pi} \frac{|d\mathbf{s} \times \hat{\mathbf{r}}|}{r^2} = \frac{\mu_0 I}{4\pi} \frac{ds}{(x^2 + R^2)}$$

The direction of  $d\mathbf{B}$  is perpendicular to the plane formed by  $\hat{\mathbf{r}}$  and  $d\mathbf{s}$ , as shown in Figure 30.5. We can resolve this vector into a component  $dB_x$  along the  $x$  axis and a component  $dB_y$  perpendicular to the  $x$  axis. When the components  $dB_y$  are summed over all elements around the loop, the resultant component is zero. That is, by symmetry the current in any element on one side of the loop sets up a perpendicular component of  $d\mathbf{B}$  that cancels the perpendicular component set up by the current through the element diametrically opposite it. Therefore, the resultant field at  $P$  must be along the  $x$  axis and we can find it by integrating the components  $dB_x = dB \cos \theta$ . That is,  $\mathbf{B} = B_x \hat{\mathbf{i}}$ , where

$$B_x = \oint dB \cos \theta = \frac{\mu_0 I}{4\pi} \oint \frac{ds \cos \theta}{x^2 + R^2}$$

and we must take the integral over the entire loop. Because  $\theta$ ,  $x$ , and  $R$  are constants for all elements of the loop and because  $\cos \theta = R/(x^2 + R^2)^{1/2}$ , we obtain

$$B_x = \frac{\mu_0 IR}{4\pi(x^2 + R^2)^{3/2}} \oint ds = \frac{\mu_0 IR^2}{2(x^2 + R^2)^{3/2}} \quad (30.7)$$

where we have used the fact that  $\oint ds = 2\pi R$  (the circumference of the loop).

To find the magnetic field at the center of the loop, we set  $x = 0$  in Equation 30.7. At this special point, therefore,

$$B = \frac{\mu_0 I}{2R} \quad (\text{at } x = 0) \quad (30.8)$$

which is consistent with the result of the exercise in Example 30.2.

It is also interesting to determine the behavior of the magnetic field far from the loop—that is, when  $x$  is much greater than  $R$ . In this case, we can neglect the term  $R^2$  in the denominator of Equation 30.7 and obtain

$$B \approx \frac{\mu_0 IR^2}{2x^3} \quad (\text{for } x \gg R) \quad (30.9)$$

Because the magnitude of the magnetic moment  $\mu$  of the loop is defined as the product of current and loop area (see Eq. 29.10)— $\mu = I(\pi R^2)$  for our circular loop—we can express Equation 30.9 as

$$B \approx \frac{\mu_0}{2\pi} \frac{\mu}{x^3} \quad (30.10)$$

This result is similar in form to the expression for the electric field due to an electric dipole,  $E = k_e(2qa/y^3)$  (see Example

**Figure 30.5** Geometry for calculating the magnetic field at a point  $P$  lying on the axis of a current loop. By symmetry, the total field  $\mathbf{B}$  is along this axis.

23.6), where  $2qa = p$  is the electric dipole moment as defined in Equation 26.16.

The pattern of the magnetic field lines for a circular current loop is shown in Figure 30.6a. For clarity, the lines are

drawn for only one plane—one that contains the axis of the loop. Note that the field-line pattern is axially symmetric and looks like the pattern around a bar magnet, shown in Figure 30.6c.

**Figure 30.6** (a) Magnetic field lines surrounding a current loop. (b) Magnetic field lines surrounding a current loop, displayed with iron filings (Education Development Center, Newton, MA). (c) Magnetic field lines surrounding a bar magnet. Note the similarity between this line pattern and that of a current loop.

## 30.2 THE MAGNETIC FORCE BETWEEN TWO PARALLEL CONDUCTORS

In Chapter 29 we described the magnetic force that acts on a current-carrying conductor placed in an external magnetic field. Because a current in a conductor sets up its own magnetic field, it is easy to understand that two current-carrying conductors exert magnetic forces on each other. As we shall see, such forces can be used as the basis for defining the ampere and the coulomb.

Consider two long, straight, parallel wires separated by a distance  $a$  and carrying currents  $I_1$  and  $I_2$  in the same direction, as illustrated in Figure 30.7. We can determine the force exerted on one wire due to the magnetic field set up by the other wire. Wire 2, which carries a current  $I_2$ , creates a magnetic field  $\mathbf{B}_2$  at the location of wire 1. The direction of  $\mathbf{B}_2$  is perpendicular to wire 1, as shown in Figure 30.7. According to Equation 29.3, the magnetic force on a length  $\ell$  of wire 1 is  $\mathbf{F}_1 = I_1 \ell \times \mathbf{B}_2$ . Because  $\ell$  is perpendicular to  $\mathbf{B}_2$  in this situation, the magnitude of  $\mathbf{F}_1$  is  $F_1 = I_1 \ell B_2$ . Because the magnitude of  $\mathbf{B}_2$  is given by Equation 30.5, we see that

$$F_1 = I_1 \ell B_2 = I_1 \ell \left( \frac{\mu_0 I_2}{2\pi a} \right) = \frac{\mu_0 I_1 I_2}{2\pi a} \ell \quad (30.11)$$

The direction of  $\mathbf{F}_1$  is toward wire 2 because  $\ell \times \mathbf{B}_2$  is in that direction. If the field set up at wire 2 by wire 1 is calculated, the force  $\mathbf{F}_2$  acting on wire 2 is found to be equal in magnitude and opposite in direction to  $\mathbf{F}_1$ . This is what we expect be-

**Figure 30.7** Two parallel wires that each carry a steady current exert a force on each other. The field  $\mathbf{B}_2$  due to the current in wire 2 exerts a force of magnitude  $F_1 = I_1 \ell B_2$  on wire 1. The force is attractive if the currents are parallel (as shown) and repulsive if the currents are antiparallel.

cause Newton's third law must be obeyed.<sup>1</sup> When the currents are in opposite directions (that is, when one of the currents is reversed in Fig. 30.7), the forces are reversed and the wires repel each other. Hence, we find that **parallel conductors carrying currents in the same direction attract each other, and parallel conductors carrying currents in opposite directions repel each other.**

Because the magnitudes of the forces are the same on both wires, we denote the magnitude of the magnetic force between the wires as simply  $F_B$ . We can rewrite this magnitude in terms of the force per unit length:

$$\frac{F_B}{\ell} = \frac{\mu_0 I_1 I_2}{2\pi a} \quad (30.12)$$

The force between two parallel wires is used to define the **ampere** as follows:

Definition of the ampere

When the magnitude of the force per unit length between two long, parallel wires that carry identical currents and are separated by 1 m is  $2 \times 10^{-7}$  N/m, the current in each wire is defined to be 1 A.

### web

Visit <http://physics.nist.gov/cuu/Units/ampere.html> for more information.

The value  $2 \times 10^{-7}$  N/m is obtained from Equation 30.12 with  $I_1 = I_2 = 1$  A and  $a = 1$  m. Because this definition is based on a force, a mechanical measurement can be used to standardize the ampere. For instance, the National Institute of Standards and Technology uses an instrument called a *current balance* for primary current measurements. The results are then used to standardize other, more conventional instruments, such as ammeters.

The SI unit of charge, the **coulomb**, is defined in terms of the ampere:

Definition of the coulomb

When a conductor carries a steady current of 1 A, the quantity of charge that flows through a cross-section of the conductor in 1 s is 1 C.

In deriving Equations 30.11 and 30.12, we assumed that both wires are long compared with their separation distance. In fact, only one wire needs to be long. The equations accurately describe the forces exerted on each other by a long wire and a straight parallel wire of limited length  $\ell$ .

### Quick Quiz 30.1

For  $I_1 = 2$  A and  $I_2 = 6$  A in Figure 30.7, which is true: (a)  $F_1 = 3F_2$ , (b)  $F_1 = F_2/3$ , or (c)  $F_1 = F_2$ ?

### Quick Quiz 30.2

A loose spiral spring is hung from the ceiling, and a large current is sent through it. Do the coils move closer together or farther apart?

<sup>1</sup> Although the total force exerted on wire 1 is equal in magnitude and opposite in direction to the total force exerted on wire 2, Newton's third law does not apply when one considers two small elements of the wires that are not exactly opposite each other. This apparent violation of Newton's third law and of the law of conservation of momentum is described in more advanced treatments on electricity and magnetism.

### 30.3 AMPÈRE'S LAW

Oersted's 1819 discovery about deflected compass needles demonstrates that a current-carrying conductor produces a magnetic field. Figure 30.8a shows how this effect can be demonstrated in the classroom. Several compass needles are placed in a horizontal plane near a long vertical wire. When no current is present in the wire, all the needles point in the same direction (that of the Earth's magnetic field), as expected. When the wire carries a strong, steady current, the needles all deflect in a direction tangent to the circle, as shown in Figure 30.8b. These observations demonstrate that the direction of the magnetic field produced by the current in the wire is consistent with the right-hand rule described in Figure 30.3. When the current is reversed, the needles in Figure 30.8b also reverse.

Because the compass needles point in the direction of  $\mathbf{B}$ , we conclude that the lines of  $\mathbf{B}$  form circles around the wire, as discussed in the preceding section. By symmetry, the magnitude of  $\mathbf{B}$  is the same everywhere on a circular path centered on the wire and lying in a plane perpendicular to the wire. By varying the current and distance  $a$  from the wire, we find that  $B$  is proportional to the current and inversely proportional to the distance from the wire, as Equation 30.5 describes.

Now let us evaluate the product  $\mathbf{B} \cdot d\mathbf{s}$  for a small length element  $d\mathbf{s}$  on the circular path defined by the compass needles, and sum the products for all elements over the closed circular path. Along this path, the vectors  $d\mathbf{s}$  and  $\mathbf{B}$  are parallel at each point (see Fig. 30.8b), so  $\mathbf{B} \cdot d\mathbf{s} = B ds$ . Furthermore, the magnitude of  $\mathbf{B}$  is constant on this circle and is given by Equation 30.5. Therefore, the sum of the products  $B ds$  over the closed path, which is equivalent to the line integral of  $\mathbf{B} \cdot d\mathbf{s}$ , is

$$\oint \mathbf{B} \cdot d\mathbf{s} = B \oint ds = \frac{\mu_0 I}{2\pi r} (2\pi r) = \mu_0 I$$

where  $\oint ds = 2\pi r$  is the circumference of the circular path. Although this result was calculated for the special case of a circular path surrounding a wire, it holds

#### Andre-Marie Ampère

(1775–1836) Ampère, a Frenchman, is credited with the discovery of electromagnetism—the relationship between electric currents and magnetic fields. Ampère's genius, particularly in mathematics, became evident by the time he was 12 years old; his personal life, however, was filled with tragedy. His father, a wealthy city official, was guillotined during the French Revolution, and his wife died young, in 1803. Ampère died at the age of 61 of pneumonia. His judgment of his life is clear from the epitaph he chose for his gravestone: *Tandem Felix* (Happy at Last). (AIP Emilio Segre Visual Archive)

**Figure 30.8** (a) When no current is present in the wire, all compass needles point in the same direction (toward the Earth's north pole). (b) When the wire carries a strong current, the compass needles deflect in a direction tangent to the circle, which is the direction of the magnetic field created by the current. (c) Circular magnetic field lines surrounding a current-carrying conductor, displayed with iron filings.

for a closed path of *any* shape surrounding a *current* that exists in an unbroken circuit. The general case, known as **Ampère's law**, can be stated as follows:

The line integral of  $\mathbf{B} \cdot d\mathbf{s}$  around any closed path equals  $\mu_0 I$ , where  $I$  is the total continuous current passing through any surface bounded by the closed path.

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I \quad (30.13)$$

Ampère's law

Ampère's law describes the creation of magnetic fields by all continuous current configurations, but at our mathematical level it is useful only for calculating the magnetic field of current configurations having a high degree of symmetry. Its use is similar to that of Gauss's law in calculating electric fields for highly symmetric charge distributions.

### Quick Quiz 30.3

Rank the magnitudes of  $\oint \mathbf{B} \cdot d\mathbf{s}$  for the closed paths in Figure 30.9, from least to greatest.

**Figure 30.9** Four closed paths around three current-carrying wires.

### Quick Quiz 30.4

Rank the magnitudes of  $\oint \mathbf{B} \cdot d\mathbf{s}$  for the closed paths in Figure 30.10, from least to greatest.

**Figure 30.10** Several closed paths near a single current-carrying wire.

**EXAMPLE 30.4** The Magnetic Field Created by a Long Current-Carrying Wire

A long, straight wire of radius  $R$  carries a steady current  $I_0$  that is uniformly distributed through the cross-section of the wire (Fig. 30.11). Calculate the magnetic field a distance  $r$  from the center of the wire in the regions  $r \geq R$  and  $r < R$ .

**Solution** For the  $r \geq R$  case, we should get the same result we obtained in Example 30.1, in which we applied the Biot–Savart law to the same situation. Let us choose for our path of integration circle 1 in Figure 30.11. From symmetry,  $\mathbf{B}$  must be constant in magnitude and parallel to  $d\mathbf{s}$  at every point on this circle. Because the total current passing through the plane of the circle is  $I_0$ , Ampère's law gives

$$\oint \mathbf{B} \cdot d\mathbf{s} = B \oint ds = B(2\pi r) = \mu_0 I_0$$

$$B = \frac{\mu_0 I_0}{2\pi r} \quad (\text{for } r \geq R) \quad (30.14)$$

which is identical in form to Equation 30.5. Note how much easier it is to use Ampère's law than to use the Biot–Savart law. This is often the case in highly symmetric situations.

Now consider the interior of the wire, where  $r < R$ . Here the current  $I$  passing through the plane of circle 2 is less than the total current  $I_0$ . Because the current is uniform over the cross-section of the wire, the fraction of the current enclosed

**Figure 30.11** A long, straight wire of radius  $R$  carrying a steady current  $I_0$  uniformly distributed across the cross-section of the wire. The magnetic field at any point can be calculated from Ampère's law using a circular path of radius  $r$ , concentric with the wire.

by circle 2 must equal the ratio of the area  $\pi r^2$  enclosed by circle 2 to the cross-sectional area  $\pi R^2$  of the wire:<sup>2</sup>

$$\frac{I}{I_0} = \frac{\pi r^2}{\pi R^2}$$

$$I = \frac{r^2}{R^2} I_0$$

Following the same procedure as for circle 1, we apply Ampère's law to circle 2:

$$\oint \mathbf{B} \cdot d\mathbf{s} = B(2\pi r) = \mu_0 I = \mu_0 \left( \frac{r^2}{R^2} I_0 \right)$$

$$B = \left( \frac{\mu_0 I_0}{2\pi R^2} \right) r \quad (\text{for } r < R) \quad (30.15)$$

This result is similar in form to the expression for the electric field inside a uniformly charged sphere (see Example 24.5). The magnitude of the magnetic field versus  $r$  for this configuration is plotted in Figure 30.12. Note that inside the wire,  $B \rightarrow 0$  as  $r \rightarrow 0$ . Note also that Equations 30.14 and 30.15 give the same value of the magnetic field at  $r = R$ , demonstrating that the magnetic field is continuous at the surface of the wire.

**Figure 30.12** Magnitude of the magnetic field versus  $r$  for the wire shown in Figure 30.11. The field is proportional to  $r$  inside the wire and varies as  $1/r$  outside the wire.

**EXAMPLE 30.5** The Magnetic Field Created by a Toroid

A device called a *toroid* (Fig. 30.13) is often used to create an almost uniform magnetic field in some enclosed area. The device consists of a conducting wire wrapped around a ring (a *torus*) made of a nonconducting material. For a toroid hav-

ing  $N$  closely spaced turns of wire, calculate the magnetic field in the region occupied by the torus, a distance  $r$  from the center.

<sup>2</sup> Another way to look at this problem is to see that the current enclosed by circle 2 must equal the product of the current density  $J = I_0/\pi R^2$  and the area  $\pi r^2$  of this circle.

**Solution** To calculate this field, we must evaluate  $\oint \mathbf{B} \cdot d\mathbf{s}$  over the circle of radius  $r$  in Figure 30.13. By symmetry, we see that the magnitude of the field is constant on this circle and tangent to it, so  $\mathbf{B} \cdot d\mathbf{s} = B ds$ . Furthermore, note that

**Figure 30.13** A toroid consisting of many turns of wire. If the turns are closely spaced, the magnetic field in the interior of the torus (the gold-shaded region) is tangent to the dashed circle and varies as  $1/r$ . The field outside the toroid is zero. The dimension  $a$  is the cross-sectional radius of the torus.

the circular closed path surrounds  $N$  loops of wire, each of which carries a current  $I$ . Therefore, the right side of Equation 30.13 is  $\mu_0 NI$  in this case.

Ampère's law applied to the circle gives

$$\oint \mathbf{B} \cdot d\mathbf{s} = B \oint ds = B(2\pi r) = \mu_0 NI$$

$$B = \frac{\mu_0 NI}{2\pi r} \quad (30.16)$$

This result shows that  $B$  varies as  $1/r$  and hence is nonuniform in the region occupied by the torus. However, if  $r$  is very large compared with the cross-sectional radius of the torus, then the field is approximately uniform inside the torus.

For an ideal toroid, in which the turns are closely spaced, the external magnetic field is zero. This can be seen by noting that the net current passing through any circular path lying outside the toroid (including the region of the "hole in the doughnut") is zero. Therefore, from Ampère's law we find that  $B = 0$  in the regions exterior to the torus.

### EXAMPLE 30.6 Magnetic Field Created by an Infinite Current Sheet

So far we have imagined currents through wires of small cross-section. Let us now consider an example in which a current exists in an extended object. A thin, infinitely large sheet lying in the  $yz$  plane carries a current of linear current density  $\mathbf{J}_s$ . The current is in the  $y$  direction, and  $J_s$  represents the current per unit length measured along the  $z$  axis. Find the magnetic field near the sheet.

**Solution** This situation brings to mind similar calculations involving Gauss's law (see Example 24.8). You may recall that

**Figure 30.14** End view of an infinite current sheet lying in the  $yz$  plane, where the current is in the  $y$  direction (out of the page). This view shows the direction of  $\mathbf{B}$  on both sides of the sheet.

the electric field due to an infinite sheet of charge does not depend on distance from the sheet. Thus, we might expect a similar result here for the magnetic field.

To evaluate the line integral in Ampère's law, let us take a rectangular path through the sheet, as shown in Figure 30.14. The rectangle has dimensions  $\ell$  and  $w$ , with the sides of length  $\ell$  parallel to the sheet surface. The net current passing through the plane of the rectangle is  $J_s \ell$ . We apply Ampère's law over the rectangle and note that the two sides of length  $w$  do not contribute to the line integral because the component of  $\mathbf{B}$  along the direction of these paths is zero. By symmetry, we can argue that the magnetic field is constant over the sides of length  $\ell$  because every point on the infinitely large sheet is equivalent, and hence the field should not vary from point to point. The only choices of field direction that are reasonable for the symmetry are perpendicular or parallel to the sheet, and a perpendicular field would pass *through* the current, which is inconsistent with the Biot-Savart law. Assuming a field that is constant in magnitude and parallel to the plane of the sheet, we obtain

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I = \mu_0 J_s \ell$$

$$2B\ell = \mu_0 J_s \ell$$

$$B = \mu_0 \frac{J_s}{2}$$

This result shows that *the magnetic field is independent of distance from the current sheet*, as we suspected.

**EXAMPLE 30.7** The Magnetic Force on a Current Segment

Wire 1 in Figure 30.15 is oriented along the  $y$  axis and carries a steady current  $I_1$ . A rectangular loop located to the right of the wire and in the  $xy$  plane carries a current  $I_2$ . Find the magnetic force exerted by wire 1 on the top wire of length  $b$  in the loop, labeled “Wire 2” in the figure.

**Solution** You may be tempted to use Equation 30.12 to obtain the force exerted on a small segment of length  $dx$  of wire 2. However, this equation applies only to two *parallel* wires and cannot be used here. The correct approach is to

Figure 30.15

consider the force exerted by wire 1 on a small segment  $ds$  of wire 2 by using Equation 29.4. This force is given by  $d\mathbf{F}_B = I ds \times \mathbf{B}$ , where  $I = I_2$  and  $\mathbf{B}$  is the magnetic field created by the current in wire 1 at the position of  $ds$ . From Amperè's law, the field at a distance  $x$  from wire 1 (see Eq. 30.14) is

$$\mathbf{B} = \frac{\mu_0 I_1}{2\pi x} (-\mathbf{k})$$

where the unit vector  $-\mathbf{k}$  is used to indicate that the field at  $ds$  points into the page. Because wire 2 is along the  $x$  axis,  $ds = dx\mathbf{i}$ , and we find that

$$d\mathbf{F}_B = \frac{\mu_0 I_1 I_2}{2\pi x} [\mathbf{i} \times (-\mathbf{k})] dx = \frac{\mu_0 I_1 I_2}{2\pi} \frac{dx}{x} \mathbf{j}$$

Integrating over the limits  $x = a$  to  $x = a + b$  gives

$$\mathbf{F}_B = \frac{\mu_0 I_1 I_2}{2\pi} \ln x \Big|_a^{a+b} \mathbf{j} = \frac{\mu_0 I_1 I_2}{2\pi} \ln \left( 1 + \frac{b}{a} \right) \mathbf{j}$$

The force points in the positive  $y$  direction, as indicated by the unit vector  $\mathbf{j}$  and as shown in Figure 30.15.

**Exercise** What are the magnitude and direction of the force exerted on the bottom wire of length  $b$ ?

**Answer** The force has the same magnitude as the force on wire 2 but is directed downward.

**Quick Quiz 30.5**

Is a net force acting on the current loop in Example 30.7? A net torque?

**30.4 THE MAGNETIC FIELD OF A SOLENOID**

A **solenoid** is a long wire wound in the form of a helix. With this configuration, a reasonably uniform magnetic field can be produced in the space surrounded by the turns of wire—which we shall call the *interior* of the solenoid—when the solenoid carries a current. When the turns are closely spaced, each can be approximated as a circular loop, and the net magnetic field is the vector sum of the fields resulting from all the turns.

Figure 30.16 shows the magnetic field lines surrounding a loosely wound solenoid. Note that the field lines in the interior are nearly parallel to one another, are uniformly distributed, and are close together, indicating that the field in this space is uniform and strong. The field lines between current elements on two adjacent turns tend to cancel each other because the field vectors from the two elements are in opposite directions. The field at exterior points such as  $P$  is weak because the field due to current elements on the right-hand portion of a turn tends to cancel the field due to current elements on the left-hand portion.

Figure 30.16 The magnetic field lines for a loosely wound solenoid.

**Figure 30.17** (a) Magnetic field lines for a tightly wound solenoid of finite length, carrying a steady current. The field in the interior space is nearly uniform and strong. Note that the field lines resemble those of a bar magnet, meaning that the solenoid effectively has north and south poles. (b) The magnetic field pattern of a bar magnet, displayed with small iron filings on a sheet of paper.

A technician studies the scan of a patient's head. The scan was obtained using a medical diagnostic technique known as magnetic resonance imaging (MRI). This instrument makes use of strong magnetic fields produced by superconducting solenoids.

If the turns are closely spaced and the solenoid is of finite length, the magnetic field lines are as shown in Figure 30.17a. This field line distribution is similar to that surrounding a bar magnet (see Fig. 30.17b). Hence, one end of the solenoid behaves like the north pole of a magnet, and the opposite end behaves like the south pole. As the length of the solenoid increases, the interior field becomes more uniform and the exterior field becomes weaker. An *ideal solenoid* is approached when the turns are closely spaced and the length is much greater than the radius of the turns. In this case, the external field is zero, and the interior field is uniform over a great volume.

**Figure 30.18** Cross-sectional view of an ideal solenoid, where the interior magnetic field is uniform and the exterior field is zero. Ampère's law applied to the red dashed path can be used to calculate the magnitude of the interior field.

We can use Ampère's law to obtain an expression for the interior magnetic field in an ideal solenoid. Figure 30.18 shows a longitudinal cross-section of part of such a solenoid carrying a current  $I$ . Because the solenoid is ideal,  $\mathbf{B}$  in the interior space is uniform and parallel to the axis, and  $\mathbf{B}$  in the exterior space is zero. Consider the rectangular path of length  $\ell$  and width  $w$  shown in Figure 30.18. We can apply Ampère's law to this path by evaluating the integral of  $\mathbf{B} \cdot d\mathbf{s}$  over each side of the rectangle. The contribution along side 3 is zero because  $B = 0$  in this region. The contributions from sides 2 and 4 are both zero because  $\mathbf{B}$  is perpendicular to  $d\mathbf{s}$  along these paths. Side 1 gives a contribution  $B\ell$  to the integral because along this path  $\mathbf{B}$  is uniform and parallel to  $d\mathbf{s}$ . The integral over the closed rectangular path is therefore

$$\oint \mathbf{B} \cdot d\mathbf{s} = \int_{\text{path 1}} \mathbf{B} \cdot d\mathbf{s} = B \int_{\text{path 1}} ds = B\ell$$

The right side of Ampère's law involves the total current passing through the area bounded by the path of integration. In this case, the total current through the rectangular path equals the current through each turn multiplied by the number of turns. If  $N$  is the number of turns in the length  $\ell$ , the total current through the rectangle is  $NI$ . Therefore, Ampère's law applied to this path gives

$$\oint \mathbf{B} \cdot d\mathbf{s} = B\ell = \mu_0 NI$$

$$B = \mu_0 \frac{N}{\ell} I = \mu_0 nI \quad (30.17)$$

where  $n = N/\ell$  is the number of turns per unit length.

We also could obtain this result by reconsidering the magnetic field of a toroid (see Example 30.5). If the radius  $r$  of the torus in Figure 30.13 containing  $N$  turns is much greater than the toroid's cross-sectional radius  $a$ , a short section of the toroid approximates a solenoid for which  $n = N/2\pi r$ . In this limit, Equation 30.16 agrees with Equation 30.17.

Equation 30.17 is valid only for points near the center (that is, far from the ends) of a very long solenoid. As you might expect, the field near each end is smaller than the value given by Equation 30.17. At the very end of a long solenoid, the magnitude of the field is one-half the magnitude at the center.

### QuickLab

Wrap a few turns of wire around a compass, essentially putting the compass inside a solenoid. Hold the ends of the wire to the two terminals of a flashlight battery. What happens to the compass? Is the effect as strong when the compass is outside the turns of wire?

Magnetic field inside a solenoid

## 30.5 MAGNETIC FLUX

**12.5** The flux associated with a magnetic field is defined in a manner similar to that used to define electric flux (see Eq. 24.3). Consider an element of area  $dA$  on an arbitrarily shaped surface, as shown in Figure 30.19. If the magnetic field at this element is  $\mathbf{B}$ , the magnetic flux through the element is  $\mathbf{B} \cdot d\mathbf{A}$ , where  $d\mathbf{A}$  is a vector that is perpendicular to the surface and has a magnitude equal to the area  $dA$ . Hence, the total magnetic flux  $\Phi_B$  through the surface is

$$\Phi_B \equiv \int \mathbf{B} \cdot d\mathbf{A} \quad (30.18)$$

Definition of magnetic flux

**Figure 30.19** The magnetic flux through an area element  $dA$  is  $\mathbf{B} \cdot d\mathbf{A} = B dA \cos \theta$ , where  $d\mathbf{A}$  is a vector perpendicular to the surface.

**Figure 30.20** Magnetic flux through a plane lying in a magnetic field. (a) The flux through the plane is zero when the magnetic field is parallel to the plane surface. (b) The flux through the plane is a maximum when the magnetic field is perpendicular to the plane.

Consider the special case of a plane of area  $A$  in a uniform field  $\mathbf{B}$  that makes an angle  $\theta$  with  $d\mathbf{A}$ . The magnetic flux through the plane in this case is

$$\Phi_B = BA \cos \theta \quad (30.19)$$

If the magnetic field is parallel to the plane, as in Figure 30.20a, then  $\theta = 90^\circ$  and the flux is zero. If the field is perpendicular to the plane, as in Figure 30.20b, then  $\theta = 0$  and the flux is  $BA$  (the maximum value).

The unit of flux is the  $\text{T} \cdot \text{m}^2$ , which is defined as a *weber* (Wb);  $1 \text{ Wb} = 1 \text{ T} \cdot \text{m}^2$ .

### EXAMPLE 30.8 Magnetic Flux Through a Rectangular Loop

A rectangular loop of width  $a$  and length  $b$  is located near a long wire carrying a current  $I$  (Fig. 30.21). The distance between the wire and the closest side of the loop is  $c$ . The wire is parallel to the long side of the loop. Find the total magnetic flux through the loop due to the current in the wire.

**Solution** From Equation 30.14, we know that the magnitude of the magnetic field created by the wire at a distance  $r$  from the wire is

**Figure 30.21** The magnetic field due to the wire carrying a current  $I$  is not uniform over the rectangular loop.

$$B = \frac{\mu_0 I}{2\pi r}$$

The factor  $1/r$  indicates that the field varies over the loop, and Figure 30.21 shows that the field is directed into the page. Because  $\mathbf{B}$  is parallel to  $d\mathbf{A}$  at any point within the loop, the magnetic flux through an area element  $dA$  is

$$\Phi_B = \int B dA = \int \frac{\mu_0 I}{2\pi r} dA$$

(Because  $B$  is not uniform but depends on  $r$ , it cannot be removed from the integral.)

To integrate, we first express the area element (the tan region in Fig. 30.21) as  $dA = b dr$ . Because  $r$  is now the only variable in the integral, we have

$$\begin{aligned} \Phi_B &= \frac{\mu_0 I b}{2\pi} \int_c^{a+c} \frac{dr}{r} = \frac{\mu_0 I b}{2\pi} \ln r \Big|_c^{a+c} \\ &= \frac{\mu_0 I b}{2\pi} \ln \left( \frac{a+c}{c} \right) = \frac{\mu_0 I b}{2\pi} \ln \left( 1 + \frac{a}{c} \right) \end{aligned}$$

**Exercise** Apply the series expansion formula for  $\ln(1+x)$  (see Appendix B.5) to this equation to show that it gives a reasonable result when the loop is far from the wire relative to the loop dimensions (in other words, when  $c \gg a$ ).

**Answer**  $\Phi_B \rightarrow 0$ .

## 30.6 GAUSS'S LAW IN MAGNETISM

**12.5** In Chapter 24 we found that the electric flux through a closed surface surrounding a net charge is proportional to that charge (Gauss's law). In other words, the number of electric field lines leaving the surface depends only on the net charge within it. This property is based on the fact that electric field lines originate and terminate on electric charges.

The situation is quite different for magnetic fields, which are continuous and form closed loops. In other words, magnetic field lines do not begin or end at any point—as illustrated by the magnetic field lines of the bar magnet in Figure 30.22. Note that for any closed surface, such as the one outlined by the dashed red line in Figure 30.22, the number of lines entering the surface equals the number leaving the surface; thus, the net magnetic flux is zero. In contrast, for a closed surface surrounding one charge of an electric dipole (Fig. 30.23), the net electric flux is not zero.

**Gauss's law in magnetism** states that

the net magnetic flux through any closed surface is always zero:

$$\oint \mathbf{B} \cdot d\mathbf{A} = 0 \quad (30.20)$$

Gauss's law for magnetism

This statement is based on the experimental fact, mentioned in the opening of Chapter 29, that **isolated magnetic poles (monopoles) have never been detected and perhaps do not exist**. Nonetheless, scientists continue the search be-

**Figure 30.22** The magnetic field lines of a bar magnet form closed loops. Note that the net magnetic flux through the closed surface (dashed red line) surrounding one of the poles (or any other closed surface) is zero.

**Figure 30.23** The electric field lines surrounding an electric dipole begin on the positive charge and terminate on the negative charge. The electric flux through a closed surface surrounding one of the charges is not zero.

cause certain theories that are otherwise successful in explaining fundamental physical behavior suggest the possible existence of monopoles.

### 30.7 DISPLACEMENT CURRENT AND THE GENERAL FORM OF AMPÈRE'S LAW

**Figure 30.24** Two surfaces  $S_1$  and  $S_2$  near the plate of a capacitor are bounded by the same path  $P$ . The conduction current in the wire passes only through  $S_1$ . This leads to a contradiction in Ampère's law that is resolved only if one postulates a displacement current through  $S_2$ .

We have seen that charges in motion produce magnetic fields. When a current-carrying conductor has high symmetry, we can use Ampère's law to calculate the magnetic field it creates. In Equation 30.13,  $\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I$ , the line integral is over any closed path through which the conduction current passes, and the conduction current is defined by the expression  $I = dq/dt$ . (In this section we use the term *conduction current* to refer to the current carried by the wire, to distinguish it from a new type of current that we shall introduce shortly.) We now show that **Ampère's law in this form is valid only if any electric fields present are constant in time.** Maxwell recognized this limitation and modified Ampère's law to include time-varying electric fields.

We can understand the problem by considering a capacitor that is being charged as illustrated in Figure 30.24. When a conduction current is present, the charge on the positive plate changes but *no conduction current passes across the gap between the plates*. Now consider the two surfaces  $S_1$  and  $S_2$  in Figure 30.24, bounded by the same path  $P$ . Ampère's law states that  $\oint \mathbf{B} \cdot d\mathbf{s}$  around this path must equal  $\mu_0 I$ , where  $I$  is the total current through any surface bounded by the path  $P$ .

When the path  $P$  is considered as bounding  $S_1$ ,  $\oint \mathbf{B} \cdot d\mathbf{s}$  is  $\mu_0 I$  because the conduction current passes through  $S_1$ . When the path is considered as bounding  $S_2$ , however,  $\oint \mathbf{B} \cdot d\mathbf{s} = 0$  because no conduction current passes through  $S_2$ . Thus, we arrive at a contradictory situation that arises from the discontinuity of the current! Maxwell solved this problem by postulating an additional term on the right side of Equation 30.13, which includes a factor called the **displacement current**  $I_d$ , defined as<sup>3</sup>

$$I_d \equiv \epsilon_0 \frac{d\Phi_E}{dt} \quad (30.21)$$

where  $\epsilon_0$  is the permittivity of free space (see Section 23.3) and  $\Phi_E = \int \mathbf{E} \cdot d\mathbf{A}$  is the electric flux (see Eq. 24.3).

As the capacitor is being charged (or discharged), the changing electric field between the plates may be considered equivalent to a current that acts as a continuation of the conduction current in the wire. When the expression for the displacement current given by Equation 30.21 is added to the conduction current on the right side of Ampère's law, the difficulty represented in Figure 30.24 is resolved. No matter which surface bounded by the path  $P$  is chosen, either conduction current or displacement current passes through it. With this new term  $I_d$ , we can express the general form of Ampère's law (sometimes called the **Ampère–Maxwell law**) as<sup>4</sup>

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 (I + I_d) = \mu_0 I + \mu_0 \epsilon_0 \frac{d\Phi_E}{dt} \quad (30.22)$$

<sup>3</sup> *Displacement* in this context does not have the meaning it does in Chapter 2. Despite the inaccurate implications, the word is historically entrenched in the language of physics, so we continue to use it.

<sup>4</sup> Strictly speaking, this expression is valid only in a vacuum. If a magnetic material is present, one must change  $\mu_0$  and  $\epsilon_0$  on the right-hand side of Equation 30.22 to the permeability  $\mu_m$  and permittivity  $\epsilon$  characteristic of the material. Alternatively, one may include a magnetizing current  $I_m$  on the righthand side of Equation 30.22 to make Ampère's law fully general. On a microscopic scale,  $I_m$  is as real as  $I$ .

Displacement current

Ampère–Maxwell law

**Figure 30.25** Because it exists only in the wires attached to the capacitor plates, the conduction current  $I = dQ/dt$  passes through  $S_1$  but not through  $S_2$ . Only the displacement current  $I_d = \epsilon_0 d\Phi_E/dt$  passes through  $S_2$ . The two currents must be equal for continuity.

We can understand the meaning of this expression by referring to Figure 30.25. The electric flux through surface  $S_2$  is  $\Phi_E = \int \mathbf{E} \cdot d\mathbf{A} = EA$ , where  $A$  is the area of the capacitor plates and  $E$  is the magnitude of the uniform electric field between the plates. If  $Q$  is the charge on the plates at any instant, then  $E = Q/\epsilon_0 A$  (see Section 26.2). Therefore, the electric flux through  $S_2$  is simply

$$\Phi_E = EA = \frac{Q}{\epsilon_0}$$

Hence, the displacement current through  $S_2$  is

$$I_d = \epsilon_0 \frac{d\Phi_E}{dt} = \frac{dQ}{dt} \quad (30.23)$$

That is, the displacement current through  $S_2$  is precisely equal to the conduction current  $I$  through  $S_1$ !

By considering surface  $S_2$ , we can identify the displacement current as the source of the magnetic field on the surface boundary. The displacement current has its physical origin in the time-varying electric field. The central point of this formalism, then, is that

magnetic fields are produced both by conduction currents and by time-varying electric fields.

This result was a remarkable example of theoretical work by Maxwell, and it contributed to major advances in the understanding of electromagnetism.

### Quick Quiz 30.6

What is the displacement current for a fully charged  $3\text{-}\mu\text{F}$  capacitor?

### EXAMPLE 30.9 Displacement Current in a Capacitor

A sinusoidally varying voltage is applied across an  $8.00\text{-}\mu\text{F}$  capacitor. The frequency of the voltage is  $3.00\text{ kHz}$ , and the voltage amplitude is  $30.0\text{ V}$ . Find the displacement current between the plates of the capacitor.

**Solution** The angular frequency of the source, from Equation 13.6, is  $\omega = 2\pi f = 2\pi(3.00 \times 10^3 \text{ Hz}) = 1.88 \times 10^4 \text{ s}^{-1}$ . Hence, the voltage across the capacitor in terms of  $t$  is

$$\Delta V = \Delta V_{\text{max}} \sin \omega t = (30.0 \text{ V}) \sin(1.88 \times 10^4 t)$$

We can use Equation 30.23 and the fact that the charge on

the capacitor is  $Q = C\Delta V$  to find the displacement current:

$$\begin{aligned} I_d &= \frac{dQ}{dt} = \frac{d}{dt}(C\Delta V) = C \frac{d}{dt}(\Delta V) \\ &= (8.00 \times 10^{-6} \text{ F}) \frac{d}{dt}[(30.0 \text{ V}) \sin(1.88 \times 10^4 t)] \\ &= (4.52 \text{ A}) \cos(1.88 \times 10^4 t) \end{aligned}$$

The displacement current varies sinusoidally with time and has a maximum value of  $4.52\text{ A}$ .

## Optional Section

## 30.8 MAGNETISM IN MATTER

The magnetic field produced by a current in a coil of wire gives us a hint as to what causes certain materials to exhibit strong magnetic properties. Earlier we found that a coil like the one shown in Figure 30.17 has a north pole and a south pole. In general, *any* current loop has a magnetic field and thus has a magnetic dipole moment, including the atomic-level current loops described in some models of the atom. Thus, the magnetic moments in a magnetized substance may be described as arising from these atomic-level current loops. For the Bohr model of the atom, these current loops are associated with the movement of electrons around the nucleus in circular orbits. In addition, a magnetic moment is intrinsic to electrons, protons, neutrons, and other particles; it arises from a property called *spin*.

## The Magnetic Moments of Atoms

It is instructive to begin our discussion with a classical model of the atom in which electrons move in circular orbits around the much more massive nucleus. In this model, an orbiting electron constitutes a tiny current loop (because it is a moving charge), and the magnetic moment of the electron is associated with this orbital motion. Although this model has many deficiencies, its predictions are in good agreement with the correct theory, which is expressed in terms of quantum physics.

Consider an electron moving with constant speed  $v$  in a circular orbit of radius  $r$  about the nucleus, as shown in Figure 30.26. Because the electron travels a distance of  $2\pi r$  (the circumference of the circle) in a time  $T$ , its orbital speed is  $v = 2\pi r/T$ . The current  $I$  associated with this orbiting electron is its charge  $e$  divided by  $T$ . Using  $T = 2\pi/\omega$  and  $\omega = v/r$ , we have

$$I = \frac{e}{T} = \frac{e\omega}{2\pi} = \frac{ev}{2\pi r}$$

The magnetic moment associated with this current loop is  $\mu = IA$ , where  $A = \pi r^2$  is the area enclosed by the orbit. Therefore,

$$\mu = IA = \left(\frac{ev}{2\pi r}\right)\pi r^2 = \frac{1}{2}evr \quad (30.24)$$

Because the magnitude of the orbital angular momentum of the electron is  $L = m_e v r$  (Eq. 11.16 with  $\phi = 90^\circ$ ), the magnetic moment can be written as

$$\mu = \left(\frac{e}{2m_e}\right)L \quad (30.25)$$

This result demonstrates that **the magnetic moment of the electron is proportional to its orbital angular momentum**. Note that because the electron is negatively charged, the vectors  $\mu$  and  $\mathbf{L}$  point in opposite directions. Both vectors are perpendicular to the plane of the orbit, as indicated in Figure 30.26.

A fundamental outcome of quantum physics is that orbital angular momentum is quantized and is equal to multiples of  $\hbar = h/2\pi = 1.05 \times 10^{-34} \text{ J}\cdot\text{s}$ , where  $h$  is Planck's constant. The smallest nonzero value of the electron's magnetic moment resulting from its orbital motion is

$$\mu = \sqrt{2} \frac{e}{2m_e} \hbar \quad (30.26)$$

We shall see in Chapter 42 how expressions such as Equation 30.26 arise.

**Figure 30.26** An electron moving in a circular orbit of radius  $r$  has an angular momentum  $\mathbf{L}$  in one direction and a magnetic moment  $\mu$  in the opposite direction.

Orbital magnetic moment

Angular momentum is quantized

Because all substances contain electrons, you may wonder why not all substances are magnetic. The main reason is that in most substances, the magnetic moment of one electron in an atom is canceled by that of another electron orbiting in the opposite direction. The net result is that, for most materials, **the magnetic effect produced by the orbital motion of the electrons is either zero or very small.**

In addition to its orbital magnetic moment, an electron has an intrinsic property called **spin** that also contributes to its magnetic moment. In this regard, the electron can be viewed as spinning about its axis while it orbits the nucleus, as shown in Figure 30.27. (Warning: This classical description should not be taken literally because spin arises from relativistic dynamics that must be incorporated into a quantum-mechanical analysis.) The magnitude of the angular momentum  $S$  associated with spin is of the same order of magnitude as the angular momentum  $L$  due to the orbital motion. The magnitude of the spin angular momentum predicted by quantum theory is

$$S = \frac{\sqrt{3}}{2} \hbar$$

The magnetic moment characteristically associated with the spin of an electron has the value

$$\mu_{\text{spin}} = \frac{e\hbar}{2m_e} \quad (30.27)$$

This combination of constants is called the **Bohr magneton**:

$$\mu_B = \frac{e\hbar}{2m_e} = 9.27 \times 10^{-24} \text{ J/T} \quad (30.28)$$

Thus, atomic magnetic moments can be expressed as multiples of the Bohr magneton. (Note that  $1 \text{ J/T} = 1 \text{ A} \cdot \text{m}^2$ .)

In atoms containing many electrons, the electrons usually pair up with their spins opposite each other; thus, the spin magnetic moments cancel. However, atoms containing an odd number of electrons must have at least one unpaired electron and therefore some spin magnetic moment. The total magnetic moment of an atom is the vector sum of the orbital and spin magnetic moments, and a few examples are given in Table 30.1. Note that helium and neon have zero moments because their individual spin and orbital moments cancel.

The nucleus of an atom also has a magnetic moment associated with its constituent protons and neutrons. However, the magnetic moment of a proton or neutron is much smaller than that of an electron and can usually be neglected. We can understand this by inspecting Equation 30.28 and replacing the mass of the electron with the mass of a proton or a neutron. Because the masses of the proton and neutron are much greater than that of the electron, their magnetic moments are on the order of  $10^3$  times smaller than that of the electron.

### Magnetization Vector and Magnetic Field Strength

The magnetic state of a substance is described by a quantity called the **magnetization vector  $\mathbf{M}$** . **The magnitude of this vector is defined as the magnetic moment per unit volume of the substance.** As you might expect, the total magnetic field  $\mathbf{B}$  at a point within a substance depends on both the applied (external) field  $\mathbf{B}_0$  and the magnetization of the substance.

To understand the problems involved in measuring the total magnetic field  $\mathbf{B}$  in such situations, consider this: Scientists use small probes that utilize the Hall ef-

Magnetization vector  $\mathbf{M}$

fect (see Section 29.6) to measure magnetic fields. What would such a probe read if it were positioned inside the solenoid mentioned in the QuickLab on page 951 when you inserted the compass? Because the compass is a magnetic material, the probe would measure a total magnetic field  $\mathbf{B}$  that is the sum of the solenoid (external) field  $\mathbf{B}_0$  and the (magnetization) field  $\mathbf{B}_m$  due to the compass. This tells us that we need a way to distinguish between magnetic fields originating from currents and those originating from magnetic materials. Consider a region in which a magnetic field  $\mathbf{B}_0$  is produced by a current-carrying conductor. If we now fill that region with a magnetic substance, the total magnetic field  $\mathbf{B}$  in the region is  $\mathbf{B} = \mathbf{B}_0 + \mathbf{B}_m$ , where  $\mathbf{B}_m$  is the field produced by the magnetic substance. We can express this contribution in terms of the magnetization vector of the substance as  $\mathbf{B}_m = \mu_0 \mathbf{M}$ ; hence, the total magnetic field in the region becomes

$$\mathbf{B} = \mathbf{B}_0 + \mu_0 \mathbf{M} \quad (30.29)$$

#### Magnetic field strength $\mathbf{H}$

When analyzing magnetic fields that arise from magnetization, it is convenient to introduce a field quantity, called the **magnetic field strength  $\mathbf{H}$**  within the substance. The magnetic field strength represents the effect of the conduction currents in wires on a substance. To emphasize the distinction between the field strength  $\mathbf{H}$  and the field  $\mathbf{B}$ , the latter is often called the *magnetic flux density* or the *magnetic induction*. The magnetic field strength is a vector defined by the relationship  $\mathbf{H} = \mathbf{B}_0/\mu_0 = (\mathbf{B}/\mu_0) - \mathbf{M}$ . Thus, Equation 30.29 can be written

$$\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M}) \quad (30.30)$$

The quantities  $\mathbf{H}$  and  $\mathbf{M}$  have the same units. In SI units, because  $\mathbf{M}$  is magnetic moment per unit volume, the units are (ampere)(meter)<sup>2</sup>/(meter)<sup>3</sup>, or amperes per meter.

To better understand these expressions, consider the torus region of a toroid that carries a current  $I$ . If this region is a vacuum,  $\mathbf{M} = 0$  (because no magnetic material is present), the total magnetic field is that arising from the current alone, and  $\mathbf{B} = \mathbf{B}_0 = \mu_0 \mathbf{H}$ . Because  $B_0 = \mu_0 nI$  in the torus region, where  $n$  is the number of turns per unit length of the toroid,  $H = B_0/\mu_0 = \mu_0 nI/\mu_0$ , or

$$H = nI \quad (30.31)$$

In this case, the magnetic field  $B$  in the torus region is due only to the current in the windings of the toroid.

If the torus is now made of some substance and the current  $I$  is kept constant,  $\mathbf{H}$  in the torus region remains unchanged (because it depends on the current only) and has magnitude  $nI$ . The total field  $\mathbf{B}$ , however, is different from that when the torus region was a vacuum. From Equation 30.30, we see that part of  $\mathbf{B}$  arises from the term  $\mu_0 \mathbf{H}$  associated with the current in the toroid, and part arises from the term  $\mu_0 \mathbf{M}$  due to the magnetization of the substance of which the torus is made.

Oxygen, a paramagnetic substance, is attracted to a magnetic field. The liquid oxygen in this photograph is suspended between the poles of the magnet.

### Classification of Magnetic Substances

Substances can be classified as belonging to one of three categories, depending on their magnetic properties. **Paramagnetic** and **ferromagnetic** materials are those made of atoms that have permanent magnetic moments. **Diamagnetic** materials are those made of atoms that do not have permanent magnetic moments.

For paramagnetic and diamagnetic substances, the magnetization vector  $\mathbf{M}$  is proportional to the magnetic field strength  $\mathbf{H}$ . For these substances placed in an external magnetic field, we can write

$$\mathbf{M} = \chi \mathbf{H} \quad (30.32)$$

**TABLE 30.2** Magnetic Susceptibilities of Some Paramagnetic and Diamagnetic Substances at 300 K

Paramagnetic Substance	$\chi$	Diamagnetic Substance	$\chi$
Aluminum	$2.3 \times 10^{-5}$	Bismuth	$-1.66 \times 10^{-5}$
Calcium	$1.9 \times 10^{-5}$	Copper	$-9.8 \times 10^{-6}$
Chromium	$2.7 \times 10^{-4}$	Diamond	$-2.2 \times 10^{-5}$
Lithium	$2.1 \times 10^{-5}$	Gold	$-3.6 \times 10^{-5}$
Magnesium	$1.2 \times 10^{-5}$	Lead	$-1.7 \times 10^{-5}$
Niobium	$2.6 \times 10^{-4}$	Mercury	$-2.9 \times 10^{-5}$
Oxygen	$2.1 \times 10^{-6}$	Nitrogen	$-5.0 \times 10^{-9}$
Platinum	$2.9 \times 10^{-4}$	Silver	$-2.6 \times 10^{-5}$
Tungsten	$6.8 \times 10^{-5}$	Silicon	$-4.2 \times 10^{-6}$

where  $\chi$  (Greek letter chi) is a dimensionless factor called the **magnetic susceptibility**. For paramagnetic substances,  $\chi$  is positive and  $\mathbf{M}$  is in the same direction as  $\mathbf{H}$ . For diamagnetic substances,  $\chi$  is negative and  $\mathbf{M}$  is opposite  $\mathbf{H}$ . (It is important to note that this linear relationship between  $\mathbf{M}$  and  $\mathbf{H}$  does not apply to ferromagnetic substances.) The susceptibilities of some substances are given in Table 30.2.

Substituting Equation 30.32 for  $\mathbf{M}$  into Equation 30.30 gives

$$\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M}) = \mu_0(\mathbf{H} + \chi\mathbf{H}) = \mu_0(1 + \chi)\mathbf{H}$$

or

$$\mathbf{B} = \mu_m \mathbf{H} \quad (30.33)$$

where the constant  $\mu_m$  is called the **magnetic permeability** of the substance and is related to the susceptibility by

$$\mu_m = \mu_0(1 + \chi) \quad (30.34)$$

Substances may be classified in terms of how their magnetic permeability  $\mu_m$  compares with  $\mu_0$  (the permeability of free space), as follows:

$$\text{Paramagnetic} \quad \mu_m > \mu_0$$

$$\text{Diamagnetic} \quad \mu_m < \mu_0$$

Because  $\chi$  is very small for paramagnetic and diamagnetic substances (see Table 30.2),  $\mu_m$  is nearly equal to  $\mu_0$  for these substances. For ferromagnetic substances, however,  $\mu_m$  is typically several thousand times greater than  $\mu_0$  (meaning that  $\chi$  is very great for ferromagnetic substances).

Although Equation 30.33 provides a simple relationship between  $\mathbf{B}$  and  $\mathbf{H}$ , we must interpret it with care when dealing with ferromagnetic substances. As mentioned earlier,  $\mathbf{M}$  is not a linear function of  $\mathbf{H}$  for ferromagnetic substances. This is because the value of  $\mu_m$  is not only a characteristic of the ferromagnetic substance but also depends on the previous state of the substance and on the process it underwent as it moved from its previous state to its present one. We shall investigate this more deeply after the following example.

Magnetic susceptibility  $\chi$

Magnetic permeability  $\mu_m$

**EXAMPLE 30.10** An Iron-Filled Toroid

A toroid wound with 60.0 turns/m of wire carries a current of 5.00 A. The torus is iron, which has a magnetic permeability of  $\mu_m = 5\,000\mu_0$  under the given conditions. Find  $H$  and  $B$  inside the iron.

**Solution** Using Equations 30.31 and 30.33, we obtain

$$H = nI = \left(60.0 \frac{\text{turns}}{\text{m}}\right)(5.00 \text{ A}) = 300 \frac{\text{A} \cdot \text{turns}}{\text{m}}$$

$$B = \mu_m H = 5\,000\mu_0 H$$

$$= 5\,000 \left(4\pi \times 10^{-7} \frac{\text{T} \cdot \text{m}}{\text{A}}\right) \left(300 \frac{\text{A} \cdot \text{turns}}{\text{m}}\right) = 1.88 \text{ T}$$

This value of  $B$  is 5 000 times the value in the absence of iron!

**Exercise** Determine the magnitude of the magnetization vector inside the iron torus.

**Answer**  $M = 1.5 \times 10^6 \text{ A/m}$ .

**Quick Quiz 30.7**

A current in a solenoid having air in the interior creates a magnetic field  $\mathbf{B} = \mu_0 \mathbf{H}$ . Describe qualitatively what happens to the magnitude of  $\mathbf{B}$  as (a) aluminum, (b) copper, and (c) iron are placed in the interior.

**Ferromagnetism**

A small number of crystalline substances in which the atoms have permanent magnetic moments exhibit strong magnetic effects called **ferromagnetism**. Some examples of ferromagnetic substances are iron, cobalt, nickel, gadolinium, and dysprosium. These substances contain atomic magnetic moments that tend to align parallel to each other even in a weak external magnetic field. Once the moments are aligned, the substance remains magnetized after the external field is removed. This permanent alignment is due to a strong coupling between neighboring moments, a coupling that can be understood only in quantum-mechanical terms.

All ferromagnetic materials are made up of microscopic regions called **domains**, regions within which all magnetic moments are aligned. These domains have volumes of about  $10^{-12}$  to  $10^{-8} \text{ m}^3$  and contain  $10^{17}$  to  $10^{21}$  atoms. The boundaries between the various domains having different orientations are called **domain walls**. In an unmagnetized sample, the domains are randomly oriented so that the net magnetic moment is zero, as shown in Figure 30.28a. When the sample is placed in an external magnetic field, the magnetic moments of the atoms tend to align with the field, which results in a magnetized sample, as in Figure 30.28b. Observations show that domains initially oriented along the external field grow larger at the expense of the less favorably oriented domains. When the external field is removed, the sample may retain a net magnetization in the direction of the original field. At ordinary temperatures, thermal agitation is not sufficient to disrupt this preferred orientation of magnetic moments.

A typical experimental arrangement that is used to measure the magnetic properties of a ferromagnetic material consists of a torus made of the material wound with  $N$  turns of wire, as shown in Figure 30.29, where the windings are represented in black and are referred to as the *primary coil*. This apparatus is sometimes referred to as a **Rowland ring**. A *secondary coil* (the red wires in Fig. 30.29) connected to a galvanometer is used to measure the total magnetic flux through the torus. The magnetic field  $\mathbf{B}$  in the torus is measured by increasing the current in the toroid from zero to  $I$ . As the current changes, the magnetic flux through

**Figure 30.28** (a) Random orientation of atomic magnetic moments in an unmagnetized substance. (b) When an external field  $\mathbf{B}_0$  is applied, the atomic magnetic moments tend to align with the field, giving the sample a net magnetization vector  $\mathbf{M}$ .

the secondary coil changes by an amount  $BA$ , where  $A$  is the cross-sectional area of the toroid. As we shall find in Chapter 31, because of this changing flux, an emf that is proportional to the rate of change in magnetic flux is induced in the secondary coil. If the galvanometer is properly calibrated, a value for  $\mathbf{B}$  corresponding to any value of the current in the primary coil can be obtained. The magnetic field  $\mathbf{B}$  is measured first in the absence of the torus and then with the torus in place. The magnetic properties of the torus material are then obtained from a comparison of the two measurements.

Now consider a torus made of unmagnetized iron. If the current in the primary coil is increased from zero to some value  $I$ , the magnitude of the magnetic field strength  $H$  increases linearly with  $I$  according to the expression  $H = nI$ . Furthermore, the magnitude of the total field  $B$  also increases with increasing current, as shown by the curve from point  $O$  to point  $a$  in Figure 30.30. At point  $O$ , the domains in the iron are randomly oriented, corresponding to  $B_m = 0$ . As the increasing current in the primary coil causes the external field  $\mathbf{B}_0$  to increase, the domains become more aligned until all of them are nearly aligned at point  $a$ . At this point the iron core is approaching *saturation*, which is the condition in which all domains in the iron are aligned.

Next, suppose that the current is reduced to zero, and the external field is consequently eliminated. The  $B$  versus  $H$  curve, called a **magnetization curve**, now follows the path  $ab$  in Figure 30.30. Note that at point  $b$ ,  $\mathbf{B}$  is not zero even though the external field is  $\mathbf{B}_0 = 0$ . The reason is that the iron is now magnetized due to the alignment of a large number of its domains (that is,  $\mathbf{B} = \mathbf{B}_m$ ). At this point, the iron is said to have a *remanent magnetization*.

If the current in the primary coil is reversed so that the direction of the external magnetic field is reversed, the domains reorient until the sample is again unmagnetized at point  $c$ , where  $B = 0$ . An increase in the reverse current causes the iron to be magnetized in the opposite direction, approaching saturation at point  $d$  in Figure 30.30. A similar sequence of events occurs as the current is reduced to zero and then increased in the original (positive) direction. In this case the magnetization curve follows the path  $def$ . If the current is increased sufficiently, the magnetization curve returns to point  $a$ , where the sample again has its maximum magnetization.

The effect just described, called **magnetic hysteresis**, shows that the magnetization of a ferromagnetic substance depends on the history of the substance as well as on the magnitude of the applied field. (The word *hysteresis* means “lagging behind.”) It is often said that a ferromagnetic substance has a “memory” because it remains magnetized after the external field is removed. The closed loop in Figure 30.30 is referred to as a hysteresis loop. Its shape and size depend on the proper-

**Figure 30.30** Magnetization curve for a ferromagnetic material.

### QuickLab

You've probably done this experiment before. Magnetize a nail by repeatedly dragging it across a bar magnet. Test the strength of the nail's magnetic field by picking up some paper clips. Now hit the nail several times with a hammer, and again test the strength of its magnetism. Explain what happens in terms of domains in the steel of the nail.

**Figure 30.29** A toroidal winding arrangement used to measure the magnetic properties of a material. The torus is made of the material under study, and the circuit containing the galvanometer measures the magnetic flux.

**Figure 30.31** Hysteresis loops for (a) a hard ferromagnetic material and (b) a soft ferromagnetic material.

**Figure 30.32** Demagnetizing a ferromagnetic material by carrying it through successive hysteresis loops.

ties of the ferromagnetic substance and on the strength of the maximum applied field. The hysteresis loop for “hard” ferromagnetic materials is characteristically wide like the one shown in Figure 30.31a, corresponding to a large remanent magnetization. Such materials cannot be easily demagnetized by an external field. “Soft” ferromagnetic materials, such as iron, have a very narrow hysteresis loop and a small remanent magnetization (Fig. 30.31b.) Such materials are easily magnetized and demagnetized. An ideal soft ferromagnet would exhibit no hysteresis and hence would have no remanent magnetization. A ferromagnetic substance can be demagnetized by being carried through successive hysteresis loops, due to a decreasing applied magnetic field, as shown in Figure 30.32.

### Quick Quiz 30.8

Which material would make a better permanent magnet, one whose hysteresis loop looks like Figure 30.31a or one whose loop looks like Figure 30.31b?

The magnetization curve is useful for another reason: **The area enclosed by the magnetization curve represents the work required to take the material through the hysteresis cycle.** The energy acquired by the material in the magnetization process originates from the source of the external field—that is, the emf in the circuit of the toroidal coil. When the magnetization cycle is repeated, dissipative processes within the material due to realignment of the domains result in a transformation of magnetic energy into internal energy, which is evidenced by an increase in the temperature of the substance. For this reason, devices subjected to alternating fields (such as ac adapters for cell phones, power tools, and so on) use cores made of soft ferromagnetic substances, which have narrow hysteresis loops and correspondingly little energy loss per cycle.

Magnetic computer disks store information by alternating the direction of **B** for portions of a thin layer of ferromagnetic material. Floppy disks have the layer on a circular sheet of plastic. Hard disks have several rigid platters with magnetic coatings on each side. Audio tapes and videotapes work the same way as floppy disks except that the ferromagnetic material is on a very long strip of plastic. Tiny coils of wire in a recording head are placed close to the magnetic material (which is moving rapidly past the head). Varying the current through the coils creates a magnetic field that magnetizes the recording material. To retrieve the information, the magnetized material is moved past a playback coil. The changing magnetism of the material induces a current in the coil, as we shall discuss in Chapter 31. This current is then amplified by audio or video equipment, or it is processed by computer circuitry.

## Paramagnetism

Paramagnetic substances have a small but positive magnetic susceptibility ( $0 < \chi \ll 1$ ) resulting from the presence of atoms (or ions) that have permanent magnetic moments. These moments interact only weakly with each other and are randomly oriented in the absence of an external magnetic field. When a paramagnetic substance is placed in an external magnetic field, its atomic moments tend to line up with the field. However, this alignment process must compete with thermal motion, which tends to randomize the magnetic moment orientations.

Pierre Curie (1859–1906) and others since him have found experimentally that, under a wide range of conditions, the magnetization of a paramagnetic substance is proportional to the applied magnetic field and inversely proportional to the absolute temperature:

$$M = C \frac{B_0}{T} \quad (30.35)$$

This relationship is known as **Curie's law** after its discoverer, and the constant  $C$  is called **Curie's constant**. The law shows that when  $B_0 = 0$ , the magnetization is zero, corresponding to a random orientation of magnetic moments. As the ratio of magnetic field to temperature becomes great, the magnetization approaches its saturation value, corresponding to a complete alignment of its moments, and Equation 30.35 is no longer valid.

When the temperature of a ferromagnetic substance reaches or exceeds a critical temperature called the **Curie temperature**, the substance loses its residual magnetization and becomes paramagnetic (Fig. 30.33). Below the Curie temperature, the magnetic moments are aligned and the substance is ferromagnetic. Above the Curie temperature, the thermal agitation is great enough to cause a random orientation of the moments, and the substance becomes paramagnetic. Curie temperatures for several ferromagnetic substances are given in Table 30.3.

## Diamagnetism

When an external magnetic field is applied to a diamagnetic substance, a weak magnetic moment is induced in the direction opposite the applied field. This causes diamagnetic substances to be weakly repelled by a magnet. Although diamagnetism is present in all matter, its effects are much smaller than those of paramagnetism or ferromagnetism, and are evident only when those other effects do not exist.

We can attain some understanding of diamagnetism by considering a classical model of two atomic electrons orbiting the nucleus in opposite directions but with the same speed. The electrons remain in their circular orbits because of the attractive electrostatic force exerted by the positively charged nucleus. Because the magnetic moments of the two electrons are equal in magnitude and opposite in direction, they cancel each other, and the magnetic moment of the atom is zero. When an external magnetic field is applied, the electrons experience an additional force  $q\mathbf{v} \times \mathbf{B}$ . This added force combines with the electrostatic force to increase the orbital speed of the electron whose magnetic moment is antiparallel to the field and to decrease the speed of the electron whose magnetic moment is parallel to the field. As a result, the two magnetic moments of the electrons no longer cancel, and the substance acquires a net magnetic moment that is opposite the applied field.

**Figure 30.33** Magnetization versus absolute temperature for a ferromagnetic substance. The magnetic moments are aligned below the Curie temperature  $T_{\text{Curie}}$ , where the substance is ferromagnetic. The substance becomes paramagnetic (magnetic moments unaligned) above  $T_{\text{Curie}}$ .

**Figure 30.34** A small permanent magnet levitated above a disk of the superconductor  $\text{YBa}_2\text{Cu}_3\text{O}_7$  cooled to liquid nitrogen temperature (77 K).

### web

For a more detailed description of the unusual properties of superconductors, visit [www.saunderscollege.com/physics/](http://www.saunderscollege.com/physics/)

As you recall from Chapter 27, a superconductor is a substance in which the electrical resistance is zero below some critical temperature. Certain types of superconductors also exhibit perfect diamagnetism in the superconducting state. As a result, an applied magnetic field is expelled by the superconductor so that the field is zero in its interior. This phenomenon of flux expulsion is known as the **Meissner effect**. If a permanent magnet is brought near a superconductor, the two objects repel each other. This is illustrated in Figure 30.34, which shows a small permanent magnet levitated above a superconductor maintained at 77 K.

### EXAMPLE 30.11 Saturation Magnetization

Estimate the saturation magnetization in a long cylinder of iron, assuming one unpaired electron spin per atom.

**Solution** The saturation magnetization is obtained when all the magnetic moments in the sample are aligned. If the sample contains  $n$  atoms per unit volume, then the saturation magnetization  $M_s$  has the value

$$M_s = n\mu$$

where  $\mu$  is the magnetic moment per atom. Because the molar mass of iron is 55 g/mol and its density is 7.9 g/cm<sup>3</sup>, the value of  $n$  for iron is  $8.6 \times 10^{28}$  atoms/m<sup>3</sup>. Assuming that

each atom contributes one Bohr magneton (due to one unpaired spin) to the magnetic moment, we obtain

$$\begin{aligned} M_s &= \left(8.6 \times 10^{28} \frac{\text{atoms}}{\text{m}^3}\right) \left(9.27 \times 10^{-24} \frac{\text{A} \cdot \text{m}^2}{\text{atom}}\right) \\ &= 8.0 \times 10^5 \text{ A/m} \end{aligned}$$

This is about one-half the experimentally determined saturation magnetization for iron, which indicates that actually two unpaired electron spins are present per atom.

### Optional Section

## 30.9 THE MAGNETIC FIELD OF THE EARTH

When we speak of a compass magnet having a north pole and a south pole, we should say more properly that it has a “north-seeking” pole and a “south-seeking” pole. By this we mean that one pole of the magnet seeks, or points to, the north geographic pole of the Earth. Because the north pole of a magnet is attracted toward the north geographic pole of the Earth, we conclude that **the Earth’s south magnetic pole is located near the north geographic pole, and the Earth’s north magnetic pole is located near the south geographic pole**. In fact, the configuration of the Earth’s magnetic field, pictured in Figure 30.35, is very much like the one that would be achieved by burying a gigantic bar magnet deep in the interior of the Earth.

**Figure 30.35** The Earth's magnetic field lines. Note that a south magnetic pole is near the north geographic pole, and a north magnetic pole is near the south geographic pole.

If a compass needle is suspended in bearings that allow it to rotate in the vertical plane as well as in the horizontal plane, the needle is horizontal with respect to the Earth's surface only near the equator. As the compass is moved northward, the needle rotates so that it points more and more toward the surface of the Earth. Finally, at a point near Hudson Bay in Canada, the north pole of the needle points directly downward. This site, first found in 1832, is considered to be the location of the south magnetic pole of the Earth. It is approximately 1 300 mi from the Earth's geographic North Pole, and its exact position varies slowly with time. Similarly, the north magnetic pole of the Earth is about 1 200 mi away from the Earth's geographic South Pole.

Because of this distance between the north geographic and south magnetic poles, it is only approximately correct to say that a compass needle points north. The difference between true north, defined as the geographic North Pole, and north indicated by a compass varies from point to point on the Earth, and the difference is referred to as *magnetic declination*. For example, along a line through Florida and the Great Lakes, a compass indicates true north, whereas in Washington state, it aligns  $25^\circ$  east of true north.

The north end of a compass needle points to the *south* magnetic pole of the Earth. The "north" compass direction varies from true geographic north depending on the magnetic declination at that point on the Earth's surface.

### QuickLab

A gold ring is very weakly repelled by a magnet. To see this, suspend a 14- or 18-karat gold ring on a long loop of thread, as shown in (a). Gently tap the ring and estimate its period of oscillation. Now bring the ring to rest, letting it hang for a few moments so that you can verify that it is not moving. Quickly bring a very strong magnet to within a few millimeters of the ring, taking care not to bump it, as shown in (b). Now pull the magnet away. Repeat this action many times, matching the oscillation period you estimated earlier. This is just like pushing a child on a swing. A small force applied at the resonant frequency results in a large-amplitude oscillation. If you have a platinum ring, you will be able to see a similar effect except that platinum is weakly attracted to a magnet because it is paramagnetic.

### Quick Quiz 30.9

If we wanted to cancel the Earth's magnetic field by running an enormous current loop around the equator, which way would the current have to flow: east to west or west to east?

Although the magnetic field pattern of the Earth is similar to the one that would be set up by a bar magnet deep within the Earth, it is easy to understand why the source of the Earth's magnetic field cannot be large masses of permanently magnetized material. The Earth does have large deposits of iron ore deep beneath its surface, but the high temperatures in the Earth's core prevent the iron from retaining any permanent magnetization. Scientists consider it more likely that the true source of the Earth's magnetic field is charge-carrying convection currents in the Earth's core. Charged ions or electrons circulating in the liquid interior could produce a magnetic field just as a current loop does. There is also strong evidence that the magnitude of a planet's magnetic field is related to the planet's rate of rotation. For example, Jupiter rotates faster than the Earth, and space probes indicate that Jupiter's magnetic field is stronger than ours. Venus, on the other hand, rotates more slowly than the Earth, and its magnetic field is found to be weaker. Investigation into the cause of the Earth's magnetism is ongoing.

There is an interesting sidelight concerning the Earth's magnetic field. It has been found that the direction of the field has been reversed several times during the last million years. Evidence for this is provided by basalt, a type of rock that contains iron and that forms from material spewed forth by volcanic activity on the ocean floor. As the lava cools, it solidifies and retains a picture of the Earth's magnetic field direction. The rocks are dated by other means to provide a timeline for these periodic reversals of the magnetic field.

### SUMMARY

The **Biot–Savart law** says that the magnetic field  $d\mathbf{B}$  at a point  $P$  due to a length element  $d\mathbf{s}$  that carries a steady current  $I$  is

$$d\mathbf{B} = \frac{\mu_0}{4\pi} \frac{I d\mathbf{s} \times \hat{\mathbf{r}}}{r^2} \quad (30.1)$$

where  $\mu_0 = 4\pi \times 10^{-7} \text{ T}\cdot\text{m}/\text{A}$  is the **permeability of free space**,  $r$  is the distance from the element to the point  $P$ , and  $\hat{\mathbf{r}}$  is a unit vector pointing from  $d\mathbf{s}$  to point  $P$ . We find the total field at  $P$  by integrating this expression over the entire current distribution.

The magnetic field at a distance  $a$  from a long, straight wire carrying an electric current  $I$  is

$$B = \frac{\mu_0 I}{2\pi a} \quad (30.5)$$

The field lines are circles concentric with the wire.

The magnetic force per unit length between two parallel wires separated by a distance  $a$  and carrying currents  $I_1$  and  $I_2$  has a magnitude

$$\frac{F_B}{\ell} = \frac{\mu_0 I_1 I_2}{2\pi a} \quad (30.12)$$

The force is attractive if the currents are in the same direction and repulsive if they are in opposite directions.

**Ampère's law** says that the line integral of  $\mathbf{B} \cdot d\mathbf{s}$  around any closed path equals  $\mu_0 I$ , where  $I$  is the total steady current passing through any surface bounded by the closed path:

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I \quad (30.13)$$

Using Ampère's law, one finds that the fields inside a toroid and solenoid are

$$B = \frac{\mu_0 N I}{2\pi r} \quad (\text{toroid}) \quad (30.16)$$

$$B = \mu_0 \frac{N}{\ell} I = \mu_0 n I \quad (\text{solenoid}) \quad (30.17)$$

where  $N$  is the total number of turns.

The **magnetic flux**  $\Phi_B$  through a surface is defined by the surface integral

$$\Phi_B \equiv \int \mathbf{B} \cdot d\mathbf{A} \quad (30.18)$$

**Gauss's law of magnetism** states that the net magnetic flux through any closed surface is zero.

The general form of Ampère's law, which is also called the **Ampère-Maxwell law**, is

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I + \mu_0 \epsilon_0 \frac{d\Phi_E}{dt} \quad (30.22)$$

This law describes the fact that magnetic fields are produced both by conduction currents and by changing electric fields.

## QUESTIONS

- Is the magnetic field created by a current loop uniform? Explain.
- A current in a conductor produces a magnetic field that can be calculated using the Biot–Savart law. Because current is defined as the rate of flow of charge, what can you conclude about the magnetic field produced by stationary charges? What about that produced by moving charges?
- Two parallel wires carry currents in opposite directions. Describe the nature of the magnetic field created by the two wires at points (a) between the wires and (b) outside the wires, in a plane containing them.
- Explain why two parallel wires carrying currents in opposite directions repel each other.
- When an electric circuit is being assembled, a common practice is to twist together two wires carrying equal currents in opposite directions. Why does this technique reduce stray magnetic fields?
- Is Ampère's law valid for all closed paths surrounding a conductor? Why is it not useful for calculating  $\mathbf{B}$  for all such paths?
- Compare Ampère's law with the Biot–Savart law. Which is more generally useful for calculating  $\mathbf{B}$  for a current-carrying conductor?
- Is the magnetic field inside a toroid uniform? Explain.
- Describe the similarities between Ampère's law in magnetism and Gauss's law in electrostatics.
- A hollow copper tube carries a current along its length. Why does  $\mathbf{B} = 0$  inside the tube? Is  $\mathbf{B}$  nonzero outside the tube?
- Why is  $\mathbf{B}$  nonzero outside a solenoid? Why does  $\mathbf{B} = 0$  outside a toroid? (Remember that the lines of  $\mathbf{B}$  must form closed paths.)
- Describe the change in the magnetic field in the interior of a solenoid carrying a steady current  $I$  (a) if the length of the solenoid is doubled but the number of turns remains the same and (b) if the number of turns is doubled but the length remains the same.
- A flat conducting loop is positioned in a uniform magnetic field directed along the  $x$  axis. For what orientation of the loop is the flux through it a maximum? A minimum?
- What new concept does Maxwell's general form of Ampère's law include?
- Many loops of wire are wrapped around a nail and then connected to a battery. Identify the source of  $\mathbf{M}$ , of  $\mathbf{H}$ , and of  $\mathbf{B}$ .

16. A magnet attracts a piece of iron. The iron can then attract another piece of iron. On the basis of domain alignment, explain what happens in each piece of iron.
17. You are stranded on a planet that does not have a magnetic field, with no test equipment. You have two bars of iron in your possession; one is magnetized, and one is not. How can you determine which is which?
18. Why does hitting a magnet with a hammer cause the magnetism to be reduced?
19. Is a nail attracted to either pole of a magnet? Explain what is happening inside the nail when it is placed near the magnet.
20. A Hindu ruler once suggested that he be entombed in a magnetic coffin with the polarity arranged so that he would be forever suspended between heaven and Earth. Is such magnetic levitation possible? Discuss.
21. Why does  $\mathbf{M} = 0$  in a vacuum? What is the relationship between  $\mathbf{B}$  and  $\mathbf{H}$  in a vacuum?
22. Explain why some atoms have permanent magnetic moments and others do not.
23. What factors contribute to the total magnetic moment of an atom?
24. Why is the magnetic susceptibility of a diamagnetic substance negative?
25. Why can the effect of diamagnetism be neglected in a paramagnetic substance?
26. Explain the significance of the Curie temperature for a ferromagnetic substance.
27. Discuss the differences among ferromagnetic, paramagnetic, and diamagnetic substances.
28. What is the difference between hard and soft ferromagnetic materials?
29. Should the surface of a computer disk be made from a hard or a soft ferromagnetic substance?
30. Explain why it is desirable to use hard ferromagnetic materials to make permanent magnets.
31. Would you expect the tape from a tape recorder to be attracted to a magnet? (Try it, but not with a recording you wish to save.)
32. Given only a strong magnet and a screwdriver, how would you first magnetize and then demagnetize the screwdriver?
33. Figure Q30.33 shows two permanent magnets, each having a hole through its center. Note that the upper magnet is levitated above the lower one. (a) How does this occur? (b) What purpose does the pencil serve? (c) What can you say about the poles of the magnets on the basis of this observation? (d) What do you suppose would happen if the upper magnet were inverted?

**Figure Q30.33** Magnetic levitation using two ceramic magnets.

## PROBLEMS

1, 2, 3 = straightforward, intermediate, challenging □ = full solution available in the *Student Solutions Manual and Study Guide*  
 WEB = solution posted at <http://www.saunderscollege.com/physics/> = Computer useful in solving problem = Interactive Physics  
 □ = paired numerical/symbolic problems

### Section 30.1 The Biot–Savart Law

1. In Niels Bohr's 1913 model of the hydrogen atom, an electron circles the proton at a distance of  $5.29 \times 10^{-11}$  m with a speed of  $2.19 \times 10^6$  m/s. Compute the magnitude of the magnetic field that this motion produces at the location of the proton.
2. A current path shaped as shown in Figure P30.2 produces a magnetic field at  $P$ , the center of the arc. If the arc subtends an angle of  $30.0^\circ$  and the radius of the arc is 0.600 m, what are the magnitude and direction of the field produced at  $P$  if the current is 3.00 A?
3. (a) A conductor in the shape of a square of edge length  $\ell = 0.400$  m carries a current  $I = 10.0$  A (Fig. P30.3). Calculate the magnitude and direction of the magnetic

**Figure P30.2**

field at the center of the square. (b) If this conductor is formed into a single circular turn and carries the same current, what is the value of the magnetic field at the center?

Figure P30.3

4. Calculate the magnitude of the magnetic field at a point 100 cm from a long, thin conductor carrying a current of 1.00 A.
- WEB 5. Determine the magnetic field at a point  $P$  located a distance  $x$  from the corner of an infinitely long wire bent at a right angle, as shown in Figure P30.5. The wire carries a steady current  $I$ .

Figure P30.5

6. A wire carrying a current of 5.00 A is to be formed into a circular loop of one turn. If the required value of the magnetic field at the center of the loop is  $10.0 \mu\text{T}$ , what is the required radius?
7. A conductor consists of a circular loop of radius  $R = 0.100$  m and two straight, long sections, as shown in Figure P30.7. The wire lies in the plane of the paper and carries a current of  $I = 7.00$  A. Determine the magnitude and direction of the magnetic field at the center of the loop.
8. A conductor consists of a circular loop of radius  $R$  and two straight, long sections, as shown in Figure P30.7. The wire lies in the plane of the paper and carries a current  $I$ . Determine the magnitude and direction of the magnetic field at the center of the loop.
9. The segment of wire in Figure P30.9 carries a current of  $I = 5.00$  A, where the radius of the circular arc is  $R = 3.00$  cm. Determine the magnitude and direction of the magnetic field at the origin.

Figure P30.7 Problems 7 and 8.

Figure P30.9

10. Consider a flat, circular current loop of radius  $R$  carrying current  $I$ . Choose the  $x$  axis to be along the axis of the loop, with the origin at the center of the loop. Graph the ratio of the magnitude of the magnetic field at coordinate  $x$  to that at the origin, for  $x = 0$  to  $x = 5R$ . It may be helpful to use a programmable calculator or a computer to solve this problem.
11. Consider the current-carrying loop shown in Figure P30.11, formed of radial lines and segments of circles whose centers are at point  $P$ . Find the magnitude and direction of  $\mathbf{B}$  at  $P$ .

Figure P30.11

12. Determine the magnetic field (in terms of  $I$ ,  $a$ , and  $d$ ) at the origin due to the current loop shown in Figure P30.12.
13. The loop in Figure P30.13 carries a current  $I$ . Determine the magnetic field at point  $A$  in terms of  $I$ ,  $R$ , and  $L$ .
14. Three long, parallel conductors carry currents of  $I = 2.00$  A. Figure P30.14 is an end view of the conductors, with each current coming out of the page. If  $a = 1.00$  cm, determine the magnitude and direction of the magnetic field at points  $A$ ,  $B$ , and  $C$ .
15. Two long, parallel conductors carry currents  $I_1 = 3.00$  A and  $I_2 = 3.00$  A, both directed into the page in

Figure P30.12

Figure P30.13

Figure P30.14

Figure P30.15

Figure P30.15. Determine the magnitude and direction of the resultant magnetic field at  $P$ .

**Section 30.2 The Magnetic Force Between Two Parallel Conductors**

16. Two long, parallel conductors separated by 10.0 cm carry currents in the same direction. The first wire carries current  $I_1 = 5.00$  A, and the second carries  $I_2 = 8.00$  A. (a) What is the magnitude of the magnetic field created by  $I_1$  and acting on  $I_2$ ? (b) What is the force per unit length exerted on  $I_2$  by  $I_1$ ? (c) What is the magnitude of the magnetic field created by  $I_2$  at the location of  $I_1$ ? (d) What is the force per unit length exerted by  $I_2$  on  $I_1$ ?

17. In Figure P30.17, the current in the long, straight wire is  $I_1 = 5.00$  A, and the wire lies in the plane of the rectangular loop, which carries 10.0 A. The dimensions are  $c = 0.100$  m,  $a = 0.150$  m, and  $\ell = 0.450$  m. Find the magnitude and direction of the net force exerted on the loop by the magnetic field created by the wire.

Figure P30.17

18. The unit of magnetic flux is named for Wilhelm Weber. The practical-size unit of magnetic field is named for Johann Karl Friedrich Gauss. Both were scientists at Göttingen, Germany. In addition to their individual accomplishments, they built a telegraph together in 1833. It consisted of a battery and switch that were positioned at one end of a transmission line 3 km long and operated an electromagnet at the other end. (Andre Ampère suggested electrical signaling in 1821; Samuel Morse built a telegraph line between Baltimore and Washington in 1844.) Suppose that Weber and Gauss's transmission line was as diagrammed in Figure P30.18. Two long, parallel wires, each having a mass per unit length of 40.0 g/m, are supported in a horizontal plane by strings 6.00 cm long. When both wires carry the same current  $I$ , the wires repel each other so that the angle  $\theta$

between the supporting strings is  $16.0^\circ$ . (a) Are the currents in the same direction or in opposite directions? (b) Find the magnitude of the current.

Figure P30.18

### Section 30.3 Ampère's Law

**WEB 19.** Four long, parallel conductors carry equal currents of  $I = 5.00$  A. Figure P30.19 is an end view of the conductors. The direction of the current is into the page at points  $A$  and  $B$  (indicated by the crosses) and out of the page at  $C$  and  $D$  (indicated by the dots). Calculate the magnitude and direction of the magnetic field at point  $P$ , located at the center of the square with an edge length of  $0.200$  m.

Figure P30.19

- 20.** A long, straight wire lies on a horizontal table and carries a current of  $1.20 \mu\text{A}$ . In a vacuum, a proton moves parallel to the wire (opposite the current) with a constant velocity of  $2.30 \times 10^4$  m/s at a distance  $d$  above the wire. Determine the value of  $d$ . You may ignore the magnetic field due to the Earth.
- 21.** Figure P30.21 is a cross-sectional view of a coaxial cable. The center conductor is surrounded by a rubber layer, which is surrounded by an outer conductor, which is surrounded by another rubber layer. In a particular application, the current in the inner conductor is  $1.00$  A out of the page, and the current in the outer conductor is  $3.00$  A into the page. Determine the magnitude and direction of the magnetic field at points  $a$  and  $b$ .
- 22.** The magnetic field  $40.0$  cm away from a long, straight wire carrying current  $2.00$  A is  $1.00 \mu\text{T}$ . (a) At what distance is it  $0.100 \mu\text{T}$ ? (b) At one instant, the two conductors in a long household extension cord carry equal

Figure P30.21

- $2.00$ -A currents in opposite directions. The two wires are  $3.00$  mm apart. Find the magnetic field  $40.0$  cm away from the middle of the straight cord, in the plane of the two wires. (c) At what distance is it one-tenth as large? (d) The center wire in a coaxial cable carries current  $2.00$  A in one direction, and the sheath around it carries current  $2.00$  A in the opposite direction. What magnetic field does the cable create at points outside?
- 23.** The magnetic coils of a tokamak fusion reactor are in the shape of a toroid having an inner radius of  $0.700$  m and an outer radius of  $1.30$  m. If the toroid has  $900$  turns of large-diameter wire, each of which carries a current of  $14.0$  kA, find the magnitude of the magnetic field inside the toroid (a) along the inner radius and (b) along the outer radius.
- 24.** A cylindrical conductor of radius  $R = 2.50$  cm carries a current of  $I = 2.50$  A along its length; this current is uniformly distributed throughout the cross-section of the conductor. (a) Calculate the magnetic field midway along the radius of the wire (that is, at  $r = R/2$ ). (b) Find the distance beyond the surface of the conductor at which the magnitude of the magnetic field has the same value as the magnitude of the field at  $r = R/2$ .
- WEB 25.** A packed bundle of  $100$  long, straight, insulated wires forms a cylinder of radius  $R = 0.500$  cm. (a) If each wire carries  $2.00$  A, what are the magnitude and direction of the magnetic force per unit length acting on a wire located  $0.200$  cm from the center of the bundle? (b) Would a wire on the outer edge of the bundle experience a force greater or less than the value calculated in part (a)?
- 26.** Niobium metal becomes a superconductor when cooled below  $9$  K. If superconductivity is destroyed when the surface magnetic field exceeds  $0.100$  T, determine the maximum current a  $2.00$ -mm-diameter niobium wire can carry and remain superconducting, in the absence of any external magnetic field.
- 27.** A long, cylindrical conductor of radius  $R$  carries a current  $I$ , as shown in Figure P30.27. The current density  $J$ , however, is not uniform over the cross-section of the

Figure P30.27

conductor but is a function of the radius according to  $J = br$ , where  $b$  is a constant. Find an expression for the magnetic field  $B$  (a) at a distance  $r_1 < R$  and (b) at a distance  $r_2 > R$ , measured from the axis.

28. In Figure P30.28, both currents are in the negative  $x$  direction. (a) Sketch the magnetic field pattern in the  $yz$  plane. (b) At what distance  $d$  along the  $z$  axis is the magnetic field a maximum?

Figure P30.28

### Section 30.4 The Magnetic Field of a Solenoid

- WEB 29. What current is required in the windings of a long solenoid that has 1 000 turns uniformly distributed over a length of 0.400 m, to produce at the center of the solenoid a magnetic field of magnitude  $1.00 \times 10^{-4}$  T?
30. A superconducting solenoid is meant to generate a magnetic field of 10.0 T. (a) If the solenoid winding has 2 000 turns/m, what current is required? (b) What force per unit length is exerted on the windings by this magnetic field?
31. A solenoid of radius  $R = 5.00$  cm is made of a long piece of wire of radius  $r = 2.00$  mm, length  $\ell = 10.0$  m ( $\ell \gg R$ ) and resistivity  $\rho = 1.70 \times 10^{-8} \Omega \cdot \text{m}$ . Find the magnetic field at the center of the solenoid if the wire is connected to a battery having an emf  $\mathcal{E} = 20.0$  V.
32. A single-turn square loop of wire with an edge length of 2.00 cm carries a clockwise current of 0.200 A. The loop is inside a solenoid, with the plane of the loop perpendicular to the magnetic field of the solenoid. The solenoid has 30 turns/cm and carries a clockwise current of 15.0 A. Find the force on each side of the loop and the torque acting on the loop.

### Section 30.5 Magnetic Flux

33. A cube of edge length  $\ell = 2.50$  cm is positioned as shown in Figure P30.33. A uniform magnetic field given by  $\mathbf{B} = (5.00\mathbf{i} + 4.00\mathbf{j} + 3.00\mathbf{k})$  T exists throughout the region. (a) Calculate the flux through the shaded face. (b) What is the total flux through the six faces?

Figure P30.33

34. A solenoid 2.50 cm in diameter and 30.0 cm long has 300 turns and carries 12.0 A. (a) Calculate the flux through the surface of a disk of radius 5.00 cm that is positioned perpendicular to and centered on the axis of the solenoid, as in Figure P30.34a. (b) Figure P30.34b shows an enlarged end view of the same solenoid. Calculate the flux through the blue area, which is defined by an annulus that has an inner radius of 0.400 cm and outer radius of 0.800 cm.

Figure P30.34

35. Consider the hemispherical closed surface in Figure P30.35. If the hemisphere is in a uniform magnetic field that makes an angle  $\theta$  with the vertical, calculate the magnetic flux (a) through the flat surface  $S_1$  and (b) through the hemispherical surface  $S_2$ .

Figure P30.35

### Section 30.6 Gauss's Law in Magnetism

### Section 30.7 Displacement Current and the General Form of Ampère's Law

36. A 0.200-A current is charging a capacitor that has circular plates 10.0 cm in radius. If the plate separation is 4.00 mm, (a) what is the time rate of increase of electric field between the plates? (b) What is the magnetic field between the plates 5.00 cm from the center?
37. A 0.100-A current is charging a capacitor that has square plates 5.00 cm on each side. If the plate separation is 4.00 mm, find (a) the time rate of change of electric flux between the plates and (b) the displacement current between the plates.

(Optional)

### Section 30.8 Magnetism in Matter

38. In Bohr's 1913 model of the hydrogen atom, the electron is in a circular orbit of radius  $5.29 \times 10^{-11}$  m, and its speed is  $2.19 \times 10^6$  m/s. (a) What is the magnitude of the magnetic moment due to the electron's motion? (b) If the electron orbits counterclockwise in a horizontal circle, what is the direction of this magnetic moment vector?
39. A toroid with a mean radius of 20.0 cm and 630 turns (see Fig. 30.29) is filled with powdered steel whose magnetic susceptibility  $\chi$  is 100. If the current in the windings is 3.00 A, find  $B$  (assumed uniform) inside the toroid.
40. A magnetic field of 1.30 T is to be set up in an iron-core toroid. The toroid has a mean radius of 10.0 cm and magnetic permeability of  $5\,000\mu_0$ . What current is re-

quired if there are 470 turns of wire in the winding? The thickness of the iron ring is small compared to 10 cm, so the field in the material is nearly uniform.

41. A coil of 500 turns is wound on an iron ring ( $\mu_m = 750\mu_0$ ) with a 20.0-cm mean radius and an 8.00-cm<sup>2</sup> cross-sectional area. Calculate the magnetic flux  $\Phi_B$  in this Rowland ring when the current in the coil is 0.500 A.
42. A uniform ring with a radius of 2.00 cm and a total charge of 6.00  $\mu\text{C}$  rotates with a constant angular speed of 4.00 rad/s around an axis perpendicular to the plane of the ring and passing through its center. What is the magnetic moment of the rotating ring?
43. Calculate the magnetic field strength  $H$  of a magnetized substance in which the magnetization is 880 kA/m and the magnetic field has a magnitude of 4.40 T.
44. At saturation, the alignment of spins in iron can contribute as much as 2.00 T to the total magnetic field  $B$ . If each electron contributes a magnetic moment of  $9.27 \times 10^{-24}$  A  $\cdot$  m<sup>2</sup> (one Bohr magneton), how many electrons per atom contribute to the saturated field of iron? (*Hint:* Iron contains  $8.50 \times 10^{28}$  atoms/m<sup>3</sup>.)
45. (a) Show that Curie's law can be stated in the following way: The magnetic susceptibility of a paramagnetic substance is inversely proportional to the absolute temperature, according to  $\chi = C\mu_0/T$ , where  $C$  is Curie's constant. (b) Evaluate Curie's constant for chromium.

(Optional)

### Section 30.9 The Magnetic Field of the Earth

46. A circular coil of 5 turns and a diameter of 30.0 cm is oriented in a vertical plane with its axis perpendicular to the horizontal component of the Earth's magnetic field. A horizontal compass placed at the center of the coil is made to deflect 45.0° from magnetic north by a current of 0.600 A in the coil. (a) What is the horizontal component of the Earth's magnetic field? (b) The current in the coil is switched off. A "dip needle" is a magnetic compass mounted so that it can rotate in a vertical north-south plane. At this location a dip needle makes an angle of 13.0° from the vertical. What is the total magnitude of the Earth's magnetic field at this location?
47. The magnetic moment of the Earth is approximately  $8.00 \times 10^{22}$  A  $\cdot$  m<sup>2</sup>. (a) If this were caused by the complete magnetization of a huge iron deposit, how many unpaired electrons would this correspond to? (b) At two unpaired electrons per iron atom, how many kilograms of iron would this correspond to? (Iron has a density of 7 900 kg/m<sup>3</sup> and approximately  $8.50 \times 10^{28}$  atoms/m<sup>3</sup>.)

### ADDITIONAL PROBLEMS

48. A lightning bolt may carry a current of  $1.00 \times 10^4$  A for a short period of time. What is the resultant magnetic

field 100 m from the bolt? Suppose that the bolt extends far above and below the point of observation.

49. The magnitude of the Earth's magnetic field at either pole is approximately  $7.00 \times 10^{-5}$  T. Suppose that the field fades away, before its next reversal. Scouts, sailors, and wire merchants around the world join together in a program to replace the field. One plan is to use a current loop around the equator, without relying on magnetization of any materials inside the Earth. Determine the current that would generate such a field if this plan were carried out. (Take the radius of the Earth as  $R_E = 6.37 \times 10^6$  m.)
50. Two parallel conductors carry current in opposite directions, as shown in Figure P30.50. One conductor carries a current of 10.0 A. Point A is at the midpoint between the wires, and point C is a distance  $d/2$  to the right of the 10.0-A current. If  $d = 18.0$  cm and  $I$  is adjusted so that the magnetic field at C is zero, find (a) the value of the current  $I$  and (b) the value of the magnetic field at A.

Figure P30.50

51. Suppose you install a compass on the center of the dashboard of a car. Compute an order-of-magnitude estimate for the magnetic field that is produced at this location by the current when you switch on the headlights. How does your estimate compare with the Earth's magnetic field? You may suppose the dashboard is made mostly of plastic.
52. Imagine a long, cylindrical wire of radius  $R$  that has a current density  $J(r) = J_0(1 - r^2/R^2)$  for  $r \leq R$  and  $J(r) = 0$  for  $r > R$ , where  $r$  is the distance from the axis of the wire. (a) Find the resulting magnetic field inside ( $r \leq R$ ) and outside ( $r > R$ ) the wire. (b) Plot the magnitude of the magnetic field as a function of  $r$ . (c) Find the location where the magnitude of the magnetic field is a maximum, and the value of that maximum field.
53. A very long, thin strip of metal of width  $w$  carries a current  $I$  along its length, as shown in Figure P30.53. Find the magnetic field at point P in the diagram. Point P is

Figure P30.53

in the plane of the strip at a distance  $b$  away from the strip.

54. For a research project, a student needs a solenoid that produces an interior magnetic field of 0.030 0 T. She decides to use a current of 1.00 A and a wire 0.500 mm in diameter. She winds the solenoid in layers on an insulating form 1.00 cm in diameter and 10.0 cm long. Determine the number of layers of wire she needs and the total length of the wire.

WEB 55. A nonconducting ring with a radius of 10.0 cm is uniformly charged with a total positive charge of  $10.0 \mu\text{C}$ . The ring rotates at a constant angular speed of 20.0 rad/s about an axis through its center, perpendicular to the plane of the ring. What is the magnitude of the magnetic field on the axis of the ring, 5.00 cm from its center?

56. A nonconducting ring of radius  $R$  is uniformly charged with a total positive charge  $q$ . The ring rotates at a constant angular speed  $\omega$  about an axis through its center, perpendicular to the plane of the ring. What is the magnitude of the magnetic field on the axis of the ring a distance  $R/2$  from its center?

57. Two circular coils of radius  $R$  are each perpendicular to a common axis. The coil centers are a distance  $R$  apart, and a steady current  $I$  flows in the same direction around each coil, as shown in Figure P30.57. (a) Show that the magnetic field on the axis at a distance  $x$  from the center of one coil is

$$B = \frac{\mu_0 IR^2}{2} \left[ \frac{1}{(R^2 + x^2)^{3/2}} + \frac{1}{(2R^2 + x^2 - 2Rx)^{3/2}} \right]$$

(b) Show that  $dB/dx$  and  $d^2B/dx^2$  are both zero at a point midway between the coils. This means that the magnetic field in the region midway between the coils is uniform. Coils in this configuration are called **Helmholtz coils**.

58. Two identical, flat, circular coils of wire each have 100 turns and a radius of 0.500 m. The coils are arranged as

**Figure P30.57** Problems 57 and 58.

a set of Helmholtz coils (see Fig. P30.57), parallel and with a separation of 0.500 m. If each coil carries a current of 10.0 A, determine the magnitude of the magnetic field at a point on the common axis of the coils and halfway between them.

59. Two circular loops are parallel, coaxial, and almost in contact, 1.00 mm apart (Fig. P30.59). Each loop is 10.0 cm in radius. The top loop carries a clockwise current of 140 A. The bottom loop carries a counterclockwise current of 140 A. (a) Calculate the magnetic force that the bottom loop exerts on the top loop. (b) The upper loop has a mass of 0.021 0 kg. Calculate its acceleration, assuming that the only forces acting on it are the force in part (a) and its weight. (*Hint:* Think about how one loop looks to a bug perched on the other loop.)

**Figure P30.59**

60. What objects experience a force in an electric field? Chapter 23 gives the answer: any electric charge, stationary or moving, other than the charge that created the field. What creates an electric field? Any electric charge, stationary or moving, also as discussed in Chapter 23. What objects experience a force in a magnetic field? An electric current or a moving electric charge other than the current or charge that created the field, as discovered in Chapter 29. What creates a magnetic field? An electric current, as you found in Section 30.11, or a moving electric charge, as in this problem. (a) To display how a moving charge creates a magnetic field, consider a charge  $q$  moving with velocity  $\mathbf{v}$ . Define the unit vector  $\hat{\mathbf{r}} = \mathbf{r}/r$  to point from the charge to some location. Show that the magnetic field at that location is

$$\mathbf{B} = \frac{\mu_0}{4\pi} \frac{q\mathbf{v} \times \hat{\mathbf{r}}}{r^2}$$

- (b) Find the magnitude of the magnetic field 1.00 mm

to the side of a proton moving at  $2.00 \times 10^7$  m/s.

(c) Find the magnetic force on a second proton at this point, moving with the same speed in the opposite direction. (d) Find the electric force on the second proton.

61. *Rail guns* have been suggested for launching projectiles into space without chemical rockets, and for ground-to-air antimissile weapons of war. A tabletop model rail gun (Fig. P30.61) consists of two long parallel horizontal rails 3.50 cm apart, bridged by a bar  $BD$  of mass 3.00 g. The bar is originally at rest at the midpoint of the rails and is free to slide without friction. When the switch is closed, electric current is very quickly established in the circuit  $ABCDEA$ . The rails and bar have low electrical resistance, and the current is limited to a constant 24.0 A by the power supply. (a) Find the magnitude of the magnetic field 1.75 cm from a single very long, straight wire carrying current 24.0 A. (b) Find the vector magnetic field at point  $C$  in the diagram, the midpoint of the bar, immediately after the switch is closed. (*Hint:* Consider what conclusions you can draw from the Biot–Savart law.) (c) At other points along the bar  $BD$ , the field is in the same direction as at point  $C$ , but greater in magnitude. Assume that the average effective magnetic field along  $BD$  is five times larger than the field at  $C$ . With this assumption, find the vector force on the bar. (d) Find the vector acceleration with which the bar starts to move. (e) Does the bar move with constant acceleration? (f) Find the velocity of the bar after it has traveled 130 cm to the end of the rails.

**Figure P30.61**

62. Two long, parallel conductors carry currents in the same direction, as shown in Figure P30.62. Conductor A carries a current of 150 A and is held firmly in position. Conductor B carries a current  $I_B$  and is allowed to slide freely up and down (parallel to A) between a set of nonconducting guides. If the mass per unit length of conductor B is 0.100 g/cm, what value of current  $I_B$  will result in equilibrium when the distance between the two conductors is 2.50 cm?
63. Charge is sprayed onto a large nonconducting belt above the left-hand roller in Figure P30.63. The belt carries the charge, with a uniform surface charge density  $\sigma$ , as it moves with a speed  $v$  between the rollers as shown. The charge is removed by a wiper at the right-hand roller. Consider a point just above the surface of the moving belt. (a) Find an expression for the magni-

Figure P30.62

Figure P30.63

tude of the magnetic field  $\mathbf{B}$  at this point. (b) If the belt is positively charged, what is the direction of  $\mathbf{B}$ ? (Note that the belt may be considered as an infinite sheet.)

64. A particular paramagnetic substance achieves 10.0% of its saturation magnetization when placed in a magnetic field of 5.00 T at a temperature of 4.00 K. The density of magnetic atoms in the sample is  $8.00 \times 10^{27}$  atoms/m<sup>3</sup>, and the magnetic moment per atom is 5.00 Bohr magnetons. Calculate the Curie constant for this substance.
65. A bar magnet (mass = 39.4 g, magnetic moment = 7.65 J/T, length = 10.0 cm) is connected to the ceiling by a string. A uniform external magnetic field is applied horizontally, as shown in Figure P30.65. The magnet is in equilibrium, making an angle  $\theta$  with the horizontal. If  $\theta = 5.00^\circ$ , determine the magnitude of the applied magnetic field.

Figure P30.65

66. An infinitely long, straight wire carrying a current  $I_1$  is partially surrounded by a loop, as shown in Figure P30.66. The loop has a length  $L$  and a radius  $R$  and carries a current  $I_2$ . The axis of the loop coincides with the wire. Calculate the force exerted on the loop.

Figure P30.66

67. A wire is bent into the shape shown in Figure P30.67a, and the magnetic field is measured at  $P_1$  when the current in the wire is  $I$ . The same wire is then formed into the shape shown in Figure P30.67b, and the magnetic field is measured at point  $P_2$  when the current is again  $I$ . If the total length of wire is the same in each case, what is the ratio of  $B_1/B_2$ ?

Figure P30.67

68. Measurements of the magnetic field of a large tornado were made at the Geophysical Observatory in Tulsa, Oklahoma, in 1962. If the tornado's field was  $B = 15.0$  nT pointing north when the tornado was 9.00 km east of the observatory, what current was carried up or down the funnel of the tornado, modeled as a long straight wire?

69. A wire is formed into a square of edge length  $L$  (Fig. P30.69). Show that when the current in the loop is  $I$ , the magnetic field at point  $P$ , a distance  $x$  from the center of the square along its axis, is

$$B = \frac{\mu_0 I L^2}{2\pi(x^2 + L^2/4)\sqrt{x^2 + L^2/2}}$$

Figure P30.69

70. The force on a magnetic dipole  $\mu$  aligned with a nonuniform magnetic field in the  $x$  direction is given by  $F_x = |\mu| dB/dx$ . Suppose that two flat loops of wire each have radius  $R$  and carry current  $I$ . (a) If the loops are arranged coaxially and separated by variable distance  $x$ , which is great compared to  $R$ , show that the magnetic force between them varies as  $1/x^4$ . (b) Evaluate the magnitude of this force if  $I = 10.0$  A,  $R = 0.500$  cm, and  $x = 5.00$  cm.
71. A wire carrying a current  $I$  is bent into the shape of an exponential spiral  $r = e^\theta$  from  $\theta = 0$  to  $\theta = 2\pi$ , as in Figure P30.71. To complete a loop, the ends of the spiral are connected by a straight wire along the  $x$  axis. Find the magnitude and direction of  $\mathbf{B}$  at the origin. *Hints:* Use the Biot–Savart law. The angle  $\beta$  between a radial line and its tangent line at any point on the curve  $r = f(\theta)$  is related to the function in the following way:

$$\tan \beta = \frac{r}{dr/d\theta}$$

Figure P30.71

Thus, in this case  $r = e^\theta$ ,  $\tan \beta = 1$ , and  $\beta = \pi/4$ . Therefore, the angle between  $ds$  and  $\hat{\mathbf{r}}$  is  $\pi - \beta = 3\pi/4$ . Also,

$$ds = \frac{dr}{\sin \pi/4} = \sqrt{2} dr$$

72. Table P30.72 contains data taken for a ferromagnetic material. (a) Construct a magnetization curve from the data. Remember that  $\mathbf{B} = \mathbf{B}_0 + \mu_0 \mathbf{M}$ . (b) Determine the ratio  $B/B_0$  for each pair of values of  $B$  and  $B_0$ , and construct a graph of  $B/B_0$  versus  $B_0$ . (The fraction  $B/B_0$  is called the relative permeability and is a measure of the induced magnetic field.)

TABLE P30.72

$B$ (T)	$B_0$ (T)
0.2	$4.8 \times 10^{-5}$
0.4	$7.0 \times 10^{-5}$
0.6	$8.8 \times 10^{-5}$
0.8	$1.2 \times 10^{-4}$
1.0	$1.8 \times 10^{-4}$
1.2	$3.1 \times 10^{-4}$
1.4	$8.7 \times 10^{-4}$
1.6	$3.4 \times 10^{-3}$
1.8	$1.2 \times 10^{-1}$

73. **Review Problem.** A sphere of radius  $R$  has a constant volume charge density  $\rho$ . Determine the magnetic field at the center of the sphere when it rotates as a rigid body with angular velocity  $\omega$  about an axis through its center (Fig. P30.73).

Figure P30.73 Problems 73 and 74.

74. **Review Problem.** A sphere of radius  $R$  has a constant volume charge density  $\rho$ . Determine the magnetic di-

pole moment of the sphere when it rotates as a rigid body with angular velocity  $\omega$  about an axis through its center (see Fig. P30.73).

75. A long, cylindrical conductor of radius  $a$  has two cylindrical cavities of diameter  $a$  through its entire length, as shown in cross-section in Figure P30.75. A current  $I$  is directed out of the page and is uniform through a cross section of the conductor. Find the magnitude and direction of the magnetic field in terms of  $\mu_0$ ,  $I$ ,  $r$ , and  $a$  (a) at point  $P_1$  and (b) at point  $P_2$ .

Figure P30.75

## ANSWERS TO QUICK QUIZZES

- 30.1 (c)  $F_1 = F_2$  because of Newton's third law. Another way to arrive at this answer is to realize that Equation 30.11 gives the same result whether the multiplication of currents is  $(2 \text{ A})(6 \text{ A})$  or  $(6 \text{ A})(2 \text{ A})$ .
- 30.2 Closer together; the coils act like wires carrying parallel currents and hence attract one another.
- 30.3  $b$ ,  $d$ ,  $a$ ,  $c$ . Equation 30.13 indicates that the value of the line integral depends only on the net current through each closed path. Path  $b$  encloses 1 A, path  $d$  encloses 3 A, path  $a$  encloses 4 A, and path  $c$  encloses 6 A.
- 30.4  $b$ , then  $a = c = d$ . Paths  $a$ ,  $c$ , and  $d$  all give the same nonzero value  $\mu_0 I$  because the size and shape of the paths do not matter. Path  $b$  does not enclose the current, and hence its line integral is zero.
- 30.5 Net force, yes; net torque, no. The forces on the top and bottom of the loop cancel because they are equal in magnitude but opposite in direction. The current in the left side of the loop is parallel to  $I_1$ , and hence the force  $F_L$  exerted by  $I_1$  on this side is attractive. The current in the right side of the loop is antiparallel to  $I_1$ , and hence the force  $F_R$  exerted by  $I_1$  on this side of the loop is repulsive. Because the left side is closer to wire 1,  $F_L > F_R$  and a net force is directed toward wire 1. Because the forces on all four sides of the loop lie in the plane of the loop, there is no net torque.
- 30.6 Zero; no charges flow into a fully charged capacitor, so no change occurs in the amount of charge on the plates, and the electric field between the plates is constant. It is only when the electric field is changing that a displacement current exists.
- 30.7 (a) Increases slightly; (b) decreases slightly; (c) increases greatly. Equations 30.33 and 30.34 indicate that, when each metal is in place, the total field is  $\mathbf{B} = \mu_0(1 + \chi)\mathbf{H}$ . Table 30.2 indicates that  $\mu_0(1 + \chi)\mathbf{H}$  is slightly greater than  $\mu_0\mathbf{H}$  for aluminum and slightly less for copper. For iron, the field can be made thousands of times stronger, as we saw in Example 30.10.
- 30.8 One whose loop looks like Figure 30.31a because the remanent magnetization at the point corresponding to point  $b$  in Figure 30.30 is greater.
- 30.9 West to east. The lines of the Earth's magnetic field enter the planet in Hudson Bay and emerge from Antarctica; thus, the field lines resulting from the current would have to go in the opposite direction. Compare Figure 30.6a with Figure 30.35.

## Chapter Outline

- 31.1** Faraday's Law of Induction
- 31.2** Motional emf
- 31.3** Lenz's Law
- 31.4** Induced emf and Electric Fields
- 31.5** (Optional) Generators and Motors
- 31.6** (Optional) Eddy Currents
- 31.7** Maxwell's Wonderful Equations

The focus of our studies in electricity and magnetism so far has been the electric fields produced by stationary charges and the magnetic fields produced by moving charges. This chapter deals with electric fields produced by changing magnetic fields.

Experiments conducted by Michael Faraday in England in 1831 and independently by Joseph Henry in the United States that same year showed that an emf can be induced in a circuit by a changing magnetic field. As we shall see, an emf (and therefore a current as well) can be induced in many ways—for instance, by moving a closed loop of wire into a region where a magnetic field exists. The results of these experiments led to a very basic and important law of electromagnetism known as *Faraday's law of induction*. This law states that the magnitude of the emf induced in a circuit equals the time rate of change of the magnetic flux through the circuit.

With the treatment of Faraday's law, we complete our introduction to the fundamental laws of electromagnetism. These laws can be summarized in a set of four equations called *Maxwell's equations*. Together with the *Lorentz force law*, which we discuss briefly, they represent a complete theory for describing the interaction of charged objects. Maxwell's equations relate electric and magnetic fields to each other and to their ultimate source, namely, electric charges.

### 31.1 FARADAY'S LAW OF INDUCTION

 To see how an emf can be induced by a changing magnetic field, let us consider a loop of wire connected to a galvanometer, as illustrated in Figure 31.1. When a magnet is moved toward the loop, the galvanometer needle deflects in one direction, arbitrarily shown to the right in Figure 31.1a. When the magnet is moved away from the loop, the needle deflects in the opposite direction, as shown in Figure 31.1c. When the magnet is held stationary relative to the loop (Fig. 31.1b), no deflection is observed. Finally, if the magnet is held stationary and the loop is moved either toward or away from it, the needle deflects. From these observations, we conclude that the loop “knows” that the magnet is moving relative to it because it experiences a change in magnetic field. Thus, it seems that a relationship exists between current and changing magnetic field.

These results are quite remarkable in view of the fact that **a current is set up even though no batteries are present in the circuit!** We call such a current an *induced current* and say that it is produced by an *induced emf*.

Now let us describe an experiment conducted by Faraday<sup>1</sup> and illustrated in Figure 31.2. A primary coil is connected to a switch and a battery. The coil is wrapped around a ring, and a current in the coil produces a magnetic field when the switch is closed. A secondary coil also is wrapped around the ring and is connected to a galvanometer. No battery is present in the secondary circuit, and the secondary coil is not connected to the primary coil. Any current detected in the secondary circuit must be induced by some external agent.

Initially, you might guess that no current is ever detected in the secondary circuit. However, something quite amazing happens when the switch in the primary

A demonstration of electromagnetic induction. A changing potential difference is applied to the lower coil. An emf is induced in the upper coil as indicated by the illuminated lamp. What happens to the lamp's intensity as the upper coil is moved over the vertical tube? (Courtesy of Central Scientific Company)

<sup>1</sup> A physicist named J. D. Colladon was the first to perform the moving-magnet experiment. To minimize the effect of the changing magnetic field on his galvanometer, he placed the meter in an adjacent room. Thus, as he moved the magnet in the loop, he could not see the meter needle deflecting. By the time he returned next door to read the galvanometer, the needle was back to zero because he had stopped moving the magnet. Unfortunately for Colladon, there must be relative motion between the loop and the magnet for an induced emf and a corresponding induced current to be observed. Thus, physics students learn Faraday's law of induction rather than “Colladon's law of induction.”

**Figure 31.1** (a) When a magnet is moved toward a loop of wire connected to a galvanometer, the galvanometer deflects as shown, indicating that a current is induced in the loop. (b) When the magnet is held stationary, there is no induced current in the loop, even when the magnet is inside the loop. (c) When the magnet is moved away from the loop, the galvanometer deflects in the opposite direction, indicating that the induced current is opposite that shown in part (a). Changing the direction of the magnet's motion changes the direction of the current induced by that motion.

circuit is either suddenly closed or suddenly opened. At the instant the switch is closed, the galvanometer needle deflects in one direction and then returns to zero. At the instant the switch is opened, the needle deflects in the opposite direction and again returns to zero. Finally, the galvanometer reads zero when there is either a steady current or no current in the primary circuit. The key to under-

**Figure 31.2** Faraday's experiment. When the switch in the primary circuit is closed, the galvanometer in the secondary circuit deflects momentarily. The emf induced in the secondary circuit is caused by the changing magnetic field through the secondary coil.

**Michael Faraday (1791–1867)**

Faraday, a British physicist and chemist, is often regarded as the greatest experimental scientist of the 1800s. His many contributions to the study of electricity include the invention of the electric motor, electric generator, and transformer, as well as the discovery of electromagnetic induction and the laws of electrolysis. Greatly influenced by religion, he refused to work on the development of poison gas for the British military. (By kind permission of the President and Council of the Royal Society)

standing what happens in this experiment is to first note that when the switch is closed, the current in the primary circuit produces a magnetic field in the region of the circuit, and it is this magnetic field that penetrates the secondary circuit. Furthermore, when the switch is closed, the magnetic field produced by the current in the primary circuit changes from zero to some value over some finite time, and it is this changing field that induces a current in the secondary circuit.

As a result of these observations, Faraday concluded that **an electric current can be induced in a circuit (the secondary circuit in our setup) by a changing magnetic field.** The induced current exists for only a short time while the magnetic field through the secondary coil is changing. Once the magnetic field reaches a steady value, the current in the secondary coil disappears. In effect, the secondary circuit behaves as though a source of emf were connected to it for a short time. It is customary to say that **an induced emf is produced in the secondary circuit by the changing magnetic field.**

The experiments shown in Figures 31.1 and 31.2 have one thing in common: In each case, an emf is induced in the circuit when the magnetic flux through the circuit changes with time. In general,

the emf induced in a circuit is directly proportional to the time rate of change of the magnetic flux through the circuit.

This statement, known as **Faraday's law of induction**, can be written

Faraday's law

$$\mathcal{E} = -\frac{d\Phi_B}{dt} \quad (31.1)$$

where  $\Phi_B = \int \mathbf{B} \cdot d\mathbf{A}$  is the magnetic flux through the circuit (see Section 30.5).

If the circuit is a coil consisting of  $N$  loops all of the same area and if  $\Phi_B$  is the flux through one loop, an emf is induced in every loop; thus, the total induced emf in the coil is given by the expression

$$\mathcal{E} = -N \frac{d\Phi_B}{dt} \quad (31.2)$$

The negative sign in Equations 31.1 and 31.2 is of important physical significance, which we shall discuss in Section 31.3.

Suppose that a loop enclosing an area  $A$  lies in a uniform magnetic field  $\mathbf{B}$ , as shown in Figure 31.3. The magnetic flux through the loop is equal to  $BA \cos \theta$ ;

**Figure 31.3** A conducting loop that encloses an area  $A$  in the presence of a uniform magnetic field  $\mathbf{B}$ . The angle between  $\mathbf{B}$  and the normal to the loop is  $\theta$ .

hence, the induced emf can be expressed as

$$\mathcal{E} = -\frac{d}{dt}(BA \cos \theta) \quad (31.3)$$

From this expression, we see that an emf can be induced in the circuit in several ways:

- The magnitude of  $\mathbf{B}$  can change with time.
- The area enclosed by the loop can change with time.
- The angle  $\theta$  between  $\mathbf{B}$  and the normal to the loop can change with time.
- Any combination of the above can occur.

### Quick Quiz 31.1

Equation 31.3 can be used to calculate the emf induced when the north pole of a magnet is moved toward a loop of wire, along the axis perpendicular to the plane of the loop passing through its center. What changes are necessary in the equation when the south pole is moved toward the loop?

### Some Applications of Faraday's Law

The ground fault interrupter (GFI) is an interesting safety device that protects users of electrical appliances against electric shock. Its operation makes use of Faraday's law. In the GFI shown in Figure 31.4, wire 1 leads from the wall outlet to the appliance to be protected, and wire 2 leads from the appliance back to the wall outlet. An iron ring surrounds the two wires, and a sensing coil is wrapped around part of the ring. Because the currents in the wires are in opposite directions, the net magnetic flux through the sensing coil due to the currents is zero. However, if the return current in wire 2 changes, the net magnetic flux through the sensing coil is no longer zero. (This can happen, for example, if the appliance gets wet, enabling current to leak to ground.) Because household current is alternating (meaning that its direction keeps reversing), the magnetic flux through the sensing coil changes with time, inducing an emf in the coil. This induced emf is used to trigger a circuit breaker, which stops the current before it is able to reach a harmful level.

Another interesting application of Faraday's law is the production of sound in an electric guitar (Fig. 31.5). The coil in this case, called the *pickup coil*, is placed near the vibrating guitar string, which is made of a metal that can be magnetized. A permanent magnet inside the coil magnetizes the portion of the string nearest

**Figure 31.4** Essential components of a ground fault interrupter.

### QuickLab

A cassette tape is made up of tiny particles of metal oxide attached to a long plastic strip. A current in a small conducting loop magnetizes the particles in a pattern related to the music being recorded. During playback, the tape is moved past a second small loop (inside the playback head) and induces a current that is then amplified. Pull a strip of tape out of a cassette (one that you don't mind recording over) and see if it is attracted or repelled by a refrigerator magnet. If you don't have a cassette, try this with an old floppy disk you are ready to trash.

This electric range cooks food on the basis of the principle of induction. An oscillating current is passed through a coil placed below the cooking surface, which is made of a special glass. The current produces an oscillating magnetic field, which induces a current in the cooking utensil. Because the cooking utensil has some electrical resistance, the electrical energy associated with the induced current is transformed to internal energy, causing the utensil and its contents to become hot. (Courtesy of Corning, Inc.)

**Figure 31.5** (a) In an electric guitar, a vibrating string induces an emf in a pickup coil. (b) The circles beneath the metallic strings of this electric guitar detect the notes being played and send this information through an amplifier and into speakers. (A switch on the guitar allows the musician to select which set of six is used.) How does a guitar “pickup” sense what music is being played? (b, Charles D. Winters)

the coil. When the string vibrates at some frequency, its magnetized segment produces a changing magnetic flux through the coil. The changing flux induces an emf in the coil that is fed to an amplifier. The output of the amplifier is sent to the loudspeakers, which produce the sound waves we hear.

### EXAMPLE 31.1 One Way to Induce an emf in a Coil

A coil consists of 200 turns of wire having a total resistance of  $2.0\ \Omega$ . Each turn is a square of side 18 cm, and a uniform magnetic field directed perpendicular to the plane of the coil is turned on. If the field changes linearly from 0 to 0.50 T in 0.80 s, what is the magnitude of the induced emf in the coil while the field is changing?

**Solution** The area of one turn of the coil is  $(0.18\ \text{m})^2 = 0.0324\ \text{m}^2$ . The magnetic flux through the coil at  $t = 0$  is zero because  $B = 0$  at that time. At  $t = 0.80\ \text{s}$ , the magnetic flux through one turn is  $\Phi_B = BA = (0.50\ \text{T})(0.0324\ \text{m}^2) = 0.0162\ \text{T}\cdot\text{m}^2$ . Therefore, the magnitude of the induced emf

is, from Equation 31.2,

$$|\mathcal{E}| = \frac{N\Delta\Phi_B}{\Delta t} = \frac{200(0.0162\ \text{T}\cdot\text{m}^2 - 0\ \text{T}\cdot\text{m}^2)}{0.80\ \text{s}} = 4.1\ \text{T}\cdot\text{m}^2/\text{s} = 4.1\ \text{V}$$

You should be able to show that  $1\ \text{T}\cdot\text{m}^2/\text{s} = 1\ \text{V}$ .

**Exercise** What is the magnitude of the induced current in the coil while the field is changing?

**Answer** 2.0 A.

### EXAMPLE 31.2 An Exponentially Decaying B Field

A loop of wire enclosing an area  $A$  is placed in a region where the magnetic field is perpendicular to the plane of the loop. The magnitude of  $\mathbf{B}$  varies in time according to the expression  $B = B_{\text{max}}e^{-at}$ , where  $a$  is some constant. That is, at  $t = 0$  the field is  $B_{\text{max}}$ , and for  $t > 0$ , the field decreases exponen-

tially (Fig. 31.6). Find the induced emf in the loop as a function of time.

**Solution** Because  $\mathbf{B}$  is perpendicular to the plane of the loop, the magnetic flux through the loop at time  $t > 0$  is

**Figure 31.6** Exponential decrease in the magnitude of the magnetic field with time. The induced emf and induced current vary with time in the same way.

$$\Phi_B = BA \cos 0 = AB_{\max} e^{-at}$$

Because  $AB_{\max}$  and  $a$  are constants, the induced emf calculated from Equation 31.1 is

$$\mathcal{E} = -\frac{d\Phi_B}{dt} = -AB_{\max} \frac{d}{dt} e^{-at} = aAB_{\max} e^{-at}$$

This expression indicates that the induced emf decays exponentially in time. Note that the maximum emf occurs at  $t = 0$ , where  $\mathcal{E}_{\max} = aAB_{\max}$ . The plot of  $\mathcal{E}$  versus  $t$  is similar to the  $B$ -versus- $t$  curve shown in Figure 31.6.

### CONCEPTUAL EXAMPLE 31.3 What Is Connected to What?

Two bulbs are connected to opposite sides of a loop of wire, as shown in Figure 31.7. A decreasing magnetic field (confined to the circular area shown in the figure) induces an emf in the loop that causes the two bulbs to light. What happens to the brightness of the bulbs when the switch is closed?

**Solution** Bulb 1 glows brighter, and bulb 2 goes out. Once the switch is closed, bulb 1 is in the large loop consisting of the wire to which it is attached and the wire connected to the switch. Because the changing magnetic flux is completely enclosed within this loop, a current exists in bulb 1. Bulb 1 now glows brighter than before the switch was closed because it is

now the only resistance in the loop. As a result, the current in bulb 1 is greater than when bulb 2 was also in the loop.

Once the switch is closed, bulb 2 is in the loop consisting of the wires attached to it and those connected to the switch. There is no changing magnetic flux through this loop and hence no induced emf.

**Exercise** What would happen if the switch were in a wire located to the left of bulb 1?

**Answer** Bulb 1 would go out, and bulb 2 would glow brighter.

**Figure 31.7**

## 31.2 MOTIONAL EMF

In Examples 31.1 and 31.2, we considered cases in which an emf is induced in a stationary circuit placed in a magnetic field when the field changes with time. In this section we describe what is called **motional emf**, which is the emf induced in a conductor moving through a constant magnetic field.

The straight conductor of length  $\ell$  shown in Figure 31.8 is moving through a uniform magnetic field directed into the page. For simplicity, we assume that the conductor is moving in a direction perpendicular to the field with constant veloc-

**Figure 31.8** A straight electrical conductor of length  $\ell$  moving with a velocity  $\mathbf{v}$  through a uniform magnetic field  $\mathbf{B}$  directed perpendicular to  $\mathbf{v}$ . A potential difference  $\Delta V = B\ell v$  is maintained between the ends of the conductor.

ity under the influence of some external agent. The electrons in the conductor experience a force  $\mathbf{F}_B = q\mathbf{v} \times \mathbf{B}$  that is directed along the length  $\ell$ , perpendicular to both  $\mathbf{v}$  and  $\mathbf{B}$  (Eq. 29.1). Under the influence of this force, the electrons move to the lower end of the conductor and accumulate there, leaving a net positive charge at the upper end. As a result of this charge separation, an electric field is produced inside the conductor. The charges accumulate at both ends until the downward magnetic force  $qvB$  is balanced by the upward electric force  $qE$ . At this point, electrons stop moving. The condition for equilibrium requires that

$$qE = qvB \quad \text{or} \quad E = vB$$

The electric field produced in the conductor (once the electrons stop moving and  $E$  is constant) is related to the potential difference across the ends of the conductor according to the relationship  $\Delta V = E\ell$  (Eq. 25.6). Thus,

$$\Delta V = E\ell = B\ell v \quad (31.4)$$

where the upper end is at a higher electric potential than the lower end. Thus, **a potential difference is maintained between the ends of the conductor as long as the conductor continues to move through the uniform magnetic field.** If the direction of the motion is reversed, the polarity of the potential difference also is reversed.

A more interesting situation occurs when the moving conductor is part of a closed conducting path. This situation is particularly useful for illustrating how a changing magnetic flux causes an induced current in a closed circuit. Consider a circuit consisting of a conducting bar of length  $\ell$  sliding along two fixed parallel conducting rails, as shown in Figure 31.9a.

For simplicity, we assume that the bar has zero resistance and that the stationary part of the circuit has a resistance  $R$ . A uniform and constant magnetic field  $\mathbf{B}$  is applied perpendicular to the plane of the circuit. As the bar is pulled to the right with a velocity  $\mathbf{v}$ , under the influence of an applied force  $\mathbf{F}_{\text{app}}$ , free charges in the bar experience a magnetic force directed along the length of the bar. This force sets up an induced current because the charges are free to move in the closed conducting path. In this case, the rate of change of magnetic flux through the loop and the corresponding induced motional emf across the moving bar are proportional to the change in area of the loop. As we shall see, if the bar is pulled to the right with a constant velocity, the work done by the applied force appears as internal energy in the resistor  $R$  (see Section 27.6).

Because the area enclosed by the circuit at any instant is  $\ell x$ , where  $x$  is the width of the circuit at any instant, the magnetic flux through that area is

$$\Phi_B = B\ell x$$

Using Faraday's law, and noting that  $x$  changes with time at a rate  $dx/dt = v$ , we find that the induced motional emf is

$$\mathcal{E} = -\frac{d\Phi_B}{dt} = -\frac{d}{dt}(B\ell x) = -B\ell \frac{dx}{dt}$$

Motional emf

$$\mathcal{E} = -B\ell v \quad (31.5)$$

Because the resistance of the circuit is  $R$ , the magnitude of the induced current is

$$I = \frac{|\mathcal{E}|}{R} = \frac{B\ell v}{R} \quad (31.6)$$

The equivalent circuit diagram for this example is shown in Figure 31.9b.

Let us examine the system using energy considerations. Because no battery is in the circuit, we might wonder about the origin of the induced current and the electrical energy in the system. We can understand the source of this current and energy by noting that the applied force does work on the conducting bar, thereby moving charges through a magnetic field. Their movement through the field causes the charges to move along the bar with some average drift velocity, and hence a current is established. Because energy must be conserved, the work done by the applied force on the bar during some time interval must equal the electrical energy supplied by the induced emf during that same interval. Furthermore, if the bar moves with constant speed, the work done on it must equal the energy delivered to the resistor during this time interval.

As it moves through the uniform magnetic field  $\mathbf{B}$ , the bar experiences a magnetic force  $\mathbf{F}_B$  of magnitude  $I\ell B$  (see Section 29.2). The direction of this force is opposite the motion of the bar, to the left in Figure 31.9a. Because the bar moves with constant velocity, the applied force must be equal in magnitude and opposite in direction to the magnetic force, or to the right in Figure 31.9a. (If  $\mathbf{F}_B$  acted in the direction of motion, it would cause the bar to accelerate. Such a situation would violate the principle of conservation of energy.) Using Equation 31.6 and the fact that  $F_{\text{app}} = I\ell B$ , we find that the power delivered by the applied force is

$$\mathcal{P} = F_{\text{app}}v = (I\ell B)v = \frac{B^2\ell^2v^2}{R} = \frac{\mathcal{E}^2}{R} \quad (31.7)$$

From Equation 27.23, we see that this power is equal to the rate at which energy is delivered to the resistor  $I^2R$ , as we would expect. It is also equal to the power  $I\mathcal{E}$  supplied by the motional emf. This example is a clear demonstration of the conversion of mechanical energy first to electrical energy and finally to internal energy in the resistor.

### Quick Quiz 31.2

As an airplane flies from Los Angeles to Seattle, it passes through the Earth's magnetic field. As a result, a motional emf is developed between the wingtips. Which wingtip is positively charged?

**Figure 31.9** (a) A conducting bar sliding with a velocity  $\mathbf{v}$  along two conducting rails under the action of an applied force  $\mathbf{F}_{\text{app}}$ . The magnetic force  $\mathbf{F}_B$  opposes the motion, and a counterclockwise current  $I$  is induced in the loop. (b) The equivalent circuit diagram for the setup shown in part (a).

### EXAMPLE 31.4 Motional emf Induced in a Rotating Bar

A conducting bar of length  $\ell$  rotates with a constant angular speed  $\omega$  about a pivot at one end. A uniform magnetic field  $\mathbf{B}$  is directed perpendicular to the plane of rotation, as shown in Figure 31.10. Find the motional emf induced between the ends of the bar.

**Solution** Consider a segment of the bar of length  $dr$  having a velocity  $\mathbf{v}$ . According to Equation 31.5, the magnitude of the emf induced in this segment is

$$d\mathcal{E} = Bv dr$$

Because every segment of the bar is moving perpendicular to  $\mathbf{B}$ , an emf  $d\mathcal{E}$  of the same form is generated across each. Summing the emfs induced across all segments, which are in series, gives the total emf between the ends of

**Figure 31.10** A conducting bar rotating around a pivot at one end in a uniform magnetic field that is perpendicular to the plane of rotation. A motional emf is induced across the ends of the bar.

the bar:

$$\mathcal{E} = \int Bv \, dr$$

To integrate this expression, we must note that the linear speed of an element is related to the angular speed  $\omega$

through the relationship  $v = r\omega$ . Therefore, because  $B$  and  $\omega$  are constants, we find that

$$\mathcal{E} = B \int_0^\ell v \, dr = B\omega \int_0^\ell r \, dr = \frac{1}{2}B\omega\ell^2$$

### EXAMPLE 31.5 Magnetic Force Acting on a Sliding Bar

The conducting bar illustrated in Figure 31.11, of mass  $m$  and length  $\ell$ , moves on two frictionless parallel rails in the presence of a uniform magnetic field directed into the page. The bar is given an initial velocity  $\mathbf{v}_i$  to the right and is released at  $t = 0$ . Find the velocity of the bar as a function of time.

**Solution** The induced current is counterclockwise, and the magnetic force is  $F_B = -I\ell B$ , where the negative sign denotes that the force is to the left and retards the motion. This is the only horizontal force acting on the bar, and hence Newton's second law applied to motion in the horizontal direction gives

$$F_x = ma = m \frac{dv}{dt} = -I\ell B$$

From Equation 31.6, we know that  $I = B\ell v/R$ , and so we can write this expression as

$$m \frac{dv}{dt} = -\frac{B^2\ell^2}{R} v$$

$$\frac{dv}{v} = -\left(\frac{B^2\ell^2}{mR}\right) dt$$

Integrating this equation using the initial condition that  $v = v_i$  at  $t = 0$ , we find that

$$\int_{v_i}^v \frac{dv}{v} = -\frac{B^2\ell^2}{mR} \int_0^t dt$$

$$\ln\left(\frac{v}{v_i}\right) = -\left(\frac{B^2\ell^2}{mR}\right)t = -\frac{t}{\tau}$$

where the constant  $\tau = mR/B^2\ell^2$ . From this result, we see

that the velocity can be expressed in the exponential form

$$v = v_i e^{-t/\tau}$$

This expression indicates that the velocity of the bar decreases exponentially with time under the action of the magnetic retarding force.

**Exercise** Find expressions for the induced current and the magnitude of the induced emf as functions of time for the bar in this example.

**Answer**  $I = \frac{B\ell v_i}{R} e^{-t/\tau}$ ;  $\mathcal{E} = B\ell v_i e^{-t/\tau}$ . (They both decrease exponentially with time.)

**Figure 31.11** A conducting bar of length  $\ell$  sliding on two fixed conducting rails is given an initial velocity  $\mathbf{v}_i$  to the right.

## 31.3 LENZ'S LAW

 Faraday's law (Eq. 31.1) indicates that the induced emf and the change in flux have opposite algebraic signs. This has a very real physical interpretation that has come to be known as **Lenz's law**<sup>2</sup>:

<sup>2</sup> Developed by the German physicist Heinrich Lenz (1804–1865).

The polarity of the induced emf is such that it tends to produce a current that creates a magnetic flux to oppose the change in magnetic flux through the area enclosed by the current loop.

That is, the induced current tends to keep the original magnetic flux through the circuit from changing. As we shall see, this law is a consequence of the law of conservation of energy.

To understand Lenz's law, let us return to the example of a bar moving to the right on two parallel rails in the presence of a uniform magnetic field that we shall refer to as the *external* magnetic field (Fig. 31.12a). As the bar moves to the right, the magnetic flux through the area enclosed by the circuit increases with time because the area increases. Lenz's law states that the induced current must be directed so that the magnetic flux it produces opposes the change in the external magnetic flux. Because the external magnetic flux is increasing into the page, the induced current, if it is to oppose this change, must produce a flux directed out of the page. Hence, the induced current must be directed counterclockwise when the bar moves to the right. (Use the right-hand rule to verify this direction.) If the bar is moving to the left, as shown in Figure 31.12b, the external magnetic flux through the area enclosed by the loop decreases with time. Because the flux is directed into the page, the direction of the induced current must be clockwise if it is to produce a flux that also is directed into the page. In either case, the induced current tends to maintain the original flux through the area enclosed by the current loop.

Let us examine this situation from the viewpoint of energy considerations. Suppose that the bar is given a slight push to the right. In the preceding analysis, we found that this motion sets up a counterclockwise current in the loop. Let us see what happens if we assume that the current is clockwise, such that the direction of the magnetic force exerted on the bar is to the right. This force would accelerate the rod and increase its velocity. This, in turn, would cause the area enclosed by the loop to increase more rapidly; this would result in an increase in the induced current, which would cause an increase in the force, which would produce an increase in the current, and so on. In effect, the system would acquire energy with no additional input of energy. This is clearly inconsistent with all experience and with the law of conservation of energy. Thus, we are forced to conclude that the current must be counterclockwise.

Let us consider another situation, one in which a bar magnet moves toward a stationary metal loop, as shown in Figure 31.13a. As the magnet moves to the right toward the loop, the external magnetic flux through the loop increases with time. To counteract this increase in flux to the right, the induced current produces a flux to the left, as illustrated in Figure 31.13b; hence, the induced current is in the direction shown. Note that the magnetic field lines associated with the induced current oppose the motion of the magnet. Knowing that like magnetic poles repel each other, we conclude that the left face of the current loop is in essence a north pole and that the right face is a south pole.

If the magnet moves to the left, as shown in Figure 31.13c, its flux through the area enclosed by the loop, which is directed to the right, decreases in time. Now the induced current in the loop is in the direction shown in Figure 31.13d because this current direction produces a magnetic flux in the same direction as the external flux. In this case, the left face of the loop is a south pole and the right face is a north pole.

**Figure 31.12** (a) As the conducting bar slides on the two fixed conducting rails, the magnetic flux through the area enclosed by the loop increases in time. By Lenz's law, the induced current must be counterclockwise so as to produce a counteracting magnetic flux directed out of the page. (b) When the bar moves to the left, the induced current must be clockwise. Why?

### QuickLab

This experiment takes steady hands, a dime, and a strong magnet. After verifying that a dime is not attracted to the magnet, carefully balance the coin on its edge. (This won't work with other coins because they require too much force to topple them.) Hold one pole of the magnet within a millimeter of the face of the dime, but don't bump it. Now very rapidly pull the magnet straight back away from the coin. Which way does the dime tip? Does the coin fall the same way most of the time? Explain what is going on in terms of Lenz's law. You may want to refer to Figure 31.13.

**Figure 31.13** (a) When the magnet is moved toward the stationary conducting loop, a current is induced in the direction shown. (b) This induced current produces its own magnetic flux that is directed to the left and so counteracts the increasing external flux to the right. (c) When the magnet is moved away from the stationary conducting loop, a current is induced in the direction shown. (d) This induced current produces a magnetic flux that is directed to the right and so counteracts the decreasing external flux to the right.

### Quick Quiz 31.3

Figure 31.14 shows a magnet being moved in the vicinity of a solenoid connected to a galvanometer. The south pole of the magnet is the pole nearest the solenoid, and the gal-

**Figure 31.14** When a magnet is moved toward or away from a solenoid attached to a galvanometer, an electric current is induced, indicated by the momentary deflection of the galvanometer needle. (Richard Megna/Fundamental Photographs)

vanometer indicates a clockwise (viewed from above) current in the solenoid. Is the person inserting the magnet or pulling it out?

### CONCEPTUAL EXAMPLE 31.6 Application of Lenz's Law

A metal ring is placed near a solenoid, as shown in Figure 31.15a. Find the direction of the induced current in the ring (a) at the instant the switch in the circuit containing the solenoid is thrown closed, (b) after the switch has been closed for several seconds, and (c) at the instant the switch is thrown open.

**Solution** (a) At the instant the switch is thrown closed, the situation changes from one in which no magnetic flux passes through the ring to one in which flux passes through in the direction shown in Figure 31.15b. To counteract this change in the flux, the current induced in the ring must set up a magnetic field directed from left to right in Figure 31.15b. This requires a current directed as shown.

(b) After the switch has been closed for several seconds, no change in the magnetic flux through the loop occurs; hence, the induced current in the ring is zero.

(c) Opening the switch changes the situation from one in which magnetic flux passes through the ring to one in which there is no magnetic flux. The direction of the induced current is as shown in Figure 31.15c because current in this di-

rection produces a magnetic field that is directed right to left and so counteracts the decrease in the field produced by the solenoid.

Figure 31.15

### CONCEPTUAL EXAMPLE 31.7 A Loop Moving Through a Magnetic Field

A rectangular metallic loop of dimensions  $\ell$  and  $w$  and resistance  $R$  moves with constant speed  $v$  to the right, as shown in Figure 31.16a, passing through a uniform magnetic field  $\mathbf{B}$  directed into the page and extending a distance  $3w$  along the  $x$  axis. Defining  $x$  as the position of the right side of the loop along the  $x$  axis, plot as functions of  $x$  (a) the magnetic flux through the area enclosed by the loop, (b) the induced motional emf, and (c) the external applied force necessary to counter the magnetic force and keep  $v$  constant.

**Solution** (a) Figure 31.16b shows the flux through the area enclosed by the loop as a function  $x$ . Before the loop enters the field, the flux is zero. As the loop enters the field, the flux increases linearly with position until the left edge of the loop is just inside the field. Finally, the flux through the loop decreases linearly to zero as the loop leaves the field.

(b) Before the loop enters the field, no motional emf is induced in it because no field is present (Fig. 31.16c). As the right side of the loop enters the field, the magnetic flux directed into the page increases. Hence, according to Lenz's law, the induced current is counterclockwise because it must produce a magnetic field directed out of the page. The motional emf  $-B\ell v$  (from Eq. 31.5) arises from the mag-

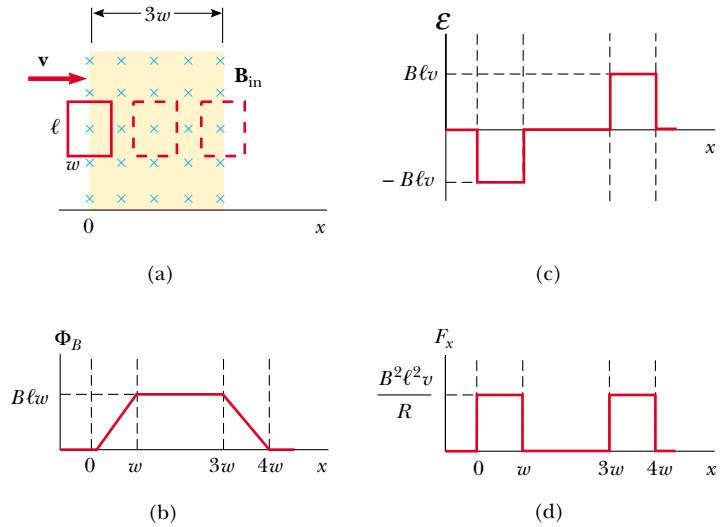

netic force experienced by charges in the right side of the loop. When the loop is entirely in the field, the change in magnetic flux is zero, and hence the motional emf vanishes. This happens because, once the left side of the loop enters the field, the motional emf induced in it cancels the motional emf present in the right side of the loop. As the right side of the loop leaves the field, the flux inward begins to decrease, a clockwise current is induced, and the induced emf is  $B\ell v$ . As soon as the left side leaves the field, the emf decreases to zero.

(c) The external force that must be applied to the loop to maintain this motion is plotted in Figure 31.16d. Before the loop enters the field, no magnetic force acts on it; hence, the applied force must be zero if  $v$  is constant. When the right side of the loop enters the field, the applied force necessary to maintain constant speed must be equal in magnitude and opposite in direction to the magnetic force exerted on that side:  $F_B = -I\ell B = -B^2\ell^2v/R$ . When the loop is entirely in the field, the flux through the loop is not changing with time. Hence, the net emf induced in the loop is zero, and the current also is zero. Therefore, no external force is needed to maintain the motion. Finally, as the right side leaves the field, the applied force must be equal in magnitude and opposite

in direction to the magnetic force acting on the left side of the loop.

From this analysis, we conclude that power is supplied only when the loop is either entering or leaving the field.

Furthermore, this example shows that the motional emf induced in the loop can be zero even when there is motion through the field! A motional emf is induced only when the magnetic flux through the loop *changes in time*.

**Figure 31.16** (a) A conducting rectangular loop of width  $w$  and length  $\ell$  moving with a velocity  $\mathbf{v}$  through a uniform magnetic field extending a distance  $3w$ . (b) Magnetic flux through the area enclosed by the loop as a function of loop position. (c) Induced emf as a function of loop position. (d) Applied force required for constant velocity as a function of loop position.

### 31.4 INDUCED EMF AND ELECTRIC FIELDS

**12.8** We have seen that a changing magnetic flux induces an emf and a current in a conducting loop. Therefore, we must conclude that **an electric field is created in the conductor as a result of the changing magnetic flux**. However, this induced electric field has two important properties that distinguish it from the electrostatic field produced by stationary charges: The induced field is nonconservative and can vary in time.

**Figure 31.17** A conducting loop of radius  $r$  in a uniform magnetic field perpendicular to the plane of the loop. If  $\mathbf{B}$  changes in time, an electric field is induced in a direction tangent to the circumference of the loop.

We can illustrate this point by considering a conducting loop of radius  $r$  situated in a uniform magnetic field that is perpendicular to the plane of the loop, as shown in Figure 31.17. If the magnetic field changes with time, then, according to Faraday's law (Eq. 31.1), an emf  $\mathcal{E} = -d\Phi_B/dt$  is induced in the loop. The induction of a current in the loop implies the presence of an induced electric field  $\mathbf{E}$ , which must be tangent to the loop because all points on the loop are equivalent. The work done in moving a test charge  $q$  once around the loop is equal to  $q\mathcal{E}$ . Because the electric force acting on the charge is  $q\mathbf{E}$ , the work done by this force in moving the charge once around the loop is  $qE(2\pi r)$ , where  $2\pi r$  is the circumference of the loop. These two expressions for the work must be equal; therefore, we see that

$$q\mathcal{E} = qE(2\pi r)$$

$$E = \frac{\mathcal{E}}{2\pi r}$$

Using this result, along with Equation 31.1 and the fact that  $\Phi_B = BA = \pi r^2 B$  for a

circular loop, we find that the induced electric field can be expressed as

$$E = -\frac{1}{2\pi r} \frac{d\Phi_B}{dt} = -\frac{r}{2} \frac{dB}{dt} \quad (31.8)$$

If the time variation of the magnetic field is specified, we can easily calculate the induced electric field from Equation 31.8. The negative sign indicates that the induced electric field opposes the change in the magnetic field.

The emf for any closed path can be expressed as the line integral of  $\mathbf{E} \cdot d\mathbf{s}$  over that path:  $\mathcal{E} = \oint \mathbf{E} \cdot d\mathbf{s}$ . In more general cases,  $E$  may not be constant, and the path may not be a circle. Hence, Faraday's law of induction,  $\mathcal{E} = -d\Phi_B/dt$ , can be written in the general form

$$\oint \mathbf{E} \cdot d\mathbf{s} = -\frac{d\Phi_B}{dt} \quad (31.9)$$

Faraday's law in general form

It is important to recognize that **the induced electric field  $\mathbf{E}$  in Equation 31.9 is a nonconservative field that is generated by a changing magnetic field.** The field  $\mathbf{E}$  that satisfies Equation 31.9 cannot possibly be an electrostatic field for the following reason: If the field were electrostatic, and hence conservative, the line integral of  $\mathbf{E} \cdot d\mathbf{s}$  over a closed loop would be zero; this would be in contradiction to Equation 31.9.

### EXAMPLE 31.8 Electric Field Induced by a Changing Magnetic Field in a Solenoid

A long solenoid of radius  $R$  has  $n$  turns of wire per unit length and carries a time-varying current that varies sinusoidally as  $I = I_{\max} \cos \omega t$ , where  $I_{\max}$  is the maximum current and  $\omega$  is the angular frequency of the alternating current source (Fig. 31.18). (a) Determine the magnitude of the induced electric field outside the solenoid, a distance  $r > R$  from its long central axis.

**Solution** First let us consider an external point and take the path for our line integral to be a circle of radius  $r$  centered on the solenoid, as illustrated in Figure 31.18. By sym-

**Figure 31.18** A long solenoid carrying a time-varying current given by  $I = I_0 \cos \omega t$ . An electric field is induced both inside and outside the solenoid.

metry we see that the magnitude of  $\mathbf{E}$  is constant on this path and that  $\mathbf{E}$  is tangent to it. The magnetic flux through the area enclosed by this path is  $BA = B\pi R^2$ ; hence, Equation 31.9 gives

$$\begin{aligned} \oint \mathbf{E} \cdot d\mathbf{s} &= -\frac{d}{dt} (B\pi R^2) = -\pi R^2 \frac{dB}{dt} \\ (1) \quad \oint \mathbf{E} \cdot d\mathbf{s} &= E(2\pi r) = -\pi R^2 \frac{dB}{dt} \end{aligned}$$

The magnetic field inside a long solenoid is given by Equation 30.17,  $B = \mu_0 nI$ . When we substitute  $I = I_{\max} \cos \omega t$  into this equation and then substitute the result into Equation (1), we find that

$$E(2\pi r) = -\pi R^2 \mu_0 n I_{\max} \frac{d}{dt} (\cos \omega t) = \pi R^2 \mu_0 n I_{\max} \omega \sin \omega t$$

$$(2) \quad E = \frac{\mu_0 n I_{\max} \omega R^2}{2r} \sin \omega t \quad (\text{for } r > R)$$

Hence, the electric field varies sinusoidally with time and its amplitude falls off as  $1/r$  outside the solenoid.

(b) What is the magnitude of the induced electric field inside the solenoid, a distance  $r$  from its axis?

**Solution** For an interior point ( $r < R$ ), the flux threading an integration loop is given by  $B\pi r^2$ . Using the same proce-

As in part (a), we find that

$$E(2\pi r) = -\pi r^2 \frac{dB}{dt} = \pi r^2 \mu_0 n I_{\max} \omega \sin \omega t$$

$$(3) \quad E = \frac{\mu_0 n I_{\max} \omega}{2} r \sin \omega t \quad (\text{for } r < R)$$

This shows that the amplitude of the electric field induced inside the solenoid by the changing magnetic flux through the solenoid increases linearly with  $r$  and varies sinusoidally with time.

**Exercise** Show that Equations (2) and (3) for the exterior and interior regions of the solenoid match at the boundary,  $r = R$ .

**Exercise** Would the electric field be different if the solenoid had an iron core?

**Answer** Yes, it could be much stronger because the maximum magnetic field (and thus the change in flux) through the solenoid could be thousands of times larger. (See Example 30.10.)

### Optional Section

## 31.5 GENERATORS AND MOTORS

Turbines turn generators at a hydroelectric power plant. (Luis Casaneda/The Image Bank)

Electric generators are used to produce electrical energy. To understand how they work, let us consider the **alternating current (ac) generator**, a device that converts mechanical energy to electrical energy. In its simplest form, it consists of a loop of wire rotated by some external means in a magnetic field (Fig. 31.19a).

In commercial power plants, the energy required to rotate the loop can be derived from a variety of sources. For example, in a hydroelectric plant, falling water directed against the blades of a turbine produces the rotary motion; in a coal-fired plant, the energy released by burning coal is used to convert water to steam, and this steam is directed against the turbine blades. As a loop rotates in a magnetic field, the magnetic flux through the area enclosed by the loop changes with time; this induces an emf and a current in the loop according to Faraday's law. The ends of the loop are connected to slip rings that rotate with the loop. Connections from these slip rings, which act as output terminals of the generator, to the external circuit are made by stationary brushes in contact with the slip rings.

**Figure 31.19** (a) Schematic diagram of an ac generator. An emf is induced in a loop that rotates in a magnetic field. (b) The alternating emf induced in the loop plotted as a function of time.

Suppose that, instead of a single turn, the loop has  $N$  turns (a more practical situation), all of the same area  $A$ , and rotates in a magnetic field with a constant angular speed  $\omega$ . If  $\theta$  is the angle between the magnetic field and the normal to the plane of the loop, as shown in Figure 31.20, then the magnetic flux through the loop at any time  $t$  is

$$\Phi_B = BA \cos \theta = BA \cos \omega t$$

where we have used the relationship  $\theta = \omega t$  between angular displacement and angular speed (see Eq. 10.3). (We have set the clock so that  $t = 0$  when  $\theta = 0$ .) Hence, the induced emf in the coil is

$$\mathcal{E} = -N \frac{d\Phi_B}{dt} = -NAB \frac{d}{dt} (\cos \omega t) = NAB\omega \sin \omega t \quad (31.10)$$

This result shows that the emf varies sinusoidally with time, as was plotted in Figure 31.19b. From Equation 31.10 we see that the maximum emf has the value

$$\mathcal{E}_{\max} = NAB\omega \quad (31.11)$$

which occurs when  $\omega t = 90^\circ$  or  $270^\circ$ . In other words,  $\mathcal{E} = \mathcal{E}_{\max}$  when the magnetic field is in the plane of the coil and the time rate of change of flux is a maximum. Furthermore, the emf is zero when  $\omega t = 0$  or  $180^\circ$ , that is, when  $\mathbf{B}$  is perpendicular to the plane of the coil and the time rate of change of flux is zero.

The frequency for commercial generators in the United States and Canada is 60 Hz, whereas in some European countries it is 50 Hz. (Recall that  $\omega = 2\pi f$ , where  $f$  is the frequency in hertz.)

**Figure 31.20** A loop enclosing an area  $A$  and containing  $N$  turns, rotating with constant angular speed  $\omega$  in a magnetic field. The emf induced in the loop varies sinusoidally in time.

### EXAMPLE 31.9 emf Induced in a Generator

An ac generator consists of 8 turns of wire, each of area  $A = 0.0900 \text{ m}^2$ , and the total resistance of the wire is  $12.0 \Omega$ . The loop rotates in a  $0.500\text{-T}$  magnetic field at a constant frequency of  $60.0 \text{ Hz}$ . (a) Find the maximum induced emf.

**Solution** First, we note that  $\omega = 2\pi f = 2\pi(60.0 \text{ Hz}) = 377 \text{ s}^{-1}$ . Thus, Equation 31.11 gives

$$\mathcal{E}_{\max} = NAB\omega = 8(0.0900 \text{ m}^2)(0.500 \text{ T})(377 \text{ s}^{-1}) = 136 \text{ V}$$

(b) What is the maximum induced current when the output terminals are connected to a low-resistance conductor?

**Solution** From Equation 27.8 and the results to part (a), we have

$$I_{\max} = \frac{\mathcal{E}_{\max}}{R} = \frac{136 \text{ V}}{12.0 \Omega} = 11.3 \text{ A}$$

**Exercise** Determine how the induced emf and induced current vary with time.

**Answer**  $\mathcal{E} = \mathcal{E}_{\max} \sin \omega t = (136 \text{ V}) \sin 377t$ ;  
 $I = I_{\max} \sin \omega t = (11.3 \text{ A}) \sin 377t$ .

The **direct current** (dc) **generator** is illustrated in Figure 31.21a. Such generators are used, for instance, in older cars to charge the storage batteries used. The components are essentially the same as those of the ac generator except that the contacts to the rotating loop are made using a split ring called a *commutator*.

In this configuration, the output voltage always has the same polarity and pulsates with time, as shown in Figure 31.21b. We can understand the reason for this by noting that the contacts to the split ring reverse their roles every half cycle. At the same time, the polarity of the induced emf reverses; hence, the polarity of the

**Figure 31.21** (a) Schematic diagram of a dc generator. (b) The magnitude of the emf varies in time but the polarity never changes.

split ring (which is the same as the polarity of the output voltage) remains the same.

A pulsating dc current is not suitable for most applications. To obtain a more steady dc current, commercial dc generators use many coils and commutators distributed so that the sinusoidal pulses from the various coils are out of phase. When these pulses are superimposed, the dc output is almost free of fluctuations.

**Motors** are devices that convert electrical energy to mechanical energy. Essentially, a motor is a generator operating in reverse. Instead of generating a current by rotating a loop, a current is supplied to the loop by a battery, and the torque acting on the current-carrying loop causes it to rotate.

Useful mechanical work can be done by attaching the rotating armature to some external device. However, as the loop rotates in a magnetic field, the changing magnetic flux induces an emf in the loop; this induced emf always acts to reduce the current in the loop. If this were not the case, Lenz's law would be violated. The back emf increases in magnitude as the rotational speed of the armature increases. (The phrase *back emf* is used to indicate an emf that tends to reduce the supplied current.) Because the voltage available to supply current equals the difference between the supply voltage and the back emf, the current in the rotating coil is limited by the back emf.

When a motor is turned on, there is initially no back emf; thus, the current is very large because it is limited only by the resistance of the coils. As the coils begin to rotate, the induced back emf opposes the applied voltage, and the current in the coils is reduced. If the mechanical load increases, the motor slows down; this causes the back emf to decrease. This reduction in the back emf increases the current in the coils and therefore also increases the power needed from the external voltage source. For this reason, the power requirements for starting a motor and for running it are greater for heavy loads than for light ones. If the motor is allowed to run under no mechanical load, the back emf reduces the current to a value just large enough to overcome energy losses due to internal energy and friction. If a very heavy load jams the motor so that it cannot rotate, the lack of a back emf can lead to dangerously high current in the motor's wire. If the problem is not corrected, a fire could result.

**EXAMPLE 31.10** The Induced Current in a Motor

Assume that a motor in which the coils have a total resistance of  $10\ \Omega$  is supplied by a voltage of  $120\ \text{V}$ . When the motor is running at its maximum speed, the back emf is  $70\ \text{V}$ . Find the current in the coils (a) when the motor is turned on and (b) when it has reached maximum speed.

**Solution** (a) When the motor is turned on, the back emf is zero (because the coils are motionless). Thus, the current in the coils is a maximum and equal to

$$I = \frac{\mathcal{E}}{R} = \frac{120\ \text{V}}{10\ \Omega} = 12\ \text{A}$$

(b) At the maximum speed, the back emf has its maximum value. Thus, the effective supply voltage is that of the external source minus the back emf. Hence, the current is reduced to

$$I = \frac{\mathcal{E} - \mathcal{E}_{\text{back}}}{R} = \frac{120\ \text{V} - 70\ \text{V}}{10\ \Omega} = \frac{50\ \text{V}}{10\ \Omega} = 5.0\ \text{A}$$

**Exercise** If the current in the motor is  $8.0\ \text{A}$  at some instant, what is the back emf at this time?

**Answer**  $40\ \text{V}$ .

*Optional Section***31.6** EDDY CURRENTS

As we have seen, an emf and a current are induced in a circuit by a changing magnetic flux. In the same manner, circulating currents called **eddy currents** are induced in bulk pieces of metal moving through a magnetic field. This can easily be demonstrated by allowing a flat copper or aluminum plate attached at the end of a rigid bar to swing back and forth through a magnetic field (Fig. 31.22). As the plate enters the field, the changing magnetic flux induces an emf in the plate, which in turn causes the free electrons in the plate to move, producing the swirling eddy currents. According to Lenz's law, the direction of the eddy currents must oppose the change that causes them. For this reason, the eddy currents must produce effective magnetic poles on the plate, which are repelled by the poles of the magnet; this gives rise to a repulsive force that opposes the motion of the plate. (If the opposite were true, the plate would accelerate and its energy would

**QuickLab**

Hang a strong magnet from two strings so that it swings back and forth in a plane. Start it oscillating and determine approximately how much time passes before it stops swinging. Start it oscillating again and quickly bring the flat surface of an aluminum cooking sheet up to within a millimeter of the plane of oscillation, taking care not to touch the magnet. How long does it take the oscillating magnet to stop now?

**Figure 31.22** Formation of eddy currents in a conducting plate moving through a magnetic field. As the plate enters or leaves the field, the changing magnetic flux induces an emf, which causes eddy currents in the plate.

**Figure 31.23** As the conducting plate enters the field (position 1), the eddy currents are counterclockwise. As the plate leaves the field (position 2), the currents are clockwise. In either case, the force on the plate is opposite the velocity, and eventually the plate comes to rest.

**Figure 31.24** When slots are cut in the conducting plate, the eddy currents are reduced and the plate swings more freely through the magnetic field.

increase after each swing, in violation of the law of conservation of energy.) As you may have noticed while carrying out the QuickLab on page 997, you can “feel” the retarding force by pulling a copper or aluminum sheet through the field of a strong magnet.

As indicated in Figure 31.23, with  $\mathbf{B}$  directed into the page, the induced eddy current is counterclockwise as the swinging plate enters the field at position 1. This is because the external magnetic flux into the page through the plate is increasing, and hence by Lenz’s law the induced current must provide a magnetic flux out of the page. The opposite is true as the plate leaves the field at position 2, where the current is clockwise. Because the induced eddy current always produces a magnetic retarding force  $\mathbf{F}_B$  when the plate enters or leaves the field, the swinging plate eventually comes to rest.

If slots are cut in the plate, as shown in Figure 31.24, the eddy currents and the corresponding retarding force are greatly reduced. We can understand this by realizing that the cuts in the plate prevent the formation of any large current loops.

The braking systems on many subway and rapid-transit cars make use of electromagnetic induction and eddy currents. An electromagnet attached to the train is positioned near the steel rails. (An electromagnet is essentially a solenoid with an iron core.) The braking action occurs when a large current is passed through the electromagnet. The relative motion of the magnet and rails induces eddy currents in the rails, and the direction of these currents produces a drag force on the moving train. The loss in mechanical energy of the train is transformed to internal energy in the rails and wheels. Because the eddy currents decrease steadily in magnitude as the train slows down, the braking effect is quite smooth. Eddy-current brakes are also used in some mechanical balances and in various machines. Some power tools use eddy currents to stop rapidly spinning blades once the device is turned off.

**Figure 31.25** As the coin enters the vending machine, a potential difference is applied across the coin at A, and its resistance is measured. If the resistance is acceptable, the holder drops down, releasing the coin and allowing it to roll along the inlet track. Two magnets induce eddy currents in the coin, and magnetic forces control its speed. If the speed sensors indicate that the coin has the correct speed, gate B swings up to allow the coin to be accepted. If the coin is not moving at the correct speed, gate C opens to allow the coin to follow the reject path.

Eddy currents are often undesirable because they represent a transformation of mechanical energy to internal energy. To reduce this energy loss, moving conducting parts are often laminated—that is, they are built up in thin layers separated by a nonconducting material such as lacquer or a metal oxide. This layered structure increases the resistance of the possible paths of the eddy currents and effectively confines the currents to individual layers. Such a laminated structure is used in transformer cores and motors to minimize eddy currents and thereby increase the efficiency of these devices.

Even a task as simple as buying a candy bar from a vending machine involves eddy currents, as shown in Figure 31.25. After entering the slot, a coin is stopped momentarily while its electrical resistance is checked. If its resistance falls within an acceptable range, the coin is allowed to continue down a ramp and through a magnetic field. As it moves through the field, eddy currents are produced in the coin, and magnetic forces slow it down slightly. How much it is slowed down depends on its metallic composition. Sensors measure the coin's speed after it moves past the magnets, and this speed is compared with expected values. If the coin is legal and passes these tests, a gate is opened and the coin is accepted; otherwise, a second gate moves it into the reject path.

### 31.7 MAXWELL'S WONDERFUL EQUATIONS

 We conclude this chapter by presenting four equations that are regarded as the basis of all electrical and magnetic phenomena. These equations, developed by James Clerk Maxwell, are as fundamental to electromagnetic phenomena as Newton's laws are to mechanical phenomena. In fact, the theory that Maxwell developed was more far-reaching than even he imagined because it turned out to be in agreement with the special theory of relativity, as Einstein showed in 1905.

Maxwell's equations represent the laws of electricity and magnetism that we have already discussed, but they have additional important consequences. In Chapter 34 we shall show that these equations predict the existence of electromagnetic waves (traveling patterns of electric and magnetic fields), which travel with a speed  $c = 1/\sqrt{\mu_0\epsilon_0} = 3.00 \times 10^8$  m/s, the speed of light. Furthermore, the theory shows that such waves are radiated by accelerating charges.

For simplicity, we present **Maxwell's equations** as applied to free space, that is, in the absence of any dielectric or magnetic material. The four equations are

$$\oint_S \mathbf{E} \cdot d\mathbf{A} = \frac{Q}{\epsilon_0} \quad (31.12)$$

Gauss's law

$$\oint_S \mathbf{B} \cdot d\mathbf{A} = 0 \quad (31.13)$$

Gauss's law in magnetism

$$\oint \mathbf{E} \cdot d\mathbf{s} = -\frac{d\Phi_B}{dt} \quad (31.14)$$

Faraday's law

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I + \epsilon_0 \mu_0 \frac{d\Phi_E}{dt} \quad (31.15)$$

Ampère–Maxwell law

Equation 31.12 is Gauss's law: **The total electric flux through any closed surface equals the net charge inside that surface divided by  $\epsilon_0$ .** This law relates an electric field to the charge distribution that creates it.

Equation 31.13, which can be considered Gauss's law in magnetism, states that **the net magnetic flux through a closed surface is zero.** That is, the number of magnetic field lines that enter a closed volume must equal the number that leave that volume. This implies that magnetic field lines cannot begin or end at any point. If they did, it would mean that isolated magnetic monopoles existed at those points. The fact that isolated magnetic monopoles have not been observed in nature can be taken as a confirmation of Equation 31.13.

Equation 31.14 is Faraday's law of induction, which describes the creation of an electric field by a changing magnetic flux. This law states that **the emf, which is the line integral of the electric field around any closed path, equals the rate of change of magnetic flux through any surface area bounded by that path.** One consequence of Faraday's law is the current induced in a conducting loop placed in a time-varying magnetic field.

Equation 31.15, usually called the Ampère–Maxwell law, is the generalized form of Ampère's law, which describes the creation of a magnetic field by an electric field and electric currents: **The line integral of the magnetic field around any closed path is the sum of  $\mu_0$  times the net current through that path and  $\epsilon_0\mu_0$  times the rate of change of electric flux through any surface bounded by that path.**

Once the electric and magnetic fields are known at some point in space, the force acting on a particle of charge  $q$  can be calculated from the expression

Lorentz force law

$$\mathbf{F} = q\mathbf{E} + q\mathbf{v} \times \mathbf{B} \quad (31.16)$$

This relationship is called the **Lorentz force law.** (We saw this relationship earlier as Equation 29.16.) Maxwell's equations, together with this force law, completely describe all classical electromagnetic interactions.

It is interesting to note the symmetry of Maxwell's equations. Equations 31.12 and 31.13 are symmetric, apart from the absence of the term for magnetic monopoles in Equation 31.13. Furthermore, Equations 31.14 and 31.15 are symmetric in that the line integrals of  $\mathbf{E}$  and  $\mathbf{B}$  around a closed path are related to the rate of change of magnetic flux and electric flux, respectively. "Maxwell's wonderful equations," as they were called by John R. Pierce,<sup>3</sup> are of fundamental importance not only to electromagnetism but to all of science. Heinrich Hertz once wrote, "One cannot escape the feeling that these mathematical formulas have an independent existence and an intelligence of their own, that they are wiser than we are, wiser even than their discoverers, that we get more out of them than we put into them."

## SUMMARY

**Faraday's law of induction** states that the emf induced in a circuit is directly proportional to the time rate of change of magnetic flux through the circuit:

$$\mathcal{E} = -\frac{d\Phi_B}{dt} \quad (31.1)$$

where  $\Phi_B = \int \mathbf{B} \cdot d\mathbf{A}$  is the magnetic flux.

<sup>3</sup> John R. Pierce, *Electrons and Waves*, New York, Doubleday Science Study Series, 1964. Chapter 6 of this interesting book is recommended as supplemental reading.

When a conducting bar of length  $\ell$  moves at a velocity  $\mathbf{v}$  through a magnetic field  $\mathbf{B}$ , where  $\mathbf{B}$  is perpendicular to the bar and to  $\mathbf{v}$ , the **motional emf** induced in the bar is

$$\mathcal{E} = -B\ell v \quad (31.5)$$

**Lenz's law** states that the induced current and induced emf in a conductor are in such a direction as to oppose the change that produced them.

A general form of **Faraday's law of induction** is

$$\mathcal{E} = \oint \mathbf{E} \cdot d\mathbf{s} = -\frac{d\Phi_B}{dt} \quad (31.9)$$

where  $\mathbf{E}$  is the nonconservative electric field that is produced by the changing magnetic flux.

When used with the Lorentz force law,  $\mathbf{F} = q\mathbf{E} + q\mathbf{v} \times \mathbf{B}$ , **Maxwell's equations** describe all electromagnetic phenomena:

$$\oint_S \mathbf{E} \cdot d\mathbf{A} = \frac{Q}{\epsilon_0} \quad (31.12)$$

$$\oint_S \mathbf{B} \cdot d\mathbf{A} = 0 \quad (31.13)$$

$$\oint \mathbf{E} \cdot d\mathbf{s} = -\frac{d\Phi_B}{dt} \quad (31.14)$$

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I + \epsilon_0 \mu_0 \frac{d\Phi_E}{dt} \quad (31.15)$$

The Ampère–Maxwell law (Eq. 31.15) describes how a magnetic field can be produced by both a conduction current and a changing electric flux.

### QUESTIONS

1. A loop of wire is placed in a uniform magnetic field. For what orientation of the loop is the magnetic flux a maximum? For what orientation is the flux zero? Draw pictures of these two situations.
2. As the conducting bar shown in Figure Q31.2 moves to the right, an electric field directed downward is set up in the bar. Explain why the electric field would be upward if the bar were to move to the left.
3. As the bar shown in Figure Q31.2 moves in a direction perpendicular to the field, is an applied force required to keep it moving with constant speed? Explain.
4. The bar shown in Figure Q31.4 moves on rails to the right with a velocity  $\mathbf{v}$ , and the uniform, constant magnetic field is directed out of the page. Why is the induced current clockwise? If the bar were moving to the left, what would be the direction of the induced current?
5. Explain why an applied force is necessary to keep the bar shown in Figure Q31.4 moving with a constant speed.
6. A large circular loop of wire lies in the horizontal plane. A bar magnet is dropped through the loop. If the axis of

the magnet remains horizontal as it falls, describe the emf induced in the loop. How is the situation altered if the axis of the magnet remains vertical as it falls?

**Figure Q31.2** (Questions 2 and 3).

**Figure Q31.4** (Questions 4 and 5).

7. When a small magnet is moved toward a solenoid, an emf is induced in the coil. However, if the magnet is moved around inside a toroid, no emf is induced. Explain.
8. Will dropping a magnet down a long copper tube produce a current in the walls of the tube? Explain.
9. How is electrical energy produced in dams (that is, how is the energy of motion of the water converted to alternating current electricity)?
10. In a beam–balance scale, an aluminum plate is sometimes used to slow the oscillations of the beam near equilibrium. The plate is mounted at the end of the beam and moves between the poles of a small horseshoe magnet attached to the frame. Why are the oscillations strongly damped near equilibrium?
11. What happens when the rotational speed of a generator coil is increased?
12. Could a current be induced in a coil by the rotation of a magnet inside the coil? If so, how?
13. When the switch shown in Figure Q31.13a is closed, a cur-

rent is set up in the coil, and the metal ring springs upward (Fig. Q31.13b). Explain this behavior.

(a)

(b)

**Figure Q31.13** (Questions 13 and 14). (Photo courtesy of Central Scientific Company)

14. Assume that the battery shown in Figure Q31.13a is replaced by an alternating current source and that the switch is held closed. If held down, the metal ring on top of the solenoid becomes hot. Why?
15. Do Maxwell's equations allow for the existence of magnetic monopoles? Explain.

## PROBLEMS

### Section 31.1 Faraday's Law of Induction

#### Section 31.2 Motional emf

#### Section 31.3 Lenz's Law

1. A 50-turn rectangular coil of dimensions  $5.00 \text{ cm} \times 10.0 \text{ cm}$  is allowed to fall from a position where  $B = 0$  to a new position where  $B = 0.500 \text{ T}$  and is directed perpendicular to the plane of the coil. Calculate the magnitude of the average emf induced in the coil if the displacement occurs in  $0.250 \text{ s}$ .
2. A flat loop of wire consisting of a single turn of cross-sectional area  $8.00 \text{ cm}^2$  is perpendicular to a magnetic field that increases uniformly in magnitude from  $0.500 \text{ T}$  to  $2.50 \text{ T}$  in  $1.00 \text{ s}$ . What is the resulting induced current if the loop has a resistance of  $2.00 \Omega$ ?

3. A 25-turn circular coil of wire has a diameter of  $1.00 \text{ m}$ . It is placed with its axis along the direction of the Earth's magnetic field of  $50.0 \mu\text{T}$ , and then in  $0.200 \text{ s}$  it is flipped  $180^\circ$ . An average emf of what magnitude is generated in the coil?
4. A rectangular loop of area  $A$  is placed in a region where the magnetic field is perpendicular to the plane of the loop. The magnitude of the field is allowed to vary in time according to the expression  $B = B_{\text{max}}e^{-t/\tau}$ , where  $B_{\text{max}}$  and  $\tau$  are constants. The field has the constant value  $B_{\text{max}}$  for  $t < 0$ . (a) Use Faraday's law to show that the emf induced in the loop is given by

$$\mathcal{E} = (AB_{\text{max}}/\tau)e^{-t/\tau}$$

- (b) Obtain a numerical value for  $\mathcal{E}$  at  $t = 4.00 \text{ s}$  when

$A = 0.160 \text{ m}^2$ ,  $B_{\text{max}} = 0.350 \text{ T}$ , and  $\tau = 2.00 \text{ s}$ . (c) For the values of  $A$ ,  $B_{\text{max}}$ , and  $\tau$  given in part (b), what is the maximum value of  $\mathcal{E}$ ?

- WEB 5.** A strong electromagnet produces a uniform field of  $1.60 \text{ T}$  over a cross-sectional area of  $0.200 \text{ m}^2$ . A coil having 200 turns and a total resistance of  $20.0 \Omega$  is placed around the electromagnet. The current in the electromagnet is then smoothly decreased until it reaches zero in  $20.0 \text{ ms}$ . What is the current induced in the coil?
- 6.** A magnetic field of  $0.200 \text{ T}$  exists within a solenoid of 500 turns and a diameter of  $10.0 \text{ cm}$ . How rapidly (that is, within what period of time) must the field be reduced to zero if the average induced emf within the coil during this time interval is to be  $10.0 \text{ kV}$ ?

- WEB 7.** An aluminum ring with a radius of  $5.00 \text{ cm}$  and a resistance of  $3.00 \times 10^{-4} \Omega$  is placed on top of a long air-core solenoid with 1 000 turns per meter and a radius of  $3.00 \text{ cm}$ , as shown in Figure P31.7. Assume that the axial component of the field produced by the solenoid over the area of the end of the solenoid is one-half as strong as at the center of the solenoid. Assume that the solenoid produces negligible field outside its cross-sectional area. (a) If the current in the solenoid is increasing at a rate of  $270 \text{ A/s}$ , what is the induced current in the ring? (b) At the center of the ring, what is the magnetic field produced by the induced current in the ring? (c) What is the direction of this field?

- 8.** An aluminum ring of radius  $r_1$  and resistance  $R$  is placed on top of a long air-core solenoid with  $n$  turns per meter and smaller radius  $r_2$ , as shown in Figure P31.7. Assume that the axial component of the field produced by the solenoid over the area of the end of the solenoid is one-half as strong as at the center of the solenoid. Assume that the solenoid produces negligible field outside its cross-sectional area. (a) If the current in the solenoid is increasing at a rate of  $\Delta I/\Delta t$ , what is the induced current in the ring? (b) At the center of the ring, what is the magnetic field produced by the induced current in the ring? (c) What is the direction of this field?

- 9.** A loop of wire in the shape of a rectangle of width  $w$  and length  $L$  and a long, straight wire carrying a current  $I$  lie on a tabletop as shown in Figure P31.9. (a) Determine the magnetic flux through the loop due to the current  $I$ . (b) Suppose that the current is changing with time according to  $I = a + bt$ , where  $a$  and  $b$  are constants. Determine the induced emf in the loop if  $b = 10.0 \text{ A/s}$ ,  $h = 1.00 \text{ cm}$ ,  $w = 10.0 \text{ cm}$ , and  $L = 100 \text{ cm}$ . What is the direction of the induced current in the rectangle?

- 10.** A coil of 15 turns and radius  $10.0 \text{ cm}$  surrounds a long solenoid of radius  $2.00 \text{ cm}$  and  $1.00 \times 10^3$  turns per meter (Fig. P31.10). If the current in the solenoid changes as  $I = (5.00 \text{ A}) \sin(120t)$ , find the induced emf in the 15-turn coil as a function of time.

**Figure P31.7** Problems 7 and 8.

**Figure P31.9** Problems 9 and 73.

**Figure P31.10**

- 11.** Find the current through section  $PQ$  of length  $a = 65.0 \text{ cm}$  shown in Figure P31.11. The circuit is located in a magnetic field whose magnitude varies with time according to the expression  $B = (1.00 \times 10^{-3} \text{ T/s})t$ . Assume that the resistance per length of the wire is  $0.100 \Omega/\text{m}$ .

Figure P31.11

12. A 30-turn circular coil of radius 4.00 cm and resistance  $1.00 \Omega$  is placed in a magnetic field directed perpendicular to the plane of the coil. The magnitude of the magnetic field varies in time according to the expression  $B = 0.010 0t + 0.040 0t^2$ , where  $t$  is in seconds and  $B$  is in tesla. Calculate the induced emf in the coil at  $t = 5.00$  s.

13. A long solenoid has 400 turns per meter and carries a current  $I = (30.0 \text{ A})(1 - e^{-1.60t})$ . Inside the solenoid and coaxial with it is a coil that has a radius of 6.00 cm and consists of a total of 250 turns of fine wire (Fig. P31.13). What emf is induced in the coil by the changing current?
14. A long solenoid has  $n$  turns per meter and carries a current  $I = I_{\text{max}}(1 - e^{-at})$ . Inside the solenoid and coaxial with it is a coil that has a radius  $R$  and consists of a total of  $N$  turns of fine wire (see Fig. P31.13). What emf is induced in the coil by the changing current?

Figure P31.13 Problems 13 and 14.

15. A coil formed by wrapping 50 turns of wire in the shape of a square is positioned in a magnetic field so that the normal to the plane of the coil makes an angle of  $30.0^\circ$  with the direction of the field. When the magnetic field is increased uniformly from  $200 \mu\text{T}$  to  $600 \mu\text{T}$  in 0.400 s, an emf of magnitude 80.0 mV is induced in the coil. What is the total length of the wire?
16. A closed loop of wire is given the shape of a circle with a radius of 0.500 m. It lies in a plane perpendicular to a uniform magnetic field of magnitude 0.400 T. If in 0.100 s the wire loop is reshaped into a square but remains in the same plane, what is the magnitude of the average induced emf in the wire during this time?

17. A toroid having a rectangular cross-section ( $a = 2.00$  cm by  $b = 3.00$  cm) and inner radius  $R = 4.00$  cm consists of 500 turns of wire that carries a current  $I = I_{\text{max}} \sin \omega t$ , with  $I_{\text{max}} = 50.0$  A and a frequency  $f = \omega/2\pi = 60.0$  Hz. A coil that consists of 20 turns of wire links with the toroid, as shown in Figure P31.17. Determine the emf induced in the coil as a function of time.

Figure P31.17

18. A single-turn, circular loop of radius  $R$  is coaxial with a long solenoid of radius  $r$  and length  $\ell$  and having  $N$  turns (Fig. P31.18). The variable resistor is changed so that the solenoid current decreases linearly from  $I_1$  to  $I_2$  in an interval  $\Delta t$ . Find the induced emf in the loop.

Figure P31.18

19. A circular coil enclosing an area of  $100 \text{ cm}^2$  is made of 200 turns of copper wire, as shown in Figure P31.19. Ini-

Figure P31.19

tially, a 1.10-T uniform magnetic field points in a perpendicular direction upward through the plane of the coil. The direction of the field then reverses. During the time the field is changing its direction, how much charge flows through the coil if  $R = 5.00 \Omega$ ?

20. Consider the arrangement shown in Figure P31.20. Assume that  $R = 6.00 \Omega$ ,  $\ell = 1.20 \text{ m}$ , and a uniform 2.50-T magnetic field is directed into the page. At what speed should the bar be moved to produce a current of 0.500 A in the resistor?

Figure P31.20 Problems 20, 21, and 22.

21. Figure P31.20 shows a top view of a bar that can slide without friction. The resistor is  $6.00 \Omega$  and a 2.50-T magnetic field is directed perpendicularly downward, into the paper. Let  $\ell = 1.20 \text{ m}$ . (a) Calculate the applied force required to move the bar to the right at a constant speed of 2.00 m/s. (b) At what rate is energy delivered to the resistor?
22. A conducting rod of length  $\ell$  moves on two horizontal, frictionless rails, as shown in Figure P31.20. If a constant force of 1.00 N moves the bar at 2.00 m/s through a magnetic field  $\mathbf{B}$  that is directed into the page, (a) what is the current through an  $8.00\text{-}\Omega$  resistor  $R$ ? (b) What is the rate at which energy is delivered to the resistor? (c) What is the mechanical power delivered by the force  $\mathbf{F}_{\text{app}}$ ?
23. A Boeing-747 jet with a wing span of 60.0 m is flying horizontally at a speed of 300 m/s over Phoenix, Arizona, at a location where the Earth's magnetic field is  $50.0 \mu\text{T}$  at  $58.0^\circ$  below the horizontal. What voltage is generated between the wingtips?
24. The square loop in Figure P31.24 is made of wires with total series resistance  $10.0 \Omega$ . It is placed in a uniform

Figure P31.24

0.100-T magnetic field directed perpendicular into the plane of the paper. The loop, which is hinged at each corner, is pulled as shown until the separation between points A and B is 3.00 m. If this process takes 0.100 s, what is the average current generated in the loop? What is the direction of the current?

25. A helicopter has blades with a length of 3.00 m extending outward from a central hub and rotating at 2.00 rev/s. If the vertical component of the Earth's magnetic field is  $50.0 \mu\text{T}$ , what is the emf induced between the blade tip and the center hub?
26. Use Lenz's law to answer the following questions concerning the direction of induced currents: (a) What is the direction of the induced current in resistor  $R$  shown in Figure P31.26a when the bar magnet is moved to the left? (b) What is the direction of the current induced in the resistor  $R$  right after the switch  $S$  in Figure P31.26b is closed? (c) What is the direction of the induced current in  $R$  when the current  $I$  in Figure P31.26c decreases rapidly to zero? (d) A copper bar is moved to the right while its axis is maintained in a direction perpendicular to a magnetic field, as shown in Figure P31.26d. If the top of the bar becomes positive relative to the bottom, what is the direction of the magnetic field?

Figure P31.26

27. A rectangular coil with resistance  $R$  has  $N$  turns, each of length  $\ell$  and width  $w$  as shown in Figure P31.27. The coil moves into a uniform magnetic field  $\mathbf{B}$  with a velocity  $\mathbf{v}$ . What are the magnitude and direction of the resultant force on the coil (a) as it enters the magnetic field, (b) as it moves within the field, and (c) as it leaves the field?

Figure P31.27

28. In 1832 Faraday proposed that the apparatus shown in Figure P31.28 could be used to generate electric current from the water flowing in the Thames River.<sup>4</sup> Two conducting plates of lengths  $a$  and widths  $b$  are placed facing each other on opposite sides of the river, a distance  $w$  apart, and are immersed entirely. The flow velocity of the river is  $\mathbf{v}$  and the vertical component of the Earth's magnetic field is  $B$ . (a) Show that the current in the load resistor  $R$  is

$$I = \frac{abvB}{\rho + abR/w}$$

where  $\rho$  is the electrical resistivity of the water. (b) Calculate the short-circuit current ( $R = 0$ ) if  $a = 100$  m,  $b = 5.00$  m,  $v = 3.00$  m/s,  $B = 50.0 \mu\text{T}$ , and  $\rho = 100 \Omega \cdot \text{m}$ .

Figure P31.28

29. In Figure P31.29, the bar magnet is moved toward the loop. Is  $V_a - V_b$  positive, negative, or zero? Explain.
30. A metal bar spins at a constant rate in the magnetic field of the Earth as in Figure 31.10. The rotation occurs in a region where the component of the Earth's magnetic field perpendicular to the plane of rotation is  $3.30 \times 10^{-5}$  T. If the bar is 1.00 m in length and its angular speed is  $5.00 \pi$  rad/s, what potential difference is developed between its ends?

<sup>4</sup> The idea for this problem and Figure P31.28 is from Oleg D. Jefimenko, *Electricity and Magnetism: An Introduction to the Theory of Electric and Magnetic Fields*. Star City, WV, Electret Scientific Co., 1989.

Figure P31.29

31. Two parallel rails with negligible resistance are 10.0 cm apart and are connected by a  $5.00\text{-}\Omega$  resistor. The circuit also contains two metal rods having resistances of  $10.0 \Omega$  and  $15.0 \Omega$  sliding along the rails (Fig. P31.31). The rods are pulled away from the resistor at constant speeds  $4.00$  m/s and  $2.00$  m/s, respectively. A uniform magnetic field of magnitude  $0.0100$  T is applied perpendicular to the plane of the rails. Determine the current in the  $5.00\text{-}\Omega$  resistor.

Figure P31.31

**Section 31.4 Induced emf and Electric Fields**

32. For the situation described in Figure P31.32, the magnetic field changes with time according to the expression  $B = (2.00t^3 - 4.00t^2 + 0.800)$  T, and  $r_2 = 2R = 5.00$  cm. (a) Calculate the magnitude and direction of

Figure P31.32 Problems 32 and 33.

the force exerted on an electron located at point  $P_2$  when  $t = 2.00$  s. (b) At what time is this force equal to zero?

33. A magnetic field directed into the page changes with time according to  $B = (0.030 \text{ } 0t^2 + 1.40) \text{ T}$ , where  $t$  is in seconds. The field has a circular cross-section of radius  $R = 2.50$  cm (see Fig. P31.32). What are the magnitude and direction of the electric field at point  $P_1$  when  $t = 3.00$  s and  $r_1 = 0.020$  m?
34. A solenoid has a radius of 2.00 cm and 1 000 turns per meter. Over a certain time interval the current varies with time according to the expression  $I = 3e^{0.2t}$ , where  $I$  is in amperes and  $t$  is in seconds. Calculate the electric field 5.00 cm from the axis of the solenoid at  $t = 10.0$  s.
35. A long solenoid with 1 000 turns per meter and radius 2.00 cm carries an oscillating current  $I = (5.00 \text{ A}) \sin(100\pi t)$ . (a) What is the electric field induced at a radius  $r = 1.00$  cm from the axis of the solenoid? (b) What is the direction of this electric field when the current is increasing counterclockwise in the coil?

(Optional)

### Section 31.5 Generators and Motors

36. In a 250-turn automobile alternator, the magnetic flux in each turn is  $\Phi_B = (2.50 \times 10^{-4} \text{ T} \cdot \text{m}^2) \cos(\omega t)$ , where  $\omega$  is the angular speed of the alternator. The alternator is geared to rotate three times for each engine revolution. When the engine is running at an angular speed of 1 000 rev/min, determine (a) the induced emf in the alternator as a function of time and (b) the maximum emf in the alternator.
- WEB 37. A coil of area  $0.100 \text{ m}^2$  is rotating at 60.0 rev/s with the axis of rotation perpendicular to a 0.200-T magnetic field. (a) If there are 1 000 turns on the coil, what is the maximum voltage induced in it? (b) What is the orientation of the coil with respect to the magnetic field when the maximum induced voltage occurs?
38. A square coil ( $20.0 \text{ cm} \times 20.0 \text{ cm}$ ) that consists of 100 turns of wire rotates about a vertical axis at 1 500 rev/min, as indicated in Figure P31.38. The horizontal component of the Earth's magnetic field at the location of the coil is  $2.00 \times 10^{-5} \text{ T}$ . Calculate the maximum emf induced in the coil by this field.

Figure P31.38

39. A long solenoid, with its axis along the  $x$  axis, consists of 200 turns per meter of wire that carries a steady current of 15.0 A. A coil is formed by wrapping 30 turns of thin wire around a circular frame that has a radius of 8.00 cm. The coil is placed inside the solenoid and mounted on an axis that is a diameter of the coil and coincides with the  $y$  axis. The coil is then rotated with an angular speed of  $4.00\pi$  rad/s. (The plane of the coil is in the  $yz$  plane at  $t = 0$ .) Determine the emf developed in the coil as a function of time.
40. A bar magnet is spun at constant angular speed  $\omega$  around an axis, as shown in Figure P31.40. A flat rectangular conducting loop surrounds the magnet, and at  $t = 0$ , the magnet is oriented as shown. Make a qualitative graph of the induced current in the loop as a function of time, plotting counterclockwise currents as positive and clockwise currents as negative.

Figure P31.40

41. (a) What is the maximum torque delivered by an electric motor if it has 80 turns of wire wrapped on a rectangular coil of dimensions 2.50 cm by 4.00 cm? Assume that the motor uses 10.0 A of current and that a uniform 0.800-T magnetic field exists within the motor. (b) If the motor rotates at 3 600 rev/min, what is the peak power produced by the motor?
42. A semicircular conductor of radius  $R = 0.250$  m is rotated about the axis AC at a constant rate of 120 rev/min (Fig. P31.42). A uniform magnetic field in all of the lower half of the figure is directed out of the plane of rotation and has a magnitude of 1.30 T. (a) Calculate the maximum value of the emf induced in the conductor. (b) What is the value of the average induced emf for each complete rotation? (c) How would the answers to parts (a) and (b) change if  $\mathbf{B}$  were allowed to extend a distance  $R$  above the axis of rotation? Sketch the emf versus time (d) when the field is as drawn in Figure P31.42 and (e) when the field is extended as described in part (c).

Figure P31.42

43. The rotating loop in an ac generator is a square 10.0 cm on a side. It is rotated at 60.0 Hz in a uniform field of 0.800 T. Calculate (a) the flux through the loop as a function of time, (b) the emf induced in the loop, (c) the current induced in the loop for a loop resistance of 1.00  $\Omega$ , (d) the power in the resistance of the loop, and (e) the torque that must be exerted to rotate the loop.

(Optional)

**Section 31.6 Eddy Currents**

44. A 0.150-kg wire in the shape of a closed rectangle 1.00 m wide and 1.50 m long has a total resistance of 0.750  $\Omega$ . The rectangle is allowed to fall through a magnetic field directed perpendicular to the direction of motion of the rectangle (Fig. P31.44). The rectangle accelerates downward as it approaches a terminal speed of 2.00 m/s, with its top not yet in the region of the field. Calculate the magnitude of  $\mathbf{B}$ .

Figure P31.44 Problems 44 and 45.

- WEB** 45. A conducting rectangular loop of mass  $M$ , resistance  $R$ , and dimensions  $w$  by  $\ell$  falls from rest into a magnetic field  $\mathbf{B}$  as in Figure P31.44. The loop approaches termi-

nal speed  $v_t$ . (a) Show that

$$v_t = \frac{MgR}{B^2 w^2}$$

- (b) Why is  $v_t$  proportional to  $R$ ? (c) Why is it inversely proportional to  $B^2$ ?
46. Figure P31.46 represents an electromagnetic brake that utilizes eddy currents. An electromagnet hangs from a railroad car near one rail. To stop the car, a large steady current is sent through the coils of the electromagnet. The moving electromagnet induces eddy currents in the rails, whose fields oppose the change in the field of the electromagnet. The magnetic fields of the eddy currents exert force on the current in the electromagnet, thereby slowing the car. The direction of the car's motion and the direction of the current in the electromagnet are shown correctly in the picture. Determine which of the eddy currents shown on the rails is correct. Explain your answer.

Figure P31.46

**Section 31.7 Maxwell's Wonderful Equations**

47. A proton moves through a uniform electric field  $\mathbf{E} = 50.0\mathbf{j}$  V/m and a uniform magnetic field  $\mathbf{B} = (0.200\mathbf{i} + 0.300\mathbf{j} + 0.400\mathbf{k})$  T. Determine the acceleration of the proton when it has a velocity  $\mathbf{v} = 200\mathbf{i}$  m/s.
48. An electron moves through a uniform electric field  $\mathbf{E} = (2.50\mathbf{i} + 5.00\mathbf{j})$  V/m and a uniform magnetic field  $\mathbf{B} = 0.400\mathbf{k}$  T. Determine the acceleration of the electron when it has a velocity  $\mathbf{v} = 10.0\mathbf{i}$  m/s.

**ADDITIONAL PROBLEMS**

49. A steel guitar string vibrates (see Fig. 31.5). The component of the magnetic field perpendicular to the area of

a pickup coil nearby is given by

$$B = 50.0 \text{ mT} + (3.20 \text{ mT}) \sin(2\pi 523 t/s)$$

The circular pickup coil has 30 turns and radius 2.70 mm. Find the emf induced in the coil as a function of time.

50. Figure P31.50 is a graph of the induced emf versus time for a coil of  $N$  turns rotating with angular velocity  $\omega$  in a uniform magnetic field directed perpendicular to the axis of rotation of the coil. Copy this graph (on a larger scale), and on the same set of axes show the graph of emf versus  $t$  (a) if the number of turns in the coil is doubled, (b) if instead the angular velocity is doubled, and (c) if the angular velocity is doubled while the number of turns in the coil is halved.

Figure P31.50

51. A technician wearing a brass bracelet enclosing an area of  $0.00500 \text{ m}^2$  places her hand in a solenoid whose magnetic field is  $5.00 \text{ T}$  directed perpendicular to the plane of the bracelet. The electrical resistance around the circumference of the bracelet is  $0.0200 \Omega$ . An unexpected power failure causes the field to drop to  $1.50 \text{ T}$  in a time of  $20.0 \text{ ms}$ . Find (a) the current induced in the bracelet and (b) the power delivered to the resistance of the bracelet. (Note: As this problem implies, you should not wear any metallic objects when working in regions of strong magnetic fields.)
52. Two infinitely long solenoids (seen in cross-section) thread a circuit as shown in Figure P31.52. The magni-

Figure P31.52

tude of  $\mathbf{B}$  inside each is the same and is increasing at the rate of  $100 \text{ T/s}$ . What is the current in each resistor?

53. A conducting rod of length  $\ell = 35.0 \text{ cm}$  is free to slide on two parallel conducting bars, as shown in Figure P31.53. Two resistors  $R_1 = 2.00 \Omega$  and  $R_2 = 5.00 \Omega$  are connected across the ends of the bars to form a loop. A constant magnetic field  $B = 2.50 \text{ T}$  is directed perpendicular into the page. An external agent pulls the rod to the left with a constant speed of  $v = 8.00 \text{ m/s}$ . Find (a) the currents in both resistors, (b) the total power delivered to the resistance of the circuit, and (c) the magnitude of the applied force that is needed to move the rod with this constant velocity.

Figure P31.53

54. Suppose you wrap wire onto the core from a roll of cellophane tape to make a coil. Describe how you can use a bar magnet to produce an induced voltage in the coil. What is the order of magnitude of the emf you generate? State the quantities you take as data and their values.
55. A bar of mass  $m$ , length  $d$ , and resistance  $R$  slides without friction on parallel rails, as shown in Figure P31.55. A battery that maintains a constant emf  $\mathcal{E}$  is connected between the rails, and a constant magnetic field  $\mathbf{B}$  is directed perpendicular to the plane of the page. If the bar starts from rest, show that at time  $t$  it moves with a speed

$$v = \frac{\mathcal{E}}{Bd} (1 - e^{-B^2 d^2 t / mR})$$

Figure P31.55

56. An automobile has a vertical radio antenna  $1.20 \text{ m}$  long. The automobile travels at  $65.0 \text{ km/h}$  on a horizontal road where the Earth's magnetic field is  $50.0 \mu\text{T}$  directed toward the north and downward at an angle of  $65.0^\circ$  below the horizontal. (a) Specify the direction that the automobile should move to generate the maxi-

imum motional emf in the antenna, with the top of the antenna positive relative to the bottom. (b) Calculate the magnitude of this induced emf.

57. The plane of a square loop of wire with edge length  $a = 0.200$  m is perpendicular to the Earth's magnetic field at a point where  $B = 15.0 \mu\text{T}$ , as shown in Figure P31.57. The total resistance of the loop and the wires connecting it to the galvanometer is  $0.500 \Omega$ . If the loop is suddenly collapsed by horizontal forces as shown, what total charge passes through the galvanometer?

Figure P31.57

58. Magnetic field values are often determined by using a device known as a *search coil*. This technique depends on the measurement of the total charge passing through a coil in a time interval during which the magnetic flux linking the windings changes either because of the motion of the coil or because of a change in the value of  $B$ . (a) Show that as the flux through the coil changes from  $\Phi_1$  to  $\Phi_2$ , the charge transferred through the coil will be given by  $Q = N(\Phi_2 - \Phi_1)/R$ , where  $R$  is the resistance of the coil and associated circuitry (galvanometer) and  $N$  is the number of turns. (b) As a specific example, calculate  $B$  when a 100-turn coil of resistance  $200 \Omega$  and cross-sectional area  $40.0 \text{ cm}^2$  produces the following results. A total charge of  $5.00 \times 10^{-4} \text{ C}$  passes through the coil when it is rotated in a uniform field from a position where the plane of the coil is perpendicular to the field to a position where the coil's plane is parallel to the field.
59. In Figure P31.59, the rolling axle, 1.50 m long, is pushed along horizontal rails at a constant speed  $v = 3.00 \text{ m/s}$ . A resistor  $R = 0.400 \Omega$  is connected to the rails at points  $a$  and  $b$ , directly opposite each other. (The wheels make good electrical contact with the rails, and so the axle, rails, and  $R$  form a closed-loop circuit. The only significant resistance in the circuit is  $R$ .) There is a uniform magnetic field  $B = 0.0800 \text{ T}$  vertically downward. (a) Find the induced current  $I$  in the resistor. (b) What horizontal force  $F$  is required to keep the

Figure P31.59

- axle rolling at constant speed? (c) Which end of the resistor,  $a$  or  $b$ , is at the higher electric potential? (d) After the axle rolls past the resistor, does the current in  $R$  reverse direction? Explain your answer.
60. A conducting rod moves with a constant velocity  $\mathbf{v}$  perpendicular to a long, straight wire carrying a current  $I$  as shown in Figure P31.60. Show that the magnitude of the emf generated between the ends of the rod is

$$|\mathcal{E}| = \frac{\mu_0 v I}{2\pi r} \ell$$

In this case, note that the emf decreases with increasing  $r$ , as you might expect.

Figure P31.60

61. A circular loop of wire of radius  $r$  is in a uniform magnetic field, with the plane of the loop perpendicular to the direction of the field (Fig. P31.61). The magnetic field varies with time according to  $B(t) = a + bt$ , where  $a$  and  $b$  are constants. (a) Calculate the magnetic flux through the loop at  $t = 0$ . (b) Calculate the emf induced in the loop. (c) If the resistance of the loop is  $R$ , what is the induced current? (d) At what rate is electrical energy being delivered to the resistance of the loop?
62. In Figure P31.62, a uniform magnetic field decreases at a constant rate  $dB/dt = -K$ , where  $K$  is a positive constant. A circular loop of wire of radius  $a$  containing a re-

Figure P31.61

Figure P31.62

distance  $R$  and a capacitance  $C$  is placed with its plane normal to the field. (a) Find the charge  $Q$  on the capacitor when it is fully charged. (b) Which plate is at the higher potential? (c) Discuss the force that causes the separation of charges.

63. A rectangular coil of 60 turns, dimensions 0.100 m by 0.200 m and total resistance  $10.0 \Omega$ , rotates with angular speed  $30.0 \text{ rad/s}$  about the  $y$  axis in a region where a  $1.00\text{-T}$  magnetic field is directed along the  $x$  axis. The rotation is initiated so that the plane of the coil is perpendicular to the direction of  $\mathbf{B}$  at  $t = 0$ . Calculate (a) the maximum induced emf in the coil, (b) the maximum rate of change of magnetic flux through the coil, (c) the induced emf at  $t = 0.050 \text{ s}$ , and (d) the torque exerted on the coil by the magnetic field at the instant when the emf is a maximum.
64. A small circular washer of radius  $0.500 \text{ cm}$  is held directly below a long, straight wire carrying a current of  $10.0 \text{ A}$ . The washer is located  $0.500 \text{ m}$  above the top of the table (Fig. P31.64). (a) If the washer is dropped from rest, what is the magnitude of the average induced

Figure P31.64

emf in the washer from the time it is released to the moment it hits the tabletop? Assume that the magnetic field is nearly constant over the area of the washer and equal to the magnetic field at the center of the washer. (b) What is the direction of the induced current in the washer?

65. To monitor the breathing of a hospital patient, a thin belt is wrapped around the patient's chest. The belt is a 200-turn coil. When the patient inhales, the area encircled by the coil increases by  $39.0 \text{ cm}^2$ . The magnitude of the Earth's magnetic field is  $50.0 \mu\text{T}$  and makes an angle of  $28.0^\circ$  with the plane of the coil. If a patient takes  $1.80 \text{ s}$  to inhale, find the average induced emf in the coil during this time.
66. A conducting rod of length  $\ell$  moves with velocity  $\mathbf{v}$  parallel to a long wire carrying a steady current  $I$ . The axis of the rod is maintained perpendicular to the wire with the near end a distance  $r$  away, as shown in Figure P31.66. Show that the magnitude of the emf induced in the rod is

$$|\mathcal{E}| = \frac{\mu_0 I}{2\pi} v \ln\left(1 + \frac{\ell}{r}\right)$$

Figure P31.66

67. A rectangular loop of dimensions  $\ell$  and  $w$  moves with a constant velocity  $\mathbf{v}$  away from a long wire that carries a current  $I$  in the plane of the loop (Fig. P31.67). The to-

Figure P31.67

tal resistance of the loop is  $R$ . Derive an expression that gives the current in the loop at the instant the near side is a distance  $r$  from the wire.

68. A horizontal wire is free to slide on the vertical rails of a conducting frame, as shown in Figure P31.68. The wire has mass  $m$  and length  $\ell$ , and the resistance of the circuit is  $R$ . If a uniform magnetic field is directed perpendicular to the frame, what is the terminal speed of the wire as it falls under the force of gravity?

Figure P31.68

69. The magnetic flux threading a metal ring varies with time  $t$  according to  $\Phi_B = 3(at^3 - bt^2)$  T·m<sup>2</sup>, with  $a = 2.00$  s<sup>-3</sup> and  $b = 6.00$  s<sup>-2</sup>. The resistance of the ring is  $3.00$   $\Omega$ . Determine the maximum current induced in the ring during the interval from  $t = 0$  to  $t = 2.00$  s.
70. **Review Problem.** The bar of mass  $m$  shown in Figure P31.70 is pulled horizontally across parallel rails by a massless string that passes over an ideal pulley and is attached to a suspended mass  $M$ . The uniform magnetic field has a magnitude  $B$ , and the distance between the rails is  $\ell$ . The rails are connected at one end by a load resistor  $R$ . Derive an expression that gives the horizon-

Figure P31.70

tal speed of the bar as a function of time, assuming that the suspended mass is released with the bar at rest at  $t = 0$ . Assume no friction between rails and bar.

71. A solenoid wound with 2 000 turns/m is supplied with current that varies in time according to  $I = 4 \sin(120\pi t)$ , where  $I$  is in A and  $t$  is in s. A small coaxial circular coil of 40 turns and radius  $r = 5.00$  cm is located inside the solenoid near its center. (a) Derive an expression that describes the manner in which the emf in the small coil varies in time. (b) At what average rate is energy transformed into internal energy in the small coil if the windings have a total resistance of  $8.00$   $\Omega$ ?
72. A wire 30.0 cm long is held parallel to and 80.0 cm above a long wire carrying 200 A and resting on the floor (Fig. P31.72). The 30.0-cm wire is released and falls, remaining parallel with the current-carrying wire as it falls. Assume that the falling wire accelerates at  $9.80$  m/s<sup>2</sup> and derive an equation for the emf induced in it. Express your result as a function of the time  $t$  after the wire is dropped. What is the induced emf 0.300 s after the wire is released?

Figure P31.72

- WEB 73. A long, straight wire carries a current  $I = I_{\max} \sin(\omega t + \phi)$  and lies in the plane of a rectangular coil of  $N$  turns of wire, as shown in Figure P31.9. The quantities  $I_{\max}$ ,  $\omega$ , and  $\phi$  are all constants. Determine the emf induced in the coil by the magnetic field created by the current in the straight wire. Assume  $I_{\max} = 50.0$  A,  $\omega = 200\pi$  s<sup>-1</sup>,  $N = 100$ ,  $h = w = 5.00$  cm, and  $L = 20.0$  cm.
74. A dime is suspended from a thread and hung between the poles of a strong horseshoe magnet as shown in Figure P31.74. The dime rotates at constant angular speed  $\omega$  about a vertical axis. Letting  $\theta$  represent the angle between the direction of  $\mathbf{B}$  and the normal to the face of the dime, sketch a graph of the torque due to induced currents as a function of  $\theta$  for  $0 < \theta < 2\pi$ .
75. The wire shown in Figure P31.75 is bent in the shape of a tent, with  $\theta = 60.0^\circ$  and  $L = 1.50$  m, and is placed in a uniform magnetic field of magnitude 0.300 T perpendicular to the tabletop. The wire is rigid but hinged at points  $a$  and  $b$ . If the "tent" is flattened out on the table in 0.100 s, what is the average induced emf in the wire during this time?

Figure P31.74

Figure P31.75

## ANSWERS TO QUICK QUIZZES

- 31.1** Because the magnetic field now points in the opposite direction, you must replace  $\theta$  with  $\theta + \pi$ . Because  $\cos(\theta + \pi) = -\cos \theta$ , the sign of the induced emf is reversed.
- 31.2** The one on the west side of the plane. As we saw in Section 30.9, the Earth's magnetic field has a downward component in the northern hemisphere. As the plane flies north, the right-hand rule illustrated in Figure 29.4 indicates that positive charge experiences a force directed toward the west. Thus, the left wingtip becomes positively charged and the right wingtip negatively charged.
- 31.3** Inserting. Because the south pole of the magnet is nearest the solenoid, the field lines created by the magnet point upward in Figure 31.14. Because the current induced in the solenoid is clockwise when viewed from above, the magnetic field lines produced by this current point downward in Figure 31.14. If the magnet were being withdrawn, it would create a decreasing upward flux. The induced current would counteract this decrease by producing its own upward flux. This would require a counterclockwise current in the solenoid, contrary to what is observed.

## Inductance

### Chapter Outline

**32.1** Self-Inductance

**32.2** *RL* Circuits

**32.3** Energy in a Magnetic Field

**32.4** Mutual Inductance

**32.5** Oscillations in an *LC* Circuit

**32.6** (*Optional*) The *RLC* Circuit

In Chapter 31, we saw that emfs and currents are induced in a circuit when the magnetic flux through the area enclosed by the circuit changes with time. This electromagnetic induction has some practical consequences, which we describe in this chapter. First, we describe an effect known as *self-induction*, in which a time-varying current in a circuit produces in the circuit an induced emf that opposes the emf that initially set up the time-varying current. Self-induction is the basis of the *inductor*, an electrical element that has an important role in circuits that use time-varying currents. We discuss the energy stored in the magnetic field of an inductor and the energy density associated with the magnetic field.

Next, we study how an emf is induced in a circuit as a result of a changing magnetic flux produced by a second circuit; this is the basic principle of *mutual induction*. Finally, we examine the characteristics of circuits that contain inductors, resistors, and capacitors in various combinations.

### 32.1 SELF-INDUCTANCE

In this chapter, we need to distinguish carefully between emfs and currents that are caused by batteries or other sources and those that are induced by changing magnetic fields. We use the adjective *source* (as in the terms *source emf* and *source current*) to describe the parameters associated with a physical source, and we use the adjective *induced* to describe those emfs and currents caused by a changing magnetic field.

Consider a circuit consisting of a switch, a resistor, and a source of emf, as shown in Figure 32.1. When the switch is thrown to its closed position, the source current does not immediately jump from zero to its maximum value  $\mathcal{E}/R$ . Faraday's law of electromagnetic induction (Eq. 31.1) can be used to describe this effect as follows: As the source current increases with time, the magnetic flux through the circuit loop due to this current also increases with time. This increasing flux creates an induced emf in the circuit. The direction of the induced emf is such that it would cause an induced current in the loop (if a current were not already flowing in the loop), which would establish a magnetic field that would oppose the change in the source magnetic field. Thus, the direction of the induced emf is opposite the direction of the source emf; this results in a gradual rather than instantaneous increase in the source current to its final equilibrium value. This effect is called *self-induction* because the changing flux through the circuit and the resultant induced emf arise from the circuit itself. The emf  $\mathcal{E}_L$  set up in this case is called a **self-induced emf**. It is also often called a **back emf**.

As a second example of self-induction, consider Figure 32.2, which shows a coil wound on a cylindrical iron core. (A practical device would have several hun-

**Figure 32.1** After the switch is thrown closed, the current produces a magnetic flux through the area enclosed by the loop. As the current increases toward its equilibrium value, this magnetic flux changes in time and induces an emf in the loop. The battery symbol drawn with dashed lines represents the self-induced emf.

#### Joseph Henry (1797–1878)

Henry, an American physicist, became the first director of the Smithsonian Institution and first president of the Academy of Natural Science. He improved the design of the electromagnet and constructed one of the first motors. He also discovered the phenomenon of self-induction but failed to publish his findings. The unit of inductance, the henry, is named in his honor. (North Wind Picture Archives)

**Figure 32.2** (a) A current in the coil produces a magnetic field directed to the left. (b) If the current increases, the increasing magnetic flux creates an induced emf having the polarity shown by the dashed battery. (c) The polarity of the induced emf reverses if the current decreases.

dred turns.) Assume that the source current in the coil either increases or decreases with time. When the source current is in the direction shown, a magnetic field directed from right to left is set up inside the coil, as seen in Figure 32.2a. As the source current changes with time, the magnetic flux through the coil also changes and induces an emf in the coil. From Lenz's law, the polarity of this induced emf must be such that it opposes the change in the magnetic field from the source current. If the source current is increasing, the polarity of the induced emf is as pictured in Figure 32.2b, and if the source current is decreasing, the polarity of the induced emf is as shown in Figure 32.2c.

To obtain a quantitative description of self-induction, we recall from Faraday's law that the induced emf is equal to the negative time rate of change of the magnetic flux. The magnetic flux is proportional to the magnetic field due to the source current, which in turn is proportional to the source current in the circuit. Therefore, **a self-induced emf  $\mathcal{E}_L$  is always proportional to the time rate of change of the source current.** For a closely spaced coil of  $N$  turns (a toroid or an ideal solenoid) carrying a source current  $I$ , we find that

Self-induced emf

$$\mathcal{E}_L = -N \frac{d\Phi_B}{dt} = -L \frac{dI}{dt} \quad (32.1)$$

where  $L$  is a proportionality constant—called the **inductance** of the coil—that depends on the geometry of the circuit and other physical characteristics. From this expression, we see that the inductance of a coil containing  $N$  turns is

Inductance of an  $N$ -turn coil

$$L = \frac{N\Phi_B}{I} \quad (32.2)$$

where it is assumed that the same flux passes through each turn. Later, we shall use this equation to calculate the inductance of some special circuit geometries.

From Equation 32.1, we can also write the inductance as the ratio

Inductance

$$L = -\frac{\mathcal{E}_L}{dI/dt} \quad (32.3)$$

Just as resistance is a measure of the opposition to current ( $R = \Delta V/I$ ), inductance is a measure of the opposition to a *change* in current.

The SI unit of inductance is the **henry** (H), which, as we can see from Equation 32.3, is 1 volt-second per ampere:

$$1 \text{ H} = 1 \frac{\text{V} \cdot \text{s}}{\text{A}}$$

That the inductance of a device depends on its geometry is analogous to the capacitance of a capacitor depending on the geometry of its plates, as we found in Chapter 26. Inductance calculations can be quite difficult to perform for complicated geometries; however, the following examples involve simple situations for which inductances are easily evaluated.

### EXAMPLE 32.1 Inductance of a Solenoid

Find the inductance of a uniformly wound solenoid having  $N$  turns and length  $\ell$ . Assume that  $\ell$  is much longer than the radius of the windings and that the core of the solenoid is air.

**Solution** We can assume that the interior magnetic field due to the source current is uniform and given by Equation 30.17:

$$B = \mu_0 n I = \mu_0 \frac{N}{\ell} I$$

where  $n = N/\ell$  is the number of turns per unit length. The magnetic flux through each turn is

$$\Phi_B = BA = \mu_0 \frac{NA}{\ell} I$$

where  $A$  is the cross-sectional area of the solenoid. Using this expression and Equation 32.2, we find that

$$L = \frac{N\Phi_B}{I} = \frac{\mu_0 N^2 A}{\ell} \quad (32.4)$$

This result shows that  $L$  depends on geometry and is proportional to the square of the number of turns. Because  $N = n\ell$ , we can also express the result in the form

$$L = \mu_0 \frac{(n\ell)^2}{\ell} A = \mu_0 n^2 A \ell = \mu_0 n^2 V \quad (32.5)$$

where  $V = A\ell$  is the volume of the solenoid.

**Exercise** What would happen to the inductance if a ferromagnetic material were placed inside the solenoid?  13.6

**Answer** The inductance would increase. For a given current, the magnetic flux is now much greater because of the increase in the field originating from the magnetization of the ferromagnetic material. For example, if the material has a magnetic permeability of  $500\mu_0$ , the inductance would increase by a factor of 500.

The fact that various materials in the vicinity of a coil can substantially alter the coil's inductance is used to great advantage by traffic engineers. A flat, horizontal coil made of numerous loops of wire is placed in a shallow groove cut into the pavement of the lane approaching an intersection. (See the photograph at the beginning of this chapter.) These loops are attached to circuitry that measures inductance. When an automobile passes over the loops, the change in inductance caused by the large amount of iron passing over the loops is used to control the lights at the intersection. 

### EXAMPLE 32.2 Calculating Inductance and emf

(a) Calculate the inductance of an air-core solenoid containing 300 turns if the length of the solenoid is 25.0 cm and its cross-sectional area is  $4.00 \text{ cm}^2$ .

**Solution** Using Equation 32.4, we obtain

$$\begin{aligned} L &= \frac{\mu_0 N^2 A}{\ell} \\ &= (4\pi \times 10^{-7} \text{ T}\cdot\text{m/A}) \frac{(300)^2 (4.00 \times 10^{-4} \text{ m}^2)}{25.0 \times 10^{-2} \text{ m}} \\ &= 1.81 \times 10^{-4} \text{ T}\cdot\text{m}^2/\text{A} = 0.181 \text{ mH} \end{aligned}$$

(b) Calculate the self-induced emf in the solenoid if the current through it is decreasing at the rate of  $50.0 \text{ A/s}$ .

**Solution** Using Equation 32.1 and given that  $dI/dt = -50.0 \text{ A/s}$ , we obtain

$$\begin{aligned} \mathcal{E}_L &= -L \frac{dI}{dt} = -(1.81 \times 10^{-4} \text{ H})(-50.0 \text{ A/s}) \\ &= 9.05 \text{ mV} \end{aligned}$$

## 32.2 RL CIRCUITS

 13.6 If a circuit contains a coil, such as a solenoid, the self-inductance of the coil prevents the current in the circuit from increasing or decreasing instantaneously. A circuit element that has a large self-inductance is called an **inductor** and has the circuit symbol . We always assume that the self-inductance of the remainder of a circuit is negligible compared with that of the inductor. Keep in mind, however, that even a circuit without a coil has some self-inductance that can affect the behavior of the circuit.

Because the inductance of the inductor results in a back emf, **an inductor in a circuit opposes changes in the current through that circuit.** If the battery voltage in the circuit is increased so that the current rises, the inductor opposes

this change, and the rise is not instantaneous. If the battery voltage is decreased, the presence of the inductor results in a slow drop in the current rather than an immediate drop. Thus, the inductor causes the circuit to be “sluggish” as it reacts to changes in the voltage.

### Quick Quiz 32.1

A switch controls the current in a circuit that has a large inductance. Is a spark more likely to be produced at the switch when the switch is being closed or when it is being opened, or doesn't it matter?

**Figure 32.3** A series  $RL$  circuit. As the current increases toward its maximum value, an emf that opposes the increasing current is induced in the inductor.

Consider the circuit shown in Figure 32.3, in which the battery has negligible internal resistance. This is an  **$RL$  circuit** because the elements connected to the battery are a resistor and an inductor. Suppose that the switch  $S$  is thrown closed at  $t = 0$ . The current in the circuit begins to increase, and a back emf that opposes the increasing current is induced in the inductor. The back emf is, from Equation 32.1,

$$\mathcal{E}_L = -L \frac{dI}{dt}$$

Because the current is increasing,  $dI/dt$  is positive; thus,  $\mathcal{E}_L$  is negative. This negative value reflects the decrease in electric potential that occurs in going from  $a$  to  $b$  across the inductor, as indicated by the positive and negative signs in Figure 32.3.

With this in mind, we can apply Kirchhoff's loop rule to this circuit, traversing the circuit in the clockwise direction:

$$\mathcal{E} - IR - L \frac{dI}{dt} = 0 \quad (32.6)$$

where  $IR$  is the voltage drop across the resistor. (We developed Kirchhoff's rules for circuits with steady currents, but we can apply them to a circuit in which the current is changing if we imagine them to represent the circuit at one *instant* of time.) We must now look for a solution to this differential equation, which is similar to that for the  $RC$  circuit (see Section 28.4).

A mathematical solution of Equation 32.6 represents the current in the circuit as a function of time. To find this solution, we change variables for convenience, letting  $x = \frac{\mathcal{E}}{R} - I$ , so that  $dx = -dI$ . With these substitutions, we can write Equation 32.6 as

$$x + \frac{L}{R} \frac{dx}{dt} = 0$$

$$\frac{dx}{x} = -\frac{R}{L} dt$$

Integrating this last expression, we have

$$\ln \frac{x}{x_0} = -\frac{R}{L} t$$

where we take the integrating constant to be  $-\ln x_0$  and  $x_0$  is the value of  $x$  at time  $t = 0$ . Taking the antilogarithm of this result, we obtain

$$x = x_0 e^{-Rt/L}$$

Because  $I = 0$  at  $t = 0$ , we note from the definition of  $x$  that  $x_0 = \mathcal{E}/R$ . Hence, this last expression is equivalent to

$$\begin{aligned}\frac{\mathcal{E}}{R} - I &= \frac{\mathcal{E}}{R} e^{-Rt/L} \\ I &= \frac{\mathcal{E}}{R} (1 - e^{-Rt/L})\end{aligned}$$

This expression shows the effect of the inductor. The current does not increase instantly to its final equilibrium value when the switch is closed but instead increases according to an exponential function. If we remove the inductance in the circuit, which we can do by letting  $L$  approach zero, the exponential term becomes zero and we see that there is no time dependence of the current in this case—the current increases instantaneously to its final equilibrium value in the absence of the inductance.

We can also write this expression as

$$I = \frac{\mathcal{E}}{R} (1 - e^{-t/\tau}) \quad (32.7)$$

where the constant  $\tau$  is the **time constant** of the  $RL$  circuit:

$$\tau = L/R \quad (32.8)$$

Physically,  $\tau$  is the time it takes the current in the circuit to reach  $(1 - e^{-1}) = 0.63$  of its final value  $\mathcal{E}/R$ . The time constant is a useful parameter for comparing the time responses of various circuits.

Figure 32.4 shows a graph of the current versus time in the  $RL$  circuit. Note that the equilibrium value of the current, which occurs as  $t$  approaches infinity, is  $\mathcal{E}/R$ . We can see this by setting  $dI/dt$  equal to zero in Equation 32.6 and solving for the current  $I$ . (At equilibrium, the change in the current is zero.) Thus, we see that the current initially increases very rapidly and then gradually approaches the equilibrium value  $\mathcal{E}/R$  as  $t$  approaches infinity.

Let us also investigate the time rate of change of the current in the circuit. Taking the first time derivative of Equation 32.7, we have

$$\frac{dI}{dt} = \frac{\mathcal{E}}{L} e^{-t/\tau} \quad (32.9)$$

From this result, we see that the time rate of change of the current is a maximum (equal to  $\mathcal{E}/L$ ) at  $t = 0$  and falls off exponentially to zero as  $t$  approaches infinity (Fig. 32.5).

Now let us consider the  $RL$  circuit shown in Figure 32.6. The circuit contains two switches that operate such that when one is closed, the other is opened. Suppose that  $S_1$  has been closed for a length of time sufficient to allow the current to reach its equilibrium value  $\mathcal{E}/R$ . In this situation, the circuit is described completely by the outer loop in Figure 32.6. If  $S_2$  is closed at the instant at which  $S_1$  is opened, the circuit changes so that it is described completely by just the upper loop in Figure 32.6. The lower loop no longer influences the behavior of the circuit. Thus, we have a circuit with no battery ( $\mathcal{E} = 0$ ). If we apply Kirchhoff's loop rule to the upper loop at the instant the switches are thrown, we obtain

$$IR + L \frac{dI}{dt} = 0$$

**Figure 32.4** Plot of the current versus time for the  $RL$  circuit shown in Figure 32.3. The switch is thrown closed at  $t = 0$ , and the current increases toward its maximum value  $\mathcal{E}/R$ . The time constant  $\tau$  is the time it takes  $I$  to reach 63% of its maximum value.

Time constant of an  $RL$  circuit

**Figure 32.5** Plot of  $dI/dt$  versus time for the  $RL$  circuit shown in Figure 32.3. The time rate of change of current is a maximum at  $t = 0$ , which is the instant at which the switch is thrown closed. The rate decreases exponentially with time as  $I$  increases toward its maximum value.

**Figure 32.6** An  $RL$  circuit containing two switches. When  $S_1$  is closed and  $S_2$  open as shown, the battery is in the circuit. At the instant  $S_2$  is closed,  $S_1$  is opened, and the battery is no longer part of the circuit.

**Figure 32.7** Current versus time for the upper loop of the circuit shown in Figure 32.6. For  $t < 0$ ,  $S_1$  is closed and  $S_2$  is open. At  $t = 0$ ,  $S_2$  is closed as  $S_1$  is opened, and the current has its maximum value  $\mathcal{E}/R$ .

It is left as a problem (Problem 18) to show that the solution of this differential equation is

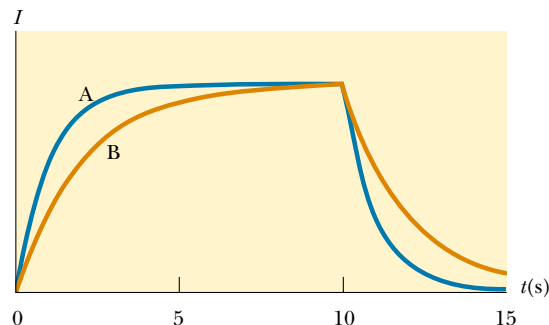

$$I = \frac{\mathcal{E}}{R} e^{-t/\tau} = I_0 e^{-t/\tau} \quad (32.10)$$

where  $\mathcal{E}$  is the emf of the battery and  $I_0 = \mathcal{E}/R$  is the current at  $t = 0$ , the instant at which  $S_2$  is closed as  $S_1$  is opened.

If no inductor were present in the circuit, the current would immediately decrease to zero if the battery were removed. When the inductor is present, it acts to oppose the decrease in the current and to maintain the current. A graph of the current in the circuit versus time (Fig. 32.7) shows that the current is continuously decreasing with time. Note that the slope  $dI/dt$  is always negative and has its maximum value at  $t = 0$ . The negative slope signifies that  $\mathcal{E}_L = -L(dI/dt)$  is now positive; that is, point  $a$  in Figure 32.6 is at a lower electric potential than point  $b$ .

### Quick Quiz 32.2

Two circuits like the one shown in Figure 32.6 are identical except for the value of  $L$ . In circuit A the inductance of the inductor is  $L_A$ , and in circuit B it is  $L_B$ . Switch  $S_1$  is thrown closed at  $t = 0$ , while switch  $S_2$  remains open. At  $t = 10$  s, switch  $S_1$  is opened and switch  $S_2$  is closed. The resulting time rates of change for the two currents are as graphed in Figure 32.8. If we assume that the time constant of each circuit is much less than 10 s, which of the following is true? (a)  $L_A > L_B$ ; (b)  $L_A < L_B$ ; (c) not enough information to tell.

**Figure 32.8**

**EXAMPLE 32.3** Time Constant of an *RL* Circuit

The switch in Figure 32.9a is thrown closed at  $t = 0$ . (a) Find the time constant of the circuit.

**Solution** The time constant is given by Equation 32.8:

$$\tau = \frac{L}{R} = \frac{30.0 \times 10^{-3} \text{ H}}{6.00 \Omega} = 5.00 \text{ ms}$$

(b) Calculate the current in the circuit at  $t = 2.00$  ms.

**Solution** Using Equation 32.7 for the current as a function of time (with  $t$  and  $\tau$  in milliseconds), we find that at  $t = 2.00$  ms

$$I = \frac{\mathcal{E}}{R} (1 - e^{-t/\tau}) = \frac{12.0 \text{ V}}{6.00 \Omega} (1 - e^{-0.400}) = 0.659 \text{ A}$$

**Figure 32.9** (a) The switch in this *RL* circuit is thrown closed at  $t = 0$ . (b) A graph of the current versus time for the circuit in part (a).

A plot of Equation 32.7 for this circuit is given in Figure 32.9b.

(c) Compare the potential difference across the resistor with that across the inductor.

**Solution** At the instant the switch is closed, there is no current and thus no potential difference across the resistor. At this instant, the battery voltage appears entirely across the inductor in the form of a back emf of 12.0 V as the inductor tries to maintain the zero-current condition. (The left end of the inductor is at a higher electric potential than the right end.) As time passes, the emf across the inductor decreases and the current through the resistor (and hence the potential difference across it) increases. The sum of the two potential differences at all times is 12.0 V, as shown in Figure 32.10.

**Exercise** Calculate the current in the circuit and the voltage across the resistor after a time interval equal to one time constant has elapsed.

**Answer** 1.26 A, 7.56 V.

**Figure 32.10** The sum of the potential differences across the resistor and inductor in Figure 32.9a is 12.0 V (the battery emf) at all times.

**32.3 ENERGY IN A MAGNETIC FIELD**

13.6 Because the emf induced in an inductor prevents a battery from establishing an instantaneous current, the battery must do work against the inductor to create a current. Part of the energy supplied by the battery appears as internal energy in the resistor, while the remaining energy is stored in the magnetic field of the inductor. If we multiply each term in Equation 32.6 by  $I$  and rearrange the expression, we have

$$I\mathcal{E} = I^2R + LI \frac{dI}{dt} \quad (32.11)$$

This expression indicates that the rate at which energy is supplied by the battery ( $I\mathcal{E}$ ) equals the sum of the rate at which energy is delivered to the resistor,  $I^2R$ , and the rate at which energy is stored in the inductor,  $LI(dI/dt)$ . Thus, Equation 32.11 is simply an expression of energy conservation. If we let  $U$  denote the energy stored in the inductor at any time, then we can write the rate  $dU/dt$  at which energy is stored as

$$\frac{dU}{dt} = LI \frac{dI}{dt}$$

To find the total energy stored in the inductor, we can rewrite this expression as  $dU = LI dI$  and integrate:

$$U = \int dU = \int_0^I LI dI = L \int_0^I I dI$$

Energy stored in an inductor

$$U = \frac{1}{2}LI^2 \quad (32.12)$$

where  $L$  is constant and has been removed from the integral. This expression represents the energy stored in the magnetic field of the inductor when the current is  $I$ . Note that this equation is similar in form to Equation 26.11 for the energy stored in the electric field of a capacitor,  $U = Q^2/2C$ . In either case, we see that energy is required to establish a field.

We can also determine the energy density of a magnetic field. For simplicity, consider a solenoid whose inductance is given by Equation 32.5:

$$L = \mu_0 n^2 A \ell$$

The magnetic field of a solenoid is given by Equation 30.17:

$$B = \mu_0 nI$$

Substituting the expression for  $L$  and  $I = B/\mu_0 n$  into Equation 32.12 gives

$$U = \frac{1}{2}LI^2 = \frac{1}{2}\mu_0 n^2 A \ell \left( \frac{B}{\mu_0 n} \right)^2 = \frac{B^2}{2\mu_0} A \ell \quad (32.13)$$

Because  $A\ell$  is the volume of the solenoid, the energy stored per unit volume in the magnetic field surrounding the inductor is

Magnetic energy density

$$u_B = \frac{U}{A\ell} = \frac{B^2}{2\mu_0} \quad (32.14)$$

Although this expression was derived for the special case of a solenoid, it is valid for any region of space in which a magnetic field exists. Note that Equation 32.14 is similar in form to Equation 26.13 for the energy per unit volume stored in an electric field,  $u_E = \frac{1}{2}\epsilon_0 E^2$ . In both cases, the energy density is proportional to the square of the magnitude of the field.

### EXAMPLE 32.4 What Happens to the Energy in the Inductor?

Consider once again the  $RL$  circuit shown in Figure 32.6, in which switch  $S_2$  is closed at the instant  $S_1$  is opened (at  $t = 0$ ). Recall that the current in the upper loop decays exponentially with time according to the expression  $I = I_0 e^{-t/\tau}$ ,

where  $I_0 = \mathcal{E}/R$  is the initial current in the circuit and  $\tau = L/R$  is the time constant. Show that all the energy initially stored in the magnetic field of the inductor appears as internal energy in the resistor as the current decays to zero.

**Solution** The rate  $dU/dt$  at which energy is delivered to the resistor (which is the power) is equal to  $I^2R$ , where  $I$  is the instantaneous current:

$$\frac{dU}{dt} = I^2R = (I_0 e^{-Rt/L})^2 R = I_0^2 R e^{-2Rt/L}$$

To find the total energy delivered to the resistor, we solve for  $dU$  and integrate this expression over the limits  $t = 0$  to  $t \rightarrow \infty$  (the upper limit is infinity because it takes an infinite amount of time for the current to reach zero):

$$(1) \quad U = \int_0^\infty I_0^2 R e^{-2Rt/L} dt = I_0^2 R \int_0^\infty e^{-2Rt/L} dt$$

The value of the definite integral is  $L/2R$  (this is left for the student to show in the exercise at the end of this example), and so  $U$  becomes

$$U = I_0^2 R \left( \frac{L}{2R} \right) = \frac{1}{2} L I_0^2$$

Note that this is equal to the initial energy stored in the magnetic field of the inductor, given by Equation 32.13, as we set out to prove.

**Exercise** Show that the integral on the right-hand side of Equation (1) has the value  $L/2R$ .

### EXAMPLE 32.5 The Coaxial Cable

Coaxial cables are often used to connect electrical devices, such as your stereo system and a loudspeaker. Model a long coaxial cable as consisting of two thin concentric cylindrical conducting shells of radii  $a$  and  $b$  and length  $\ell$ , as shown in Figure 32.11. The conducting shells carry the same current  $I$  in opposite directions. Imagine that the inner conductor carries current to a device and that the outer one acts as a return path carrying the current back to the source. (a) Calculate the self-inductance  $L$  of this cable.

**Solution** To obtain  $L$ , we must know the magnetic flux through any cross-section in the region between the two shells, such as the light blue rectangle in Figure 32.11. Am-

**Figure 32.11** Section of a long coaxial cable. The inner and outer conductors carry equal currents in opposite directions.

père's law (see Section 30.3) tells us that the magnetic field in the region between the shells is  $B = \mu_0 I / 2\pi r$ , where  $r$  is measured from the common center of the shells. The magnetic field is zero outside the outer shell ( $r > b$ ) because the net current through the area enclosed by a circular path surrounding the cable is zero, and hence from Ampère's law,  $\oint \mathbf{B} \cdot d\mathbf{s} = 0$ . The magnetic field is zero inside the inner shell because the shell is hollow and no current is present within a radius  $r < a$ .

The magnetic field is perpendicular to the light blue rectangle of length  $\ell$  and width  $b - a$ , the cross-section of interest. Because the magnetic field varies with radial position across this rectangle, we must use calculus to find the total magnetic flux. Dividing this rectangle into strips of width  $dr$ , such as the dark blue strip in Figure 32.11, we see that the area of each strip is  $\ell dr$  and that the flux through each strip is  $B dA = B \ell dr$ . Hence, we find the total flux through the entire cross-section by integrating:

$$\Phi_B = \int B dA = \int_a^b \frac{\mu_0 I}{2\pi r} \ell dr = \frac{\mu_0 I \ell}{2\pi} \int_a^b \frac{dr}{r} = \frac{\mu_0 I \ell}{2\pi} \ln\left(\frac{b}{a}\right)$$

Using this result, we find that the self-inductance of the cable is

$$L = \frac{\Phi_B}{I} = \frac{\mu_0 \ell}{2\pi} \ln\left(\frac{b}{a}\right)$$

(b) Calculate the total energy stored in the magnetic field of the cable.

**Solution** Using Equation 32.12 and the results to part (a) gives

$$U = \frac{1}{2} L I^2 = \frac{\mu_0 \ell I^2}{4\pi} \ln\left(\frac{b}{a}\right)$$

### 32.4 MUTUAL INDUCTANCE

Very often, the magnetic flux through the area enclosed by a circuit varies with time because of time-varying currents in nearby circuits. This condition induces an emf through a process known as *mutual induction*, so called because it depends on the interaction of two circuits.

Consider the two closely wound coils of wire shown in cross-sectional view in Figure 32.12. The current  $I_1$  in coil 1, which has  $N_1$  turns, creates magnetic field lines, some of which pass through coil 2, which has  $N_2$  turns. The magnetic flux caused by the current in coil 1 and passing through coil 2 is represented by  $\Phi_{12}$ . In analogy to Equation 32.2, we define the **mutual inductance**  $M_{12}$  of coil 2 with respect to coil 1:

Definition of mutual inductance

$$M_{12} \equiv \frac{N_2 \Phi_{12}}{I_1} \quad (32.15)$$

#### Quick Quiz 32.3

Referring to Figure 32.12, tell what happens to  $M_{12}$  (a) if coil 1 is brought closer to coil 2 and (b) if coil 1 is rotated so that it lies in the plane of the page.

Quick Quiz 32.3 demonstrates that mutual inductance depends on the geometry of both circuits and on their orientation with respect to each other. As the circuit separation distance increases, the mutual inductance decreases because the flux linking the circuits decreases.

If the current  $I_1$  varies with time, we see from Faraday's law and Equation 32.15 that the emf induced by coil 1 in coil 2 is

$$\mathcal{E}_2 = -N_2 \frac{d\Phi_{12}}{dt} = -N_2 \frac{d}{dt} \left( \frac{M_{12} I_1}{N_2} \right) = -M_{12} \frac{dI_1}{dt} \quad (32.16)$$

In the preceding discussion, we assumed that the source current is in coil 1. We can also imagine a source current  $I_2$  in coil 2. The preceding discussion can be repeated to show that there is a mutual inductance  $M_{21}$ . If the current  $I_2$  varies with time, the emf induced by coil 2 in coil 1 is

$$\mathcal{E}_1 = -M_{21} \frac{dI_2}{dt} \quad (32.17)$$

**In mutual induction, the emf induced in one coil is always proportional to the rate at which the current in the other coil is changing.** Although the

**Figure 32.12** A cross-sectional view of two adjacent coils. A current in coil 1 sets up a magnetic flux, part of which passes through coil 2.

proportionality constants  $M_{12}$  and  $M_{21}$  appear to have different values, it can be shown that they are equal. Thus, with  $M_{12} = M_{21} = M$ , Equations 32.16 and 32.17 become

$$\mathcal{E}_2 = -M \frac{dI_1}{dt} \quad \text{and} \quad \mathcal{E}_1 = -M \frac{dI_2}{dt}$$

These two equations are similar in form to Equation 32.1 for the self-induced emf  $\mathcal{E} = -L(dI/dt)$ . The unit of mutual inductance is the henry.

### Quick Quiz 32.4

(a) Can you have mutual inductance without self-inductance? (b) How about self-inductance without mutual inductance?

### QuickLab

Tune in to a relatively weak station on a radio. Now slowly rotate the radio about a vertical axis through its center. What happens to the reception? Can you explain this in terms of the mutual induction of the station's broadcast antenna and your radio's antenna?

### EXAMPLE 32.6 "Wireless" Battery Charger

An electric toothbrush has a base designed to hold the toothbrush handle when not in use. As shown in Figure 32.13a, the handle has a cylindrical hole that fits loosely over a matching cylinder on the base. When the handle is placed on the base, a changing current in a solenoid inside the base cylinder induces a current in a coil inside the handle. This induced current charges the battery in the handle.

We can model the base as a solenoid of length  $\ell$  with  $N_B$  turns (Fig. 32.13b), carrying a source current  $I$ , and having a cross-sectional area  $A$ . The handle coil contains  $N_H$  turns. Find the mutual inductance of the system.

(a)

(b)

**Figure 32.13** (a) This electric toothbrush uses the mutual induction of solenoids as part of its battery-charging system. (b) A coil of  $N_H$  turns wrapped around the center of a solenoid of  $N_B$  turns.

**Solution** Because the base solenoid carries a source current  $I$ , the magnetic field in its interior is

$$B = \frac{\mu_0 N_B I}{\ell}$$

Because the magnetic flux  $\Phi_{BH}$  through the handle's coil caused by the magnetic field of the base coil is  $BA$ , the mutual inductance is

$$M = \frac{N_H \Phi_{BH}}{I} = \frac{N_H B A}{I} = \mu_0 \frac{N_H N_B A}{\ell}$$

**Exercise** Calculate the mutual inductance of two solenoids with  $N_B = 1\,500$  turns,  $A = 1.0 \times 10^{-4} \text{ m}^2$ ,  $\ell = 0.02 \text{ m}$ , and  $N_H = 800$  turns.

**Answer** 7.5 mH.

### 32.5 OSCILLATIONS IN AN LC CIRCUIT

13.7

When a capacitor is connected to an inductor as illustrated in Figure 32.14, the combination is an **LC circuit**. If the capacitor is initially charged and the switch is then closed, both the current in the circuit and the charge on the capacitor oscillate between maximum positive and negative values. If the resistance of the circuit is zero, no energy is transformed to internal energy. In the following analysis, we neglect the resistance in the circuit. We also assume an idealized situation in which energy is not radiated away from the circuit. We shall discuss this radiation in Chapter 34, but we neglect it for now. With these idealizations—zero resistance and no radiation—the oscillations in the circuit persist indefinitely.

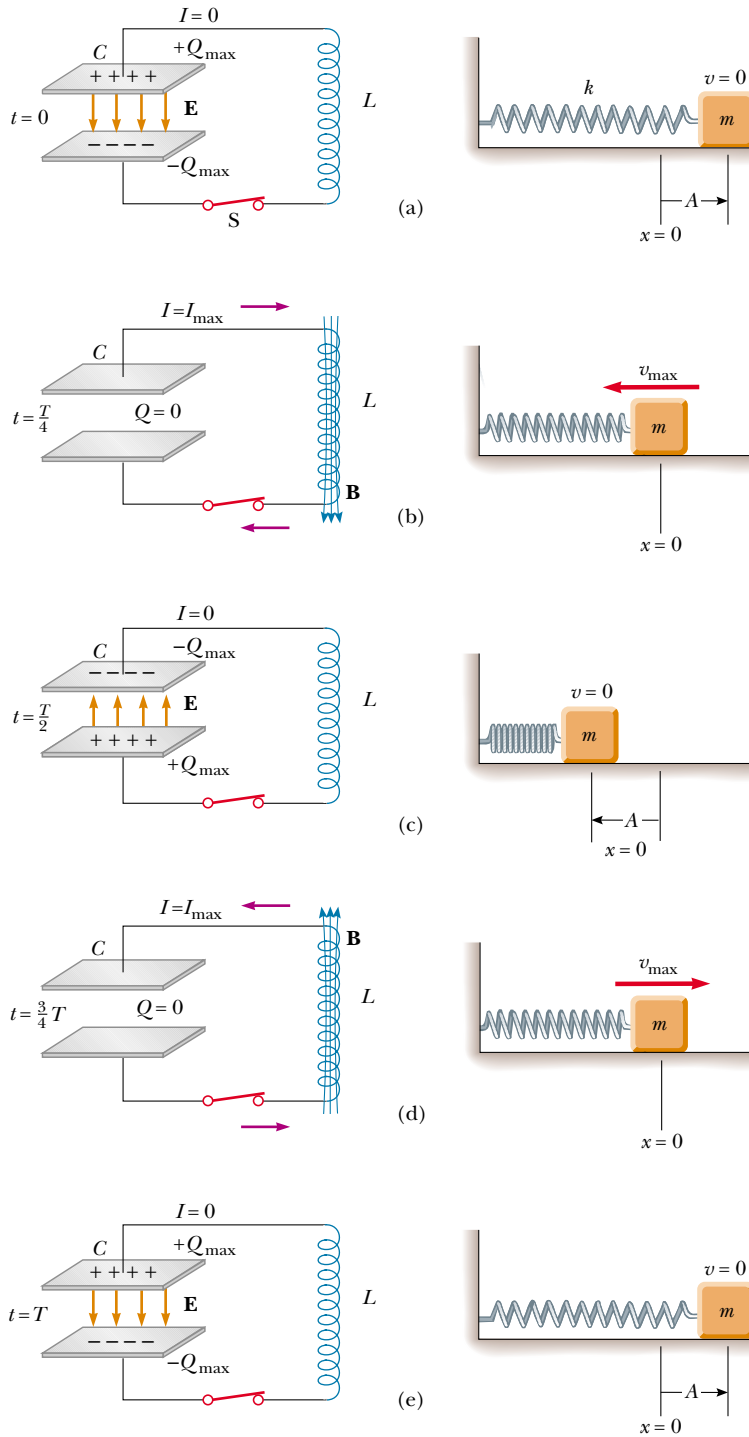

**Figure 32.14** A simple LC circuit. The capacitor has an initial charge  $Q_{\max}$ , and the switch is thrown closed at  $t = 0$ .

Assume that the capacitor has an initial charge  $Q_{\max}$  (the maximum charge) and that the switch is thrown closed at  $t = 0$ . Let us look at what happens from an energy viewpoint.

When the capacitor is fully charged, the energy  $U$  in the circuit is stored in the electric field of the capacitor and is equal to  $Q_{\max}^2/2C$  (Eq. 26.11). At this time, the current in the circuit is zero, and thus no energy is stored in the inductor. After the switch is thrown closed, the rate at which charges leave or enter the capacitor plates (which is also the rate at which the charge on the capacitor changes) is equal to the current in the circuit. As the capacitor begins to discharge after the switch is closed, the energy stored in its electric field decreases. The discharge of the capacitor represents a current in the circuit, and hence some energy is now stored in the magnetic field of the inductor. Thus, energy is transferred from the electric field of the capacitor to the magnetic field of the inductor. When the capacitor is fully discharged, it stores no energy. At this time, the current reaches its maximum value, and all of the energy is stored in the inductor. The current continues in the same direction, decreasing in magnitude, with the capacitor eventually becoming fully charged again but with the polarity of its plates now opposite the initial polarity. This is followed by another discharge until the circuit returns to its original state of maximum charge  $Q_{\max}$  and the plate polarity shown in Figure 32.14. The energy continues to oscillate between inductor and capacitor.

The oscillations of the LC circuit are an electromagnetic analog to the mechanical oscillations of a block–spring system, which we studied in Chapter 13. Much of what we discussed is applicable to LC oscillations. For example, we investigated the effect of driving a mechanical oscillator with an external force, which leads to the phenomenon of *resonance*. We observe the same phenomenon in the LC circuit. For example, a radio tuner has an LC circuit with a natural frequency, which we determine as follows: When the circuit is driven by the electromagnetic oscillations of a radio signal detected by the antenna, the tuner circuit responds with a large amplitude of electrical oscillation only for the station frequency that matches the natural frequency. Thus, only the signal from one station is passed on to the amplifier, even though signals from all stations are driving the circuit at the same time. When you turn the knob on the radio tuner to change the station, you are changing the natural frequency of the circuit so that it will exhibit a resonance response to a different driving frequency.

A graphical description of the energy transfer between the inductor and the capacitor in an LC circuit is shown in Figure 32.15. The right side of the figure shows the analogous energy transfer in the oscillating block–spring system studied in Chapter 13. In each case, the situation is shown at intervals of one-fourth the period of oscillation  $T$ . The potential energy  $\frac{1}{2}kx^2$  stored in a stretched spring is analogous to the electric potential energy  $Q_{\max}^2/2C$  stored in the capacitor. The kinetic energy  $\frac{1}{2}mv^2$  of the moving block is analogous to the magnetic energy  $\frac{1}{2}LI^2$

**Figure 32.15** Energy transfer in a resistanceless, non-radiating LC circuit. The capacitor has a charge  $Q_{\max}$  at  $t = 0$ , the instant at which the switch is thrown closed. The mechanical analog of this circuit is a block-spring system.

stored in the inductor, which requires the presence of moving charges. In Figure 32.15a, all of the energy is stored as electric potential energy in the capacitor at  $t = 0$ . In Figure 32.15b, which is one fourth of a period later, all of the energy is stored as magnetic energy  $\frac{1}{2}LI_{\max}^2$  in the inductor, where  $I_{\max}$  is the maximum current in the circuit. In Figure 32.15c, the energy in the  $LC$  circuit is stored completely in the capacitor, with the polarity of the plates now opposite what it was in Figure 32.15a. In parts d and e the system returns to the initial configuration over the second half of the cycle. At times other than those shown in the figure, part of the energy is stored in the electric field of the capacitor and part is stored in the magnetic field of the inductor. In the analogous mechanical oscillation, part of the energy is potential energy in the spring and part is kinetic energy of the block.

Let us consider some arbitrary time  $t$  after the switch is closed, so that the capacitor has a charge  $Q < Q_{\max}$  and the current is  $I < I_{\max}$ . At this time, both elements store energy, but the sum of the two energies must equal the total initial energy  $U$  stored in the fully charged capacitor at  $t = 0$ :

Total energy stored in an  $LC$  circuit

$$U = U_C + U_L = \frac{Q^2}{2C} + \frac{1}{2}LI^2 \quad (32.18)$$

Because we have assumed the circuit resistance to be zero, no energy is transformed to internal energy, and hence *the total energy must remain constant in time*. This means that  $dU/dt = 0$ . Therefore, by differentiating Equation 32.18 with respect to time while noting that  $Q$  and  $I$  vary with time, we obtain

The total energy in an ideal  $LC$  circuit remains constant;  $dU/dt = 0$

$$\frac{dU}{dt} = \frac{d}{dt} \left( \frac{Q^2}{2C} + \frac{1}{2}LI^2 \right) = \frac{Q}{C} \frac{dQ}{dt} + LI \frac{dI}{dt} = 0 \quad (32.19)$$

We can reduce this to a differential equation in one variable by remembering that the current in the circuit is equal to the rate at which the charge on the capacitor changes:  $I = dQ/dt$ . From this, it follows that  $dI/dt = d^2Q/dt^2$ . Substitution of these relationships into Equation 32.19 gives

$$\begin{aligned} \frac{Q}{C} + L \frac{d^2Q}{dt^2} &= 0 \\ \frac{d^2Q}{dt^2} &= -\frac{1}{LC} Q \end{aligned} \quad (32.20)$$

We can solve for  $Q$  by noting that this expression is of the same form as the analogous Equations 13.16 and 13.17 for a block–spring system:

$$\frac{d^2x}{dt^2} = -\frac{k}{m} x = -\omega^2 x$$

where  $k$  is the spring constant,  $m$  is the mass of the block, and  $\omega = \sqrt{k/m}$ . The solution of this equation has the general form

$$x = A \cos(\omega t + \phi)$$

where  $\omega$  is the angular frequency of the simple harmonic motion,  $A$  is the amplitude of motion (the maximum value of  $x$ ), and  $\phi$  is the phase constant; the values of  $A$  and  $\phi$  depend on the initial conditions. Because it is of the same form as the differential equation of the simple harmonic oscillator, we see that Equation 32.20 has the solution

Charge versus time for an ideal  $LC$  circuit

$$Q = Q_{\max} \cos(\omega t + \phi) \quad (32.21)$$

where  $Q_{\max}$  is the maximum charge of the capacitor and the angular frequency  $\omega$  is

$$\omega = \frac{1}{\sqrt{LC}} \quad (32.22)$$

Note that the angular frequency of the oscillations depends solely on the inductance and capacitance of the circuit. This is the *natural frequency* of oscillation of the LC circuit.

Because  $Q$  varies sinusoidally, the current in the circuit also varies sinusoidally. We can easily show this by differentiating Equation 32.21 with respect to time:

$$I = \frac{dQ}{dt} = -\omega Q_{\max} \sin(\omega t + \phi) \quad (32.23)$$

To determine the value of the phase angle  $\phi$ , we examine the initial conditions, which in our situation require that at  $t = 0$ ,  $I = 0$  and  $Q = Q_{\max}$ . Setting  $I = 0$  at  $t = 0$  in Equation 32.23, we have

$$0 = -\omega Q_{\max} \sin \phi$$

which shows that  $\phi = 0$ . This value for  $\phi$  also is consistent with Equation 32.21 and with the condition that  $Q = Q_{\max}$  at  $t = 0$ . Therefore, in our case, the expressions for  $Q$  and  $I$  are

$$Q = Q_{\max} \cos \omega t \quad (32.24)$$

$$I = -\omega Q_{\max} \sin \omega t = -I_{\max} \sin \omega t \quad (32.25)$$

Graphs of  $Q$  versus  $t$  and  $I$  versus  $t$  are shown in Figure 32.16. Note that the charge on the capacitor oscillates between the extreme values  $Q_{\max}$  and  $-Q_{\max}$ , and that the current oscillates between  $I_{\max}$  and  $-I_{\max}$ . Furthermore, the current is  $90^\circ$  out of phase with the charge. That is, when the charge is a maximum, the current is zero, and when the charge is zero, the current has its maximum value.

### Quick Quiz 32.5

What is the relationship between the amplitudes of the two curves in Figure 32.16?

Let us return to the energy discussion of the LC circuit. Substituting Equations 32.24 and 32.25 in Equation 32.18, we find that the total energy is

$$U = U_C + U_L = \frac{Q_{\max}^2}{2C} \cos^2 \omega t + \frac{LI_{\max}^2}{2} \sin^2 \omega t \quad (32.26)$$

This expression contains all of the features described qualitatively at the beginning of this section. It shows that the energy of the LC circuit continuously oscillates between energy stored in the electric field of the capacitor and energy stored in the magnetic field of the inductor. When the energy stored in the capacitor has its maximum value  $Q_{\max}^2/2C$ , the energy stored in the inductor is zero. When the energy stored in the inductor has its maximum value  $\frac{1}{2}LI_{\max}^2$ , the energy stored in the capacitor is zero.

Plots of the time variations of  $U_C$  and  $U_L$  are shown in Figure 32.17. The sum  $U_C + U_L$  is a constant and equal to the total energy  $Q_{\max}^2/2C$  or  $LI_{\max}^2/2$ . Analytical verification of this is straightforward. The amplitudes of the two graphs in Figure 32.17 must be equal because the maximum energy stored in the capacitor

Angular frequency of oscillation

Current versus time for an ideal LC circuit

**Figure 32.16** Graphs of charge versus time and current versus time for a resistanceless, nonradiating LC circuit. Note that  $Q$  and  $I$  are  $90^\circ$  out of phase with each other.

**Figure 32.17** Plots of  $U_C$  versus  $t$  and  $U_L$  versus  $t$  for a resistanceless, nonradiating LC circuit. The sum of the two curves is a constant and equal to the total energy stored in the circuit.

(when  $I = 0$ ) must equal the maximum energy stored in the inductor (when  $Q = 0$ ). This is mathematically expressed as

$$\frac{Q_{\max}^2}{2C} = \frac{LI_{\max}^2}{2}$$

Using this expression in Equation 32.26 for the total energy gives

$$U = \frac{Q_{\max}^2}{2C} (\cos^2 \omega t + \sin^2 \omega t) = \frac{Q_{\max}^2}{2C} \quad (32.27)$$

because  $\cos^2 \omega t + \sin^2 \omega t = 1$ .

In our idealized situation, the oscillations in the circuit persist indefinitely; however, we remember that the total energy  $U$  of the circuit remains constant only if energy transfers and transformations are neglected. In actual circuits, there is always some resistance, and hence energy is transformed to internal energy. We mentioned at the beginning of this section that we are also ignoring radiation from the circuit. In reality, radiation is inevitable in this type of circuit, and the total energy in the circuit continuously decreases as a result of this process.

### EXAMPLE 32.7 An Oscillatory LC Circuit

In Figure 32.18, the capacitor is initially charged when switch  $S_1$  is open and  $S_2$  is closed. Switch  $S_1$  is then thrown closed at the same instant that  $S_2$  is opened, so that the capacitor is connected directly across the inductor. (a) Find the frequency of oscillation of the circuit.

**Solution** Using Equation 32.22 gives for the frequency

$$\begin{aligned} f &= \frac{\omega}{2\pi} = \frac{1}{2\pi\sqrt{LC}} \\ &= \frac{1}{2\pi[(2.81 \times 10^{-3} \text{ H})(9.00 \times 10^{-12} \text{ F})]^{1/2}} \\ &= 1.00 \times 10^6 \text{ Hz} \end{aligned}$$

**Figure 32.18** First the capacitor is fully charged with the switch  $S_1$  open and  $S_2$  closed. Then,  $S_1$  is thrown closed at the same time that  $S_2$  is thrown open.

(b) What are the maximum values of charge on the capacitor and current in the circuit?

**Solution** The initial charge on the capacitor equals the maximum charge, and because  $C = Q/\mathcal{E}$ , we have

$$Q_{\max} = C\mathcal{E} = (9.00 \times 10^{-12} \text{ F})(12.0 \text{ V}) = 1.08 \times 10^{-10} \text{ C}$$

From Equation 32.25, we can see how the maximum current is related to the maximum charge:

$$\begin{aligned} I_{\max} &= \omega Q_{\max} = 2\pi f Q_{\max} \\ &= (2\pi \times 10^6 \text{ s}^{-1})(1.08 \times 10^{-10} \text{ C}) \\ &= 6.79 \times 10^{-4} \text{ A} \end{aligned}$$

(c) Determine the charge and current as functions of time.

**Solution** Equations 32.24 and 32.25 give the following expressions for the time variation of  $Q$  and  $I$ :

$$\begin{aligned} Q &= Q_{\max} \cos \omega t \\ &= (1.08 \times 10^{-10} \text{ C}) \cos[(2\pi \times 10^6 \text{ rad/s})t] \\ I &= -I_{\max} \sin \omega t \\ &= (-6.79 \times 10^{-4} \text{ A}) \sin[(2\pi \times 10^6 \text{ rad/s})t] \end{aligned}$$

**Exercise** What is the total energy stored in the circuit?

**Answer**  $6.48 \times 10^{-10} \text{ J}$ .

## Optional Section

## 32.6 THE RLC CIRCUIT

**13.7** We now turn our attention to a more realistic circuit consisting of an inductor, a capacitor, and a resistor connected in series, as shown in Figure 32.19. We let the resistance of the resistor represent all of the resistance in the circuit. We assume that the capacitor has an initial charge  $Q_{\max}$  before the switch is closed. Once the switch is thrown closed and a current is established, the total energy stored in the capacitor and inductor at any time is given, as before, by Equation 32.18. However, the total energy is no longer constant, as it was in the  $LC$  circuit, because the resistor causes transformation to internal energy. Because the rate of energy transformation to internal energy within a resistor is  $I^2R$ , we have

$$\frac{dU}{dt} = -I^2R$$

where the negative sign signifies that the energy  $U$  of the circuit is decreasing in time. Substituting this result into Equation 32.19 gives

$$LI \frac{dI}{dt} + \frac{Q}{C} \frac{dQ}{dt} = -I^2R \quad (32.28)$$

To convert this equation into a form that allows us to compare the electrical oscillations with their mechanical analog, we first use the fact that  $I = dQ/dt$  and move all terms to the left-hand side to obtain

$$LI \frac{d^2Q}{dt^2} + \frac{Q}{C} I + I^2R = 0$$

Now we divide through by  $I$ :

$$\begin{aligned} L \frac{d^2Q}{dt^2} + \frac{Q}{C} + IR &= 0 \\ L \frac{d^2Q}{dt^2} + R \frac{dQ}{dt} + \frac{Q}{C} &= 0 \end{aligned} \quad (32.29)$$

The  $RLC$  circuit is analogous to the damped harmonic oscillator discussed in Section 13.6 and illustrated in Figure 32.20. The equation of motion for this mechanical system is, from Equation 13.32,

$$m \frac{d^2x}{dt^2} + b \frac{dx}{dt} + kx = 0 \quad (32.30)$$

Comparing Equations 32.29 and 32.30, we see that  $Q$  corresponds to the position  $x$  of the block at any instant,  $L$  to the mass  $m$  of the block,  $R$  to the damping coefficient  $b$ , and  $C$  to  $1/k$ , where  $k$  is the force constant of the spring. These and other relationships are listed in Table 32.1.

Because the analytical solution of Equation 32.29 is cumbersome, we give only a qualitative description of the circuit behavior. In the simplest case, when  $R = 0$ , Equation 32.29 reduces to that of a simple  $LC$  circuit, as expected, and the charge and the current oscillate sinusoidally in time. This is equivalent to removal of all damping in the mechanical oscillator.

When  $R$  is small, a situation analogous to light damping in the mechanical oscillator, the solution of Equation 32.29 is

$$Q = Q_{\max} e^{-Rt/2L} \cos \omega_d t \quad (32.31)$$

**Figure 32.19** A series  $RLC$  circuit. The capacitor has a charge  $Q_{\max}$  at  $t = 0$ , the instant at which the switch is thrown closed.

**Figure 32.20** A block–spring system moving in a viscous medium with damped harmonic motion is analogous to an  $RLC$  circuit.

**TABLE 32.1** Analogies Between Electrical and Mechanical Systems

Electric Circuit		One-Dimensional Mechanical System
Charge	$Q \leftrightarrow x$	Displacement
Current	$I \leftrightarrow v_x$	Velocity
Potential difference	$\Delta V \leftrightarrow F_x$	Force
Resistance	$R \leftrightarrow b$	Viscous damping coefficient
Capacitance	$C \leftrightarrow 1/k$	( $k$ = spring constant)
Inductance	$L \leftrightarrow m$	Mass
Current = time derivative of charge	$I = \frac{dQ}{dt} \leftrightarrow v_x = \frac{dx}{dt}$	Velocity = time derivative of position
Rate of change of current = second time derivative of charge	$\frac{dI}{dt} = \frac{d^2Q}{dt^2} \leftrightarrow a_x = \frac{dv_x}{dt} = \frac{d^2x}{dt^2}$	Acceleration = second time derivative of position
Energy in inductor	$U_L = \frac{1}{2}LI^2 \leftrightarrow K = \frac{1}{2}mv^2$	Kinetic energy of moving mass
Energy in capacitor	$U_C = \frac{1}{2}\frac{Q^2}{C} \leftrightarrow U = \frac{1}{2}kx^2$	Potential energy stored in a spring
Rate of energy loss due to resistance	$I^2R \leftrightarrow bv^2$	Rate of energy loss due to friction
<i>RLC</i> circuit	$L\frac{d^2Q}{dt^2} + R\frac{dQ}{dt} + \frac{Q}{C} = 0 \leftrightarrow m\frac{d^2x}{dt^2} + b\frac{dx}{dt} + kx = 0$	Damped mass on a spring

where

$$\omega_d = \left[ \frac{1}{LC} - \left( \frac{R}{2L} \right)^2 \right]^{1/2} \quad (32.32)$$

is the angular frequency at which the circuit oscillates. That is, the value of the charge on the capacitor undergoes a damped harmonic oscillation in analogy with a mass–spring system moving in a viscous medium. From Equation 32.32, we see that, when  $R \ll \sqrt{4L/C}$  (so that the second term in the brackets is much smaller than the first), the frequency  $\omega_d$  of the damped oscillator is close to that of the undamped oscillator,  $1/\sqrt{LC}$ . Because  $I = dQ/dt$ , it follows that the current also undergoes damped harmonic oscillation. A plot of the charge versus time for the damped oscillator is shown in Figure 32.21a. Note that the maximum value of  $Q$  decreases after each oscillation, just as the amplitude of a damped block–spring system decreases in time.

### Quick Quiz 32.6

Figure 32.21a has two dashed blue lines that form an “envelope” around the curve. What is the equation for the upper dashed line?

When we consider larger values of  $R$ , we find that the oscillations damp out more rapidly; in fact, there exists a critical resistance value  $R_c = \sqrt{4L/C}$  above which no oscillations occur. A system with  $R = R_c$  is said to be *critically damped*. When  $R$  exceeds  $R_c$ , the system is said to be *overdamped* (Fig. 32.22).

**Figure 32.21** (a) Charge versus time for a damped  $RLC$  circuit. The charge decays in this way when  $R \ll \sqrt{4L/C}$ . The  $Q$ -versus- $t$  curve represents a plot of Equation 32.31. (b) Oscilloscope pattern showing the decay in the oscillations of an  $RLC$  circuit. The parameters used were  $R = 75 \Omega$ ,  $L = 10 \text{ mH}$ , and  $C = 0.19 \mu\text{F}$ .

**Figure 32.22** Plot of  $Q$  versus  $t$  for an overdamped  $RLC$  circuit, which occurs for values of  $R > \sqrt{4L/C}$ .

## SUMMARY

When the current in a coil changes with time, an emf is induced in the coil according to Faraday's law. The **self-induced emf** is

$$\mathcal{E}_L = -L \frac{dI}{dt} \quad (32.1)$$

where  $L$  is the **inductance** of the coil. Inductance is a measure of how much opposition an electrical device offers to a change in current passing through the device. Inductance has the SI unit of **henry** (H), where  $1 \text{ H} = 1 \text{ V} \cdot \text{s}/\text{A}$ .

The inductance of any coil is

$$L = \frac{N\Phi_B}{I} \quad (32.2)$$

where  $\Phi_B$  is the magnetic flux through the coil and  $N$  is the total number of turns. The inductance of a device depends on its geometry. For example, the inductance of an air-core solenoid is

$$L = \frac{\mu_0 N^2 A}{\ell} \quad (32.4)$$

where  $A$  is the cross-sectional area, and  $\ell$  is the length of the solenoid.

If a resistor and inductor are connected in series to a battery of emf  $\mathcal{E}$ , and if a switch in the circuit is thrown closed at  $t = 0$ , then the current in the circuit varies in time according to the expression

$$I = \frac{\mathcal{E}}{R} (1 - e^{-t/\tau}) \quad (32.7)$$

where  $\tau = L/R$  is the time constant of the  $RL$  circuit. That is, the current increases to an equilibrium value of  $\mathcal{E}/R$  after a time that is long compared with  $\tau$ . If the battery in the circuit is replaced by a resistanceless wire, the current decays exponentially with time according to the expression

$$I = \frac{\mathcal{E}}{R} e^{-t/\tau} \quad (32.10)$$

where  $\mathcal{E}/R$  is the initial current in the circuit.

The energy stored in the magnetic field of an inductor carrying a current  $I$  is

$$U = \frac{1}{2}LI^2 \quad (32.12)$$

This energy is the magnetic counterpart to the energy stored in the electric field of a charged capacitor.

The energy density at a point where the magnetic field is  $B$  is

$$u_B = \frac{B^2}{2\mu_0} \quad (32.14)$$

The mutual inductance of a system of two coils is given by

$$M_{12} = \frac{N_2\Phi_{12}}{I_1} = M_{21} = \frac{N_1\Phi_{21}}{I_2} = M \quad (32.15)$$

This mutual inductance allows us to relate the induced emf in a coil to the changing source current in a nearby coil using the relationships

$$\mathcal{E}_2 = -M_{12} \frac{dI_1}{dt} \quad \text{and} \quad \mathcal{E}_1 = -M_{21} \frac{dI_2}{dt} \quad (32.16, 32.17)$$

In an  $LC$  circuit that has zero resistance and does not radiate electromagnetically (an idealization), the values of the charge on the capacitor and the current in the circuit vary in time according to the expressions

$$Q = Q_{\max} \cos(\omega t + \phi) \quad (32.21)$$

$$I = \frac{dQ}{dt} = -\omega Q_{\max} \sin(\omega t + \phi) \quad (32.23)$$

where  $Q_{\max}$  is the maximum charge on the capacitor,  $\phi$  is a phase constant, and  $\omega$  is the angular frequency of oscillation:

$$\omega = \frac{1}{\sqrt{LC}} \quad (32.22)$$

The energy in an  $LC$  circuit continuously transfers between energy stored in the capacitor and energy stored in the inductor. The total energy of the  $LC$  circuit at any time  $t$  is

$$U = U_C + U_L = \frac{Q_{\max}^2}{2C} \cos^2 \omega t + \frac{LI_{\max}^2}{2} \sin^2 \omega t \quad (32.26)$$

At  $t = 0$ , all of the energy is stored in the electric field of the capacitor ( $U = Q_{\max}^2/2C$ ). Eventually, all of this energy is transferred to the inductor ( $U = LI_{\max}^2/2$ ). However, the total energy remains constant because energy transformations are neglected in the ideal  $LC$  circuit.

## QUESTIONS

- Why is the induced emf that appears in an inductor called a “counter” or “back” emf?
- The current in a circuit containing a coil, resistor, and battery reaches a constant value. Does the coil have an inductance? Does the coil affect the value of the current?
- What parameters affect the inductance of a coil? Does the inductance of a coil depend on the current in the coil?
- How can a long piece of wire be wound on a spool so that the wire has a negligible self-inductance?
- A long, fine wire is wound as a solenoid with a self-inductance  $L$ . If it is connected across the terminals of a battery, how does the maximum current depend on  $L$ ?
- For the series  $RL$  circuit shown in Figure Q32.6, can the back emf ever be greater than the battery emf? Explain.

Figure Q32.6

7. Consider this thesis: "Joseph Henry, America's first professional physicist, changed the view of the Universe during a school vacation at the Albany Academy in 1830. Before that time, one could think of the Universe as consisting of just one thing: matter. In Henry's experiment, after a battery is removed from a coil, the energy that keeps the current flowing for a while does not belong to any piece of matter. This energy belongs to the magnetic field surrounding the coil. With Henry's discovery of self-induction, Nature forced us to admit that the Universe consists of fields as well as matter." What in your view constitutes the Universe? Argue for your answer.

8. Discuss the similarities and differences between the energy stored in the electric field of a charged capacitor and the energy stored in the magnetic field of a current-carrying coil.
9. What is the inductance of two inductors connected in series? Does it matter if they are solenoids or toroids?
10. The centers of two circular loops are separated by a fixed distance. For what relative orientation of the loops is their mutual inductance a maximum? a minimum? Explain.
11. Two solenoids are connected in series so that each carries the same current at any instant. Is mutual induction present? Explain.
12. In the  $LC$  circuit shown in Figure 32.15, the charge on the capacitor is sometimes zero, even though current is in the circuit. How is this possible?
13. If the resistance of the wires in an  $LC$  circuit were not zero, would the oscillations persist? Explain.
14. How can you tell whether an  $RLC$  circuit is overdamped or underdamped?
15. What is the significance of critical damping in an  $RLC$  circuit?
16. Can an object exert a force on itself? When a coil induces an emf in itself, does it exert a force on itself?

## PROBLEMS

1, 2, 3 = straightforward, intermediate, challenging  = full solution available in the *Student Solutions Manual and Study Guide*

WEB = solution posted at <http://www.saunderscollege.com/physics/> = Computer useful in solving problem = Interactive Physics

= paired numerical/symbolic problems

### Section 32.1 Self-Inductance

1. A coil has an inductance of 3.00 mH, and the current through it changes from 0.200 A to 1.50 A in a time of 0.200 s. Find the magnitude of the average induced emf in the coil during this time.
2. A coiled telephone cord forms a spiral with 70 turns, a diameter of 1.30 cm, and an unstretched length of 60.0 cm. Determine the self-inductance of one conductor in the unstretched cord.
3. A 2.00-H inductor carries a steady current of 0.500 A. When the switch in the circuit is thrown open, the current is effectively zero in 10.0 ms. What is the average induced emf in the inductor during this time?
4. A small air-core solenoid has a length of 4.00 cm and a radius of 0.250 cm. If the inductance is to be 0.0600 mH, how many turns per centimeter are required?
5. Calculate the magnetic flux through the area enclosed by a 300-turn, 7.20-mH coil when the current in the coil is 10.0 mA.
6. The current in a solenoid is increasing at a rate of 10.0 A/s. The cross-sectional area of the solenoid is  $\pi$  cm<sup>2</sup>, and there are 300 turns on its 15.0-cm length. What is the induced emf opposing the increasing current?

- WEB 7. A 10.0-mH inductor carries a current  $I = I_{\max} \sin \omega t$ , with  $I_{\max} = 5.00$  A and  $\omega/2\pi = 60.0$  Hz. What is the back emf as a function of time?
8. An emf of 24.0 mV is induced in a 500-turn coil at an instant when the current is 4.00 A and is changing at the rate of 10.0 A/s. What is the magnetic flux through each turn of the coil?
  9. An inductor in the form of a solenoid contains 420 turns, is 16.0 cm in length, and has a cross-sectional area of 3.00 cm<sup>2</sup>. What uniform rate of decrease of current through the inductor induces an emf of 175  $\mu$ V?
  10. An inductor in the form of a solenoid contains  $N$  turns, has length  $\ell$ , and has cross-sectional area  $A$ . What uniform rate of decrease of current through the inductor induces an emf  $\mathcal{E}$ ?
  11. The current in a 90.0-mH inductor changes with time as  $I = t^2 - 6.00t$  (in SI units). Find the magnitude of the induced emf at (a)  $t = 1.00$  s and (b)  $t = 4.00$  s. (c) At what time is the emf zero?
  12. A 40.0-mA current is carried by a uniformly wound air-core solenoid with 450 turns, a 15.0-mm diameter, and 12.0-cm length. Compute (a) the magnetic field inside the solenoid, (b) the magnetic flux through each turn,

and (c) the inductance of the solenoid. (d) Which of these quantities depends on the current?

13. A solenoid has 120 turns uniformly wrapped around a wooden core, which has a diameter of 10.0 mm and a length of 9.00 cm. (a) Calculate the inductance of the solenoid. (b) The wooden core is replaced with a soft iron rod that has the same dimensions but a magnetic permeability  $\mu_m = 800\mu_0$ . What is the new inductance?
14. A toroid has a major radius  $R$  and a minor radius  $r$ , and it is tightly wound with  $N$  turns of wire, as shown in Figure P32.14. If  $R \gg r$ , the magnetic field within the region of the torus, of cross-sectional area  $A = \pi r^2$ , is essentially that of a long solenoid that has been bent into a large circle of radius  $R$ . Using the uniform field of a long solenoid, show that the self-inductance of such a toroid is approximately

$$L \cong \mu_0 N^2 A / 2\pi R$$

(An exact expression for the inductance of a toroid with a rectangular cross-section is derived in Problem 64.)

Figure P32.14

15. An emf self-induced in a solenoid of inductance  $L$  changes in time as  $\mathcal{E} = \mathcal{E}_0 e^{-kt}$ . Find the total charge that passes through the solenoid, if the charge is finite.

### Section 32.2 RL Circuits

16. Calculate the resistance in an  $RL$  circuit in which  $L = 2.50$  H and the current increases to 90.0% of its final value in 3.00 s.
17. A 12.0-V battery is connected into a series circuit containing a 10.0- $\Omega$  resistor and a 2.00-H inductor. How long will it take the current to reach (a) 50.0% and (b) 90.0% of its final value?
18. Show that  $I = I_0 e^{-t/\tau}$  is a solution of the differential equation

$$IR + L \frac{dI}{dt} = 0$$

where  $\tau = L/R$  and  $I_0$  is the current at  $t = 0$ .

19. Consider the circuit in Figure P32.19, taking  $\mathcal{E} = 6.00$  V,  $L = 8.00$  mH, and  $R = 4.00$   $\Omega$ . (a) What is

the inductive time constant of the circuit? (b) Calculate the current in the circuit 250  $\mu$ s after the switch is closed. (c) What is the value of the final steady-state current? (d) How long does it take the current to reach 80.0% of its maximum value?

Figure P32.19 Problems 19, 20, 21, and 24.

20. In the circuit shown in Figure P32.19, let  $L = 7.00$  H,  $R = 9.00$   $\Omega$ , and  $\mathcal{E} = 120$  V. What is the self-induced emf 0.200 s after the switch is closed?
21. For the  $RL$  circuit shown in Figure P32.19, let  $L = 3.00$  H,  $R = 8.00$   $\Omega$ , and  $\mathcal{E} = 36.0$  V. (a) Calculate the ratio of the potential difference across the resistor to that across the inductor when  $I = 2.00$  A. (b) Calculate the voltage across the inductor when  $I = 4.50$  A.
22. A 12.0-V battery is connected in series with a resistor and an inductor. The circuit has a time constant of 500  $\mu$ s, and the maximum current is 200 mA. What is the value of the inductance?
23. An inductor that has an inductance of 15.0 H and a resistance of 30.0  $\Omega$  is connected across a 100-V battery. What is the rate of increase of the current (a) at  $t = 0$  and (b) at  $t = 1.50$  s?
24. When the switch in Figure P32.19 is thrown closed, the current takes 3.00 ms to reach 98.0% of its final value. If  $R = 10.0$   $\Omega$ , what is the inductance?
25. The switch in Figure P32.25 is closed at time  $t = 0$ . Find the current in the inductor and the current through the switch as functions of time thereafter.

Figure P32.25

26. A series  $RL$  circuit with  $L = 3.00$  H and a series  $RC$  circuit with  $C = 3.00$   $\mu$ F have equal time constants. If the two circuits contain the same resistance  $R$ , (a) what is the value of  $R$  and (b) what is the time constant?

27. A current pulse is fed to the partial circuit shown in Figure P32.27. The current begins at zero, then becomes 10.0 A between  $t = 0$  and  $t = 200 \mu\text{s}$ , and then is zero once again. Determine the current in the inductor as a function of time.

Figure P32.27

28. One application of an  $RL$  circuit is the generation of time-varying high voltage from a low-voltage source, as shown in Figure P32.28. (a) What is the current in the circuit a long time after the switch has been in position A? (b) Now the switch is thrown quickly from A to B. Compute the initial voltage across each resistor and the inductor. (c) How much time elapses before the voltage across the inductor drops to 12.0 V?

Figure P32.28

- WEB 29. A 140-mH inductor and a 4.90- $\Omega$  resistor are connected with a switch to a 6.00-V battery, as shown in Figure P32.29. (a) If the switch is thrown to the left (connecting the battery), how much time elapses before the current reaches 220 mA? (b) What is the current in the inductor 10.0 s after the switch is closed? (c) Now the switch is quickly thrown from A to B. How much time elapses before the current falls to 160 mA?
30. Consider two ideal inductors,  $L_1$  and  $L_2$ , that have zero internal resistance and are far apart, so that their magnetic fields do not influence each other. (a) If these inductors are connected in series, show that they are equivalent to a single ideal inductor having  $L_{\text{eq}} = L_1 + L_2$ . (b) If these same two inductors are connected in parallel, show that they are equivalent to a

Figure P32.29

single ideal inductor having  $1/L_{\text{eq}} = 1/L_1 + 1/L_2$ . (c) Now consider two inductors  $L_1$  and  $L_2$  that have nonzero internal resistances  $R_1$  and  $R_2$ , respectively. Assume that they are still far apart so that their magnetic fields do not influence each other. If these inductors are connected in series, show that they are equivalent to a single inductor having  $L_{\text{eq}} = L_1 + L_2$  and  $R_{\text{eq}} = R_1 + R_2$ . (d) If these same inductors are now connected in parallel, is it necessarily true that they are equivalent to a single ideal inductor having  $1/L_{\text{eq}} = 1/L_1 + 1/L_2$  and  $1/R_{\text{eq}} = 1/R_1 + 1/R_2$ ? Explain your answer.

### Section 32.3 Energy in a Magnetic Field

31. Calculate the energy associated with the magnetic field of a 200-turn solenoid in which a current of 1.75 A produces a flux of  $3.70 \times 10^{-4} \text{ T} \cdot \text{m}^2$  in each turn.
32. The magnetic field inside a superconducting solenoid is 4.50 T. The solenoid has an inner diameter of 6.20 cm and a length of 26.0 cm. Determine (a) the magnetic energy density in the field and (b) the energy stored in the magnetic field within the solenoid.
33. An air-core solenoid with 68 turns is 8.00 cm long and has a diameter of 1.20 cm. How much energy is stored in its magnetic field when it carries a current of 0.770 A?
34. At  $t = 0$ , an emf of 500 V is applied to a coil that has an inductance of 0.800 H and a resistance of 30.0  $\Omega$ . (a) Find the energy stored in the magnetic field when the current reaches half its maximum value. (b) After the emf is connected, how long does it take the current to reach this value?
- WEB 35. On a clear day there is a 100-V/m vertical electric field near the Earth's surface. At the same place, the Earth's magnetic field has a magnitude of  $0.500 \times 10^{-4} \text{ T}$ . Compute the energy densities of the two fields.
36. An  $RL$  circuit in which  $L = 4.00 \text{ H}$  and  $R = 5.00 \Omega$  is connected to a 22.0-V battery at  $t = 0$ . (a) What energy is stored in the inductor when the current is 0.500 A? (b) At what rate is energy being stored in the inductor when  $I = 1.00 \text{ A}$ ? (c) What power is being delivered to the circuit by the battery when  $I = 0.500 \text{ A}$ ?
37. A 10.0-V battery, a 5.00- $\Omega$  resistor, and a 10.0-H inductor are connected in series. After the current in the circuit

has reached its maximum value, calculate (a) the power being supplied by the battery, (b) the power being delivered to the resistor, (c) the power being delivered to the inductor, and (d) the energy stored in the magnetic field of the inductor.

38. A uniform electric field with a magnitude of 680 kV/m throughout a cylindrical volume results in a total energy of 3.40  $\mu\text{J}$ . What magnetic field over this same region stores the same total energy?
39. Assume that the magnitude of the magnetic field outside a sphere of radius  $R$  is  $B = B_0(R/r)^2$ , where  $B_0$  is a constant. Determine the total energy stored in the magnetic field outside the sphere and evaluate your result for  $B_0 = 5.00 \times 10^{-5} \text{ T}$  and  $R = 6.00 \times 10^6 \text{ m}$ , values appropriate for the Earth's magnetic field.

### Section 32.4 Mutual Inductance

40. Two coils are close to each other. The first coil carries a time-varying current given by  $I(t) = (5.00 \text{ A}) e^{-0.025 0t} \sin(377t)$ . At  $t = 0.800 \text{ s}$ , the voltage measured across the second coil is  $-3.20 \text{ V}$ . What is the mutual inductance of the coils?
41. Two coils, held in fixed positions, have a mutual inductance of 100  $\mu\text{H}$ . What is the peak voltage in one when a sinusoidal current given by  $I(t) = (10.0 \text{ A}) \sin(1000t)$  flows in the other?
42. An emf of 96.0 mV is induced in the windings of a coil when the current in a nearby coil is increasing at the rate of 1.20 A/s. What is the mutual inductance of the two coils?
43. Two solenoids A and B, spaced close to each other and sharing the same cylindrical axis, have 400 and 700 turns, respectively. A current of 3.50 A in coil A produces an average flux of 300  $\mu\text{T} \cdot \text{m}^2$  through each turn of A and a flux of 90.0  $\mu\text{T} \cdot \text{m}^2$  through each turn of B. (a) Calculate the mutual inductance of the two solenoids. (b) What is the self-inductance of A? (c) What emf is induced in B when the current in A increases at the rate of 0.500 A/s?
44. A 70-turn solenoid is 5.00 cm long and 1.00 cm in diameter and carries a 2.00-A current. A single loop of wire, 3.00 cm in diameter, is held so that the plane of the loop is perpendicular to the long axis of the solenoid, as illustrated in Figure P31.18 (page 1004). What is the mutual inductance of the two if the plane of the loop passes through the solenoid 2.50 cm from one end?
45. Two single-turn circular loops of wire have radii  $R$  and  $r$ , with  $R \gg r$ . The loops lie in the same plane and are concentric. (a) Show that the mutual inductance of the pair is  $M = \mu_0 \pi r^2 / 2R$ . (*Hint:* Assume that the larger loop carries a current  $I$  and compute the resulting flux through the smaller loop.) (b) Evaluate  $M$  for  $r = 2.00 \text{ cm}$  and  $R = 20.0 \text{ cm}$ .
46. On a printed circuit board, a relatively long straight conductor and a conducting rectangular loop lie in the same plane, as shown in Figure P31.9 (page 1003). If

$h = 0.400 \text{ mm}$ ,  $w = 1.30 \text{ mm}$ , and  $L = 2.70 \text{ mm}$ , what is their mutual inductance?

47. Two inductors having self-inductances  $L_1$  and  $L_2$  are connected in parallel, as shown in Figure P32.47a. The mutual inductance between the two inductors is  $M$ . Determine the equivalent self-inductance  $L_{\text{eq}}$  for the system (Fig. P32.47b).

Figure P32.47

### Section 32.5 Oscillations in an LC Circuit

48. A 1.00- $\mu\text{F}$  capacitor is charged by a 40.0-V power supply. The fully-charged capacitor is then discharged through a 10.0-mH inductor. Find the maximum current in the resulting oscillations.
49. An LC circuit consists of a 20.0-mH inductor and a 0.500- $\mu\text{F}$  capacitor. If the maximum instantaneous current is 0.100 A, what is the greatest potential difference across the capacitor?
50. In the circuit shown in Figure P32.50,  $\mathcal{E} = 50.0 \text{ V}$ ,  $R = 250 \Omega$ , and  $C = 0.500 \mu\text{F}$ . The switch S is closed for a long time, and no voltage is measured across the capacitor. After the switch is opened, the voltage across the capacitor reaches a maximum value of 150 V. What is the inductance  $L$ ?

Figure P32.50

51. A fixed inductance  $L = 1.05 \mu\text{H}$  is used in series with a variable capacitor in the tuning section of a radio. What capacitance tunes the circuit to the signal from a station broadcasting at 6.30 MHz?
52. Calculate the inductance of an LC circuit that oscillates at 120 Hz when the capacitance is 8.00  $\mu\text{F}$ .
53. An LC circuit like the one shown in Figure 32.14 contains an 82.0-mH inductor and a 17.0- $\mu\text{F}$  capacitor that initially carries a 180- $\mu\text{C}$  charge. The switch is thrown closed at  $t = 0$ . (a) Find the frequency (in hertz) of the resulting oscillations. At  $t = 1.00 \text{ ms}$ , find (b) the charge on the capacitor and (c) the current in the circuit.

54. The switch in Figure P32.54 is connected to point *a* for a long time. After the switch is thrown to point *b*, what are (a) the frequency of oscillation of the *LC* circuit, (b) the maximum charge that appears on the capacitor, (c) the maximum current in the inductor, and (d) the total energy the circuit possesses at  $t = 3.00$  s?

Figure P32.54

- WEB 55. An *LC* circuit like that illustrated in Figure 32.14 consists of a 3.30-H inductor and an 840-pF capacitor, initially carrying a  $105\text{-}\mu\text{C}$  charge. At  $t = 0$  the switch is thrown closed. Compute the following quantities at  $t = 2.00$  ms: (a) the energy stored in the capacitor; (b) the energy stored in the inductor; (c) the total energy in the circuit.

(Optional)

### Section 32.6 The RLC Circuit

56. In Figure 32.19, let  $R = 7.60\ \Omega$ ,  $L = 2.20$  mH, and  $C = 1.80\ \mu\text{F}$ . (a) Calculate the frequency of the damped oscillation of the circuit. (b) What is the critical resistance?
57. Consider an *LC* circuit in which  $L = 500$  mH and  $C = 0.100\ \mu\text{F}$ . (a) What is the resonant frequency  $\omega_0$ ? (b) If a resistance of  $1.00\ \text{k}\Omega$  is introduced into this circuit, what is the frequency of the (damped) oscillations? (c) What is the percent difference between the two frequencies?
58. Show that Equation 32.29 in the text is Kirchhoff's loop rule as applied to Figure 32.19.
59. Electrical oscillations are initiated in a series circuit containing a capacitance  $C$ , inductance  $L$ , and resistance  $R$ . (a) If  $R \ll \sqrt{4L/C}$  (weak damping), how much time elapses before the amplitude of the current oscillation falls off to 50.0% of its initial value? (b) How long does it take the energy to decrease to 50.0% of its initial value?

### ADDITIONAL PROBLEMS

60. Initially, the capacitor in a series *LC* circuit is charged. A switch is closed, allowing the capacitor to discharge, and after time  $t$  the energy stored in the capacitor is one-fourth its initial value. Determine  $L$  if  $C$  is known.
61. A 1.00-mH inductor and a  $1.00\text{-}\mu\text{F}$  capacitor are connected in series. The current in the circuit is described by  $I = 20.0t$ , where  $t$  is in seconds and  $I$  is in amperes.

The capacitor initially has no charge. Determine (a) the voltage across the inductor as a function of time, (b) the voltage across the capacitor as a function of time, and (c) the time when the energy stored in the capacitor first exceeds that in the inductor.

62. An inductor having inductance  $L$  and a capacitor having capacitance  $C$  are connected in series. The current in the circuit increases linearly in time as described by  $I = Kt$ . The capacitor is initially uncharged. Determine (a) the voltage across the inductor as a function of time, (b) the voltage across the capacitor as a function of time, and (c) the time when the energy stored in the capacitor first exceeds that in the inductor.
63. A capacitor in a series *LC* circuit has an initial charge  $Q$  and is being discharged. Find, in terms of  $L$  and  $C$ , the flux through each of the  $N$  turns in the coil, when the charge on the capacitor is  $Q/2$ .
64. The toroid in Figure P32.64 consists of  $N$  turns and has a rectangular cross-section. Its inner and outer radii are  $a$  and  $b$ , respectively. (a) Show that

$$L = \frac{\mu_0 N^2 h}{2\pi} \ln \frac{b}{a}$$

(b) Using this result, compute the self-inductance of a 500-turn toroid for which  $a = 10.0$  cm,  $b = 12.0$  cm, and  $h = 1.00$  cm. (c) In Problem 14, an approximate formula for the inductance of a toroid with  $R \gg r$  was derived. To get a feel for the accuracy of that result, use the expression in Problem 14 to compute the approximate inductance of the toroid described in part (b). Compare the result with the answer to part (b).

Figure P32.64

65. (a) A flat circular coil does not really produce a uniform magnetic field in the area it encloses, but estimate the self-inductance of a flat circular coil, with radius  $R$  and  $N$  turns, by supposing that the field at its center is uniform over its area. (b) A circuit on a laboratory table consists of a 1.5-V battery, a  $270\text{-}\Omega$  resistor, a switch, and three 30-cm-long cords connecting them. Suppose that the circuit is arranged to be circular. Think of it as a flat coil with one turn. Compute the order of magnitude of its self-inductance and (c) of the time constant describing how fast the current increases when you close the switch.
66. A soft iron rod ( $\mu_m = 800\ \mu_0$ ) is used as the core of a solenoid. The rod has a diameter of 24.0 mm and is

10.0 cm long. A 10.0-m piece of 22-gauge copper wire (diameter = 0.644 mm) is wrapped around the rod in a single uniform layer, except for a 10.0-cm length at each end, which is to be used for connections. (a) How many turns of this wire can wrap around the rod? (*Hint:* The diameter of the wire adds to the diameter of the rod in determining the circumference of each turn. Also, the wire spirals diagonally along the surface of the rod.) (b) What is the resistance of this inductor? (c) What is its inductance?

67. A wire of nonmagnetic material with radius  $R$  carries current uniformly distributed over its cross-section. If the total current carried by the wire is  $I$ , show that the magnetic energy per unit length inside the wire is  $\mu_0 I^2 / 16\pi$ .
68. An 820-turn wire coil of resistance  $24.0 \Omega$  is placed around a 12 500-turn solenoid, 7.00 cm long, as shown in Figure P32.68. Both coil and solenoid have cross-sectional areas of  $1.00 \times 10^{-4} \text{ m}^2$ . (a) How long does it take the solenoid current to reach 63.2 percent of its maximum value? Determine (b) the average back emf caused by the self-inductance of the solenoid during this interval, (c) the average rate of change in magnetic flux through the coil during this interval, and (d) the magnitude of the average induced current in the coil.

Figure P32.68

69. At  $t = 0$ , the switch in Figure P32.69 is thrown closed. Using Kirchhoff's laws for the instantaneous currents and voltages in this two-loop circuit, show that the current in the inductor is

$$I(t) = \frac{\mathcal{E}}{R_1} [1 - e^{-(R'/L)t}]$$

where  $R' = R_1 R_2 / (R_1 + R_2)$ .

70. In Figure P32.69, take  $\mathcal{E} = 6.00 \text{ V}$ ,  $R_1 = 5.00 \Omega$ , and  $R_2 = 1.00 \Omega$ . The inductor has negligible resistance. When the switch is thrown open after having been

Figure P32.69 Problems 69 and 70.

closed for a long time, the current in the inductor drops to 0.250 A in 0.150 s. What is the inductance of the inductor?

71. In Figure P32.71, the switch is closed for  $t < 0$ , and steady-state conditions are established. The switch is thrown open at  $t = 0$ . (a) Find the initial voltage  $\mathcal{E}_0$  across  $L$  just after  $t = 0$ . Which end of the coil is at the higher potential:  $a$  or  $b$ ? (b) Make freehand graphs of the currents in  $R_1$  and in  $R_2$  as a function of time, treating the steady-state directions as positive. Show values before and after  $t = 0$ . (c) How long after  $t = 0$  does the current in  $R_2$  have the value 2.00 mA?

Figure P32.71

72. The switch in Figure P32.72 is thrown closed at  $t = 0$ . Before the switch is closed, the capacitor is uncharged, and all currents are zero. Determine the currents in  $L$ ,  $C$ , and  $R$  and the potential differences across  $L$ ,  $C$ , and  $R$  (a) the instant after the switch is closed and (b) long after it is closed.

Figure P32.72

- 73.** To prevent damage from arcing in an electric motor, a discharge resistor is sometimes placed in parallel with the armature. If the motor is suddenly unplugged while running, this resistor limits the voltage that appears across the armature coils. Consider a 12.0-V dc motor with an armature that has a resistance of  $7.50\ \Omega$  and an inductance of 450 mH. Assume that the back emf in the armature coils is 10.0 V when the motor is running at normal speed. (The equivalent circuit for the armature is shown in Fig. P32.73.) Calculate the maximum resistance  $R$  that limits the voltage across the armature to 80.0 V when the motor is unplugged.

**Figure P32.73**

- 74.** An air-core solenoid 0.500 m in length contains 1 000 turns and has a cross-sectional area of  $1.00\ \text{cm}^2$ . (a) If end effects are neglected, what is the self-inductance? (b) A secondary winding wrapped around the center of the solenoid has 100 turns. What is the mutual inductance? (c) The secondary winding carries a constant current of 1.00 A, and the solenoid is connected to a load of  $1.00\ \text{k}\Omega$ . The constant current is suddenly stopped. How much charge flows through the load resistor?
- 75.** The lead-in wires from a television antenna are often constructed in the form of two parallel wires (Fig. P32.75). (a) Why does this configuration of conductors have an inductance? (b) What constitutes the flux loop for this configuration? (c) Neglecting any magnetic flux inside the wires, show that the inductance of a length  $x$

**Figure P32.75**

of this type of lead-in is

$$L = \frac{\mu_0 x}{\pi} \ln\left(\frac{w - a}{a}\right)$$

where  $a$  is the radius of the wires and  $w$  is their center-to-center separation.

*Note:* Problems 76 through 79 require the application of ideas from this chapter and earlier chapters to some properties of superconductors, which were introduced in Section 27.5.

- 76. Review Problem.** *The resistance of a superconductor.* In an experiment carried out by S. C. Collins between 1955 and 1958, a current was maintained in a superconducting lead ring for 2.50 yr with no observed loss. If the inductance of the ring was  $3.14 \times 10^{-8}\ \text{H}$  and the sensitivity of the experiment was 1 part in  $10^9$ , what was the maximum resistance of the ring? (*Hint:* Treat this as a decaying current in an  $RL$  circuit, and recall that  $e^{-x} \cong 1 - x$  for small  $x$ .)
- 77. Review Problem.** A novel method of storing electrical energy has been proposed. A huge underground superconducting coil, 1.00 km in diameter, would be fabricated. It would carry a maximum current of 50.0 kA through each winding of a 150-turn  $\text{Nb}_3\text{Sn}$  solenoid. (a) If the inductance of this huge coil were 50.0 H, what would be the total energy stored? (b) What would be the compressive force per meter length acting between two adjacent windings 0.250 m apart?
- 78. Review Problem.** *Superconducting Power Transmission.* The use of superconductors has been proposed for the manufacture of power transmission lines. A single coaxial cable (Fig. P32.78) could carry  $1.00 \times 10^3\ \text{MW}$  (the output of a large power plant) at 200 kV, dc, over a distance of 1 000 km without loss. An inner wire with a radius of 2.00 cm, made from the superconductor  $\text{Nb}_3\text{Sn}$ , carries the current  $I$  in one direction. A surrounding superconducting cylinder, of radius 5.00 cm, would carry the return current  $I$ . In such a system, what is the magnetic field (a) at the surface of the inner conductor and (b) at the inner surface of the outer conductor? (c) How much energy would be stored in the space between the conductors in a 1 000-km superconducting line? (d) What is the pressure exerted on the outer conductor?

**Figure P32.78**

**79. Review Problem.** *The Meissner Effect.* Compare this problem with Problem 63 in Chapter 26 on the force attracting a perfect dielectric into a strong electric field. A fundamental property of a Type I superconducting material is *perfect diamagnetism*, or demonstration of the *Meissner effect*, illustrated in the photograph on page 855 and again in Figure 30.34, and described as follows: The superconducting material has  $\mathbf{B} = 0$  everywhere inside it. If a sample of the material is placed into an externally produced magnetic field, or if it is cooled to become superconducting while it is in a magnetic field, electric currents appear on the surface of the sample. The currents have precisely the strength and orientation required to make the total magnetic field zero throughout the interior of the sample. The following problem will help you to understand the magnetic force that can then act on the superconducting sample.

Consider a vertical solenoid with a length of 120 cm and a diameter of 2.50 cm consisting of 1 400 turns of copper wire carrying a counterclockwise current of 2.00 A, as shown in Figure P32.79a. (a) Find the magnetic field in the vacuum inside the solenoid. (b) Find the energy density of the magnetic field, and note that the units  $\text{J}/\text{m}^3$  of energy density are the same as the units  $\text{N}/\text{m}^2 (= \text{Pa})$  of pressure. (c) A superconducting bar 2.20 cm in diameter is inserted partway into the solenoid. Its upper end is far outside the solenoid, where the magnetic field is small. The lower end of the bar is deep inside the solenoid. Identify the direction required for the current on the curved surface of the bar so that the total magnetic field is zero within the bar. The field created by the supercurrents is sketched in Figure P32.79b, and the total field is sketched in Figure

**Figure P32.79**

P32.79c. (d) The field of the solenoid exerts a force on the current in the superconductor. Identify the direction of the force on the bar. (e) Calculate the magnitude of the force by multiplying the energy density of the solenoid field by the area of the bottom end of the superconducting bar.

## ANSWERS TO QUICK QUIZZES

- 32.1** When it is being opened. When the switch is initially open, there is no current in the circuit; when the switch is then closed, the inductor tends to maintain the no-current condition, and as a result there is very little chance of sparking. When the switch is initially closed, there is current in the circuit; when the switch is then opened, the current decreases. An induced emf is set up across the inductor, and this emf tends to maintain the original current. Sparking can occur as the current bridges the air gap between the poles of the switch.
- 32.2** (b). Figure 32.8 shows that circuit B has the greater time constant because in this circuit it takes longer for the current to reach its maximum value and then longer for this current to decrease to zero after switch  $S_2$  is closed. Equation 32.8 indicates that, for equal resistances  $R_A$  and  $R_B$ , the condition  $\tau_B > \tau_A$  means that  $L_A < L_B$ .
- 32.3** (a)  $M_{12}$  increases because the magnetic flux through coil 2 increases. (b)  $M_{12}$  decreases because rotation of coil 1 decreases its flux through coil 2.
- 32.4** (a) No. Mutual inductance requires a system of coils, and each coil has self-inductance. (b) Yes. A single coil has self-inductance but no mutual inductance because it does not interact with any other coils.
- 32.5** From Equation 32.25,  $I_{\text{max}} = \omega Q_{\text{max}}$ . Thus, the amplitude of the  $I$ - $t$  graph is  $\omega$  times the amplitude of the  $Q$ - $t$  graph.
- 32.6** Equation 32.31 without the cosine factor. The dashed lines represent the positive and negative amplitudes (maximum values) for each oscillation period, and it is the  $Q = Q_{\text{max}} e^{-Rt/2L}$  part of Equation 32.31 that gives the value of the ever-decreasing amplitude.

## PUZZLER

Small “black boxes” like this one are commonly used to supply power to electronic devices such as CD players and tape players. Whereas these devices need only about 12 V to operate, wall outlets provide an output of 120 V. What do the black boxes do, and how do they work? (*George Semple*)

## Alternating-Current Circuits

### Chapter Outline

- 33.1** ac Sources and Phasors
- 33.2** Resistors in an ac Circuit
- 33.3** Inductors in an ac Circuit
- 33.4** Capacitors in an ac Circuit
- 33.5** The *RLC* Series Circuit
- 33.6** Power in an ac Circuit
- 33.7** Resonance in a Series *RLC* Circuit
- 33.8** The Transformer and Power Transmission
- 33.9** (*Optional*) Rectifiers and Filters

In this chapter we describe alternating-current (ac) circuits. Every time we turn on a television set, a stereo, or any of a multitude of other electrical appliances, we are calling on alternating currents to provide the power to operate them. We begin our study by investigating the characteristics of simple series circuits that contain resistors, inductors, and capacitors and that are driven by a sinusoidal voltage. We shall find that the maximum alternating current in each element is proportional to the maximum alternating voltage across the element. We shall also find that when the applied voltage is sinusoidal, the current in each element is sinusoidal, too, but not necessarily in phase with the applied voltage. We conclude the chapter with two sections concerning transformers, power transmission, and  $RC$  filters.

### 33.1 AC SOURCES AND PHASORS

An ac circuit consists of circuit elements and a generator that provides the alternating current. As you recall from Section 31.5, the basic principle of the ac generator is a direct consequence of Faraday's law of induction. When a conducting loop is rotated in a magnetic field at constant angular frequency  $\omega$ , a sinusoidal voltage (emf) is induced in the loop. This instantaneous voltage  $\Delta v$  is

$$\Delta v = \Delta V_{\max} \sin \omega t$$

where  $\Delta V_{\max}$  is the maximum output voltage of the ac generator, or the **voltage amplitude**. From Equation 13.6, the angular frequency is

$$\omega = 2\pi f = \frac{2\pi}{T}$$

where  $f$  is the frequency of the generator (the voltage source) and  $T$  is the period. The generator determines the frequency of the current in any circuit connected to the generator. Because the output voltage of an ac generator varies sinusoidally with time, the voltage is positive during one half of the cycle and negative during the other half. Likewise, the current in any circuit driven by an ac generator is an alternating current that also varies sinusoidally with time. Commercial electric-power plants in the United States use a frequency of 60 Hz, which corresponds to an angular frequency of 377 rad/s.

The primary aim of this chapter can be summarized as follows: If an ac generator is connected to a series circuit containing resistors, inductors, and capacitors, we want to know the amplitude and time characteristics of the alternating current. To simplify our analysis of circuits containing two or more elements, we use graphical constructions called *phasor diagrams*. In these constructions, alternating (sinusoidal) quantities, such as current and voltage, are represented by rotating vectors called **phasors**. The length of the phasor represents the amplitude (maximum value) of the quantity, and the projection of the phasor onto the vertical axis represents the instantaneous value of the quantity. As we shall see, a phasor diagram greatly simplifies matters when we must combine several sinusoidally varying currents or voltages that have different phases.

### 33.2 RESISTORS IN AN AC CIRCUIT

Consider a simple ac circuit consisting of a resistor and an ac generator , as shown in Figure 33.1. At any instant, the algebraic sum of the voltages around a

closed loop in a circuit must be zero (Kirchhoff's loop rule). Therefore,  $\Delta v - \Delta v_R = 0$ , or<sup>1</sup>

$$\Delta v = \Delta v_R = \Delta V_{\max} \sin \omega t \quad (33.1)$$

where  $\Delta v_R$  is the **instantaneous voltage across the resistor**. Therefore, the instantaneous current in the resistor is

$$i_R = \frac{\Delta v_R}{R} = \frac{\Delta V_{\max}}{R} \sin \omega t = I_{\max} \sin \omega t \quad (33.2)$$

where  $I_{\max}$  is the maximum current:

$$I_{\max} = \frac{\Delta V_{\max}}{R}$$

From Equations 33.1 and 33.2, we see that the instantaneous voltage across the resistor is

$$\Delta v_R = I_{\max} R \sin \omega t \quad (33.3)$$

Let us discuss the current-versus-time curve shown in Figure 33.2a. At point  $a$ , the current has a maximum value in one direction, arbitrarily called the positive direction. Between points  $a$  and  $b$ , the current is decreasing in magnitude but is still in the positive direction. At  $b$ , the current is momentarily zero; it then begins to increase in the negative direction between points  $b$  and  $c$ . At  $c$ , the current has reached its maximum value in the negative direction.

The current and voltage are in step with each other because they vary identically with time. Because  $i_R$  and  $\Delta v_R$  both vary as  $\sin \omega t$  and reach their maximum values at the same time, as shown in Figure 33.2a, they are said to be **in phase**. Thus we can say that, for a sinusoidal applied voltage, the current in a resistor is always in phase with the voltage across the resistor.

A *phasor diagram* is used to represent current–voltage phase relationships. The lengths of the arrows correspond to  $\Delta V_{\max}$  and  $I_{\max}$ . The projections of the phasor arrows onto the vertical axis give  $\Delta v_R$  and  $i_R$  values. As we showed in Section 13.5, if the phasor arrow is imagined to rotate steadily with angular speed  $\omega$ , its vertical-axis component oscillates sinusoidally in time. In the case of the single-loop resistive circuit of Figure 33.1, the current and voltage phasors lie along the same line, as in Figure 33.2b, because  $i_R$  and  $\Delta v_R$  are in phase.

Note that **the average value of the current over one cycle is zero**. That is, the current is maintained in the positive direction for the same amount of time and at the same magnitude as it is maintained in the negative direction. However, the direction of the current has no effect on the behavior of the resistor. We can understand this by realizing that collisions between electrons and the fixed atoms of the resistor result in an increase in the temperature of the resistor. Although this temperature increase depends on the magnitude of the current, it is independent of the direction of the current.

We can make this discussion quantitative by recalling that the rate at which electrical energy is converted to internal energy in a resistor is the power  $\mathcal{P} = i^2 R$ , where  $i$  is the instantaneous current in the resistor. Because this rate is proportional to the square of the current, it makes no difference whether the current is direct or alternating—that is, whether the sign associated with the current is positive or negative. However, the temperature increase produced by an alternating

Maximum current in a resistor

The current in a resistor is in phase with the voltage

**Figure 33.1** A circuit consisting of a resistor of resistance  $R$  connected to an ac generator, designated by the symbol

<sup>1</sup> The lowercase symbols  $v$  and  $i$  are used to indicate the instantaneous values of the voltage and the current.

**Figure 33.2** (a) Plots of the instantaneous current  $i_R$  and instantaneous voltage  $\Delta v_R$  across a resistor as functions of time. The current is in phase with the voltage, which means that the current is zero when the voltage is zero, maximum when the voltage is maximum, and minimum when the voltage is minimum. At time  $t = T$ , one cycle of the time-varying voltage and current has been completed. (b) Phasor diagram for the resistive circuit showing that the current is in phase with the voltage.

current having a maximum value  $I_{\max}$  is not the same as that produced by a direct current equal to  $I_{\max}$ . This is because the alternating current is at this maximum value for only an instant during each cycle (Fig. 33.3a). What is of importance in an ac circuit is an average value of current, referred to as the **rms current**. As we learned in Section 21.1, the notation *rms* stands for *root mean square*, which in this case means the square root of the mean (average) value of the square of the current:  $I_{\text{rms}} = \sqrt{\overline{i^2}}$ . Because  $i^2$  varies as  $\sin^2 \omega t$  and because the average value of  $i^2$  is  $\frac{1}{2} I_{\max}^2$  (see Fig. 33.3b), the rms current is<sup>2</sup>

rms current

$$I_{\text{rms}} = \frac{I_{\max}}{\sqrt{2}} = 0.707 I_{\max} \quad (33.4)$$

This equation states that an alternating current whose maximum value is 2.00 A delivers to a resistor the same power as a direct current that has a value of  $(0.707)(2.00 \text{ A}) = 1.41 \text{ A}$ . Thus, we can say that the average power delivered to a resistor that carries an alternating current is

Average power delivered to a resistor

$$\mathcal{P}_{\text{av}} = I_{\text{rms}}^2 R$$

<sup>2</sup> That the square root of the average value of  $i^2$  is equal to  $I_{\max}/\sqrt{2}$  can be shown as follows: The current in the circuit varies with time according to the expression  $i = I_{\max} \sin \omega t$ , so  $i^2 = I_{\max}^2 \sin^2 \omega t$ . Therefore, we can find the average value of  $i^2$  by calculating the average value of  $\sin^2 \omega t$ . A graph of  $\cos^2 \omega t$  versus time is identical to a graph of  $\sin^2 \omega t$  versus time, except that the points are shifted on the time axis. Thus, the time average of  $\sin^2 \omega t$  is equal to the time average of  $\cos^2 \omega t$  when taken over one or more complete cycles. That is,

$$(\sin^2 \omega t)_{\text{av}} = (\cos^2 \omega t)_{\text{av}}$$

Using this fact and the trigonometric identity  $\sin^2 \theta + \cos^2 \theta = 1$ , we obtain

$$\begin{aligned} (\sin^2 \omega t)_{\text{av}} + (\cos^2 \omega t)_{\text{av}} &= 2(\sin^2 \omega t)_{\text{av}} = 1 \\ (\sin^2 \omega t)_{\text{av}} &= \frac{1}{2} \end{aligned}$$

When we substitute this result in the expression  $i^2 = I_{\max}^2 \sin^2 \omega t$ , we obtain  $(i^2)_{\text{av}} = \overline{i^2} = I_{\text{rms}}^2 = I_{\max}^2/2$ , or  $I_{\text{rms}} = I_{\max}/\sqrt{2}$ . The factor  $1/\sqrt{2}$  is valid only for sinusoidally varying currents. Other waveforms, such as sawtooth variations, have different factors.

**Figure 33.3** (a) Graph of the current in a resistor as a function of time. (b) Graph of the current squared in a resistor as a function of time. Notice that the gray shaded regions *under* the curve and *above* the dashed line for  $I_{\max}^2/2$  have the same area as the gray shaded regions *above* the curve and *below* the dashed line for  $I_{\max}^2/2$ . Thus, the average value of  $i^2$  is  $I_{\max}^2/2$ .

Alternating voltage also is best discussed in terms of rms voltage, and the relationship is identical to that for current:

$$\Delta V_{\text{rms}} = \frac{\Delta V_{\text{max}}}{\sqrt{2}} = 0.707 \Delta V_{\text{max}} \quad (33.5)$$

rms voltage

When we speak of measuring a 120-V alternating voltage from an electrical outlet, we are referring to an rms voltage of 120 V. A quick calculation using Equation 33.5 shows that such an alternating voltage has a maximum value of about 170 V. One reason we use rms values when discussing alternating currents and voltages in this chapter is that ac ammeters and voltmeters are designed to read rms values. Furthermore, with rms values, many of the equations we use have the same form as their direct-current counterparts.

### Quick Quiz 33.1

Which of the following statements might be true for a resistor connected to an ac generator? (a)  $\mathcal{P}_{\text{av}} = 0$  and  $i_{\text{av}} = 0$ ; (b)  $\mathcal{P}_{\text{av}} = 0$  and  $i_{\text{av}} > 0$ ; (c)  $\mathcal{P}_{\text{av}} > 0$  and  $i_{\text{av}} = 0$ ; (d)  $\mathcal{P}_{\text{av}} > 0$  and  $i_{\text{av}} > 0$ .

### EXAMPLE 33.1 What Is the rms Current?

The voltage output of a generator is given by  $\Delta v = (200 \text{ V})\sin \omega t$ . Find the rms current in the circuit when this generator is connected to a  $100\text{-}\Omega$  resistor.

**Solution** Comparing this expression for voltage output with the general form  $\Delta v = \Delta V_{\text{max}} \sin \omega t$ , we see that  $\Delta V_{\text{max}} = 200 \text{ V}$ . Thus, the rms voltage is

$$\Delta V_{\text{rms}} = \frac{\Delta V_{\text{max}}}{\sqrt{2}} = \frac{200 \text{ V}}{\sqrt{2}} = 141 \text{ V}$$

Therefore,

$$I_{\text{rms}} = \frac{\Delta V_{\text{rms}}}{R} = \frac{141 \text{ V}}{100 \text{ }\Omega} = 1.41 \text{ A}$$

**Exercise** Find the maximum current in the circuit.

**Answer** 2.00 A.

**Figure 33.4** A circuit consisting of an inductor of inductance  $L$  connected to an ac generator.

**Figure 33.5** (a) Plots of the instantaneous current  $i_L$  and instantaneous voltage  $\Delta v_L$  across an inductor as functions of time. The current lags behind the voltage by  $90^\circ$ . (b) Phasor diagram for the inductive circuit, showing that the current lags behind the voltage by  $90^\circ$ .

The current in an inductor lags the voltage by  $90^\circ$

### 33.3 INDUCTORS IN AN AC CIRCUIT

Now consider an ac circuit consisting only of an inductor connected to the terminals of an ac generator, as shown in Figure 33.4. If  $\Delta v_L = \mathcal{E}_L = -L(di/dt)$  is the self-induced instantaneous voltage across the inductor (see Eq. 32.1), then Kirchhoff's loop rule applied to this circuit gives  $\Delta v + \Delta v_L = 0$ , or

$$\Delta v - L \frac{di}{dt} = 0$$

When we substitute  $\Delta V_{\max} \sin \omega t$  for  $\Delta v$  and rearrange, we obtain

$$L \frac{di}{dt} = \Delta V_{\max} \sin \omega t \quad (33.6)$$

Solving this equation for  $di$ , we find that

$$di = \frac{\Delta V_{\max}}{L} \sin \omega t dt$$

Integrating this expression<sup>3</sup> gives the instantaneous current in the inductor as a function of time:

$$i_L = \frac{\Delta V_{\max}}{L} \int \sin \omega t dt = -\frac{\Delta V_{\max}}{\omega L} \cos \omega t \quad (33.7)$$

When we use the trigonometric identity  $\cos \omega t = -\sin(\omega t - \pi/2)$ , we can express Equation 33.7 as

$$i_L = \frac{\Delta V_{\max}}{\omega L} \sin\left(\omega t - \frac{\pi}{2}\right) \quad (33.8)$$

Comparing this result with Equation 33.6, we see that the instantaneous current  $i_L$  in the inductor and the instantaneous voltage  $\Delta v_L$  across the inductor are out of phase by  $(\pi/2)$  rad =  $90^\circ$ .

In general, inductors in an ac circuit produce a current that is out of phase with the ac voltage. A plot of voltage and current versus time is provided in Figure 33.5a. At point  $a$ , the current begins to increase in the positive direction. At this instant the rate of change of current is at a maximum, and thus the voltage across the inductor is also at a maximum. As the current increases between points  $a$  and  $b$ ,  $di/dt$  (the slope of the current curve) gradually decreases until it reaches zero at point  $b$ . As a result, the voltage across the inductor is decreasing during this same time interval, as the curve segment between  $c$  and  $d$  indicates. Immediately after point  $b$ , the current begins to decrease, although it still has the same direction it had during the previous quarter cycle (from  $a$  to  $b$ ). As the current decreases to zero (from  $b$  to  $e$ ), a voltage is again induced in the inductor ( $d$  to  $f$ ), but the polarity of this voltage is opposite that of the voltage induced between  $c$  and  $d$  (because back emfs are always directed to oppose the change in the current). Note that the voltage reaches its maximum value one quarter of a period before the current reaches its maximum value. Thus, we see that

for a sinusoidal applied voltage, the current in an inductor always lags behind the voltage across the inductor by  $90^\circ$  (one-quarter cycle in time).

<sup>3</sup> We neglect the constant of integration here because it depends on the initial conditions, which are not important for this situation.

The phasor diagram for the inductive circuit of Figure 33.4 is shown in Figure 33.5b.

From Equation 33.7 we see that the current in an inductive circuit reaches its maximum value when  $\cos \omega t = -1$ :

$$I_{\max} = \frac{\Delta V_{\max}}{\omega L} = \frac{\Delta V_{\max}}{X_L} \quad (33.9)$$

Maximum current in an inductor

where the quantity  $X_L$ , called the **inductive reactance**, is

$$X_L = \omega L \quad (33.10)$$

Inductive reactance

Equation 33.9 indicates that, for a given applied voltage, the maximum current decreases as the inductive reactance increases. The expression for the rms current in an inductor is similar to Equation 33.9, with  $I_{\max}$  replaced by  $I_{\text{rms}}$  and  $\Delta V_{\max}$  replaced by  $\Delta V_{\text{rms}}$ .

Inductive reactance, like resistance, has units of ohms. However, unlike resistance, reactance depends on frequency as well as on the characteristics of the inductor. Note that the reactance of an inductor in an ac circuit increases as the frequency of the current increases. This is because at higher frequencies, the instantaneous current must change more rapidly than it does at the lower frequencies; this causes an increase in the maximum induced emf associated with a given maximum current.

Using Equations 33.6 and 33.9, we find that the instantaneous voltage across the inductor is

$$\Delta v_L = -L \frac{di}{dt} = -\Delta V_{\max} \sin \omega t = -I_{\max} X_L \sin \omega t \quad (33.11)$$

### CONCEPTUAL EXAMPLE 33.2

Figure 33.6 shows a circuit consisting of a series combination of an alternating voltage source, a switch, an inductor, and a lightbulb. The switch is thrown closed, and the circuit is allowed to come to equilibrium so that the lightbulb glows steadily. An iron rod is then inserted into the interior of the inductor. What happens to the brightness of the lightbulb, and why?

**Solution** The bulb gets dimmer. As the rod is inserted, the inductance increases because the magnetic field inside the inductor increases. According to Equation 33.10, this increase in  $L$  means that the inductive reactance of the inductor also increases. The voltage across the inductor increases while the voltage across the lightbulb decreases. With less

voltage across it, the lightbulb glows more dimly. In theatrical productions of the early 20th century, this method was used to dim the lights in the theater gradually.

Figure 33.6

### EXAMPLE 33.3 A Purely Inductive ac Circuit

In a purely inductive ac circuit (see Fig. 33.4),  $L = 25.0$  mH and the rms voltage is 150 V. Calculate the inductive reactance and rms current in the circuit if the frequency is 60.0 Hz.

**Solution** Equation 33.10 gives

$$X_L = \omega L = 2\pi fL = 2\pi(60.0 \text{ Hz})(25.0 \times 10^{-3} \text{ H}) = 9.42 \Omega$$

From a modified version of Equation 33.9, the rms current is

$$I_{\text{rms}} = \frac{\Delta V_{L,\text{rms}}}{X_L} = \frac{150 \text{ V}}{9.42 \Omega} = 15.9 \text{ A}$$

**Exercise** Calculate the inductive reactance and rms current in the circuit if the frequency is 6.00 kHz.

**Answer** 942  $\Omega$ , 0.159 A.

**Exercise** Show that inductive reactance has SI units of ohms.

**Figure 33.7** A circuit consisting of a capacitor of capacitance  $C$  connected to an ac generator.

**Figure 33.8** (a) Plots of the instantaneous current  $i_C$  and instantaneous voltage  $\Delta v_C$  across a capacitor as functions of time. The voltage lags the current by  $90^\circ$ . (b) Phasor diagram for the capacitive circuit, showing that the current leads the voltage by  $90^\circ$ .

### 33.4 CAPACITORS IN AN AC CIRCUIT

Figure 33.7 shows an ac circuit consisting of a capacitor connected across the terminals of an ac generator. Kirchhoff's loop rule applied to this circuit gives  $\Delta v - \Delta v_C = 0$ , or

$$\Delta v = \Delta v_C = \Delta V_{\max} \sin \omega t \quad (33.12)$$

where  $\Delta v_C$  is the instantaneous voltage across the capacitor. We know from the definition of capacitance that  $C = q/\Delta v_C$ ; hence, Equation 33.12 gives

$$q = C \Delta V_{\max} \sin \omega t \quad (33.13)$$

where  $q$  is the instantaneous charge on the capacitor. Because  $i = dq/dt$ , differentiating Equation 33.13 gives the instantaneous current in the circuit:

$$i_C = \frac{dq}{dt} = \omega C \Delta V_{\max} \cos \omega t \quad (33.14)$$

Using the trigonometric identity

$$\cos \omega t = \sin\left(\omega t + \frac{\pi}{2}\right)$$

we can express Equation 33.14 in the alternative form

$$i_C = \omega C \Delta V_{\max} \sin\left(\omega t + \frac{\pi}{2}\right) \quad (33.15)$$

Comparing this expression with Equation 33.12, we see that the current is  $\pi/2$  rad =  $90^\circ$  out of phase with the voltage across the capacitor. A plot of current and voltage versus time (Fig. 33.8a) shows that the current reaches its maximum value one quarter of a cycle sooner than the voltage reaches its maximum value.

Looking more closely, we see that the segment of the current curve from  $a$  to  $b$  indicates that the current starts out at a relatively high value. We can understand this by recognizing that there is no charge on the capacitor at  $t = 0$ ; as a consequence, nothing in the circuit except the resistance of the wires can hinder the flow of charge at this instant. However, the current decreases as the voltage across the capacitor increases (from  $c$  to  $d$  on the voltage curve), and the capacitor is charging. When the voltage is at point  $d$ , the current reverses and begins to increase in the opposite direction (from  $b$  to  $e$  on the current curve). During this time, the voltage across the capacitor decreases from  $d$  to  $f$  because the plates are now losing the charge they accumulated earlier. During the second half of the cycle, the current is initially at its maximum value in the opposite direction (point  $e$ ) and then decreases as the voltage across the capacitor builds up. The phasor diagram in Figure 33.8b also shows that

for a sinusoidally applied voltage, the current in a capacitor always leads the voltage across the capacitor by  $90^\circ$ .

From Equation 33.14, we see that the current in the circuit reaches its maximum value when  $\cos \omega t = 1$ :

$$I_{\max} = \omega C \Delta V_{\max} = \frac{\Delta V_{\max}}{X_C} \quad (33.16)$$

where  $X_C$  is called the **capacitive reactance**:

$$X_C = \frac{1}{\omega C} \quad (33.17)$$

Capacitive reactance

Note that capacitive reactance also has units of ohms.

The rms current is given by an expression similar to Equation 33.16, with  $I_{\max}$  replaced by  $I_{\text{rms}}$  and  $\Delta V_{\max}$  replaced by  $\Delta V_{\text{rms}}$ .

Combining Equations 33.12 and 33.16, we can express the instantaneous voltage across the capacitor as

$$\Delta v_C = \Delta V_{\max} \sin \omega t = I_{\max} X_C \sin \omega t \quad (33.18)$$

Equations 33.16 and 33.17 indicate that as the frequency of the voltage source increases, the capacitive reactance decreases and therefore the maximum current increases. Again, note that the frequency of the current is determined by the frequency of the voltage source driving the circuit. As the frequency approaches zero, the capacitive reactance approaches infinity, and hence the current approaches zero. This makes sense because the circuit approaches direct-current conditions as  $\omega$  approaches 0.

### EXAMPLE 33.4 A Purely Capacitive ac Circuit

An  $8.00\text{-}\mu\text{F}$  capacitor is connected to the terminals of a  $60.0\text{-Hz}$  ac generator whose rms voltage is  $150\text{ V}$ . Find the capacitive reactance and the rms current in the circuit.

**Solution** Using Equation 33.17 and the fact that  $\omega = 2\pi f = 377\text{ s}^{-1}$  gives

$$X_C = \frac{1}{\omega C} = \frac{1}{(377\text{ s}^{-1})(8.00 \times 10^{-6}\text{ F})} = 332\ \Omega$$

Hence, from a modified Equation 33.16, the rms current is

$$I_{\text{rms}} = \frac{\Delta V_{\text{rms}}}{X_C} = \frac{150\text{ V}}{332\ \Omega} = 0.452\text{ A}$$

**Exercise** If the frequency is doubled, what happens to the capacitive reactance and the current?

**Answer**  $X_C$  is halved, and  $I_{\text{rms}}$  is doubled.

## 33.5 THE RLC SERIES CIRCUIT

13.7 Figure 33.9a shows a circuit that contains a resistor, an inductor, and a capacitor connected in series across an alternating-voltage source. As before, we assume that the applied voltage varies sinusoidally with time. It is convenient to assume that the instantaneous applied voltage is given by

$$\Delta v = \Delta V_{\max} \sin \omega t$$

while the current varies as

$$i = I_{\max} \sin(\omega t - \phi)$$

where  $\phi$  is the **phase angle** between the current and the applied voltage. Our aim

Phase angle  $\phi$

**Figure 33.9** (a) A series circuit consisting of a resistor, an inductor, and a capacitor connected to an ac generator. (b) Phase relationships for instantaneous voltages in the series  $RLC$  circuit.

is to determine  $\phi$  and  $I_{\max}$ . Figure 33.9b shows the voltage versus time across each element in the circuit and their phase relationships.

To solve this problem, we must analyze the phasor diagram for this circuit. First, we note that because the elements are in series, the current everywhere in the circuit must be the same at any instant. That is, **the current at all points in a series ac circuit has the same amplitude and phase**. Therefore, as we found in the preceding sections, the voltage across each element has a different amplitude and phase, as summarized in Figure 33.10. In particular, the voltage across the resistor is in phase with the current, the voltage across the inductor leads the current by  $90^\circ$ , and the voltage across the capacitor lags behind the current by  $90^\circ$ . Using these phase relationships, we can express the instantaneous voltages across the three elements as

$$\Delta v_R = I_{\max} R \sin \omega t = \Delta V_R \sin \omega t \quad (33.19)$$

$$\Delta v_L = I_{\max} X_L \sin\left(\omega t + \frac{\pi}{2}\right) = \Delta V_L \cos \omega t \quad (33.20)$$

$$\Delta v_C = I_{\max} X_C \sin\left(\omega t - \frac{\pi}{2}\right) = -\Delta V_C \cos \omega t \quad (33.21)$$

where  $\Delta V_R$ ,  $\Delta V_L$ , and  $\Delta V_C$  are the maximum voltage values across the elements:

$$\Delta V_R = I_{\max} R \quad \Delta V_L = I_{\max} X_L \quad \Delta V_C = I_{\max} X_C$$

At this point, we could proceed by noting that the instantaneous voltage  $\Delta v$  across the three elements equals the sum

$$\Delta v = \Delta v_R + \Delta v_L + \Delta v_C$$

### Quick Quiz 33.2

For the circuit of Figure 33.9a, is the voltage of the ac source equal to (a) the sum of the maximum voltages across the elements, (b) the sum of the instantaneous voltages across the elements, or (c) the sum of the rms voltages across the elements?

Although this analytical approach is correct, it is simpler to obtain the sum by examining the phasor diagram. Because the current at any instant is the same in all

**Figure 33.10** Phase relationships between the voltage and current phasors for (a) a resistor, (b) an inductor, and (c) a capacitor connected in series.

elements, we can obtain a phasor diagram for the circuit. We combine the three phasor pairs shown in Figure 33.10 to obtain Figure 33.11a, in which a single phasor  $I_{\max}$  is used to represent the current in each element. To obtain the vector sum of the three voltage phasors in Figure 33.11a, we redraw the phasor diagram as in Figure 33.11b. From this diagram, we see that the vector sum of the voltage amplitudes  $\Delta V_R$ ,  $\Delta V_L$ , and  $\Delta V_C$  equals a phasor whose length is the maximum applied voltage  $\Delta V_{\max}$ , where the phasor  $\Delta V_{\max}$  makes an angle  $\phi$  with the current phasor  $I_{\max}$ . Note that the voltage phasors  $\Delta V_L$  and  $\Delta V_C$  are in opposite directions along the same line, and hence we can construct the difference phasor  $\Delta V_L - \Delta V_C$ , which is perpendicular to the phasor  $\Delta V_R$ . From either one of the right triangles in Figure 33.11b, we see that

$$\begin{aligned}\Delta V_{\max} &= \sqrt{\Delta V_R^2 + (\Delta V_L - \Delta V_C)^2} = \sqrt{(I_{\max}R)^2 + (I_{\max}X_L - I_{\max}X_C)^2} \\ \Delta V_{\max} &= I_{\max} \sqrt{R^2 + (X_L - X_C)^2}\end{aligned}\quad (33.22)$$

Therefore, we can express the maximum current as

$$I_{\max} = \frac{\Delta V_{\max}}{\sqrt{R^2 + (X_L - X_C)^2}}$$

The **impedance**  $Z$  of the circuit is defined as

$$Z \equiv \sqrt{R^2 + (X_L - X_C)^2}\quad (33.23)$$

where impedance also has units of ohms. Therefore, we can write Equation 33.22 in the form

$$\Delta V_{\max} = I_{\max}Z\quad (33.24)$$

We can regard Equation 33.24 as the ac equivalent of Equation 27.8, which defined *resistance* in a dc circuit as the ratio of the voltage across a conductor to the current in that conductor. Note that the impedance and therefore the current in an ac circuit depend upon the resistance, the inductance, the capacitance, and the frequency (because the reactances are frequency-dependent).

By removing the common factor  $I_{\max}$  from each phasor in Figure 33.11a, we can construct the *impedance triangle* shown in Figure 33.12. From this phasor diagram we find that the phase angle  $\phi$  between the current and the voltage is

$$\phi = \tan^{-1}\left(\frac{X_L - X_C}{R}\right)\quad (33.25)$$

Also, from Figure 33.12, we see that  $\cos \phi = R/Z$ . When  $X_L > X_C$  (which occurs at high frequencies), the phase angle is positive, signifying that the current lags behind the applied voltage, as in Figure 33.11a. When  $X_L < X_C$ , the phase angle is negative, signifying that the current leads the applied voltage. When  $X_L = X_C$ , the phase angle is zero. In this case, the impedance equals the resistance and the current has its maximum value, given by  $\Delta V_{\max}/R$ . The frequency at which this occurs is called the *resonance frequency*; it is described further in Section 33.7.

Table 33.1 gives impedance values and phase angles for various series circuits containing different combinations of elements.

**Figure 33.11** (a) Phasor diagram for the series RLC circuit shown in Figure 33.9a. The phasor  $\Delta V_R$  is in phase with the current phasor  $I_{\max}$ , the phasor  $\Delta V_L$  leads  $I_{\max}$  by  $90^\circ$ , and the phasor  $\Delta V_C$  lags  $I_{\max}$  by  $90^\circ$ . The total voltage  $\Delta V_{\max}$  makes an angle  $\phi$  with  $I_{\max}$ . (b) Simplified version of the phasor diagram shown in (a).

**Figure 33.12** An impedance triangle for a series RLC circuit gives the relationship  $Z = \sqrt{R^2 + (X_L - X_C)^2}$ .

**TABLE 33.1** Impedance Values and Phase Angles for Various Circuit-Element Combinations<sup>a</sup>

Circuit Elements	Impedance $Z$	Phase Angle $\phi$
	$R$	$0^\circ$
	$X_C$	$-90^\circ$
	$X_L$	$+90^\circ$
	$\sqrt{R^2 + X_C^2}$	Negative, between $-90^\circ$ and $0^\circ$
	$\sqrt{R^2 + X_L^2}$	Positive, between $0^\circ$ and $90^\circ$
	$\sqrt{R^2 + (X_L - X_C)^2}$	Negative if $X_C > X_L$ Positive if $X_C < X_L$

<sup>a</sup> In each case, an ac voltage (not shown) is applied across the elements.

**Quick Quiz 33.3**

Label each part of Figure 33.13 as being  $X_L > X_C$ ,  $X_L = X_C$ , or  $X_L < X_C$ .

**Figure 33.13****EXAMPLE 33.5** Finding  $L$  from a Phasor Diagram

In a series  $RLC$  circuit, the applied voltage has a maximum value of 120 V and oscillates at a frequency of 60.0 Hz. The

circuit contains an inductor whose inductance can be varied, a 200- $\Omega$  resistor, and a 4.00- $\mu\text{F}$  capacitor. What value of  $L$

should an engineer analyzing the circuit choose such that the voltage across the capacitor lags the applied voltage by  $30.0^\circ$ ?

**Solution** The phase relationships for the drops in voltage across the elements are shown in Figure 33.14. From the figure we see that the phase angle is  $\phi = -60.0^\circ$ . This is because the phasors representing  $I_{\max}$  and  $\Delta V_R$  are in the same direction (they are in phase). From Equation 33.25, we find that

$$X_L = X_C + R \tan \phi$$

Substituting Equations 33.10 and 33.17 (with  $\omega = 2\pi f$ ) into this expression gives

$$2\pi fL = \frac{1}{2\pi fC} + R \tan \phi$$

$$L = \frac{1}{2\pi f} \left[ \frac{1}{2\pi fC} + R \tan \phi \right]$$

Substituting the given values into the equation gives  $L =$

0.84 H.

Figure 33.14

### EXAMPLE 33.6 Analyzing a Series RLC Circuit

A series RLC ac circuit has  $R = 425 \Omega$ ,  $L = 1.25 \text{ H}$ ,  $C = 3.50 \mu\text{F}$ ,  $\omega = 377 \text{ s}^{-1}$ , and  $\Delta V_{\max} = 150 \text{ V}$ . (a) Determine the inductive reactance, the capacitive reactance, and the impedance of the circuit.

**Solution** The reactances are  $X_L = \omega L = 471 \Omega$  and

$X_C = 1/\omega C = 758 \Omega$ . The impedance is

$$Z = \sqrt{R^2 + (X_L - X_C)^2}$$

$$= \sqrt{(425 \Omega)^2 + (471 \Omega - 758 \Omega)^2} = 513 \Omega$$

(b) Find the maximum current in the circuit.

**Solution**

$$I_{\max} = \frac{V_{\max}}{Z} = \frac{150 \text{ V}}{513 \Omega} = 0.292 \text{ A}$$

(c) Find the phase angle between the current and voltage.

**Solution**

$$\phi = \tan^{-1} \left( \frac{X_L - X_C}{R} \right) = \tan^{-1} \left( \frac{471 \Omega - 758 \Omega}{425 \Omega} \right)$$

$$= -34.0^\circ$$

Because the circuit is more capacitive than inductive,  $\phi$  is negative and the current leads the applied voltage.

(d) Find both the maximum and the instantaneous voltage across each element.

**Solution** The maximum voltages are

$$\Delta V_R = I_{\max} R = (0.292 \text{ A})(425 \Omega) = 124 \text{ V}$$

$$\Delta V_L = I_{\max} X_L = (0.292 \text{ A})(471 \Omega) = 138 \text{ V}$$

$$\Delta V_C = I_{\max} X_C = (0.292 \text{ A})(758 \Omega) = 221 \text{ V}$$

Using Equations 33.19, 33.20, and 33.21, we find that we can write the instantaneous voltages across the three elements as

$$\Delta v_R = (124 \text{ V}) \sin 377t$$

$$\Delta v_L = (138 \text{ V}) \cos 377t$$

$$\Delta v_C = (-221 \text{ V}) \cos 377t$$

**Comments** The sum of the maximum voltages across the elements is  $\Delta V_R + \Delta V_L + \Delta V_C = 483 \text{ V}$ . Note that this sum is much greater than the maximum voltage of the generator, 150 V. As we saw in Quick Quiz 33.2, the sum of the maximum voltages is a meaningless quantity because when sinusoidally varying quantities are added, *both their amplitudes and their phases* must be taken into account. We know that the

maximum voltages across the various elements occur at different times. That is, the voltages must be added in a way that takes account of the different phases. When this is done, Equation 33.22 is satisfied. You should verify this result.

**Exercise** Construct a phasor diagram to scale, showing the voltages across the elements and the applied voltage. From your diagram, verify that the phase angle is  $-34.0^\circ$ .

### 33.6 POWER IN AN AC CIRCUIT

**No power losses are associated with pure capacitors and pure inductors in an ac circuit.** To see why this is true, let us first analyze the power in an ac circuit containing only a generator and a capacitor.

When the current begins to increase in one direction in an ac circuit, charge begins to accumulate on the capacitor, and a voltage drop appears across it. When this voltage drop reaches its maximum value, the energy stored in the capacitor is  $\frac{1}{2}C(\Delta V_{\max})^2$ . However, this energy storage is only momentary. The capacitor is charged and discharged twice during each cycle: Charge is delivered to the capacitor during two quarters of the cycle and is returned to the voltage source during the remaining two quarters. Therefore, **the average power supplied by the source is zero.** In other words, **no power losses occur in a capacitor in an ac circuit.**

Similarly, the voltage source must do work against the back emf of the inductor. When the current reaches its maximum value, the energy stored in the inductor is a maximum and is given by  $\frac{1}{2}LI_{\max}^2$ . When the current begins to decrease in the circuit, this stored energy is returned to the source as the inductor attempts to maintain the current in the circuit.

In Example 28.1 we found that the power delivered by a battery to a dc circuit is equal to the product of the current and the emf of the battery. Likewise, the instantaneous power delivered by an ac generator to a circuit is the product of the generator current and the applied voltage. For the *RLC* circuit shown in Figure 33.9a, we can express the instantaneous power  $\mathcal{P}$  as

$$\begin{aligned}\mathcal{P} &= i \Delta v = I_{\max} \sin(\omega t - \phi) \Delta V_{\max} \sin \omega t \\ &= I_{\max} \Delta V_{\max} \sin \omega t \sin(\omega t - \phi)\end{aligned}\quad (33.26)$$

Clearly, this result is a complicated function of time and therefore is not very useful from a practical viewpoint. What is generally of interest is the average power over one or more cycles. Such an average can be computed by first using the trigonometric identity  $\sin(\omega t - \phi) = \sin \omega t \cos \phi - \cos \omega t \sin \phi$ . Substituting this into Equation 33.26 gives

$$\mathcal{P} = I_{\max} \Delta V_{\max} \sin^2 \omega t \cos \phi - I_{\max} \Delta V_{\max} \sin \omega t \cos \omega t \sin \phi \quad (33.27)$$

We now take the time average of  $\mathcal{P}$  over one or more cycles, noting that  $I_{\max}$ ,  $\Delta V_{\max}$ ,  $\phi$ , and  $\omega$  are all constants. The time average of the first term on the right in Equation 33.27 involves the average value of  $\sin^2 \omega t$ , which is  $\frac{1}{2}$  (as shown in footnote 2). The time average of the second term on the right is identically zero because  $\sin \omega t \cos \omega t = \frac{1}{2} \sin 2\omega t$ , and the average value of  $\sin 2\omega t$  is zero. Therefore, we can express the **average power**  $\mathcal{P}_{\text{av}}$  as

$$\mathcal{P}_{\text{av}} = \frac{1}{2} I_{\max} \Delta V_{\max} \cos \phi \quad (33.28)$$

It is convenient to express the average power in terms of the rms current and rms voltage defined by Equations 33.4 and 33.5:

$$\mathcal{P}_{\text{av}} = I_{\text{rms}} \Delta V_{\text{rms}} \cos \phi \quad (33.29)$$

where the quantity  $\cos \phi$  is called the **power factor**. By inspecting Figure 33.11b, we see that the maximum voltage drop across the resistor is given by  $\Delta V_R = \Delta V_{\max} \cos \phi = I_{\max} R$ . Using Equation 33.5 and the fact that  $\cos \phi = I_{\max} R / \Delta V_{\max}$ , we find that we can express  $\mathcal{P}_{\text{av}}$  as

$$\mathcal{P}_{\text{av}} = I_{\text{rms}} \Delta V_{\text{rms}} \cos \phi = I_{\text{rms}} \left( \frac{\Delta V_{\max}}{\sqrt{2}} \right) \frac{I_{\max} R}{\Delta V_{\max}} = I_{\text{rms}} \frac{I_{\max} R}{\sqrt{2}}$$

After making the substitution  $I_{\max} = \sqrt{2} I_{\text{rms}}$  from Equation 33.4, we have

$$\mathcal{P}_{\text{av}} = I_{\text{rms}}^2 R \quad (33.30)$$

Average power delivered to an RLC circuit

In words, the **average power delivered by the generator is converted to internal energy in the resistor**, just as in the case of a dc circuit. **No power loss occurs in an ideal inductor or capacitor.** When the load is purely resistive, then  $\phi = 0$ ,  $\cos \phi = 1$ , and from Equation 33.29 we see that

$$\mathcal{P}_{\text{av}} = I_{\text{rms}} \Delta V_{\text{rms}}$$

Equation 33.29 shows that the power delivered by an ac source to any circuit depends on the phase, and this result has many interesting applications. For example, a factory that uses large motors in machines, generators, or transformers has a large inductive load (because of all the windings). To deliver greater power to such devices in the factory without using excessively high voltages, technicians introduce capacitance in the circuits to shift the phase.

### EXAMPLE 33.7 Average Power in an RLC Series Circuit

Calculate the average power delivered to the series RLC circuit described in Example 33.6.

**Solution** First, let us calculate the rms voltage and rms current, using the values of  $\Delta V_{\max}$  and  $I_{\max}$  from Example 33.6:

$$\Delta V_{\text{rms}} = \frac{\Delta V_{\max}}{\sqrt{2}} = \frac{150 \text{ V}}{\sqrt{2}} = 106 \text{ V}$$

$$I_{\text{rms}} = \frac{I_{\max}}{\sqrt{2}} = \frac{0.292 \text{ A}}{\sqrt{2}} = 0.206 \text{ A}$$

Because  $\phi = -34.0^\circ$ , the power factor,  $\cos \phi$ , is 0.829; hence, the average power delivered is

$$\begin{aligned} \mathcal{P}_{\text{av}} &= I_{\text{rms}} \Delta V_{\text{rms}} \cos \phi = (0.206 \text{ A})(106 \text{ V})(0.829) \\ &= 18.1 \text{ W} \end{aligned}$$

We can obtain the same result using Equation 33.30.

## 33.7 RESONANCE IN A SERIES RLC CIRCUIT

A series RLC circuit is said to be **in resonance** when the current has its maximum value. In general, the rms current can be written

$$I_{\text{rms}} = \frac{\Delta V_{\text{rms}}}{Z} \quad (33.31)$$

where  $Z$  is the impedance. Substituting the expression for  $Z$  from Equation 33.23 into 33.31 gives

$$I_{\text{rms}} = \frac{\Delta V_{\text{rms}}}{\sqrt{R^2 + (X_L - X_C)^2}} \quad (33.32)$$

Because the impedance depends on the frequency of the source, the current in the  $RLC$  circuit also depends on the frequency. The frequency  $\omega_0$  at which  $X_L - X_C = 0$  is called the **resonance frequency** of the circuit. To find  $\omega_0$ , we use the condition  $X_L = X_C$ , from which we obtain  $\omega_0 L = 1/\omega_0 C$ , or

Resonance frequency

$$\omega_0 = \frac{1}{\sqrt{LC}} \quad (33.33)$$

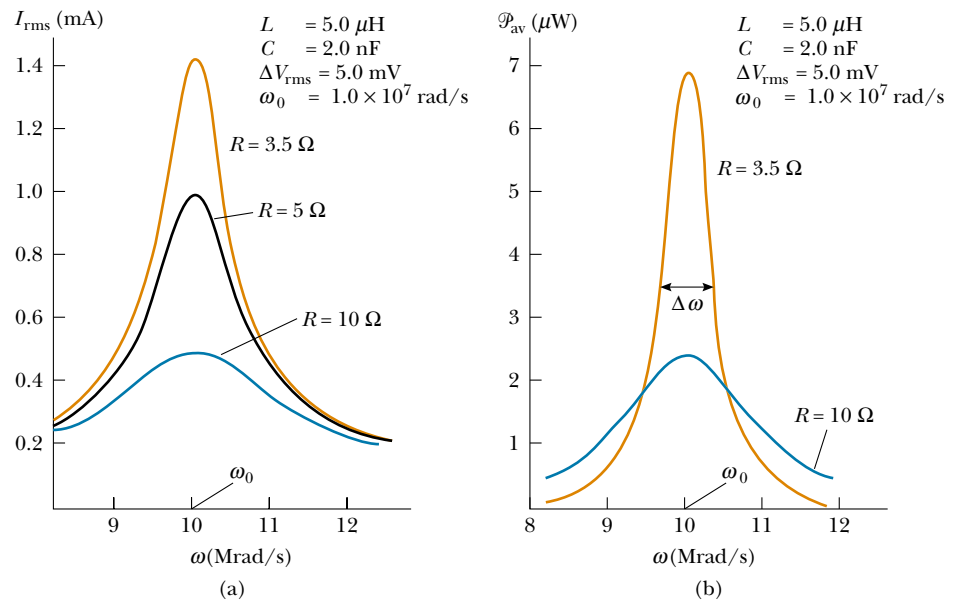

Note that this frequency also corresponds to the natural frequency of oscillation of an  $LC$  circuit (see Section 32.5). Therefore, the current in a series  $RLC$  circuit reaches its maximum value when the frequency of the applied voltage matches the natural oscillator frequency—which depends only on  $L$  and  $C$ . Furthermore, at this frequency the current is in phase with the applied voltage.

### Quick Quiz 33.4

What is the impedance of a series  $RLC$  circuit at resonance? What is the current in the circuit at resonance?

A plot of rms current versus frequency for a series  $RLC$  circuit is shown in Figure 33.15a. The data assume a constant  $\Delta V_{\text{rms}} = 5.0$  mV, that  $L = 5.0$   $\mu\text{H}$ , and that  $C = 2.0$  nF. The three curves correspond to three values of  $R$ . Note that in each case the current reaches its maximum value at the resonance frequency  $\omega_0$ . Furthermore, the curves become narrower and taller as the resistance decreases.

By inspecting Equation 33.32, we must conclude that, when  $R = 0$ , the current becomes infinite at resonance. Although the equation predicts this, real circuits always have some resistance, which limits the value of the current.

**Figure 33.15** (a) The rms current versus frequency for a series  $RLC$  circuit, for three values of  $R$ . The current reaches its maximum value at the resonance frequency  $\omega_0$ . (b) Average power versus frequency for the series  $RLC$  circuit, for two values of  $R$ .

It is also interesting to calculate the average power as a function of frequency for a series RLC circuit. Using Equations 33.30, 33.31, and 33.23, we find that

$$\mathcal{P}_{\text{av}} = I_{\text{rms}}^2 R = \frac{(\Delta V_{\text{rms}})^2}{Z^2} R = \frac{(\Delta V_{\text{rms}})^2 R}{R^2 + (X_L - X_C)^2} \quad (33.34)$$

Because  $X_L = \omega L$ ,  $X_C = 1/\omega C$ , and  $\omega_0^2 = 1/LC$ , we can express the term  $(X_L - X_C)^2$  as

$$(X_L - X_C)^2 = \left( \omega L - \frac{1}{\omega C} \right)^2 = \frac{L^2}{\omega^2} (\omega^2 - \omega_0^2)^2$$

Using this result in Equation 33.34 gives

$$\mathcal{P}_{\text{av}} = \frac{(\Delta V_{\text{rms}})^2 R \omega^2}{R^2 \omega^2 + L^2 (\omega^2 - \omega_0^2)^2} \quad (33.35)$$

This expression shows that at resonance, when  $\omega = \omega_0$ , **the average power is a maximum** and has the value  $(\Delta V_{\text{rms}})^2/R$ . Figure 33.15b is a plot of average power versus frequency for two values of  $R$  in a series RLC circuit. As the resistance is made smaller, the curve becomes sharper in the vicinity of the resonance frequency. This curve sharpness is usually described by a dimensionless parameter known as the **quality factor**, denoted by  $Q$ :<sup>4</sup>

$$Q = \frac{\omega_0}{\Delta\omega}$$

where  $\Delta\omega$  is the width of the curve measured between the two values of  $\omega$  for which  $\mathcal{P}_{\text{av}}$  has half its maximum value, called the *half-power points* (see Fig. 33.15b.) It is left as a problem (Problem 70) to show that the width at the half-power points has the value  $\Delta\omega = R/L$ , so

$$Q = \frac{\omega_0 L}{R} \quad (33.36)$$

The curves plotted in Figure 33.16 show that a high- $Q$  circuit responds to only a very narrow range of frequencies, whereas a low- $Q$  circuit can detect a much broader range of frequencies. Typical values of  $Q$  in electronic circuits range from 10 to 100.

The receiving circuit of a radio is an important application of a resonant circuit. One tunes the radio to a particular station (which transmits a specific electromagnetic wave or signal) by varying a capacitor, which changes the resonant frequency of the receiving circuit. When the resonance frequency of the circuit matches that of the incoming electromagnetic wave, the current in the receiving circuit increases. This signal caused by the incoming wave is then amplified and fed to a speaker. Because many signals are often present over a range of frequencies, it is important to design a high- $Q$  circuit to eliminate unwanted signals. In this manner, stations whose frequencies are near but not equal to the resonance frequency give signals at the receiver that are negligibly small relative to the signal that matches the resonance frequency.

<sup>4</sup> The quality factor is also defined as the ratio  $2\pi E/\Delta E$ , where  $E$  is the energy stored in the oscillating system and  $\Delta E$  is the energy lost per cycle of oscillation. The quality factor for a mechanical system can also be defined, as noted in Section 13.7.

Average power as a function of frequency in an RLC circuit

Quality factor

### QuickLab

Tune a radio to your favorite station. Can you determine what the product of  $LC$  must be for the radio's tuning circuitry?

**Figure 33.16** Average power versus frequency for a series RLC circuit. The width  $\Delta\omega$  of each curve is measured between the two points where the power is half its maximum value. The power is a maximum at the resonance frequency  $\omega_0$ .

**Quick Quiz 33.5**

An airport metal detector (Fig. 33.17) is essentially a resonant circuit. The portal you step through is an inductor (a large loop of conducting wire) that is part of the circuit. The frequency of the circuit is tuned to the resonant frequency of the circuit when there is no metal in the inductor. Any metal on your body increases the effective inductance of the loop and changes the current in it. If you want the detector to be able to detect a small metallic object, should the circuit have a high quality factor or a low one?

**Figure 33.17** When you pass through a metal detector, you become part of a resonant circuit. As you step through the detector, the inductance of the circuit changes, and thus the current in the circuit changes. (Terry Qing/FPG International)

**EXAMPLE 33.8** A Resonating Series *RLC* Circuit

Consider a series *RLC* circuit for which  $R = 150 \, \Omega$ ,  $L = 20.0 \, \text{mH}$ ,  $\Delta V_{\text{rms}} = 20.0 \, \text{V}$ , and  $\omega = 5000 \, \text{s}^{-1}$ . Determine the value of the capacitance for which the current is a maximum.

**Solution** The current has its maximum value at the resonance frequency  $\omega_0$ , which should be made to match the “driving” frequency of  $5000 \, \text{s}^{-1}$ :

$$\omega_0 = 5.00 \times 10^3 \, \text{s}^{-1} = \frac{1}{\sqrt{LC}}$$

$$C = \frac{1}{\omega_0^2 L} = \frac{1}{(25.0 \times 10^6 \, \text{s}^{-2})(20.0 \times 10^{-3} \, \text{H})} = 2.00 \, \mu\text{F}$$

**Exercise** Calculate the maximum value of the rms current in the circuit as the frequency is varied.

**Answer** 0.133 A.

**33.8 THE TRANSFORMER AND POWER TRANSMISSION**

When electric power is transmitted over great distances, it is economical to use a high voltage and a low current to minimize the  $I^2R$  loss in the transmission lines.

Consequently, 350-kV lines are common, and in many areas even higher-voltage (765-kV) lines are under construction. At the receiving end of such lines, the consumer requires power at a low voltage (for safety and for efficiency in design). Therefore, a device is required that can change the alternating voltage and current without causing appreciable changes in the power delivered. The ac transformer is that device.

In its simplest form, the **ac transformer** consists of two coils of wire wound around a core of iron, as illustrated in Figure 33.18. The coil on the left, which is connected to the input alternating voltage source and has  $N_1$  turns, is called the *primary winding* (or the *primary*). The coil on the right, consisting of  $N_2$  turns and connected to a load resistor  $R$ , is called the *secondary winding* (or the *secondary*). The purpose of the iron core is to increase the magnetic flux through the coil and to provide a medium in which nearly all the flux through one coil passes through the other coil. Eddy current losses are reduced by using a laminated core. Iron is used as the core material because it is a soft ferromagnetic substance and hence reduces hysteresis losses. Transformation of energy to internal energy in the finite resistance of the coil wires is usually quite small. Typical transformers have power efficiencies from 90% to 99%. In the discussion that follows, we assume an *ideal transformer*, one in which the energy losses in the windings and core are zero.

First, let us consider what happens in the primary circuit when the switch in the secondary circuit is open. If we assume that the resistance of the primary is negligible relative to its inductive reactance, then the primary circuit is equivalent to a simple circuit consisting of an inductor connected to an ac generator. Because the current is  $90^\circ$  out of phase with the voltage, the power factor  $\cos \phi$  is zero, and hence the average power delivered from the generator to the primary circuit is zero. Faraday's law states that the voltage  $\Delta V_1$  across the primary is

$$\Delta V_1 = -N_1 \frac{d\Phi_B}{dt} \quad (33.37)$$

where  $\Phi_B$  is the magnetic flux through each turn. If we assume that all magnetic field lines remain within the iron core, the flux through each turn of the primary equals the flux through each turn of the secondary. Hence, the voltage across the secondary is

$$\Delta V_2 = -N_2 \frac{d\Phi_B}{dt} \quad (33.38)$$

Solving Equation 33.37 for  $d\Phi_B/dt$  and substituting the result into Equation 33.38, we find that

$$\Delta V_2 = \frac{N_2}{N_1} \Delta V_1 \quad (33.39)$$

When  $N_2 > N_1$ , the output voltage  $\Delta V_2$  exceeds the input voltage  $\Delta V_1$ . This setup is referred to as a *step-up transformer*. When  $N_2 < N_1$ , the output voltage is less than the input voltage, and we have a *step-down transformer*.

When the switch in the secondary circuit is thrown closed, a current  $I_2$  is induced in the secondary. If the load in the secondary circuit is a pure resistance, the induced current is in phase with the induced voltage. The power supplied to the secondary circuit must be provided by the ac generator connected to the primary circuit, as shown in Figure 33.19. In an ideal transformer, where there are no losses, the power  $I_1 \Delta V_1$  supplied by the generator is equal to the power  $I_2 \Delta V_2$  in

**Figure 33.18** An ideal transformer consists of two coils wound on the same iron core. An alternating voltage  $\Delta V_1$  is applied to the primary coil, and the output voltage  $\Delta V_2$  is across the resistor of resistance  $R$ .

**Figure 33.19** Circuit diagram for a transformer.

This cylindrical step-down transformer drops the voltage from 4 000 V to 220 V for delivery to a group of residences. (George Semple)

**Nikola Tesla (1856–1943)** Tesla was born in Croatia but spent most of his professional life as an inventor in the United States. He was a key figure in the development of alternating-current electricity, high-voltage transformers, and the transport of electric power via ac transmission lines. Tesla's viewpoint was at odds with the ideas of Thomas Edison, who committed himself to the use of direct current in power transmission. Tesla's ac approach won out. (UPI/Bettmann)

the secondary circuit. That is,

$$I_1 \Delta V_1 = I_2 \Delta V_2 \quad (33.40)$$

The value of the load resistance  $R_L$  determines the value of the secondary current because  $I_2 = \Delta V_2/R_L$ . Furthermore, the current in the primary is  $I_1 = \Delta V_1/R_{\text{eq}}$ , where

$$R_{\text{eq}} = \left( \frac{N_1}{N_2} \right)^2 R_L \quad (33.41)$$

is the equivalent resistance of the load resistance when viewed from the primary side. From this analysis we see that a transformer may be used to match resistances between the primary circuit and the load. In this manner, maximum power transfer can be achieved between a given power source and the load resistance. For example, a transformer connected between the 1-k $\Omega$  output of an audio amplifier and an 8- $\Omega$  speaker ensures that as much of the audio signal as possible is transferred into the speaker. In stereo terminology, this is called *impedance matching*.

We can now also understand why transformers are useful for transmitting power over long distances. Because the generator voltage is stepped up, the current in the transmission line is reduced, and hence  $I^2R$  losses are reduced. In practice, the voltage is stepped up to around 230 000 V at the generating station, stepped down to around 20 000 V at a distributing station, then to 4 000 V for delivery to residential areas, and finally to 120–240 V at the customer's site. The power is supplied by a three-wire cable. In the United States, two of these wires are "hot," with voltages of 120 V with respect to a common ground wire. Home appliances operating on 120 V are connected in parallel between one of the hot wires and ground. Larger appliances, such as electric stoves and clothes dryers, require 240 V. This is obtained across the two hot wires, which are 180° out of phase so that the voltage difference between them is 240 V.

There is a practical upper limit to the voltages that can be used in transmission lines. Excessive voltages could ionize the air surrounding the transmission lines, which could result in a conducting path to ground or to other objects in the vicinity. This, of course, would present a serious hazard to any living creatures. For this reason, a long string of insulators is used to keep high-voltage wires away from their supporting metal towers. Other insulators are used to maintain separation between wires.

**Figure 33.20** The primary winding in this transformer is directly attached to the prongs of the plug. The secondary winding is connected to the wire on the right, which runs to an electronic device. Many of these power-supply transformers also convert alternating current to direct current. (George Semple)

Many common household electronic devices require low voltages to operate properly. A small transformer that plugs directly into the wall, like the one illustrated in the photograph at the beginning of this chapter, can provide the proper voltage. Figure 33.20 shows the two windings wrapped around a common iron core that is found inside all these little “black boxes.” This particular transformer converts the 120-V ac in the wall socket to 12.5-V ac. (Can you determine the ratio of the numbers of turns in the two coils?) Some black boxes also make use of diodes to convert the alternating current to direct current (see Section 33.9).

**web**

For information on how small transformers and hundreds of other everyday devices operate, visit <http://www.howstuffworks.com>

**EXAMPLE 33.9** The Economics of ac Power

An electricity-generating station needs to deliver 20 MW of power to a city 1.0 km away. (a) If the resistance of the wires is  $2.0 \Omega$  and the electricity costs about  $10\text{¢/kWh}$ , estimate what it costs the utility company to send the power to the city for one day. A common voltage for commercial power generators is 22 kV, but a step-up transformer is used to boost the voltage to 230 kV before transmission.

**Solution** The power losses in the transmission line are the result of the resistance of the line. We can determine the loss from Equation 27.23,  $\mathcal{P} = I^2R$ . Because this is an estimate, we can use dc equations and calculate  $I$  from Equation 27.22:

$$I = \frac{\mathcal{P}}{\Delta V} = \frac{20 \times 10^6 \text{ W}}{230 \times 10^3 \text{ V}} = 87 \text{ A}$$

Therefore,

$$\mathcal{P} = I^2R = (87 \text{ A})^2(2.0 \Omega) = 15 \text{ kW}$$

Over the course of a day, the energy loss due to the resistance of the wires is  $(15 \text{ kW})(24 \text{ h}) = 360 \text{ kWh}$ , at a cost of **\$36**.

(b) Repeat the calculation for the situation in which the power plant delivers the electricity at its original voltage of 22 kV.

**Solution**

$$I = \frac{\mathcal{P}}{\Delta V} = \frac{20 \times 10^6 \text{ W}}{22 \times 10^3 \text{ V}} = 910 \text{ A}$$

$$\mathcal{P} = I^2R = (910 \text{ A})^2(2.0 \Omega) = 1.7 \times 10^3 \text{ kW}$$

$$\text{Cost per day} = (1.7 \times 10^3 \text{ kW})(24 \text{ h})(\$0.10/\text{kWh})$$

$$= \text{\$4 100}$$

The tremendous savings that are possible through the use of transformers and high-voltage transmission lines, along with the efficiency of using alternating current to operate motors, led to the universal adoption of alternating current instead of direct current for commercial power grids.

*Optional Section***33.9** RECTIFIERS AND FILTERS

Portable electronic devices such as radios and compact disc (CD) players are often powered by direct current supplied by batteries. Many devices come with ac–dc converters that provide a readily available direct-current source if the batteries are low. Such a converter contains a transformer that steps the voltage down from 120 V to typically 9 V and a circuit that converts alternating current to direct current. The process of converting alternating current to direct current is called **rectification**, and the converting device is called a **rectifier**.

The most important element in a rectifier circuit is a **diode**, a circuit element that conducts current in one direction but not the other. Most diodes used in modern electronics are semiconductor devices. The circuit symbol for a diode is  , where the arrow indicates the direction of the current through the diode. A diode has low resistance to current in one direction (the direction of the arrow) and high resistance to current in the opposite direction. We can understand how a diode rectifies a current by considering Figure 33.21a, which shows a

diode and a resistor connected to the secondary of a transformer. The transformer reduces the voltage from 120-V ac to the lower voltage that is needed for the device having a resistance  $R$  (the load resistance). Because current can pass through the diode in only one direction, the alternating current in the load resistor is reduced to the form shown by the solid curve in Figure 33.21b. The diode conducts current only when the side of the symbol containing the arrowhead has a positive potential relative to the other side. In this situation, the diode acts as a *half-wave rectifier* because current is present in the circuit during only half of each cycle.

When a capacitor is added to the circuit, as shown by the dashed lines and the capacitor symbol in Figure 33.21a, the circuit is a simple dc power supply. The time variation in the current in the load resistor (the dashed curve in Fig. 33.21b) is close to being zero, as determined by the  $RC$  time constant of the circuit.

The  $RC$  circuit in Figure 33.21a is one example of a **filter circuit**, which is used to smooth out or eliminate a time-varying signal. For example, radios are usually powered by a 60-Hz alternating voltage. After rectification, the voltage still contains a small ac component at 60 Hz (sometimes called *ripple*), which must be filtered. By “filtered,” we mean that the 60-Hz ripple must be reduced to a value much less than that of the audio signal to be amplified, because without filtering, the resulting audio signal includes an annoying hum at 60 Hz.

To understand how a filter works, let us consider the simple series  $RC$  circuit shown in Figure 33.22a. The input voltage is across the two elements and is represented by  $\Delta V_{\max} \sin \omega t$ . Because we are interested only in maximum values, we can use Equation 33.24, taking  $X_L = 0$  and substituting  $X_C = 1/\omega C$ . This shows that the maximum input voltage is related to the maximum current by

$$\Delta V_{\text{in}} = I_{\text{max}} Z = I_{\text{max}} \sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2}$$

(a)

(b)

**Figure 33.21** (a) A half-wave rectifier with an optional filter capacitor. (b) Current versus time in the resistor. The solid curve represents the current with no filter capacitor, and the dashed curve is the current when the circuit includes the capacitor.

**Figure 33.22** (a) A simple  $RC$  high-pass filter. (b) Ratio of output voltage to input voltage for an  $RC$  high-pass filter as a function of the angular frequency of the circuit.

If the voltage across the resistor is considered to be the output voltage, then the maximum output voltage is

$$\Delta V_{\text{out}} = I_{\text{max}}R$$

Therefore, the ratio of the output voltage to the input voltage is

$$\frac{\Delta V_{\text{out}}}{\Delta V_{\text{in}}} = \frac{R}{\sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2}} \quad (33.42)$$

High-pass filter

A plot of this ratio as a function of angular frequency (see Fig. 33.22b) shows that at low frequencies  $\Delta V_{\text{out}}$  is much smaller than  $\Delta V_{\text{in}}$ , whereas at high frequencies the two voltages are equal. Because the circuit preferentially passes signals of higher frequency while blocking low-frequency signals, the circuit is called an  $RC$  high-pass filter. Physically, a high-pass filter works because a capacitor “blocks out” direct current and ac current at low frequencies.

Now let us consider the circuit shown in Figure 33.23a, where the output voltage is taken across the capacitor. In this case, the maximum voltage equals the voltage across the capacitor. Because the impedance across the capacitor is  $X_C = 1/\omega C$ , we have

$$\Delta V_{\text{out}} = I_{\text{max}}X_C = \frac{I_{\text{max}}}{\omega C}$$

**Figure 33.23** (a) A simple  $RC$  low-pass filter. (b) Ratio of output voltage to input voltage for an  $RC$  low-pass filter as a function of the angular frequency of the circuit.

Low-pass filter

Therefore, the ratio of the output voltage to the input voltage is

$$\frac{\Delta V_{\text{out}}}{\Delta V_{\text{in}}} = \frac{1/\omega C}{\sqrt{R^2 + \left(\frac{1}{\omega C}\right)^2}} \quad (33.43)$$

This ratio, plotted as a function of  $\omega$  in Figure 33.23b, shows that in this case the circuit preferentially passes signals of low frequency. Hence, the circuit is called an *RC* low-pass filter.

You may be familiar with crossover networks, which are an important part of the speaker systems for high-fidelity audio systems. These networks utilize low-pass filters to direct low frequencies to a special type of speaker, the “woofer,” which is designed to reproduce the low notes accurately. The high frequencies are sent to the “tweeter” speaker.

### Quick Quiz 33.6

Suppose you are designing a high-fidelity system containing both large loudspeakers (woofers) and small loudspeakers (tweeters). (a) What circuit element would you place in series with a woofer, which passes low-frequency signals? (b) What circuit element would you place in series with a tweeter, which passes high-frequency signals?

### SUMMARY

If an ac circuit consists of a generator and a resistor, the current is in phase with the voltage. That is, the current and voltage reach their maximum values at the same time.

The **rms current** and **rms voltage** in an ac circuit in which the voltages and current vary sinusoidally are given by the expressions

$$I_{\text{rms}} = \frac{I_{\text{max}}}{\sqrt{2}} = 0.707I_{\text{max}} \quad (33.4)$$

$$\Delta V_{\text{rms}} = \frac{\Delta V_{\text{max}}}{\sqrt{2}} = 0.707\Delta V_{\text{max}} \quad (33.5)$$

where  $I_{\text{max}}$  and  $\Delta V_{\text{max}}$  are the maximum values.

If an ac circuit consists of a generator and an inductor, the current lags behind the voltage by  $90^\circ$ . That is, the voltage reaches its maximum value one quarter of a period before the current reaches its maximum value.

If an ac circuit consists of a generator and a capacitor, the current leads the voltage by  $90^\circ$ . That is, the current reaches its maximum value one quarter of a period before the voltage reaches its maximum value.

In ac circuits that contain inductors and capacitors, it is useful to define the **inductive reactance**  $X_L$  and the **capacitive reactance**  $X_C$  as

$$X_L = \omega L \quad (33.10)$$

$$X_C = \frac{1}{\omega C} \quad (33.17)$$

where  $\omega$  is the angular frequency of the ac generator. The SI unit of reactance is the ohm.

The **impedance**  $Z$  of an  $RLC$  series ac circuit, which also has the ohm as its unit, is

$$Z \equiv \sqrt{R^2 + (X_L - X_C)^2} \quad (33.23)$$

This expression illustrates that we cannot simply add the resistance and reactances in a circuit. We must account for the fact that the applied voltage and current are out of phase, with the **phase angle**  $\phi$  between the current and voltage being

$$\phi = \tan^{-1}\left(\frac{X_L - X_C}{R}\right) \quad (33.25)$$

The sign of  $\phi$  can be positive or negative, depending on whether  $X_L$  is greater or less than  $X_C$ . The phase angle is zero when  $X_L = X_C$ .

The **average power** delivered by the generator in an  $RLC$  ac circuit is

$$\mathcal{P}_{\text{av}} = I_{\text{rms}} \Delta V_{\text{rms}} \cos \phi \quad (33.29)$$

An equivalent expression for the average power is

$$\mathcal{P}_{\text{av}} = I_{\text{rms}}^2 R \quad (33.30)$$

The average power delivered by the generator results in increasing internal energy in the resistor. No power loss occurs in an ideal inductor or capacitor.

The rms current in a series  $RLC$  circuit is

$$I_{\text{rms}} = \frac{\Delta V_{\text{rms}}}{\sqrt{R^2 + (X_L - X_C)^2}} \quad (33.32)$$

A series  $RLC$  circuit is in resonance when the inductive reactance equals the capacitive reactance. When this condition is met, the current given by Equation 33.32 reaches its maximum value. When  $X_L = X_C$  in a circuit, the **resonance frequency**  $\omega_0$  of the circuit is

$$\omega_0 = \frac{1}{\sqrt{LC}} \quad (33.33)$$

The current in a series  $RLC$  circuit reaches its maximum value when the frequency of the generator equals  $\omega_0$ —that is, when the “driving” frequency matches the resonance frequency.

Transformers allow for easy changes in alternating voltage. Because energy (and therefore power) are conserved, we can write

$$I_1 \Delta V_1 = I_2 \Delta V_2 \quad (33.40)$$

to relate the currents and voltages in the primary and secondary windings of a transformer.

## QUESTIONS

- Fluorescent lights flicker on and off 120 times every second. Explain what causes this. Why can't you see it happening?
- Why does a capacitor act as a short circuit at high frequencies? Why does it act as an open circuit at low frequencies?
- Explain how the acronyms in the mnemonic “ELI the ICE man” can be used to recall whether current leads voltage or voltage leads current in  $RLC$  circuits. (Note that “E” represents voltage.)
- Why is the sum of the maximum voltages across the elements in a series  $RLC$  circuit usually greater than the maximum applied voltage? Doesn't this violate Kirchhoff's second rule?
- Does the phase angle depend on frequency? What is the phase angle when the inductive reactance equals the capacitive reactance?
- Energy is delivered to a series  $RLC$  circuit by a generator. This energy appears as internal energy in the resistor. What is the source of this energy?

- Explain why the average power delivered to an  $RLC$  circuit by the generator depends on the phase between the current and the applied voltage.
- A particular experiment requires a beam of light of very stable intensity. Why would an ac voltage be unsuitable for powering the light source?
- Consider a series  $RLC$  circuit in which  $R$  is an incandescent lamp,  $C$  is some fixed capacitor, and  $L$  is a variable inductance. The source is 120-V ac. Explain why the lamp glows brightly for some values of  $L$  and does not glow at all for other values.
- What determines the maximum voltage that can be used on a transmission line?
- Will a transformer operate if a battery is used for the input voltage across the primary? Explain.
- How can the average value of a current be zero and yet the square root of the average squared current not be zero?
- What is the time average of the “square-wave” voltage shown in Figure Q33.13? What is its rms voltage?

Figure Q33.13

- Explain how the quality factor is related to the response characteristics of a radio receiver. Which variable most strongly determines the quality factor?

- Why are the primary and secondary windings of a transformer wrapped on an iron core that passes through both coils?
- With reference to Figure Q33.16, explain why the capacitor prevents a dc signal from passing between circuits A and B, yet allows an ac signal to pass from circuit A to circuit B. (The circuits are said to be capacitively coupled.)

Figure Q33.16

- With reference to Figure Q33.17, if  $C$  is made sufficiently large, an ac signal passes from circuit A to ground rather than from circuit A to circuit B. Hence, the capacitor acts as a filter. Explain.

Figure Q33.17

## PROBLEMS

1, 2, 3 = straightforward, intermediate, challenging □ = full solution available in the *Student Solutions Manual and Study Guide*  
 WEB = solution posted at <http://www.saunderscollege.com/physics/> = Computer useful in solving problem = Interactive Physics  
 □ = paired numerical/symbolic problems

Note: Assume that all ac voltages and currents are sinusoidal unless stated otherwise.

### Section 33.1 ac Sources and Phasors

### Section 33.2 Resistors in an ac Circuit

- The rms output voltage of an ac generator is 200 V, and the operating frequency is 100 Hz. Write the equation giving the output voltage as a function of time.
- (a) What is the resistance of a lightbulb that uses an average power of 75.0 W when connected to a 60.0-Hz power source having a maximum voltage of 170 V?  
(b) What is the resistance of a 100-W bulb?
- An ac power supply produces a maximum voltage  $\Delta V_{\max} = 100$  V. This power supply is connected to a  $24.0\text{-}\Omega$  resistor, and the current and resistor voltage are measured with an ideal ac ammeter and voltmeter, as shown in Figure P33.3. What does each meter read?

Note that an ideal ammeter has zero resistance and that an ideal voltmeter has infinite resistance.

Figure P33.3

4. In the simple ac circuit shown in Figure 33.1,  $R = 70.0 \Omega$  and  $\Delta v = \Delta V_{\max} \sin \omega t$ . (a) If  $\Delta v_R = 0.250 \Delta V_{\max}$  for the first time at  $t = 0.0100$  s, what is the angular frequency of the generator? (b) What is the next value of  $t$  for which  $\Delta v_R = 0.250 \Delta V_{\max}$ ?
5. The current in the circuit shown in Figure 33.1 equals 60.0% of the peak current at  $t = 7.00$  ms. What is the smallest frequency of the generator that gives this current?
6. Figure P33.6 shows three lamps connected to a 120-V ac (rms) household supply voltage. Lamps 1 and 2 have 150-W bulbs; lamp 3 has a 100-W bulb. Find the rms current and the resistance of each bulb.

Figure P33.6

7. An audio amplifier, represented by the ac source and resistor in Figure P33.7, delivers to the speaker alternating voltage at audio frequencies. If the source voltage has an amplitude of 15.0 V,  $R = 8.20 \Omega$ , and the speaker is equivalent to a resistance of  $10.4 \Omega$ , what time-averaged power is transferred to it?

Figure P33.7

### Section 33.3 Inductors in an ac Circuit

8. An inductor is connected to a 20.0-Hz power supply that produces a 50.0-V rms voltage. What inductance is needed to keep the instantaneous current in the circuit below 80.0 mA?
9. In a purely inductive ac circuit, such as that shown in Figure 33.4,  $\Delta V_{\max} = 100$  V. (a) If the maximum current is 7.50 A at 50.0 Hz, what is the inductance  $L$ ? (b) At what angular frequency  $\omega$  is the maximum current 2.50 A?
10. An inductor has a  $54.0\text{-}\Omega$  reactance at 60.0 Hz. What is the maximum current when this inductor is connected to a 50.0-Hz source that produces a 100-V rms voltage?

- WEB 11. For the circuit shown in Figure 33.4,  $\Delta V_{\max} = 80.0$  V,  $\omega = 65.0\pi$  rad/s, and  $L = 70.0$  mH. Calculate the current in the inductor at  $t = 15.5$  ms.
12. A 20.0-mH inductor is connected to a standard outlet ( $\Delta V_{\text{rms}} = 120$  V,  $f = 60.0$  Hz). Determine the energy stored in the inductor at  $t = (1/180)$  s, assuming that this energy is zero at  $t = 0$ .
13. **Review Problem.** Determine the maximum magnetic flux through an inductor connected to a standard outlet ( $\Delta V_{\text{rms}} = 120$  V,  $f = 60.0$  Hz).

### Section 33.4 Capacitors in an ac Circuit

14. (a) For what frequencies does a  $22.0\text{-}\mu\text{F}$  capacitor have a reactance below  $175 \Omega$ ? (b) Over this same frequency range, what is the reactance of a  $44.0\text{-}\mu\text{F}$  capacitor?
15. What maximum current is delivered by a  $2.20\text{-}\mu\text{F}$  capacitor when it is connected across (a) a North American outlet having  $\Delta V_{\text{rms}} = 120$  V and  $f = 60.0$  Hz? (b) a European outlet having  $\Delta V_{\text{rms}} = 240$  V and  $f = 50.0$  Hz?
16. A capacitor  $C$  is connected to a power supply that operates at a frequency  $f$  and produces an rms voltage  $\Delta V$ . What is the maximum charge that appears on either of the capacitor plates?
17. What maximum current is delivered by an ac generator with  $\Delta V_{\max} = 48.0$  V and  $f = 90.0$  Hz when it is connected across a  $3.70\text{-}\mu\text{F}$  capacitor?
18. A  $1.00\text{-mF}$  capacitor is connected to a standard outlet ( $\Delta V_{\text{rms}} = 120$  V,  $f = 60.0$  Hz). Determine the current in the capacitor at  $t = (1/180)$  s, assuming that at  $t = 0$  the energy stored in the capacitor is zero.

### Section 33.5 The RLC Series Circuit

19. An inductor ( $L = 400$  mH), a capacitor ( $C = 4.43 \mu\text{F}$ ), and a resistor ( $R = 500 \Omega$ ) are connected in series. A 50.0-Hz ac generator produces a peak current of 250 mA in the circuit. (a) Calculate the required peak voltage  $\Delta V_{\max}$ . (b) Determine the phase angle by which the current leads or lags the applied voltage.
20. At what frequency does the inductive reactance of a  $57.0\text{-}\mu\text{H}$  inductor equal the capacitive reactance of a  $57.0\text{-}\mu\text{F}$  capacitor?
21. A series ac circuit contains the following components:  $R = 150 \Omega$ ,  $L = 250$  mH,  $C = 2.00 \mu\text{F}$ , and a generator with  $\Delta V_{\max} = 210$  V operating at 50.0 Hz. Calculate the (a) inductive reactance, (b) capacitive reactance, (c) impedance, (d) maximum current, and (e) phase angle between current and generator voltage.
22. A sinusoidal voltage  $\Delta v(t) = (40.0 \text{ V}) \sin(100t)$  is applied to a series RLC circuit with  $L = 160$  mH,  $C = 99.0 \mu\text{F}$ , and  $R = 68.0 \Omega$ . (a) What is the impedance of the circuit? (b) What is the maximum current? (c) Determine the numerical values for  $I_{\max}$ ,  $\omega$ , and  $\phi$  in the equation  $i(t) = I_{\max} \sin(\omega t - \phi)$ .
- WEB 23. An RLC circuit consists of a  $150\text{-}\Omega$  resistor, a  $21.0\text{-}\mu\text{F}$  capacitor, and a  $460\text{-mH}$  inductor, connected in series with a 120-V, 60.0-Hz power supply. (a) What is the

phase angle between the current and the applied voltage? (b) Which reaches its maximum earlier, the current or the voltage?

24. A person is working near the secondary of a transformer, as shown in Figure P33.24. The primary voltage is 120 V at 60.0 Hz. The capacitance  $C_s$ , which is the stray capacitance between the person's hand and the secondary winding, is 20.0 pF. Assuming that the person has a body resistance to ground  $R_b = 50.0$  k $\Omega$ , determine the rms voltage across the body. (*Hint*: Redraw the circuit with the secondary of the transformer as a simple ac source.)

Figure P33.24

25. An ac source with  $\Delta V_{\text{max}} = 150$  V and  $f = 50.0$  Hz is connected between points  $a$  and  $d$  in Figure P33.25. Calculate the maximum voltages between points (a)  $a$  and  $b$ , (b)  $b$  and  $c$ , (c)  $c$  and  $d$ , and (d)  $b$  and  $d$ .

Figure P33.25 Problems 25 and 64.

26. Draw to scale a phasor diagram showing  $Z$ ,  $X_L$ ,  $X_C$ , and  $\phi$  for an ac series circuit for which  $R = 300$   $\Omega$ ,  $C = 11.0$   $\mu\text{F}$ ,  $L = 0.200$  H, and  $f = (500/\pi)$  Hz.
27. A coil of resistance 35.0  $\Omega$  and inductance 20.5 H is in series with a capacitor and a 200-V (rms), 100-Hz source. The rms current in the circuit is 4.00 A. (a) Calculate the capacitance in the circuit. (b) What is  $\Delta V_{\text{rms}}$  across the coil?

### Section 33.6 Power in an ac Circuit

28. The voltage source in Figure P33.28 has an output  $\Delta V_{\text{rms}} = 100$  V at  $\omega = 1\,000$  rad/s. Determine (a) the current in the circuit and (b) the power supplied by the source. (c) Show that the power delivered to the resistor is equal to the power supplied by the source.

Figure P33.28

- WEB 29. An ac voltage of the form  $\Delta v = (100 \text{ V}) \sin(1\,000t)$  is applied to a series  $RLC$  circuit. If  $R = 400$   $\Omega$ ,  $C = 5.00$   $\mu\text{F}$ , and  $L = 0.500$  H, what is the average power delivered to the circuit?
30. A series  $RLC$  circuit has a resistance of 45.0  $\Omega$  and an impedance of 75.0  $\Omega$ . What average power is delivered to this circuit when  $\Delta V_{\text{rms}} = 210$  V?
31. In a certain series  $RLC$  circuit,  $I_{\text{rms}} = 9.00$  A,  $\Delta V_{\text{rms}} = 180$  V, and the current leads the voltage by 37.0°. (a) What is the total resistance of the circuit? (b) What is the reactance of the circuit ( $X_L - X_C$ )?
32. Suppose you manage a factory that uses many electric motors. The motors create a large inductive load to the electric power line, as well as a resistive load. The electric company builds an extra-heavy distribution line to supply you with a component of current that is 90° out of phase with the voltage, as well as with current in phase with the voltage. The electric company charges you an extra fee for “reactive volt-amps” in addition to the amount you pay for the energy you use. You can avoid the extra fee by installing a capacitor between the power line and your factory. The following problem models this solution.
- In an  $LR$  circuit, a 120-V (rms), 60.0-Hz source is in series with a 25.0-mH inductor and a 20.0- $\Omega$  resistor. What are (a) the rms current and (b) the power factor? (c) What capacitor must be added in series to make the power factor 1? (d) To what value can the supply voltage be reduced if the power supplied is to be the same as that provided before installation of the capacitor?

**33. Review Problem.** Over a distance of 100 km, power of 100 MW is to be transmitted at 50.0 kV with only 1.00% loss. Copper wire of what diameter should be used for each of the two conductors of the transmission line? Assume that the current density in the conductors is uniform.

**34. Review Problem.** Suppose power  $\mathcal{P}$  is to be transmitted over a distance  $d$  at a voltage  $\Delta V$ , with only 1.00% loss. Copper wire of what diameter should be used for each of the two conductors of the transmission line? Assume that the current density in the conductors is uniform.

35. A diode is a device that allows current to pass in only one direction (the direction indicated by the arrowhead in its circuit-diagram symbol). Find, in terms of  $\Delta V$  and

$R$ , the average power delivered to the diode circuit shown in Figure P33.35.

Figure P33.35

### Section 33.7 Resonance in a Series RLC Circuit

36. The tuning circuit of an AM radio contains an  $LC$  combination. The inductance is  $0.200$  mH, and the capacitor is variable, so the circuit can resonate at any frequency between  $550$  kHz and  $1\,650$  kHz. Find the range of values required for  $C$ .
37. An  $RLC$  circuit is used in a radio to tune in to an FM station broadcasting at  $99.7$  MHz. The resistance in the circuit is  $12.0\ \Omega$ , and the inductance is  $1.40\ \mu\text{H}$ . What capacitance should be used?
38. A series  $RLC$  circuit has the following values:  $L = 20.0$  mH,  $C = 100$  nF,  $R = 20.0\ \Omega$ , and  $\Delta V_{\text{max}} = 100$  V, with  $\Delta v = \Delta V_{\text{max}} \sin \omega t$ . Find (a) the resonant frequency, (b) the amplitude of the current at the resonant frequency, (c) the  $Q$  of the circuit, and (d) the amplitude of the voltage across the inductor at resonance.
39. A  $10.0\text{-}\Omega$  resistor, a  $10.0\text{-mH}$  inductor, and a  $100\text{-}\mu\text{F}$  capacitor are connected in series to a  $50.0\text{-V}$  (rms) source having variable frequency. What is the energy delivered to the circuit during one period if the operating frequency is twice the resonance frequency?
40. A resistor  $R$ , an inductor  $L$ , and a capacitor  $C$  are connected in series to an ac source of rms voltage  $\Delta V$  and variable frequency. What is the energy delivered to the circuit during one period if the operating frequency is twice the resonance frequency?
41. Compute the quality factor for the circuits described in Problems 22 and 23. Which circuit has the sharper resonance?

### Section 33.8 The Transformer and Power Transmission

42. A step-down transformer is used for recharging the batteries of portable devices such as tape players. The turns ratio inside the transformer is  $13:1$ , and it is used with  $120\text{-V}$  (rms) household service. If a particular ideal transformer draws  $0.350$  A from the house outlet, what (a) voltage and (b) current are supplied to a tape player from the transformer? (c) How much power is delivered?

43. A transformer has  $N_1 = 350$  turns and  $N_2 = 2\,000$  turns. If the input voltage is  $\Delta v(t) = (170\ \text{V}) \cos \omega t$ , what rms voltage is developed across the secondary coil?
44. A step-up transformer is designed to have an output voltage of  $2\,200$  V (rms) when the primary is connected across a  $110\text{-V}$  (rms) source. (a) If there are  $80$  turns on the primary winding, how many turns are required on the secondary? (b) If a load resistor across the secondary draws a current of  $1.50$  A, what is the current in the primary under ideal conditions? (c) If the transformer actually has an efficiency of  $95.0\%$ , what is the current in the primary when the secondary current is  $1.20$  A?
45. In the transformer shown in Figure P33.45, the load resistor is  $50.0\ \Omega$ . The turns ratio  $N_1:N_2$  is  $5:2$ , and the source voltage is  $80.0$  V (rms). If a voltmeter across the load measures  $25.0$  V (rms), what is the source resistance  $R_s$ ?

Figure P33.45

46. The secondary voltage of an ignition transformer in a furnace is  $10.0$  kV. When the primary operates at an rms voltage of  $120$  V, the primary impedance is  $24.0\ \Omega$  and the transformer is  $90.0\%$  efficient. (a) What turns ratio is required? What are (b) the current in the secondary and (c) the impedance in the secondary?
47. A transmission line that has a resistance per unit length of  $4.50 \times 10^{-4}\ \Omega/\text{m}$  is to be used to transmit  $5.00$  MW over  $400$  mi ( $6.44 \times 10^5$  m). The output voltage of the generator is  $4.50$  kV. (a) What is the power loss if a transformer is used to step up the voltage to  $500$  kV? (b) What fraction of the input power is lost to the line under these circumstances? (c) What difficulties would be encountered on attempting to transmit the  $5.00$  MW at the generator voltage of  $4.50$  kV?

(Optional)

### Section 33.9 Rectifiers and Filters

48. The  $RC$  low-pass filter shown in Figure 33.23 has a resistance  $R = 90.0\ \Omega$  and a capacitance  $C = 8.00$  nF. Calculate the gain ( $\Delta V_{\text{out}}/\Delta V_{\text{in}}$ ) for input frequencies of (a)  $600$  Hz and (b)  $600$  kHz.
- WEB 49. The  $RC$  high-pass filter shown in Figure 33.22 has a resistance  $R = 0.500\ \Omega$ . (a) What capacitance gives an output signal that has one-half the amplitude of a  $300\text{-Hz}$  input signal? (b) What is the gain ( $\Delta V_{\text{out}}/\Delta V_{\text{in}}$ ) for a  $600\text{-Hz}$  signal?

50. The circuit in Figure P33.50 represents a high-pass filter in which the inductor has internal resistance. What is the source frequency if the output voltage  $\Delta V_2$  is one-half the input voltage?

Figure P33.50

51. The resistor in Figure P33.51 represents the midrange speaker in a three-speaker system. Assume that its resistance is constant at  $8.00\ \Omega$ . The source represents an audio amplifier producing signals of uniform amplitude  $\Delta V_{\text{in}} = 10.0\ \text{V}$  at all audio frequencies. The inductor and capacitor are to function as a bandpass filter with  $\Delta V_{\text{out}}/\Delta V_{\text{in}} = \frac{1}{2}$  at 200 Hz and at 4 000 Hz. (a) Determine the required values of  $L$  and  $C$ . (b) Find the maximum value of the gain ratio  $\Delta V_{\text{out}}/\Delta V_{\text{in}}$ . (c) Find the frequency  $f_0$  at which the gain ratio has its maximum value. (d) Find the phase shift between  $\Delta V_{\text{in}}$  and  $\Delta V_{\text{out}}$  at 200 Hz, at  $f_0$ , and at 4 000 Hz. (e) Find the average power transferred to the speaker at 200 Hz, at  $f_0$ , and at 4 000 Hz. (f) Treating the filter as a resonant circuit, find its quality factor.

Figure P33.51

52. Show that two successive high-pass filters having the same values of  $R$  and  $C$  give a combined gain

$$\frac{\Delta V_{\text{out}}}{\Delta V_{\text{in}}} = \frac{1}{1 + (1/\omega RC)^2}$$

53. Consider a low-pass filter followed by a high-pass filter, as shown in Figure P33.53. If  $R = 1\ 000\ \Omega$  and  $C = 0.050\ 0\ \mu\text{F}$ , determine  $\Delta V_{\text{out}}/\Delta V_{\text{in}}$  for a 2.00-kHz input frequency.

### ADDITIONAL PROBLEMS

54. Show that the rms value for the sawtooth voltage shown in Figure P33.54 is  $\Delta V_{\text{max}}/\sqrt{3}$ .

Figure P33.53

Figure P33.54

- WEB 55. A series  $RLC$  circuit consists of an  $8.00\text{-}\Omega$  resistor, a  $5.00\text{-}\mu\text{F}$  capacitor, and a  $50.0\text{-mH}$  inductor. A variable frequency source applies an emf of  $400\ \text{V}$  (rms) across the combination. Determine the power delivered to the circuit when the frequency is equal to one-half the resonance frequency.
56. To determine the inductance of a coil used in a research project, a student first connects the coil to a  $12.0\text{-V}$  battery and measures a current of  $0.630\ \text{A}$ . The student then connects the coil to a  $24.0\text{-V}$  (rms),  $60.0\text{-Hz}$  generator and measures an rms current of  $0.570\ \text{A}$ . What is the inductance?
57. In Figure P33.57, find the current delivered by the  $45.0\text{-V}$  (rms) power supply (a) when the frequency is very large and (b) when the frequency is very small.

Figure P33.57

58. In the circuit shown in Figure P33.58, assume that all parameters except  $C$  are given. (a) Find the current as a function of time. (b) Find the power delivered to the circuit. (c) Find the current as a function of time after *only* switch 1 is opened. (d) After switch 2 is *also* opened, the current and voltage are in phase. Find the capacitance  $C$ . (e) Find the impedance of the circuit when both switches are open. (f) Find the maximum

energy stored in the capacitor during oscillations. (g) Find the maximum energy stored in the inductor during oscillations. (h) Now the frequency of the voltage source is doubled. Find the phase difference between the current and the voltage. (i) Find the frequency that makes the inductive reactance one-half the capacitive reactance.

Figure P33.58

59. As an alternative to the  $RC$  filters described in Section 33.9,  $LC$  filters are used as both high- and low-pass filters. However, all real inductors have resistance, as indicated in Figure P33.59, and this resistance must be taken into account. (a) Determine which circuit in Figure P33.59 is the high-pass filter and which is the low-pass filter. (b) Derive the output/input ratio for each

Figure P33.59

circuit, following the procedure used for the  $RC$  filters in Section 33.9.

60. An  $80.0\text{-}\Omega$  resistor and a  $200\text{-mH}$  inductor are connected in *parallel* across a  $100\text{-V}$  (rms),  $60.0\text{-Hz}$  source. (a) What is the rms current in the resistor? (b) By what angle does the total current lead or lag behind the voltage?
61. Make an order-of-magnitude estimate of the electric current that the electric company delivers to a town from a remote generating station. State the data that you measure or estimate. If you wish, you may consider a suburban bedroom community of 20 000 people.
62. A voltage  $\Delta v = (100\text{ V}) \sin \omega t$  (in SI units) is applied across a series combination of a  $2.00\text{-H}$  inductor, a  $10.0\text{-}\mu\text{F}$  capacitor, and a  $10.0\text{-}\Omega$  resistor. (a) Determine the angular frequency  $\omega_0$  at which the power delivered to the resistor is a maximum. (b) Calculate the power at that frequency. (c) Determine the two angular frequencies  $\omega_1$  and  $\omega_2$  at which the power delivered is one-half the maximum value. [The  $Q$  of the circuit is approximately  $\omega_0/(\omega_2 - \omega_1)$ .]
63. Consider a series  $RLC$  circuit having the following circuit parameters:  $R = 200\ \Omega$ ,  $L = 663\ \text{mH}$ , and  $C = 26.5\ \mu\text{F}$ . The applied voltage has an amplitude of  $50.0\ \text{V}$  and a frequency of  $60.0\ \text{Hz}$ . Find the following: (a) the current  $I_{\text{max}}$ , including its phase constant  $\phi$  relative to the applied voltage  $\Delta v$ ; (b) the voltage  $\Delta V_R$  across the resistor and its phase relative to the current; (c) the voltage  $\Delta V_C$  across the capacitor and its phase relative to the current; and (d) the voltage  $\Delta V_L$  across the inductor and its phase relative to the current.
64. A power supply with  $\Delta V_{\text{rms}} = 120\ \text{V}$  is connected between points  $a$  and  $d$  in Figure P33.25. At what frequency will it deliver a power of  $250\ \text{W}$ ?
65. Example 28.2 showed that maximum power is transferred when the internal resistance of a dc source is equal to the resistance of the load. A transformer may be used to provide maximum power transfer between two ac circuits that have different impedances. (a) Show that the ratio of turns  $N_1/N_2$  needed to meet this condition is

$$\frac{N_1}{N_2} = \sqrt{\frac{Z_1}{Z_2}}$$

- (b) Suppose you want to use a transformer as an impedance-matching device between an audio amplifier that has an output impedance of  $8.00\ \text{k}\Omega$  and a speaker that has an input impedance of  $8.00\ \Omega$ . What should your  $N_1/N_2$  ratio be?
66. Figure P33.66a shows a parallel  $RLC$  circuit, and the corresponding phasor diagram is provided in Figure P33.66b. The instantaneous voltages and rms voltages across the three circuit elements are the same, and each is in phase with the current through the resistor. The currents in  $C$  and  $L$  lead or lag behind the current in the resistor, as shown in Figure P33.66b. (a) Show that the rms current delivered by the source is

$$I_{\text{rms}} = \Delta V_{\text{rms}} \left[ \frac{1}{R^2} + \left( \omega C - \frac{1}{\omega L} \right)^2 \right]^{1/2}$$

(b) Show that the phase angle  $\phi$  between  $\Delta V_{\text{rms}}$  and  $I_{\text{rms}}$  is

$$\tan \phi = R \left( \frac{1}{X_C} - \frac{1}{X_L} \right)$$

(a)

(b)

Figure P33.66

67. An  $80.0\text{-}\Omega$  resistor, a  $200\text{-mH}$  inductor, and a  $0.150\text{-}\mu\text{F}$  capacitor are connected *in parallel* across a  $120\text{-V}$  (rms) source operating at  $374\text{ rad/s}$ . (a) What is the resonant frequency of the circuit? (b) Calculate the rms current in the resistor, the inductor, and the capacitor. (c) What

rms current is delivered by the source? (d) Is the current leading or lagging behind the voltage? By what angle?

68. Consider the phase-shifter circuit shown in Figure P33.68. The input voltage is described by the expression  $\Delta v = (10.0\text{ V}) \sin 200t$  (in SI units). Assuming that  $L = 500\text{ mH}$ , find (a) the value of  $R$  such that the output voltage lags behind the input voltage by  $30.0^\circ$  and (b) the amplitude of the output voltage.

Figure P33.68

69. A series  $RLC$  circuit is operating at  $2\,000\text{ Hz}$ . At this frequency,  $X_L = X_C = 1\,884\ \Omega$ . The resistance of the circuit is  $40.0\ \Omega$ . (a) Prepare a table showing the values of  $X_L$ ,  $X_C$ , and  $Z$  for  $f = 300, 600, 800, 1\,000, 1\,500, 2\,000, 3\,000, 4\,000, 6\,000,$  and  $10\,000\text{ Hz}$ . (b) Plot on the same set of axes  $X_L$ ,  $X_C$ , and  $Z$  as functions of  $\ln f$ .
70. A series  $RLC$  circuit in which  $R = 1.00\ \Omega$ ,  $L = 1.00\text{ mH}$ , and  $C = 1.00\text{ nF}$  is connected to an ac generator delivering  $1.00\text{ V}$  (rms). Make a precise graph of the power delivered to the circuit as a function of the frequency, and verify that the full width of the resonance peak at half-maximum is  $R/2\pi L$ .
71. Suppose the high-pass filter shown in Figure 33.22 has  $R = 1\,000\ \Omega$  and  $C = 0.050\,0\ \mu\text{F}$ . (a) At what frequency does  $\Delta V_{\text{out}}/\Delta V_{\text{in}} = \frac{1}{2}$ ? (b) Plot  $\log_{10}(\Delta V_{\text{out}}/\Delta V_{\text{in}})$  versus  $\log_{10}(f)$  over the frequency range from  $1\text{ Hz}$  to  $1\text{ MHz}$ . (This log-log plot of gain versus frequency is known as a *Bode plot*.)

## ANSWERS TO QUICK QUIZZES

- 33.1 (c)  $\mathcal{P}_{\text{av}} > 0$  and  $i_{\text{av}} = 0$ . The average power is proportional to the rms current—which, as Figure 33.3 shows, is nonzero even though the average current is zero. Condition (a) is valid only for an open circuit, and conditions (b) and (d) can never be true because  $i_{\text{av}} = 0$  for ac circuits even though  $i_{\text{rms}} > 0$ .
- 33.2 (b) Sum of instantaneous voltages across elements. Choices (a) and (c) are incorrect because the unaligned sine curves in Figure 33.9b mean that the voltages are out of phase, so we cannot simply add the maximum (or rms) voltages across the elements. (In other words,  $\Delta V \neq \Delta V_R + \Delta V_L + \Delta V_C$  even though it is true that  $\Delta v = \Delta v_R + \Delta v_L + \Delta v_C$ .)
- 33.3 (a)  $X_L < X_C$ . (b)  $X_L = X_C$ . (c)  $X_L > X_C$ .
- 33.4 Equation 33.23 indicates that at resonance (when  $X_L = X_C$ ) the impedance is due strictly to the resistor,  $Z = R$ . At resonance, the current is given by the expression  $I_{\text{rms}} = \Delta V_{\text{rms}}/R$ .
- 33.5 High. The higher the quality factor, the more sensitive the detector. As you can see from Figure 33.15a, when  $Q = \omega_0/\Delta\omega$  is high, as it is in the  $R = 3.5\ \Omega$  case, a slight change in the resonance frequency (as might happen when a small piece of metal passes through the portal) causes a large change in current that can be detected easily.
- 33.6 (a) An inductor. The current in an inductive circuit decreases with increasing frequency (see Eq. 33.9). Thus, an inductor connected in series with a woofer blocks high-frequency signals and passes low-frequency signals. (b) A capacitor. The current in a capacitive circuit decreases with decreasing frequency (see Eq. 33.16). When a capacitor is connected in series with a tweeter, the capacitor blocks low-frequency signals and passes high-frequency signals.

## Electromagnetic Waves

### Chapter Outline

- 34.1** Maxwell's Equations and Hertz's Discoveries
- 34.2** Plane Electromagnetic Waves
- 34.3** Energy Carried by Electromagnetic Waves
- 34.4** Momentum and Radiation Pressure
- 34.5** *(Optional)* Radiation from an Infinite Current Sheet
- 34.6** *(Optional)* Production of Electromagnetic Waves by an Antenna
- 34.7** The Spectrum of Electromagnetic Waves

**James Clerk Maxwell** Scottish theoretical physicist (1831–1879)

Maxwell developed the electromagnetic theory of light and the kinetic theory of gases, and he explained the nature of color vision and of Saturn's rings. His successful interpretation of the electromagnetic field produced the field equations that bear his name. Formidable mathematical ability combined with great insight enabled Maxwell to lead the way in the study of electromagnetism and kinetic theory. He died of cancer before he was 50. (North Wind Picture Archives)

The waves described in Chapters 16, 17, and 18 are mechanical waves. By definition, the propagation of mechanical disturbances—such as sound waves, water waves, and waves on a string—requires the presence of a medium. This chapter is concerned with the properties of electromagnetic waves, which (unlike mechanical waves) can propagate through empty space.

In Section 31.7 we gave a brief description of Maxwell's equations, which form the theoretical basis of all electromagnetic phenomena. The consequences of Maxwell's equations are far-reaching and dramatic. The Ampère–Maxwell law predicts that a time-varying electric field produces a magnetic field, just as Faraday's law tells us that a time-varying magnetic field produces an electric field. Maxwell's introduction of the concept of displacement current as a new source of a magnetic field provided the final important link between electric and magnetic fields in classical physics.

Astonishingly, Maxwell's equations also predict the existence of electromagnetic waves that propagate through space at the speed of light  $c$ . This chapter begins with a discussion of how Heinrich Hertz confirmed Maxwell's prediction when he generated and detected electromagnetic waves in 1887. That discovery has led to many practical communication systems, including radio, television, and radar. On a conceptual level, Maxwell unified the subjects of light and electromagnetism by developing the idea that light is a form of electromagnetic radiation.

Next, we learn how electromagnetic waves are generated by oscillating electric charges. The waves consist of oscillating electric and magnetic fields that are at right angles to each other and to the direction of wave propagation. Thus, electromagnetic waves are transverse waves. Maxwell's prediction of electromagnetic radiation shows that the amplitudes of the electric and magnetic fields in an electromagnetic wave are related by the expression  $E = cB$ . The waves radiated from the oscillating charges can be detected at great distances. Furthermore, electromagnetic waves carry energy and momentum and hence can exert pressure on a surface.

The chapter concludes with a look at the wide range of frequencies covered by electromagnetic waves. For example, radio waves (frequencies of about  $10^7$  Hz) are electromagnetic waves produced by oscillating currents in a radio tower's transmitting antenna. Light waves are a high-frequency form of electromagnetic radiation (about  $10^{14}$  Hz) produced by oscillating electrons in atoms.

### 34.1 MAXWELL'S EQUATIONS AND HERTZ'S DISCOVERIES

In his unified theory of electromagnetism, Maxwell showed that electromagnetic waves are a natural consequence of the fundamental laws expressed in the following four equations (see Section 31.7):

$$\oint_S \mathbf{E} \cdot d\mathbf{A} = \frac{Q}{\epsilon_0} \quad (34.1)$$

$$\oint_S \mathbf{B} \cdot d\mathbf{A} = 0 \quad (34.2)$$

$$\oint \mathbf{E} \cdot d\mathbf{s} = -\frac{d\Phi_B}{dt} \quad (34.3)$$

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 I + \mu_0 \epsilon_0 \frac{d\Phi_E}{dt} \quad (34.4)$$

As we shall see in the next section, Equations 34.3 and 34.4 can be combined to obtain a wave equation for both the electric field and the magnetic field. In empty space ( $Q = 0, I = 0$ ), the solution to these two equations shows that the speed at which electromagnetic waves travel equals the measured speed of light. This result led Maxwell to predict that light waves are a form of electromagnetic radiation.

The experimental apparatus that Hertz used to generate and detect electromagnetic waves is shown schematically in Figure 34.1. An induction coil is connected to a transmitter made up of two spherical electrodes separated by a narrow gap. The coil provides short voltage surges to the electrodes, making one positive and the other negative. A spark is generated between the spheres when the electric field near either electrode surpasses the dielectric strength for air ( $3 \times 10^6$  V/m; see Table 26.1). In a strong electric field, the acceleration of free electrons provides them with enough energy to ionize any molecules they strike. This ionization provides more electrons, which can accelerate and cause further ionizations. As the air in the gap is ionized, it becomes a much better conductor, and the discharge between the electrodes exhibits an oscillatory behavior at a very high frequency. From an electric-circuit viewpoint, this is equivalent to an  $LC$  circuit in which the inductance is that of the coil and the capacitance is due to the spherical electrodes.

Because  $L$  and  $C$  are quite small in Hertz's apparatus, the frequency of oscillation is very high,  $\approx 100$  MHz. (Recall from Eq. 32.22 that  $\omega = 1/\sqrt{LC}$  for an  $LC$  circuit.) Electromagnetic waves are radiated at this frequency as a result of the oscillation (and hence acceleration) of free charges in the transmitter circuit. Hertz was able to detect these waves by using a single loop of wire with its own spark gap (the receiver). Such a receiver loop, placed several meters from the transmitter, has its own effective inductance, capacitance, and natural frequency of oscillation. In Hertz's experiment, sparks were induced across the gap of the receiving electrodes when the frequency of the receiver was adjusted to match that of the transmitter. Thus, Hertz demonstrated that the oscillating current induced in the receiver was produced by electromagnetic waves radiated by the transmitter. His experiment is analogous to the mechanical phenomenon in which a tuning fork responds to acoustic vibrations from an identical tuning fork that is oscillating.

**Heinrich Rudolf Hertz** German physicist (1857–1894) Hertz made his most important discovery—radio waves—in 1887. After finding that the speed of a radio wave was the same as that of light, he showed that radio waves, like light waves, could be reflected, refracted, and diffracted. Hertz died of blood poisoning at age 36. He made many contributions to science during his short life. The hertz, equal to one complete vibration or cycle per second, is named after him. (*The Bettmann Archive*)

**Figure 34.1** Schematic diagram of Hertz's apparatus for generating and detecting electromagnetic waves. The transmitter consists of two spherical electrodes connected to an induction coil, which provides short voltage surges to the spheres, setting up oscillations in the discharge between the electrodes (suggested by the red dots). The receiver is a nearby loop of wire containing a second spark gap.

A large oscillator (bottom) and circular, octagonal, and square receivers used by Heinrich Hertz.

### QuickLab

Some electric motors use commutators that make and break electrical contact, creating sparks reminiscent of Hertz's method for generating electromagnetic waves. Try running an electric shaver or kitchen mixer near an AM radio. What happens to the reception?

Additionally, Hertz showed in a series of experiments that the radiation generated by his spark-gap device exhibited the wave properties of interference, diffraction, reflection, refraction, and polarization, all of which are properties exhibited by light. Thus, it became evident that the radio-frequency waves Hertz was generating had properties similar to those of light waves and differed only in frequency and wavelength. Perhaps his most convincing experiment was the measurement of the speed of this radiation. Radio-frequency waves of known frequency were reflected from a metal sheet and created a standing-wave interference pattern whose nodal points could be detected. The measured distance between the nodal points enabled determination of the wavelength  $\lambda$ . Using the relationship  $v = \lambda f$  (Eq. 16.14), Hertz found that  $v$  was close to  $3 \times 10^8$  m/s, the known speed  $c$  of visible light.

**Figure 34.2** An electromagnetic wave traveling at velocity  $\mathbf{c}$  in the positive  $x$  direction. The electric field is along the  $y$  direction, and the magnetic field is along the  $z$  direction. These fields depend only on  $x$  and  $t$ .

## 34.2 PLANE ELECTROMAGNETIC WAVES

The properties of electromagnetic waves can be deduced from Maxwell's equations. One approach to deriving these properties is to solve the second-order differential equation obtained from Maxwell's third and fourth equations. A rigorous mathematical treatment of that sort is beyond the scope of this text. To circumvent this problem, we assume that the vectors for the electric field and magnetic field in an electromagnetic wave have a specific space–time behavior that is simple but consistent with Maxwell's equations.

To understand the prediction of electromagnetic waves more fully, let us focus our attention on an electromagnetic wave that travels in the  $x$  direction (the *direction of propagation*). In this wave, the electric field  $\mathbf{E}$  is in the  $y$  direction, and the magnetic field  $\mathbf{B}$  is in the  $z$  direction, as shown in Figure 34.2. Waves such as this one, in which the electric and magnetic fields are restricted to being parallel to a pair of perpendicular axes, are said to be **linearly polarized waves**.<sup>1</sup> Furthermore, we assume that at any point  $P$ , the magnitudes  $E$  and  $B$  of the fields depend

<sup>1</sup> Waves having other particular patterns of vibration of the electric and magnetic fields include circularly polarized waves. The most general polarization pattern is elliptical.

upon  $x$  and  $t$  only, and not upon the  $y$  or  $z$  coordinate. A collection of such waves from individual sources is called a **plane wave**. A surface connecting points of equal phase on all waves, which we call a **wave front**, would be a geometric plane. In comparison, a point source of radiation sends waves out in all directions. A surface connecting points of equal phase is a sphere for this situation, so we call this a **spherical wave**.

We can relate  $E$  and  $B$  to each other with Equations 34.3 and 34.4. In empty space, where  $Q = 0$  and  $I = 0$ , Equation 34.3 remains unchanged and Equation 34.4 becomes

$$\oint \mathbf{B} \cdot d\mathbf{s} = \mu_0 \epsilon_0 \frac{d\Phi_E}{dt} \quad (34.5)$$

Using Equations 34.3 and 34.5 and the plane-wave assumption, we obtain the following differential equations relating  $E$  and  $B$ . (We shall derive these equations formally later in this section.) For simplicity, we drop the subscripts on the components  $E_y$  and  $B_z$ :

$$\frac{\partial E}{\partial x} = -\frac{\partial B}{\partial t} \quad (34.6)$$

$$\frac{\partial B}{\partial x} = -\mu_0 \epsilon_0 \frac{\partial E}{\partial t} \quad (34.7)$$

Note that the derivatives here are partial derivatives. For example, when we evaluate  $\partial E/\partial x$ , we assume that  $t$  is constant. Likewise, when we evaluate  $\partial B/\partial t$ ,  $x$  is held constant. Taking the derivative of Equation 34.6 with respect to  $x$  and combining the result with Equation 34.7, we obtain

$$\frac{\partial^2 E}{\partial x^2} = -\frac{\partial}{\partial x} \left( \frac{\partial B}{\partial t} \right) = -\frac{\partial}{\partial t} \left( \frac{\partial B}{\partial x} \right) = -\frac{\partial}{\partial t} \left( -\mu_0 \epsilon_0 \frac{\partial E}{\partial t} \right)$$

$$\frac{\partial^2 E}{\partial x^2} = \mu_0 \epsilon_0 \frac{\partial^2 E}{\partial t^2} \quad (34.8)$$

In the same manner, taking the derivative of Equation 34.7 with respect to  $x$  and combining it with Equation 34.6, we obtain

$$\frac{\partial^2 B}{\partial x^2} = \mu_0 \epsilon_0 \frac{\partial^2 B}{\partial t^2} \quad (34.9)$$

Equations 34.8 and 34.9 both have the form of the general wave equation<sup>2</sup> with the wave speed  $v$  replaced by  $c$ , where

$$c = \frac{1}{\sqrt{\mu_0 \epsilon_0}} \quad (34.10)$$

Speed of electromagnetic waves

Taking  $\mu_0 = 4\pi \times 10^{-7} \text{ T} \cdot \text{m/A}$  and  $\epsilon_0 = 8.85419 \times 10^{-12} \text{ C}^2/\text{N} \cdot \text{m}^2$  in Equation 34.10, we find that  $c = 2.99792 \times 10^8 \text{ m/s}$ . Because this speed is precisely the same as the speed of light in empty space, we are led to believe (correctly) that light is an electromagnetic wave.

<sup>2</sup> The general wave equation is of the form  $(\partial^2 y/\partial x^2) = (1/v^2)(\partial^2 y/\partial t^2)$ , where  $v$  is the speed of the wave and  $y$  is the wave function. The general wave equation was introduced as Equation 16.26, and it would be useful for you to review Section 16.9.

**Figure 34.3** Representation of a sinusoidal, linearly polarized plane electromagnetic wave moving in the positive  $x$  direction with velocity  $\mathbf{c}$ . (a) The wave at some instant. Note the sinusoidal variations of  $E$  and  $B$  with  $x$ . (b) A time sequence illustrating the electric and magnetic field vectors present in the  $yz$  plane, as seen by an observer looking in the negative  $x$  direction. Note the sinusoidal variations of  $E$  and  $B$  with  $t$ .

The simplest solution to Equations 34.8 and 34.9 is a sinusoidal wave, for which the field magnitudes  $E$  and  $B$  vary with  $x$  and  $t$  according to the expressions

$$E = E_{\max} \cos(kx - \omega t) \quad (34.11)$$

$$B = B_{\max} \cos(kx - \omega t) \quad (34.12)$$

where  $E_{\max}$  and  $B_{\max}$  are the maximum values of the fields. The angular wave number is the constant  $k = 2\pi/\lambda$ , where  $\lambda$  is the wavelength. The angular frequency is  $\omega = 2\pi f$ , where  $f$  is the wave frequency. The ratio

$\omega/k$  equals the speed  $c$ :

$$\frac{\omega}{k} = \frac{2\pi f}{2\pi/\lambda} = \lambda f = c$$

We have used Equation 16.14,  $v = c = \lambda f$ , which relates the speed, frequency, and wavelength of any continuous wave. Figure 34.3a is a pictorial representation, at one instant, of a sinusoidal, linearly polarized plane wave moving in the positive  $x$  direction. Figure 34.3b shows how the electric and magnetic field vectors at a fixed location vary with time.

### Quick Quiz 34.1

What is the phase difference between  $B$  and  $E$  in Figure 34.3?

Taking partial derivatives of Equations 34.11 (with respect to  $x$ ) and 34.12

(with respect to  $t$ ), we find that

$$\frac{\partial E}{\partial x} = -kE_{\max}\sin(kx - \omega t)$$

$$\frac{\partial B}{\partial t} = \omega B_{\max}\sin(kx - \omega t)$$

Substituting these results into Equation 34.6, we find that at any instant

$$kE_{\max} = \omega B_{\max}$$

$$\frac{E_{\max}}{B_{\max}} = \frac{\omega}{k} = c$$

Using these results together with Equations 34.11 and 34.12, we see that

$$\frac{E_{\max}}{B_{\max}} = \frac{E}{B} = c \quad (34.13)$$

That is, **at every instant the ratio of the magnitude of the electric field to the magnitude of the magnetic field in an electromagnetic wave equals the speed of light.**

Finally, note that electromagnetic waves obey the superposition principle (which we discussed in Section 16.4 with respect to mechanical waves) because the differential equations involving  $E$  and  $B$  are linear equations. For example, we can add two waves with the same frequency simply by adding the magnitudes of the two electric fields algebraically.

- The solutions of Maxwell's third and fourth equations are wave-like, with both  $E$  and  $B$  satisfying a wave equation.
- Electromagnetic waves travel through empty space at the speed of light  $c = 1/\sqrt{\mu_0\epsilon_0}$ .
- The components of the electric and magnetic fields of plane electromagnetic waves are perpendicular to each other and perpendicular to the direction of wave propagation. We can summarize the latter property by saying that electromagnetic waves are transverse waves.
- The magnitudes of  $\mathbf{E}$  and  $\mathbf{B}$  in empty space are related by the expression  $E/B = c$ .
- Electromagnetic waves obey the principle of superposition.

Properties of electromagnetic waves

### EXAMPLE 34.1 An Electromagnetic Wave

A sinusoidal electromagnetic wave of frequency 40.0 MHz travels in free space in the  $x$  direction, as shown in Figure 34.4. (a) Determine the wavelength and period of the wave.

**Solution** Using Equation 16.14 for light waves,  $c = \lambda f$ , and given that  $f = 40.0 \text{ MHz} = 4.00 \times 10^7 \text{ s}^{-1}$ , we have

$$\lambda = \frac{c}{f} = \frac{3.00 \times 10^8 \text{ m/s}}{4.00 \times 10^7 \text{ s}^{-1}} = 7.50 \text{ m}$$

The period  $T$  of the wave is the inverse of the frequency:

$$T = \frac{1}{f} = \frac{1}{4.00 \times 10^7 \text{ s}^{-1}} = 2.50 \times 10^{-8} \text{ s}$$

(b) At some point and at some instant, the electric field has its maximum value of 750 N/C and is along the  $y$  axis. Calculate the magnitude and direction of the magnetic field at this position and time.

**Solution** From Equation 34.13 we see that

$$B_{\max} = \frac{E_{\max}}{c} = \frac{750 \text{ N/C}}{3.00 \times 10^8 \text{ m/s}} = 2.50 \times 10^{-6} \text{ T}$$

Because  $\mathbf{E}$  and  $\mathbf{B}$  must be perpendicular to each other and perpendicular to the direction of wave propagation ( $x$  in this case), we conclude that  $\mathbf{B}$  is in the  $z$  direction.

**Figure 34.4** At some instant, a plane electromagnetic wave moving in the  $x$  direction has a maximum electric field of  $750 \text{ N/C}$  in the positive  $y$  direction. The corresponding magnetic field at that point has a magnitude  $E/c$  and is in the  $z$  direction.

(c) Write expressions for the space-time variation of the components of the electric and magnetic fields for this wave.

**Solution** We can apply Equations 34.11 and 34.12 directly:

$$E = E_{\max} \cos(kx - \omega t) = (750 \text{ N/C}) \cos(kx - \omega t)$$

$$B = B_{\max} \cos(kx - \omega t) = (2.50 \times 10^{-6} \text{ T}) \cos(kx - \omega t)$$

where

$$\omega = 2\pi f = 2\pi(4.00 \times 10^7 \text{ s}^{-1}) = 2.51 \times 10^8 \text{ rad/s}$$

$$k = \frac{2\pi}{\lambda} = \frac{2\pi}{7.50 \text{ m}} = 0.838 \text{ rad/m}$$

Let us summarize the properties of electromagnetic waves as we have described them:

### Optional Section

#### Derivation of Equations 34.6 and 34.7

To derive Equation 34.6, we start with Faraday's law, Equation 34.3:

$$\oint \mathbf{E} \cdot d\mathbf{s} = -\frac{d\Phi_B}{dt}$$

Let us again assume that the electromagnetic wave is traveling in the  $x$  direction, with the electric field  $\mathbf{E}$  in the positive  $y$  direction and the magnetic field  $\mathbf{B}$  in the positive  $z$  direction.

Consider a rectangle of width  $dx$  and height  $\ell$  lying in the  $xy$  plane, as shown in Figure 34.5. To apply Equation 34.3, we must first evaluate the line integral of  $\mathbf{E} \cdot d\mathbf{s}$  around this rectangle. The contributions from the top and bottom of the rectangle are zero because  $\mathbf{E}$  is perpendicular to  $d\mathbf{s}$  for these paths. We can express the electric field on the right side of the rectangle as

$$E(x + dx, t) \approx E(x, t) + \left. \frac{dE}{dx} \right]_{t \text{ constant}} dx = E(x, t) + \frac{\partial E}{\partial x} dx$$

while the field on the left side is simply  $E(x, t)$ .<sup>3</sup> Therefore, the line integral over this rectangle is approximately

$$\oint \mathbf{E} \cdot d\mathbf{s} = E(x + dx, t) \cdot \ell - E(x, t) \cdot \ell \approx (\partial E / \partial x) dx \cdot \ell \quad (34.14)$$

Because the magnetic field is in the  $z$  direction, the magnetic flux through the rectangle of area  $\ell dx$  is approximately  $\Phi_B = B\ell dx$ . (This assumes that  $dx$  is very small compared with the wavelength of the wave.) Taking the time derivative of

**Figure 34.5** As a plane wave passes through a rectangular path of width  $dx$  lying in the  $xy$  plane, the electric field in the  $y$  direction varies from  $\mathbf{E}$  to  $\mathbf{E} + d\mathbf{E}$ . This spatial variation in  $\mathbf{E}$  gives rise to a time-varying magnetic field along the  $z$  direction, according to Equation 34.6.

<sup>3</sup> Because  $dE/dx$  in this equation is expressed as the change in  $E$  with  $x$  at a given instant  $t$ ,  $dE/dx$  is equivalent to the partial derivative  $\partial E/\partial x$ . Likewise,  $dB/dt$  means the change in  $B$  with time at a particular position  $x$ , so in Equation 34.15 we can replace  $dB/dt$  with  $\partial B/\partial t$ .

the magnetic flux gives

$$\left. \frac{d\Phi_B}{dt} = \ell \, dx \frac{dB}{dt} \right]_{x \text{ constant}} = \ell \, dx \frac{\partial B}{\partial t} \quad (34.15)$$

Substituting Equations 34.14 and 34.15 into Equation 34.3, we obtain

$$\begin{aligned} \left( \frac{\partial E}{\partial x} \right) dx \cdot \ell &= -\ell \, dx \frac{\partial B}{\partial t} \\ \frac{\partial E}{\partial x} &= -\frac{\partial B}{\partial t} \end{aligned}$$

This expression is Equation 34.6.

In a similar manner, we can verify Equation 34.7 by starting with Maxwell's fourth equation in empty space (Eq. 34.5). In this case, we evaluate the line integral of  $\mathbf{B} \cdot d\mathbf{s}$  around a rectangle lying in the  $xz$  plane and having width  $dx$  and length  $\ell$ , as shown in Figure 34.6. Noting that the magnitude of the magnetic field changes from  $B(x, t)$  to  $B(x + dx, t)$  over the width  $dx$ , we find the line integral over this rectangle to be approximately

$$\oint \mathbf{B} \cdot d\mathbf{s} = B(x, t) \cdot \ell - B(x + dx, t) \cdot \ell \approx -(\partial B / \partial x) \, dx \cdot \ell \quad (34.16)$$

The electric flux through the rectangle is  $\Phi_E = E\ell \, dx$ , which, when differentiated with respect to time, gives

$$\frac{\partial \Phi_E}{\partial t} = \ell \, dx \frac{\partial E}{\partial t} \quad (34.17)$$

Substituting Equations 34.16 and 34.17 into Equation 34.5 gives

$$\begin{aligned} -(\partial B / \partial x) \, dx \cdot \ell &= \mu_0 \epsilon_0 \ell \, dx (\partial E / \partial t) \\ \frac{\partial B}{\partial x} &= -\mu_0 \epsilon_0 \frac{\partial E}{\partial t} \end{aligned}$$

which is Equation 34.7.

**Figure 34.6** As a plane wave passes through a rectangular path of width  $dx$  lying in the  $xz$  plane, the magnetic field in the  $z$  direction varies from  $\mathbf{B}$  to  $\mathbf{B} + d\mathbf{B}$ . This spatial variation in  $\mathbf{B}$  gives rise to a time-varying electric field along the  $y$  direction, according to Equation 34.7.

### 34.3 ENERGY CARRIED BY ELECTROMAGNETIC WAVES

Electromagnetic waves carry energy, and as they propagate through space they can transfer energy to objects placed in their path. The rate of flow of energy in an electromagnetic wave is described by a vector  $\mathbf{S}$ , called the **Poynting vector**, which is defined by the expression

$$\mathbf{S} \equiv \frac{1}{\mu_0} \mathbf{E} \times \mathbf{B} \quad (34.18)$$

The magnitude of the Poynting vector represents the rate at which energy flows through a unit surface area perpendicular to the direction of wave propagation. Thus, the magnitude of the Poynting vector represents *power per unit area*. The direction of the vector is along the direction of wave propagation (Fig. 34.7). The SI units of the Poynting vector are  $\text{J/s} \cdot \text{m}^2 = \text{W/m}^2$ .

Poynting vector

Magnitude of the Poynting vector for a plane wave

As an example, let us evaluate the magnitude of  $\mathbf{S}$  for a plane electromagnetic wave where  $|\mathbf{E} \times \mathbf{B}| = EB$ . In this case,

$$S = \frac{EB}{\mu_0} \quad (34.19)$$

Because  $B = E/c$ , we can also express this as

$$S = \frac{E^2}{\mu_0 c} = \frac{c}{\mu_0} B^2$$

These equations for  $S$  apply at any instant of time and represent the *instantaneous* rate at which energy is passing through a unit area.

What is of greater interest for a sinusoidal plane electromagnetic wave is the time average of  $S$  over one or more cycles, which is called the *wave intensity*  $I$ . (We discussed the intensity of sound waves in Chapter 17.) When this average is taken, we obtain an expression involving the time average of  $\cos^2(kx - \omega t)$ , which equals  $\frac{1}{2}$ . Hence, the average value of  $S$  (in other words, the intensity of the wave) is

$$I = S_{\text{av}} = \frac{E_{\text{max}} B_{\text{max}}}{2\mu_0} = \frac{E_{\text{max}}^2}{2\mu_0 c} = \frac{c}{2\mu_0} B_{\text{max}}^2 \quad (34.20)$$

Recall that the energy per unit volume, which is the instantaneous energy density  $u_E$  associated with an electric field, is given by Equation 26.13,

$$u_E = \frac{1}{2} \epsilon_0 E^2$$

and that the instantaneous energy density  $u_B$  associated with a magnetic field is given by Equation 32.14:

$$u_B = \frac{B^2}{2\mu_0}$$

Because  $E$  and  $B$  vary with time for an electromagnetic wave, the energy densities also vary with time. When we use the relationships  $B = E/c$  and  $c = 1/\sqrt{\mu_0 \epsilon_0}$ , Equation 32.14 becomes

$$u_B = \frac{(E/c)^2}{2\mu_0} = \frac{\mu_0 \epsilon_0}{2\mu_0} E^2 = \frac{1}{2} \epsilon_0 E^2$$

Comparing this result with the expression for  $u_E$ , we see that

$$u_B = u_E = \frac{1}{2} \epsilon_0 E^2 = \frac{B^2}{2\mu_0}$$

That is, **for an electromagnetic wave, the instantaneous energy density associated with the magnetic field equals the instantaneous energy density associated with the electric field.** Hence, in a given volume the energy is equally shared by the two fields.

The **total instantaneous energy density**  $u$  is equal to the sum of the energy densities associated with the electric and magnetic fields:

$$u = u_E + u_B = \epsilon_0 E^2 = \frac{B^2}{\mu_0}$$

When this total instantaneous energy density is averaged over one or more cycles of an electromagnetic wave, we again obtain a factor of  $\frac{1}{2}$ . Hence, for any electromagnetic wave, the total average energy per unit volume is

Wave intensity

**Figure 34.7** The Poynting vector  $\mathbf{S}$  for a plane electromagnetic wave is along the direction of wave propagation.

Total instantaneous energy density

Average energy density of an electromagnetic wave

$$u_{\text{av}} = \epsilon_0 (E^2)_{\text{av}} = \frac{1}{2} \epsilon_0 E_{\text{max}}^2 = \frac{B_{\text{max}}^2}{2\mu_0} \quad (34.21)$$

### EXAMPLE 34.2 Fields on the Page

Estimate the maximum magnitudes of the electric and magnetic fields of the light that is incident on this page because of the visible light coming from your desk lamp. Treat the bulb as a point source of electromagnetic radiation that is about 5% efficient at converting electrical energy to visible light.

**Solution** Recall from Equation 17.8 that the wave intensity  $I$  a distance  $r$  from a point source is  $I = \mathcal{P}_{\text{av}}/4\pi r^2$ , where  $\mathcal{P}_{\text{av}}$  is the average power output of the source and  $4\pi r^2$  is the area of a sphere of radius  $r$  centered on the source. Because the intensity of an electromagnetic wave is also given by Equation 34.20, we have

$$I = \frac{\mathcal{P}_{\text{av}}}{4\pi r^2} = \frac{E_{\text{max}}^2}{2\mu_0 c}$$

We must now make some assumptions about numbers to enter in this equation. If we have a 60-W lightbulb, its output at 5% efficiency is approximately 3.0 W in the form of visible light. (The remaining energy transfers out of the bulb by conduction and invisible radiation.) A reasonable distance from the bulb to the page might be 0.30 m. Thus, we have

$$\begin{aligned} E_{\text{max}} &= \sqrt{\frac{\mu_0 c \mathcal{P}_{\text{av}}}{2\pi r^2}} \\ &= \sqrt{\frac{(4\pi \times 10^{-7} \text{ T}\cdot\text{m/A})(3.00 \times 10^8 \text{ m/s})(3.0 \text{ W})}{2\pi(0.30 \text{ m})^2}} \\ &= 45 \text{ V/m} \end{aligned}$$

From Equation 34.13,

$$B_{\text{max}} = \frac{E_{\text{max}}}{c} = \frac{45 \text{ V/m}}{3.00 \times 10^8 \text{ m/s}} = 1.5 \times 10^{-7} \text{ T}$$

This value is two orders of magnitude smaller than the Earth's magnetic field, which, unlike the magnetic field in the light wave from your desk lamp, is not oscillating.

**Exercise** Estimate the energy density of the light wave just before it strikes this page.

**Answer**  $9.0 \times 10^{-9} \text{ J/m}^3$ .

Comparing this result with Equation 34.20 for the average value of  $S$ , we see that

$$I = S_{\text{av}} = cu_{\text{av}} \quad (34.22)$$

In other words, **the intensity of an electromagnetic wave equals the average energy density multiplied by the speed of light.**

## 34.4 MOMENTUM AND RADIATION PRESSURE

Electromagnetic waves transport linear momentum as well as energy. It follows that, as this momentum is absorbed by some surface, pressure is exerted on the surface. We shall assume in this discussion that the electromagnetic wave strikes the surface at normal incidence and transports a total energy  $U$  to the surface in a time  $t$ . Maxwell showed that, if the surface absorbs all the incident energy  $U$  in this time (as does a black body, introduced in Chapter 20), the total momentum  $\mathbf{p}$  transported to the surface has a magnitude

$$p = \frac{U}{c} \quad (\text{complete absorption}) \quad (34.23)$$

The pressure exerted on the surface is defined as force per unit area  $F/A$ . Let us combine this with Newton's second law:

Momentum transported to a perfectly absorbing surface

Radiation pressure exerted on a perfectly absorbing surface

### QuickLab

Using Example 34.2 as a starting point, estimate the total force exerted on this page by the light from your desk lamp. Does it make a difference if the page contains large, dark photographs instead of mostly white space?

Radiation pressure exerted on a perfectly reflecting surface

### web

Visit <http://pds.jpl.nasa.gov> for more information about missions to the planets. You may also want to read Arthur C. Clarke's 1963 science fiction story *The Wind from the Sun* about a solar yacht race.

**Figure 34.8** An apparatus for measuring the pressure exerted by light. In practice, the system is contained in a high vacuum.

$$P = \frac{F}{A} = \frac{1}{A} \frac{dp}{dt}$$

If we now replace  $p$ , the momentum transported to the surface by light, from Equation 34.23, we have

$$P = \frac{1}{A} \frac{dp}{dt} = \frac{1}{A} \frac{d}{dt} \left( \frac{U}{c} \right) = \frac{1}{c} \frac{(dU/dt)}{A}$$

We recognize  $(dU/dt)/A$  as the rate at which energy is arriving at the surface per unit area, which is the magnitude of the Poynting vector. Thus, the radiation pressure  $P$  exerted on the perfectly absorbing surface is

$$P = \frac{S}{c} \quad (34.24)$$

Note that Equation 34.24 is an expression for uppercase  $P$ , the pressure, while Equation 34.23 is an expression for lowercase  $p$ , linear momentum.

If the surface is a perfect reflector (such as a mirror) and incidence is normal, then the momentum transported to the surface in a time  $t$  is twice that given by Equation 34.23. That is, the momentum transferred to the surface by the incoming light is  $p = U/c$ , and that transferred by the reflected light also is  $p = U/c$ . Therefore,

$$p = \frac{2U}{c} \quad (\text{complete reflection}) \quad (34.25)$$

The momentum delivered to a surface having a reflectivity somewhere between these two extremes has a value between  $U/c$  and  $2U/c$ , depending on the properties of the surface. Finally, the radiation pressure exerted on a perfectly reflecting surface for normal incidence of the wave is<sup>4</sup>

$$P = \frac{2S}{c} \quad (34.26)$$

Although radiation pressures are very small (about  $5 \times 10^{-6}$  N/m<sup>2</sup> for direct sunlight), they have been measured with torsion balances such as the one shown in Figure 34.8. A mirror (a perfect reflector) and a black disk (a perfect absorber) are connected by a horizontal rod suspended from a fine fiber. Normal-incidence light striking the black disk is completely absorbed, so all of the momentum of the

**Figure 34.9** Mariner 10 used its solar panels to “sail on sunlight.”

<sup>4</sup> For oblique incidence on a perfectly reflecting surface, the momentum transferred is  $(2U \cos \theta)/c$  and the pressure is  $P = (2S \cos^2 \theta)/c$ , where  $\theta$  is the angle between the normal to the surface and the direction of wave propagation.

light is transferred to the disk. Normal-incidence light striking the mirror is totally reflected, and hence the momentum transferred to the mirror is twice as great as that transferred to the disk. The radiation pressure is determined by measuring the angle through which the horizontal connecting rod rotates. The apparatus

### CONCEPTUAL EXAMPLE 34.3 Sweeping the Solar System

A great amount of dust exists in interplanetary space. Although in theory these dust particles can vary in size from molecular size to much larger, very little of the dust in our solar system is smaller than about  $0.2 \mu\text{m}$ . Why?

**Solution** The dust particles are subject to two significant forces—the gravitational force that draws them toward the Sun and the radiation-pressure force that pushes them away from the Sun. The gravitational force is proportional to the

cube of the radius of a spherical dust particle because it is proportional to the mass and therefore to the volume  $4\pi r^3/3$  of the particle. The radiation pressure is proportional to the square of the radius because it depends on the planar cross-section of the particle. For large particles, the gravitational force is greater than the force from radiation pressure. For particles having radii less than about  $0.2 \mu\text{m}$ , the radiation-pressure force is greater than the gravitational force, and as a result these particles are swept out of the Solar System.

### EXAMPLE 34.4 Pressure from a Laser Pointer

Many people giving presentations use a laser pointer to direct the attention of the audience. If a 3.0-mW pointer creates a spot that is 2.0 mm in diameter, determine the radiation pressure on a screen that reflects 70% of the light that strikes it. The power 3.0 mW is a time-averaged value.

**Solution** We certainly do not expect the pressure to be very large. Before we can calculate it, we must determine the Poynting vector of the beam by dividing the time-averaged power delivered via the electromagnetic wave by the cross-sectional area of the beam:

$$S = \frac{\mathcal{P}}{A} = \frac{\mathcal{P}}{\pi r^2} = \frac{3.0 \times 10^{-3} \text{ W}}{\pi \left( \frac{2.0 \times 10^{-3} \text{ m}}{2} \right)^2} = 955 \text{ W/m}^2$$

This is about the same as the intensity of sunlight at the Earth's surface. (Thus, it is not safe to shine the beam of a laser pointer into a person's eyes; that may be more dangerous than looking directly at the Sun.)

Now we can determine the radiation pressure from the laser beam. Equation 34.26 indicates that a completely re-

flected beam would apply a pressure of  $P = 2S/c$ . We can model the actual reflection as follows: Imagine that the surface absorbs the beam, resulting in pressure  $P = S/c$ . Then the surface emits the beam, resulting in additional pressure  $P = S/c$ . If the surface emits only a fraction  $f$  of the beam (so that  $f$  is the amount of the incident beam reflected), then the pressure due to the emitted beam is  $P = fS/c$ . Thus, the total pressure on the surface due to absorption and re-emission (reflection) is

$$P = \frac{S}{c} + f \frac{S}{c} = (1 + f) \frac{S}{c}$$

Notice that if  $f = 1$ , which represents complete reflection, this equation reduces to Equation 34.26. For a beam that is 70% reflected, the pressure is

$$P = (1 + 0.70) \frac{955 \text{ W/m}^2}{3.0 \times 10^8 \text{ m/s}} = 5.4 \times 10^{-6} \text{ N/m}^2$$

This is an extremely small value, as expected. (Recall from Section 15.2 that atmospheric pressure is approximately  $10^5 \text{ N/m}^2$ .)

### EXAMPLE 34.5 Solar Energy

As noted in the preceding example, the Sun delivers about  $1\,000 \text{ W/m}^2$  of energy to the Earth's surface via electromagnetic radiation. (a) Calculate the total power that is incident on a roof of dimensions  $8.00 \text{ m} \times 20.0 \text{ m}$ .

**Solution** The magnitude of the Poynting vector for solar radiation at the surface of the Earth is  $S = 1\,000 \text{ W/m}^2$ ; this

represents the power per unit area, or the light intensity. Assuming that the radiation is incident normal to the roof, we obtain

$$\begin{aligned} \mathcal{P} &= SA = (1\,000 \text{ W/m}^2)(8.00 \times 20.0 \text{ m}^2) \\ &= 1.60 \times 10^5 \text{ W} \end{aligned}$$

If all of this power could be converted to electrical energy, it would provide more than enough power for the average home. However, solar energy is not easily harnessed, and the prospects for large-scale conversion are not as bright as may appear from this calculation. For example, the efficiency of conversion from solar to electrical energy is typically 10% for photovoltaic cells. Roof systems for converting solar energy to internal energy are approximately 50% efficient; however, solar energy is associated with other practical problems, such as overcast days, geographic location, and methods of energy storage.

(b) Determine the radiation pressure and the radiation force exerted on the roof, assuming that the roof covering is a perfect absorber.

**Solution** Using Equation 34.24 with  $S = 1\,000\text{ W/m}^2$ , we find that the radiation pressure is

$$P = \frac{S}{c} = \frac{1\,000\text{ W/m}^2}{3.00 \times 10^8\text{ m/s}} = 3.33 \times 10^{-6}\text{ N/m}^2$$

Because pressure equals force per unit area, this corresponds to a radiation force of

$$F = PA = (3.33 \times 10^{-6}\text{ N/m}^2)(160\text{ m}^2) = 5.33 \times 10^{-4}\text{ N}$$

**Exercise** How much solar energy is incident on the roof in 1 h?

**Answer**  $5.76 \times 10^8\text{ J}$ .

must be placed in a high vacuum to eliminate the effects of air currents.

NASA is exploring the possibility of *solar sailing* as a low-cost means of sending spacecraft to the planets. Large reflective sheets would be used in much the way canvas sheets are used on earthbound sailboats. In 1973 NASA engineers took advantage of the momentum of the sunlight striking the solar panels of Mariner 10 (Fig. 34.9) to make small course corrections when the spacecraft's fuel supply was running low. (This procedure was carried out when the spacecraft was in the vicinity of the planet Mercury. Would it have worked as well near Pluto?)

**Figure 34.10** A portion of an infinite current sheet lying in the  $yz$  plane. The current density is sinusoidal and is given by the expression  $J_s = J_{\max} \cos \omega t$ . The magnetic field is everywhere parallel to the sheet and lies along  $z$ .

### Optional Section

## 34.5 RADIATION FROM AN INFINITE CURRENT SHEET

In this section, we describe the electric and magnetic fields radiated by a flat conductor carrying a time-varying current. In the symmetric plane geometry employed here, the mathematics is less complex than that required in lower-symmetry situations.

Consider an infinite conducting sheet lying in the  $yz$  plane and carrying a surface current in the  $y$  direction, as shown in Figure 34.10. The current is distributed across the  $z$  direction such that the current per unit length is  $J_s$ . Let us assume that  $J_s$  varies sinusoidally with time as

$$J_s = J_{\max} \cos \omega t$$

where  $J_{\max}$  is the amplitude of the current variation and  $\omega$  is the angular frequency of the variation. A similar problem concerning the case of a steady current was treated in Example 30.6, in which we found that the magnetic field outside the sheet is everywhere parallel to the sheet and lies along the  $z$  axis. The magnetic field was found to have a magnitude

$$B_z = \mu_0 \frac{J_s}{2}$$

Radiated magnetic field

<sup>5</sup> Note that the solution could also be written in the form  $\cos(\omega t - kx)$ , which is equivalent to  $\cos(kx - \omega t)$ . That is,  $\cos \theta$  is an even function, which means that  $\cos(-\theta) = \cos \theta$ .

**Figure 34.11** Representation of the plane electromagnetic wave radiated by an infinite current sheet lying in the  $yz$  plane. The vector  $\mathbf{B}$  is in the  $z$  direction, the vector  $\mathbf{E}$  is in the  $y$  direction, and the direction of wave motion is along  $x$ . Both vector  $\mathbf{B}$  and vector  $\mathbf{E}$  behave according to the expression  $\cos(kx - \omega t)$ . Compare this drawing with Figure 34.3a.

In the present situation, where  $J_s$  varies with time, this equation for  $B_z$  is valid only for distances close to the sheet. Substituting the expression for  $J_s$ , we have

$$B_z = \frac{\mu_0}{2} J_{\max} \cos \omega t \quad (\text{for small values of } x)$$

To obtain the expression valid for  $B_z$  for arbitrary values of  $x$ , we can investigate the solution:<sup>5</sup>

$$B_z = \frac{\mu_0 J_{\max}}{2} \cos(kx - \omega t) \quad (34.27)$$

Radiated electric field

You should note two things about this solution, which is unique to the geometry under consideration. First, when  $x$  is very small, it agrees with our original solution. Second, it satisfies the wave equation as expressed in Equation 34.9. We conclude that the magnetic field lies along the  $z$  axis, varies with time, and is characterized by a transverse traveling wave having an angular frequency  $\omega$  and an angular wave number  $k = 2\pi/\lambda$ .

We can obtain the electric field radiating from our infinite current sheet by using Equation 34.13:

$$E_y = cB_z = \frac{\mu_0 J_{\max} c}{2} \cos(kx - \omega t) \quad (34.28)$$

That is, the electric field is in the  $y$  direction, perpendicular to  $\mathbf{B}$ , and has the same space and time dependencies. These expressions for  $B_z$  and  $E_y$  show that the radiation field of an infinite current sheet carrying a sinusoidal current is a plane electromagnetic wave propagating with a speed  $c$  along the  $x$  axis, as shown in Figure 34.11.

We can calculate the Poynting vector for this wave from Equations 34.19,

### EXAMPLE 34.6 An Infinite Sheet Carrying a Sinusoidal Current

An infinite current sheet lying in the  $yz$  plane carries a sinusoidal current that has a maximum density of 5.00 A/m. (a) Find the maximum values of the radiated magnetic and electric fields.

**Solution** From Equations 34.27 and 34.28, we see that the maximum values of  $B_z$  and  $E_y$  are

$$B_{\max} = \frac{\mu_0 J_{\max}}{2} \quad \text{and} \quad E_{\max} = \frac{\mu_0 J_{\max} c}{2}$$

Using the values  $\mu_0 = 4\pi \times 10^{-7} \text{ T}\cdot\text{m/A}$ ,  $J_{\text{max}} = 5.00 \text{ A/m}$ , and  $c = 3.00 \times 10^8 \text{ m/s}$ , we get

$$B_{\text{max}} = \frac{(4\pi \times 10^{-7} \text{ T}\cdot\text{m/A})(5.00 \text{ A/m})}{2}$$

$$= 3.14 \times 10^{-6} \text{ T}$$

$$E_{\text{max}} = \frac{(4\pi \times 10^{-7} \text{ T}\cdot\text{m/A})(5.00 \text{ A/m})(3.00 \times 10^8 \text{ m/s})}{2}$$

$$= 942 \text{ V/m}$$

(b) What is the average power incident on a flat surface that is parallel to the sheet and has an area of  $3.00 \text{ m}^2$ ? (The length and width of this surface are both much greater than the wavelength of the radiation.)

**Solution** The intensity, or power per unit area, radiated in each direction by the current sheet is given by Equation 34.30:

$$I = \frac{\mu_0 J_{\text{max}}^2 c}{8}$$

$$= \frac{(4\pi \times 10^{-7} \text{ T}\cdot\text{m/A})(5.00 \text{ A/m})^2(3.00 \times 10^8 \text{ m/s})}{8}$$

$$= 1.18 \times 10^3 \text{ W/m}^2$$

Multiplying this by the area of the surface, we obtain the incident power:

$$\mathcal{P} = IA = (1.18 \times 10^3 \text{ W/m}^2)(3.00 \text{ m}^2)$$

$$= 3.54 \times 10^3 \text{ W}$$

The result is independent of the distance from the current sheet because we are dealing with a plane wave.

34.27, and 34.28:

$$S = \frac{EB}{\mu_0} = \frac{\mu_0 J_{\text{max}}^2 c}{4} \cos^2(kx - \omega t) \quad (34.29)$$

The intensity of the wave, which equals the average value of  $S$ , is

$$I = S_{\text{av}} = \frac{\mu_0 J_{\text{max}}^2 c}{8} \quad (34.30)$$

Accelerating charges produce electromagnetic radiation

This intensity represents the power per unit area of the outgoing wave on each side of the sheet. The total rate of energy emitted per unit area of the conductor is  $2S_{\text{av}} = \mu_0 J_{\text{max}}^2 c/4$ .

### Optional Section

## 34.6 PRODUCTION OF ELECTROMAGNETIC WAVES BY AN ANTENNA

Neither stationary charges nor steady currents can produce electromagnetic waves. Whenever the current through a wire changes with time, however, the wire emits

**Figure 34.12** The electric field set up by charges oscillating in an antenna. The field moves away from the antenna with the speed of light.

**Figure 34.13** A pair of metal rods connected to a battery. (a) When the switch is open and no current exists, the electric and magnetic fields are both zero. (b) Immediately after the switch is closed, the rods are being charged (so a current exists). Because the current is changing, the rods generate changing electric and magnetic fields. (c) When the rods are fully charged, the current is zero, the electric field is a maximum, and the magnetic field is zero.

electromagnetic radiation. **The fundamental mechanism responsible for this radiation is the acceleration of a charged particle. Whenever a charged particle accelerates, it must radiate energy.**

An alternating voltage applied to the wires of an antenna forces an electric charge in the antenna to oscillate. This is a common technique for accelerating charges and is the source of the radio waves emitted by the transmitting antenna of a radio station. Figure 34.12 shows how this is done. Two metal rods are connected to a generator that provides a sinusoidally oscillating voltage. This causes charges to oscillate in the two rods. At  $t = 0$ , the upper rod is given a maximum positive charge and the bottom rod an equal negative charge, as shown in Figure 34.12a. The electric field near the antenna at this instant is also shown in Figure 34.12a. As the positive and negative charges decrease from their maximum values, the rods become less charged, the field near the rods decreases in strength, and the downward-directed maximum electric field produced at  $t = 0$  moves away from the rod. (A magnetic field oscillating in a direction perpendicular to the plane of the diagram in Fig. 34.12 accompanies the oscillating electric field, but it is not shown for the sake of clarity.) When the charges on the rods are momentarily zero (Fig. 34.12b), the electric field at the rod has dropped to zero. This occurs at a time equal to one quarter of the period of oscillation.

As the generator charges the rods in the opposite sense from that at the beginning, the upper rod soon obtains a maximum negative charge and the lower rod a maximum positive charge (Fig. 34.12c); this results in an electric field near the rod that is directed upward after a time equal to one-half the period of oscillation. The oscillations continue as indicated in Figure 34.12d. The electric field near the antenna oscillates in phase with the charge distribution. That is, the field points down when the upper rod is positive and up when the upper rod is negative. Furthermore, the magnitude of the field at any instant depends on the amount of charge on the rods at that instant.

As the charges continue to oscillate (and accelerate) between the rods, the

<sup>6</sup> We have neglected the fields caused by the wires leading to the rods. This is a good approximation if the circuit dimensions are much less than the length of the rods.

**Figure 34.14** A half-wave antenna consists of two metal rods connected to an alternating voltage source. This diagram shows  $\mathbf{E}$  and  $\mathbf{B}$  at an instant when the current is upward. Note that the electric field lines resemble those of a dipole (shown in Fig. 23.21).

electric field they set up moves away from the antenna at the speed of light. As you can see from Figure 34.12, one cycle of charge oscillation produces one wavelength in the electric-field pattern.

Next, consider what happens when two conducting rods are connected to the terminals of a battery (Fig. 34.13). Before the switch is closed, the current is zero, so no fields are present (Fig. 34.13a). Just after the switch is closed, positive charge begins to build up on one rod and negative charge on the other (Fig. 34.13b), a situation that corresponds to a time-varying current. The changing charge distribution causes the electric field to change; this in turn produces a magnetic field around the rods.<sup>6</sup> Finally, when the rods are fully charged, the current is zero; hence, no magnetic field exists at that instant (Fig. 34.13c).

Now let us consider the production of electromagnetic waves by a *half-wave antenna*. In this arrangement, two conducting rods are connected to a source of alternating voltage (such as an  $LC$  oscillator), as shown in Figure 34.14. The length of each rod is equal to one quarter of the wavelength of the radiation that will be emitted when the oscillator operates at frequency  $f$ . The oscillator forces charges to accelerate back and forth between the two rods. Figure 34.14 shows the configuration of the electric and magnetic fields at some instant when the current is upward. The electric field lines resemble those of an electric dipole. (As a result, this type of antenna is sometimes called a *dipole antenna*.) Because these charges are continuously oscillating between the two rods, the antenna can be approximated by an oscillating electric dipole. The magnetic field lines form concentric circles around the antenna and are perpendicular to the electric field lines at all points. The magnetic field is zero at all points along the axis of the antenna. Furthermore,  $\mathbf{E}$  and  $\mathbf{B}$  are  $90^\circ$  out of phase in time because the current is zero when the charges at the outer ends of the rods are at a maximum.

At the two points where the magnetic field is shown in Figure 34.14, the Poynting vector  $\mathbf{S}$  is directed radially outward. This indicates that energy is flowing away from the antenna at this instant. At later times, the fields and the Poynting vector change direction as the current alternates. Because  $\mathbf{E}$  and  $\mathbf{B}$  are  $90^\circ$  out of phase at points near the dipole, the net energy flow is zero. From this, we might conclude (incorrectly) that no energy is radiated by the dipole.

**Figure 34.15** Electric field lines surrounding a dipole antenna at a given instant. The radiation fields propagate outward from the antenna with a speed  $c$ .

However, we find that energy is indeed radiated. Because the dipole fields fall off as  $1/r^3$  (as shown in Example 23.6 for the electric field of a static dipole), they are not important at great distances from the antenna. However, at these great distances, something else causes a type of radiation different from that close to the antenna. The source of this radiation is the continuous induction of an electric field by the time-varying magnetic field and the induction of a magnetic field by the time-varying electric field, predicted by Equations 34.3 and 34.4. The electric and magnetic fields produced in this manner are in phase with each other and vary as  $1/r$ . The result is an outward flow of energy at all times.

The electric field lines produced by a dipole antenna at some instant are shown in Figure 34.15 as they propagate away from the antenna. Note that the intensity and the power radiated are a maximum in a plane that is perpendicular to the antenna and passing through its midpoint. Furthermore, the power radiated is zero along the antenna's axis. A mathematical solution to Maxwell's equations for the dipole antenna shows that the intensity of the radiation varies as  $(\sin^2\theta)/r^2$ , where  $\theta$  is measured from the axis of the antenna. The angular dependence of the radiation intensity is sketched in Figure 34.16.

Electromagnetic waves can also induce currents in a receiving antenna. The response of a dipole receiving antenna at a given position is a maximum when the antenna axis is parallel to the electric field at that point and zero when the axis is perpendicular to the electric field.

**Figure 34.16** Angular dependence of the intensity of radiation produced by an oscillating electric dipole.

### QuickLab

Rotate a portable radio (with a telescoping antenna) about a horizontal axis while it is tuned to a weak station. Can you use what you learn from this movement to verify the answer to Quick Quiz 34.2?

### Quick Quiz 34.2

If the plane electromagnetic wave in Figure 34.11 represents the signal from a distant radio station, what would be the best orientation for your portable radio antenna—(a) along the  $x$  axis, (b) along the  $y$  axis, or (c) along the  $z$  axis?

## 34.7 THE SPECTRUM OF ELECTROMAGNETIC WAVES

The various types of electromagnetic waves are listed in Figure 34.17, which shows the **electromagnetic spectrum**. Note the wide ranges of frequencies and wavelengths. No sharp dividing point exists between one type of wave and the next. Remember that **all forms of the various types of radiation are produced by the same phenomenon—accelerating charges**. The names given to the types of waves are simply for convenience in describing the region of the spectrum in which they lie.

**Radio waves** are the result of charges accelerating through conducting wires. Ranging from more than  $10^4$  m to about 0.1 m in wavelength, they are generated by such electronic devices as  $LC$  oscillators and are used in radio and television communication systems.

**Microwaves** have wavelengths ranging from approximately 0.3 m to  $10^{-4}$  m and are also generated by electronic devices. Because of their short wavelengths, they are well suited for radar systems and for studying the atomic and molecular properties of matter. Microwave ovens (in which the wavelength of the radiation is  $\lambda = 0.122$  m) are an interesting domestic application of these waves. It has been suggested that solar energy could be harnessed by beaming microwaves to the Earth from a solar collector in space.<sup>7</sup>

<sup>7</sup> P. Glaser, "Solar Power from Satellites," *Phys. Today*, February 1977, p. 30.

Radio waves

Microwaves

Infrared waves

Visible light waves

Satellite-dish television antennas receive television-station signals from satellites in orbit around the Earth.

**Figure 34.17** The electromagnetic spectrum. Note the overlap between adjacent wave types.

**Infrared waves** have wavelengths ranging from  $10^{-3}$  m to the longest wavelength of visible light,  $7 \times 10^{-7}$  m. These waves, produced by molecules and room-temperature objects, are readily absorbed by most materials. The infrared (IR) energy absorbed by a substance appears as internal energy because the energy agitates the atoms of the object, increasing their vibrational or translational motion, which results in a temperature increase. Infrared radiation has practical and scientific applications in many areas, including physical therapy, IR photography, and vibrational spectroscopy.

**Visible light**, the most familiar form of electromagnetic waves, is the part of the electromagnetic spectrum that the human eye can detect. Light is produced by the rearrangement of electrons in atoms and molecules. The various wavelengths of visible light, which correspond to different colors, range from red ( $\lambda \approx 7 \times 10^{-7}$  m) to violet ( $\lambda \approx 4 \times 10^{-7}$  m). The sensitivity of the human eye is a function of wavelength, being a maximum at a wavelength of about  $5.5 \times 10^{-7}$  m. With this in mind, why do you suppose tennis balls often have a yellow-green color?

**Ultraviolet waves** cover wavelengths ranging from approximately  $4 \times 10^{-7}$  m to  $6 \times 10^{-10}$  m. The Sun is an important source of ultraviolet (UV) light, which is the main cause of sunburn. Sunscreen lotions are transparent to visible light but absorb most UV light. The higher a sunscreen's solar protection factor (SPF), the greater the percentage of UV light absorbed. Ultraviolet rays have also been impli-

cated in the formation of cataracts, a clouding of the lens inside the eye. Wearing sunglasses that do not block UV light is worse for your eyes than wearing no sunglasses. The lenses of any sunglasses absorb some visible light, thus causing the wearer's pupils to dilate. If the glasses do not also block UV light, then more damage may be done to the lens of the eye because of the dilated pupils. If you wear no sunglasses at all, your pupils are contracted, you squint, and a lot less UV light enters your eyes. High-quality sunglasses block nearly all the eye-damaging UV light.

Most of the UV light from the Sun is absorbed by ozone ( $O_3$ ) molecules in the Earth's upper atmosphere, in a layer called the stratosphere. This ozone shield converts lethal high-energy UV radiation to infrared radiation, which in turn warms the stratosphere. Recently, a great deal of controversy has arisen concerning the possible depletion of the protective ozone layer as a result of the chemicals emitted from aerosol spray cans and used as refrigerants.

**X-rays** have wavelengths in the range from approximately  $10^{-8}$  m to  $10^{-12}$  m. The most common source of x-rays is the deceleration of high-energy electrons bombarding a metal target. X-rays are used as a diagnostic tool in medicine and as a treatment for certain forms of cancer. Because x-rays damage or destroy living tissues and organisms, care must be taken to avoid unnecessary exposure or overexposure. X-rays are also used in the study of crystal structure because x-ray wavelengths are comparable to the atomic separation distances in solids (about 0.1 nm).

X-rays

Gamma rays

### EXAMPLE 34.7 A Half-Wave Antenna

A half-wave antenna works on the principle that the optimum length of the antenna is one-half the wavelength of the radiation being received. What is the optimum length of a car antenna when it receives a signal of frequency 94.0 MHz?

**Solution** Equation 16.14 tells us that the wavelength of

the signal is

$$\lambda = \frac{c}{f} = \frac{3.00 \times 10^8 \text{ m/s}}{9.40 \times 10^7 \text{ Hz}} = 3.19 \text{ m}$$

Thus, to operate most efficiently, the antenna should have a length of  $(3.19 \text{ m})/2 = 1.60 \text{ m}$ . For practical reasons, car antennas are usually one-quarter wavelength in size.

**Gamma rays** are electromagnetic waves emitted by radioactive nuclei (such as  $^{60}\text{Co}$  and  $^{137}\text{Cs}$ ) and during certain nuclear reactions. High-energy gamma rays are a component of cosmic rays that enter the Earth's atmosphere from space. They have wavelengths ranging from approximately  $10^{-10}$  m to less than  $10^{-14}$  m. They are highly penetrating and produce serious damage when absorbed by living tissues. Consequently, those working near such dangerous radiation must be protected with heavily absorbing materials, such as thick layers of lead.

### Quick Quiz 34.3

The *AM* in *AM radio* stands for *amplitude modulation*, and *FM* stands for *frequency modulation*. (The word *modulate* means "to change.") If our eyes could see the electromagnetic waves from a radio antenna, how could you tell an AM wave from an FM wave?

## SUMMARY

**Electromagnetic waves**, which are predicted by Maxwell's equations, have the

following properties:

- The electric field and the magnetic field each satisfy a wave equation. These two wave equations, which can be obtained from Maxwell's third and fourth equations, are

$$\frac{\partial^2 E}{\partial x^2} = \mu_0 \epsilon_0 \frac{\partial^2 E}{\partial t^2} \quad (34.8)$$

$$\frac{\partial^2 B}{\partial x^2} = \mu_0 \epsilon_0 \frac{\partial^2 B}{\partial t^2} \quad (34.9)$$

- The waves travel through a vacuum with the speed of light  $c$ , where

$$c = \frac{1}{\sqrt{\mu_0 \epsilon_0}} = 3.00 \times 10^8 \text{ m/s} \quad (34.10)$$

- The electric and magnetic fields are perpendicular to each other and perpendicular to the direction of wave propagation. (Hence, electromagnetic waves are transverse waves.)
- The instantaneous magnitudes of  $\mathbf{E}$  and  $\mathbf{B}$  in an electromagnetic wave are related by the expression

$$\frac{E}{B} = c \quad (34.13)$$

- The waves carry energy. The rate of flow of energy crossing a unit area is described by the Poynting vector  $\mathbf{S}$ , where

$$\mathbf{S} \equiv \frac{1}{\mu_0} \mathbf{E} \times \mathbf{B} \quad (34.18)$$

- They carry momentum and hence exert pressure on surfaces. If an electromagnetic wave whose Poynting vector is  $\mathbf{S}$  is completely absorbed by a surface upon which it is normally incident, the radiation pressure on that surface is

$$P = \frac{S}{c} \quad (\text{complete absorption}) \quad (34.24)$$

If the surface totally reflects a normally incident wave, the pressure is doubled.

The electric and magnetic fields of a sinusoidal plane electromagnetic wave propagating in the positive  $x$  direction can be written

$$E = E_{\max} \cos(kx - \omega t) \quad (34.11)$$

$$B = B_{\max} \cos(kx - \omega t) \quad (34.12)$$

where  $\omega$  is the angular frequency of the wave and  $k$  is the angular wave number. These equations represent special solutions to the wave equations for  $E$  and  $B$ . Be-

## QUESTIONS

1. For a given incident energy of an electromagnetic wave, why is the radiation pressure on a perfectly reflecting surface twice as great as that on a perfectly absorbing surface?
2. Describe the physical significance of the Poynting vector.
3. Do all current-carrying conductors emit electromagnetic waves? Explain.
4. What is the fundamental cause of electromagnetic radiation?
5. Electrical engineers often speak of the radiation resistance of an antenna. What do you suppose they mean by this phrase?
6. If a high-frequency current is passed through a solenoid containing a metallic core, the core warms up by induc-

tion. This process also cooks foods in microwave ovens. Explain why the materials warm up in these situations.

7. Before the advent of cable television and satellite dishes, homeowners either mounted a television antenna on the roof or used “rabbit ears” atop their sets (Fig. Q34.7). Certain orientations of the receiving antenna on a television set gave better reception than others. Furthermore, the best orientation varied from station to station. Explain.

**Figure Q34.7** Questions 7, 12, 13, and 14. The V-shaped antenna is the VHF antenna. (George Semple)

8. Does a wire connected to the terminals of a battery emit an electromagnetic wave? Explain.

9. If you charge a comb by running it through your hair and then hold the comb next to a bar magnet, do the electric and magnetic fields that are produced constitute an electromagnetic wave?
10. An empty plastic or glass dish is cool to the touch right after it is removed from a microwave oven. How can this be possible? (Assume that your electric bill has been paid.)
11. Often when you touch the indoor antenna on a radio or television receiver, the reception instantly improves. Why?
12. Explain how the (dipole) VHF antenna of a television set works. (See Fig. Q34.7.)
13. Explain how the UHF (loop) antenna of a television set works. (See Fig. Q34.7.)
14. Explain why the voltage induced in a UHF (loop) antenna depends on the frequency of the signal, whereas the voltage in a VHF (dipole) antenna does not. (See Fig. Q34.7.)
15. List as many similarities and differences between sound waves and light waves as you can.
16. What does a radio wave do to the charges in the receiving antenna to provide a signal for your car radio?
17. What determines the height of an AM radio station’s broadcast antenna?
18. Some radio transmitters use a “phased array” of antennas. What is their purpose?
19. What happens to the radio reception in an airplane as it flies over the (vertical) dipole antenna of the control tower?
20. When light (or other electromagnetic radiation) travels across a given region, what oscillates?
21. Why should an infrared photograph of a person look different from a photograph of that person taken with visible light?
22. Suppose a creature from another planet had eyes that were sensitive to infrared radiation. Describe what the creature would see if it looked around the room you are now in. That is, what would be bright and what would be dim?

## PROBLEMS

### Section 34.1 Maxwell’s Equations and Hertz’s Discoveries

#### Section 34.2 Plane Electromagnetic Waves

*Note:* Assume that the medium is vacuum unless specified otherwise.

- If the North Star, Polaris, were to burn out today, in what year would it disappear from our vision? Take the distance from the Earth to Polaris as  $6.44 \times 10^{18}$  m.
- The speed of an electromagnetic wave traveling in a

transparent nonmagnetic substance is  $v = 1/\sqrt{\kappa\mu_0\epsilon_0}$ , where  $\kappa$  is the dielectric constant of the substance. Determine the speed of light in water, which has a dielectric constant at optical frequencies of 1.78.

- An electromagnetic wave in vacuum has an electric field amplitude of 220 V/m. Calculate the amplitude of the corresponding magnetic field.
- Calculate the maximum value of the magnetic field of an electromagnetic wave in a medium where the speed of light is two thirds of the speed of light in vacuum and where the electric field amplitude is 7.60 mV/m.

- WEB 5.** Figure 34.3a shows a plane electromagnetic sinusoidal wave propagating in what we choose as the  $x$  direction. Suppose that the wavelength is 50.0 m, and the electric field vibrates in the  $xy$  plane with an amplitude of 22.0 V/m. Calculate (a) the frequency of the wave and (b) the magnitude and direction of  $\mathbf{B}$  when the electric field has its maximum value in the negative  $y$  direction. (c) Write an expression for  $B$  in the form

$$B = B_{\max} \cos(kx - \omega t)$$

with numerical values for  $B_{\max}$ ,  $k$ , and  $\omega$ .

- 6.** Write down expressions for the electric and magnetic fields of a sinusoidal plane electromagnetic wave having a frequency of 3.00 GHz and traveling in the positive  $x$  direction. The amplitude of the electric field is 300 V/m.
- 7.** In SI units, the electric field in an electromagnetic wave is described by

$$E_y = 100 \sin(1.00 \times 10^7 x - \omega t)$$

Find (a) the amplitude of the corresponding magnetic field, (b) the wavelength  $\lambda$ , and (c) the frequency  $f$ .

- 8.** Verify by substitution that the following equations are solutions to Equations 34.8 and 34.9, respectively:
- $$E = E_{\max} \cos(kx - \omega t)$$
- $$B = B_{\max} \cos(kx - \omega t)$$
- 9. Review Problem.** A standing-wave interference pattern is set up by radio waves between two metal sheets 2.00 m apart. This is the shortest distance between the plates that will produce a standing-wave pattern. What is the fundamental frequency?
- 10.** A microwave oven is powered by an electron tube called a magnetron, which generates electromagnetic waves of frequency 2.45 GHz. The microwaves enter the oven and are reflected by the walls. The standing-wave pattern produced in the oven can cook food unevenly, with hot spots in the food at antinodes and cool spots at nodes, so a turntable is often used to rotate the food and distribute the energy. If a microwave oven intended for use with a turntable is instead used with a cooking dish in a fixed position, the antinodes can appear as burn marks on foods such as carrot strips or cheese. The separation distance between the burns is measured to be  $6 \text{ cm} \pm 5\%$ . From these data, calculate the speed of the microwaves.

### Section 34.3 Energy Carried by Electromagnetic Waves

- 11.** How much electromagnetic energy per cubic meter is contained in sunlight, if the intensity of sunlight at the Earth's surface under a fairly clear sky is  $1\,000 \text{ W/m}^2$ ?
- 12.** An AM radio station broadcasts isotropically (equally in all directions) with an average power of 4.00 kW. A dipole receiving antenna 65.0 cm long is at a location 4.00 miles from the transmitter. Compute the emf that

is induced by this signal between the ends of the receiving antenna.

- 13.** What is the average magnitude of the Poynting vector 5.00 miles from a radio transmitter broadcasting isotropically with an average power of 250 kW?
- 14.** A monochromatic light source emits 100 W of electromagnetic power uniformly in all directions. (a) Calculate the average electric-field energy density 1.00 m from the source. (b) Calculate the average magnetic-field energy density at the same distance from the source. (c) Find the wave intensity at this location.
- WEB 15.** A community plans to build a facility to convert solar radiation to electric power. They require 1.00 MW of power, and the system to be installed has an efficiency of 30.0% (that is, 30.0% of the solar energy incident on the surface is converted to electrical energy). What must be the effective area of a perfectly absorbing surface used in such an installation, assuming a constant intensity of  $1\,000 \text{ W/m}^2$ ?
- 16.** Assuming that the antenna of a 10.0-kW radio station radiates spherical electromagnetic waves, compute the maximum value of the magnetic field 5.00 km from the antenna, and compare this value with the surface magnetic field of the Earth.
- WEB 17.** The filament of an incandescent lamp has a  $150\text{-}\Omega$  resistance and carries a direct current of 1.00 A. The filament is 8.00 cm long and 0.900 mm in radius. (a) Calculate the Poynting vector at the surface of the filament. (b) Find the magnitude of the electric and magnetic fields at the surface of the filament.
- 18.** In a region of free space the electric field at an instant of time is  $\mathbf{E} = (80.0\mathbf{i} + 32.0\mathbf{j} - 64.0\mathbf{k}) \text{ N/C}$  and the magnetic field is  $\mathbf{B} = (0.200\mathbf{i} + 0.080\mathbf{j} + 0.290\mathbf{k}) \mu\text{T}$ . (a) Show that the two fields are perpendicular to each other. (b) Determine the Poynting vector for these fields.
- 19.** A lightbulb filament has a resistance of  $110 \Omega$ . The bulb is plugged into a standard 120-V (rms) outlet and emits 1.00% of the electric power delivered to it as electromagnetic radiation of frequency  $f$ . Assuming that the bulb is covered with a filter that absorbs all other frequencies, find the amplitude of the magnetic field 1.00 m from the bulb.
- 20.** A certain microwave oven contains a magnetron that has an output of 700 W of microwave power for an electrical input power of 1.40 kW. The microwaves are entirely transferred from the magnetron into the oven chamber through a waveguide, which is a metal tube of rectangular cross-section with a width of 6.83 cm and a height of 3.81 cm. (a) What is the efficiency of the magnetron? (b) Assuming that the food is absorbing all the microwaves produced by the magnetron and that no energy is reflected back into the waveguide, find the direction and magnitude of the Poynting vector, averaged over time, in the waveguide near the entrance to the oven chamber. (c) What is the maximum electric field magnitude at this point?

21. High-power lasers in factories are used to cut through cloth and metal (Fig. P34.21). One such laser has a beam diameter of 1.00 mm and generates an electric field with an amplitude of 0.700 MV/m at the target. Find (a) the amplitude of the magnetic field produced, (b) the intensity of the laser, and (c) the power delivered by the laser.

**Figure P34.21** A laser cutting device mounted on a robot arm is being used to cut through a metallic plate. (Philippe Plailly/SPL/Photo Researchers)

22. At what distance from a 100-W electromagnetic-wave point source does  $E_{\max} = 15.0 \text{ V/m}$ ?
23. A 10.0-mW laser has a beam diameter of 1.60 mm. (a) What is the intensity of the light, assuming it is uniform across the circular beam? (b) What is the average energy density of the beam?
24. At one location on the Earth, the rms value of the magnetic field caused by solar radiation is  $1.80 \mu\text{T}$ . From this value, calculate (a) the average electric field due to solar radiation, (b) the average energy density of the solar component of electromagnetic radiation at this location, and (c) the magnitude of the Poynting vector for the Sun's radiation. (d) Compare the value found in part (c) with the value of the solar intensity given in Example 34.5.

#### Section 34.4 Momentum and Radiation Pressure

25. A radio wave transmits  $25.0 \text{ W/m}^2$  of power per unit area. A flat surface of area  $A$  is perpendicular to the direction of propagation of the wave. Calculate the radiation pressure on it if the surface is a perfect absorber.
26. A plane electromagnetic wave of intensity  $6.00 \text{ W/m}^2$  strikes a small pocket mirror, of area  $40.0 \text{ cm}^2$ , held perpendicular to the approaching wave. (a) What momen-

tum does the wave transfer to the mirror each second? (b) Find the force that the wave exerts on the mirror.

27. A possible means of space flight is to place a perfectly reflecting aluminized sheet into orbit around the Earth and then use the light from the Sun to push this "solar sail." Suppose a sail of area  $6.00 \times 10^5 \text{ m}^2$  and mass 6 000 kg is placed in orbit facing the Sun. (a) What force is exerted on the sail? (b) What is the sail's acceleration? (c) How long does it take the sail to reach the Moon,  $3.84 \times 10^8 \text{ m}$  away? Ignore all gravitational effects, assume that the acceleration calculated in part (b) remains constant, and assume a solar intensity of  $1\,340 \text{ W/m}^2$ .
28. A 100-mW laser beam is reflected back upon itself by a mirror. Calculate the force on the mirror.
- WEB 29. A 15.0-mW helium–neon laser ( $\lambda = 632.8 \text{ nm}$ ) emits a beam of circular cross-section with a diameter of 2.00 mm. (a) Find the maximum electric field in the beam. (b) What total energy is contained in a 1.00-m length of the beam? (c) Find the momentum carried by a 1.00-m length of the beam.
30. Given that the intensity of solar radiation incident on the upper atmosphere of the Earth is  $1\,340 \text{ W/m}^2$ , determine (a) the solar radiation incident on Mars, (b) the total power incident on Mars, and (c) the total force acting on the planet. (d) Compare this force to the gravitational attraction between Mars and the Sun (see Table 14.2).
31. A plane electromagnetic wave has an intensity of  $750 \text{ W/m}^2$ . A flat rectangular surface of dimensions  $50.0 \text{ cm} \times 100 \text{ cm}$  is placed perpendicular to the direction of the wave. If the surface absorbs half of the energy and reflects half, calculate (a) the total energy absorbed by the surface in 1.00 min and (b) the momentum absorbed in this time.

(Optional)

#### Section 34.5 Radiation from an Infinite Current Sheet

32. A large current-carrying sheet emits radiation in each direction (normal to the plane of the sheet) with an intensity of  $570 \text{ W/m}^2$ . What maximum value of sinusoidal current density is required?
33. A rectangular surface of dimensions  $120 \text{ cm} \times 40.0 \text{ cm}$  is parallel to and 4.40 m away from a much larger conducting sheet in which a sinusoidally varying surface current exists that has a maximum value of  $10.0 \text{ A/m}$ . (a) Calculate the average power that is incident on the smaller sheet. (b) What power per unit area is radiated by the larger sheet?

(Optional)

#### Section 34.6 Production of Electromagnetic Waves by an Antenna

34. Two hand-held radio transceivers with dipole antennas are separated by a great fixed distance. Assuming that the transmitting antenna is vertical, what fraction of the

maximum received power will occur in the receiving antenna when it is inclined from the vertical by (a)  $15.0^\circ$ ? (b)  $45.0^\circ$ ? (c)  $90.0^\circ$ ?

- 35.** Two radio-transmitting antennas are separated by half the broadcast wavelength and are driven in phase with each other. In which directions are (a) the strongest and (b) the weakest signals radiated?
- 36.** Figure 34.14 shows a Hertz antenna (also known as a half-wave antenna, since its length is  $\lambda/2$ ). The antenna is far enough from the ground that reflections do not significantly affect its radiation pattern. Most AM radio stations, however, use a Marconi antenna, which consists of the top half of a Hertz antenna. The lower end of this (quarter-wave) antenna is connected to earth ground, and the ground itself serves as the missing lower half. What are the heights of the Marconi antennas for radio stations broadcasting at (a) 560 kHz and (b) 1 600 kHz?

**37. Review Problem.** Accelerating charges radiate electromagnetic waves. Calculate the wavelength of radiation produced by a proton in a cyclotron with a radius of 0.500 m and a magnetic field with a magnitude of 0.350 T.

**38. Review Problem.** Accelerating charges radiate electromagnetic waves. Calculate the wavelength of radiation produced by a proton in a cyclotron of radius  $R$  and magnetic field  $B$ .

### Section 34.7 The Spectrum of Electromagnetic Waves

- 39.** (a) Classify waves with frequencies of 2 Hz, 2 kHz, 2 MHz, 2 GHz, 2 THz, 2 PHz, 2 EHz, 2 ZHz, and 2 YHz on the electromagnetic spectrum. (b) Classify waves with wavelengths of 2 km, 2 m, 2 mm,  $2\ \mu\text{m}$ , 2 nm, 2 pm, 2 fm, and 2 am.
- 40.** Compute an order-of-magnitude estimate for the frequency of an electromagnetic wave with a wavelength equal to (a) your height; (b) the thickness of this sheet of paper. How is each wave classified on the electromagnetic spectrum?
- 41.** The human eye is most sensitive to light having a wavelength of  $5.50 \times 10^{-7}$  m, which is in the green–yellow region of the visible electromagnetic spectrum. What is the frequency of this light?
- 42.** Suppose you are located 180 m from a radio transmitter. (a) How many wavelengths are you from the transmitter if the station calls itself 1150 AM? (The AM band frequencies are in kilohertz.) (b) What if this station were 98.1 FM? (The FM band frequencies are in megahertz.)
- 43.** What are the wavelengths of electromagnetic waves in free space that have frequencies of (a)  $5.00 \times 10^{19}$  Hz and (b)  $4.00 \times 10^9$  Hz?
- 44.** A radar pulse returns to the receiver after a total travel time of  $4.00 \times 10^{-4}$  s. How far away is the object that reflected the wave?
- 45.** *This just in!* An important news announcement is transmitted by radio waves to people sitting next to their radios, 100 km from the station, and by sound waves to people sitting across the newsroom, 3.00 m from the newscaster. Who receives the news first? Explain. Take the speed of sound in air to be 343 m/s.
- 46.** The U.S. Navy has long proposed the construction of extremely low-frequency (ELF) communication systems. Such waves could penetrate the oceans to reach distant submarines. Calculate the length of a quarter-wavelength antenna for a transmitter generating ELF waves with a frequency of 75.0 Hz. How practical is this?
- 47.** What are the wavelength ranges in (a) the AM radio band (540–1 600 kHz), and (b) the FM radio band (88.0–108 MHz)?
- 48.** There are 12 VHF television channels (Channels 2–13) that lie in the range of frequencies between 54.0 MHz and 216 MHz. Each channel is assigned a width of 6.0 MHz, with the two ranges 72.0–76.0 MHz and 88.0–174 MHz reserved for non-TV purposes. (Channel 2, for example, lies between 54.0 and 60.0 MHz.) Calculate the wavelength ranges for (a) Channel 4, (b) Channel 6, and (c) Channel 8.

### ADDITIONAL PROBLEMS

- 49.** Assume that the intensity of solar radiation incident on the cloud tops of Earth is  $1\ 340\ \text{W/m}^2$ . (a) Calculate the total power radiated by the Sun, taking the average Earth–Sun separation to be  $1.496 \times 10^{11}$  m. (b) Determine the maximum values of the electric and magnetic fields at the Earth’s location due to solar radiation.
- 50.** The intensity of solar radiation at the top of the Earth’s atmosphere is  $1\ 340\ \text{W/m}^2$ . Assuming that 60% of the incoming solar energy reaches the Earth’s surface and assuming that you absorb 50% of the incident energy, make an order-of-magnitude estimate of the amount of solar energy you absorb in a 60-min sunbath.
- 51. Review Problem.** In the absence of cable input or a satellite dish, a television set can use a dipole-receiving antenna for VHF channels and a loop antenna for UHF channels (see Fig. Q34.7). The UHF antenna produces an emf from the changing magnetic flux through the loop. The TV station broadcasts a signal with a frequency  $f$  and the signal has an electric-field amplitude  $E_{\text{max}}$  and a magnetic-field amplitude  $B_{\text{max}}$  at the location of the receiving antenna. (a) Using Faraday’s law, derive an expression for the amplitude of the emf that appears in a single-turn circular loop antenna with a radius  $r$ , which is small compared to the wavelength of the wave. (b) If the electric field in the signal points vertically, what should be the orientation of the loop for best reception?
- 52.** Consider a small, spherical particle of radius  $r$  located in space a distance  $R$  from the Sun. (a) Show that the ratio  $F_{\text{rad}}/F_{\text{grav}}$  is proportional to  $1/r$ , where  $F_{\text{rad}}$  is the

force exerted by solar radiation and  $F_{\text{grav}}$  is the force of gravitational attraction. (b) The result of part (a) means that, for a sufficiently small value of  $r$ , the force exerted on the particle by solar radiation exceeds the force of gravitational attraction. Calculate the value of  $r$  for which the particle is in equilibrium under the two forces. (Assume that the particle has a perfectly absorbing surface and a mass density of  $1.50 \text{ g/cm}^3$ . Let the particle be located  $3.75 \times 10^{11} \text{ m}$  from the Sun, and use  $214 \text{ W/m}^2$  as the value of the solar intensity at that point.)

53. A dish antenna with a diameter of  $20.0 \text{ m}$  receives (at normal incidence) a radio signal from a distant source, as shown in Figure P34.53. The radio signal is a continuous sinusoidal wave with amplitude  $E_{\text{max}} = 0.200 \text{ } \mu\text{V/m}$ . Assume that the antenna absorbs all the radiation that falls on the dish. (a) What is the amplitude of the magnetic field in this wave? (b) What is the intensity of the radiation received by this antenna? (c) What power is received by the antenna? (d) What force is exerted on the antenna by the radio waves?

Figure P34.53

54. A parallel-plate capacitor has circular plates of radius  $r$  separated by distance  $\ell$ . It has been charged to voltage  $\Delta V$  and is being discharged as current  $i$  is drawn from it. Assume that the plate separation  $\ell$  is very small compared to  $r$ , so the electric field is essentially constant in the volume between the plates and is zero outside this volume. Note that the displacement current between the capacitor plates creates a magnetic field. (a) Determine the magnitude and direction of the Poynting vector at the cylindrical surface surrounding the electric field volume. (b) Use the value of the Poynting vector and the lateral surface area of the cylinder to find the total power transfer for the capacitor. (c) What are the changes to these results if the direction of the current is reversed, so the capacitor is charging?
55. A section of a very long air-core solenoid, far from either end, forms an inductor with radius  $r$ , length  $\ell$ , and

$n$  turns of wire per unit length. At a particular instant, the solenoid current is  $i$  and is increasing at the rate  $di/dt$ . Ignore the resistance of the wire. (a) Find the magnitude and direction of the Poynting vector over the interior surface of this section of solenoid. (b) Find the rate at which the energy stored in the magnetic field of the inductor is increasing. (c) Express the power in terms of the voltage  $\Delta V$  across the inductor.

56. A goal of the Russian space program is to illuminate dark northern cities with sunlight reflected to Earth from a  $200\text{-m}$ -diameter mirrored surface in orbit. Several smaller prototypes have already been constructed and put into orbit. (a) Assume that sunlight with an intensity of  $1340 \text{ W/m}^2$  falls on the mirror nearly perpendicularly, and that the atmosphere of the Earth allows  $74.6\%$  of the energy of sunlight to pass through it in clear weather. What power is received by a city when the space mirror is reflecting light to it? (b) The plan is for the reflected sunlight to cover a circle with a diameter of  $8.00 \text{ km}$ . What is the intensity of the light (the average magnitude of the Poynting vector) received by the city? (c) This intensity is what percentage of the vertical component of sunlight at Saint Petersburg in January, when the sun reaches an angle of  $7.00^\circ$  above the horizon at noon?
57. In 1965 Arno Penzias and Robert Wilson discovered the cosmic microwave radiation that was left over from the Big Bang expansion of the Universe. Suppose the energy density of this background radiation is equal to  $4.00 \times 10^{-14} \text{ J/m}^3$ . Determine the corresponding electric-field amplitude.
58. A hand-held cellular telephone operates in the  $860\text{-}$  to  $900\text{-MHz}$  band and has a power output of  $0.600 \text{ W}$  from an antenna  $10.0 \text{ cm}$  long (Fig. P34.58). (a) Find the average magnitude of the Poynting vector  $4.00 \text{ cm}$  from the antenna, at the location of a typical person's head. Assume that the antenna emits energy with cylindrical wave fronts. (The actual radiation from antennas follows a more complicated pattern, as suggested by Fig. 34.15.) (b) The ANSI/IEEE C95.1-1991 maximum exposure standard is  $0.57 \text{ mW/cm}^2$  for persons living near

Figure P34.58. (©1998 Adam Smith/FPG International)

cellular telephone base stations, who would be continuously exposed to the radiation. Compare the answer to part (a) with this standard.

59. A linearly polarized microwave with a wavelength of 1.50 cm is directed along the positive  $x$  axis. The electric field vector has a maximum value of 175 V/m and vibrates in the  $xy$  plane. (a) Assume that the magnetic-field component of the wave can be written in the form  $B = B_{\max} \sin(kx - \omega t)$ , and give values for  $B_{\max}$ ,  $k$ , and  $\omega$ . Also, determine in which plane the magnetic-field vector vibrates. (b) Calculate the magnitude of the Poynting vector for this wave. (c) What maximum radiation pressure would this wave exert if it were directed at normal incidence onto a perfectly reflecting sheet? (d) What maximum acceleration would be imparted to a 500-g sheet (perfectly reflecting and at normal incidence) with dimensions of  $1.00 \text{ m} \times 0.750 \text{ m}$ ?
60. *Review Section 20.7 on thermal radiation.* (a) An elderly couple have installed a solar water heater on the roof of their house (Fig. P34.60). The solar-energy collector consists of a flat closed box with extraordinarily good thermal insulation. Its interior is painted black, and its front face is made of insulating glass. Assume that its emissivity for visible light is 0.900 and its emissivity for infrared light is 0.700. Assume that the noon Sun shines in perpendicular to the glass, with intensity  $1\,000 \text{ W/m}^2$ , and that no water is then entering or leaving the box. Find the steady-state temperature of the interior of the box. (b) The couple have built an identical box with no water tubes. It lies flat on the ground in front of the house. They use it as a cold frame, where they plant seeds in early spring. If the same noon Sun is at an elevation angle of  $50.0^\circ$ , find the steady-state temperature of the interior of this box, assuming that the ventilation slots are tightly closed.

Figure P34.60 (©Bill Banaszewski/Visuals Unlimited)

61. An astronaut, stranded in space 10.0 m from his spacecraft and at rest relative to it, has a mass (including equipment) of 110 kg. Since he has a 100-W light source that forms a directed beam, he decides to use the beam as a photon rocket to propel himself continu-

ously toward the spacecraft. (a) Calculate how long it takes him to reach the spacecraft by this method. (b) Suppose, instead, that he decides to throw the light source away in a direction opposite the spacecraft. If the light source has a mass of 3.00 kg and, after being thrown, moves at  $12.0 \text{ m/s}$  relative to the recoiling astronaut, how long does it take for the astronaut to reach the spacecraft?

62. The Earth reflects approximately 38.0% of the incident sunlight from its clouds and surface. (a) Given that the intensity of solar radiation is  $1\,340 \text{ W/m}^2$ , what is the radiation pressure on the Earth, in pascals, when the Sun is straight overhead? (b) Compare this to normal atmospheric pressure at the Earth's surface, which is 101 kPa.
63. Lasers have been used to suspend spherical glass beads in the Earth's gravitational field. (a) If a bead has a mass of  $1.00 \mu\text{g}$  and a density of  $0.200 \text{ g/cm}^3$ , determine the radiation intensity needed to support the bead. (b) If the beam has a radius of 0.200 cm, what power is required for this laser?
64. Lasers have been used to suspend spherical glass beads in the Earth's gravitational field. (a) If a bead has a mass  $m$  and a density  $\rho$ , determine the radiation intensity needed to support the bead. (b) If the beam has a radius  $r$ , what power is required for this laser?
65. **Review Problem.** A 1.00-m-diameter mirror focuses the Sun's rays onto an absorbing plate 2.00 cm in radius, which holds a can containing 1.00 L of water at  $20.0^\circ\text{C}$ . (a) If the solar intensity is  $1.00 \text{ kW/m}^2$ , what is the intensity on the absorbing plate? (b) What are the maximum magnitudes of the fields  $\mathbf{E}$  and  $\mathbf{B}$ ? (c) If 40.0% of the energy is absorbed, how long would it take to bring the water to its boiling point?
66. A microwave source produces pulses of 20.0-GHz radiation, with each pulse lasting 1.00 ns. A parabolic reflector ( $R = 6.00 \text{ cm}$ ) is used to focus these pulses into a parallel beam of radiation, as shown in Figure P34.66. The average power during each pulse is 25.0 kW. (a) What is the wavelength of these microwaves? (b) What is the total energy contained in each pulse? (c) Compute the average energy density inside each pulse. (d) Determine the amplitude of the electric and magnetic fields in these microwaves. (e) Compute the force exerted on the surface during the 1.00-ns duration of each pulse if the pulsed beam strikes an absorbing surface.

Figure P34.66

67. The electromagnetic power radiated by a nonrelativistic moving point charge  $q$  having an acceleration  $a$  is

$$\mathcal{P} = \frac{q^2 a^2}{6\pi\epsilon_0 c^3}$$

where  $\epsilon_0$  is the permittivity of vacuum (free space) and  $c$  is the speed of light in vacuum. (a) Show that the right side of this equation is in watts. (b) If an electron is placed in a constant electric field of 100 N/C, determine the acceleration of the electron and the electromagnetic power radiated by this electron. (c) If a proton is placed in a cyclotron with a radius of 0.500 m and a magnetic field of magnitude 0.350 T, what electromagnetic power is radiated by this proton?

68. A thin tungsten filament with a length of 1.00 m radiates 60.0 W of power in the form of electromagnetic waves. A perfectly absorbing surface, in the form of a hollow cylinder with a radius of 5.00 cm and a length of 1.00 m, is placed concentrically with the filament. Calculate the radiation pressure acting on the cylinder. (Assume that the radiation is emitted in the radial direction, and neglect end effects.)
69. The torsion balance shown in Figure 34.8 is used in an experiment to measure radiation pressure. The suspension fiber exerts an elastic restoring torque. Its torque constant is  $1.00 \times 10^{-11}$  N·m/degree, and the length of the horizontal rod is 6.00 cm. The beam from a 3.00-mW helium–neon laser is incident on the black disk, and the mirror disk is completely shielded. Calculate the angle between the equilibrium positions of the horizontal bar when the beam is switched from “off” to “on.”
70. **Review Problem.** The study of Creation suggests a Creator with a remarkable liking for beetles and for small red stars. A red star, typical of the most common kind, radiates electromagnetic waves with a power of  $6.00 \times 10^{23}$  W, which is only 0.159% of the luminosity of the Sun. Consider a spherical planet in a circular orbit around this star. Assume that the emissivity of the planet, as defined in Section 20.7, is equal for infrared and visible light. Assume that the planet has a uniform surface temperature. Identify the projected area over which the planet absorbs starlight, and the radiating area of the planet. If beetles thrive at a temperature of 310 K, what should the radius of the planet’s orbit be?
71. A “laser cannon” of a spacecraft has a beam of cross-sectional area  $A$ . The maximum electric field in the beam is  $E$ . At what rate  $a$  will an asteroid accelerate away from the spacecraft if the laser beam strikes the asteroid perpendicularly to its surface, and the surface is nonreflecting? The mass of the asteroid is  $m$ . Neglect the acceleration of the spacecraft.
72. A plane electromagnetic wave varies sinusoidally at 90.0 MHz as it travels along the  $+x$  direction. The peak value of the electric field is 2.00 mV/m, and it is directed along the  $\pm y$  direction. (a) Find the wavelength, the period, and the maximum value of the magnetic field. (b) Write expressions in SI units for the space and time variations of the electric field and of the magnetic field. Include numerical values, and include subscripts to indicate coordinate directions. (c) Find the average power per unit area that this wave propagates through space. (d) Find the average energy density in the radiation (in joules per cubic meter). (e) What radiation pressure would this wave exert upon a perfectly reflecting surface at normal incidence?

## ANSWERS TO QUICK QUIZZES

- 34.1 Zero. Figure 34.3b shows that the **B** and **E** vectors reach their maximum and minimum values at the same time.
- 34.2 (b) Along the  $y$  axis because that is the orientation of the electric field. The electric field moves electrons in the antenna, thus inducing a current that is detected and amplified.
- 34.3 The AM wave, because its amplitude is changing, would appear to vary in brightness. The FM wave would have changing colors because the color we perceive is related to the frequency of the light.

Figure Q35.10

- areas of the Earth see a total eclipse, other areas see a partial eclipse, and most areas see no eclipse.
17. The display windows of some department stores are slanted slightly inward at the bottom. This is to decrease the glare from streetlights or the Sun, which would make it difficult for shoppers to see the display inside. Sketch a light ray reflecting off such a window to show how this technique works.

18. When two colors of light X and Y are sent through a glass prism, X is bent more than Y. Which color travels more slowly in the prism?
19. Why does the arc of a rainbow appear with red on top and violet on the bottom?
20. Under what conditions is a mirage formed? On a hot day, what are we seeing when we observe “water on the road”?

### Section 35.1 The Nature of Light

#### Section 35.2 Measurements of the Speed of Light

- The Apollo 11 astronauts set up a highly reflecting panel on the Moon's surface. The speed of light can be found by measuring the time it takes a laser beam to travel from Earth, reflect from the retroreflector, and return to Earth. If this interval is measured to be 2.51 s, what is the measured speed of light? Take the center-to-center distance from the Earth to the Moon to be  $3.84 \times 10^8$  m, and do not neglect the sizes of the Earth and the Moon.
- As a result of his observations, Roemer concluded that eclipses of Io by Jupiter were delayed by 22 min during a six-month period as the Earth moved from the point in its orbit where it is closest to Jupiter to the diametrically opposite point where it is farthest from Jupiter. Using  $1.50 \times 10^8$  km as the average radius of the Earth's orbit around the Sun, calculate the speed of light from these data.
- In an experiment to measure the speed of light using the apparatus of Fizeau (see Fig. 35.2), the distance between light source and mirror was 11.45 km and the wheel had 720 notches. The experimentally determined value of  $c$  was  $2.998 \times 10^8$  m/s. Calculate the minimum angular speed of the wheel for this experiment.
- Figure P35.4 shows an apparatus used to measure the speed distribution of gas molecules. It consists of two slotted rotating disks separated by a distance  $d$ , with the slots displaced by the angle  $\theta$ . Suppose that the speed of light is measured by sending a light beam from the left through this apparatus. (a) Show that a light beam will be seen in the detector (that is, will make it through both slots) only if its speed is given by  $c = \omega d / \theta$ , where  $\omega$  is the angular speed of the disks and  $\theta$  is measured in radians. (b) What is the measured speed of light if the distance between the two slotted rotating disks is 2.50 m, the slot in the second disk is displaced  $1/60$  of  $1^\circ$  from the slot in the first disk, and the disks are rotating at 5 555 rev/s?

Figure P35.4

**Section 35.3 The Ray Approximation in Geometric Optics****Section 35.4 Reflection****Section 35.5 Refraction****Section 35.6 Huygens's Principle**

Note: In this section, if an index of refraction value is not given, refer to Table 35.1.

5. A narrow beam of sodium yellow light, with wavelength 589 nm in vacuum, is incident from air onto a smooth water surface at an angle  $\theta_1 = 35.0^\circ$ . Determine the angle of refraction  $\theta_2$  and the wavelength of the light in water.
6. The wavelength of red helium–neon laser light in air is 632.8 nm. (a) What is its frequency? (b) What is its wavelength in glass that has an index of refraction of 1.50? (c) What is its speed in the glass?
7. An underwater scuba diver sees the Sun at an apparent angle of  $45.0^\circ$  from the vertical. What is the actual direction of the Sun?
8. A laser beam is incident at an angle of  $30.0^\circ$  from the vertical onto a solution of corn syrup in water. If the beam is refracted to  $19.24^\circ$  from the vertical, (a) what is the index of refraction of the syrup solution? Suppose that the light is red, with a vacuum wavelength of 632.8 nm. Find its (b) wavelength, (c) frequency, and (d) speed in the solution.
9. Find the speed of light in (a) flint glass, (b) water, and (c) cubic zirconia.
10. A light ray initially in water enters a transparent substance at an angle of incidence of  $37.0^\circ$ , and the transmitted ray is refracted at an angle of  $25.0^\circ$ . Calculate the speed of light in the transparent substance.
11. A ray of light strikes a flat block of glass ( $n = 1.50$ ) of thickness 2.00 cm at an angle of  $30.0^\circ$  with the normal. Trace the light beam through the glass, and find the angles of incidence and refraction at each surface.
12. Light of wavelength 436 nm in air enters a fishbowl filled with water and then exits through the crown glass wall of the container. What is the wavelength of the light (a) in the water and (b) in the glass?

13. An opaque cylindrical tank with an open top has a diameter of 3.00 m and is completely filled with water. When the setting Sun reaches an angle of  $28.0^\circ$  above the horizon, sunlight ceases to illuminate any part of the bottom of the tank. How deep is the tank?
14. The angle between the two mirrors illustrated in Figure P35.14 is a right angle. The beam of light in the vertical plane  $P$  strikes mirror 1 as shown. (a) Determine the distance that the reflected light beam travels before striking mirror 2. (b) In what direction does the light beam travel after being reflected from mirror 2?

Figure P35.14

15. How many times will the incident beam shown in Figure P35.15 be reflected by each of the parallel mirrors?

Figure P35.15

16. When the light illustrated in Figure P35.16 passes through the glass block, it is shifted laterally by the distance  $d$ . If  $n = 1.50$ , what is the value of  $d$ ?
17. Find the time required for the light to pass through the glass block described in Problem 16.
18. The light beam shown in Figure P35.18 makes an angle of  $20.0^\circ$  with the normal line  $NN'$  in the linseed oil. Determine the angles  $\theta$  and  $\theta'$ . (The index of refraction for linseed oil is 1.48.)

Figure P35.16 Problems 16 and 17.

Figure P35.18

19. Two light pulses are emitted simultaneously from a source. Both pulses travel to a detector, but one first passes through 6.20 m of ice. Determine the difference in the pulses' times of arrival at the detector.
20. When you look through a window, by how much time is the light you see delayed by having to go through glass instead of air? Make an order-of-magnitude estimate on the basis of data you specify. By how many wavelengths is it delayed?
21. Light passes from air into flint glass. (a) What angle of incidence must the light have if the component of its velocity perpendicular to the interface is to remain constant? (b) Can the component of velocity parallel to the interface remain constant during refraction?
22. The reflecting surfaces of two intersecting flat mirrors are at an angle of  $\theta$  ( $0^\circ < \theta < 90^\circ$ ), as shown in Figure

Figure P35.22

P35.22. If a light ray strikes the horizontal mirror, show that the emerging ray will intersect the incident ray at an angle of  $\beta = 180^\circ - 2\theta$ .

23. A light ray enters the atmosphere of a planet and descends vertically 20.0 km to the surface. The index of refraction where the light enters the atmosphere is 1.000, and it increases linearly to the surface where it has a value of 1.005. (a) How long does it take the ray to traverse this path? (b) Compare this to the time it takes in the absence of an atmosphere.
24. A light ray enters the atmosphere of a planet and descends vertically to the surface a distance  $h$ . The index of refraction where the light enters the atmosphere is 1.000, and it increases linearly to the surface where it has a value of  $n$ . (a) How long does it take the ray to traverse this path? (b) Compare this to the time it takes in the absence of an atmosphere.

### Section 35.7 Dispersion and Prisms

25. A narrow white light beam is incident on a block of fused quartz at an angle of  $30.0^\circ$ . Find the angular width of the light beam inside the quartz.
26. A ray of light strikes the midpoint of one face of an equiangular glass prism ( $n = 1.50$ ) at an angle of incidence of  $30.0^\circ$ . Trace the path of the light ray through the glass, and find the angles of incidence and refraction at each surface.
27. A prism that has an apex angle of  $50.0^\circ$  is made of cubic zirconia, with  $n = 2.20$ . What is its angle of minimum deviation?
28. Light with a wavelength of 700 nm is incident on the face of a fused quartz prism at an angle of  $75.0^\circ$  (with respect to the normal to the surface). The apex angle of the prism is  $60.0^\circ$ . Using the value of  $n$  from Figure 35.20, calculate the angle (a) of refraction at this first surface, (b) of incidence at the second surface, (c) of refraction at the second surface, and (d) between the incident and emerging rays.
29. The index of refraction for violet light in silica flint glass is 1.66, and that for red light is 1.62. What is the angular dispersion of visible light passing through a prism of apex angle  $60.0^\circ$  if the angle of incidence is  $50.0^\circ$ ? (See Fig. P35.29.)
30. Show that if the apex angle  $\Phi$  of a prism is small, an approximate value for the angle of minimum deviation is  $\delta_{\min} = (n - 1)\Phi$ .
31. A triangular glass prism with an apex angle of  $\Phi = 60.0^\circ$  has an index of refraction  $n = 1.50$  (Fig. P35.31). What is the smallest angle of incidence  $\theta_1$  for which a light ray can emerge from the other side?
32. A triangular glass prism with an apex angle of  $\Phi$  has an index of refraction  $n$  (Fig. P35.31). What is the smallest angle of incidence  $\theta_1$  for which a light ray can emerge from the other side?

Figure P35.29

Figure P35.31

33. An experimental apparatus includes a prism made of sodium chloride. The angle of minimum deviation for light of wavelength 589 nm is to be  $10.0^\circ$ . What is the required apex angle of the prism?
34. A triangular glass prism with an apex angle of  $60.0^\circ$  has an index of refraction of 1.50. (a) Show that if its angle of incidence on the first surface is  $\theta_1 = 48.6^\circ$ , light will pass symmetrically through the prism, as shown in Figure 35.26. (b) Find the angle of deviation  $\delta_{\min}$  for  $\theta_1 = 48.6^\circ$ . (c) Find the angle of deviation if the angle of incidence on the first surface is  $45.6^\circ$ . (d) Find the angle of deviation if  $\theta_1 = 51.6^\circ$ .

### Section 35.8 Total Internal Reflection

35. For 589-nm light, calculate the critical angle for the following materials surrounded by air: (a) diamond, (b) flint glass, and (c) ice.
36. Repeat Problem 35 for the situation in which the materials are surrounded by water.
37. Consider a common mirage formed by super-heated air just above a roadway. A truck driver whose eyes are 2.00 m above the road, where  $n = 1.0003$ , looks forward. She perceives the illusion of a patch of water ahead on the road, where her line of sight makes an angle of  $1.20^\circ$  below the horizontal. Find the index of refraction of the air just above the road surface. (*Hint:* Treat this as a problem in total internal reflection.)
38. Determine the maximum angle  $\theta$  for which the light

Figure P35.38

- rays incident on the end of the pipe shown in Figure P35.38 are subject to total internal reflection along the walls of the pipe. Assume that the pipe has an index of refraction of 1.36 and the outside medium is air.
39. A glass fiber ( $n = 1.50$ ) is submerged in water ( $n = 1.33$ ). What is the critical angle for light to stay inside the optical fiber?
40. A glass cube is placed on a newspaper, which rests on a table. A person reads all of the words the cube covers, through all of one vertical side. Determine the maximum possible index of refraction of the glass.
41. A large Lucite cube ( $n = 1.59$ ) has a small air bubble (a defect in the casting process) below one surface. When a penny (diameter, 1.90 cm) is placed directly over the bubble on the outside of the cube, one cannot see the bubble by looking down into the cube at any angle. However, when a dime (diameter, 1.75 cm) is placed directly over it, one can see the bubble by looking down into the cube. What is the range of the possible depths of the air bubble beneath the surface?
42. A room contains air in which the speed of sound is 343 m/s. The walls of the room are made of concrete, in which the speed of sound is 1850 m/s. (a) Find the critical angle for total internal reflection of sound at the concrete-air boundary. (b) In which medium must the sound be traveling to undergo total internal reflection? (c) "A bare concrete wall is a highly efficient mirror for sound." Give evidence for or against this statement.
43. In about 1965, engineers at the Toro Company invented a gasoline gauge for small engines, diagrammed in Figure P35.43. The gauge has no moving parts. It consists of a flat slab of transparent plastic fitting vertically into a slot in the cap on the gas tank. None of the plastic has a reflective coating. The plastic projects from the horizontal top down nearly to the bottom of the opaque tank. Its lower edge is cut with facets making angles of  $45^\circ$  with the horizontal. A lawnmower operator looks down from above and sees a boundary between bright and dark on the gauge. The location of the boundary, across the width of the plastic, indicates the quantity of gasoline in the tank. Explain how the gauge works. Explain the design requirements, if any, for the index of refraction of the plastic.

Figure P35.43

(Optional)

**Section 35.9 Fermat's Principle**

44. The shoreline of a lake runs from east to west. A swimmer gets into trouble 20.0 m out from shore and 26.0 m to the east of a lifeguard, whose station is 16.0 m in from the shoreline. The lifeguard takes a negligible amount of time to accelerate. He can run at 7.00 m/s and swim at 1.40 m/s. To reach the swimmer as quickly as possible, in what direction should the lifeguard start running? You will need to solve a transcendental equation numerically.

**ADDITIONAL PROBLEMS**

45. A narrow beam of light is incident from air onto a glass surface with an index of refraction of 1.56. Find the angle of incidence for which the corresponding angle of refraction is one half the angle of incidence. (*Hint:* You might want to use the trigonometric identity  $\sin 2\theta = 2 \sin \theta \cos \theta$ .)
46. (a) Consider a horizontal interface between air above and glass with an index of 1.55 below. Draw a light ray incident from the air at an angle of incidence of  $30.0^\circ$ . Determine the angles of the reflected and refracted rays and show them on the diagram. (b) Suppose instead that the light ray is incident from the glass at an angle of incidence of  $30.0^\circ$ . Determine the angles of the reflected and refracted rays and show all three rays on a new diagram. (c) For rays incident from the air onto the air-glass surface, determine and tabulate the angles of reflection and refraction for all the angles of incidence at  $10.0^\circ$  intervals from  $0$  to  $90.0^\circ$ . (d) Do the same for light rays traveling up to the interface through the glass.
47. A small underwater pool light is 1.00 m below the surface. The light emerging from the water forms a circle
- on the water's surface. What is the diameter of this circle?
48. One technique for measuring the angle of a prism is shown in Figure P35.48. A parallel beam of light is directed on the angle so that the beam reflects from opposite sides. Show that the angular separation of the two beams is given by  $B = 2A$ .
49. The walls of a prison cell are perpendicular to the four cardinal compass directions. On the first day of spring, light from the rising Sun enters a rectangular window in the eastern wall. The light traverses 2.37 m horizontally to shine perpendicularly on the wall opposite the window. A young prisoner observes the patch of light moving across this western wall and for the first time forms his own understanding of the rotation of the Earth. (a) With what speed does the illuminated rectangle move? (b) The prisoner holds a small square mirror flat against the wall at one corner of the rectangle of light. The mirror reflects light back to a spot on the eastern wall close beside the window. How fast does the smaller square of light move across that wall? (c) Seen from a latitude of  $40.0^\circ$  north, the rising Sun moves through the sky along a line making a  $50.0^\circ$  angle with the southeastern horizon. In what direction does the rectangular patch of light on the western wall of the prisoner's cell move? (d) In what direction does the smaller square of light on the eastern wall move?
50. The laws of refraction and reflection are the same for sound as for light. The speed of sound in air is 340 m/s, and that of sound in water is 1 510 m/s. If a sound wave approaches a plane water surface at an angle of incidence of  $12.0^\circ$ , what is the angle of refraction?
51. Cold sodium atoms (near absolute zero) in a state called a *Bose-Einstein condensate* can slow the speed of light from its normally high value to a speed approaching that of an automobile in a city. The speed of light in one such medium was recorded as 61.15 km/h. (a) Find the index of refraction of this medium. (b) What is the critical angle for total internal reflection if the condensate is surrounded by vacuum?
52. A narrow beam of white light is incident at  $25.0^\circ$  onto a slab of heavy flint glass 5.00 cm thick. The indices of

Figure P35.48

refraction of the glass at wavelengths of 400 nm and 700 nm are 1.689 and 1.642, respectively. Find the width of the visible beam as it emerges from the slab.

53. A hiker stands on a mountain peak near sunset and observes a rainbow caused by water droplets in the air 8.00 km away. The valley is 2.00 km below the mountain peak and entirely flat. What fraction of the complete circular arc of the rainbow is visible to the hiker? (See Fig. 35.25.)

54. A fish is at a depth  $d$  under water. Take the index of refraction of water as  $4/3$ . Show that when the fish is viewed at an angle of refraction  $\theta_1$ , the apparent depth  $z$  of the fish is

$$z = \frac{3d \cos \theta_1}{\sqrt{7 + 9 \cos^2 \theta_1}}$$

- WEB 55. A laser beam strikes one end of a slab of material, as shown in Figure P35.55. The index of refraction of the slab is 1.48. Determine the number of internal reflections of the beam before it emerges from the opposite end of the slab.

Figure P35.55

56. When light is normally incident on the interface between two transparent optical media, the intensity of the reflected light is given by the expression

$$S'_1 = \left( \frac{n_2 - n_1}{n_2 + n_1} \right)^2 S_1$$

In this equation,  $S_1$  represents the average magnitude of the Poynting vector in the incident light (the incident intensity),  $S'_1$  is the reflected intensity, and  $n_1$  and  $n_2$  are the refractive indices of the two media. (a) What fraction of the incident intensity is reflected for 589-nm light normally incident on an interface between air and crown glass? (b) In part (a), does it matter whether the light is in the air or in the glass as it strikes the interface? (c) A Bose–Einstein condensate (see Problem 51) has an index of refraction of  $1.76 \times 10^7$ . Find the percent reflection for light falling perpendicularly on its surface. What would the condensate look like?

57. Refer to Problem 56 for a description of the reflected intensity of light normally incident on an interface between two transparent media. (a) When light is normally incident on an interface between vacuum and a transparent medium of index  $n$ , show that the intensity  $S_2$  of the transmitted light is given by the expression

$S_2/S_1 = 4n/(n + 1)^2$ . (b) Light travels perpendicularly through a diamond slab, surrounded by air, with parallel surfaces of entry and exit. Apply the transmission fraction in part (a) to find the approximate overall transmission through the slab of diamond as a percentage. Ignore light reflected back and forth within the slab.

58. This problem builds upon the results of Problems 56 and 57. Light travels perpendicularly through a diamond slab, surrounded by air, with parallel surfaces of entry and exit. What fraction of the incident intensity is the intensity of the transmitted light? Include the effects of light reflected back and forth inside the slab.
59. The light beam shown in Figure P35.59 strikes surface 2 at the critical angle. Determine the angle of incidence,  $\theta_1$ .

Figure P35.59

60. A 4.00-m-long pole stands vertically in a lake having a depth of 2.00 m. When the Sun is  $40.0^\circ$  above the horizontal, determine the length of the pole's shadow on the bottom of the lake. Take the index of refraction for water to be 1.33.

- WEB 61. A light ray of wavelength 589 nm is incident at an angle  $\theta$  on the top surface of a block of polystyrene, as shown in Figure P35.61. (a) Find the maximum value of  $\theta$  for which the refracted ray undergoes total internal reflection.

Figure P35.61

tion at the left vertical face of the block. Repeat the calculation for the case in which the polystyrene block is immersed in (b) water and (c) carbon disulfide.

62. A ray of light passes from air into water. For its deviation angle  $\delta = |\theta_1 - \theta_2|$  to be  $10.0^\circ$ , what must be its angle of incidence?

63. A shallow glass dish is 4.00 cm wide at the bottom, as shown in Figure P35.63. When an observer's eye is positioned as shown, the observer sees the edge of the bottom of the empty dish. When this dish is filled with water, the observer sees the center of the bottom of the dish. Find the height of the dish.

Figure P35.63

64. A material having an index of refraction  $n$  is surrounded by a vacuum and is in the shape of a quarter circle of radius  $R$  (Fig. P35.64). A light ray parallel to the base of the material is incident from the left at a distance of  $L$  above the base and emerges out of the material at the angle  $\theta$ . Determine an expression for  $\theta$ .

Figure P35.64

65. Derive the law of reflection (Eq. 35.2) from Fermat's principle of least time. (See the procedure outlined in Section 35.9 for the derivation of the law of refraction from Fermat's principle.)

66. A transparent cylinder of radius  $R = 2.00$  m has a mirrored surface on its right half, as shown in Figure P35.66. A light ray traveling in air is incident on the left side of the cylinder. The incident light ray and exiting light ray are parallel and  $d = 2.00$  m. Determine the index of refraction of the material.

Figure P35.66

67. A. H. Pfund's method for measuring the index of refraction of glass is illustrated in Figure P35.67. One face of a slab of thickness  $t$  is painted white, and a small hole scraped clear at point  $P$  serves as a source of diverging rays when the slab is illuminated from below. Ray  $PBB'$  strikes the clear surface at the critical angle and is totally reflected, as are rays such as  $PCC'$ . Rays such as  $PAA'$  emerge from the clear surface. On the painted surface there appears a dark circle of diameter  $d$ , surrounded by an illuminated region, or halo. (a) Derive a formula for  $n$  in terms of the measured quantities  $d$  and  $t$ . (b) What is the diameter of the dark circle if  $n = 1.52$  for a slab 0.600 cm thick? (c) If white light is used, the critical angle depends on color caused by dispersion. Is the inner edge of the white halo tinged with red light or violet light? Explain.

Figure P35.67

68. A light ray traveling in air is incident on one face of a right-angle prism with an index of refraction of  $n = 1.50$ , as shown in Figure P35.68, and the ray follows the path shown in the figure. If  $\theta = 60.0^\circ$  and the base of the prism is mirrored, what is the angle  $\phi$  made by

Figure P35.68

the outgoing ray with the normal to the right face of the prism?

69. A light ray enters a rectangular block of plastic at an angle of  $\theta_1 = 45.0^\circ$  and emerges at an angle of  $\theta_2 = 76.0^\circ$ , as shown in Figure P35.69. (a) Determine the index of refraction for the plastic. (b) If the light ray enters the plastic at a point  $L = 50.0$  cm from the bottom edge, how long does it take the light ray to travel through the plastic?
70. Students allow a narrow beam of laser light to strike a water surface. They arrange to measure the angle of refraction for selected angles of incidence and record the data shown in the accompanying table. Use the data to verify Snell's law of refraction by plotting the sine of the angle of incidence versus the sine of the angle of refraction.

Figure P35.69

tion. Use the resulting plot to deduce the index of refraction of water.

Angle of Incidence (degrees)	Angle of Refraction (degrees)
10.0	7.5
20.0	15.1
30.0	22.3
40.0	28.7
50.0	35.2
60.0	40.3
70.0	45.3
80.0	47.7

## ANSWERS TO QUICK QUIZZES

- 35.1 Beams ② and ④ are reflected; beams ③ and ⑤ are refracted.
- 35.2 Fused quartz. An ideal lens would have an index of refraction that does not vary with wavelength so that all colors would be bent through the same angle by the lens. Of the three choices, fused quartz has the least variation in  $n$  across the visible spectrum. Thus, it is the best choice for a single-element lens.
- 35.3 The two rays on the right result from total internal reflection at the right face of the prism. Because all of the light in these rays is reflected (rather than partly refracted), these two rays are brightest. The light from the other three rays is divided into reflected and refracted parts.

## PUZZLER

Most car headlights have lines across their faces, like those shown here. Without these lines, the headlights either would not function properly or would be much more likely to break from the jarring of the car on a bumpy road. What is the purpose of the lines? (*George Semple*)

This chapter is concerned with the images that result when spherical waves fall on flat and spherical surfaces. We find that images can be formed either by reflection or by refraction and that mirrors and lenses work because of reflection and refraction. We continue to use the ray approximation and to assume that light travels in straight lines. Both of these steps lead to valid predictions in the field called *geometric optics*. In subsequent chapters, we shall concern ourselves with interference and diffraction effects—the objects of study in the field of *wave optics*.

### 36.1 IMAGES FORMED BY FLAT MIRRORS

**Figure 36.1** An image formed by reflection from a flat mirror. The image point  $I$  is located behind the mirror a perpendicular distance  $q$  from the mirror (the image distance). Study of Figure 36.2 shows that this image distance has the same magnitude as the object distance  $p$ .

**Figure 36.2** A geometric construction that is used to locate the image of an object placed in front of a flat mirror. Because the triangles  $PQR$  and  $P'QR$  are congruent,  $|p| = |q|$  and  $h = h'$ .

We begin by considering the simplest possible mirror, the flat mirror. Consider a point source of light placed at  $O$  in Figure 36.1, a distance  $p$  in front of a flat mirror. The distance  $p$  is called the **object distance**. Light rays leave the source and are reflected from the mirror. Upon reflection, the rays continue to diverge (spread apart), but they appear to the viewer to come from a point  $I$  behind the mirror. Point  $I$  is called the **image** of the object at  $O$ . Regardless of the system under study, we always locate images by extending diverging rays back to a point from which they appear to diverge. **Images are located either at the point from which rays of light actually diverge or at the point from which they appear to diverge.** Because the rays in Figure 36.1 appear to originate at  $I$ , which is a distance  $q$  behind the mirror, this is the location of the image. The distance  $q$  is called the **image distance**.

Images are classified as real or virtual. **A real image is formed when light rays pass through and diverge from the image point; a virtual image is formed when the light rays do not pass through the image point but appear to diverge from that point.** The image formed by the mirror in Figure 36.1 is virtual. The image of an object seen in a flat mirror is always virtual. Real images can be displayed on a screen (as at a movie), but virtual images cannot be displayed on a screen.

We can use the simple geometric techniques shown in Figure 36.2 to examine the properties of the images formed by flat mirrors. Even though an infinite number of light rays leave each point on the object, we need to follow only two of them to determine where an image is formed. One of those rays starts at  $P$ , follows a horizontal path to the mirror, and reflects back on itself. The second ray follows the oblique path  $PR$  and reflects as shown, according to the law of reflection. An observer in front of the mirror would trace the two reflected rays back to the point at which they appear to have originated, which is point  $P'$  behind the mirror. A continuation of this process for points other than  $P$  on the object would result in a virtual image (represented by a yellow arrow) behind the mirror. Because triangles  $PQR$  and  $P'QR$  are congruent,  $PQ = P'Q$ . We conclude that **the image formed by an object placed in front of a flat mirror is as far behind the mirror as the object is in front of the mirror.**

Geometry also reveals that the object height  $h$  equals the image height  $h'$ . Let us define **lateral magnification**  $M$  as follows:

Lateral magnification

$$M \equiv \frac{\text{Image height}}{\text{Object height}} = \frac{h'}{h} \quad (36.1)$$

Mt. Hood reflected in Trillium Lake. Why is the image inverted and the same size as the mountain?

This is a general definition of the lateral magnification for any type of mirror. For a flat mirror,  $M = 1$  because  $h' = h$ .

Finally, note that a flat mirror produces an image that has an *apparent* left–right reversal. You can see this reversal by standing in front of a mirror and raising your right hand, as shown in Figure 36.3. The image you see raises its left hand. Likewise, your hair appears to be parted on the side opposite your real part, and a mole on your right cheek appears to be on your left cheek.

This reversal is not *actually* a left–right reversal. Imagine, for example, lying on your left side on the floor, with your body parallel to the mirror surface. Now your head is on the left and your feet are on the right. If you shake your feet, the image does not shake its head! If you raise your right hand, however, the image again raises its left hand. Thus, the mirror again appears to produce a left–right reversal but in the up–down direction!

The reversal is actually a *front–back reversal*, caused by the light rays going forward toward the mirror and then reflecting back from it. An interesting exercise is to stand in front of a mirror while holding an overhead transparency in front of you so that you can read the writing on the transparency. You will be able to read the writing on the image of the transparency, also. You may have had a similar experience if you have attached a transparent decal with words on it to the rear window of your car. If the decal can be read from outside the car, you can also read it when looking into your rearview mirror from inside the car.

We conclude that the image that is formed by a flat mirror has the following properties.

- The image is as far behind the mirror as the object is in front of the mirror.
- The image is unmagnified, virtual, and upright. (By *upright* we mean that, if the object arrow points upward as in Figure 36.2, so does the image arrow.)
- The image has front–back reversal.

### QuickLab

View yourself in a full-length mirror. Standing close to the mirror, place one piece of tape at the top of the image of your head and another piece at the very bottom of the image of your feet. Now step back a few meters and observe your image. How big is it relative to its original size? How does the distance between the pieces of tape compare with your actual height? You may want to refer to Problem 3.

**Figure 36.3** The image in the mirror of a person's right hand is reversed front to back. This makes the right hand appear to be a left hand. Notice that the thumb is on the left side of both real hands and on the left side of the image. That the thumb is not on the right side of the image indicates that there is no left-to-right reversal.

**Quick Quiz 36.1**

In the overhead view of Figure 36.4, the image of the stone seen by observer 1 is at  $C$ . Where does observer 2 see the image—at  $A$ , at  $B$ , at  $C$ , at  $D$ , at  $E$ , or not at all?

Figure 36.4

**CONCEPTUAL EXAMPLE 36.1** Multiple Images Formed by Two Mirrors

Two flat mirrors are at right angles to each other, as illustrated in Figure 36.5, and an object is placed at point  $O$ . In this situation, multiple images are formed. Locate the positions of these images.

**Solution** The image of the object is at  $I_1$  in mirror 1 and at  $I_2$  in mirror 2. In addition, a third image is formed at  $I_3$ . This third image is the image of  $I_1$  in mirror 2 or, equivalently, the image of  $I_2$  in mirror 1. That is, the image at  $I_1$  (or  $I_2$ ) serves as the object for  $I_3$ . Note that to form this image at  $I_3$ , the rays reflect twice after leaving the object at  $O$ .

Figure 36.5 When an object is placed in front of two mutually perpendicular mirrors as shown, three images are formed.

**CONCEPTUAL EXAMPLE 36.2** The Levitated Professor

The professor in the box shown in Figure 36.6 appears to be balancing himself on a few fingers, with his feet off the floor. He can maintain this position for a long time, and he appears to defy gravity. How was this illusion created?

**Solution** This is one of many magicians' optical illusions that make use of a mirror. The box in which the professor stands is a cubical frame that contains a flat vertical mirror positioned in a diagonal plane of the frame. The professor straddles the mirror so that one foot, which you see, is in front of the mirror, and one foot, which you cannot see, is behind the mirror. When he raises the foot in front of the mirror, the reflection of that foot also rises, so he appears to float in air.

Figure 36.6 An optical illusion.

**CONCEPTUAL EXAMPLE 36.3** The Tilting Rearview Mirror

Most rearview mirrors in cars have a day setting and a night setting. The night setting greatly diminishes the intensity of the image in order that lights from trailing vehicles do not blind the driver. How does such a mirror work?

**Solution** Figure 36.7 shows a cross-sectional view of a rearview mirror for each setting. The unit consists of a reflective coating on the back of a wedge of glass. In the day setting (Fig. 36.7a), the light from an object behind the car strikes the glass wedge at point  $I$ . Most of the light enters the wedge, refracting as it crosses the front surface, and reflects

from the back surface to return to the front surface, where it is refracted again as it re-enters the air as ray  $B$  (for *bright*). In addition, a small portion of the light is reflected at the front surface of the glass, as indicated by ray  $D$  (for *dim*).

This dim reflected light is responsible for the image that is observed when the mirror is in the night setting (Fig. 36.7b). In this case, the wedge is rotated so that the path followed by the bright light (ray  $B$ ) does not lead to the eye. Instead, the dim light reflected from the front surface of the wedge travels to the eye, and the brightness of trailing headlights does not become a hazard.

**Figure 36.7** Cross-sectional views of a rearview mirror. (a) With the day setting, the silvered back surface of the mirror reflects a bright ray  $B$  into the driver's eyes. (b) With the night setting, the glass of the unsilvered front surface of the mirror reflects a dim ray  $D$  into the driver's eyes.

**36.2 IMAGES FORMED BY SPHERICAL MIRRORS****Concave Mirrors**

**14.7** A **spherical mirror**, as its name implies, has the shape of a section of a sphere. This type of mirror focuses incoming parallel rays to a point, as demonstrated by the colored light rays in Figure 36.8. Figure 36.9a shows a cross-section of a spherical mirror, with its surface represented by the solid, curved black line. (The blue band represents the structural support for the mirrored surface, such as a curved piece of glass on which the silvered surface is deposited.) Such a mirror, in which light is reflected from the inner, concave surface, is called a **concave mirror**. The mirror has a radius of curvature  $R$ , and its center of curvature is point  $C$ . Point  $V$  is the center of the spherical section, and a line through  $C$  and  $V$  is called the **principal axis** of the mirror.

Now consider a point source of light placed at point  $O$  in Figure 36.9b, where  $O$  is any point on the principal axis to the left of  $C$ . Two diverging rays that originate at  $O$  are shown. After reflecting from the mirror, these rays converge (come together) at the image point  $I$ . They then continue to diverge from  $I$  as if an object were there. As a result, we have at point  $I$  a real image of the light source at  $O$ .

We shall consider in this section only rays that diverge from the object and make a small angle with the principal axis. Such rays are called **paraxial rays**. All

**Figure 36.8** Red, blue, and green light rays are reflected by a curved mirror. Note that the point where the three colors meet is white.

**Figure 36.9** (a) A concave mirror of radius  $R$ . The center of curvature  $C$  is located on the principal axis. (b) A point object placed at  $O$  in front of a concave spherical mirror of radius  $R$ , where  $O$  is any point on the principal axis farther than  $R$  from the mirror surface, forms a real image at  $I$ . If the rays diverge from  $O$  at small angles, they all reflect through the same image point.

such rays reflect through the image point, as shown in Figure 36.9b. Rays that are far from the principal axis, such as those shown in Figure 36.10, converge to other points on the principal axis, producing a blurred image. This effect, which is called **spherical aberration**, is present to some extent for any spherical mirror and is discussed in Section 36.5.

We can use Figure 36.11 to calculate the image distance  $q$  from a knowledge of the object distance  $p$  and radius of curvature  $R$ . By convention, these distances are measured from point  $V$ . Figure 36.11 shows two rays leaving the tip of the object. One of these rays passes through the center of curvature  $C$  of the mirror, hitting the mirror perpendicular to the mirror surface and reflecting back on itself. The second ray strikes the mirror at its center (point  $V$ ) and reflects as shown, obeying the law of reflection. The image of the tip of the arrow is located at the point where these two rays intersect. From the gold right triangle in Figure 36.11, we see that  $\tan \theta = h/p$ , and from the blue right triangle we see that  $\tan \theta = -h'/q$ . The negative sign is introduced because the image is inverted, so  $h'$  is taken to be negative. Thus, from Equation 36.1 and these results, we find that the magnification of the mirror is

$$M = \frac{h'}{h} = -\frac{q}{p} \tag{36.2}$$

**Figure 36.10** Rays diverging from the object at large angles from the principal axis reflect from a spherical concave mirror to intersect the principal axis at different points, resulting in a blurred image. This condition is called *spherical aberration*.

**Figure 36.11** The image formed by a spherical concave mirror when the object  $O$  lies outside the center of curvature  $C$ .

We also note from the two triangles in Figure 36.11 that have  $\alpha$  as one angle that

$$\tan \alpha = \frac{h}{p - R} \quad \text{and} \quad \tan \alpha = -\frac{h'}{R - q}$$

from which we find that

$$\frac{h'}{h} = -\frac{R - q}{p - R} \quad (36.3)$$

If we compare Equations 36.2 and 36.3, we see that

$$\frac{R - q}{p - R} = \frac{q}{p}$$

Simple algebra reduces this to

$$\frac{1}{p} + \frac{1}{q} = \frac{2}{R} \quad (36.4)$$

Mirror equation in terms of  $R$

This expression is called the **mirror equation**. It is applicable only to paraxial rays.

If the object is very far from the mirror—that is, if  $p$  is so much greater than  $R$  that  $p$  can be said to approach infinity—then  $1/p \approx 0$ , and we see from Equation 36.4 that  $q \approx R/2$ . That is, when the object is very far from the mirror, the image point is halfway between the center of curvature and the center point on the mirror, as shown in Figure 36.12a. The incoming rays from the object are essentially parallel in this figure because the source is assumed to be very far from the mirror. We call the image point in this special case the **focal point**  $F$  and the image distance the **focal length**  $f$ , where

$$f = \frac{R}{2} \quad (36.5)$$

Focal length

**Figure 36.12** (a) Light rays from a distant object ( $p \approx \infty$ ) reflect from a concave mirror through the focal point  $F$ . In this case, the image distance  $q \approx R/2 = f$ , where  $f$  is the focal length of the mirror. (b) Reflection of parallel rays from a concave mirror.

**Figure 36.13** Formation of an image by a spherical convex mirror. The image formed by the real object is virtual and upright.

Focal length is a parameter particular to a given mirror and therefore can be used to compare one mirror with another. The mirror equation can be expressed in terms of the focal length:

Mirror equation in terms of  $f$

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{f} \tag{36.6}$$

Notice that the focal length of a mirror depends only on the curvature of the mirror and not on the material from which the mirror is made. This is because the formation of the image results from rays reflected from the surface of the material. We shall find in Section 36.4 that the situation is different for lenses; in that case the light actually passes through the material.

### Convex Mirrors

Figure 36.13 shows the formation of an image by a **convex mirror**—that is, one silvered so that light is reflected from the outer, convex surface. This is sometimes called a **diverging mirror** because the rays from any point on an object diverge after reflection as though they were coming from some point behind the mirror. The image in Figure 36.13 is virtual because the reflected rays only appear to originate at the image point, as indicated by the dashed lines. Furthermore, the image is always upright and smaller than the object. This type of mirror is often used in stores to foil shoplifters. A single mirror can be used to survey a large field of view because it forms a smaller image of the interior of the store.

We do not derive any equations for convex spherical mirrors because we can use Equations 36.2, 36.4, and 36.6 for either concave or convex mirrors if we adhere to the following procedure. Let us refer to the region in which light rays move toward the mirror as the *front side* of the mirror, and the other side as the *back side*. For example, in Figures 36.10 and 36.12, the side to the left of the mirrors is the front side, and the side to the right of the mirrors is the back side. Figure 36.14 states the sign conventions for object and image distances, and Table 36.1 summarizes the sign conventions for all quantities.

**Figure 36.14** Signs of  $p$  and  $q$  for convex and concave mirrors.

**TABLE 36.1** Sign Conventions for Mirrors

$p$  is **positive** if object is in **front** of mirror (real object).  
 $p$  is **negative** if object is in **back** of mirror (virtual object).  
 $q$  is **positive** if image is in **front** of mirror (real image).  
 $q$  is **negative** if image is in **back** of mirror (virtual image).

Both  $f$  and  $R$  are **positive** if center of curvature is in **front** of mirror (concave mirror).  
 Both  $f$  and  $R$  are **negative** if center of curvature is in **back** of mirror (convex mirror).

If  $M$  is **positive**, image is **upright**.  
 If  $M$  is **negative**, image is **inverted**.

Reflection of parallel lines from a convex cylindrical mirror. The image is virtual, upright, and reduced in size.

### Ray Diagrams for Mirrors

The positions and sizes of images formed by mirrors can be conveniently determined with *ray diagrams*. These graphical constructions reveal the nature of the image and can be used to check results calculated from the mirror and magnification equations. To draw a ray diagram, we need to know the position of the object and the locations of the mirror's focal point and center of curvature. We then draw three rays to locate the image, as shown by the examples in Figure 36.15. These rays all start from the same object point and are drawn as follows. We may choose any point on the object; here, we choose the top of the object for simplicity:

- Ray 1 is drawn from the top of the object parallel to the principal axis and is reflected through the focal point  $F$ .
- Ray 2 is drawn from the top of the object through the focal point and is reflected parallel to the principal axis.
- Ray 3 is drawn from the top of the object through the center of curvature  $C$  and is reflected back on itself.

The intersection of any two of these rays locates the image. The third ray serves as a check of the construction. The image point obtained in this fashion must always agree with the value of  $q$  calculated from the mirror equation.

With concave mirrors, note what happens as the object is moved closer to the mirror. The real, inverted image in Figure 36.15a moves to the left as the object approaches the focal point. When the object is at the focal point, the image is infinitely far to the left. However, when the object lies between the focal point and the mirror surface, as shown in Figure 36.15b, the image is virtual, upright, and enlarged. This latter situation applies in the use of a shaving mirror or a makeup mirror. Your face is closer to the mirror than the focal point, and you see an upright, enlarged image of your face.

In a convex mirror (see Fig. 36.15c), the image of an object is always virtual, upright, and reduced in size. In this case, as the object distance increases, the virtual image decreases in size and approaches the focal point as  $p$  approaches infinity. You should construct other diagrams to verify how image position varies with object position.

### QuickLab

Compare the images formed of your face when you look first at the front side and then at the back side of a shiny soup spoon. Why do the two images look so different from each other?

(a)

(b)

(c)

**Figure 36.15** Ray diagrams for spherical mirrors, along with corresponding photographs of the images of candles. (a) When the object is located so that the center of curvature lies between the object and a concave mirror surface, the image is real, inverted, and reduced in size. (b) When the object is located between the focal point and a concave mirror surface, the image is virtual, upright, and enlarged. (c) When the object is in front of a convex mirror, the image is virtual, upright, and reduced in size.

**EXAMPLE 36.4** The Image from a Mirror

Assume that a certain spherical mirror has a focal length of +10.0 cm. Locate and describe the image for object distances of (a) 25.0 cm, (b) 10.0 cm, and (c) 5.00 cm.

**Solution** Because the focal length is positive, we know that this is a concave mirror (see Table 36.1). (a) This situation is analogous to that in Figure 36.15a; hence, we expect the image to be real and closer to the mirror than the object. According to the figure, it should also be inverted and reduced in size. We find the image distance by using the Equation 36.6 form of the mirror equation:

$$\begin{aligned}\frac{1}{p} + \frac{1}{q} &= \frac{1}{f} \\ \frac{1}{25.0 \text{ cm}} + \frac{1}{q} &= \frac{1}{10.0 \text{ cm}} \\ q &= 16.7 \text{ cm}\end{aligned}$$

The magnification is given by Equation 36.2:

$$M = -\frac{q}{p} = -\frac{16.7 \text{ cm}}{25.0 \text{ cm}} = -0.668$$

The fact that the absolute value of  $M$  is less than unity tells us that the image is smaller than the object, and the negative sign for  $M$  tells us that the image is inverted. Because  $q$  is positive, the image is located on the front side of the mirror and is real. Thus, we see that our predictions were correct.

(b) When the object distance is 10.0 cm, the object is located at the focal point. Now we find that

$$\frac{1}{10.0 \text{ cm}} + \frac{1}{q} = \frac{1}{10.0 \text{ cm}}$$

$$q = \infty$$

which means that rays originating from an object positioned at the focal point of a mirror are reflected so that the image is formed at an infinite distance from the mirror; that is, the rays travel parallel to one another after reflection. This is the situation in a flashlight, where the bulb filament is placed at the focal point of a reflector, producing a parallel beam of light.

(c) When the object is at  $p = 5.00$  cm, it lies between the focal point and the mirror surface, as shown in Figure 36.15b. Thus, we expect a magnified, virtual, upright image. In this case, the mirror equation gives

$$\begin{aligned}\frac{1}{5.00 \text{ cm}} + \frac{1}{q} &= \frac{1}{10.0 \text{ cm}} \\ q &= -10.0 \text{ cm}\end{aligned}$$

The image is virtual because it is located behind the mirror, as expected. The magnification is

$$M = -\frac{q}{p} = -\left(\frac{-10.0 \text{ cm}}{5.00 \text{ cm}}\right) = 2.00$$

The image is twice as large as the object, and the positive sign for  $M$  indicates that the image is upright (see Fig. 36.15b).

**Exercise** At what object distance is the magnification  $-1.00$ ?

**Answer** 20.0 cm.

**EXAMPLE 36.5** The Image from a Convex Mirror

A woman who is 1.5 m tall is located 3.0 m from an anti-shoplifting mirror, as shown in Figure 36.16. The focal length of the mirror is  $-0.25$  m. Find (a) the position of her image and (b) the magnification.

**Solution** (a) This situation is depicted in Figure 36.15c. We should expect to find an upright, reduced, virtual image. To find the image position, we use Equation 36.6:

$$\begin{aligned}\frac{1}{p} + \frac{1}{q} &= \frac{1}{f} = \frac{1}{-0.25 \text{ m}} \\ \frac{1}{q} &= \frac{1}{-0.25 \text{ m}} - \frac{1}{3.0 \text{ m}} \\ q &= -0.23 \text{ m}\end{aligned}$$

**Figure 36.16** Convex mirrors, often used for security in department stores, provide wide-angle viewing.

The negative value of  $q$  indicates that her image is virtual, or behind the mirror, as shown in Figure 36.15c.

(b) The magnification is

$$M = -\frac{q}{p} = -\left(\frac{-0.23 \text{ m}}{3.0 \text{ m}}\right) = 0.077$$

The image is much smaller than the woman, and it is upright because  $M$  is positive.

**Exercise** Find the height of the image.

**Answer** 0.12 m.

### 36.3 IMAGES FORMED BY REFRACTION

In this section we describe how images are formed when light rays are refracted at the boundary between two transparent materials. Consider two transparent media having indices of refraction  $n_1$  and  $n_2$ , where the boundary between the two media is a spherical surface of radius  $R$  (Fig. 36.17). We assume that the object at  $O$  is in the medium for which the index of refraction is  $n_1$ , where  $n_1 < n_2$ . Let us consider the paraxial rays leaving  $O$ . As we shall see, all such rays are refracted at the spherical surface and focus at a single point  $I$ , the image point.

Figure 36.18 shows a single ray leaving point  $O$  and focusing at point  $I$ . Snell's law of refraction applied to this refracted ray gives

$$n_1 \sin \theta_1 = n_2 \sin \theta_2$$

Because  $\theta_1$  and  $\theta_2$  are assumed to be small, we can use the small-angle approximation  $\sin \theta \approx \theta$  (angles in radians) and say that

$$n_1 \theta_1 = n_2 \theta_2$$

Now we use the fact that an exterior angle of any triangle equals the sum of the two opposite interior angles. Applying this rule to triangles  $OPC$  and  $PIC$  in Figure 36.18 gives

$$\theta_1 = \alpha + \beta$$

$$\beta = \theta_2 + \gamma$$

If we combine all three expressions and eliminate  $\theta_1$  and  $\theta_2$ , we find that

$$n_1 \alpha + n_2 \gamma = (n_2 - n_1) \beta \quad (36.7)$$

Looking at Figure 36.18, we see three right triangles that have a common vertical leg of length  $d$ . For paraxial rays (unlike the relatively large-angle ray shown in Fig.

**Figure 36.17** An image formed by refraction at a spherical surface. Rays making small angles with the principal axis diverge from a point object at  $O$  and are refracted through the image point  $I$ .

**Figure 36.18** Geometry used to derive Equation 36.8.

36.18), the horizontal legs of these triangles are approximately  $p$  for the triangle containing angle  $\alpha$ ,  $R$  for the triangle containing angle  $\beta$ , and  $q$  for the triangle containing angle  $\gamma$ . In the small-angle approximation,  $\tan \theta \approx \theta$ , so we can write the approximate relationships from these triangles as follows:

$$\tan \alpha \approx \alpha \approx \frac{d}{p} \quad \tan \beta \approx \beta \approx \frac{d}{R} \quad \tan \gamma \approx \gamma \approx \frac{d}{q}$$

We substitute these expressions into Equation 36.7 and divide through by  $d$  to get

$$\frac{n_1}{p} + \frac{n_2}{q} = \frac{n_2 - n_1}{R} \quad (36.8)$$

For a fixed object distance  $p$ , the image distance  $q$  is independent of the angle that the ray makes with the axis. This result tells us that all paraxial rays focus at the same point  $I$ .

As with mirrors, we must use a sign convention if we are to apply this equation to a variety of cases. We define the side of the surface in which light rays originate as the front side. The other side is called the back side. Real images are formed by refraction in back of the surface, in contrast with mirrors, where real images are formed in front of the reflecting surface. Because of the difference in location of real images, the refraction sign conventions for  $q$  and  $R$  are opposite the reflection sign conventions. For example,  $q$  and  $R$  are both positive in Figure 36.18. The sign conventions for spherical refracting surfaces are summarized in Table 36.2.

We derived Equation 36.8 from an assumption that  $n_1 < n_2$ . This assumption is not necessary, however. Equation 36.8 is valid regardless of which index of refraction is greater.

### TABLE 36.2 Sign Conventions for Refracting Surfaces

- $p$  is **positive** if object is in **front** of surface (real object).
- $p$  is **negative** if object is in **back** of surface (virtual object).
- $q$  is **positive** if image is in **back** of surface (real image).
- $q$  is **negative** if image is in **front** of surface (virtual image).
- $R$  is **positive** if center of curvature is in **back** of convex surface.
- $R$  is **negative** if center of curvature is in **front** of concave surface.

**Figure 36.19** The image formed by a flat refracting surface is virtual and on the same side of the surface as the object. All rays are assumed to be paraxial.

### Flat Refracting Surfaces

If a refracting surface is flat, then  $R$  is infinite and Equation 36.8 reduces to

$$\frac{n_1}{p} = -\frac{n_2}{q}$$

$$q = -\frac{n_2}{n_1} p \quad (36.9)$$

From this expression we see that the sign of  $q$  is opposite that of  $p$ . Thus, according to Table 36.2, **the image formed by a flat refracting surface is on the same side of the surface as the object.** This is illustrated in Figure 36.19 for the situation in which the object is in the medium of index  $n_1$  and  $n_1$  is greater than  $n_2$ . In this case, a virtual image is formed between the object and the surface. If  $n_1$  is less than  $n_2$ , the rays in the back side diverge from each other at lesser angles than those in Figure 36.19. As a result, the virtual image is formed to the left of the object.

### CONCEPTUAL EXAMPLE 36.6 Let's Go Scuba Diving!

It is well known that objects viewed under water with the naked eye appear blurred and out of focus. However, a scuba diver using a mask has a clear view of underwater objects. (a) Explain how this works, using the facts that the indices of refraction of the cornea, water, and air are 1.376, 1.333, and 1.000 29, respectively.

**Solution** Because the cornea and water have almost identical indices of refraction, very little refraction occurs when a person under water views objects with the naked eye. In this case, light rays from an object focus behind the retina, resulting in a blurred image. When a mask is used, the air space between the eye and the mask surface provides the normal

amount of refraction at the eye–air interface, and the light from the object is focused on the retina.

(b) If a lens prescription is ground into the glass of a mask, should the curved surface be on the inside of the mask, the outside, or both?

**Solution** If a lens prescription is ground into the glass of the mask so that the wearer can see without eyeglasses, only the inside surface is curved. In this way the prescription is accurate whether the mask is used under water or in air. If the curvature were on the outer surface, the refraction at the outer surface of the glass would change depending on whether air or water were present on the outside of the mask.

### EXAMPLE 36.7 Gaze into the Crystal Ball

A dandelion seed ball 4.0 cm in diameter is embedded in the center of a spherical plastic paperweight having a diameter of 6.0 cm (Fig. 36.20a). The index of refraction of the plastic is  $n_1 = 1.50$ . Find the position of the image of the near edge of the seed ball.

**Solution** Because  $n_1 > n_2$ , where  $n_2 = 1.00$  is the index of refraction for air, the rays originating from the seed ball are refracted away from the normal at the surface and diverge outward, as shown in Figure 36.20b. Hence, the image is formed inside the paperweight and is virtual. From the given dimensions, we know that the near edge of the seed ball is 1.0 cm beneath the surface of the paperweight. Applying Equation 36.8 and noting from Table 36.2 that  $R$  is negative, we obtain

$$\frac{n_1}{p} + \frac{n_2}{q} = \frac{n_2 - n_1}{R}$$

$$\frac{1.50}{1.0 \text{ cm}} + \frac{1}{q} = \frac{1.00 - 1.50}{-3.0 \text{ cm}}$$

$$q = -0.75 \text{ cm}$$

The negative sign for  $q$  indicates that the image is in front of the surface—in other words, in the same medium as the object, as shown in Figure 36.20b. Being in the same medium as the object, the image must be virtual (see Table 36.2). The surface of the seed ball appears to be closer to the paperweight surface than it actually is.

**Figure 36.20** (a) An object embedded in a plastic sphere forms a virtual image between the surface of the object and the sphere surface. All rays are assumed paraxial. Because the object is inside the sphere, the front of the refracting surface is the *interior* of the sphere. (b) Rays from the surface of the object form an image that is still inside the plastic sphere but closer to the plastic surface.

### EXAMPLE 36.8 The One That Got Away

A small fish is swimming at a depth  $d$  below the surface of a pond (Fig. 36.21). What is the apparent depth of the fish, as viewed from directly overhead?

**Solution** Because the refracting surface is flat,  $R$  is infinite. Hence, we can use Equation 36.9 to determine the location of the image with  $p = d$ . Using the indices of refraction given in Figure 36.21, we obtain

$$q = -\frac{n_2}{n_1} p = -\frac{1.00}{1.33} d = -0.752d$$

Because  $q$  is negative, the image is virtual, as indicated by the dashed lines in Figure 36.21. The apparent depth is three-fourths the actual depth.

**Figure 36.21** The apparent depth  $q$  of the fish is less than the true depth  $d$ . All rays are assumed to be paraxial.

### 36.4 THIN LENSES

 Lenses are commonly used to form images by refraction in optical instruments, such as cameras, telescopes, and microscopes. We can use what we just learned about images formed by refracting surfaces to help us locate the image formed by a lens. We recognize that light passing through a lens experiences refraction at two surfaces. The development we shall follow is based on the notion that **the image formed by one refracting surface serves as the object for the second surface**. We shall analyze a thick lens first and then let the thickness of the lens be approximately zero.

Consider a lens having an index of refraction  $n$  and two spherical surfaces with radii of curvature  $R_1$  and  $R_2$ , as in Figure 36.22. (Note that  $R_1$  is the radius of curvature of the lens surface that the light leaving the object reaches first and that  $R_2$  is the radius of curvature of the other surface of the lens.) An object is placed at point  $O$  at a distance  $p_1$  in front of surface 1. If the object were far from surface 1, the light rays from the object that struck the surface would be almost parallel to each other. The refraction at the surface would focus these rays, forming a real image to the right of surface 1 in Figure 36.22 (as in Fig. 36.17). If the object is placed close to surface 1, as shown in Figure 36.22, the rays diverging from the object and striking the surface cover a wide range of angles and are not parallel to each other. In this case, the refraction at the surface is not sufficient to cause the rays to converge on the right side of the surface. They still diverge, although they are closer to parallel than they were before they struck the surface. This results in a virtual image of the object at  $I_1$  to the left of the surface, as shown in Figure 36.22. This image is then used as the object for surface 2, which results in a real image  $I_2$  to the right of the lens.

Let us begin with the virtual image formed by surface 1. Using Equation 36.8 and assuming that  $n_1 = 1$  because the lens is surrounded by air, we find that the image  $I_1$  formed by surface 1 satisfies the equation

$$(1) \quad \frac{1}{p_1} + \frac{n}{q_1} = \frac{n-1}{R_1}$$

where  $q_1$  is a negative number because it represents a virtual image formed on the front side of surface 1.

Now we apply Equation 36.8 to surface 2, taking  $n_1 = n$  and  $n_2 = 1$ . (We make this switch in index because the light rays from  $I_1$  approaching surface 2 are *in the material of the lens*, and this material has index  $n$ . We could also imagine removing the object at  $O$ , filling all of the space to the left of surface 1 with the mate-

**Figure 36.22** To locate the image formed by a lens, we use the virtual image at  $I_1$  formed by surface 1 as the object for the image formed by surface 2. The final image is real and is located at  $I_2$ .

rial of the lens, and placing the object at  $I_1$ ; the light rays approaching surface 2 would be the same as in the actual situation in Fig. 36.22.) Taking  $p_2$  as the object distance for surface 2 and  $q_2$  as the image distance gives

$$(2) \quad \frac{n}{p_2} + \frac{1}{q_2} = \frac{1-n}{R_2}$$

We now introduce mathematically the fact that the image formed by the first surface acts as the object for the second surface. We do this by noting from Figure 36.22 that  $p_2$  is the sum of  $q_1$  and  $t$  and by setting  $p_2 = -q_1 + t$ , where  $t$  is the thickness of the lens. (Remember that  $q_1$  is a negative number and that  $p_2$  must be positive by our sign convention—thus, we must introduce a negative sign for  $q_1$ .) For a *thin* lens (for which the thickness is small compared to the radii of curvature), we can neglect  $t$ . In this approximation, we see that  $p_2 = -q_1$ . Hence, Equation (2) becomes

$$(3) \quad -\frac{n}{q_1} + \frac{1}{q_2} = \frac{1-n}{R_2}$$

Adding Equations (1) and (3), we find that

$$(4) \quad \frac{1}{p_1} + \frac{1}{q_2} = (n-1) \left( \frac{1}{R_1} - \frac{1}{R_2} \right)$$

For a thin lens, we can omit the subscripts on  $p_1$  and  $q_2$  in Equation (4) and call the object distance  $p$  and the image distance  $q$ , as in Figure 36.23. Hence, we can write Equation (4) in the form

$$\frac{1}{p} + \frac{1}{q} = (n-1) \left( \frac{1}{R_1} - \frac{1}{R_2} \right) \quad (36.10)$$

This expression relates the image distance  $q$  of the image formed by a thin lens to the object distance  $p$  and to the thin-lens properties (index of refraction and radii of curvature). It is valid only for paraxial rays and only when the lens thickness is much less than  $R_1$  and  $R_2$ .

The **focal length**  $f$  of a thin lens is the image distance that corresponds to an infinite object distance, just as with mirrors. Letting  $p$  approach  $\infty$  and  $q$  approach  $f$  in Equation 36.10, we see that the inverse of the focal length for a thin lens is

$$\frac{1}{f} = (n-1) \left( \frac{1}{R_1} - \frac{1}{R_2} \right) \quad (36.11)$$

This relationship is called the **lens makers' equation** because it can be used to determine the values of  $R_1$  and  $R_2$  that are needed for a given index of refraction and a desired focal length  $f$ . Conversely, if the index of refraction and the radii of curvature of a lens are given, this equation enables a calculation of the focal length. If the lens is immersed in something other than air, this same equation can be used, with  $n$  interpreted as the *ratio* of the index of refraction of the lens material to that of the surrounding fluid.

**Figure 36.23** Simplified geometry for a thin lens.

Lens makers' equation

### Quick Quiz 36.2

What is the focal length of a pane of window glass?

**Figure 36.24** (Left) Effects of a converging lens (top) and a diverging lens (bottom) on parallel rays. (Right) The object and image focal points of (a) a converging lens and (b) a diverging lens.

Using Equation 36.11, we can write Equation 36.10 in a form identical to Equation 36.6 for mirrors:

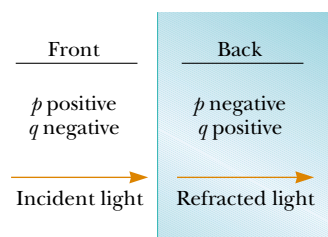

Thin-lens equation

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{f} \tag{36.12}$$

This equation, called the **thin-lens equation**, can be used to relate the image distance and object distance for a thin lens.

Because light can travel in either direction through a lens, each lens has two focal points, one for light rays passing through in one direction and one for rays passing through in the other direction. This is illustrated in Figure 36.24 for a biconvex lens (two convex surfaces, resulting in a converging lens) and a biconcave lens (two concave surfaces, resulting in a diverging lens). Focal point  $F_1$  is sometimes called the *object focal point*, and  $F_2$  is called the *image focal point*.

Figure 36.25 is useful for obtaining the signs of  $p$  and  $q$ , and Table 36.3 gives the sign conventions for thin lenses. Note that these sign conventions are the same as those for refracting surfaces (see Table 36.2). Applying these rules to a biconvex lens, we see that when  $p > f$ , the quantities  $p$ ,  $q$ , and  $R_1$  are positive, and  $R_2$  is negative. Therefore,  $p$ ,  $q$ , and  $f$  are all positive when a converging lens forms a real image of an object. For a biconcave lens,  $p$  and  $R_2$  are positive and  $q$  and  $R_1$  are negative, with the result that  $f$  is negative.

**Figure 36.25** A diagram for obtaining the signs of  $p$  and  $q$  for a thin lens. (This diagram also applies to a refracting surface.)

Various lens shapes are shown in Figure 36.26. Note that a converging lens is thicker at the center than at the edge, whereas a diverging lens is thinner at the center than at the edge.

**TABLE 36.3** Sign Conventions for Thin Lenses

$p$  is **positive** if object is in **front** of lens (real object).  
 $p$  is **negative** if object is in **back** of lens (virtual object).  
 $q$  is **positive** if image is in **back** of lens (real image).  
 $q$  is **negative** if image is in **front** of lens (virtual image).

$R_1$  and  $R_2$  are **positive** if center of curvature is in **back** of lens.  
 $R_1$  and  $R_2$  are **negative** if center of curvature is in **front** of lens.

$f$  is **positive** if the lens is **converging**.  
 $f$  is **negative** if the lens is **diverging**.

**Figure 36.26** Various lens shapes. (a) Biconvex, convex–concave, and plano–convex. These are all converging lenses; they have a positive focal length and are thickest at the middle. (b) Biconcave, convex–concave, and plano–concave. These are all diverging lenses; they have a negative focal length and are thickest at the edges.

## Magnification of Images

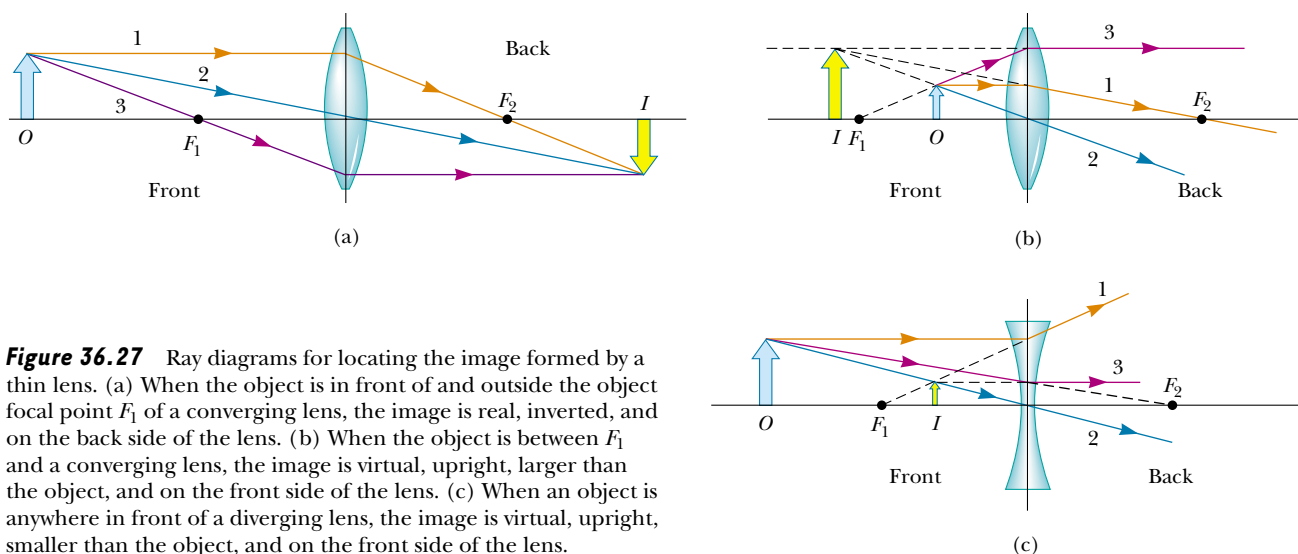

Consider a thin lens through which light rays from an object pass. As with mirrors (Eq. 36.2), the lateral magnification of the lens is defined as the ratio of the image height  $h'$  to the object height  $h$ :

$$M = \frac{h'}{h} = -\frac{q}{p}$$

From this expression, it follows that when  $M$  is positive, the image is upright and on the same side of the lens as the object. When  $M$  is negative, the image is inverted and on the side of the lens opposite the object.

## Ray Diagrams for Thin Lenses

Ray diagrams are convenient for locating the images formed by thin lenses or systems of lenses. They also help clarify our sign conventions. Figure 36.27 shows such diagrams for three single-lens situations. To locate the image of a converg-

**Figure 36.27** Ray diagrams for locating the image formed by a thin lens. (a) When the object is in front of and outside the object focal point  $F_1$  of a converging lens, the image is real, inverted, and on the back side of the lens. (b) When the object is between  $F_1$  and a converging lens, the image is virtual, upright, larger than the object, and on the front side of the lens. (c) When an object is anywhere in front of a diverging lens, the image is virtual, upright, smaller than the object, and on the front side of the lens.

ing lens (Fig. 36.27a and b), the following three rays are drawn from the top of the object:

- Ray 1 is drawn parallel to the principal axis. After being refracted by the lens, this ray passes through the focal point on the back side of the lens.
- Ray 2 is drawn through the center of the lens and continues in a straight line.
- Ray 3 is drawn through that focal point on the front side of the lens (or as if coming from the focal point if  $p < f$ ) and emerges from the lens parallel to the principal axis.

To locate the image of a diverging lens (Fig. 36.27c), the following three rays are drawn from the top of the object:

- Ray 1 is drawn parallel to the principal axis. After being refracted by the lens, this ray emerges such that it appears to have passed through the focal point on the front side of the lens. (This apparent direction is indicated by the dashed line in Fig. 36.27c.)
- Ray 2 is drawn through the center of the lens and continues in a straight line.
- Ray 3 is drawn toward the focal point on the back side of the lens and emerges from the lens parallel to the optic axis.

### Quick Quiz 36.3

In Figure 36.27a, the blue object arrow is replaced by one that is much taller than the lens. How many rays from the object will strike the lens?

For the converging lens in Figure 36.27a, where the object is to the left of the object focal point ( $p > f_1$ ), the image is real and inverted. When the object is between the object focal point and the lens ( $p < f_1$ ), as shown in Figure 36.27b, the image is virtual and upright. For a diverging lens (see Fig. 36.27c), the image is always virtual and upright, regardless of where the object is placed. These geometric constructions are reasonably accurate only if the distance between the rays and the principal axis is much less than the radii of the lens surfaces.

It is important to realize that refraction occurs only at the surfaces of the lens. A certain lens design takes advantage of this fact to produce the *Fresnel lens*, a powerful lens without great thickness. Because only the surface curvature is important in the refracting qualities of the lens, material in the middle of a Fresnel lens is removed, as shown in Figure 36.28. Because the edges of the curved segments cause some distortion, Fresnel lenses are usually used only in situations in which image quality is less important than reduction of weight.

The lines that are visible across the faces of most automobile headlights are the edges of these curved segments. A headlight requires a short-focal-length lens to collimate light from the nearby filament into a parallel beam. If it were not for the Fresnel design, the glass would be very thick in the center and quite heavy. The weight of the glass would probably cause the thin edge where the lens is supported to break when subjected to the shocks and vibrations that are typical of travel on rough roads.

**Figure 36.28** The Fresnel lens on the left has the same focal length as the thick lens on the right but is made of much less glass.

**Quick Quiz 36.4**

If you cover the top half of a lens, which of the following happens to the appearance of the image of an object? (a) The bottom half disappears; (b) the top half disappears; (c) the entire image is visible but has half the intensity; (d) no change occurs; (e) the entire image disappears.

**EXAMPLE 36.9** An Image Formed by a Diverging Lens

A diverging lens has a focal length of  $-20.0$  cm. An object  $2.00$  cm tall is placed  $30.0$  cm in front of the lens. Locate the image.

**Solution** Using the thin-lens equation (Eq. 36.12) with  $p = 30.0$  cm and  $f = -20.0$  cm, we obtain

$$\frac{1}{30.0 \text{ cm}} + \frac{1}{q} = \frac{1}{-20.0 \text{ cm}}$$

$$q = -12.0 \text{ cm}$$

The negative sign tells us that the image is in front of the lens and virtual, as indicated in Figure 36.27c.

**Exercise** Determine both the magnification and the height of the image.

**Answer**  $M = 0.400$ ;  $h' = 0.800$  cm.

**EXAMPLE 36.10** An Image Formed by a Converging Lens

A converging lens of focal length  $10.0$  cm forms an image of each of three objects placed (a)  $30.0$  cm, (b)  $10.0$  cm, and (c)  $5.00$  cm in front of the lens. In each case, find the image distance and describe the image.

**Solution** (a) The thin-lens equation can be used again:

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{f}$$

$$\frac{1}{30.0 \text{ cm}} + \frac{1}{q} = \frac{1}{10.0 \text{ cm}}$$

$$q = 15.0 \text{ cm}$$

The positive sign indicates that the image is in back of the lens and real. The magnification is

$$M = -\frac{q}{p} = -\frac{15.0 \text{ cm}}{30.0 \text{ cm}} = -0.500$$

The image is reduced in size by one half, and the negative

sign for  $M$  means that the image is inverted. The situation is like that pictured in Figure 36.27a.

(b) No calculation is necessary for this case because we know that, when the object is placed at the focal point, the image is formed at infinity. We can readily verify this by substituting  $p = 10.0$  cm into the thin-lens equation.

(c) We now move inside the focal point, to an object distance of  $5.00$  cm:

$$\frac{1}{5.00 \text{ cm}} + \frac{1}{q} = \frac{1}{10.0 \text{ cm}}$$

$$q = -10.0 \text{ cm}$$

$$M = -\frac{q}{p} = -\left(\frac{-10.0 \text{ cm}}{5.00 \text{ cm}}\right) = 2.00$$

The negative image distance indicates that the image is in front of the lens and virtual. The image is enlarged, and the positive sign for  $M$  tells us that the image is upright, as shown in Figure 36.27b.

**EXAMPLE 36.11** A Lens Under Water

A converging glass lens ( $n = 1.52$ ) has a focal length of  $40.0$  cm in air. Find its focal length when it is immersed in water, which has an index of refraction of  $1.33$ .

**Solution** We can use the lens makers' equation (Eq. 36.11) in both cases, noting that  $R_1$  and  $R_2$  remain the same in air and water:

$$\frac{1}{f_{\text{air}}} = (n - 1) \left( \frac{1}{R_1} - \frac{1}{R_2} \right)$$

$$\frac{1}{f_{\text{water}}} = (n' - 1) \left( \frac{1}{R_1} - \frac{1}{R_2} \right)$$

where  $n'$  is the ratio of the index of refraction of glass to that of water:  $n' = 1.52/1.33 = 1.14$ . Dividing the first equation by the second gives

$$\frac{f_{\text{water}}}{f_{\text{air}}} = \frac{n - 1}{n' - 1} = \frac{1.52 - 1}{1.14 - 1} = 3.71$$

Because  $f_{\text{air}} = 40.0$  cm, we find that

$$f_{\text{water}} = 3.71 f_{\text{air}} = 3.71(40.0 \text{ cm}) = 148 \text{ cm}$$

The focal length of any glass lens is increased by a factor  $(n - 1)/(n' - 1)$  when the lens is immersed in water.

### Combination of Thin Lenses

If two thin lenses are used to form an image, the system can be treated in the following manner. First, the image formed by the first lens is located as if the second lens were not present. Then a ray diagram is drawn for the second lens, with the image formed by the first lens now serving as the object for the second lens. The second image formed is the final image of the system. One configuration is particularly straightforward; that is, if the image formed by the first lens lies on the back side of the second lens, then that image is treated as a **virtual object** for the second lens (that is,  $p$  is negative). The same procedure can be extended to a system of three or more lenses. The overall magnification of a system of thin lenses equals the product of the magnifications of the separate lenses.

Let us consider the special case of a system of two lenses in contact. Suppose two thin lenses of focal lengths  $f_1$  and  $f_2$  are placed in contact with each other. If  $p$  is the object distance for the combination, application of the thin-lens equation (Eq. 36.12) to the first lens gives

$$\frac{1}{p} + \frac{1}{q_1} = \frac{1}{f_1}$$

where  $q_1$  is the image distance for the first lens. Treating this image as the object for the second lens, we see that the object distance for the second lens must be  $-q_1$  (negative because the object is virtual). Therefore, for the second lens,

$$\frac{1}{-q_1} + \frac{1}{q} = \frac{1}{f_2}$$

where  $q$  is the final image distance from the second lens. Adding these equations eliminates  $q_1$  and gives

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{f_1} + \frac{1}{f_2}$$

$$\frac{1}{f} = \frac{1}{f_1} + \frac{1}{f_2} \quad (36.13)$$

Because the two thin lenses are touching,  $q$  is also the distance of the final image from the first lens. Therefore, **two thin lenses in contact with each other are equivalent to a single thin lens having a focal length given by Equation 36.13.**

Light from a distant object brought into focus by two converging lenses.

Focal length of two thin lenses in contact

**EXAMPLE 36.12** Where Is the Final Image?

Even when the conditions just described do not apply, the lens equations yield image position and magnification. For example, two thin converging lenses of focal lengths  $f_1 = 10.0$  cm and  $f_2 = 20.0$  cm are separated by 20.0 cm, as illustrated in Figure 36.29. An object is placed 15.0 cm to the left of lens 1. Find the position of the final image and the magnification of the system.

**Solution** First we locate the image formed by lens 1 while ignoring lens 2:

$$\frac{1}{p_1} + \frac{1}{q_1} = \frac{1}{f_1}$$

$$\frac{1}{15.0 \text{ cm}} + \frac{1}{q_1} = \frac{1}{10.0 \text{ cm}}$$

$$q_1 = 30.0 \text{ cm}$$

where  $q_1$  is measured from lens 1. A positive value for  $q_1$  means that this first image is in back of lens 1.

Because  $q_1$  is greater than the separation between the two lenses, this image formed by lens 1 lies 10.0 cm to the right of lens 2. We take this as the object distance for the second lens, so  $p_2 = -10.0$  cm, where distances are now measured from lens 2:

$$\frac{1}{p_2} + \frac{1}{q_2} = \frac{1}{f_2}$$

$$\frac{1}{-10.0 \text{ cm}} + \frac{1}{q_2} = \frac{1}{20.0 \text{ cm}}$$

$$q_2 = 6.67 \text{ cm}$$

The final image lies 6.67 cm to the right of lens 2.

The individual magnifications of the images are

$$M_1 = -\frac{q_1}{p_1} = -\frac{30.0 \text{ cm}}{15.0 \text{ cm}} = -2.00$$

$$M_2 = -\frac{q_2}{p_2} = -\frac{6.67 \text{ cm}}{-10.0 \text{ cm}} = 0.667$$

The total magnification  $M$  is equal to the product  $M_1 M_2 = (-2.00)(0.667) = -1.33$ . The final image is real because  $q_2$  is positive. The image is also inverted and enlarged.

**Figure 36.29** A combination of two converging lenses.

**CONCEPTUAL EXAMPLE 36.13** Watch Your  $p$ 's and  $q$ 's!

Use a spreadsheet or a similar tool to create two graphs of image distance as a function of object distance—one for a lens for which the focal length is 10 cm and one for a lens for which the focal length is  $-10$  cm.

**Solution** The graphs are shown in Figure 36.30. In each graph a gap occurs where  $p = f$ , which we shall discuss. Note the similarity in the shapes—a result of the fact that image and object distances for both lenses are related according to the same equation—the thin-lens equation.

The curve in the upper right portion of the  $f = +10$  cm graph corresponds to an object on the *front* side of a lens, which we have drawn as the left side of the lens in our previous diagrams. When the object is at positive infinity, a real image forms at the focal point on the back side (the positive side) of the lens,  $q = f$ . (The incoming rays are parallel in this case.) As the object gets closer to the lens, the image moves farther from the lens, corresponding to the upward path of the curve. This continues until the object is located at the focal point on the

near side of the lens. At this point, the rays leaving the lens are parallel, making the image infinitely far away. This is described in the graph by the asymptotic approach of the curve to the line  $p = f = 10$  cm.

As the object moves inside the focal point, the image becomes virtual and located near  $q = -\infty$ . We are now following the curve in the lower left portion of Figure 36.30a. As the object moves closer to the lens, the virtual image also moves closer to the lens. As  $p \rightarrow 0$ , the image distance  $q$  also approaches 0. Now imagine that we bring the object to the back side of the lens, where  $p < 0$ . The object is now a virtual object, so it must have been formed by some other lens. For all locations of the virtual object, the image distance is positive and less than the focal length. The final image is real, and its position approaches the focal point as  $p$  gets more and more negative.

The  $f = -10$  cm graph shows that a distant real object forms an image at the focal point on the front side of the lens. As the object approaches the lens, the image remains

virtual and moves closer to the lens. But as we continue toward the left end of the  $p$  axis, the object becomes virtual. As the position of this virtual object approaches the focal point, the image recedes toward infinity. As we pass the focal point,

the image shifts from a location at positive infinity to one at negative infinity. Finally, as the virtual object continues moving away from the lens, the image is virtual, starts moving in from negative infinity, and approaches the focal point.

**Figure 36.30** (a) Image position as a function of object position for a lens having a focal length of  $+10$  cm. (b) Image position as a function of object position for a lens having a focal length of  $-10$  cm.

## 36.5 LENS ABERRATIONS

One problem with lenses is imperfect images. The theory of mirrors and lenses that we have been using assumes that rays make small angles with the principal axis and that the lenses are thin. In this simple model, all rays leaving a point source focus at a single point, producing a sharp image. Clearly, this is not always true. When the approximations used in this theory do not hold, imperfect images are formed.

A precise analysis of image formation requires tracing each ray, using Snell's law at each refracting surface and the law of reflection at each reflecting surface. This procedure shows that the rays from a point object do not focus at a single point, with the result that the image is blurred. The departures of actual (imperfect) images from the ideal predicted by theory are called **aberrations**.

**Figure 36.31** Spherical aberration caused by a converging lens. Does a diverging lens cause spherical aberration?

### Spherical Aberrations

Spherical aberrations occur because the focal points of rays far from the principal axis of a spherical lens (or mirror) are different from the focal points of rays of the same wavelength passing near the axis. Figure 36.31 illustrates spherical aberration for parallel rays passing through a converging lens. Rays passing through points near the center of the lens are imaged farther from the lens than rays passing through points near the edges.

Many cameras have an adjustable aperture to control light intensity and reduce spherical aberration. (An aperture is an opening that controls the amount of light passing through the lens.) Sharper images are produced as the aperture size is reduced because with a small aperture only the central portion of the lens is exposed to the light; as a result, a greater percentage of the rays are paraxial. At the

Lens aberrations. (a) *Spherical aberration* occurs when light passing through the lens at different distances from the principal axis is focused at different points. (b) *Astigmatism* occurs for objects not located on the principal axis of the lens. (c) *Coma* occurs as light passing through the lens far from the principal axis and light passing near the center of the lens focus at different parts of the focal plane.

same time, however, less light passes through the lens. To compensate for this lower light intensity, a longer exposure time is used.

In the case of mirrors used for very distant objects, spherical aberration can be minimized through the use of a parabolic reflecting surface rather than a spherical surface. Parabolic surfaces are not used often, however, because those with high-quality optics are very expensive to make. Parallel light rays incident on a parabolic surface focus at a common point, regardless of their distance from the principal axis. Parabolic reflecting surfaces are used in many astronomical telescopes to enhance image quality.

## Chromatic Aberrations

The fact that different wavelengths of light refracted by a lens focus at different points gives rise to chromatic aberrations. In Chapter 35 we described how the index of refraction of a material varies with wavelength. For instance, when white light passes through a lens, violet rays are refracted more than red rays (Fig. 36.32). From this we see that the focal length is greater for red light than for violet light. Other wavelengths (not shown in Fig. 36.32) have focal points intermediate between those of red and violet.

Chromatic aberration for a diverging lens also results in a shorter focal length for violet light than for red light, but on the front side of the lens. Chromatic aberration can be greatly reduced by combining a converging lens made of one type of glass and a diverging lens made of another type of glass.

**Figure 36.32** Chromatic aberration caused by a converging lens. Rays of different wavelengths focus at different points.

## 36.6 THE CAMERA

The photographic **camera** is a simple optical instrument whose essential features are shown in Figure 36.33. It consists of a light-tight box, a converging lens that produces a real image, and a film behind the lens to receive the image. One focuses the camera by varying the distance between lens and film. This is accom-

**Figure 36.33** Cross-sectional view of a simple camera. Note that in reality,  $p \gg q$ .

plished with an adjustable bellows in older-style cameras and with some other mechanical arrangement in modern cameras. For proper focusing—which is necessary for the formation of sharp images—the lens-to-film distance depends on the object distance as well as on the focal length of the lens.

The shutter, positioned behind the lens, is a mechanical device that is opened for selected time intervals, called *exposure times*. One can photograph moving objects by using short exposure times, or photograph dark scenes (with low light levels) by using long exposure times. If this adjustment were not available, it would be impossible to take stop-action photographs. For example, a rapidly moving vehicle could move enough in the time that the shutter was open to produce a blurred image. Another major cause of blurred images is the movement of the camera while the shutter is open. To prevent such movement, either short exposure times or a tripod should be used, even for stationary objects. Typical shutter speeds (that is, exposure times) are 1/30, 1/60, 1/125, and 1/250 s. For handheld cameras, the use of slower speeds can result in blurred images (due to movement), but the use of faster speeds reduces the gathered light intensity. In practice, stationary objects are normally shot with an intermediate shutter speed of 1/60 s.

More expensive cameras have an aperture of adjustable diameter to further control the intensity of the light reaching the film. As noted earlier, when an aperture of small diameter is used, only light from the central portion of the lens reaches the film; in this way spherical aberration is reduced.

The intensity  $I$  of the light reaching the film is proportional to the area of the lens. Because this area is proportional to the square of the diameter  $D$ , we conclude that  $I$  is also proportional to  $D^2$ . Light intensity is a measure of the rate at which energy is received by the film per unit area of the image. Because the area of the image is proportional to  $q^2$ , and  $q \approx f$  (when  $p \gg f$ , so  $p$  can be approximated as infinite), we conclude that the intensity is also proportional to  $1/f^2$ , and thus  $I \propto D^2/f^2$ . The brightness of the image formed on the film depends on the light intensity, so we see that the image brightness depends on both the focal length and the diameter of the lens.

The ratio  $f/D$  is called the ***f*-number** of a lens:

$$f\text{-number} \equiv \frac{f}{D} \quad (36.14)$$

Hence, the intensity of light incident on the film can be expressed as

$$I \propto \frac{1}{(f/D)^2} \propto \frac{1}{(f\text{-number})^2} \quad (36.15)$$

The *f*-number is often given as a description of the lens “speed.” The lower the *f*-number, the wider the aperture and the higher the rate at which energy from the light exposes the film—thus, a lens with a low *f*-number is a “fast” lens. The conventional notation for an *f*-number is “*f*/” followed by the actual number. For example, “*f*/4” means an *f*-number of 4—it *does not* mean to divide *f* by 4! Extremely fast lenses, which have *f*-numbers as low as approximately *f*/1.2, are expensive because it is very difficult to keep aberrations acceptably small with light rays passing through a large area of the lens. Camera lens systems (that is, combinations of lenses with adjustable apertures) are often marked with multiple *f*-numbers, usually *f*/2.8, *f*/4, *f*/5.6, *f*/8, *f*/11, and *f*/16. Any one of these settings can be selected by adjusting the aperture, which changes the value of *D*. Increasing the setting from one *f*-number to the next higher value (for example, from *f*/2.8 to *f*/4) decreases the area of the aperture by a factor of two. The lowest *f*-number set-

ting on a camera lens corresponds to a wide-open aperture and the use of the maximum possible lens area.

Simple cameras usually have a fixed focal length and a fixed aperture size, with an  $f$ -number of about  $f/11$ . This high value for the  $f$ -number allows for a large **depth of field**, meaning that objects at a wide range of distances from the lens form reasonably sharp images on the film. In other words, the camera does not have to be focused.

### EXAMPLE 36.14 Finding the Correct Exposure Time

The lens of a certain 35-mm camera (where 35 mm is the width of the film strip) has a focal length of 55 mm and a speed (an  $f$ -number) of  $f/1.8$ . The correct exposure time for this speed under certain conditions is known to be  $(1/500)$  s. (a) Determine the diameter of the lens.

**Solution** From Equation 36.14, we find that

$$D = \frac{f}{f\text{-number}} = \frac{55 \text{ mm}}{1.8} = 31 \text{ mm}$$

(b) Calculate the correct exposure time if the  $f$ -number is changed to  $f/4$  under the same lighting conditions.

**Solution** The total light energy hitting the film is proportional to the product of the intensity and the exposure time. If  $I$  is the light intensity reaching the film, then in a time  $t$

the energy per unit area received by the film is proportional to  $It$ . Comparing the two situations, we require that  $I_1 t_1 = I_2 t_2$ , where  $t_1$  is the correct exposure time for  $f/1.8$  and  $t_2$  is the correct exposure time for  $f/4$ . Using this result together with Equation 36.15, we find that

$$\begin{aligned} \frac{t_1}{(f_1\text{-number})^2} &= \frac{t_2}{(f_2\text{-number})^2} \\ t_2 &= \left( \frac{f_2\text{-number}}{f_1\text{-number}} \right)^2 t_1 \\ &= \left( \frac{4}{1.8} \right)^2 \left( \frac{1}{500} \text{ s} \right) \approx \frac{1}{100} \text{ s} \end{aligned}$$

As the aperture size is reduced, exposure time must increase.

### Optional Section

## 36.7 THE EYE

Like a camera, a normal eye focuses light and produces a sharp image. However, the mechanisms by which the eye controls the amount of light admitted and adjusts to produce correctly focused images are far more complex, intricate, and effective than those in even the most sophisticated camera. In all respects, the eye is a physiological wonder.

Figure 36.34 shows the essential parts of the human eye. Light entering the eye passes through a transparent structure called the *cornea*, behind which are a clear liquid (the *aqueous humor*), a variable aperture (the *pupil*, which is an opening in the *iris*), and the *crystalline lens*. Most of the refraction occurs at the outer surface of the eye, where the cornea is covered with a film of tears. Relatively little refraction occurs in the crystalline lens because the aqueous humor in contact with the lens has an average index of refraction close to that of the lens. The iris, which is the colored portion of the eye, is a muscular diaphragm that controls pupil size. The iris regulates the amount of light entering the eye by dilating the pupil in low-light conditions and contracting the pupil in high-light conditions. The  $f$ -number range of the eye is from about  $f/2.8$  to  $f/16$ .

The cornea–lens system focuses light onto the back surface of the eye, the *retina*, which consists of millions of sensitive receptors called *rods* and *cones*. When stimulated by light, these receptors send impulses via the optic nerve to the brain,

Close-up photograph of the cornea of the human eye.

**Figure 36.34** Essential parts of the eye.

where an image is perceived. By this process, a distinct image of an object is observed when the image falls on the retina.

The eye focuses on an object by varying the shape of the pliable crystalline lens through an amazing process called **accommodation**. An important component of accommodation is the *ciliary muscle*, which is situated in a circle around the rim of the lens. Thin filaments, called *zonules*, run from this muscle to the edge of the lens. When the eye is focused on a distant object, the ciliary muscle is relaxed, tightening the zonules that attach the muscle to the edge of the lens. The force of the zonules causes the lens to flatten, increasing its focal length. For an object distance of infinity, the focal length of the eye is equal to the fixed distance between lens and retina, about 1.7 cm. The eye focuses on nearby objects by tensing the ciliary muscle, which relaxes the zonules. This action allows the lens to bulge a bit, and its focal length decreases, resulting in the image being focused on the retina. All these lens adjustments take place so swiftly that we are not even aware of the change. In this respect, even the finest electronic camera is a toy compared with the eye.

Accommodation is limited in that objects that are very close to the eye produce blurred images. The **near point** is the closest distance for which the lens can accommodate to focus light on the retina. This distance usually increases with age and has an average value of 25 cm. Typically, at age 10 the near point of the eye is about 18 cm. It increases to about 25 cm at age 20, to 50 cm at age 40, and to 500 cm or greater at age 60. The **far point** of the eye represents the greatest distance for which the lens of the relaxed eye can focus light on the retina. A person with normal vision can see very distant objects, such as the Moon, and thus has a far point near infinity.

Recall that the light leaving the mirror in Figure 36.8 becomes white where it comes together but then diverges into separate colors again. Because nothing but air exists at the point where the rays cross (and hence nothing exists to cause the colors to separate again), seeing white light as a result of a combination of colors must be a visual illusion. In fact, this is the case. Only three types of color-sensitive

### QuickLab

Move this book toward your face until the letters just begin to blur. The distance from the book to your eyes is your near point.

**Figure 36.35** Approximate color sensitivity of the three types of cones in the retina.

cells are present in the retina; they are called red, green, and blue cones because of the peaks of the color ranges to which they respond (Fig. 36.35). If the red and green cones are stimulated simultaneously (as would be the case if yellow light were shining on them), the brain interprets what we see as yellow. If all three types of cones are stimulated by the separate colors red, blue, and green, as in Figure 36.8, we see white. If all three types of cones are stimulated by light that contains *all* colors, such as sunlight, we again see white light.

Color televisions take advantage of this visual illusion by having only red, green, and blue dots on the screen. With specific combinations of brightness in these three primary colors, our eyes can be made to see any color in the rainbow. Thus, the yellow lemon you see in a television commercial is not really yellow, it is red and green! The paper on which this page is printed is made of tiny, matted, translucent fibers that scatter light in all directions; the resultant mixture of colors appears white to the eye. Snow, clouds, and white hair are not really white. In fact, there is no such thing as a white pigment. The appearance of these things is a consequence of the scattering of light containing all colors, which we interpret as white.

### Conditions of the Eye

When the eye suffers a mismatch between the focusing range of the lens–cornea system and the length of the eye, with the result that light rays reach the retina before they converge to form an image, as shown in Figure 36.36a, the condition is known as **farsightedness** (or *hyperopia*). A farsighted person can usually see faraway objects clearly but not nearby objects. Although the near point of a normal eye is approximately 25 cm, the near point of a farsighted person is much farther away. The eye of a farsighted person tries to focus by accommodation—that is, by shortening its focal length. This works for distant objects, but because the focal length of the farsighted eye is greater than normal, the light from nearby objects cannot be brought to a sharp focus before it reaches the retina, and it thus causes a blurred image. The refracting power in the cornea and lens is insufficient to focus the light from all but distant objects satisfactorily. The condition can be corrected by placing a converging lens in front of the eye, as shown in Figure 36.36b. The lens refracts the incoming rays more toward the principal axis before entering the eye, allowing them to converge and focus on the retina.

A person with **nearsightedness** (or *myopia*), another mismatch condition, can focus on nearby objects but not on faraway objects. In the case of *axial myopia*, the nearsightedness is caused by the lens being too far from the retina. In *refractive my-*

### QuickLab

Pour a pile of salt or sugar into your palm. Compare its white appearance with the transparency of a single grain.

**Figure 36.36** (a) When a farsighted eye looks at an object located between the near point and the eye, the image point is behind the retina, resulting in blurred vision. The eye muscle contracts to try to bring the object into focus. (b) Farsightedness is corrected with a converging lens.

**Figure 36.37** (a) When a nearsighted eye looks at an object that lies beyond the eye's far point, the image is formed in front of the retina, resulting in blurred vision. (b) Nearsightedness is corrected with a diverging lens.

*opia*, the lens–cornea system is too powerful for the length of the eye. The far point of the nearsighted eye is not infinity and may be less than 1 m. The maximum focal length of the nearsighted eye is insufficient to produce a sharp image on the retina, and rays from a distant object converge to a focus in front of the retina. They then continue past that point, diverging before they finally reach the retina and causing blurred vision (Fig. 36.37a). Nearsightedness can be corrected with a diverging lens, as shown in Figure 36.37b. The lens refracts the rays away from the principal axis before they enter the eye, allowing them to focus on the retina.

### Quick Quiz 36.5

Which glasses in Figure 36.38 correct nearsightedness and which correct farsightedness?

**Figure 36.38**

Beginning in middle age, most people lose some of their accommodation ability as the ciliary muscle weakens and the lens hardens. Unlike farsightedness, which is a mismatch between focusing power and eye length, **presbyopia** (literally, “old-age vision”) is due to a reduction in accommodation ability. The cornea and lens do not have sufficient focusing power to bring nearby objects into focus on the retina. The symptoms are the same as those of farsightedness, and the condition can be corrected with converging lenses.

In the eye defect known as **astigmatism**, light from a point source produces a line image on the retina. This condition arises when either the cornea or the lens or both are not perfectly symmetric. Astigmatism can be corrected with lenses that have different curvatures in two mutually perpendicular directions.

Optometrists and ophthalmologists usually prescribe lenses<sup>1</sup> measured in **diopters**:

The **power**  $P$  of a lens in diopters equals the inverse of the focal length in meters:  $P = 1/f$ .

For example, a converging lens of focal length  $+20$  cm has a power of  $+5.0$  diopters, and a diverging lens of focal length  $-40$  cm has a power of  $-2.5$  diopters.

### EXAMPLE 36.15 A Case of Nearsightedness

A particular nearsighted person is unable to see objects clearly when they are beyond 2.5 m away (the far point of this particular eye). What should the focal length be in a lens prescribed to correct this problem?

**Solution** The purpose of the lens in this instance is to “move” an object from infinity to a distance where it can be seen clearly. This is accomplished by having the lens produce an image at the far point. From the thin-lens equation, we have

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{\infty} + \frac{1}{-2.5 \text{ m}} = \frac{1}{f}$$

$$f = -2.5 \text{ m}$$

Why did we use a negative sign for the image distance? As you should have suspected, the lens must be a diverging lens (one with a negative focal length) to correct nearsightedness.

**Exercise** What is the power of this lens?

**Answer**  $-0.40$  diopter.

### Optional Section

## 36.8 THE SIMPLE MAGNIFIER

The simple magnifier consists of a single converging lens. As the name implies, this device increases the apparent size of an object.

Suppose an object is viewed at some distance  $p$  from the eye, as illustrated in Figure 36.39. The size of the image formed at the retina depends on the angle  $\theta$  subtended by the object at the eye. As the object moves closer to the eye,  $\theta$  increases and a larger image is observed. However, an average normal eye cannot focus on an object closer than about 25 cm, the near point (Fig. 36.40a). Therefore,  $\theta$  is maximum at the near point.

To further increase the apparent angular size of an object, a converging lens can be placed in front of the eye as in Figure 36.40b, with the object located at point  $O$ , just inside the focal point of the lens. At this location, the lens forms a virtual, upright, enlarged image. We define **angular magnification**  $m$  as the ratio of the angle subtended by an object with a lens in use (angle  $\theta$  in Fig. 36.40b) to the angle subtended by the object placed at the near point with no lens in use (angle

**Figure 36.39** The size of the image formed on the retina depends on the angle  $\theta$  subtended at the eye.

<sup>1</sup> The word *lens* comes from *lentil*, the name of an Italian legume. (You may have eaten lentil soup.) Early eyeglasses were called “glass lentils” because the biconvex shape of their lenses resembled the shape of a lentil. The first lenses for farsightedness and presbyopia appeared around 1280; concave eyeglasses for correcting nearsightedness did not appear for more than 100 years after that.

**Figure 36.40** (a) An object placed at the near point of the eye ( $p = 25$  cm) subtends an angle  $\theta_0 \approx h/25$  at the eye. (b) An object placed near the focal point of a converging lens produces a magnified image that subtends an angle  $\theta \approx h'/25$  at the eye.

$\theta_0$  in Fig. 36.40a):

$$m \equiv \frac{\theta}{\theta_0} \quad (36.16)$$

Angular magnification with the object at the near point

The angular magnification is a maximum when the image is at the near point of the eye—that is, when  $q = -25$  cm. The object distance corresponding to this image distance can be calculated from the thin-lens equation:

$$\frac{1}{p} + \frac{1}{-25 \text{ cm}} = \frac{1}{f}$$

$$p = \frac{25f}{25 + f}$$

where  $f$  is the focal length of the magnifier in centimeters. If we make the small-angle approximations

$$\tan \theta_0 \approx \theta_0 \approx \frac{h}{25} \quad \text{and} \quad \tan \theta \approx \theta \approx \frac{h}{p} \quad (36.17)$$

Equation 36.16 becomes

$$m_{\max} = \frac{\theta}{\theta_0} = \frac{h/p}{h/25} = \frac{25}{p} = \frac{25}{25f/(25 + f)}$$

$$m_{\max} = 1 + \frac{25 \text{ cm}}{f} \quad (36.18)$$

Although the eye can focus on an image formed anywhere between the near point and infinity, it is most relaxed when the image is at infinity. For the image formed by the magnifying lens to appear at infinity, the object has to be at the focal point of the lens. In this case, Equations 36.17 become

$$\theta_0 \approx \frac{h}{25} \quad \text{and} \quad \theta \approx \frac{h}{f}$$

and the magnification is

$$m_{\min} = \frac{\theta}{\theta_0} = \frac{25 \text{ cm}}{f} \quad (36.19)$$

With a single lens, it is possible to obtain angular magnifications up to about 4 without serious aberrations. Magnifications up to about 20 can be achieved by using one or two additional lenses to correct for aberrations.

### EXAMPLE 36.16 Maximum Magnification of a Lens

What is the maximum magnification that is possible with a lens having a focal length of 10 cm, and what is the magnification of this lens when the eye is relaxed?

**Solution** The maximum magnification occurs when the image is located at the near point of the eye. Under these circumstances, Equation 36.18 gives

$$m_{\max} = 1 + \frac{25 \text{ cm}}{f} = 1 + \frac{25 \text{ cm}}{10 \text{ cm}} = 3.5$$

When the eye is relaxed, the image is at infinity. In this case, we use Equation 36.19:

$$m_{\min} = \frac{25 \text{ cm}}{f} = \frac{25 \text{ cm}}{10 \text{ cm}} = 2.5$$

### Optional Section

## 36.9 THE COMPOUND MICROSCOPE

A simple magnifier provides only limited assistance in inspecting minute details of an object. Greater magnification can be achieved by combining two lenses in a device called a **compound microscope**, a schematic diagram of which is shown in Figure 36.41a. It consists of one lens, the *objective*, that has a very short focal length

**Figure 36.41** (a) Diagram of a compound microscope, which consists of an objective lens and an eyepiece lens. (b) A compound microscope. The three-objective turret allows the user to choose from several powers of magnification. Combinations of eyepieces with different focal lengths and different objectives can produce a wide range of magnifications.

$f_o < 1$  cm and a second lens, the *eyepiece*, that has a focal length  $f_e$  of a few centimeters. The two lenses are separated by a distance  $L$  that is much greater than either  $f_o$  or  $f_e$ . The object, which is placed just outside the focal point of the objective, forms a real, inverted image at  $I_1$ , and this image is located at or close to the focal point of the eyepiece. The eyepiece, which serves as a simple magnifier, produces at  $I_2$  a virtual, inverted image of  $I_1$ . The lateral magnification  $M_1$  of the first image is  $-q_1/p_1$ . Note from Figure 36.41a that  $q_1$  is approximately equal to  $L$  and that the object is very close to the focal point of the objective:  $p_1 \approx f_o$ . Thus, the lateral magnification by the objective is

$$M_1 \approx -\frac{L}{f_o}$$

The angular magnification by the eyepiece for an object (corresponding to the image at  $I_1$ ) placed at the focal point of the eyepiece is, from Equation 36.19,

$$m_e = \frac{25 \text{ cm}}{f_e}$$

The overall magnification of the compound microscope is defined as the product of the lateral and angular magnifications:

$$M = M_1 m_e = -\frac{L}{f_o} \left( \frac{25 \text{ cm}}{f_e} \right) \quad (36.20)$$

The negative sign indicates that the image is inverted.

The microscope has extended human vision to the point where we can view previously unknown details of incredibly small objects. The capabilities of this instrument have steadily increased with improved techniques for precision grinding of lenses. An often-asked question about microscopes is: “If one were extremely patient and careful, would it be possible to construct a microscope that would enable the human eye to see an atom?” The answer is no, as long as light is used to illuminate the object. The reason is that, for an object under an optical microscope (one that uses visible light) to be seen, the object must be at least as large as a wavelength of light. Because the diameter of any atom is many times smaller than the wavelengths of visible light, the mysteries of the atom must be probed using other types of “microscopes.”

The ability to use other types of waves to “see” objects also depends on wavelength. We can illustrate this with water waves in a bathtub. Suppose you vibrate your hand in the water until waves having a wavelength of about 15 cm are moving along the surface. If you hold a small object, such as a toothpick, so that it lies in the path of the waves, it does not appreciably disturb the waves; they continue along their path “oblivious” to it. Now suppose you hold a larger object, such as a toy sailboat, in the path of the 15-cm waves. In this case, the waves are considerably disturbed by the object. Because the toothpick was smaller than the wavelength of the waves, the waves did not “see” it (the intensity of the scattered waves was low). Because it is about the same size as the wavelength of the waves, however, the boat creates a disturbance. In other words, the object acts as the source of scattered waves that appear to come from it.

Light waves behave in this same general way. The ability of an optical microscope to view an object depends on the size of the object relative to the wavelength of the light used to observe it. Hence, we can never observe atoms with an optical

microscope<sup>2</sup> because their dimensions are small ( $\approx 0.1$  nm) relative to the wavelength of the light ( $\approx 500$  nm).

### Optional Section

## 36.10 THE TELESCOPE

 Two fundamentally different types of **telescopes** exist; both are designed to aid in viewing distant objects, such as the planets in our Solar System. The **refracting telescope** uses a combination of lenses to form an image, and the **reflecting telescope** uses a curved mirror and a lens.

The lens combination shown in Figure 36.42a is that of a refracting telescope. Like the compound microscope, this telescope has an objective and an eyepiece. The two lenses are arranged so that the objective forms a real, inverted image of the distant object very near the focal point of the eyepiece. Because the object is essentially at infinity, this point at which  $I_1$  forms is the focal point of the objective. Hence, the two lenses are separated by a distance  $f_o + f_e$ , which corresponds to the length of the telescope tube. The eyepiece then forms, at  $I_2$ , an enlarged, inverted image of the image at  $I_1$ .

The angular magnification of the telescope is given by  $\theta/\theta_o$ , where  $\theta_o$  is the angle subtended by the object at the objective and  $\theta$  is the angle subtended by the final image at the viewer's eye. Consider Figure 36.42a, in which the object is a very great distance to the left of the figure. The angle  $\theta_o$  (to the *left* of the objective) subtended by the object at the objective is the same as the angle (to the *right* of the objective) subtended by the first image at the objective. Thus,

$$\tan \theta_o \approx \theta_o \approx -\frac{h'}{f_o}$$

where the negative sign indicates that the image is inverted.

The angle  $\theta$  subtended by the final image at the eye is the same as the angle that a ray coming from the tip of  $I_1$  and traveling parallel to the principal axis makes with the principal axis after it passes through the lens. Thus,

$$\tan \theta \approx \theta \approx \frac{h'}{f_e}$$

We have not used a negative sign in this equation because the final image is not inverted; the object creating this final image  $I_2$  is  $I_1$ , and both it and  $I_2$  point in the same direction. To see why the adjacent side of the triangle containing angle  $\theta$  is  $f_e$  and not  $2f_e$ , note that we must use only the bent length of the refracted ray. Hence, the angular magnification of the telescope can be expressed as

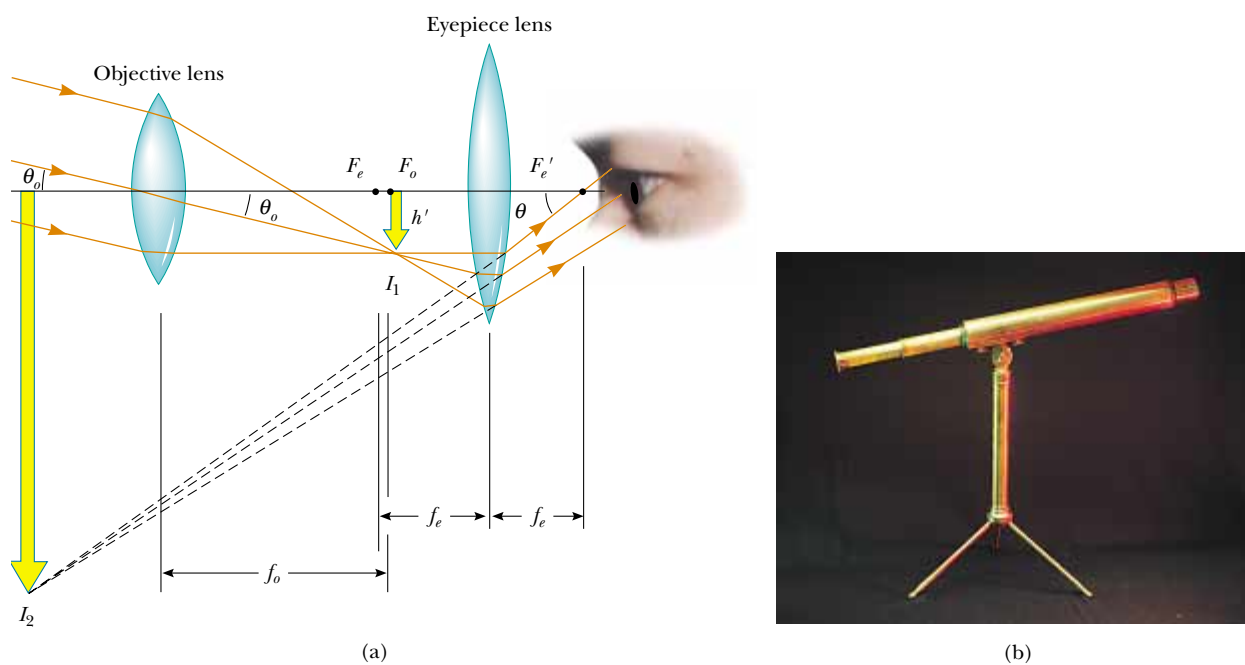

$$m = \frac{\theta}{\theta_o} = \frac{h'/f_e}{-h'/f_o} = -\frac{f_o}{f_e} \quad (36.21)$$

and we see that the angular magnification of a telescope equals the ratio of the objective focal length to the eyepiece focal length. The negative sign indicates that the image is inverted.

### Quick Quiz 36.6

Why isn't the lateral magnification given by Equation 36.1 a useful concept for telescopes?

<sup>2</sup> Single-molecule near-field optic studies are routinely performed with visible light having wavelengths of about 500 nm. The technique uses very small apertures to produce images having resolution as small as 10 nm.

**Figure 36.42** (a) Lens arrangement in a refracting telescope, with the object at infinity. (b) A refracting telescope.

When we look through a telescope at such relatively nearby objects as the Moon and the planets, magnification is important. However, stars are so far away that they always appear as small points of light no matter how great the magnification. A large research telescope that is used to study very distant objects must have a great diameter to gather as much light as possible. It is difficult and expensive to manufacture large lenses for refracting telescopes. Another difficulty with large lenses is that their weight leads to sagging, which is an additional source of aberration. These problems can be partially overcome by replacing the objective with a concave mirror, which results in a reflecting telescope. Because light is reflected from the mirror and does not pass through a lens, the mirror can have rigid supports on the back side. Such supports eliminate the problem of sagging.

Figure 36.43 shows the design for a typical reflecting telescope. Incoming light rays pass down the barrel of the telescope and are reflected by a parabolic mirror at the base. These rays converge toward point *A* in the figure, where an image would be formed. However, before this image is formed, a small, flat mirror *M* reflects the light toward an opening in the side of the tube that passes into an eyepiece. This particular design is said to have a Newtonian focus because Newton developed it. Note that in the reflecting telescope the light never passes through glass (except through the small eyepiece). As a result, problems associated with chromatic aberration are virtually eliminated.

The largest reflecting telescopes in the world are at the Keck Observatory on Mauna Kea, Hawaii. The site includes two telescopes with diameters of 10 m, each containing 36 hexagonally shaped, computer-controlled mirrors that work together to form a large reflecting surface. In contrast, the largest refracting telescope in the world, at the Yerkes Observatory in Williams Bay, Wisconsin, has a diameter of only 1 m.

**Figure 36.43** A Newtonian-focus reflecting telescope.

**web**

For more information on the Keck telescopes, visit <http://www2.keck.hawaii.edu:3636/>

### SUMMARY

The **lateral magnification**  $M$  of a mirror or lens is defined as the ratio of the image height  $h'$  to the object height  $h$ :

$$M = \frac{h'}{h} \quad (36.1)$$

In the paraxial ray approximation, the object distance  $p$  and image distance  $q$  for a spherical mirror of radius  $R$  are related by the **mirror equation**:

$$\frac{1}{p} + \frac{1}{q} = \frac{2}{R} = \frac{1}{f} \quad (36.4, 36.6)$$

where  $f = R/2$  is the **focal length** of the mirror.

An image can be formed by refraction from a spherical surface of radius  $R$ . The object and image distances for refraction from such a surface are related by

$$\frac{n_1}{p} + \frac{n_2}{q} = \frac{n_2 - n_1}{R} \quad (36.8)$$

where the light is incident in the medium for which the index of refraction is  $n_1$  and is refracted in the medium for which the index of refraction is  $n_2$ .

The inverse of the **focal length**  $f$  of a thin lens surrounded by air is given by the **lens makers' equation**:

$$\frac{1}{f} = (n - 1) \left( \frac{1}{R_1} - \frac{1}{R_2} \right) \quad (36.11)$$

**Converging lenses** have positive focal lengths, and **diverging lenses** have negative focal lengths.

For a thin lens, and in the paraxial ray approximation, the object and image distances are related by the **thin-lens equation**:

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{f} \quad (36.12)$$

### QUESTIONS

1. What is wrong with the caption of the cartoon shown in Figure Q36.1?
2. Using a simple ray diagram, such as the one shown in Figure 36.2, show that a flat mirror whose top is at eye level need not be as long as you are for you to see your entire body in it.
3. Consider a concave spherical mirror with a real object. Is the image always inverted? Is the image always real? Give conditions for your answers.
4. Repeat the preceding question for a convex spherical mirror.
5. Why does a clear stream of water, such as a creek, always appear to be shallower than it actually is? By how much is its depth apparently reduced?
6. Consider the image formed by a thin converging lens. Under what conditions is the image (a) inverted, (b) up-right, (c) real, (d) virtual, (e) larger than the object, and (f) smaller than the object?
7. Repeat Question 6 for a thin diverging lens.
8. Use the lens makers' equation to verify the sign of the focal length of each of the lenses in Figure 36.26.

"Most mirrors reverse left and right. This one reverses top and bottom."

**Figure Q36.1**

9. If a cylinder of solid glass or clear plastic is placed above the words LEAD OXIDE and viewed from the side as shown in Figure Q36.9, the LEAD appears inverted but the OXIDE does not. Explain.

Figure Q36.9

10. If the camera “sees” a movie actor’s reflection in a mirror, what does the actor see in the mirror?  
 11. Explain why a mirror cannot give rise to chromatic aberration.  
 12. Why do some automobile mirrors have printed on them the statement “Objects in mirror are closer than they appear”? (See Fig. Q36.12.)

Figure Q36.12

13. Why do some emergency vehicles have the symbol  $\text{A} \text{I} \text{U} \text{B} \text{M} \text{A}$  written on the front?

14. Explain why a fish in a spherical goldfish bowl appears larger than it really is.  
 15. Lenses used in eyeglasses, whether converging or diverging, are always designed such that the middle of the lens curves away from the eye, like the center lenses of Figure 36.26a and b. Why?  
 16. A mirage is formed when the air gets gradually cooler with increasing altitude. What might happen if the air grew gradually warmer with altitude? This often happens over bodies of water or snow-covered ground; the effect is called *looming*.  
 17. Consider a spherical concave mirror, with an object positioned to the left of the mirror beyond the focal point. Using ray diagrams, show that the image moves to the left as the object approaches the focal point.  
 18. In a Jules Verne novel, a piece of ice is shaped into a magnifying lens to focus sunlight to start a fire. Is this possible?  
 19. The  $f$ -number of a camera is the focal length of the lens divided by its aperture (or diameter). How can the  $f$ -number of the lens be changed? How does changing this number affect the required exposure time?  
 20. A solar furnace can be constructed through the use of a concave mirror to reflect and focus sunlight into a furnace enclosure. What factors in the design of the reflecting mirror would guarantee very high temperatures?  
 21. One method for determining the position of an image, either real or virtual, is by means of *parallax*. If a finger or another object is placed at the position of the image, as shown in Figure Q36.21, and the finger and the image are viewed simultaneously (the image is viewed through the lens if it is virtual), the finger and image have the same parallax; that is, if the image is viewed from different positions, it will appear to move along with the finger. Use this method to locate the image formed by a lens. Explain why the method works.

Figure Q36.21

22. Figure Q36.22 shows a lithograph by M. C. Escher titled *Hand with Reflection Sphere (Self-Portrait in Spherical Mirror)*. Escher had this to say about the work: “The picture shows a spherical mirror, resting on a left hand. But as a print is the reverse of the original drawing on stone, it was my right hand that you see depicted. (Being left-handed, I needed my left hand to make the drawing.) Such a globe reflection collects almost one’s whole surroundings in one disk-shaped image. The whole room, four walls, the

floor, and the ceiling, everything, albeit distorted, is compressed into that one small circle. Your own head, or more exactly the point between your eyes, is the absolute center. No matter how you turn or twist yourself, you can't get out of that central point. You are immovably the focus, the unshakable core, of your world." Comment on the accuracy of Escher's description.

23. You can make a corner reflector by placing three flat mirrors in the corner of a room where the ceiling meets the walls. Show that no matter where you are in the room, you can see yourself reflected in the mirrors—upside down.

### Section 36.1 Images Formed by Flat Mirrors

- Does your bathroom mirror show you older or younger than you actually are? Compute an order-of-magnitude estimate for the age difference, based on data that you specify.
- In a church choir loft, two parallel walls are 5.30 m apart. The singers stand against the north wall. The organist faces the south wall, sitting 0.800 m away from it. To enable her to see the choir, a flat mirror 0.600 m wide is mounted on the south wall, straight in front of her. What width of the north wall can she see? *Hint:* Draw a top-view diagram to justify your answer.
-  Determine the minimum height of a vertical flat mirror in which a person 5'10" in height can see his or her full image. (A ray diagram would be helpful.)
- Two flat mirrors have their reflecting surfaces facing each other, with an edge of one mirror in contact with an edge of the other, so that the angle between the mirrors is  $\alpha$ . When an object is placed between the mirrors, a number of images are formed. In general, if the angle  $\alpha$  is such that  $n\alpha = 360^\circ$ , where  $n$  is an integer, the number of images formed is  $n - 1$ . Graphically, find all the image positions for the case  $n = 6$  when a point object is between the mirrors (but not on the angle bisector).

- A person walks into a room with two flat mirrors on opposite walls, which produce multiple images. When the person is 5.00 ft from the mirror on the left wall and 10.0 ft from the mirror on the right wall, find the distances from that person to the first three images seen in the mirror on the left.

### Section 36.2 Images Formed by Spherical Mirrors

- A concave spherical mirror has a radius of curvature of 20.0 cm. Find the location of the image for object distances of (a) 40.0 cm, (b) 20.0 cm, and (c) 10.0 cm. For each case, state whether the image is real or virtual and upright or inverted, and find the magnification.
- At an intersection of hospital hallways, a convex mirror is mounted high on a wall to help people avoid collisions. The mirror has a radius of curvature of 0.550 m. Locate and describe the image of a patient 10.0 m from the mirror. Determine the magnification.
- A large church has a niche in one wall. On the floor plan it appears as a semicircular indentation of radius 2.50 m. A worshiper stands on the center line of the niche, 2.00 m out from its deepest point, and whispers a prayer. Where is the sound concentrated after reflection from the back wall of the niche?

- WEB 9.** A spherical convex mirror has a radius of curvature of 40.0 cm. Determine the position of the virtual image and the magnification (a) for an object distance of 30.0 cm and (b) for an object distance of 60.0 cm. (c) Are the images upright or inverted?
- 10.** The height of the real image formed by a concave mirror is four times the object height when the object is 30.0 cm in front of the mirror. (a) What is the radius of curvature of the mirror? (b) Use a ray diagram to locate this image.
- 11.** A concave mirror has a radius of curvature of 60.0 cm. Calculate the image position and magnification of an object placed in front of the mirror (a) at a distance of 90.0 cm and (b) at a distance of 20.0 cm. (c) In each case, draw ray diagrams to obtain the image characteristics.
- 12.** A concave mirror has a focal length of 40.0 cm. Determine the object position for which the resulting image is upright and four times the size of the object.
- 13.** A spherical mirror is to be used to form, on a screen 5.00 m from the object, an image five times the size of the object. (a) Describe the type of mirror required. (b) Where should the mirror be positioned relative to the object?
- 14.** A rectangle 10.0 cm  $\times$  20.0 cm is placed so that its right edge is 40.0 cm to the left of a concave spherical mirror, as in Figure P36.14. The radius of curvature of the mirror is 20.0 cm. (a) Draw the image formed by this mirror. (b) What is the area of the image?

**Figure P36.14**

- 15.** A dedicated sports-car enthusiast polishes the inside and outside surfaces of a hubcap that is a section of a sphere. When she looks into one side of the hubcap, she sees an image of her face 30.0 cm in back of the hubcap. She then flips the hubcap over and sees another image of her face 10.0 cm in back of the hubcap. (a) How far is her face from the hubcap? (b) What is the radius of curvature of the hubcap?
- 16.** An object is 15.0 cm from the surface of a reflective spherical Christmas-tree ornament 6.00 cm in diameter. What are the magnification and position of the image?
- 17.** A ball is dropped from rest 3.00 m directly above the vertex of a concave mirror that has a radius of 1.00 m and lies in a horizontal plane. (a) Describe the motion of the ball's image in the mirror. (b) At what time do the ball and its image coincide?

### Section 36.3 Images Formed by Refraction

- 18.** A flint-glass plate ( $n = 1.66$ ) rests on the bottom of an aquarium tank. The plate is 8.00 cm thick (vertical dimension) and covered with water ( $n = 1.33$ ) to a depth of 12.0 cm. Calculate the apparent thickness of the plate as viewed from above the water. (Assume nearly normal incidence.)
- 19.** A cubical block of ice 50.0 cm on a side is placed on a level floor over a speck of dust. Find the location of the image of the speck if the index of refraction of ice is 1.309.
- 20.** A simple model of the human eye ignores its lens entirely. Most of what the eye does to light happens at the transparent cornea. Assume that this outer surface has a 6.00-mm radius of curvature, and assume that the eyeball contains just one fluid with an index of refraction of 1.40. Prove that a very distant object will be imaged on the retina, 21.0 mm behind the cornea. Describe the image.
- 21.** A glass sphere ( $n = 1.50$ ) with a radius of 15.0 cm has a tiny air bubble 5.00 cm above its center. The sphere is viewed looking down along the extended radius containing the bubble. What is the apparent depth of the bubble below the surface of the sphere?
- 22.** A transparent sphere of unknown composition is observed to form an image of the Sun on the surface of the sphere opposite the Sun. What is the refractive index of the sphere material?
- 23.** One end of a long glass rod ( $n = 1.50$ ) is formed into a convex surface of radius 6.00 cm. An object is positioned in air along the axis of the rod. Find the image positions corresponding to object distances of (a) 20.0 cm, (b) 10.0 cm, and (c) 3.00 cm from the end of the rod.
- 24.** A goldfish is swimming at 2.00 cm/s toward the front wall of a rectangular aquarium. What is the apparent speed of the fish as measured by an observer looking in from outside the front wall of the tank? The index of refraction of water is 1.33.
- 25.** A goldfish is swimming inside a spherical plastic bowl of water, with an index of refraction of 1.33. If the goldfish is 10.0 cm from the wall of the 15.0-cm-radius bowl, where does it appear to an observer outside the bowl?

### Section 36.4 Thin Lenses

- 26.** A contact lens is made of plastic with an index of refraction of 1.50. The lens has an outer radius of curvature of +2.00 cm and an inner radius of curvature of +2.50 cm. What is the focal length of the lens?
- WEB 27.** The left face of a biconvex lens has a radius of curvature of magnitude 12.0 cm, and the right face has a radius of curvature of magnitude 18.0 cm. The index of refraction of the glass is 1.44. (a) Calculate the focal length of the lens. (b) Calculate the focal length if the radii of curvature of the two faces are interchanged.

28. A converging lens has a focal length of 20.0 cm. Locate the image for object distances of (a) 40.0 cm, (b) 20.0 cm, and (c) 10.0 cm. For each case, state whether the image is real or virtual and upright or inverted. Find the magnification in each case.
29. A thin lens has a focal length of 25.0 cm. Locate and describe the image when the object is placed (a) 26.0 cm and (b) 24.0 cm in front of the lens.
30. An object positioned 32.0 cm in front of a lens forms an image on a screen 8.00 cm behind the lens. (a) Find the focal length of the lens. (b) Determine the magnification. (c) Is the lens converging or diverging?
- WEB 31. The nickel's image in Figure P36.31 has twice the diameter of the nickel and is 2.84 cm from the lens. Determine the focal length of the lens.

Figure P36.31

32. A magnifying glass is a converging lens of focal length 15.0 cm. At what distance from a postage stamp should you hold this lens to get a magnification of +2.00?
33. A transparent photographic slide is placed in front of a converging lens with a focal length of 2.44 cm. The lens forms an image of the slide 12.9 cm from the slide. How far is the lens from the slide if the image is (a) real? (b) virtual?
34. A person looks at a gem with a jeweler's loupe—a converging lens that has a focal length of 12.5 cm. The loupe forms a virtual image 30.0 cm from the lens. (a) Determine the magnification. Is the image upright or inverted? (b) Construct a ray diagram for this arrangement.
35. Suppose an object has thickness  $dp$  so that it extends from object distance  $p$  to  $p + dp$ . Prove that the thickness  $dq$  of its image is given by  $(-q^2/p^2)dp$ , so the longitudinal magnification  $dq/dp = -M^2$ , where  $M$  is the lateral magnification.
36. The projection lens in a certain slide projector is a single thin lens. A slide 24.0 mm high is to be projected so that its image fills a screen 1.80 m high. The slide-to-screen distance is 3.00 m. (a) Determine the focal length of the projection lens. (b) How far from the slide should the lens of the projector be placed to form the image on the screen?
37. An object is positioned 20.0 cm to the left of a diverging lens with focal length  $f = -32.0$  cm. Determine (a) the

location and (b) the magnification of the image. (c) Construct a ray diagram for this arrangement.

38. Figure P36.38 shows a thin glass ( $n = 1.50$ ) converging lens for which the radii of curvature are  $R_1 = 15.0$  cm and  $R_2 = -12.0$  cm. To the left of the lens is a cube with a face area of  $100$  cm<sup>2</sup>. The base of the cube is on the axis of the lens, and the right face is 20.0 cm to the left of the lens. (a) Determine the focal length of the lens. (b) Draw the image of the square face formed by the lens. What type of geometric figure is this? (c) Determine the area of the image.

Figure P36.38

39. An object is 5.00 m to the left of a flat screen. A converging lens for which the focal length is  $f = 0.800$  m is placed between object and screen. (a) Show that two lens positions exist that form images on the screen, and determine how far these positions are from the object. (b) How do the two images differ from each other?
40. An object is at a distance  $d$  to the left of a flat screen. A converging lens with focal length  $f < d/4$  is placed between object and screen. (a) Show that two lens positions exist that form an image on the screen, and determine how far these positions are from the object. (b) How do the two images differ from each other?
41. Figure 36.33 diagrams a cross-section of a camera. It has a single lens with a focal length of 65.0 mm, which is to form an image on the film at the back of the camera. Suppose the position of the lens has been adjusted to focus the image of a distant object. How far and in what direction must the lens be moved to form a sharp image of an object that is 2.00 m away?

(Optional)

### Section 36.5 Lens Aberrations

42. The magnitudes of the radii of curvature are 32.5 cm and 42.5 cm for the two faces of a biconcave lens. The glass has index 1.53 for violet light and 1.51 for red light. For a very distant object, locate and describe (a) the image formed by violet light and (b) the image formed by red light.

43. Two rays traveling parallel to the principal axis strike a large plano-convex lens having a refractive index of 1.60 (Fig. P36.43). If the convex face is spherical, a ray near the edge does not pass through the focal point (spherical aberration occurs). If this face has a radius of curvature of magnitude 20.0 cm and the two rays are  $h_1 = 0.500$  cm and  $h_2 = 12.0$  cm from the principal axis, find the difference in the positions where they cross the principal axis.

Figure P36.43

(Optional)

### Section 36.7 The Eye

44. The accommodation limits for Nearsighted Nick's eyes are 18.0 cm and 80.0 cm. When he wears his glasses, he can see faraway objects clearly. At what minimum distance can he see objects clearly?
45. A nearsighted person cannot see objects clearly beyond 25.0 cm (her far point). If she has no astigmatism and contact lenses are prescribed for her, what power and type of lens are required to correct her vision?
46. A person sees clearly when he wears eyeglasses that have a power of  $-4.00$  diopters and sit 2.00 cm in front of his eyes. If he wants to switch to contact lenses, which are placed directly on the eyes, what lens power should be prescribed?

(Optional)

### Section 36.8 The Simple Magnifier

### Section 36.9 The Compound Microscope

### Section 36.10 The Telescope

47. A philatelist examines the printing detail on a stamp, using a biconvex lens with a focal length of 10.0 cm as a simple magnifier. The lens is held close to the eye, and the lens-to-object distance is adjusted so that the virtual image is formed at the normal near point (25.0 cm). Calculate the magnification.
48. A lens that has a focal length of 5.00 cm is used as a magnifying glass. (a) Where should the object be placed to obtain maximum magnification? (b) What is the magnification?
49. The distance between the eyepiece and the objective lens in a certain compound microscope is 23.0 cm. The

focal length of the eyepiece is 2.50 cm, and that of the objective is 0.400 cm. What is the overall magnification of the microscope?

50. The desired overall magnification of a compound microscope is  $140\times$ . The objective alone produces a lateral magnification of  $12.0\times$ . Determine the required focal length of the eyepiece.
51. The Yerkes refracting telescope has a 1.00-m-diameter objective lens with a focal length of 20.0 m. Assume that it is used with an eyepiece that has a focal length of 2.50 cm. (a) Determine the magnification of the planet Mars as seen through this telescope. (b) Are the Martian polar caps seen right side up or upside down?
52. Astronomers often take photographs with the objective lens or the mirror of a telescope alone, without an eyepiece. (a) Show that the image size  $h'$  for this telescope is given by  $h' = fh/(f - p)$ , where  $h$  is the object size,  $f$  is the objective focal length, and  $p$  is the object distance. (b) Simplify the expression in part (a) for the case in which the object distance is much greater than objective focal length. (c) The "wingspan" of the International Space Station is 108.6 m, the overall width of its solar-panel configuration. Find the width of the image formed by a telescope objective of focal length 4.00 m when the station is orbiting at an altitude of 407 km.
53. Galileo devised a simple terrestrial telescope that produces an upright image. It consists of a converging objective lens and a diverging eyepiece at opposite ends of the telescope tube. For distant objects, the tube length is the objective focal length less the absolute value of the eyepiece focal length. (a) Does the user of the telescope see a real or virtual image? (b) Where is the final image? (c) If a telescope is to be constructed with a tube 10.0 cm long and a magnification of 3.00, what are the focal lengths of the objective and eyepiece?
54. A certain telescope has an objective mirror with an aperture diameter of 200 mm and a focal length of 2 000 mm. It captures the image of a nebula on photographic film at its prime focus with an exposure time of 1.50 min. To produce the same light energy per unit area on the film, what is the required exposure time to photograph the same nebula with a smaller telescope, which has an objective lens with an aperture diameter of 60.0 mm and a focal length of 900 mm?

### ADDITIONAL PROBLEMS

55. The distance between an object and its upright image is 20.0 cm. If the magnification is 0.500, what is the focal length of the lens that is being used to form the image?
56. The distance between an object and its upright image is  $d$ . If the magnification is  $M$ , what is the focal length of the lens that is being used to form the image?
57. The lens and mirror in Figure P36.57 have focal lengths of  $+80.0$  cm and  $-50.0$  cm, respectively. An object is

Figure P36.57

placed 1.00 m to the left of the lens, as shown. Locate the final image, which is formed by light that has gone through the lens twice. State whether the image is upright or inverted, and determine the overall magnification.

58. Your friend needs glasses with diverging lenses of focal length  $-65.0$  cm for both eyes. You tell him he looks good when he does not squint, but he is worried about how thick the lenses will be. If the radius of curvature of the first surface is  $R_1 = 50.0$  cm and the high-index plastic has a refractive index of 1.66, (a) find the required radius of curvature of the second surface. (b) Assume that the lens is ground from a disk 4.00 cm in diameter and 0.100 cm thick at the center. Find the thickness of the plastic at the edge of the lens, measured parallel to the axis. *Hint:* Draw a large cross-sectional diagram.
59. The object in Figure P36.59 is midway between the lens and the mirror. The mirror's radius of curvature is 20.0 cm, and the lens has a focal length of  $-16.7$  cm. Considering only the light that leaves the object and travels first toward the mirror, locate the final image formed by this system. Is this image real or virtual? Is it upright or inverted? What is the overall magnification?

Figure P36.59

60. An object placed 10.0 cm from a concave spherical mirror produces a real image 8.00 cm from the mirror. If the object is moved to a new position 20.0 cm from the

mirror, what is the position of the image? Is the latter image real or virtual?

- WEB 61. A parallel beam of light enters a glass hemisphere perpendicular to the flat face, as shown in Figure P36.61. The radius is  $|R| = 6.00$  cm, and the index of refraction is  $n = 1.560$ . Determine the point at which the beam is focused. (Assume paraxial rays.)

Figure P36.61

62. **Review Problem.** A spherical lightbulb with a diameter of 3.20 cm radiates light equally in all directions, with a power of 4.50 W. (a) Find the light intensity at the surface of the bulb. (b) Find the light intensity 7.20 m from the center of the bulb. (c) At this 7.20-m distance, a lens is set up with its axis pointing toward the bulb. The lens has a circular face with a diameter of 15.0 cm and a focal length of 35.0 cm. Find the diameter of the image of the bulb. (d) Find the light intensity at the image.
63. An object is placed 12.0 cm to the left of a diverging lens with a focal length of  $-6.00$  cm. A converging lens with a focal length of 12.0 cm is placed a distance  $d$  to the right of the diverging lens. Find the distance  $d$  that corresponds to a final image at infinity. Draw a ray diagram for this case.
64. Assume that the intensity of sunlight is  $1.00$  kW/m<sup>2</sup> at a particular location. A highly reflecting concave mirror is to be pointed toward the Sun to produce a power of at least 350 W at the image. (a) Find the required radius  $R_a$  of the circular face area of the mirror. (b) Now suppose the light intensity is to be at least 120 kW/m<sup>2</sup> at the image. Find the required relationship between  $R_a$  and the radius of curvature  $R$  of the mirror. The disk of the Sun subtends an angle of  $0.533^\circ$  at the Earth.
- WEB 65. The disk of the Sun subtends an angle of  $0.533^\circ$  at the Earth. What are the position and diameter of the solar image formed by a concave spherical mirror with a radius of curvature of 3.00 m?
66. Figure P36.66 shows a thin converging lens for which the radii are  $R_1 = 9.00$  cm and  $R_2 = -11.0$  cm. The lens is in front of a concave spherical mirror of radius  $R = 8.00$  cm. (a) If its focal points  $F_1$  and  $F_2$  are 5.00 cm from the vertex of the lens, determine its index of refraction. (b) If the lens and mirror are 20.0 cm apart and an object is placed 8.00 cm to the left of the

Figure P36.66

lens, determine the position of the final image and its magnification as seen by the eye in the figure. (c) Is the final image inverted or upright? Explain.

67. In a darkened room, a burning candle is placed 1.50 m from a white wall. A lens is placed between candle and wall at a location that causes a larger, inverted image to form on the wall. When the lens is moved 90.0 cm toward the wall, another image of the candle is formed. Find (a) the two object distances that produce the specified images and (b) the focal length of the lens. (c) Characterize the second image.
68. A thin lens of focal length  $f$  lies on a horizontal front-surfaced flat mirror. How far above the lens should an object be held if its image is to coincide with the object?
69. A compound microscope has an objective of focal length 0.300 cm and an eyepiece of focal length 2.50 cm. If an object is 3.40 mm from the objective, what is the magnification? (*Hint:* Use the lens equation for the objective.)
70. Two converging lenses with focal lengths of 10.0 cm and 20.0 cm are positioned 50.0 cm apart, as shown in Figure P36.70. The final image is to be located between the lenses, at the position indicated. (a) How far to the left

Figure P36.70

of the first lens should the object be? (b) What is the overall magnification? (c) Is the final image upright or inverted?

71. A cataract-impaired lens in an eye may be surgically removed and replaced by a manufactured lens. The focal length required for the new lens is determined by the lens-to-retina distance, which is measured by a sonar-

like device, and by the requirement that the implant provide for correct distant vision. (a) If the distance from lens to retina is 22.4 mm, calculate the power of the implanted lens in diopters. (b) Since no accommodation occurs and the implant allows for correct distant vision, a corrective lens for close work or reading must be used. Assume a reading distance of 33.0 cm, and calculate the power of the lens in the reading glasses.

72. A floating strawberry illusion consists of two parabolic mirrors, each with a focal length of 7.50 cm, facing each other so that their centers are 7.50 cm apart (Fig. P36.72). If a strawberry is placed on the lower mirror, an image of the strawberry is formed at the small opening at the center of the top mirror. Show that the final image is formed at that location, and describe its characteristics. (*Note:* A very startling effect is to shine a flashlight beam on these images. Even at a glancing angle, the incoming light beam is seemingly reflected off the images! Do you understand why?)

Figure P36.72

73. An object 2.00 cm high is placed 40.0 cm to the left of a converging lens with a focal length of 30.0 cm. A diverging lens with a focal length of  $-20.0$  cm is placed 110 cm to the right of the converging lens. (a) Determine the final position and magnification of the final image. (b) Is the image upright or inverted? (c) Repeat parts (a) and (b) for the case in which the second lens is a converging lens with a focal length of  $+20.0$  cm.

## ANSWERS TO QUICK QUIZZES

**36.1** At *C*. A ray traced from the stone to the mirror and then to observer 2 looks like this:

**Figure QQA36.1**

**36.2** The focal length is infinite. Because the flat surfaces of the pane have infinite radii of curvature, Equation 36.11 indicates that the focal length is also infinite. Parallel rays striking the pane focus at infinity, which means that they remain parallel after passing through the glass.

**36.3** An infinite number. In general, an infinite number of rays leave each point of any object and travel outward in all directions. (The three principal rays that we use to locate an image make up a selected subset of the infinite number of rays.) When an object is taller than a lens, we merely extend the plane containing the lens, as shown in Figure QQA36.2.

**36.4** (c) The entire image is visible but has half the intensity. Each point on the object is a source of rays that travel in all directions. Thus, light from all parts of the object goes through all parts of the lens and forms an image. If you block part of the lens, you are blocking some of the

**Figure QQA36.2**

rays, but the remaining ones still come from all parts of the object.

**36.5** The eyeglasses on the left are diverging lenses, which correct for nearsightedness. If you look carefully at the edge of the person's face through the lens, you will see that everything viewed through these glasses is reduced in size. The eyeglasses on the right are converging lenses, which correct for farsightedness. These lenses make everything that is viewed through them look larger.

**36.6** The lateral magnification of a telescope is not well defined. For viewing with the eye relaxed, the user may slightly adjust the position of the eyepiece to place the final image  $I_2$  in Figure 36.42a at infinity. Then, its height and its lateral magnification also are infinite. The angular magnification of a telescope as we define it is the factor by which the telescope increases in the diameter—on the retina of the viewer's eye—of the real image of an extended object.

## PUZZLER

The brilliant colors seen in peacock feathers are not caused by pigments in the feathers. If they are not produced by pigments, how are these beautiful colors created? (Terry Qing/FPG International)

# 37

## Interference of Light Waves

### Chapter Outline

- 37.1** Conditions for Interference
- 37.2** Young's Double-Slit Experiment
- 37.3** Intensity Distribution of the Double-Slit Interference Pattern
- 37.4** Phasor Addition of Waves

- 37.5** Change of Phase Due to Reflection
- 37.6** Interference in Thin Films
- 37.7** (Optional) The Michelson Interferometer

In the preceding chapter on geometric optics, we used light rays to examine what happens when light passes through a lens or reflects from a mirror. Here in Chapter 37 and in the next chapter, we are concerned with *wave optics*, the study of interference, diffraction, and polarization of light. These phenomena cannot be adequately explained with the ray optics used in Chapter 36. We now learn how treating light as waves rather than as rays leads to a satisfying description of such phenomena.

### 37.1 CONDITIONS FOR INTERFERENCE

In Chapter 18, we found that the adding together of two mechanical waves can be constructive or destructive. In constructive interference, the amplitude of the resultant wave is greater than that of either individual wave, whereas in destructive interference, the resultant amplitude is less than that of either individual wave. Light waves also interfere with each other. Fundamentally, all interference associated with light waves arises when the electromagnetic fields that constitute the individual waves combine.

If two lightbulbs are placed side by side, no interference effects are observed because the light waves from one bulb are emitted independently of those from the other bulb. The emissions from the two lightbulbs do not maintain a constant phase relationship with each other over time. Light waves from an ordinary source such as a lightbulb undergo random changes about once every  $10^{-8}$  s. Therefore, the conditions for constructive interference, destructive interference, or some intermediate state last for lengths of time of the order of  $10^{-8}$  s. Because the eye cannot follow such short-term changes, no interference effects are observed. (In 1993 interference from two separate light sources was photographed in an extremely fast exposure. Nonetheless, we do not ordinarily see interference effects because of the rapidly changing phase relationship between the light waves.) Such light sources are said to be **incoherent**.

Interference effects in light waves are not easy to observe because of the short wavelengths involved (from  $4 \times 10^{-7}$  m to  $7 \times 10^{-7}$  m). For sustained interference in light waves to be observed, the following conditions must be met:

- The sources must be **coherent**—that is, they must maintain a constant phase with respect to each other.
- The sources should be **monochromatic**—that is, of a single wavelength.

We now describe the characteristics of coherent sources. As we saw when we studied mechanical waves, two sources (producing two traveling waves) are needed to create interference. In order to produce a stable interference pattern, **the individual waves must maintain a constant phase relationship with one another**. As an example, the sound waves emitted by two side-by-side loudspeakers driven by a single amplifier can interfere with each other because the two speakers are coherent—that is, they respond to the amplifier in the same way at the same time.

A common method for producing two coherent light sources is to use one monochromatic source to illuminate a barrier containing two small openings (usually in the shape of slits). The light emerging from the two slits is coherent because a single source produces the original light beam and the two slits serve only to separate the original beam into two parts (which, after all, is what was done to the sound signal from the side-by-side loudspeakers). Any random change in the light

emitted by the source occurs in both beams at the same time, and as a result interference effects can be observed when the light from the two slits arrives at a viewing screen.

### 37.2 YOUNG'S DOUBLE-SLIT EXPERIMENT

Interference in light waves from two sources was first demonstrated by Thomas Young in 1801. A schematic diagram of the apparatus that Young used is shown in Figure 37.1a. Light is incident on a first barrier in which there is a slit  $S_0$ . The waves emerging from this slit arrive at a second barrier that contains two parallel slits  $S_1$  and  $S_2$ . These two slits serve as a pair of coherent light sources because waves emerging from them originate from the same wave front and therefore maintain a constant phase relationship. The light from  $S_1$  and  $S_2$  produces on a viewing screen a visible pattern of bright and dark parallel bands called **fringes** (Fig. 37.1b). When the light from  $S_1$  and that from  $S_2$  both arrive at a point on the screen such that constructive interference occurs at that location, a bright fringe appears. When the light from the two slits combines destructively at any location on the screen, a dark fringe results. Figure 37.2 is a photograph of an interference pattern produced by two coherent vibrating sources in a water tank.

**Figure 37.1** (a) Schematic diagram of Young's double-slit experiment. Slits  $S_1$  and  $S_2$  behave as coherent sources of light waves that produce an interference pattern on the viewing screen (drawing not to scale). (b) An enlargement of the center of a fringe pattern formed on the viewing screen with many slits could look like this.

**Figure 37.2** An interference pattern involving water waves is produced by two vibrating sources at the water's surface. The pattern is analogous to that observed in Young's double-slit experiment. Note the regions of constructive ( $A$ ) and destructive ( $B$ ) interference.

**Quick Quiz 37.1**

If you were to blow smoke into the space between the second barrier and the viewing screen of Figure 37.1a, what would you see?

**QuickLab**

Look through the fabric of an umbrella at a distant streetlight. Can you explain what you see? (The fringe pattern in Figure 37.1b is from rectangular slits. The fabric of the umbrella creates a two-dimensional set of square holes.)

**Quick Quiz 37.2**

Figure 37.2 is an overhead view of a shallow water tank. If you wanted to use a small ruler to measure the water's depth, would this be easier to do at location *A* or at location *B*?

Figure 37.3 shows some of the ways in which two waves can combine at the screen. In Figure 37.3a, the two waves, which leave the two slits in phase, strike the screen at the central point *P*. Because both waves travel the same distance, they arrive at *P* in phase. As a result, constructive interference occurs at this location, and a bright fringe is observed. In Figure 37.3b, the two waves also start in phase, but in this case the upper wave has to travel one wavelength farther than the lower wave to reach point *Q*. Because the upper wave falls behind the lower one by exactly one wavelength, they still arrive in phase at *Q*, and so a second bright fringe appears at this location. At point *R* in Figure 37.3c, however, midway between points *P* and *Q*, the upper wave has fallen half a wavelength behind the lower wave. This means that a trough of the lower wave overlaps a crest of the upper wave; this gives rise to destructive interference at point *R*. For this reason, a dark fringe is observed at this location.

We can describe Young's experiment quantitatively with the help of Figure 37.4. The viewing screen is located a perpendicular distance *L* from the double-slitted barrier. *S*<sub>1</sub> and *S*<sub>2</sub> are separated by a distance *d*, and the source is monochromatic. To reach any arbitrary point *P*, a wave from the lower slit travels farther than a wave from the upper slit by a distance *d* sin  $\theta$ . This distance is called the **path difference**  $\delta$  (lowercase Greek delta). If we assume that *r*<sub>1</sub> and *r*<sub>2</sub> are parallel, which is approximately true because *L* is much greater than *d*, then  $\delta$  is given by

Path difference

$$\delta = r_2 - r_1 = d \sin \theta \quad (37.1)$$

**Figure 37.3** (a) Constructive interference occurs at point *P* when the waves combine. (b) Constructive interference also occurs at point *Q*. (c) Destructive interference occurs at *R* when the two waves combine because the upper wave falls half a wavelength behind the lower wave (all figures not to scale).

**Figure 37.4** (a) Geometric construction for describing Young's double-slit experiment (not to scale). (b) When we assume that  $r_1$  is parallel to  $r_2$ , the path difference between the two rays is  $r_2 - r_1 = d \sin \theta$ . For this approximation to be valid, it is essential that  $L \gg d$ .

The value of  $\delta$  determines whether the two waves are in phase when they arrive at point  $P$ . If  $\delta$  is either zero or some integer multiple of the wavelength, then the two waves are in phase at point  $P$  and constructive interference results. Therefore, the condition for bright fringes, or **constructive interference**, at point  $P$  is

$$\delta = d \sin \theta = m\lambda \quad m = 0, \pm 1, \pm 2, \dots \quad (37.2)$$

Conditions for constructive interference

The number  $m$  is called the **order number**. The central bright fringe at  $\theta = 0$  ( $m = 0$ ) is called the *zeroth-order maximum*. The first maximum on either side, where  $m = \pm 1$ , is called the *first-order maximum*, and so forth.

When  $\delta$  is an odd multiple of  $\lambda/2$ , the two waves arriving at point  $P$  are  $180^\circ$  out of phase and give rise to destructive interference. Therefore, the condition for dark fringes, or **destructive interference**, at point  $P$  is

$$d \sin \theta = (m + \frac{1}{2})\lambda \quad m = 0, \pm 1, \pm 2, \dots \quad (37.3)$$

Conditions for destructive interference

It is useful to obtain expressions for the positions of the bright and dark fringes measured vertically from  $O$  to  $P$ . In addition to our assumption that  $L \gg d$ , we assume that  $d \gg \lambda$ . These can be valid assumptions because in practice  $L$  is often of the order of 1 m,  $d$  a fraction of a millimeter, and  $\lambda$  a fraction of a micrometer for visible light. Under these conditions,  $\theta$  is small; thus, we can use the approximation  $\sin \theta \approx \tan \theta$ . Then, from triangle  $OPQ$  in Figure 37.4, we see that

$$y = L \tan \theta \approx L \sin \theta \quad (37.4)$$

Solving Equation 37.2 for  $\sin \theta$  and substituting the result into Equation 37.4, we see that the positions of the bright fringes measured from  $O$  are given by the expression

$$y_{\text{bright}} = \frac{\lambda L}{d} m \quad (37.5)$$

Using Equations 37.3 and 37.4, we find that the dark fringes are located at

$$y_{\text{dark}} = \frac{\lambda L}{d} \left( m + \frac{1}{2} \right) \quad (37.6)$$

As we demonstrate in Example 37.1, Young's double-slit experiment provides a method for measuring the wavelength of light. In fact, Young used this technique to do just that. Additionally, the experiment gave the wave model of light a great deal of credibility. It was inconceivable that particles of light coming through the slits could cancel each other in a way that would explain the dark fringes.

### EXAMPLE 37.1 Measuring the Wavelength of a Light Source

A viewing screen is separated from a double-slit source by 1.2 m. The distance between the two slits is 0.030 mm. The second-order bright fringe ( $m = 2$ ) is 4.5 cm from the center line. (a) Determine the wavelength of the light.

**Solution** We can use Equation 37.5, with  $m = 2$ ,  $y_2 = 4.5 \times 10^{-2}$  m,  $L = 1.2$  m, and  $d = 3.0 \times 10^{-5}$  m:

$$\begin{aligned} \lambda &= \frac{dy_2}{mL} = \frac{(3.0 \times 10^{-5} \text{ m})(4.5 \times 10^{-2} \text{ m})}{2(1.2 \text{ m})} \\ &= 5.6 \times 10^{-7} \text{ m} = \boxed{560 \text{ nm}} \end{aligned}$$

(b) Calculate the distance between adjacent bright fringes.

**Solution** From Equation 37.5 and the results of part (a), we obtain

$$\begin{aligned} y_{m+1} - y_m &= \frac{\lambda L(m+1)}{d} - \frac{\lambda Lm}{d} \\ &= \frac{\lambda L}{d} = \frac{(5.6 \times 10^{-7} \text{ m})(1.2 \text{ m})}{3.0 \times 10^{-5} \text{ m}} \\ &= 2.2 \times 10^{-2} \text{ m} = \boxed{2.2 \text{ cm}} \end{aligned}$$

Note that the spacing between all fringes is equal.

### EXAMPLE 37.2 Separating Double-Slit Fringes of Two Wavelengths

A light source emits visible light of two wavelengths:  $\lambda = 430$  nm and  $\lambda' = 510$  nm. The source is used in a double-slit interference experiment in which  $L = 1.5$  m and  $d = 0.025$  mm. Find the separation distance between the third-order bright fringes.

**Solution** Using Equation 37.5, with  $m = 3$ , we find that the fringe positions corresponding to these two wavelengths are

$$y_3 = \frac{\lambda L}{d} m = 3 \frac{\lambda L}{d} = 7.74 \times 10^{-2} \text{ m}$$

$$y'_3 = \frac{\lambda' L}{d} m = 3 \frac{\lambda' L}{d} = 9.18 \times 10^{-2} \text{ m}$$

Hence, the separation distance between the two fringes is

$$\begin{aligned} \Delta y &= y'_3 - y_3 = 9.18 \times 10^{-2} \text{ m} - 7.74 \times 10^{-2} \text{ m} \\ &= 1.4 \times 10^{-2} \text{ m} = \boxed{1.4 \text{ cm}} \end{aligned}$$

## 37.3 INTENSITY DISTRIBUTION OF THE DOUBLE-SLIT INTERFERENCE PATTERN

Note that the edges of the bright fringes in Figure 37.1b are fuzzy. So far we have discussed the locations of only the centers of the bright and dark fringes on a distant screen. We now direct our attention to the intensity of the light at other points between the positions of maximum constructive and destructive interference. In other words, we now calculate the distribution of light intensity associated with the double-slit interference pattern.

Again, suppose that the two slits represent coherent sources of sinusoidal waves such that the two waves from the slits have the same angular frequency  $\omega$  and a constant phase difference  $\phi$ . The total magnitude of the electric field at point  $P$  on the screen in Figure 37.5 is the vector superposition of the two waves. Assuming that the two waves have the same amplitude  $E_0$ , we can write the magnitude of the electric field at point  $P$  due to each wave separately as

$$E_1 = E_0 \sin \omega t \quad \text{and} \quad E_2 = E_0 \sin(\omega t + \phi) \quad (37.7)$$

Although the waves are in phase at the slits, *their phase difference  $\phi$  at point  $P$  depends on the path difference  $\delta = r_2 - r_1 = d \sin \theta$* . Because a path difference of  $\lambda$  (constructive interference) corresponds to a phase difference of  $2\pi$  rad, we obtain the ratio

$$\frac{\delta}{\lambda} = \frac{\phi}{2\pi}$$

$$\phi = \frac{2\pi}{\lambda} \delta = \frac{2\pi}{\lambda} d \sin \theta \quad (37.8)$$

This equation tells us precisely how the phase difference  $\phi$  depends on the angle  $\theta$  in Figure 37.4.

Using the superposition principle and Equation 37.7, we can obtain the magnitude of the resultant electric field at point  $P$ :

$$E_P = E_1 + E_2 = E_0[\sin \omega t + \sin(\omega t + \phi)] \quad (37.9)$$

To simplify this expression, we use the trigonometric identity

$$\sin A + \sin B = 2 \sin\left(\frac{A+B}{2}\right) \cos\left(\frac{A-B}{2}\right)$$

Taking  $A = \omega t + \phi$  and  $B = \omega t$ , we can write Equation 37.9 in the form

$$E_P = 2E_0 \cos\left(\frac{\phi}{2}\right) \sin\left(\omega t + \frac{\phi}{2}\right) \quad (37.10)$$

This result indicates that the electric field at point  $P$  has the same frequency  $\omega$  as the light at the slits, but that the amplitude of the field is multiplied by the factor  $2 \cos(\phi/2)$ . To check the consistency of this result, note that if  $\phi = 0, 2\pi, 4\pi, \dots$ , then the electric field at point  $P$  is  $2E_0$ , corresponding to the condition for constructive interference. These values of  $\phi$  are consistent with Equation 37.2 for constructive interference. Likewise, if  $\phi = \pi, 3\pi, 5\pi, \dots$ , then the magnitude of the electric field at point  $P$  is zero; this is consistent with Equation 37.3 for destructive interference.

Finally, to obtain an expression for the light intensity at point  $P$ , recall from Section 34.3 that *the intensity of a wave is proportional to the square of the resultant electric field magnitude at that point* (Eq. 34.20). Using Equation 37.10, we can therefore express the light intensity at point  $P$  as

$$I \propto E_P^2 = 4E_0^2 \cos^2\left(\frac{\phi}{2}\right) \sin^2\left(\omega t + \frac{\phi}{2}\right)$$

Most light-detecting instruments measure time-averaged light intensity, and the time-averaged value of  $\sin^2(\omega t + \phi/2)$  over one cycle is  $\frac{1}{2}$ . Therefore, we can write the average light intensity at point  $P$  as

$$I = I_{\max} \cos^2\left(\frac{\phi}{2}\right) \quad (37.11)$$

**Figure 37.5** Construction for analyzing the double-slit interference pattern. A bright fringe, or intensity maximum, is observed at  $O$ .

Phase difference

**Figure 37.6** Light intensity versus  $d \sin \theta$  for a double-slit interference pattern when the screen is far from the slits ( $L \gg d$ ).

where  $I_{\max}$  is the maximum intensity on the screen and the expression represents the time average. Substituting the value for  $\phi$  given by Equation 37.8 into this expression, we find that

$$I = I_{\max} \cos^2\left(\frac{\pi d \sin \theta}{\lambda}\right) \quad (37.12)$$

Alternatively, because  $\sin \theta \approx y/L$  for small values of  $\theta$  in Figure 37.4, we can write Equation 37.12 in the form

$$I = I_{\max} \cos^2\left(\frac{\pi d}{\lambda L} y\right) \quad (37.13)$$

Constructive interference, which produces light intensity maxima, occurs when the quantity  $\pi dy/\lambda L$  is an integral multiple of  $\pi$ , corresponding to  $y = (\lambda L/d)m$ . This is consistent with Equation 37.5.

A plot of light intensity versus  $d \sin \theta$  is given in Figure 37.6. Note that the interference pattern consists of equally spaced fringes of equal intensity. Remember, however, that this result is valid only if the slit-to-screen distance  $L$  is much greater than the slit separation, and only for small values of  $\theta$ .

We have seen that the interference phenomena arising from two sources depend on the relative phase of the waves at a given point. Furthermore, the phase difference at a given point depends on the path difference between the two waves. **The resultant light intensity at a point is proportional to the square of the resultant electric field at that point.** That is, the light intensity is proportional to  $(E_1 + E_2)^2$ . It would be incorrect to calculate the light intensity by adding the intensities of the individual waves. This procedure would give  $E_1^2 + E_2^2$ , which of course is not the same as  $(E_1 + E_2)^2$ . Note, however, that  $(E_1 + E_2)^2$  has the same *average* value as  $E_1^2 + E_2^2$  when the time average is taken over all values of the

phase difference between  $E_1$  and  $E_2$ . Hence, the law of conservation of energy is not violated.

### 37.4 PHASOR ADDITION OF WAVES

In the preceding section, we combined two waves algebraically to obtain the resultant wave amplitude at some point on a screen. Unfortunately, this analytical procedure becomes cumbersome when we must add several wave amplitudes. Because we shall eventually be interested in combining a large number of waves, we now describe a graphical procedure for this purpose.

Let us again consider a sinusoidal wave whose electric field component is given by

$$E_1 = E_0 \sin \omega t$$

where  $E_0$  is the wave amplitude and  $\omega$  is the angular frequency. This wave can be represented graphically by a phasor of magnitude  $E_0$  rotating about the origin counterclockwise with an angular frequency  $\omega$ , as shown in Figure 37.7a. Note that the phasor makes an angle  $\omega t$  with the horizontal axis. The projection of the phasor on the vertical axis represents  $E_1$ , the magnitude of the wave disturbance at some time  $t$ . Hence, as the phasor rotates in a circle, the projection  $E_1$  oscillates along the vertical axis about the origin.

Now consider a second sinusoidal wave whose electric field component is given by

$$E_2 = E_0 \sin(\omega t + \phi)$$

This wave has the same amplitude and frequency as  $E_1$ , but its phase is  $\phi$  with respect to  $E_1$ . The phasor representing  $E_2$  is shown in Figure 37.7b. We can obtain the resultant wave, which is the sum of  $E_1$  and  $E_2$ , graphically by redrawing the phasors as shown in Figure 37.7c, in which the tail of the second phasor is placed at the tip of the first. As with vector addition, the resultant phasor  $\mathbf{E}_R$  runs from the tail of the first phasor to the tip of the second. Furthermore,  $\mathbf{E}_R$  rotates along with the two individual phasors at the same angular frequency  $\omega$ . The projection of  $\mathbf{E}_R$  along the vertical axis equals the sum of the projections of the two other phasors:  $E_P = E_1 + E_2$ .

It is convenient to construct the phasors at  $t = 0$  as in Figure 37.8. From the geometry of one of the right triangles, we see that

$$\cos \alpha = \frac{E_R/2}{E_0}$$

which gives

$$E_R = 2E_0 \cos \alpha$$

Because the sum of the two opposite interior angles equals the exterior angle  $\phi$ , we see that  $\alpha = \phi/2$ ; thus,

$$E_R = 2E_0 \cos\left(\frac{\phi}{2}\right)$$

Hence, the projection of the phasor  $\mathbf{E}_R$  along the vertical axis at any time  $t$  is

$$E_P = E_R \sin\left(\omega t + \frac{\phi}{2}\right) = 2E_0 \cos\left(\frac{\phi}{2}\right) \sin\left(\omega t + \frac{\phi}{2}\right)$$

**Figure 37.7** (a) Phasor diagram for the wave disturbance  $E_1 = E_0 \sin \omega t$ . The phasor is a vector of length  $E_0$  rotating counterclockwise. (b) Phasor diagram for the wave  $E_2 = E_0 \sin(\omega t + \phi)$ . (c) The disturbance  $\mathbf{E}_R$  is the resultant phasor formed from the phasors of parts (a) and (b).

**Figure 37.8** A reconstruction of the resultant phasor  $\mathbf{E}_R$ . From the geometry, note that  $\alpha = \phi/2$ .

**Figure 37.9** The phasor  $\mathbf{E}_R$  is the resultant of four phasors of equal amplitude  $E_0$ . The phase of  $\mathbf{E}_R$  with respect to the first phasor is  $\alpha$ .

This is consistent with the result obtained algebraically, Equation 37.10. The resultant phasor has an amplitude  $2E_0 \cos(\phi/2)$  and makes an angle  $\phi/2$  with the first phasor. Furthermore, the average light intensity at point  $P$ , which varies as  $E_P^2$ , is proportional to  $\cos^2(\phi/2)$ , as described in Equation 37.11.

We can now describe how to obtain the resultant of several waves that have the same frequency:

- Represent the waves by phasors, as shown in Figure 37.9, remembering to maintain the proper phase relationship between one phasor and the next.
- The resultant phasor  $\mathbf{E}_R$  is the vector sum of the individual phasors. At each instant, the projection of  $\mathbf{E}_R$  along the vertical axis represents the time variation of the resultant wave. The phase angle  $\alpha$  of the resultant wave is the angle between  $\mathbf{E}_R$  and the first phasor. From Figure 37.9, drawn for four phasors, we see that the phasor of the resultant wave is given by the expression  $E_P = E_R \sin(\omega t + \alpha)$ .

### Phasor Diagrams for Two Coherent Sources

As an example of the phasor method, consider the interference pattern produced by two coherent sources. Figure 37.10 represents the phasor diagrams for various values of the phase difference  $\phi$  and the corresponding values of the path difference  $\delta$ , which are obtained from Equation 37.8. The light intensity at a point is a maximum when  $\mathbf{E}_R$  is a maximum; this occurs at  $\phi = 0, 2\pi, 4\pi, \dots$ . The light intensity at some point is zero when  $\mathbf{E}_R$  is zero; this occurs at  $\phi = \pi, 3\pi, 5\pi, \dots$ . These results are in complete agreement with the analytical procedure described in the preceding section.

**Figure 37.10** Phasor diagrams for a double-slit interference pattern. The resultant phasor  $\mathbf{E}_R$  is a maximum when  $\phi = 0, 2\pi, 4\pi, \dots$  and is zero when  $\phi = \pi, 3\pi, 5\pi, \dots$ .

### Three-Slit Interference Pattern

Using phasor diagrams, let us analyze the interference pattern caused by three equally spaced slits. We can express the electric field components at a point  $P$  on the screen caused by waves from the individual slits as

$$E_1 = E_0 \sin \omega t$$

$$E_2 = E_0 \sin(\omega t + \phi)$$

$$E_3 = E_0 \sin(\omega t + 2\phi)$$

where  $\phi$  is the phase difference between waves from adjacent slits. We can obtain the resultant magnitude of the electric field at point  $P$  from the phasor diagram in Figure 37.11.

The phasor diagrams for various values of  $\phi$  are shown in Figure 37.12. Note that the resultant magnitude of the electric field at  $P$  has a maximum value of  $3E_0$ , a condition that occurs when  $\phi = 0, \pm 2\pi, \pm 4\pi, \dots$ . These points are called *primary maxima*. Such primary maxima occur whenever the three phasors are aligned as shown in Figure 37.12a. We also find secondary maxima of amplitude  $E_0$  occurring between the primary maxima at points where  $\phi = \pm \pi, \pm 3\pi, \dots$ . For these points, the wave from one slit exactly cancels that from another slit (Fig. 37.12d). This means that only light from the third slit contributes to the resultant, which consequently has a total amplitude of  $E_0$ . Total destructive interference occurs whenever the three phasors form a closed triangle, as shown in Figure 37.12c. These points where  $E_R = 0$  correspond to  $\phi = \pm 2\pi/3, \pm 4\pi/3, \dots$ . You should be able to construct other phasor diagrams for values of  $\phi$  greater than  $\pi$ .

Figure 37.13 shows multiple-slit interference patterns for a number of configurations. For three slits, note that the primary maxima are nine times more intense than the secondary maxima as measured by the height of the curve. This is because the intensity varies as  $E_R^2$ . For  $N$  slits, the intensity of the primary maxima is  $N^2$  times greater than that due to a single slit. As the number of slits increases, the primary maxima increase in intensity and become narrower, while the secondary maxima decrease in intensity relative to the primary maxima. Figure 37.13 also shows that as the number of slits increases, the number of secondary maxima also increases. In fact, the number of secondary maxima is always  $N - 2$ , where  $N$  is the number of slits.

**Figure 37.11** Phasor diagram for three equally spaced slits.

**Figure 37.12** Phasor diagrams for three equally spaced slits at various values of  $\phi$ . Note from (a) that there are primary maxima of amplitude  $3E_0$  and from (d) that there are secondary maxima of amplitude  $E_0$ .

**Figure 37.13** Multiple-slit interference patterns. As  $N$ , the number of slits, is increased, the primary maxima (the tallest peaks in each graph) become narrower but remain fixed in position, and the number of secondary maxima increases. For any value of  $N$ , the decrease in intensity in maxima to the left and right of the central maximum, indicated by the blue dashed arcs, is due to diffraction, which is discussed in Chapter 38.

**Figure 37.14** Lloyd's mirror. An interference pattern is produced at point  $P$  on the screen as a result of the combination of the direct ray (blue) and the reflected ray (red). The reflected ray undergoes a phase change of  $180^\circ$ .

### Quick Quiz 37.3

Using Figure 37.13 as a model, sketch the interference pattern from six slits.

### 37.5 CHANGE OF PHASE DUE TO REFLECTION

Young's method for producing two coherent light sources involves illuminating a pair of slits with a single source. Another simple, yet ingenious, arrangement for producing an interference pattern with a single light source is known as *Lloyd's mirror* (Fig. 37.14). A light source is placed at point  $S$  close to a mirror, and a viewing screen is positioned some distance away at right angles to the mirror. Light waves can reach point  $P$  on the screen either by the direct path  $SP$  or by the path involving reflection from the mirror. The reflected ray can be treated as a ray originating from a virtual source at point  $S'$ . As a result, we can think of this arrangement as a double-slit source with the distance between

points  $S$  and  $S'$  comparable to length  $d$  in Figure 37.4. Hence, at observation points far from the source ( $L \gg d$ ), we expect waves from points  $S$  and  $S'$  to form an interference pattern just like the one we see from two real coherent sources. An interference pattern is indeed observed. However, the positions of the dark and bright fringes are reversed relative to the pattern created by two real coherent sources (Young's experiment). This is because the coherent sources at points  $S$  and  $S'$  differ in phase by  $180^\circ$ , a phase change produced by reflection.

To illustrate this further, consider point  $P'$ , the point where the mirror intersects the screen. This point is equidistant from points  $S$  and  $S'$ . If path difference alone were responsible for the phase difference, we would see a bright fringe at point  $P'$  (because the path difference is zero for this point), corresponding to the central bright fringe of the two-slit interference pattern. Instead, we observe a dark fringe at point  $P'$  because of the  $180^\circ$  phase change produced by reflection. In general,

an electromagnetic wave undergoes a phase change of  $180^\circ$  upon reflection from a medium that has a higher index of refraction than the one in which the wave is traveling.

It is useful to draw an analogy between reflected light waves and the reflections of a transverse wave pulse on a stretched string (see Section 16.6). The reflected pulse on a string undergoes a phase change of  $180^\circ$  when reflected from the boundary of a denser medium, but no phase change occurs when the pulse is reflected from the boundary of a less dense medium. Similarly, an electromagnetic wave undergoes a  $180^\circ$  phase change when reflected from a boundary leading to an optically denser medium, but no phase change occurs when the wave is reflected from a boundary leading to a less dense medium. These rules, summarized in Figure 37.15, can be deduced from Maxwell's equations, but the treatment is beyond the scope of this text.

**Figure 37.15** (a) For  $n_1 < n_2$ , a light ray traveling in medium 1 when reflected from the surface of medium 2 undergoes a  $180^\circ$  phase change. The same thing happens with a reflected pulse traveling along a string fixed at one end. (b) For  $n_1 > n_2$ , a light ray traveling in medium 1 undergoes no phase change when reflected from the surface of medium 2. The same is true of a reflected wave pulse on a string whose supported end is free to move.

### 37.6 INTERFERENCE IN THIN FILMS

**Figure 37.16** Interference in light reflected from a thin film is due to a combination of rays reflected from the upper and lower surfaces of the film.

Interference effects are commonly observed in thin films, such as thin layers of oil on water or the thin surface of a soap bubble. The varied colors observed when white light is incident on such films result from the interference of waves reflected from the two surfaces of the film.

Consider a film of uniform thickness  $t$  and index of refraction  $n$ , as shown in Figure 37.16. Let us assume that the light rays traveling in air are nearly normal to the two surfaces of the film. To determine whether the reflected rays interfere constructively or destructively, we first note the following facts:

- A wave traveling from a medium of index of refraction  $n_1$  toward a medium of index of refraction  $n_2$  undergoes a  $180^\circ$  phase change upon reflection when  $n_2 > n_1$  and undergoes no phase change if  $n_2 < n_1$ .
- The wavelength of light  $\lambda_n$  in a medium whose refraction index is  $n$  (see Section 35.5) is

$$\lambda_n = \frac{\lambda}{n} \quad (37.14)$$

where  $\lambda$  is the wavelength of the light in free space.

Let us apply these rules to the film of Figure 37.16, where  $n_{\text{film}} > n_{\text{air}}$ . Reflected ray 1, which is reflected from the upper surface (A), undergoes a phase change of  $180^\circ$  with respect to the incident wave. Reflected ray 2, which is reflected from the lower film surface (B), undergoes no phase change because it is reflected from a medium (air) that has a lower index of refraction. Therefore, ray 1 is  $180^\circ$  out of phase with ray 2, which is equivalent to a path difference of  $\lambda_n/2$ .

Interference in soap bubbles. The colors are due to interference between light rays reflected from the front and back surfaces of the thin film of soap making up the bubble. The color depends on the thickness of the film, ranging from black where the film is thinnest to red where it is thickest.

 The brilliant colors in a peacock's feathers are due to interference. The multilayer structure of the feathers causes constructive interference for certain colors, such as blue and green. The colors change as you view a peacock's feathers from different angles. Iridescent colors of butterflies and hummingbirds are the result of similar interference effects.

However, we must also consider that ray 2 travels an extra distance  $2t$  before the waves recombine in the air above surface  $A$ . If  $2t = \lambda_n/2$ , then rays 1 and 2 recombine in phase, and the result is constructive interference. In general, the condition for constructive interference in such situations is

$$2t = (m + \frac{1}{2})\lambda_n \quad m = 0, 1, 2, \dots \quad (37.15)$$

This condition takes into account two factors: (1) the difference in path length for the two rays (the term  $m\lambda_n$ ) and (2) the  $180^\circ$  phase change upon reflection (the term  $\lambda_n/2$ ). Because  $\lambda_n = \lambda/n$ , we can write Equation 37.15 as

$$2nt = (m + \frac{1}{2})\lambda \quad m = 0, 1, 2, \dots \quad (37.16)$$

If the extra distance  $2t$  traveled by ray 2 corresponds to a multiple of  $\lambda_n$ , then the two waves combine out of phase, and the result is destructive interference. The general equation for destructive interference is

$$2nt = m\lambda \quad m = 0, 1, 2, \dots \quad (37.17)$$

The foregoing conditions for constructive and destructive interference are valid when the medium above the top surface of the film is the same as the medium below the bottom surface. The medium surrounding the film may have a refractive index less than or greater than that of the film. In either case, the rays reflected from the two surfaces are out of phase by  $180^\circ$ . If the film is placed between two different media, one with  $n < n_{\text{film}}$  and the other with  $n > n_{\text{film}}$ , then the conditions for constructive and destructive interference are reversed. In this case, either there is a phase change of  $180^\circ$  for both ray 1 reflecting from surface  $A$  and ray 2 reflecting from surface  $B$ , or there is no phase change for either ray; hence, the net change in relative phase due to the reflections is zero.

### Quick Quiz 37.4

In Figure 37.17, where does the oil film thickness vary the least?

### Newton's Rings

Another method for observing interference in light waves is to place a plano-convex lens on top of a flat glass surface, as shown in Figure 37.18a. With this arrangement, the air film between the glass surfaces varies in thickness from zero at the point of contact to some value  $t$  at point  $P$ . If the radius of curvature  $R$  of the lens is much greater than the distance  $r$ , and if the system is viewed from above using light of a single wavelength  $\lambda$ , a pattern of light and dark rings is observed, as shown in Figure 37.18b. These circular fringes, discovered by Newton, are called **Newton's rings**.

The interference effect is due to the combination of ray 1, reflected from the flat plate, with ray 2, reflected from the curved surface of the lens. Ray 1 undergoes a phase change of  $180^\circ$  upon reflection (because it is reflected from a medium of higher refractive index), whereas ray 2 undergoes no phase change (because it is reflected from a medium of lower refractive index). Hence, the conditions for constructive and destructive interference are given by Equations 37.16 and 37.17, respectively, with  $n = 1$  because the film is air.

The contact point at  $O$  is dark, as seen in Figure 37.18b, because ray 1 undergoes a  $180^\circ$  phase change upon external reflection (from the flat surface); in con-

Conditions for constructive interference in thin films

Conditions for destructive interference in thin films

**Figure 37.17** A thin film of oil floating on water displays interference, as shown by the pattern of colors produced when white light is incident on the film. Variations in film thickness produce the interesting color pattern. The razor blade gives one an idea of the size of the colored bands.

**Figure 37.18** (a) The combination of rays reflected from the flat plate and the curved lens surface gives rise to an interference pattern known as Newton's rings. (b) Photograph of Newton's rings.

**Figure 37.19** This asymmetrical interference pattern indicates imperfections in the lens of a Newton's-rings apparatus.

trast, ray 2 undergoes no phase change upon internal reflection (from the curved surface).

Using the geometry shown in Figure 37.18a, we can obtain expressions for the radii of the bright and dark bands in terms of the radii of curvature  $R$  and wavelength  $\lambda$ . For example, the dark rings have radii given by the expression  $r \approx \sqrt{m\lambda R/n}$ . The details are left as a problem for you to solve (see Problem 67). We can obtain the wavelength of the light causing the interference pattern by measuring the radii of the rings, provided  $R$  is known. Conversely, we can use a known wavelength to obtain  $R$ .

One important use of Newton's rings is in the testing of optical lenses. A circular pattern like that pictured in Figure 37.18b is obtained only when the lens is ground to a perfectly symmetric curvature. Variations from such symmetry might produce a pattern like that shown in Figure 37.19. These variations indicate how the lens must be reground and repolished to remove the imperfections.

### Problem-Solving Hints

#### Thin-Film Interference

You should keep the following ideas in mind when you work thin-film interference problems:

- Identify the thin film causing the interference.
- The type of interference that occurs is determined by the phase relationship between the portion of the wave reflected at the upper surface of the film and the portion reflected at the lower surface.
- Phase differences between the two portions of the wave have two causes: (1) differences in the distances traveled by the two portions and (2) phase changes that may occur upon reflection.
- When the distance traveled and phase changes upon reflection are both taken into account, the interference is constructive if the equivalent path difference between the two waves is an integral multiple of  $\lambda$ , and it is destructive if the path difference is  $\lambda/2$ ,  $3\lambda/2$ ,  $5\lambda/2$ , and so forth.

### QuickLab

Observe the colors appearing to swirl on the surface of a soap bubble. What do you see just before a bubble bursts? Why?

**EXAMPLE 37.3** Interference in a Soap Film

Calculate the minimum thickness of a soap-bubble film ( $n = 1.33$ ) that results in constructive interference in the reflected light if the film is illuminated with light whose wavelength in free space is  $\lambda = 600$  nm.

**Solution** The minimum film thickness for constructive interference in the reflected light corresponds to  $m = 0$  in Equation 37.16. This gives  $2nt = \lambda/2$ , or

$$t = \frac{\lambda}{4n} = \frac{600 \text{ nm}}{4(1.33)} = 113 \text{ nm}$$

**Exercise** What other film thicknesses produce constructive interference?

**Answer** 338 nm, 564 nm, 789 nm, and so on.

**EXAMPLE 37.4** Nonreflective Coatings for Solar Cells

Solar cells—devices that generate electricity when exposed to sunlight—are often coated with a transparent, thin film of silicon monoxide ( $\text{SiO}$ ,  $n = 1.45$ ) to minimize reflective losses from the surface. Suppose that a silicon solar cell ( $n = 3.5$ ) is coated with a thin film of silicon monoxide for this purpose (Fig. 37.20). Determine the minimum film thickness that produces the least reflection at a wavelength of 550 nm, near the center of the visible spectrum.

**Solution** The reflected light is a minimum when rays 1 and 2 in Figure 37.20 meet the condition of destructive interference. Note that both rays undergo a  $180^\circ$  phase change upon reflection—ray 1 from the upper  $\text{SiO}$  surface and ray 2 from the lower  $\text{SiO}$  surface. The net change in phase due to reflection is therefore zero, and the condition for a reflection minimum requires a path difference of  $\lambda_n/2$ . Hence,

$2t = \lambda/2n$ , and the required thickness is

$$t = \frac{\lambda}{4n} = \frac{550 \text{ nm}}{4(1.45)} = 94.8 \text{ nm}$$

A typical uncoated solar cell has reflective losses as high as 30%; a  $\text{SiO}$  coating can reduce this value to about 10%. This significant decrease in reflective losses increases the cell's efficiency because less reflection means that more sunlight enters the silicon to create charge carriers in the cell. No coating can ever be made perfectly nonreflecting because the required thickness is wavelength-dependent and the incident light covers a wide range of wavelengths.

Glass lenses used in cameras and other optical instruments are usually coated with a transparent thin film to reduce or eliminate unwanted reflection and enhance the transmission of light through the lenses.

**Figure 37.20** Reflective losses from a silicon solar cell are minimized by coating the surface of the cell with a thin film of silicon monoxide.

This camera lens has several coatings (of different thicknesses) that minimize reflection of light waves having wavelengths near the center of the visible spectrum. As a result, the little light that is reflected by the lens has a greater proportion of the far ends of the spectrum and appears reddish-violet.

**EXAMPLE 37.5** Interference in a Wedge-Shaped Film

A thin, wedge-shaped film of refractive index  $n$  is illuminated with monochromatic light of wavelength  $\lambda$ , as illustrated in Figure 37.21a. Describe the interference pattern observed for this case.

**Solution** The interference pattern, because it is created by a thin film of variable thickness surrounded by air, is a series of alternating bright and dark parallel fringes. A dark fringe corresponding to destructive interference appears at point  $O$ , the apex, because here the upper reflected ray undergoes a  $180^\circ$  phase change while the lower one undergoes no phase change.

According to Equation 37.17, other dark minima appear when  $2nt = m\lambda$ ; thus,  $t_1 = \lambda/2n$ ,  $t_2 = \lambda/n$ ,  $t_3 = 3\lambda/2n$ , and so on. Similarly, the bright maxima appear at locations where

the thickness satisfies Equation 37.16,  $2nt = (m + \frac{1}{2})\lambda$ , corresponding to thicknesses of  $\lambda/4n$ ,  $3\lambda/4n$ ,  $5\lambda/4n$ , and so on.

If white light is used, bands of different colors are observed at different points, corresponding to the different wavelengths of light (see Fig. 37.21b). This is why we see different colors in soap bubbles.

**Figure 37.21** (a) Interference bands in reflected light can be observed by illuminating a wedge-shaped film with monochromatic light. The darker areas correspond to regions where rays tend to cancel each other because of interference effects. (b) Interference in a vertical film of variable thickness. The top of the film appears darkest where the film is thinnest.

Optional Section**37.7** THE MICHELSON INTERFEROMETER

The **interferometer**, invented by the American physicist A. A. Michelson (1852–1931), splits a light beam into two parts and then recombines the parts to form an interference pattern. The device can be used to measure wavelengths or other lengths with great precision.

A schematic diagram of the interferometer is shown in Figure 37.22. A ray of light from a monochromatic source is split into two rays by mirror  $M$ , which is inclined at  $45^\circ$  to the incident light beam. Mirror  $M$ , called a *beam splitter*, transmits half the light incident on it and reflects the rest. One ray is reflected from  $M$  vertically upward toward mirror  $M_1$ , and the second ray is transmitted horizontally through  $M$  toward mirror  $M_2$ . Hence, the two rays travel separate paths  $L_1$  and  $L_2$ . After reflecting from  $M_1$  and  $M_2$ , the two rays eventually recombine at  $M$  to produce an interference pattern, which can be viewed through a telescope. The glass plate  $P$ , equal in thickness to mirror  $M$ , is placed in the path of the horizontal ray to ensure that the two returning rays travel the same thickness of glass.

**Figure 37.22** Diagram of the Michelson interferometer. A single ray of light is split into two rays by mirror M, which is called a beam splitter. The path difference between the two rays is varied with the adjustable mirror  $M_1$ . As  $M_1$  is moved toward M, an interference pattern moves across the field of view.

The interference condition for the two rays is determined by their path length differences. When the two rays are viewed as shown, the image of  $M_2$  produced by the mirror M is at  $M_2'$ , which is nearly parallel to  $M_1$ . (Because  $M_1$  and  $M_2$  are not exactly perpendicular to each other, the image  $M_2'$  is at a slight angle to  $M_1$ .) Hence, the space between  $M_2'$  and  $M_1$  is the equivalent of a wedge-shaped air film. The effective thickness of the air film is varied by moving mirror  $M_1$  parallel to itself with a finely threaded screw adjustment. Under these conditions, the interference pattern is a series of bright and dark parallel fringes as described in Example 37.5. As  $M_1$  is moved, the fringe pattern shifts. For example, if a dark fringe appears in the field of view (corresponding to destructive interference) and  $M_1$  is then moved a distance  $\lambda/4$  toward M, the path difference changes by  $\lambda/2$  (twice the separation between  $M_1$  and  $M_2'$ ). What was a dark fringe now becomes a bright fringe. As  $M_1$  is moved an additional distance  $\lambda/4$  toward M, the bright fringe becomes a dark fringe. Thus, the fringe pattern shifts by one-half fringe each time  $M_1$  is moved a distance  $\lambda/4$ . The wavelength of light is then measured by counting the number of fringe shifts for a given displacement of  $M_1$ . If the wavelength is accurately known (as with a laser beam), mirror displacements can be measured to within a fraction of the wavelength.

### SUMMARY

**Interference** in light waves occurs whenever two or more waves overlap at a given point. A sustained interference pattern is observed if (1) the sources are coherent and (2) the sources have identical wavelengths.

In Young's double-slit experiment, two slits  $S_1$  and  $S_2$  separated by a distance  $d$  are illuminated by a single-wavelength light source. An interference pattern consisting of bright and dark fringes is observed on a viewing screen. The condition for bright fringes (**constructive interference**) is

$$d \sin \theta = m\lambda \quad m = 0, \pm 1, \pm 2, \dots \quad (37.2)$$

The condition for dark fringes (**destructive interference**) is

$$d \sin \theta = (m + \frac{1}{2})\lambda \quad m = 0, \pm 1, \pm 2, \dots \quad (37.3)$$

The number  $m$  is called the **order number** of the fringe.

The **intensity** at a point in the double-slit interference pattern is

$$I = I_{\max} \cos^2\left(\frac{\pi d \sin \theta}{\lambda}\right) \quad (37.12)$$

where  $I_{\max}$  is the maximum intensity on the screen and the expression represents the time average.

A wave traveling from a medium of index of refraction  $n_1$  toward a medium of index of refraction  $n_2$  undergoes a  $180^\circ$  phase change upon reflection when  $n_2 > n_1$  and undergoes no phase change when  $n_2 < n_1$ .

The condition for constructive interference in a film of thickness  $t$  and refractive index  $n$  surrounded by air is

$$2nt = (m + \frac{1}{2})\lambda \quad m = 0, 1, 2, \dots \quad (37.16)$$

where  $\lambda$  is the wavelength of the light in free space.

Similarly, the condition for destructive interference in a thin film is

$$2nt = m\lambda \quad m = 0, 1, 2, \dots \quad (37.17)$$

### QUESTIONS

- What is the necessary condition on the path length difference between two waves that interfere (a) constructively and (b) destructively?
- Explain why two flashlights held close together do not produce an interference pattern on a distant screen.
- If Young's double-slit experiment were performed under water, how would the observed interference pattern be affected?
- In Young's double-slit experiment, why do we use monochromatic light? If white light is used, how would the pattern change?
- Consider a dark fringe in an interference pattern, at which almost no light is arriving. Light from both slits is arriving at this point, but the waves are canceling. Where does the energy go?
- An oil film on water appears brightest at the outer regions, where it is thinnest. From this information, what can you say about the index of refraction of oil relative to that of water?
- In our discussion of thin-film interference, we looked at light *reflecting* from a thin film. Consider one light ray, the direct ray, that transmits through the film without reflecting. Consider a second ray, the reflected ray, that transmits through the first surface, reflects from the second, reflects again from the first, and then transmits out into the air, parallel to the direct ray. For normal incidence, how thick must the film be, in terms of the wavelength of light, for the outgoing rays to interfere destructively? Is it the same thickness as for reflected destructive interference?
- Suppose that you are watching television connected to an antenna rather than a cable system. If an airplane flies near your location, you may notice wavering ghost images in the television picture. What might cause this?
- If we are to observe interference in a thin film, why must the film not be very thick (on the order of a few wavelengths)?
- A lens with outer radius of curvature  $R$  and index of re-

fraction  $n$  rests on a flat glass plate, and the combination is illuminated with white light from above. Is there a dark spot or a light spot at the center of the lens? What does it mean if the observed rings are noncircular?

- Why is the lens on a high-quality camera coated with a thin film?
- Why is it so much easier to perform interference experiments with a laser than with an ordinary light source?

### Section 37.1 Conditions for Interference

#### Section 37.2 Young's Double-Slit Experiment

- A laser beam ( $\lambda = 632.8 \text{ nm}$ ) is incident on two slits  $0.200 \text{ mm}$  apart. How far apart are the bright interference fringes on a screen  $5.00 \text{ m}$  away from the slits?
- A Young's interference experiment is performed with monochromatic light. The separation between the slits is  $0.500 \text{ mm}$ , and the interference pattern on a screen  $3.30 \text{ m}$  away shows the first maximum  $3.40 \text{ mm}$  from the center of the pattern. What is the wavelength?
- Two radio antennas separated by  $300 \text{ m}$  as shown in Figure P37.3 simultaneously broadcast identical signals at the same wavelength. A radio in a car traveling due north receives the signals. (a) If the car is at the position of the second maximum, what is the wavelength of the signals? (b) How much farther must the car travel to encounter the next minimum in reception? (*Note:* Do not use the small-angle approximation in this problem.)

Figure P37.3

- In a location where the speed of sound is  $354 \text{ m/s}$ , a  $2000\text{-Hz}$  sound wave impinges on two slits  $30.0 \text{ cm}$  apart. (a) At what angle is the first maximum located? (b) If the sound wave is replaced by  $3.00\text{-cm}$  microwaves, what slit separation gives the same angle for the first maximum? (c) If the slit separation is  $1.00 \mu\text{m}$ , what frequency of light gives the same first maximum angle?

- Young's double-slit experiment is performed with  $589\text{-nm}$  light and a slit-to-screen distance of  $2.00 \text{ m}$ . The tenth interference minimum is observed  $7.26 \text{ mm}$  from the central maximum. Determine the spacing of the slits.
- The two speakers of a boom box are  $35.0 \text{ cm}$  apart. A single oscillator makes the speakers vibrate in phase at a frequency of  $2.00 \text{ kHz}$ . At what angles, measured from the perpendicular bisector of the line joining the speakers, would a distant observer hear maximum sound intensity? minimum sound intensity? (Take the speed of sound as  $340 \text{ m/s}$ .)
- A pair of narrow, parallel slits separated by  $0.250 \text{ mm}$  are illuminated by green light ( $\lambda = 546.1 \text{ nm}$ ). The interference pattern is observed on a screen  $1.20 \text{ m}$  away from the plane of the slits. Calculate the distance (a) from the central maximum to the first bright region on either side of the central maximum and (b) between the first and second dark bands.
- Light with a wavelength of  $442 \text{ nm}$  passes through a double-slit system that has a slit separation  $d = 0.400 \text{ mm}$ . Determine how far away a screen must be placed so that a dark fringe appears directly opposite both slits, with just one bright fringe between them.
- A riverside warehouse has two open doors, as illustrated in Figure P37.9. Its walls are lined with sound-absorbing material. A boat on the river sounds its horn. To person A, the sound is loud and clear. To person B, the sound is barely audible. The principal wavelength of the sound waves is  $3.00 \text{ m}$ . Assuming that person B is at the position of the first minimum, determine the distance between the doors, center to center.

Figure P37.9

10. Two slits are separated by 0.320 mm. A beam of 500-nm light strikes the slits, producing an interference pattern. Determine the number of maxima observed in the angular range  $-30.0^\circ < \theta < 30.0^\circ$ .

11. In Figure 37.4 let  $L = 1.20$  m and  $d = 0.120$  mm, and assume that the slit system is illuminated with monochromatic 500-nm light. Calculate the phase difference between the two wavefronts arriving at point  $P$  when (a)  $\theta = 0.500^\circ$  and (b)  $y = 5.00$  mm. (c) What is the value of  $\theta$  for which the phase difference is 0.333 rad? (d) What is the value of  $\theta$  for which the path difference is  $\lambda/4$ ?

12. Coherent light rays of wavelength  $\lambda$  strike a pair of slits separated by distance  $d$  at an angle of  $\theta_1$ , as shown in Figure P37.12. If an interference maximum is formed at an angle of  $\theta_2$  a great distance from the slits, show that  $d(\sin \theta_2 - \sin \theta_1) = m\lambda$ , where  $m$  is an integer.

Figure P37.12

13. In the double-slit arrangement of Figure 37.4,  $d = 0.150$  mm,  $L = 140$  cm,  $\lambda = 643$  nm, and  $y = 1.80$  cm. (a) What is the path difference  $\delta$  for the rays from the two slits arriving at point  $P$ ? (b) Express this path difference in terms of  $\lambda$ . (c) Does point  $P$  correspond to a maximum, a minimum, or an intermediate condition?

### Section 37.3 Intensity Distribution of the Double-Slit Interference Pattern

14. The intensity on the screen at a certain point in a double-slit interference pattern is 64.0% of the maximum value. (a) What minimum phase difference (in radians) between sources produces this result? (b) Express this phase difference as a path difference for 486.1-nm light.

WEB 15. In Figure 37.4, let  $L = 120$  cm and  $d = 0.250$  cm. The slits are illuminated with coherent 600-nm light. Calculate the distance  $y$  above the central maximum for which the average intensity on the screen is 75.0% of the maximum.

16. Two slits are separated by 0.180 mm. An interference pattern is formed on a screen 80.0 cm away by 656.3-nm light. Calculate the fraction of the maximum intensity 0.600 cm above the central maximum.

17. Two narrow parallel slits separated by 0.850 mm are illuminated by 600-nm light, and the viewing screen is 2.80 m away from the slits. (a) What is the phase difference between the two interfering waves on a screen at a point 2.50 mm from the central bright fringe? (b) What is the ratio of the intensity at this point to the intensity at the center of a bright fringe?

18. Monochromatic coherent light of amplitude  $E_0$  and angular frequency  $\omega$  passes through three parallel slits each separated by a distance  $d$  from its neighbor. (a) Show that the time-averaged intensity as a function of the angle  $\theta$  is

$$I(\theta) = I_{\max} \left[ 1 + 2 \cos \left( \frac{2\pi d \sin \theta}{\lambda} \right) \right]^2$$

(b) Determine the ratio of the intensities of the primary and secondary maxima.

### Section 37.4 Phasor Addition of Waves

19. Marie Cornu invented phasors in about 1880. This problem helps you to see their utility. Find the amplitude and phase constant of the sum of two waves represented by the expressions

$$E_1 = (12.0 \text{ kN/C}) \sin(15x - 4.5t)$$

and

$$E_2 = (12.0 \text{ kN/C}) \sin(15x - 4.5t + 70^\circ)$$

(a) by using a trigonometric identity (see Appendix B) and (b) by representing the waves by phasors. (c) Find the amplitude and phase constant of the sum of the three waves represented by

$$E_1 = (12.0 \text{ kN/C}) \sin(15x - 4.5t + 70^\circ)$$

$$E_2 = (15.5 \text{ kN/C}) \sin(15x - 4.5t - 80^\circ)$$

and

$$E_3 = (17.0 \text{ kN/C}) \sin(15x - 4.5t + 160^\circ)$$

20. The electric fields from three coherent sources are described by  $E_1 = E_0 \sin \omega t$ ,  $E_2 = E_0 \sin(\omega t + \phi)$ , and  $E_3 = E_0 \sin(\omega t + 2\phi)$ . Let the resultant field be represented by  $E_P = E_R \sin(\omega t + \alpha)$ . Use phasors to find  $E_R$  and  $\alpha$  when (a)  $\phi = 20.0^\circ$ , (b)  $\phi = 60.0^\circ$ , and (c)  $\phi = 120^\circ$ . (d) Repeat when  $\phi = (3\pi/2)$  rad.

WEB 21. Determine the resultant of the two waves  $E_1 = 6.0 \sin(100\pi t)$  and  $E_2 = 8.0 \sin(100\pi t + \pi/2)$ .

22. Suppose that the slit openings in a Young's double-slit experiment have different sizes so that the electric fields and the intensities from each slit are different. If  $E_1 = E_{01} \sin(\omega t)$  and  $E_2 = E_{02} \sin(\omega t + \phi)$ , show that the resultant electric field is  $E = E_0 \sin(\omega t + \theta)$ , where

$$E_0 = \sqrt{E_{01}^2 + E_{02}^2 + 2E_{01}E_{02} \cos \phi}$$

and

$$\sin \theta = \frac{E_{02} \sin \phi}{E_0}$$

23. Use phasors to find the resultant (magnitude and phase angle) of two fields represented by  $E_1 = 12 \sin \omega t$  and  $E_2 = 18 \sin(\omega t + 60^\circ)$ . (Note that in this case the amplitudes of the two fields are unequal.)
24. Two coherent waves are described by the expressions

$$E_1 = E_0 \sin\left(\frac{2\pi x_1}{\lambda} - 2\pi ft + \frac{\pi}{6}\right)$$

$$E_2 = E_0 \sin\left(\frac{2\pi x_2}{\lambda} - 2\pi ft + \frac{\pi}{8}\right)$$

Determine the relationship between  $x_1$  and  $x_2$  that produces constructive interference when the two waves are superposed.

25. When illuminated, four equally spaced parallel slits act as multiple coherent sources, each differing in phase from the adjacent one by an angle  $\phi$ . Use a phasor diagram to determine the smallest value of  $\phi$  for which the resultant of the four waves (assumed to be of equal amplitude) is zero.
26. Sketch a phasor diagram to illustrate the resultant of  $E_1 = E_{01} \sin \omega t$  and  $E_2 = E_{02} \sin(\omega t + \phi)$ , where  $E_{02} = 1.50E_{01}$  and  $\pi/6 \leq \phi \leq \pi/3$ . Use the sketch and the law of cosines to show that, for two coherent waves, the resultant intensity can be written in the form  $I_R = I_1 + I_2 + 2\sqrt{I_1 I_2} \cos \phi$ .
27. Consider  $N$  coherent sources described by  $E_1 = E_0 \sin(\omega t + \phi)$ ,  $E_2 = E_0 \sin(\omega t + 2\phi)$ ,  $E_3 = E_0 \sin(\omega t + 3\phi)$ , . . . ,  $E_N = E_0 \sin(\omega t + N\phi)$ . Find the minimum value of  $\phi$  for which  $E_R = E_1 + E_2 + E_3 + \dots + E_N$  is zero.

### Section 37.5 Change of Phase Due to Reflection

### Section 37.6 Interference in Thin Films

28. A soap bubble ( $n = 1.33$ ) is floating in air. If the thickness of the bubble wall is 115 nm, what is the wavelength of the light that is most strongly reflected?
29. An oil film ( $n = 1.45$ ) floating on water is illuminated by white light at normal incidence. The film is 280 nm thick. Find (a) the dominant observed color in the reflected light and (b) the dominant color in the transmitted light. Explain your reasoning.
30. A thin film of oil ( $n = 1.25$ ) is located on a smooth, wet pavement. When viewed perpendicular to the pavement, the film appears to be predominantly red (640 nm) and has no blue color (512 nm). How thick is the oil film?
31. A possible means for making an airplane invisible to radar is to coat the plane with an antireflective polymer. If radar waves have a wavelength of 3.00 cm and the index of refraction of the polymer is  $n = 1.50$ , how thick would you make the coating?
32. A material having an index of refraction of 1.30 is used

to coat a piece of glass ( $n = 1.50$ ). What should be the minimum thickness of this film if it is to minimize reflection of 500-nm light?

33. A film of  $\text{MgF}_2$  ( $n = 1.38$ ) having a thickness of  $1.00 \times 10^{-5}$  cm is used to coat a camera lens. Are any wavelengths in the visible spectrum intensified in the reflected light?
34. Astronomers observe the chromosphere of the Sun with a filter that passes the red hydrogen spectral line of wavelength 656.3 nm, called the  $H_\alpha$  line. The filter consists of a transparent dielectric of thickness  $d$  held between two partially aluminized glass plates. The filter is held at a constant temperature. (a) Find the minimum value of  $d$  that produces maximum transmission of perpendicular  $H_\alpha$  light, if the dielectric has an index of refraction of 1.378. (b) Assume that the temperature of the filter increases above its normal value and that its index of refraction does not change significantly. What happens to the transmitted wavelength? (c) The dielectric will also pass what near-visible wavelength? One of the glass plates is colored red to absorb this light.
35. A beam of 580-nm light passes through two closely spaced glass plates, as shown in Figure P37.35. For what minimum nonzero value of the plate separation  $d$  is the transmitted light bright?

Figure P37.35

36. When a liquid is introduced into the air space between the lens and the plate in a Newton's-rings apparatus, the diameter of the tenth ring changes from 1.50 to 1.31 cm. Find the index of refraction of the liquid.
- WEB 37. An air wedge is formed between two glass plates separated at one edge by a very fine wire, as shown in Figure P37.37. When the wedge is illuminated from above by 600-nm light, 30 dark fringes are observed. Calculate the radius of the wire.

Figure P37.37 Problems 37 and 38.

38. Two rectangular flat glass plates ( $n = 1.52$ ) are in contact along one end and separated along the other end by a sheet of paper  $4.00 \times 10^{-3}$  cm thick (see Fig. P37.37). The top plate is illuminated by monochromatic light ( $\lambda = 546.1$  nm). Calculate the number of dark parallel bands crossing the top plate (include the dark band at zero thickness along the edge of contact between the two plates).
39. Two glass plates 10.0 cm long are in contact at one end and separated at the other end by a thread 0.050 0 mm in diameter. Light containing the two wavelengths 400 nm and 600 nm is incident perpendicularly. At what distance from the contact point is the next dark fringe?

(Optional)

### Section 37.7 The Michelson Interferometer

40. Light of wavelength 550.5 nm is used to calibrate a Michelson interferometer, and mirror  $M_1$  is moved 0.180 mm. How many dark fringes are counted?
41. Mirror  $M_1$  in Figure 37.22 is displaced a distance  $\Delta L$ . During this displacement, 250 fringe reversals (formation of successive dark or bright bands) are counted. The light being used has a wavelength of 632.8 nm. Calculate the displacement  $\Delta L$ .
42. Monochromatic light is beamed into a Michelson interferometer. The movable mirror is displaced 0.382 mm; this causes the interferometer pattern to reproduce itself 1 700 times. Determine the wavelength and the color of the light.
43. One leg of a Michelson interferometer contains an evacuated cylinder 3.00 cm long having glass plates on each end. A gas is slowly leaked into the cylinder until a pressure of 1 atm is reached. If 35 bright fringes pass on the screen when light of wavelength 633 nm is used, what is the index of refraction of the gas?
44. One leg of a Michelson interferometer contains an evacuated cylinder of length  $L$  having glass plates on each end. A gas is slowly leaked into the cylinder until a pressure of 1 atm is reached. If  $N$  bright fringes pass on the screen when light of wavelength  $\lambda$  is used, what is the index of refraction of the gas?

### ADDITIONAL PROBLEMS

45. One radio transmitter  $A$  operating at 60.0 MHz is 10.0 m from another similar transmitter  $B$  that is  $180^\circ$  out of phase with transmitter  $A$ . How far must an observer move from transmitter  $A$  toward transmitter  $B$  along the line connecting  $A$  and  $B$  to reach the nearest point where the two beams are in phase?
46. Raise your hand and hold it flat. Think of the space between your index finger and your middle finger as one slit, and think of the space between middle finger and ring finger as a second slit. (a) Consider the interference resulting from sending coherent visible light perpendicularly through this pair of openings. Compute an order-of-magnitude estimate for the angle between adja-

cent zones of constructive interference. (b) To make the angles in the interference pattern easy to measure with a plastic protractor, you should use an electromagnetic wave with frequency of what order of magnitude? How is this wave classified on the electromagnetic spectrum?

47. In a Young's double-slit experiment using light of wavelength  $\lambda$ , a thin piece of Plexiglas having index of refraction  $n$  covers one of the slits. If the center point on the screen is a dark spot instead of a bright spot, what is the minimum thickness of the Plexiglas?
48. **Review Problem.** A flat piece of glass is held stationary and horizontal above the flat top end of a 10.0-cm-long vertical metal rod that has its lower end rigidly fixed. The thin film of air between the rod and glass is observed to be bright by reflected light when it is illuminated by light of wavelength 500 nm. As the temperature is slowly increased by  $25.0^\circ\text{C}$ , the film changes from bright to dark and back to bright 200 times. What is the coefficient of linear expansion of the metal?
49. A certain crude oil has an index of refraction of 1.25. A ship dumps  $1.00 \text{ m}^3$  of this oil into the ocean, and the oil spreads into a thin uniform slick. If the film produces a first-order maximum of light of wavelength 500 nm normally incident on it, how much surface area of the ocean does the oil slick cover? Assume that the index of refraction of the ocean water is 1.34.
50. Interference effects are produced at point  $P$  on a screen as a result of direct rays from a 500-nm source and reflected rays off the mirror, as shown in Figure P37.50. If the source is 100 m to the left of the screen and 1.00 cm above the mirror, find the distance  $y$  (in millimeters) to the first dark band above the mirror.

Figure P37.50

51. Astronomers observed a 60.0-MHz radio source both directly and by reflection from the sea. If the receiving dish is 20.0 m above sea level, what is the angle of the radio source above the horizon at first maximum?
52. The waves from a radio station can reach a home receiver by two paths. One is a straight-line path from transmitter to home, a distance of 30.0 km. The second path is by reflection from the ionosphere (a layer of ionized air molecules high in the atmosphere). Assume that this reflection takes place at a point midway between the receiver and the transmitter. The wavelength broadcast by the radio station is 350 m. Find the minimum height of the ionospheric layer that produces destructive inter-

ference between the direct and reflected beams. (Assume that no phase changes occur on reflection.)

53. Measurements are made of the intensity distribution in a Young's interference pattern (see Fig. 37.6). At a particular value of  $y$ , it is found that  $I/I_{\max} = 0.810$  when 600-nm light is used. What wavelength of light should be used if the relative intensity at the same location is to be reduced to 64.0%?
54. In a Young's interference experiment, the two slits are separated by 0.150 mm, and the incident light includes light of wavelengths  $\lambda_1 = 540$  nm and  $\lambda_2 = 450$  nm. The overlapping interference patterns are formed on a screen 1.40 m from the slits. Calculate the minimum distance from the center of the screen to the point where a bright line of the  $\lambda_1$  light coincides with a bright line of the  $\lambda_2$  light.
55. An air wedge is formed between two glass plates in contact along one edge and slightly separated at the opposite edge. When the plates are illuminated with monochromatic light from above, the reflected light has 85 dark fringes. Calculate the number of dark fringes that would appear if water ( $n = 1.33$ ) were to replace the air between the plates.
56. Our discussion of the techniques for determining constructive and destructive interference by reflection from a thin film in air has been confined to rays striking the film at nearly normal incidence. Assume that a ray is incident at an angle of  $30.0^\circ$  (relative to the normal) on a film with an index of refraction of 1.38. Calculate the minimum thickness for constructive interference if the light is sodium light with a wavelength of 590 nm.
57. The condition for constructive interference by reflection from a thin film in air as developed in Section 37.6 assumes nearly normal incidence. Show that if the light is incident on the film at a nonzero angle  $\phi_1$  (relative to the normal), then the condition for constructive interference is  $2nt \cos \theta_2 = (m + \frac{1}{2})\lambda$ , where  $\theta_2$  is the angle of refraction.
58. (a) Both sides of a uniform film that has index of refraction  $n$  and thickness  $d$  are in contact with air. For normal incidence of light, an intensity minimum is observed in the reflected light at  $\lambda_2$ , and an intensity maximum is observed at  $\lambda_1$ , where  $\lambda_1 > \lambda_2$ . If no intensity minima are observed between  $\lambda_1$  and  $\lambda_2$ , show that the integer  $m$  in Equations 37.16 and 37.17 is given by  $m = \lambda_1/2(\lambda_1 - \lambda_2)$ . (b) Determine the thickness of the film if  $n = 1.40$ ,  $\lambda_1 = 500$  nm, and  $\lambda_2 = 370$  nm.
59. Figure P37.59 shows a radio wave transmitter and a receiver separated by a distance  $d$  and located a distance  $h$  above the ground. The receiver can receive signals both directly from the transmitter and indirectly from signals that reflect off the ground. Assume that the ground is level between the transmitter and receiver and that a  $180^\circ$  phase shift occurs upon reflection. Determine the longest wavelengths that interfere (a) constructively and (b) destructively.

Figure P37.59

60. Consider the double-slit arrangement shown in Figure P37.60, where the separation  $d$  is 0.300 mm and the distance  $L$  is 1.00 m. A sheet of transparent plastic ( $n = 1.50$ ) 0.050 0 mm thick (about the thickness of this page) is placed over the upper slit. As a result, the central maximum of the interference pattern moves upward a distance  $y'$ . Find  $y'$ .

Figure P37.60 Problems 60 and 61.

61. Consider the double-slit arrangement shown in Figure P37.60, where the slit separation is  $d$  and the slit to screen distance is  $L$ . A sheet of transparent plastic having an index of refraction  $n$  and thickness  $t$  is placed over the upper slit. As a result, the central maximum of the interference pattern moves upward a distance  $y'$ . Find  $y'$ .
62. Waves broadcast by a 1 500-kHz radio station arrive at a home receiver by two paths. One is a direct path, and the other is from reflection off an airplane directly above the receiver. The airplane is approximately 100 m above the receiver, and the direct distance from station to home is 20.0 km. What is the precise height of the airplane if destructive interference is occurring? (Assume that no phase change occurs on reflection.)
63. In a Newton's-rings experiment, a plano-convex glass ( $n = 1.52$ ) lens having a diameter of 10.0 cm is placed on a flat plate, as shown in Figure 37.18a. When 650-nm light is incident normally, 55 bright rings are observed, with the last ring right on the edge of the lens. (a) What is the radius of curvature of the convex surface of the lens? (b) What is the focal length of the lens?
64. A piece of transparent material having an index of re-

fraction  $n$  is cut into the shape of a wedge, as shown in Figure P37.64. The angle of the wedge is small, and monochromatic light of wavelength  $\lambda$  is normally incident from above. If the height of the wedge is  $h$  and the width is  $\ell$ , show that bright fringes occur at the positions  $x = \lambda \ell (m + \frac{1}{2}) / 2hn$  and that dark fringes occur at the positions  $x = \lambda \ell m / 2hn$ , where  $m = 0, 1, 2, \dots$  and  $x$  is measured as shown.

Figure P37.64

65. Use phasor addition to find the resultant amplitude and phase constant when the following three harmonic functions are combined:  $E_1 = \sin(\omega t + \pi/6)$ ,  $E_2 = 3.0 \sin(\omega t + 7\pi/2)$ ,  $E_3 = 6.0 \sin(\omega t + 4\pi/3)$ .
66. A plano-convex lens having a radius of curvature of  $r = 4.00$  m is placed on a concave reflecting surface whose radius of curvature is  $R = 12.0$  m, as shown in Figure P37.66. Determine the radius of the 100th bright ring if 500-nm light is incident normal to the flat surface of the lens.
67. A plano-convex lens has index of refraction  $n$ . The curved side of the lens has radius of curvature  $R$  and rests on a flat glass surface of the same index of refraction, with a film of index  $n_{\text{film}}$  between them. The lens is illuminated from above by light of wavelength  $\lambda$ . Show that the dark Newton's rings have radii given approximately by

Figure P37.66

$$r \cong \sqrt{m\lambda R / n_{\text{film}}}$$

- where  $m$  is an integer and  $r$  is much less than  $R$ .
68. A soap film ( $n = 1.33$ ) is contained within a rectangular wire frame. The frame is held vertically so that the film drains downward and becomes thicker at the bottom than at the top, where the thickness is essentially zero. The film is viewed in white light with near-normal incidence, and the first violet ( $\lambda = 420$  nm) interference band is observed 3.00 cm from the top edge of the film. (a) Locate the first red ( $\lambda = 680$  nm) interference band. (b) Determine the film thickness at the positions of the violet and red bands. (c) What is the wedge angle of the film?
69. Interference fringes are produced using Lloyd's mirror and a 606-nm source, as shown in Figure 37.14. Fringes 1.20 mm apart are formed on a screen 2.00 m from the real source S. Find the vertical distance  $h$  of the source above the reflecting surface.
70. Slit 1 of a double slit is wider than slit 2, so that the light from slit 1 has an amplitude 3.00 times that of the light from slit 2. Show that Equation 37.11 is replaced by the equation  $I = (4I_{\text{max}}/9)(1 + 3 \cos^2 \phi/2)$  for this situation.

## ANSWERS TO QUICK QUIZZES

- 37.1 Bands of light along the orange lines interspersed with dark bands running along the dashed black lines.
- 37.2 At location B. At A, which is on a line of constructive interference, the water surface undulates so much that you probably could not determine the depth. Because B is on a line of destructive interference, the water level does not change, and you should be able to read the ruler easily.
- 37.3 The graph is shown in Figure QQA37.1. The width of the primary maxima is slightly narrower than the  $N = 5$  primary width but wider than the  $N = 10$  primary width. Because  $N = 6$ , the secondary maxima are  $\frac{1}{36}$  as intense as the primary maxima.
- 37.4 The greater the variation in thickness, the narrower the bands of color (like the lines on a topographic map). The widest bands are the gold ones along the left edge

of the photograph and at the bottom right corner of the razor blade. Thus, the thickness of the oil film changes most slowly with position in these areas.

Figure QQA37.1

## PUZZLER

At sunset, the sky is ablaze with brilliant reds, pinks, and oranges. Yet, we wouldn't be able to see this sunset were it not for the fact that someone else is simultaneously seeing a blue sky. What causes the beautiful colors of a sunset, and why must the sky be blue somewhere else for us to enjoy one? (© W. A. Banaszewski/Visuals Unlimited)

## Diffraction and Polarization

### Chapter Outline

- 38.1** Introduction to Diffraction
- 38.2** Diffraction from Narrow Slits
- 38.3** Resolution of Single-Slit and Circular Apertures
- 38.4** The Diffraction Grating
- 38.5** (Optional) Diffraction of X-Rays by Crystals
- 38.6** Polarization of Light Waves

**Figure 38.1** (a) If light waves did not spread out after passing through the slits, no interference would occur. (b) The light waves from the two slits overlap as they spread out, filling what we expect to be shadowed regions with light and producing interference fringes.

When light waves pass through a small aperture, an interference pattern is observed rather than a sharp spot of light. This behavior indicates that light, once it has passed through the aperture, spreads beyond the narrow path defined by the aperture into regions that would be in shadow if light traveled in straight lines. Other waves, such as sound waves and water waves, also have this property of spreading when passing through apertures or by sharp edges. This phenomenon, known as diffraction, can be described only with a wave model for light.

In Chapter 34, we learned that electromagnetic waves are transverse. That is, the electric and magnetic field vectors are perpendicular to the direction of wave propagation. In this chapter, we see that under certain conditions these transverse waves can be polarized in various ways.

### 38.1 INTRODUCTION TO DIFFRACTION

In Section 37.2 we learned that an interference pattern is observed on a viewing screen when two slits are illuminated by a single-wavelength light source. If the light traveled only in its original direction after passing through the slits, as shown in Figure 38.1a, the waves would not overlap and no interference pattern would be seen. Instead, Huygens's principle requires that the waves spread out from the slits as shown in Figure 38.1b. In other words, the light deviates from a straight-line path and enters the region that would otherwise be shadowed. As noted in Section 35.1, this divergence of light from its initial line of travel is called **diffraction**.

In general, diffraction occurs when waves pass through small openings, around obstacles, or past sharp edges, as shown in Figure 38.2. When an opaque object is placed between a point source of light and a screen, no sharp boundary exists on the screen between a shadowed region and an illuminated region. The illuminated region above the shadow of the object contains alternating light and dark fringes. Such a display is called a **diffraction pattern**.

Figure 38.3 shows a diffraction pattern associated with the shadow of a penny. A bright spot occurs at the center, and circular fringes extend outward from the shadow's edge. We can explain the central bright spot only by using the wave the-

**Figure 38.2** Light from a small source passes by the edge of an opaque object. We might expect no light to appear on the screen below the position of the edge of the object. In reality, light bends around the top edge of the object and enters this region. Because of these effects, a diffraction pattern consisting of bright and dark fringes appears in the region above the edge of the object.

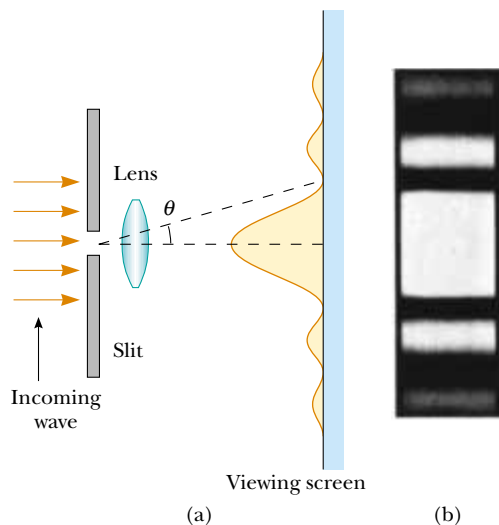

**Figure 38.3** Diffraction pattern created by the illumination of a penny, with the penny positioned midway between screen and light source.

ory of light, which predicts constructive interference at this point. From the viewpoint of geometric optics (in which light is viewed as rays traveling in straight lines), we expect the center of the shadow to be dark because that part of the viewing screen is completely shielded by the penny.

It is interesting to point out an historical incident that occurred shortly before the central bright spot was first observed. One of the supporters of geometric optics, Simeon Poisson, argued that if Augustin Fresnel's wave theory of light were valid, then a central bright spot should be observed in the shadow of a circular object illuminated by a point source of light. To Poisson's astonishment, the spot was observed by Dominique Arago shortly thereafter. Thus, Poisson's prediction reinforced the wave theory rather than disproving it.

In this chapter we restrict our attention to **Fraunhofer diffraction**, which occurs, for example, when all the rays passing through a narrow slit are approximately parallel to one another. This can be achieved experimentally either by placing the screen far from the opening used to create the diffraction or by using a converging lens to focus the rays once they pass through the opening, as shown in Figure 38.4a. A bright fringe is observed along the axis at  $\theta = 0$ , with alternating dark and bright fringes occurring on either side of the central bright one. Figure 38.4b is a photograph of a single-slit Fraunhofer diffraction pattern.

**Figure 38.4** (a) Fraunhofer diffraction pattern of a single slit. The pattern consists of a central bright fringe flanked by much weaker maxima alternating with dark fringes (drawing not to scale). (b) Photograph of a single-slit Fraunhofer diffraction pattern.

### 38.2 DIFFRACTION FROM NARROW SLITS

Until now, we have assumed that slits are point sources of light. In this section, we abandon that assumption and see how the finite width of slits is the basis for understanding Fraunhofer diffraction.

We can deduce some important features of this phenomenon by examining waves coming from various portions of the slit, as shown in Figure 38.5. According to Huygens's principle, **each portion of the slit acts as a source of light waves.** Hence, light from one portion of the slit can interfere with light from another portion, and the resultant light intensity on a viewing screen depends on the direction  $\theta$ .

**Figure 38.5** Diffraction of light by a narrow slit of width  $a$ . Each portion of the slit acts as a point source of light waves. The path difference between rays 1 and 3 or between rays 2 and 4 is  $(a/2)\sin\theta$  (drawing not to scale).

To analyze the diffraction pattern, it is convenient to divide the slit into two halves, as shown in Figure 38.5. Keeping in mind that all the waves are in phase as they leave the slit, consider rays 1 and 3. As these two rays travel toward a viewing screen far to the right of the figure, ray 1 travels farther than ray 3 by an amount equal to the path difference  $(a/2)\sin\theta$ , where  $a$  is the width of the slit. Similarly, the path difference between rays 2 and 4 is also  $(a/2)\sin\theta$ . If this path difference is exactly half a wavelength (corresponding to a phase difference of  $180^\circ$ ), then the two waves cancel each other and destructive interference results. This is true for any two rays that originate at points separated by half the slit width because the phase difference between two such points is  $180^\circ$ . Therefore, waves from the upper half of the slit interfere destructively with waves from the lower half when

$$\frac{a}{2}\sin\theta = \frac{\lambda}{2}$$

or when

$$\sin\theta = \frac{\lambda}{a}$$

If we divide the slit into four equal parts and use similar reasoning, we find that the viewing screen is also dark when

$$\sin\theta = \frac{2\lambda}{a}$$

Likewise, we can divide the slit into six equal parts and show that darkness occurs on the screen when

$$\sin\theta = \frac{3\lambda}{a}$$

Therefore, the general condition for destructive interference is

Condition for destructive interference

$$\sin\theta = m\frac{\lambda}{a} \quad m = \pm 1, \pm 2, \pm 3, \dots \quad (38.1)$$

This equation gives the values of  $\theta$  for which the diffraction pattern has zero light intensity—that is, when a dark fringe is formed. However, it tells us nothing about the variation in light intensity along the screen. The general features of the intensity distribution are shown in Figure 38.6. A broad central bright fringe is ob-

**Figure 38.6** Intensity distribution for a Fraunhofer diffraction pattern from a single slit of width  $a$ . The positions of two minima on each side of the central maximum are labeled (drawing not to scale).

The diffraction pattern that appears on a screen when light passes through a narrow vertical slit. The pattern consists of a broad central bright fringe and a series of less intense and narrower side bright fringes.

served; this fringe is flanked by much weaker bright fringes alternating with dark fringes. The various dark fringes occur at the values of  $\theta$  that satisfy Equation 38.1. Each bright-fringe peak lies approximately halfway between its bordering dark-fringe minima. Note that the central bright maximum is twice as wide as the secondary maxima.

### Quick Quiz 38.1

If the door to an adjoining room is slightly ajar, why is it that you can hear sounds from the room but cannot see much of what is happening in the room?

### EXAMPLE 38.1 Where Are the Dark Fringes?

Light of wavelength 580 nm is incident on a slit having a width of 0.300 mm. The viewing screen is 2.00 m from the slit. Find the positions of the first dark fringes and the width of the central bright fringe.

**Solution** The two dark fringes that flank the central bright fringe correspond to  $m = \pm 1$  in Equation 38.1. Hence, we find that

$$\sin\theta = \pm \frac{\lambda}{a} = \pm \frac{5.80 \times 10^{-7} \text{ m}}{0.300 \times 10^{-3} \text{ m}} = \pm 1.93 \times 10^{-3}$$

From the triangle in Figure 38.6, note that  $\tan\theta = y_1/L$ . Because  $\theta$  is very small, we can use the approximation  $\sin\theta \approx \tan\theta$ ; thus,  $\sin\theta \approx y_1/L$ . Therefore, the positions of the first minima measured from the central axis are given by

$$y_1 \approx L \sin\theta = \pm L \frac{\lambda}{a} = \pm 3.87 \times 10^{-3} \text{ m}$$

The positive and negative signs correspond to the dark fringes on either side of the central bright fringe. Hence, the width of the central bright fringe is equal to  $2|y_1| = 7.74 \times 10^{-3} \text{ m} = 7.74 \text{ mm}$ . Note that this value is much greater than the width of the slit. However, as the slit width is increased, the diffraction pattern narrows, corresponding to smaller values of  $\theta$ . In fact, for large values of  $a$ , the various maxima and minima are so closely spaced that only a large central bright area resembling the geometric image of the slit is observed. This is of great importance in the design of lenses used in telescopes, microscopes, and other optical instruments.

**Exercise** Determine the width of the first-order ( $m = 1$ ) bright fringe.

**Answer** 3.87 mm.

### Intensity of Single-Slit Diffraction Patterns

We can use phasors to determine the light intensity distribution for a single-slit diffraction pattern. Imagine a slit divided into a large number of small zones, each of width  $\Delta y$  as shown in Figure 38.7. Each zone acts as a source of coherent radiation,

**Figure 38.7** Fraunhofer diffraction by a single slit. The light intensity at point  $P$  is the resultant of all the incremental electric field magnitudes from zones of width  $\Delta y$ .

### QuickLab

Make a V with your index and middle fingers. Hold your hand up very close to your eye so that you are looking between your two fingers toward a bright area. Now bring the fingers together until there is only a very tiny slit between them. You should be able to see a series of parallel lines. Although the lines appear to be located in the narrow space between your fingers, what you are actually seeing is a diffraction pattern cast upon your retina.

and each contributes an incremental electric field of magnitude  $\Delta E$  at some point  $P$  on the screen. We obtain the total electric field magnitude  $E$  at point  $P$  by summing the contributions from all the zones. The light intensity at point  $P$  is proportional to the square of the magnitude of the electric field (see Section 37.3).

The incremental electric field magnitudes between adjacent zones are out of phase with one another by an amount  $\Delta\beta$ , where the phase difference  $\Delta\beta$  is related to the path difference  $\Delta y \sin \theta$  between adjacent zones by the expression

$$\Delta\beta = \frac{2\pi}{\lambda} \Delta y \sin \theta \quad (38.2)$$

To find the magnitude of the total electric field on the screen at any angle  $\theta$ , we sum the incremental magnitudes  $\Delta E$  due to each zone. For small values of  $\theta$ , we can assume that all the  $\Delta E$  values are the same. It is convenient to use phasor diagrams for various angles, as shown in Figure 38.8. When  $\theta = 0$ , all phasors are aligned as shown in Figure 38.8a because all the waves from the various zones are in phase. In this case, the total electric field at the center of the screen is  $E_0 = N\Delta E$ , where  $N$  is the number of zones. The resultant magnitude  $E_R$  at some small angle  $\theta$  is shown in Figure 38.8b, where each phasor differs in phase from an adjacent one by an amount  $\Delta\beta$ . In this case,  $E_R$  is the vector sum of the incremental

**Figure 38.8** Phasor diagrams for obtaining the various maxima and minima of a single-slit diffraction pattern.

magnitudes and hence is given by the length of the chord. Therefore,  $E_R < E_0$ . The total phase difference  $\beta$  between waves from the top and bottom portions of the slit is

$$\beta = N\Delta\beta = \frac{2\pi}{\lambda} N\Delta y \sin \theta = \frac{2\pi}{\lambda} a \sin \theta \quad (38.3)$$

where  $a = N\Delta y$  is the width of the slit.

As  $\theta$  increases, the chain of phasors eventually forms the closed path shown in Figure 38.8c. At this point, the vector sum is zero, and so  $E_R = 0$ , corresponding to the first minimum on the screen. Noting that  $\beta = N\Delta\beta = 2\pi$  in this situation, we see from Equation 38.3 that

$$2\pi = \frac{2\pi}{\lambda} a \sin \theta$$

$$\sin \theta = \frac{\lambda}{a}$$

That is, the first minimum in the diffraction pattern occurs where  $\sin \theta = \lambda/a$ ; this is in agreement with Equation 38.1.

At greater values of  $\theta$ , the spiral chain of phasors tightens. For example, Figure 38.8d represents the situation corresponding to the second maximum, which occurs when  $\beta = 360^\circ + 180^\circ = 540^\circ$  ( $3\pi$  rad). The second minimum (two complete circles, not shown) corresponds to  $\beta = 720^\circ$  ( $4\pi$  rad), which satisfies the condition  $\sin \theta = 2\lambda/a$ .

We can obtain the total electric field magnitude  $E_R$  and light intensity  $I$  at any point  $P$  on the screen in Figure 38.7 by considering the limiting case in which  $\Delta y$  becomes infinitesimal ( $dy$ ) and  $N$  approaches  $\infty$ . In this limit, the phasor chains in Figure 38.8 become the red curve of Figure 38.9. The arc length of the curve is  $E_0$  because it is the sum of the magnitudes of the phasors (which is the total electric field magnitude at the center of the screen). From this figure, we see that at some angle  $\theta$ , the resultant electric field magnitude  $E_R$  on the screen is equal to the chord length. From the triangle containing the angle  $\beta/2$ , we see that

$$\sin \frac{\beta}{2} = \frac{E_R/2}{R}$$

where  $R$  is the radius of curvature. But the arc length  $E_0$  is equal to the product  $R\beta$ , where  $\beta$  is measured in radians. Combining this information with the previous expression gives

$$E_R = 2R \sin \frac{\beta}{2} = 2 \left( \frac{E_0}{\beta} \right) \sin \frac{\beta}{2} = E_0 \left[ \frac{\sin (\beta/2)}{\beta/2} \right]$$

Because the resultant light intensity  $I$  at point  $P$  on the screen is proportional to the square of the magnitude  $E_R$ , we find that

$$I = I_{\max} \left[ \frac{\sin (\beta/2)}{\beta/2} \right]^2 \quad (38.4)$$

where  $I_{\max}$  is the intensity at  $\theta = 0$  (the central maximum). Substituting the expression for  $\beta$  (Eq. 38.3) into Equation 38.4, we have

$$I = I_{\max} \left[ \frac{\sin (\pi a \sin \theta / \lambda)}{\pi a \sin \theta / \lambda} \right]^2 \quad (38.5)$$

**Figure 38.9** Phasor diagram for a large number of coherent sources. All the ends of the phasors lie on the circular red arc of radius  $R$ . The resultant electric field magnitude  $E_R$  equals the length of the chord.

Intensity of a single-slit Fraunhofer diffraction pattern

**Figure 38.10** (a) A plot of light intensity  $I$  versus  $\beta/2$  for the single-slit Fraunhofer diffraction pattern. (b) Photograph of a single-slit Fraunhofer diffraction pattern.

From this result, we see that minima occur when

$$\frac{\pi a \sin \theta}{\lambda} = m\pi$$

or

$$\sin \theta = m \frac{\lambda}{a} \quad m = \pm 1, \pm 2, \pm 3, \dots$$

Condition for intensity minima

in agreement with Equation 38.1.

Figure 38.10a represents a plot of Equation 38.5, and Figure 38.10b is a photograph of a single-slit Fraunhofer diffraction pattern. Note that most of the light intensity is concentrated in the central bright fringe.

### EXAMPLE 38.2 Relative Intensities of the Maxima

Find the ratio of the intensities of the secondary maxima to the intensity of the central maximum for the single-slit Fraunhofer diffraction pattern.

**Solution** To a good approximation, the secondary maxima lie midway between the zero points. From Figure 38.10a, we see that this corresponds to  $\beta/2$  values of  $3\pi/2$ ,  $5\pi/2$ ,  $7\pi/2$ , . . . . Substituting these values into Equation 38.4 gives for the first two ratios

$$\frac{I_1}{I_{\max}} = \left[ \frac{\sin(3\pi/2)}{(3\pi/2)} \right]^2 = \frac{1}{9\pi^2/4} = 0.045$$

$$\frac{I_2}{I_{\max}} = \left[ \frac{\sin(5\pi/2)}{5\pi/2} \right]^2 = \frac{1}{25\pi^2/4} = 0.016$$

That is, the first secondary maxima (the ones adjacent to the central maximum) have an intensity of 4.5% that of the central maximum, and the next secondary maxima have an intensity of 1.6% that of the central maximum.

**Exercise** Determine the intensity, relative to the central maximum, of the secondary maxima corresponding to  $m = \pm 3$ .

**Answer** 0.008 3.

### Intensity of Two-Slit Diffraction Patterns

When more than one slit is present, we must consider not only diffraction due to the individual slits but also the interference of the waves coming from different slits. You may have noticed the curved dashed line in Figure 37.13, which indicates a decrease in intensity of the interference maxima as  $\theta$  increases. This decrease is

due to diffraction. To determine the effects of both interference and diffraction, we simply combine Equation 37.12 and Equation 38.5:

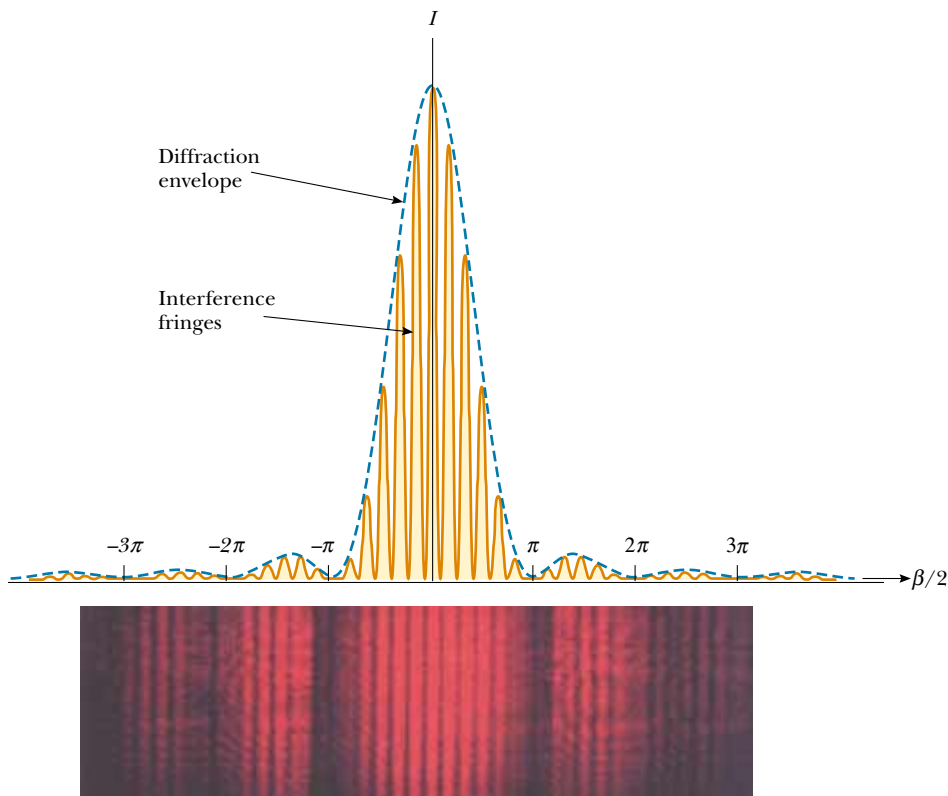

$$I = I_{\max} \cos^2\left(\frac{\pi d \sin \theta}{\lambda}\right) \left[ \frac{\sin(\pi a \sin \theta / \lambda)}{\pi a \sin \theta / \lambda} \right]^2 \quad (38.6)$$

Although this formula looks complicated, it merely represents the diffraction pattern (the factor in brackets) acting as an “envelope” for a two-slit interference pattern (the cosine-squared factor), as shown in Figure 38.11.

Equation 37.2 indicates the conditions for interference maxima as  $d \sin \theta = m\lambda$ , where  $d$  is the distance between the two slits. Equation 38.1 specifies that the first diffraction minimum occurs when  $a \sin \theta = \lambda$ , where  $a$  is the slit width. Dividing Equation 37.2 by Equation 38.1 (with  $m = 1$ ) allows us to determine which interference maximum coincides with the first diffraction minimum:

$$\begin{aligned} \frac{d \sin \theta}{a \sin \theta} &= \frac{m\lambda}{\lambda} \\ \frac{d}{a} &= m \end{aligned} \quad (38.7)$$

In Figure 38.11,  $d/a = 18 \mu\text{m}/3.0 \mu\text{m} = 6$ . Thus, the sixth interference maximum (if we count the central maximum as  $m = 0$ ) is aligned with the first diffraction minimum and cannot be seen.

**Figure 38.11** The combined effects of diffraction and interference. This is the pattern produced when 650-nm light waves pass through two 3.0- $\mu\text{m}$  slits that are 18  $\mu\text{m}$  apart. Notice how the diffraction pattern acts as an “envelope” and controls the intensity of the regularly spaced interference maxima.

**Quick Quiz 38.2**

Using Figure 38.11 as a starting point, make a sketch of the combined diffraction and interference pattern for 650-nm light waves striking two  $3.0\text{-}\mu\text{m}$  slits located  $9.0\ \mu\text{m}$  apart.

**38.3 RESOLUTION OF SINGLE-SLIT AND CIRCULAR APERTURES**

The ability of optical systems to distinguish between closely spaced objects is limited because of the wave nature of light. To understand this difficulty, let us consider Figure 38.12, which shows two light sources far from a narrow slit of width  $a$ . The sources can be considered as two noncoherent point sources  $S_1$  and  $S_2$ —for example, they could be two distant stars. If no diffraction occurred, two distinct bright spots (or images) would be observed on the viewing screen. However, because of diffraction, each source is imaged as a bright central region flanked by weaker bright and dark fringes. What is observed on the screen is the sum of two diffraction patterns: one from  $S_1$ , and the other from  $S_2$ .

If the two sources are far enough apart to keep their central maxima from overlapping, as shown in Figure 38.12a, their images can be distinguished and are said to be *resolved*. If the sources are close together, however, as shown in Figure 38.12b, the two central maxima overlap, and the images are not resolved. In determining whether two images are resolved, the following condition is often used:

When the central maximum of one image falls on the first minimum of the other image, the images are said to be just resolved. This limiting condition of resolution is known as **Rayleigh's criterion**.

Figure 38.13 shows diffraction patterns for three situations. When the objects are far apart, their images are well resolved (Fig. 38.13a). When the angular separation

**Figure 38.12** Two point sources far from a narrow slit each produce a diffraction pattern. (a) The angle subtended by the sources at the slit is large enough for the diffraction patterns to be distinguishable. (b) The angle subtended by the sources is so small that their diffraction patterns overlap, and the images are not well resolved. (Note that the angles are greatly exaggerated. The drawing is not to scale.)

**Figure 38.13** Individual diffraction patterns of two point sources (solid curves) and the resultant patterns (dashed curves) for various angular separations of the sources. In each case, the dashed curve is the sum of the two solid curves. (a) The sources are far apart, and the patterns are well resolved. (b) The sources are closer together such that the angular separation just satisfies Rayleigh's criterion, and the patterns are just resolved. (c) The sources are so close together that the patterns are not resolved.

ration of the objects satisfies Rayleigh's criterion (Fig. 38.13b), the images are just resolved. Finally, when the objects are close together, the images are not resolved (Fig. 38.13c).

From Rayleigh's criterion, we can determine the minimum angular separation  $\theta_{\min}$  subtended by the sources at the slit for which the images are just resolved. Equation 38.1 indicates that the first minimum in a single-slit diffraction pattern occurs at the angle for which

$$\sin \theta = \frac{\lambda}{a}$$

where  $a$  is the width of the slit. According to Rayleigh's criterion, this expression gives the smallest angular separation for which the two images are resolved. Because  $\lambda \ll a$  in most situations,  $\sin \theta$  is small, and we can use the approximation  $\sin \theta \approx \theta$ . Therefore, the limiting angle of resolution for a slit of width  $a$  is

$$\theta_{\min} = \frac{\lambda}{a} \quad (38.8)$$

where  $\theta_{\min}$  is expressed in radians. Hence, the angle subtended by the two sources at the slit must be greater than  $\lambda/a$  if the images are to be resolved.

Many optical systems use circular apertures rather than slits. The diffraction pattern of a circular aperture, shown in Figure 38.14, consists of a central circular

**Figure 38.14** The diffraction pattern of a circular aperture consists of a central bright disk surrounded by concentric bright and dark rings.

bright disk surrounded by progressively fainter bright and dark rings. Analysis shows that the limiting angle of resolution of the circular aperture is

Limiting angle of resolution for a circular aperture

$$\theta_{\min} = 1.22 \frac{\lambda}{D} \quad (38.9)$$

where  $D$  is the diameter of the aperture. Note that this expression is similar to Equation 38.8 except for the factor 1.22, which arises from a complex mathematical analysis of diffraction from the circular aperture.

### EXAMPLE 38.3 Limiting Resolution of a Microscope

Light of wavelength 589 nm is used to view an object under a microscope. If the aperture of the objective has a diameter of 0.900 cm, (a) what is the limiting angle of resolution?

**Solution** (a) Using Equation 38.9, we find that the limiting angle of resolution is

$$\theta_{\min} = 1.22 \left( \frac{589 \times 10^{-9} \text{ m}}{0.900 \times 10^{-2} \text{ m}} \right) = 7.98 \times 10^{-5} \text{ rad}$$

This means that any two points on the object subtending an angle smaller than this at the objective cannot be distinguished in the image.

(b) If it were possible to use visible light of any wavelength, what would be the maximum limit of resolution for this microscope?

**Solution** To obtain the smallest limiting angle, we have to use the shortest wavelength available in the visible spectrum.

Violet light (400 nm) gives a limiting angle of resolution of

$$\theta_{\min} = 1.22 \left( \frac{400 \times 10^{-9} \text{ m}}{0.900 \times 10^{-2} \text{ m}} \right) = 5.42 \times 10^{-5} \text{ rad}$$

(c) Suppose that water ( $n = 1.33$ ) fills the space between the object and the objective. What effect does this have on resolving power when 589-nm light is used?

**Solution** We find the wavelength of the 589-nm light in the water using Equation 35.7:

$$\lambda_{\text{water}} = \frac{\lambda_{\text{air}}}{n_{\text{water}}} = \frac{589 \text{ nm}}{1.33} = 443 \text{ nm}$$

The limiting angle of resolution at this wavelength is now smaller than that calculated in part (a):

$$\theta_{\min} = 1.22 \left( \frac{443 \times 10^{-9} \text{ m}}{0.900 \times 10^{-2} \text{ m}} \right) = 6.00 \times 10^{-5} \text{ rad}$$

### EXAMPLE 38.4 Resolution of a Telescope

The Hale telescope at Mount Palomar has a diameter of 200 in. What is its limiting angle of resolution for 600-nm light?

**Solution** Because  $D = 200 \text{ in.} = 5.08 \text{ m}$  and  $\lambda = 6.00 \times 10^{-7} \text{ m}$ , Equation 38.9 gives

$$\begin{aligned} \theta_{\min} &= 1.22 \frac{\lambda}{D} = 1.22 \left( \frac{6.00 \times 10^{-7} \text{ m}}{5.08 \text{ m}} \right) \\ &= 1.44 \times 10^{-7} \text{ rad} \approx 0.03 \text{ s of arc} \end{aligned}$$

Any two stars that subtend an angle greater than or equal to this value are resolved (if atmospheric conditions are ideal).

The Hale telescope can never reach its diffraction limit because the limiting angle of resolution is always set by at-

mospheric blurring. This seeing limit is usually about 1 s of arc and is never smaller than about 0.1 s of arc. (This is one of the reasons for the superiority of photographs from the Hubble Space Telescope, which views celestial objects from an orbital position above the atmosphere.)

**Exercise** The large radio telescope at Arecibo, Puerto Rico, has a diameter of 305 m and is designed to detect 0.75-m radio waves. Calculate the minimum angle of resolution for this telescope and compare your answer with that for the Hale telescope.

**Answer**  $3.0 \times 10^{-3} \text{ rad}$  (10 min of arc), more than 10 000 times larger (that is, *worse*) than the Hale minimum.

### EXAMPLE 38.5 Resolution of the Eye

Estimate the limiting angle of resolution for the human eye, assuming its resolution is limited only by diffraction.

**Solution** Let us choose a wavelength of 500 nm, near the center of the visible spectrum. Although pupil diameter

varies from person to person, we estimate a diameter of 2 mm. We use Equation 38.9, taking  $\lambda = 500 \text{ nm}$  and  $D = 2 \text{ mm}$ :

$$\theta_{\min} = 1.22 \frac{\lambda}{D} = 1.22 \left( \frac{5.00 \times 10^{-7} \text{ m}}{2 \times 10^{-3} \text{ m}} \right) \\ \approx 3 \times 10^{-4} \text{ rad} \approx 1 \text{ min of arc}$$

We can use this result to determine the minimum separation distance  $d$  between two point sources that the eye can distinguish if they are a distance  $L$  from the observer (Fig. 38.15). Because  $\theta_{\min}$  is small, we see that

$$\sin \theta_{\min} \approx \theta_{\min} \approx \frac{d}{L} \\ d = L\theta_{\min}$$

For example, if the point sources are 25 cm from the eye (the near point), then

$$d = (25 \text{ cm})(3 \times 10^{-4} \text{ rad}) = 8 \times 10^{-3} \text{ cm}$$

This is approximately equal to the thickness of a human hair.

**Figure 38.15** Two point sources separated by a distance  $d$  as observed by the eye.

**Exercise** Suppose that the pupil is dilated to a diameter of 5.0 mm and that two point sources 3.0 m away are being viewed. How far apart must the sources be if the eye is to resolve them?

**Answer** 0.037 cm.

### APPLICATION Loudspeaker Design

The three-way speaker system shown in Figure 38.16 contains a woofer, a midrange speaker, and a tweeter. The small-diameter tweeter is for high frequencies, and the large-diameter woofer is for low frequencies. The midrange speaker, of intermediate diameter, is used for the frequency band above the high-frequency cutoff of the woofer and below the low-frequency cutoff of the tweeter. Circuits known as crossover networks include low-pass, midrange, and high-pass filters that direct the electrical signal to the appropriate speaker. The effective aperture size of a speaker is approximately its diameter. Because the wavelengths of sound waves are comparable to the typical sizes of the speakers, diffraction effects determine the angular radiation pattern. To be most useful, a speaker should radiate sound over a broad range of angles so that the listener does not have to stand at a particular spot in the room to hear maximum sound intensity. On the basis of the angular radiation pattern, let us investigate the frequency range for which a 6-in. (0.15-m) midrange speaker is most useful.

The speed of sound in air is 344 m/s, and for a circular aperture, diffraction effects become important when  $\lambda = 1.22D$ , where  $D$  is the speaker diameter. Therefore, we would expect this speaker to radiate non-uniformly for all frequencies above

$$\frac{344 \text{ m/s}}{1.22(0.15 \text{ m})} = 1900 \text{ Hz}$$

Suppose our design specifies that the midrange speaker operates between 500 Hz (the high-frequency woofer cutoff) and 2000 Hz. Measurements of the dispersion of radiated

**Figure 38.16** An audio speaker system for high-fidelity sound reproduction. The tweeter is at the top, the midrange speaker is in the middle, and the woofer is at the bottom. (*International Stock Photography*)

sound at a suitably great distance from the speaker yield the angular profiles of sound intensity shown in Figure 38.17. In examining these plots, we see that the dispersion pattern for a 500-Hz sound is fairly uniform. This angular range is suffi-

ciently great for us to say that this midrange speaker satisfies the design criterion. The intensity of a 2 000-Hz sound decreases to about half its maximum value about 30° from the centerline.

**Figure 38.17** Angular dispersion of sound intensity  $I$  for a midrange speaker at (a) 500 Hz and (b) 2 000 Hz.

### 38.4 THE DIFFRACTION GRATING

The **diffraction grating**, a useful device for analyzing light sources, consists of a large number of equally spaced parallel slits. A *transmission grating* can be made by cutting parallel lines on a glass plate with a precision ruling machine. The spaces between the lines are transparent to the light and hence act as separate slits. A *reflection grating* can be made by cutting parallel lines on the surface of a reflective material. The reflection of light from the spaces between the lines is specular, and the reflection from the lines cut into the material is diffuse. Thus, the spaces between the lines act as parallel sources of reflected light, like the slits in a transmission grating. Gratings that have many lines very close to each other can have very small slit spacings. For example, a grating ruled with 5 000 lines/cm has a slit spacing  $d = (1/5\,000)\text{ cm} = 2.00 \times 10^{-4}\text{ cm}$ .

**Figure 38.18** Side view of a diffraction grating. The slit separation is  $d$ , and the path difference between adjacent slits is  $d \sin \theta$ .

A section of a diffraction grating is illustrated in Figure 38.18. A plane wave is incident from the left, normal to the plane of the grating. A converging lens brings the rays together at point  $P$ . The pattern observed on the screen is the result of the combined effects of interference and diffraction. Each slit produces diffraction, and the diffracted beams interfere with one another to produce the final pattern.

The waves from all slits are in phase as they leave the slits. However, for some arbitrary direction  $\theta$  measured from the horizontal, the waves must travel different path lengths before reaching point  $P$ . From Figure 38.18, note that the path difference  $\delta$  between rays from any two adjacent slits is equal to  $d \sin \theta$ . If this path difference equals one wavelength or some integral multiple of a wavelength, then waves from all slits are in phase at point  $P$  and a bright fringe is observed. Therefore, the condition for maxima in the interference pattern at the angle  $\theta$  is

$$d \sin \theta = m\lambda \quad m = 0, 1, 2, 3, \dots \quad (38.10)$$

We can use this expression to calculate the wavelength if we know the grating spacing and the angle  $\theta$ . If the incident radiation contains several wavelengths, the  $m$ th-order maximum for each wavelength occurs at a specific angle. All wavelengths are seen at  $\theta = 0$ , corresponding to  $m = 0$ , the zeroth-order maximum. The first-order maximum ( $m = 1$ ) is observed at an angle that satisfies the relationship  $\sin \theta = \lambda/d$ ; the second-order maximum ( $m = 2$ ) is observed at a larger angle  $\theta$ , and so on.

The intensity distribution for a diffraction grating obtained with the use of a monochromatic source is shown in Figure 38.19. Note the sharpness of the principal maxima and the broadness of the dark areas. This is in contrast to the broad bright fringes characteristic of the two-slit interference pattern (see Fig. 37.6). Because the principal maxima are so sharp, they are very much brighter than two-slit

**Figure 38.19** Intensity versus  $\sin \theta$  for a diffraction grating. The zeroth-, first-, and second-order maxima are shown.

Condition for interference maxima for a grating

**Figure 38.20** (a) Addition of two wave fronts from two slits. (b) Addition of ten wave fronts from ten slits. The resultant wave is much stronger in part (b) than in part (a).

### QuickLab

Stand a couple of meters from a light bulb. Facing away from the light, hold a compact disc about 10 cm from your eye and tilt it until the reflection of the bulb is located in the hole at the disc's center. You should see spectra radiating out from the center, with violet on the inside and red on the outside. Now move the disc away from your eye until the violet band is at the outer edge. Carefully measure the distance from your eye to the center of the disc and also determine the radius of the disc. Use this information to find the angle  $\theta$  to the first-order maximum for violet light. Now use Equation 38.10 to determine the spacing between the grooves on the disc. The industry standard is  $1.6 \mu\text{m}$ . How close did you come?

interference maxima. The reason for this is illustrated in Figure 38.20, in which the combination of multiple wave fronts for a ten-slit grating is compared with the wave fronts for a two-slit system. Actual gratings have thousands of times more slits, and therefore the maxima are even stronger.

A schematic drawing of a simple apparatus used to measure angles in a diffraction pattern is shown in Figure 38.21. This apparatus is a diffraction grating spectrometer. The light to be analyzed passes through a slit, and a collimated beam of light is incident on the grating. The diffracted light leaves the grating at angles that satisfy Equation 38.10, and a telescope is used to view the image of the slit. The wavelength can be determined by measuring the precise angles at which the images of the slit appear for the various orders.

**Figure 38.21** Diagram of a diffraction grating spectrometer. The collimated beam incident on the grating is diffracted into the various orders at the angles  $\theta$  that satisfy the equation  $d \sin \theta = m\lambda$ , where  $m = 0, 1, 2, \dots$

**CONCEPTUAL EXAMPLE 38.6** A Compact Disc Is a Diffraction Grating

Light reflected from the surface of a compact disc is multicolored, as shown in Figure 38.22. The colors and their intensities depend on the orientation of the disc relative to the eye and relative to the light source. Explain how this works.

**Solution** The surface of a compact disc has a spiral grooved track (with adjacent grooves having a separation on the order of  $1\ \mu\text{m}$ ). Thus, the surface acts as a reflection grating. The light reflecting from the regions between these closely spaced grooves interferes constructively only in certain directions that depend on the wavelength and on the direction of the incident light. Any one section of the disc serves as a diffraction grating for white light, sending different colors in different directions. The different colors you see when viewing one section change as the light source, the disc, or you move to change the angles of incidence or diffraction.

**Figure 38.22** A compact disc observed under white light. The colors observed in the reflected light and their intensities depend on the orientation of the disc relative to the eye and relative to the light source.

**EXAMPLE 38.7** The Orders of a Diffraction Grating

Monochromatic light from a helium-neon laser ( $\lambda = 632.8\ \text{nm}$ ) is incident normally on a diffraction grating containing 6 000 lines per centimeter. Find the angles at which the first-order, second-order, and third-order maxima are observed.

**Solution** First, we must calculate the slit separation, which is equal to the inverse of the number of lines per centimeter:

$$d = \frac{1}{6\,000}\ \text{cm} = 1.667 \times 10^{-4}\ \text{cm} = 1\,667\ \text{nm}$$

For the first-order maximum ( $m = 1$ ), we obtain

$$\sin \theta_1 = \frac{\lambda}{d} = \frac{632.8\ \text{nm}}{1\,667\ \text{nm}} = 0.379\,6$$

$$\theta_1 = 22.31^\circ$$

For the second-order maximum ( $m = 2$ ), we find

$$\sin \theta_2 = \frac{2\lambda}{d} = \frac{2(632.8\ \text{nm})}{1\,667\ \text{nm}} = 0.759\,2$$

$$\theta_2 = 49.39^\circ$$

For  $m = 3$ , we find that  $\sin \theta_3 = 1.139$ . Because  $\sin \theta$  cannot exceed unity, this does not represent a realistic solution. Hence, only zeroth-, first-, and second-order maxima are observed for this situation.

**Resolving Power of the Diffraction Grating**

The diffraction grating is most useful for measuring wavelengths accurately. Like the prism, the diffraction grating can be used to disperse a spectrum into its wavelength components. Of the two devices, the grating is the more precise if one wants to distinguish two closely spaced wavelengths.

For two nearly equal wavelengths  $\lambda_1$  and  $\lambda_2$  between which a diffraction grating can just barely distinguish, the **resolving power**  $R$  of the grating is defined as

$$R = \frac{\lambda}{\lambda_2 - \lambda_1} = \frac{\lambda}{\Delta\lambda} \quad (38.11)$$

where  $\lambda = (\lambda_1 + \lambda_2)/2$  and  $\Delta\lambda = \lambda_2 - \lambda_1$ . Thus, a grating that has a high resolving power can distinguish small differences in wavelength. If  $N$  lines of the grating

Resolving power

are illuminated, it can be shown that the resolving power in the  $m$ th-order diffraction is

Resolving power of a grating

$$R = Nm \quad (38.12)$$

Thus, resolving power increases with increasing order number and with increasing number of illuminated slits.

Note that  $R = 0$  for  $m = 0$ ; this signifies that all wavelengths are indistinguishable for the zeroth-order maximum. However, consider the second-order diffraction pattern ( $m = 2$ ) of a grating that has 5 000 rulings illuminated by the light source. The resolving power of such a grating in second order is  $R = 5\,000 \times 2 = 10\,000$ . Therefore, for a mean wavelength of, for example, 600 nm, the minimum wavelength separation between two spectral lines that can be just resolved is  $\Delta\lambda = \lambda/R = 6.00 \times 10^{-2}$  nm. For the third-order principal maximum,  $R = 15\,000$  and  $\Delta\lambda = 4.00 \times 10^{-2}$  nm, and so on.

One of the most interesting applications of diffraction is holography, which is used to create three-dimensional images found practically everywhere, from credit cards to postage stamps. The production of these special diffracting films is discussed in Chapter 42 of the extended version of this text.

### EXAMPLE 38.8 Resolving Sodium Spectral Lines

When an element is raised to a very high temperature, the atoms emit radiation having discrete wavelengths. The set of wavelengths for a given element is called its *atomic spectrum*. Two strong components in the atomic spectrum of sodium have wavelengths of 589.00 nm and 589.59 nm. (a) What must be the resolving power of a grating if these wavelengths are to be distinguished?

#### Solution

$$R = \frac{\lambda}{\Delta\lambda} = \frac{589.30 \text{ nm}}{589.59 \text{ nm} - 589.00 \text{ nm}} = \frac{589.30}{0.59} = 999$$

(b) To resolve these lines in the second-order spectrum, how many lines of the grating must be illuminated?

**Solution** From Equation 38.12 and the results to part (a), we find that

$$N = \frac{R}{m} = \frac{999}{2} = 500 \text{ lines}$$

#### Optional Section

### 38.5 DIFFRACTION OF X-RAYS BY CRYSTALS

In principle, the wavelength of any electromagnetic wave can be determined if a grating of the proper spacing (of the order of  $\lambda$ ) is available. X-rays, discovered by Wilhelm Roentgen (1845–1923) in 1895, are electromagnetic waves of very short wavelength (of the order of 0.1 nm). It would be impossible to construct a grating having such a small spacing by the cutting process described at the beginning of Section 38.4. However, the atomic spacing in a solid is known to be about 0.1 nm. In 1913, Max von Laue (1879–1960) suggested that the regular array of atoms in a crystal could act as a three-dimensional diffraction grating for x-rays. Subsequent experiments confirmed this prediction. The diffraction patterns are complex because of the three-dimensional nature of the crystal. Nevertheless, x-ray diffraction

has proved to be an invaluable technique for elucidating crystalline structures and for understanding the structure of matter.<sup>1</sup>

Figure 38.23 is one experimental arrangement for observing x-ray diffraction from a crystal. A collimated beam of x-rays is incident on a crystal. The diffracted beams are very intense in certain directions, corresponding to constructive interference from waves reflected from layers of atoms in the crystal. The diffracted beams can be detected by a photographic film, and they form an array of spots known as a *Laue pattern*. One can deduce the crystalline structure by analyzing the positions and intensities of the various spots in the pattern.

The arrangement of atoms in a crystal of sodium chloride (NaCl) is shown in Figure 38.24. Each unit cell (the geometric solid that repeats throughout the crystal) is a cube having an edge length  $a$ . A careful examination of the NaCl structure shows that the ions lie in discrete planes (the shaded areas in Fig. 38.24). Now suppose that an incident x-ray beam makes an angle  $\theta$  with one of the planes, as shown in Figure 38.25. The beam can be reflected from both the upper plane and the lower one. However, the beam reflected from the lower plane travels farther than the beam reflected from the upper plane. The effective path difference is  $2d \sin \theta$ . The two beams reinforce each other (constructive interference) when this path difference equals some integer multiple of  $\lambda$ . The same is true for reflection from the entire family of parallel planes. Hence, the condition for constructive interference (maxima in the reflected beam) is

$$2d \sin \theta = m\lambda \quad m = 1, 2, 3, \dots \quad (38.13)$$

This condition is known as **Bragg's law**, after W. L. Bragg (1890–1971), who first derived the relationship. If the wavelength and diffraction angle are measured, Equation 38.13 can be used to calculate the spacing between atomic planes.

### Quick Quiz 38.3

When you receive a chest x-ray at a hospital, the rays pass through a series of parallel ribs in your chest. Do the ribs act as a diffraction grating for x-rays?

**Figure 38.25** A two-dimensional description of the reflection of an x-ray beam from two parallel crystalline planes separated by a distance  $d$ . The beam reflected from the lower plane travels farther than the one reflected from the upper plane by a distance  $2d \sin \theta$ .

**Figure 38.23** Schematic diagram of the technique used to observe the diffraction of x-rays by a crystal. The array of spots formed on the film is called a Laue pattern.

### Bragg's law

**Figure 38.24** Crystalline structure of sodium chloride (NaCl). The blue spheres represent  $\text{Cl}^-$  ions, and the red spheres represent  $\text{Na}^+$  ions. The length of the cube edge is  $a = 0.562\,737\text{ nm}$ .

## 38.6 POLARIZATION OF LIGHT WAVES

In Chapter 34 we described the transverse nature of light and all other electromagnetic waves. Polarization is firm evidence of this transverse nature.

An ordinary beam of light consists of a large number of waves emitted by the atoms of the light source. Each atom produces a wave having some particular orientation of the electric field vector  $\mathbf{E}$ , corresponding to the direction of atomic vibration. The *direction of polarization* of each individual wave is defined to be the direction in which the electric field is vibrating. In Figure 38.26, this direction happens to lie along the  $y$  axis. However, an individual electromagnetic wave could have its  $\mathbf{E}$  vector in the  $yz$  plane, making any possible angle with the  $y$  axis. Because all directions of vibration from a wave source are possible, the resultant electromagnetic wave is a superposition of waves vibrating in many different directions. The result is an **unpolarized** light beam, represented in Figure 38.27a. The direction of wave propagation in this figure is perpendicular to the page. The arrows show a few possible directions of the electric field vectors for the individual waves making up the resultant beam. At any given point and at some instant of time, all these individual electric field vectors add to give one resultant electric field vector.

As noted in Section 34.2, a wave is said to be **linearly polarized** if the resultant electric field  $\mathbf{E}$  vibrates in the same direction *at all times* at a particular point, as shown in Figure 38.27b. (Sometimes, such a wave is described as *plane-polarized*, or simply *polarized*.) The plane formed by  $\mathbf{E}$  and the direction of propagation is called the *plane of polarization* of the wave. If the wave in Figure 38.26 represented the resultant of all individual waves, the plane of polarization is the  $xy$  plane.

It is possible to obtain a linearly polarized beam from an unpolarized beam by removing all waves from the beam except those whose electric field vectors oscillate in a single plane. We now discuss four processes for producing polarized light from unpolarized light.

### Polarization by Selective Absorption

The most common technique for producing polarized light is to use a material that transmits waves whose electric fields vibrate in a plane parallel to a certain direction and that absorbs waves whose electric fields vibrate in all other directions.

In 1938, E. H. Land (1909–1991) discovered a material, which he called *polaroid*, that polarizes light through selective absorption by oriented molecules. This material is fabricated in thin sheets of long-chain hydrocarbons. The sheets are stretched during manufacture so that the long-chain molecules align. After a sheet is dipped into a solution containing iodine, the molecules become good electrical conductors. However, conduction takes place primarily along the hydrocarbon chains because electrons can move easily only along the chains. As a result, the

**Figure 38.26** Schematic diagram of an electromagnetic wave propagating at velocity  $c$  in the  $x$  direction. The electric field vibrates in the  $xy$  plane, and the magnetic field vibrates in the  $xz$  plane.

molecules readily absorb light whose electric field vector is parallel to their length and allow light through whose electric field vector is perpendicular to their length.

It is common to refer to the direction perpendicular to the molecular chains as the *transmission axis*. In an ideal polarizer, all light with  $\mathbf{E}$  parallel to the transmission axis is transmitted, and all light with  $\mathbf{E}$  perpendicular to the transmission axis is absorbed.

Figure 38.28 represents an unpolarized light beam incident on a first polarizing sheet, called the *polarizer*. Because the transmission axis is oriented vertically in the figure, the light transmitted through this sheet is polarized vertically. A second polarizing sheet, called the *analyzer*, intercepts the beam. In Figure 38.28, the analyzer transmission axis is set at an angle  $\theta$  to the polarizer axis. We call the electric field vector of the transmitted beam  $\mathbf{E}_0$ . The component of  $\mathbf{E}_0$  perpendicular to the analyzer axis is completely absorbed. The component of  $\mathbf{E}_0$  parallel to the analyzer axis, which is allowed through by the analyzer, is  $E_0 \cos \theta$ . Because the intensity of the transmitted beam varies as the square of its magnitude, we conclude that the intensity of the (polarized) beam transmitted through the analyzer varies as

$$I = I_{\max} \cos^2 \theta \quad (38.14)$$

where  $I_{\max}$  is the intensity of the polarized beam incident on the analyzer. This expression, known as **Malus's law**,<sup>2</sup> applies to any two polarizing materials whose transmission axes are at an angle  $\theta$  to each other. From this expression, note that the intensity of the transmitted beam is maximum when the transmission axes are parallel ( $\theta = 0$  or  $180^\circ$ ) and that it is zero (complete absorption by the analyzer) when the transmission axes are perpendicular to each other. This variation in transmitted intensity through a pair of polarizing sheets is illustrated in Figure 38.29. Because the average value of  $\cos^2 \theta$  is  $\frac{1}{2}$ , the intensity of the light passed through an ideal polarizer is one-half the intensity of unpolarized light.

### Polarization by Reflection

When an unpolarized light beam is reflected from a surface, the reflected light may be completely polarized, partially polarized, or unpolarized, depending on the angle of incidence. If the angle of incidence is  $0^\circ$ , the reflected beam is unpolarized. For other angles of incidence, the reflected light is polarized to some ex-

**Figure 38.27** (a) An unpolarized light beam viewed along the direction of propagation (perpendicular to the page). The transverse electric field can vibrate in any direction in the plane of the page with equal probability. (b) A linearly polarized light beam with the electric field vibrating in the vertical direction.

**Figure 38.28** Two polarizing sheets whose transmission axes make an angle  $\theta$  with each other. Only a fraction of the polarized light incident on the analyzer is transmitted through it.

<sup>2</sup> Named after its discoverer, E. L. Malus (1775–1812). Malus discovered that reflected light was polarized by viewing it through a calcite ( $\text{CaCO}_3$ ) crystal.

**Figure 38.29** The intensity of light transmitted through two polarizers depends on the relative orientation of their transmission axes. (a) The transmitted light has maximum intensity when the transmission axes are aligned with each other. (b) The transmitted light has lesser intensity when the transmission axes are at an angle of  $45^\circ$  with each other. (c) The transmitted light intensity is a minimum when the transmission axes are at right angles to each other.

tent, and for one particular angle of incidence, the reflected light is completely polarized. Let us now investigate reflection at that special angle.

Suppose that an unpolarized light beam is incident on a surface, as shown in Figure 38.30a. Each individual electric field vector can be resolved into two components: one parallel to the surface (and perpendicular to the page in Fig. 38.30, represented by the dots), and the other (represented by the red arrows) perpendicular both to the first component and to the direction of propagation. Thus, the polarization of the entire beam can be described by two electric field components in these directions. It is found that the parallel component reflects more strongly than the perpendicular component, and this results in a partially polarized reflected beam. Furthermore, the refracted beam is also partially polarized.

**Figure 38.30** (a) When unpolarized light is incident on a reflecting surface, the reflected and refracted beams are partially polarized. (b) The reflected beam is completely polarized when the angle of incidence equals the polarizing angle  $\theta_p$ , which satisfies the equation  $n = \tan \theta_p$ .

Now suppose that the angle of incidence  $\theta_1$  is varied until the angle between the reflected and refracted beams is  $90^\circ$ , as shown in Figure 38.30b. At this particular angle of incidence, the reflected beam is completely polarized (with its electric field vector parallel to the surface), and the refracted beam is still only partially polarized. The angle of incidence at which this polarization occurs is called the **polarizing angle**  $\theta_p$ .

We can obtain an expression relating the polarizing angle to the index of refraction of the reflecting substance by using Figure 38.30b. From this figure, we see that  $\theta_p + 90^\circ + \theta_2 = 180^\circ$ ; thus,  $\theta_2 = 90^\circ - \theta_p$ . Using Snell's law of refraction (Eq. 35.8) and taking  $n_1 = 1.00$  for air and  $n_2 = n$ , we have

$$n = \frac{\sin \theta_1}{\sin \theta_2} = \frac{\sin \theta_p}{\sin \theta_2}$$

Because  $\sin \theta_2 = \sin(90^\circ - \theta_p) = \cos \theta_p$ , we can write this expression for  $n$  as  $n = \sin \theta_p / \cos \theta_p$ , which means that

$$n = \tan \theta_p \quad (38.15)$$

This expression is called **Brewster's law**, and the polarizing angle  $\theta_p$  is sometimes called **Brewster's angle**, after its discoverer, David Brewster (1781–1868). Because  $n$  varies with wavelength for a given substance, Brewster's angle is also a function of wavelength.

Polarization by reflection is a common phenomenon. Sunlight reflected from water, glass, and snow is partially polarized. If the surface is horizontal, the electric field vector of the reflected light has a strong horizontal component. Sunglasses made of polarizing material reduce the glare of reflected light. The transmission axes of the lenses are oriented vertically so that they absorb the strong horizontal component of the reflected light. If you rotate sunglasses  $90^\circ$ , they will not be as effective at blocking the glare from shiny horizontal surfaces.

## Polarization by Double Refraction

Solids can be classified on the basis of internal structure. Those in which the atoms are arranged in a specific order are called *crystalline*; the NaCl structure of Figure 38.24 is just one example of a crystalline solid. Those solids in which the atoms are distributed randomly are called *amorphous*. When light travels through an amorphous material, such as glass, it travels with a speed that is the same in all directions. That is, glass has a single index of refraction. In certain crystalline materials, however, such as calcite and quartz, the speed of light is not the same in all directions. Such materials are characterized by two indices of refraction. Hence, they are often referred to as **double-refracting** or **birefringent** materials.

Upon entering a calcite crystal, unpolarized light splits into two plane-polarized rays that travel with different velocities, corresponding to two angles of refraction, as shown in Figure 38.31. The two rays are polarized in two mutually perpendicular directions, as indicated by the dots and arrows. One ray, called the **ordinary (O) ray**, is characterized by an index of refraction  $n_O$  that is the same in all directions. This means that if one could place a point source of light inside the crystal, as shown in Figure 38.32, the ordinary waves would spread out from the source as spheres.

The second plane-polarized ray, called the **extraordinary (E) ray**, travels with different speeds in different directions and hence is characterized by an index of refraction  $n_E$  that varies with the direction of propagation. The point source in Fig-

Polarizing angle

Brewster's law

## QuickLab

Devise a way to use a protractor, desk lamp, and polarizing sunglasses to measure Brewster's angle for the glass in a window. From this, determine the index of refraction of the glass. Compare your results with the values given in Table 35.1.

**Figure 38.31** Unpolarized light incident on a calcite crystal splits into an ordinary (O) ray and an extraordinary (E) ray. These two rays are polarized in mutually perpendicular directions (drawing not to scale).

**Figure 38.32** A point source  $S$  inside a double-refracting crystal produces a spherical wave front corresponding to the ordinary ray and an elliptical wave front corresponding to the extraordinary ray. The two waves propagate with the same velocity along the optic axis.

Figure 38.32 sends out an extraordinary wave having wave fronts that are elliptical in cross-section. Note from Figure 38.32 that there is one direction, called the **optic axis**, along which the ordinary and extraordinary rays have the same speed, corresponding to the direction for which  $n_O = n_E$ . The difference in speed for the two rays is a maximum in the direction perpendicular to the optic axis. For example, in calcite,  $n_O = 1.658$  at a wavelength of 589.3 nm, and  $n_E$  varies from 1.658 along the optic axis to 1.486 perpendicular to the optic axis. Values for  $n_O$  and  $n_E$  for various double-refracting crystals are given in Table 38.1.

If we place a piece of calcite on a sheet of paper and then look through the crystal at any writing on the paper, we see two images, as shown in Figure 38.33. As can be seen from Figure 38.31, these two images correspond to one formed by the ordinary ray and one formed by the extraordinary ray. If the two images are viewed through a sheet of rotating polarizing glass, they alternately appear and disappear because the ordinary and extraordinary rays are plane-polarized along mutually perpendicular directions.

### Polarization by Scattering

When light is incident on any material, the electrons in the material can absorb and reradiate part of the light. Such absorption and reradiation of light by electrons in the gas molecules that make up air is what causes sunlight reaching an observer on the Earth to be partially polarized. You can observe this effect—called **scattering**—by looking directly up at the sky through a pair of sunglasses whose lenses are made of polarizing material. Less light passes through at certain orientations of the lenses than at others.

Figure 38.34 illustrates how sunlight becomes polarized when it is scattered. An unpolarized beam of sunlight traveling in the horizontal direction (parallel to

**Figure 38.33** A calcite crystal produces a double image because it is a birefringent (double-refracting) material.

**TABLE 38.1** Indices of Refraction for Some Double-Refraction Crystals at a Wavelength of 589.3 nm

Crystal	$n_O$	$n_E$	$n_O/n_E$
Calcite ( $\text{CaCO}_3$ )	1.658	1.486	1.116
Quartz ( $\text{SiO}_2$ )	1.544	1.553	0.994
Sodium nitrate ( $\text{NaNO}_3$ )	1.587	1.336	1.188
Sodium sulfite ( $\text{NaSO}_3$ )	1.565	1.515	1.033
Zinc chloride ( $\text{ZnCl}_2$ )	1.687	1.713	0.985
Zinc sulfide ( $\text{ZnS}$ )	2.356	2.378	0.991

the ground) strikes a molecule of one of the gases that make up air, setting the electrons of the molecule into vibration. These vibrating charges act like the vibrating charges in an antenna. The horizontal component of the electric field vector in the incident wave results in a horizontal component of the vibration of the charges, and the vertical component of the vector results in a vertical component of vibration. If the observer in Figure 38.34 is looking straight up (perpendicular to the original direction of propagation of the light), the vertical oscillations of the charges send no radiation toward the observer. Thus, the observer sees light that is completely polarized in the horizontal direction, as indicated by the red arrows. If the observer looks in other directions, the light is partially polarized in the horizontal direction.

Some phenomena involving the scattering of light in the atmosphere can be understood as follows. When light of various wavelengths  $\lambda$  is incident on gas molecules of diameter  $d$ , where  $d \ll \lambda$ , the relative intensity of the scattered light varies as  $1/\lambda^4$ . The condition  $d \ll \lambda$  is satisfied for scattering from oxygen ( $O_2$ ) and nitrogen ( $N_2$ ) molecules in the atmosphere, whose diameters are about 0.2 nm. Hence, short wavelengths (blue light) are scattered more efficiently than long wavelengths (red light). Therefore, when sunlight is scattered by gas molecules in the air, the short-wavelength radiation (blue) is scattered more intensely than the long-wavelength radiation (red).

When you look up into the sky in a direction that is not toward the Sun, you see the scattered light, which is predominantly blue; hence, you see a blue sky. If you look toward the west at sunset (or toward the east at sunrise), you are looking in a direction toward the Sun and are seeing light that has passed through a large distance of air. Most of the blue light has been scattered by the air between you and the Sun. The light that survives this trip through the air to you has had much of its blue component scattered and is thus heavily weighted toward the red end of the spectrum; as a result, you see the red and orange colors of sunset. However, a blue sky is seen by someone to your west for whom it is still a quarter hour before sunset.

### Optical Activity

Many important applications of polarized light involve materials that display **optical activity**. A material is said to be optically active if it rotates the plane of polarization of any light transmitted through the material. The angle through which the light is rotated by a specific material depends on the length of the path through the material and on concentration if the material is in solution. One optically active material is a solution of the common sugar dextrose. A standard method for determining the concentration of sugar solutions is to measure the rotation produced by a fixed length of the solution.

Molecular asymmetry determines whether a material is optically active. For example, some proteins are optically active because of their spiral shape. Other materials, such as glass and plastic, become optically active when stressed. Suppose that an unstressed piece of plastic is placed between a polarizer and an analyzer so that light passes from polarizer to plastic to analyzer. When the plastic is unstressed and the analyzer axis is perpendicular to the polarizer axis, none of the polarized light passes through the analyzer. In other words, the unstressed plastic has no effect on the light passing through it. If the plastic is stressed, however, the regions of greatest stress rotate the polarized light through the largest angles. Hence, a series of bright and dark bands is observed in the transmitted light, with the bright bands corresponding to regions of greatest stress.

**Figure 38.34** The scattering of unpolarized sunlight by air molecules. The scattered light traveling perpendicular to the incident light is plane-polarized because the vertical vibrations of the charges in the air molecule send no light in this direction.

**Figure 38.35** (a) Strain distribution in a plastic model of a hip replacement used in a medical research laboratory. The pattern is produced when the plastic model is viewed between a polarizer and analyzer oriented perpendicular to each other. (b) A plastic model of an arch structure under load conditions observed between perpendicular polarizers. Such patterns are useful in the optimum design of architectural components.

Engineers often use this technique, called *optical stress analysis*, in designing structures ranging from bridges to small tools. They build a plastic model and analyze it under different load conditions to determine regions of potential weakness and failure under stress. Some examples of a plastic model under stress are shown in Figure 38.35.

The liquid crystal displays found in most calculators have their optical activity changed by the application of electric potential across different parts of the display. Try using a pair of polarizing sunglasses to investigate the polarization used in the display of your calculator.

## SUMMARY

**Diffraction** is the deviation of light from a straight-line path when the light passes through an aperture or around an obstacle.

The **Fraunhofer diffraction pattern** produced by a single slit of width  $a$  on a distant screen consists of a central bright fringe and alternating bright and dark fringes of much lower intensities. The angles  $\theta$  at which the diffraction pattern has zero intensity, corresponding to destructive interference, are given by

$$\sin \theta = m \frac{\lambda}{a} \quad m = \pm 1, \pm 2, \pm 3, \dots \quad (38.1)$$

How the intensity  $I$  of a single-slit diffraction pattern varies with angle  $\theta$  is given by the expression

$$I = I_{\max} \left[ \frac{\sin (\beta/2)}{\beta/2} \right]^2 \quad (38.4)$$

where  $\beta = (2\pi a \sin \theta)/\lambda$  and  $I_{\max}$  is the intensity at  $\theta = 0$ .

**Rayleigh's criterion**, which is a limiting condition of resolution, states that two images formed by an aperture are just distinguishable if the central maximum of the diffraction pattern for one image falls on the first minimum of the diffrac-

tion pattern for the other image. The limiting angle of resolution for a slit of width  $a$  is  $\theta_{\min} = \lambda/a$ , and the limiting angle of resolution for a circular aperture of diameter  $D$  is  $\theta_{\min} = 1.22\lambda/D$ .

A **diffraction grating** consists of a large number of equally spaced, identical slits. The condition for intensity maxima in the interference pattern of a diffraction grating for normal incidence is

$$d \sin \theta = m\lambda \quad m = 0, 1, 2, 3, \dots \quad (38.10)$$

where  $d$  is the spacing between adjacent slits and  $m$  is the order number of the diffraction pattern. The resolving power of a diffraction grating in the  $m$ th order of the diffraction pattern is

$$R = Nm \quad (38.12)$$

where  $N$  is the number of lines in the grating that are illuminated.

When polarized light of intensity  $I_0$  is emitted by a polarizer and then incident on an analyzer, the light transmitted through the analyzer has an intensity equal to  $I_{\max} \cos^2 \theta$ , where  $\theta$  is the angle between the polarizer and analyzer transmission axes.

In general, reflected light is partially polarized. However, reflected light is completely polarized when the angle of incidence is such that the angle between the reflected and refracted beams is  $90^\circ$ . This angle of incidence, called the **polarizing angle**  $\theta_p$ , satisfies **Brewster's law**:

$$n = \tan \theta_p \quad (38.15)$$

where  $n$  is the index of refraction of the reflecting medium.

## QUESTIONS

- Why can you hear around corners but not see around them?
- Observe the shadow of your book when it is held a few inches above a table while illuminated by a lamp several feet above it. Why is the shadow somewhat fuzzy at the edges?
- Knowing that radio waves travel at the speed of light and that a typical AM radio frequency is 1 000 kHz while an FM radio frequency might be 100 MHz, estimate the wavelengths of typical AM and FM radio signals. Use this information to explain why FM radio stations often fade out when you drive through a short tunnel or underpass but AM radio stations do not.
- Describe the change in width of the central maximum of the single-slit diffraction pattern as the width of the slit is made narrower.
- Assuming that the headlights of a car are point sources, estimate the maximum observer-to-car distance at which the headlights are distinguishable from each other.
- A laser beam is incident at a shallow angle on a machinist's ruler that has a finely calibrated scale. The engraved rulings on the scale give rise to a diffraction pattern on a screen. Discuss how you can use this arrangement to obtain a measure of the wavelength of the laser light.
- Certain sunglasses use a polarizing material to reduce the intensity of light reflected from shiny surfaces. What orientation of polarization should the material have to be most effective?
- During the "day" on the Moon (that is, when the Sun is visible), you see a black sky and the stars are clearly visible. During the day on the Earth, you see a blue sky and no stars. Account for this difference.
- You can make the path of a light beam visible by placing dust in the air (perhaps by shaking a blackboard eraser in the path of the light beam). Explain why you can see the beam under these circumstances.
- Is light from the sky polarized? Why is it that clouds seen through Polaroid glasses stand out in bold contrast to the sky?
- If a coin is glued to a glass sheet and the arrangement is held in front of a laser beam, the projected shadow has diffraction rings around its edge and a bright spot in the center. How is this possible?
- If a fine wire is stretched across the path of a laser beam, is it possible to produce a diffraction pattern?
- How could the index of refraction of a flat piece of dark obsidian glass be determined?

### Section 38.1 Introduction to Diffraction

#### Section 38.2 Diffraction from Narrow Slits

- Helium-neon laser light ( $\lambda = 632.8$  nm) is sent through a 0.300-mm-wide single slit. What is the width of the central maximum on a screen 1.00 m from the slit?
- A beam of green light is diffracted by a slit with a width of 0.550 mm. The diffraction pattern forms on a wall 2.06 m beyond the slit. The distance between the positions of zero intensity on both sides of the central bright fringe is 4.10 mm. Calculate the wavelength of the laser light.
- WEB A screen is placed 50.0 cm from a single slit, which is illuminated with 690-nm light. If the distance between the first and third minima in the diffraction pattern is 3.00 mm, what is the width of the slit?
- Coherent microwaves of wavelength 5.00 cm enter a long, narrow window in a building otherwise essentially opaque to the microwaves. If the window is 36.0 cm wide, what is the distance from the central maximum to the first-order minimum along a wall 6.50 m from the window?
- Sound with a frequency of 650 Hz from a distant source passes through a doorway 1.10 m wide in a sound-absorbing wall. Find the number and approximate directions of the diffraction-maximum beams radiated into the space beyond.
- Light with a wavelength of 587.5 nm illuminates a single slit 0.750 mm in width. (a) At what distance from the slit should a screen be located if the first minimum in the diffraction pattern is to be 0.850 mm from the center of the screen? (b) What is the width of the central maximum?
- A diffraction pattern is formed on a screen 120 cm away from a 0.400-mm-wide slit. Monochromatic 546.1-nm light is used. Calculate the fractional intensity  $I/I_0$  at a point on the screen 4.10 mm from the center of the principal maximum.
- The second-order bright fringe in a single-slit diffraction pattern is 1.40 mm from the center of the central maximum. The screen is 80.0 cm from a slit of width 0.800 mm. Assuming that the incident light is monochromatic, calculate the light's approximate wavelength.
- If the light in Figure 38.5 strikes the single slit at an angle  $\beta$  from the perpendicular direction, show that Equation 38.1, the condition for destructive interference, must be modified to read

$$\sin \theta = m \left( \frac{\lambda}{a} \right) - \sin \beta$$

- Coherent light with a wavelength of 501.5 nm is sent through two parallel slits in a large flat wall. Each slit is 0.700  $\mu\text{m}$  wide, and the slits' centers are 2.80  $\mu\text{m}$  apart. The light falls on a semicylindrical screen, with its axis at the midline between the slits. (a) Predict the direction of each interference maximum on the screen, as an angle away from the bisector of the line joining the slits. (b) Describe the pattern of light on the screen, specifying the number of bright fringes and the location of each. (c) Find the intensity of light on the screen at the center of each bright fringe, expressed as a fraction of the light intensity  $I_0$  at the center of the pattern.

### Section 38.3 Resolution of Single-Slit and Circular Apertures

- The pupil of a cat's eye narrows to a vertical slit of width 0.500 mm in daylight. What is the angular resolution for horizontally separated mice? Assume that the average wavelength of the light is 500 nm.
- Find the radius of a star image formed on the retina of the eye if the aperture diameter (the pupil) at night is 0.700 cm and the length of the eye is 3.00 cm. Assume that the representative wavelength of starlight in the eye is 500 nm.
- WEB A helium-neon laser emits light that has a wavelength of 632.8 nm. The circular aperture through which the beam emerges has a diameter of 0.500 cm. Estimate the diameter of the beam 10.0 km from the laser.
- On the night of April 18, 1775, a signal was to be sent from the steeple of Old North Church in Boston to Paul Revere, who was 1.80 mi away: "One if by land, two if by sea." At what minimum separation did the sexton have to set the lanterns for Revere to receive the correct message? Assume that Revere's pupils had a diameter of 4.00 mm at night and that the lantern light had a predominant wavelength of 580 nm.
- The Impressionist painter Georges Seurat created paintings with an enormous number of dots of pure pigment, each of which was approximately 2.00 mm in diameter. The idea was to locate colors such as red and green next to each other to form a scintillating canvas (Fig. P38.15). Outside what distance would one be unable to discern individual dots on the canvas? (Assume that  $\lambda = 500$  nm and that the pupil diameter is 4.00 mm.)
- A binary star system in the constellation Orion has an angular interstellar separation of  $1.00 \times 10^{-5}$  rad. If  $\lambda = 500$  nm, what is the smallest diameter a telescope must have to just resolve the two stars?

**Figure P38.15** *Sunday Afternoon on the Isle of La Grande Jatte*, by Georges Seurat. (SuperStock)

17. A child is standing at the edge of a straight highway watching her grandparents' car driving away at 20.0 m/s. The air is perfectly clear and steady, and after 10.0 min the car's two taillights appear to merge into one. Assuming the diameter of the child's pupils is 5.00 mm, estimate the width of the car.
18. Suppose that you are standing on a straight highway and watching a car moving away from you at a speed  $v$ . The air is perfectly clear and steady, and after a time  $t$  the taillights appear to merge into one. Assuming the diameter of your pupil is  $d$ , estimate the width of the car.
19. A circular radar antenna on a Coast Guard ship has a diameter of 2.10 m and radiates at a frequency of 15.0 GHz. Two small boats are located 9.00 km away from the ship. How close together could the boats be and still be detected as two objects?
20. If we were to send a ruby laser beam ( $\lambda = 694.3$  nm) outward from the barrel of a 2.70-m-diameter telescope, what would be the diameter of the big red spot when the beam hit the Moon 384 000 km away? (Neglect atmospheric dispersion.)
21. The angular resolution of a radio telescope is to be  $0.100^\circ$  when the incident waves have a wavelength of 3.00 mm. What minimum diameter is required for the telescope's receiving dish?
22. When Mars is nearest the Earth, the distance separating the two planets is  $88.6 \times 10^6$  km. Mars is viewed through a telescope whose mirror has a diameter of 30.0 cm. (a) If the wavelength of the light is 590 nm, what is the angular resolution of the telescope? (b) What is the smallest distance that can be resolved between two points on Mars?
23. White light is spread out into its spectral components by a diffraction grating. If the grating has 2 000 lines per centimeter, at what angle does red light of wavelength 640 nm appear in first order?
24. Light from an argon laser strikes a diffraction grating that has 5 310 lines per centimeter. The central and first-order principal maxima are separated by 0.488 m on a wall 1.72 m from the grating. Determine the wavelength of the laser light.
- WEB 25. The hydrogen spectrum has a red line at 656 nm and a violet line at 434 nm. What is the angular separation between two spectral lines obtained with a diffraction grating that has 4 500 lines per centimeter?
26. A helium-neon laser ( $\lambda = 632.8$  nm) is used to calibrate a diffraction grating. If the first-order maximum occurs at  $20.5^\circ$ , what is the spacing between adjacent grooves in the grating?
27. Three discrete spectral lines occur at angles of  $10.09^\circ$ ,  $13.71^\circ$ , and  $14.77^\circ$  in the first-order spectrum of a grating spectroscopy. (a) If the grating has 3 660 slits per centimeter, what are the wavelengths of the light? (b) At what angles are these lines found in the second-order spectrum?
28. A diffraction grating has 800 rulings per millimeter. A beam of light containing wavelengths from 500 to 700 nm hits the grating. Do the spectra of different orders overlap? Explain.
- WEB 29. A diffraction grating with a width of 4.00 cm has been ruled with 3 000 grooves per centimeter. (a) What is the resolving power of this grating in the first three orders? (b) If two monochromatic waves incident on this grating have a mean wavelength of 400 nm, what is their wavelength separation if they are just resolved in the third order?
30. Show that, whenever white light is passed through a diffraction grating of any spacing size, the violet end of the continuous visible spectrum in third order always overlaps the red light at the other end of the second-order spectrum.
31. A source emits 531.62-nm and 531.81-nm light. (a) What minimum number of lines is required for a grating that resolves the two wavelengths in the first-order spectrum? (b) Determine the slit spacing for a grating 1.32 cm wide that has the required minimum number of lines.
32. Two wavelengths  $\lambda$  and  $\lambda + \Delta\lambda$  (with  $\Delta\lambda \ll \lambda$ ) are incident on a diffraction grating. Show that the angular separation between the spectral lines in the  $m$ th order spectrum is
- $$\Delta\theta = \frac{\Delta\lambda}{\sqrt{(d/m)^2 - \lambda^2}}$$
- where  $d$  is the slit spacing and  $m$  is the order number.
33. A grating with 250 lines per millimeter is used with an incandescent light source. Assume that the visible spectrum ranges in wavelength from 400 to 700 nm. In how

### Section 38.4 The Diffraction Grating

*Note:* In the following problems, assume that the light is incident normally on the gratings.

many orders can one see (a) the entire visible spectrum and (b) the short-wavelength region?

34. A diffraction grating has 4 200 rulings per centimeter. On a screen 2.00 m from the grating, it is found that for a particular order  $m$ , the maxima corresponding to two closely spaced wavelengths of sodium (589.0 nm and 589.6 nm) are separated by 1.59 mm. Determine the value of  $m$ .

(Optional)

### Section 38.5 Diffraction of X-Rays by Crystals

35. Potassium iodide (KI) has the same crystalline structure as NaCl, with  $d = 0.353$  nm. A monochromatic x-ray beam shows a diffraction maximum when the grazing angle is  $7.60^\circ$ . Calculate the x-ray wavelength. (Assume first order.)
36. A wavelength of 0.129 nm characterizes  $K_\alpha$  x-rays from zinc. When a beam of these x-rays is incident on the surface of a crystal whose structure is similar to that of NaCl, a first-order maximum is observed at  $8.15^\circ$ . Calculate the interplanar spacing on the basis of this information.
- WEB 37. If the interplanar spacing of NaCl is 0.281 nm, what is the predicted angle at which 0.140-nm x-rays are diffracted in a first-order maximum?
38. The first-order diffraction maximum is observed at  $12.6^\circ$  for a crystal in which the interplanar spacing is 0.240 nm. How many other orders can be observed?
39. Monochromatic x-rays of the  $K_\alpha$  line from a nickel target ( $\lambda = 0.166$  nm) are incident on a potassium chloride (KCl) crystal surface. The interplanar distance in KCl is 0.314 nm. At what angle (relative to the surface) should the beam be directed for a second-order maximum to be observed?
40. In water of uniform depth, a wide pier is supported on pilings in several parallel rows 2.80 m apart. Ocean waves of uniform wavelength roll in, moving in a direction that makes an angle of  $80.0^\circ$  with the rows of posts. Find the three longest wavelengths of waves that will be strongly reflected by the pilings.

### Section 38.6 Polarization of Light Waves

41. Unpolarized light passes through two polaroid sheets. The axis of the first is vertical, and that of the second is at  $30.0^\circ$  to the vertical. What fraction of the initial light is transmitted?
42. Three polarizing disks whose planes are parallel are centered on a common axis. The direction of the transmission axis in each case is shown in Figure P38.42 relative to the common vertical direction. A plane-polarized beam of light with  $E_0$  parallel to the vertical reference direction is incident from the left on the first disk with an intensity of  $I_i = 10.0$  units (arbitrary). Calculate the transmitted intensity  $I_f$  when (a)  $\theta_1 = 20.0^\circ$ ,  $\theta_2 = 40.0^\circ$ , and  $\theta_3 = 60.0^\circ$ ; (b)  $\theta_1 = 0^\circ$ ,  $\theta_2 = 30.0^\circ$ , and  $\theta_3 = 60.0^\circ$ .

Figure P38.42 Problems 42 and 48.

43. Plane-polarized light is incident on a single polarizing disk with the direction of  $E_0$  parallel to the direction of the transmission axis. Through what angle should the disk be rotated so that the intensity in the transmitted beam is reduced by a factor of (a) 3.00, (b) 5.00, (c) 10.0?
44. The angle of incidence of a light beam onto a reflecting surface is continuously variable. The reflected ray is found to be completely polarized when the angle of incidence is  $48.0^\circ$ . What is the index of refraction of the reflecting material?
45. The critical angle for total internal reflection for sapphire surrounded by air is  $34.4^\circ$ . Calculate the polarizing angle for sapphire.
46. For a particular transparent medium surrounded by air, show that the critical angle for total internal reflection and the polarizing angle are related by the expression  $\cot \theta_p = \sin \theta_c$ .
47. How far above the horizon is the Moon when its image reflected in calm water is completely polarized? ( $n_{\text{water}} = 1.33$ .)

### ADDITIONAL PROBLEMS

48. In Figure P38.42, suppose that the transmission axes of the left and right polarizing disks are perpendicular to each other. Also, let the center disk be rotated on the common axis with an angular speed  $\omega$ . Show that if unpolarized light is incident on the left disk with an intensity  $I_{\text{max}}$ , the intensity of the beam emerging from the right disk is

$$I = \frac{1}{16} I_{\text{max}} (1 - \cos 4\omega t)$$

This means that the intensity of the emerging beam is modulated at a rate that is four times the rate of rotation of the center disk. [Hint: Use the trigonometric identities  $\cos^2 \theta = (1 + \cos 2\theta)/2$  and  $\sin^2 \theta = (1 - \cos 2\theta)/2$ , and recall that  $\theta = \omega t$ .]

49. You want to rotate the plane of polarization of a polarized light beam by  $45.0^\circ$  with a maximum intensity reduction of 10.0%. (a) How many sheets of perfect polarizers do you need to achieve your goal? (b) What is the angle between adjacent polarizers?

50. Figure P38.50 shows a megaphone in use. Construct a theoretical description of how a megaphone works. You may assume that the sound of your voice radiates just through the opening of your mouth. Most of the information in speech is carried not in a signal at the fundamental frequency, but rather in noises and in harmonics, with frequencies of a few thousand hertz. Does your theory allow any prediction that is simple to test?

**Figure P38.50** (Susan Allen Sigmon/Allsport USA)

51. Light from a helium-neon laser ( $\lambda = 632.8 \text{ nm}$ ) is incident on a single slit. What is the maximum width for which no diffraction minima are observed?
52. What are the approximate dimensions of the smallest object on Earth that astronauts can resolve by eye when they are orbiting 250 km above the Earth? Assume that  $\lambda = 500 \text{ nm}$  and that a pupil's diameter is 5.00 mm.
53. **Review Problem.** A beam of 541-nm light is incident on a diffraction grating that has 400 lines per millimeter. (a) Determine the angle of the second-order ray. (b) If the entire apparatus is immersed in water, what is the new second-order angle of diffraction? (c) Show that the two diffracted rays of parts (a) and (b) are related through the law of refraction.
54. The Very Large Array is a set of 27 radio telescope dishes in Caton and Socorro Counties, New Mexico (Fig. P38.54). The antennas can be moved apart on railroad tracks, and their combined signals give the resolving power of a synthetic aperture 36.0 km in diameter. (a) If the detectors are tuned to a frequency of 1.40 GHz, what is the angular resolution of the VLA? (b) Clouds of hydrogen radiate at this frequency. What must be the separation distance for two clouds at the center of the galaxy, 26 000 lightyears away, if they are to be resolved? (c) As the telescope looks up, a circling hawk looks down. For comparison, find the angular resolution of the hawk's eye. Assume that it is most sensitive to green light having a wavelength of 500 nm and that it has a pupil with a diameter of 12.0 mm. (d) A mouse is on the ground 30.0 m below. By what distance must the mouse's whiskers be separated for the hawk to resolve them?

**Figure P38.54** A rancher in New Mexico rides past one of the 27 radio telescopes that make up the Very Large Array (VLA). © Danny Lehman

55. Grote Reber was a pioneer in radio astronomy. He constructed a radio telescope with a 10.0-m diameter receiving dish. What was the telescope's angular resolution for 2.00-m radio waves?
56. A 750-nm light beam hits the flat surface of a certain liquid, and the beam is split into a reflected ray and a refracted ray. If the reflected ray is completely polarized at  $36.0^\circ$ , what is the wavelength of the refracted ray?
57. Light of wavelength 500 nm is incident normally on a diffraction grating. If the third-order maximum of the diffraction pattern is observed at  $32.0^\circ$ , (a) what is the number of rulings per centimeter for the grating? (b) Determine the total number of primary maxima that can be observed in this situation.
58. Light strikes a water surface at the polarizing angle. The part of the beam refracted into the water strikes a submerged glass slab (index of refraction, 1.50), as shown in Figure P38.58. If the light reflected from the upper surface of the slab is completely polarized, what is the angle between the water surface and the glass slab?

**Figure P38.58**

59. An American standard television picture is composed of about 485 horizontal lines of varying light intensity. Assume that your ability to resolve the lines is limited only

by the Rayleigh criterion and that the pupils of your eyes are 5.00 mm in diameter. Calculate the ratio of minimum viewing distance to the vertical dimension of the picture such that you will not be able to resolve the lines. Assume that the average wavelength of the light coming from the screen is 550 nm.

60. (a) If light traveling in a medium for which the index of refraction is  $n_1$  is incident at an angle  $\theta$  on the surface of a medium of index  $n_2$  so that the angle between the reflected and refracted rays is  $\beta$ , show that

$$\tan \theta = \frac{n_2 \sin \beta}{n_1 - n_2 \cos \beta}$$

[Hint: Use the identity  $\sin(A + B) = \sin A \cos B + \cos A \sin B$ .] (b) Show that this expression for  $\tan \theta$  reduces to Brewster's law when  $\beta = 90^\circ$ ,  $n_1 = 1$ , and  $n_2 = n$ .

61. Suppose that the single slit in Figure 38.6 is 6.00 cm wide and in front of a microwave source operating at 7.50 GHz. (a) Calculate the angle subtended by the first minimum in the diffraction pattern. (b) What is the relative intensity  $I/I_{\max}$  at  $\theta = 15.0^\circ$ ? (c) Consider the case when there are two such sources, separated laterally by 20.0 cm, behind the slit. What must the maximum distance between the plane of the sources and the slit be if the diffraction patterns are to be resolved? (In this case, the approximation  $\sin \theta \approx \tan \theta$  is not valid because of the relatively small value of  $a/\lambda$ .)
62. Two polarizing sheets are placed together with their transmission axes crossed so that no light is transmitted. A third sheet is inserted between them with its transmission axis at an angle of  $45.0^\circ$  with respect to each of the other axes. Find the fraction of incident unpolarized light intensity transmitted by the three-sheet combination. (Assume that each polarizing sheet is ideal.)

63. Figure P38.63a is a three-dimensional sketch of a birefringent crystal. The dotted lines illustrate how a thin parallel-faced slab of material could be cut from the larger specimen with the optic axis of the crystal parallel to the faces of the plate. A section cut from the crystal in this manner is known as a *retardation plate*. When a beam of light is incident on the plate perpendicular to the direction of the optic axis, as shown in Figure P38.63b, the O ray and the E ray travel along a single straight line but with different speeds. (a) Letting the thickness of the plate be  $d$ , show that the phase difference between the O ray and the E ray is

$$\theta = \frac{2\pi d}{\lambda} (n_O - n_E)$$

where  $\lambda$  is the wavelength in air. (b) If in a particular case the incident light has a wavelength of 550 nm, what is the minimum value of  $d$  for a quartz plate for which  $\theta = \pi/2$ ? Such a plate is called a *quarter-wave plate*. (Use values of  $n_O$  and  $n_E$  from Table 38.1.)

(a)

(b)

Figure P38.63

64. Derive Equation 38.12 for the resolving power of a grating,  $R = Nm$ , where  $N$  is the number of lines illuminated and  $m$  is the order in the diffraction pattern. Remember that Rayleigh's criterion (see Section 38.3) states that two wavelengths will be resolved when the principal maximum for one falls on the first minimum for the other.
65. Light of wavelength 632.8 nm illuminates a single slit, and a diffraction pattern is formed on a screen 1.00 m from the slit. Using the data in the table on the following page, plot relative intensity versus distance. Choose an appropriate value for the slit width  $a$ , and on the same graph used for the experimental data, plot the theoretical expression for the relative intensity

$$\frac{I}{I_{\max}} = \frac{\sin^2(\beta/2)}{(\beta/2)^2}$$

What value of  $a$  gives the best fit of theory and experiment?

66. How much diffraction spreading does a light beam undergo? One quantitative answer is the *full width at half maximum* of the central maximum of the Fraunhofer diffraction pattern of a single slit. You can evaluate this angle of spreading in this problem and in the next. (a) In Equation 38.4, define  $\beta/2 = \phi$  and show that, at the point where  $I = 0.5I_{\max}$ , we must have  $\sin \phi = \phi/\sqrt{2}$ . (b) Let  $y_1 = \sin \phi$  and  $y_2 = \phi/\sqrt{2}$ . Plot  $y_1$  and  $y_2$  on the same set of axes over a range from  $\phi = 1$  rad to  $\phi = \pi/2$  rad. Determine  $\phi$  from the point of inter-

Relative Intensity	Distance from Center of Central Maximum (mm)
1.00	0
0.95	0.8
0.80	1.6
0.60	2.4
0.39	3.2
0.21	4.0
0.079	4.8
0.014	5.6
0.003	6.5
0.015	7.3
0.036	8.1
0.047	8.9
0.043	9.7
0.029	10.5
0.013	11.3
0.002	12.1
0.000 3	12.9
0.005	13.7
0.012	14.5
0.016	15.3
0.015	16.1
0.010	16.9
0.004 4	17.7
0.000 6	18.5
0.000 3	19.3
0.003	20.2

section of the two curves. (c) Then show that, if the fraction  $\lambda/a$  is not large, the angular full width at half maximum of the central diffraction maximum is  $\Delta\theta =$

$0.886\lambda/a$ .

**67.** Another method to solve the equation  $\phi = \sqrt{2} \sin \phi$  in Problem 66 is to use a calculator, guess a first value of  $\phi$ , see if it fits, and continue to update your estimate until the equation balances. How many steps (iterations) does this take?

**68.** In the diffraction pattern of a single slit, described by the equation

$$I_\theta = I_{\max} \left[ \frac{\sin(\beta/2)}{\beta/2} \right]^2$$

with  $\beta = (2\pi a \sin \theta)/\lambda$ , the central maximum is at  $\beta = 0$  and the side maxima are *approximately* at  $\beta/2 = (m + \frac{1}{2})\pi$  for  $m = 1, 2, 3, \dots$ . Determine more precisely (a) the location of the first side maximum, where  $m = 1$ , and (b) the location of the second side maximum. Observe in Figure 38.10a that the graph of intensity versus  $\beta/2$  has a horizontal tangent at maxima and also at minima. You will need to solve a transcendental equation.

**69.** A *pinhole camera* has a small circular aperture of diameter  $D$ . Light from distant objects passes through the aperture into an otherwise dark box, falling upon a screen located a distance  $L$  away. If  $D$  is too large, the display on the screen will be fuzzy because a bright point in the field of view will send light onto a circle of diameter slightly larger than  $D$ . On the other hand, if  $D$  is too small, diffraction will blur the display on the screen. The screen shows a reasonably sharp image if the diameter of the central disk of the diffraction pattern, specified by Equation 38.9, is equal to  $D$  at the screen. (a) Show that for monochromatic light with plane wave fronts and  $L \gg D$ , the condition for a sharp view is fulfilled if  $D^2 = 2.44 \lambda L$ . (b) Find the optimum pinhole diameter if 500-nm light is projected onto a screen 15.0 cm away.

## ANSWERS TO QUICK QUIZZES

- 38.1** The space between the slightly open door and the door-frame acts as a single slit. Sound waves have wavelengths that are approximately the same size as the opening and so are diffracted and spread throughout the room you are in. Because light wavelengths are much smaller than the slit width, they are virtually undiffracted. As a result, you must have a direct line of sight to detect the light waves.
- 38.2** The situation is like that depicted in Figure 38.11 except that now the slits are only half as far apart. The diffraction pattern is the same, but the interference pattern is stretched out because  $d$  is smaller. Because  $d/a = 3$ , the third interference maximum coincides with the first diffraction minimum. Your sketch should look like the figure to the right.
- 38.3** Yes, but no diffraction effects are observed because the separation distance between adjacent ribs is so much greater than the wavelength of the x-rays.

## PUZZLER

The wristwatches worn by the people in this commercial jetliner properly record the passage of time as experienced by the travelers. Amazingly, however, the duration of the trip as measured by an Earth-bound observer is very slightly longer. How can high-speed travel affect something as regular as the ticking of a clock? - 39.7** Relativistic Energy
- 39.8** Equivalence of Mass and Energy
- 39.9** Relativity and Electromagnetism
- 39.10** (Optional) The General Theory of Relativity

**M**ost of our everyday experiences and observations have to do with objects that move at speeds much less than the speed of light. Newtonian mechanics was formulated to describe the motion of such objects, and this formalism is still very successful in describing a wide range of phenomena that occur at low speeds. It fails, however, when applied to particles whose speeds approach that of light.

Experimentally, the predictions of Newtonian theory can be tested at high speeds by accelerating electrons or other charged particles through a large electric potential difference. For example, it is possible to accelerate an electron to a speed of  $0.99c$  (where  $c$  is the speed of light) by using a potential difference of several million volts. According to Newtonian mechanics, if the potential difference is increased by a factor of 4, the electron's kinetic energy is four times greater and its speed should double to  $1.98c$ . However, experiments show that the speed of the electron—as well as the speed of any other particle in the Universe—always remains less than the speed of light, regardless of the size of the accelerating voltage. Because it places no upper limit on speed, Newtonian mechanics is contrary to modern experimental results and is clearly a limited theory.

In 1905, at the age of only 26, Einstein published his special theory of relativity. Regarding the theory, Einstein wrote:

The relativity theory arose from necessity, from serious and deep contradictions in the old theory from which there seemed no escape. The strength of the new theory lies in the consistency and simplicity with which it solves all these difficulties . . . .<sup>1</sup>

Although Einstein made many other important contributions to science, the special theory of relativity alone represents one of the greatest intellectual achievements of all time. With this theory, experimental observations can be correctly predicted over the range of speeds from  $v = 0$  to speeds approaching the speed of light. At low speeds, Einstein's theory reduces to Newtonian mechanics as a limiting situation. It is important to recognize that Einstein was working on electromagnetism when he developed the special theory of relativity. He was convinced that Maxwell's equations were correct, and in order to reconcile them with one of his postulates, he was forced into the bizarre notion of assuming that space and time are not absolute.

This chapter gives an introduction to the special theory of relativity, with emphasis on some of its consequences. The special theory covers phenomena such as the slowing down of clocks and the contraction of lengths in moving reference frames as measured by a stationary observer. We also discuss the relativistic forms of momentum and energy, as well as some consequences of the famous mass–energy formula,  $E = mc^2$ .

In addition to its well-known and essential role in theoretical physics, the special theory of relativity has practical applications, including the design of nuclear power plants and modern global positioning system (GPS) units. These devices do not work if designed in accordance with nonrelativistic principles.

We shall have occasion to use relativity in some subsequent chapters of the extended version of this text, most often presenting only the outcome of relativistic effects.

### 39.1 THE PRINCIPLE OF GALILEAN RELATIVITY

Inertial frame of reference

To describe a physical event, it is necessary to establish a frame of reference. You should recall from Chapter 5 that Newton's laws are valid in all inertial frames of reference. Because an inertial frame is defined as one in which Newton's first law is valid, we can say that **an inertial frame of reference is one in which an object is observed to have no acceleration when no forces act on it.** Furthermore, any system moving with constant velocity with respect to an inertial system must also be an inertial system.

There is no preferred inertial reference frame. This means that the results of an experiment performed in a vehicle moving with uniform velocity will be identical to the results of the same experiment performed in a stationary vehicle. The formal statement of this result is called the **principle of Galilean relativity:**

The laws of mechanics must be the same in all inertial frames of reference.

Let us consider an observation that illustrates the equivalence of the laws of mechanics in different inertial frames. A pickup truck moves with a constant velocity, as shown in Figure 39.1a. If a passenger in the truck throws a ball straight up, and if air effects are neglected, the passenger observes that the ball moves in a vertical path. The motion of the ball appears to be precisely the same as if the ball were thrown by a person at rest on the Earth. The law of gravity and the equations of motion under constant acceleration are obeyed whether the truck is at rest or in uniform motion.

Now consider the same situation viewed by an observer at rest on the Earth. This stationary observer sees the path of the ball as a parabola, as illustrated in Figure 39.1b. Furthermore, according to this observer, the ball has a horizontal component of velocity equal to the velocity of the truck. Although the two observers disagree on certain aspects of the situation, they agree on the validity of Newton's laws and on such classical principles as conservation of energy and conservation of linear momentum. This agreement implies that no mechanical experiment can detect any difference between the two inertial frames. The only thing that can be detected is the relative motion of one frame with respect to the other. That is, the notion of absolute motion through space is meaningless, as is the notion of a preferred reference frame.

**Figure 39.1** (a) The observer in the truck sees the ball move in a vertical path when thrown upward. (b) The Earth observer sees the path of the ball as a parabola.

**Quick Quiz 39.1**

Which observer in Figure 39.1 is right about the ball's path?

Suppose that some physical phenomenon, which we call an *event*, occurs in an inertial system. The event's location and time of occurrence can be specified by the four coordinates  $(x, y, z, t)$ . We would like to be able to transform these coordinates from one inertial system to another one moving with uniform relative velocity.

Consider two inertial systems S and S' (Fig. 39.2). The system S' moves with a constant velocity  $\mathbf{v}$  along the  $xx'$  axes, where  $\mathbf{v}$  is measured relative to S. We assume that an event occurs at the point P and that the origins of S and S' coincide at  $t = 0$ . An observer in S describes the event with space–time coordinates  $(x, y, z, t)$ , whereas an observer in S' uses the coordinates  $(x', y', z', t')$  to describe the same event. As we see from Figure 39.2, the relationships between these various coordinates can be written

$$\begin{aligned}x' &= x - vt \\y' &= y \\z' &= z \\t' &= t\end{aligned}\tag{39.1}$$

These equations are the **Galilean space–time transformation equations**. Note that time is assumed to be the same in both inertial systems. That is, within the framework of classical mechanics, all clocks run at the same rate, regardless of their velocity, so that the time at which an event occurs for an observer in S is the same as the time for the same event in S'. Consequently, the time interval between two successive events should be the same for both observers. Although this assumption may seem obvious, it turns out to be incorrect in situations where  $v$  is comparable to the speed of light.

Now suppose that a particle moves a distance  $dx$  in a time interval  $dt$  as measured by an observer in S. It follows from Equations 39.1 that the corresponding distance  $dx'$  measured by an observer in S' is  $dx' = dx - v dt$ , where frame S' is moving with speed  $v$  relative to frame S. Because  $dt = dt'$ , we find that

$$\frac{dx'}{dt'} = \frac{dx}{dt} - v$$

or

$$u'_x = u_x - v\tag{39.2}$$

where  $u_x$  and  $u'_x$  are the  $x$  components of the velocity relative to S and S', respectively. (We use the symbol  $\mathbf{u}$  for particle velocity rather than  $\mathbf{v}$ , which is used for the relative velocity of two reference frames.) This is the **Galilean velocity transformation equation**. It is used in everyday observations and is consistent with our intuitive notion of time and space. As we shall soon see, however, it leads to serious contradictions when applied to electromagnetic waves.

**Quick Quiz 39.2**

Applying the Galilean velocity transformation equation, determine how fast (relative to the Earth) a baseball pitcher with a 90-mi/h fastball can throw a ball while standing in a boxcar moving at 110 mi/h.

**Figure 39.2** An event occurs at a point P. The event is seen by two observers in inertial frames S and S', where S' moves with a velocity  $\mathbf{v}$  relative to S.

Galilean space–time transformation equations

Galilean velocity transformation equation

## The Speed of Light

It is quite natural to ask whether the principle of Galilean relativity also applies to electricity, magnetism, and optics. Experiments indicate that the answer is no. Recall from Chapter 34 that Maxwell showed that the speed of light in free space is  $c = 3.00 \times 10^8$  m/s. Physicists of the late 1800s thought that light waves moved through a medium called the *ether* and that the speed of light was  $c$  only in a special, absolute frame at rest with respect to the ether. The Galilean velocity transformation equation was expected to hold in any frame moving at speed  $v$  relative to the absolute ether frame.

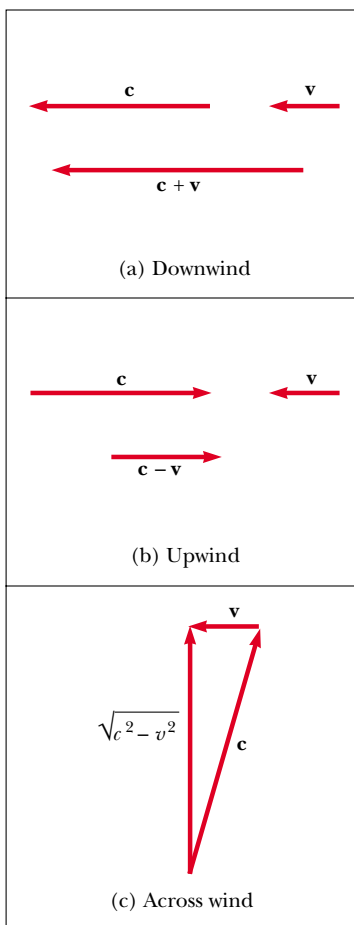

Because the existence of a preferred, absolute ether frame would show that light was similar to other classical waves and that Newtonian ideas of an absolute frame were true, considerable importance was attached to establishing the existence of the ether frame. Prior to the late 1800s, experiments involving light traveling in media moving at the highest laboratory speeds attainable at that time were not capable of detecting changes as small as  $c \pm v$ . Starting in about 1880, scientists decided to use the Earth as the moving frame in an attempt to improve their chances of detecting these small changes in the speed of light.

As observers fixed on the Earth, we can say that we are stationary and that the absolute ether frame containing the medium for light propagation moves past us with speed  $v$ . Determining the speed of light under these circumstances is just like determining the speed of an aircraft traveling in a moving air current, or wind; consequently, we speak of an “ether wind” blowing through our apparatus fixed to the Earth.

A direct method for detecting an ether wind would use an apparatus fixed to the Earth to measure the wind’s influence on the speed of light. If  $v$  is the speed of the ether relative to the Earth, then the speed of light should have its maximum value,  $c + v$ , when propagating downwind, as shown in Figure 39.3a. Likewise, the speed of light should have its minimum value,  $c - v$ , when propagating upwind, as shown in Figure 39.3b, and an intermediate value,  $(c^2 - v^2)^{1/2}$ , in the direction perpendicular to the ether wind, as shown in Figure 39.3c. If the Sun is assumed to be at rest in the ether, then the velocity of the ether wind would be equal to the orbital velocity of the Earth around the Sun, which has a magnitude of approximately  $3 \times 10^4$  m/s. Because  $c = 3 \times 10^8$  m/s, it should be possible to detect a change in speed of about 1 part in  $10^4$  for measurements in the upwind or downwind directions. However, as we shall see in the next section, all attempts to detect such changes and establish the existence of the ether wind (and hence the absolute frame) proved futile! (You may want to return to Problem 40 in Chapter 4 to see a situation in which the Galilean velocity transformation equation does hold.)

If it is assumed that the laws of electricity and magnetism are the same in all inertial frames, a paradox concerning the speed of light immediately arises. We can understand this by recognizing that Maxwell’s equations seem to imply that the speed of light always has the fixed value  $3.00 \times 10^8$  m/s in all inertial frames, a result in direct contradiction to what is expected based on the Galilean velocity transformation equation. According to Galilean relativity, the speed of light should not be the same in all inertial frames.

For example, suppose a light pulse is sent out by an observer  $S'$  standing in a boxcar moving with a velocity  $\mathbf{v}$  relative to a stationary observer standing alongside the track (Fig. 39.4). The light pulse has a speed  $c$  relative to  $S'$ . According to Galilean relativity, the pulse speed relative to  $S$  should be  $c + v$ . This is in contradiction to Einstein’s special theory of relativity, which, as we shall see, postulates that the speed of the pulse is the same for all observers.

**Figure 39.3** If the velocity of the ether wind relative to the Earth is  $\mathbf{v}$  and the velocity of light relative to the ether is  $\mathbf{c}$ , then the speed of light relative to the Earth is (a)  $c + v$  in the downwind direction, (b)  $c - v$  in the upwind direction, and (c)  $(c^2 - v^2)^{1/2}$  in the direction perpendicular to the wind.

**Figure 39.4** A pulse of light is sent out by a person in a moving boxcar. According to Galilean relativity, the speed of the pulse should be  $c + v$  relative to a stationary observer.

To resolve this contradiction in theories, we must conclude that either (1) the laws of electricity and magnetism are not the same in all inertial frames or (2) the Galilean velocity transformation equation is incorrect. If we assume the first alternative, then a preferred reference frame in which the speed of light has the value  $c$  must exist and the measured speed must be greater or less than this value in any other reference frame, in accordance with the Galilean velocity transformation equation. If we assume the second alternative, then we are forced to abandon the notions of absolute time and absolute length that form the basis of the Galilean space–time transformation equations.

### 39.2 THE MICHELSON–MORLEY EXPERIMENT

The most famous experiment designed to detect small changes in the speed of light was first performed in 1881 by Albert A. Michelson (see Section 37.7) and later repeated under various conditions by Michelson and Edward W. Morley (1838–1923). We state at the outset that the outcome of the experiment contradicted the ether hypothesis.

The experiment was designed to determine the velocity of the Earth relative to that of the hypothetical ether. The experimental tool used was the Michelson interferometer, which was discussed in Section 37.7 and is shown again in Figure 39.5. Arm 2 is aligned along the direction of the Earth's motion through space. The Earth moving through the ether at speed  $v$  is equivalent to the ether flowing past the Earth in the opposite direction with speed  $v$ . This ether wind blowing in the direction opposite the direction of Earth's motion should cause the speed of light measured in the Earth frame to be  $c - v$  as the light approaches mirror  $M_2$  and  $c + v$  after reflection, where  $c$  is the speed of light in the ether frame.

The two beams reflected from  $M_1$  and  $M_2$  recombine, and an interference pattern consisting of alternating dark and bright fringes is formed. The interference pattern was observed while the interferometer was rotated through an angle of  $90^\circ$ . This rotation supposedly would change the speed of the ether wind along the arms of the interferometer. The rotation should have caused the fringe pattern to shift slightly but measurably, but measurements failed to show any change in the interference pattern! The Michelson–Morley experiment was repeated at different times of the year when the ether wind was expected to change direction

**Figure 39.5** According to the ether wind theory, the speed of light should be  $c - v$  as the beam approaches mirror  $M_2$  and  $c + v$  after reflection.

### Albert Einstein (1879–1955)

Einstein, one of the greatest physicists of all times, was born in Ulm, Germany. In 1905, at the age of 26, he published four scientific papers that revolutionized physics. Two of these papers were concerned with what is now considered his most important contribution: the special theory of relativity.

In 1916, Einstein published his work on the general theory of relativity. The most dramatic prediction of this theory is the degree to which light is deflected by a gravitational field. Measurements made by astronomers on bright stars in the vicinity of the eclipsed Sun in 1919 confirmed Einstein's prediction, and as a result Einstein became a world celebrity.

Einstein was deeply disturbed by the development of quantum mechanics in the 1920s despite his own role as a scientific revolutionary. In particular, he could never accept the probabilistic view of events in nature that is a central feature of quantum theory. The last few decades of his life were devoted to an unsuccessful search for a unified theory that would combine gravitation and electromagnetism. (*AIP Niels Bohr Library*)

and magnitude, but the results were always the same: **no fringe shift of the magnitude required was ever observed.**<sup>2</sup>

The negative results of the Michelson–Morley experiment not only contradicted the ether hypothesis but also showed that it was impossible to measure the absolute velocity of the Earth with respect to the ether frame. However, as we shall see in the next section, Einstein offered a postulate for his special theory of relativity that places quite a different interpretation on these null results. In later years, when more was known about the nature of light, the idea of an ether that permeates all of space was relegated to the ash heap of worn-out concepts. **Light is now understood to be an electromagnetic wave, which requires no medium for its propagation.** As a result, the idea of an ether in which these waves could travel became unnecessary.

### Optional Section

#### Details of the Michelson–Morley Experiment

To understand the outcome of the Michelson–Morley experiment, let us assume that the two arms of the interferometer in Figure 39.5 are of equal length  $L$ . We shall analyze the situation as if there were an ether wind, because that is what Michelson and Morley expected to find. As noted above, the speed of the light beam along arm 2 should be  $c - v$  as the beam approaches  $M_2$  and  $c + v$  after the beam is reflected. Thus, the time of travel to the right is  $L/(c - v)$ , and the time of travel to the left is  $L/(c + v)$ . The total time needed for the round trip along arm 2 is

$$t_1 = \frac{L}{c + v} + \frac{L}{c - v} = \frac{2Lc}{c^2 - v^2} = \frac{2L}{c} \left(1 - \frac{v^2}{c^2}\right)^{-1}$$

Now consider the light beam traveling along arm 1, perpendicular to the ether wind. Because the speed of the beam relative to the Earth is  $(c^2 - v^2)^{1/2}$  in this case (see Fig. 39.3), the time of travel for each half of the trip is  $L/(c^2 - v^2)^{1/2}$ , and the total time of travel for the round trip is

$$t_2 = \frac{2L}{(c^2 - v^2)^{1/2}} = \frac{2L}{c} \left(1 - \frac{v^2}{c^2}\right)^{-1/2}$$

Thus, the time difference between the horizontal round trip (arm 2) and the vertical round trip (arm 1) is

$$\Delta t = t_1 - t_2 = \frac{2L}{c} \left[ \left(1 - \frac{v^2}{c^2}\right)^{-1} - \left(1 - \frac{v^2}{c^2}\right)^{-1/2} \right]$$

Because  $v^2/c^2 \ll 1$ , we can simplify this expression by using the following binomial expansion after dropping all terms higher than second order:

$$(1 - x)^n \approx 1 - nx \quad \text{for } x \ll 1$$

In our case,  $x = v^2/c^2$ , and we find that

$$\Delta t = t_1 - t_2 \approx \frac{Lv^2}{c^3} \quad (39.3)$$

This time difference between the two instants at which the reflected beams arrive at the viewing telescope gives rise to a phase difference between the beams,

<sup>2</sup> From an Earth observer's point of view, changes in the Earth's speed and direction of motion in the course of a year are viewed as ether wind shifts. Even if the speed of the Earth with respect to the ether were zero at some time, six months later the speed of the Earth would be 60 km/s with respect to the ether, and as a result a fringe shift should be noticed. No shift has ever been observed, however.

producing an interference pattern when they combine at the position of the telescope. A shift in the interference pattern should be detected when the interferometer is rotated through  $90^\circ$  in a horizontal plane, so that the two beams exchange roles. This results in a time difference twice that given by Equation 39.3. Thus, the path difference that corresponds to this time difference is

$$\Delta d = c(2 \Delta t) = \frac{2Lv^2}{c^2}$$

Because a change in path length of one wavelength corresponds to a shift of one fringe, the corresponding fringe shift is equal to this path difference divided by the wavelength of the light:

$$\text{Shift} = \frac{2Lv^2}{\lambda c^2} \quad (39.4)$$

In the experiments by Michelson and Morley, each light beam was reflected by mirrors many times to give an effective path length  $L$  of approximately 11 m. Using this value and taking  $v$  to be equal to  $3.0 \times 10^4$  m/s, the speed of the Earth around the Sun, we obtain a path difference of

$$\Delta d = \frac{2(11 \text{ m})(3.0 \times 10^4 \text{ m/s})^2}{(3.0 \times 10^8 \text{ m/s})^2} = 2.2 \times 10^{-7} \text{ m}$$

This extra travel distance should produce a noticeable shift in the fringe pattern. Specifically, using 500-nm light, we expect a fringe shift for rotation through  $90^\circ$  of

$$\text{Shift} = \frac{\Delta d}{\lambda} = \frac{2.2 \times 10^{-7} \text{ m}}{5.0 \times 10^{-7} \text{ m}} \approx 0.44$$

The instrument used by Michelson and Morley could detect shifts as small as 0.01 fringe. However, **it detected no shift whatsoever in the fringe pattern.** Since then, the experiment has been repeated many times by different scientists under a wide variety of conditions, and no fringe shift has ever been detected. Thus, it was concluded that the motion of the Earth with respect to the postulated ether cannot be detected.

Many efforts were made to explain the null results of the Michelson–Morley experiment and to save the ether frame concept and the Galilean velocity transformation equation for light. All proposals resulting from these efforts have been shown to be wrong. No experiment in the history of physics received such valiant efforts to explain the absence of an expected result as did the Michelson–Morley experiment. The stage was set for Einstein, who solved the problem in 1905 with his special theory of relativity.

### 39.3 EINSTEIN'S PRINCIPLE OF RELATIVITY

In the previous section we noted the impossibility of measuring the speed of the ether with respect to the Earth and the failure of the Galilean velocity transformation equation in the case of light. Einstein proposed a theory that boldly removed these difficulties and at the same time completely altered our notion of space and time.<sup>3</sup> He based his special theory of relativity on two postulates:

<sup>3</sup> A. Einstein, "On the Electrodynamics of Moving Bodies," *Ann. Physik* 17:891, 1905. For an English translation of this article and other publications by Einstein, see the book by H. Lorentz, A. Einstein, H. Minkowski, and H. Weyl, *The Principle of Relativity*, Dover, 1958.

The postulates of the special theory of relativity

1. **The principle of relativity:** The laws of physics must be the same in all inertial reference frames.
2. **The constancy of the speed of light:** The speed of light in vacuum has the same value,  $c = 3.00 \times 10^8$  m/s, in all inertial frames, regardless of the velocity of the observer or the velocity of the source emitting the light.

The first postulate asserts that *all* the laws of physics—those dealing with mechanics, electricity and magnetism, optics, thermodynamics, and so on—are the same in all reference frames moving with constant velocity relative to one another. This postulate is a sweeping generalization of the principle of Galilean relativity, which refers only to the laws of mechanics. From an experimental point of view, Einstein's principle of relativity means that any kind of experiment (measuring the speed of light, for example) performed in a laboratory at rest must give the same result when performed in a laboratory moving at a constant velocity past the first one. Hence, no preferred inertial reference frame exists, and it is impossible to detect absolute motion.

Note that postulate 2 is required by postulate 1: If the speed of light were not the same in all inertial frames, measurements of different speeds would make it possible to distinguish between inertial frames; as a result, a preferred, absolute frame could be identified, in contradiction to postulate 1.

Although the Michelson–Morley experiment was performed before Einstein published his work on relativity, it is not clear whether or not Einstein was aware of the details of the experiment. Nonetheless, the null result of the experiment can be readily understood within the framework of Einstein's theory. According to his principle of relativity, the premises of the Michelson–Morley experiment were incorrect. In the process of trying to explain the expected results, we stated that when light traveled against the ether wind its speed was  $c - v$ , in accordance with the Galilean velocity transformation equation. However, if the state of motion of the observer or of the source has no influence on the value found for the speed of light, one always measures the value to be  $c$ . Likewise, the light makes the return trip after reflection from the mirror at speed  $c$ , not at speed  $c + v$ . Thus, the motion of the Earth does not influence the fringe pattern observed in the Michelson–Morley experiment, and a null result should be expected.

If we accept Einstein's theory of relativity, we must conclude that relative motion is unimportant when measuring the speed of light. At the same time, we shall see that we must alter our common-sense notion of space and time and be prepared for some bizarre consequences. It may help as you read the pages ahead to keep in mind that our common-sense ideas are based on a lifetime of everyday experiences and not on observations of objects moving at hundreds of thousands of kilometers per second.

### **39.4** CONSEQUENCES OF THE SPECIAL THEORY OF RELATIVITY

Before we discuss the consequences of Einstein's special theory of relativity, we must first understand how an observer located in an inertial reference frame describes an event. As mentioned earlier, an event is an occurrence describable by three space coordinates and one time coordinate. Different observers in different inertial frames usually describe the same event with different coordinates.

**Figure 39.6** In studying relativity, we use a reference frame consisting of a coordinate grid and a set of synchronized clocks.

The reference frame used to describe an event consists of a coordinate grid and a set of synchronized clocks located at the grid intersections, as shown in Figure 39.6 in two dimensions. The clocks can be synchronized in many ways with the help of light signals. For example, suppose an observer is located at the origin with a master clock and sends out a pulse of light at  $t = 0$ . The pulse takes a time  $r/c$  to reach a clock located a distance  $r$  from the origin. Hence, this clock is synchronized with the master clock if this clock reads  $r/c$  at the instant the pulse reaches it. This procedure of synchronization assumes that the speed of light has the same value in all directions and in all inertial frames. Furthermore, the procedure concerns an event recorded by an observer in a specific inertial reference frame. An observer in some other inertial frame would assign different space–time coordinates to events being observed by using another coordinate grid and another array of clocks.

As we examine some of the consequences of relativity in the remainder of this section, we restrict our discussion to the concepts of simultaneity, time, and length, all three of which are quite different in relativistic mechanics from what they are in Newtonian mechanics. For example, in relativistic mechanics the distance between two points and the time interval between two events depend on the frame of reference in which they are measured. That is, **in relativistic mechanics there is no such thing as absolute length or absolute time.** Furthermore, **events at different locations that are observed to occur simultaneously in one frame are not observed to be simultaneous in another frame moving uniformly past the first.**

### Simultaneity and the Relativity of Time

A basic premise of Newtonian mechanics is that a universal time scale exists that is the same for all observers. In fact, Newton wrote that “Absolute, true, and mathematical time, of itself, and from its own nature, flows equably without relation to anything external.” Thus, Newton and his followers simply took simultaneity for granted. In his special theory of relativity, Einstein abandoned this assumption.

Einstein devised the following thought experiment to illustrate this point. A boxcar moves with uniform velocity, and two lightning bolts strike its ends, as illustrated in Figure 39.7a, leaving marks on the boxcar and on the ground. The marks on the boxcar are labeled  $A'$  and  $B'$ , and those on the ground are labeled  $A$  and  $B$ . An observer  $O'$  moving with the boxcar is midway between  $A'$  and  $B'$ , and a ground observer  $O$  is midway between  $A$  and  $B$ . The events recorded by the observers are the striking of the boxcar by the two lightning bolts.

**Figure 39.7** (a) Two lightning bolts strike the ends of a moving boxcar. (b) The events appear to be simultaneous to the stationary observer  $O$ , standing midway between  $A$  and  $B$ . The events do not appear to be simultaneous to observer  $O'$ , who claims that the front of the car is struck before the rear. Note that in (b) the leftward-traveling light signal has already passed  $O'$  but the rightward-traveling signal has not yet reached  $O'$ .

The light signals recording the instant at which the two bolts strike reach observer  $O$  at the same time, as indicated in Figure 39.7b. This observer realizes that the signals have traveled at the same speed over equal distances, and so rightly concludes that the events at  $A$  and  $B$  occurred simultaneously. Now consider the same events as viewed by observer  $O'$ . By the time the signals have reached observer  $O$ , observer  $O'$  has moved as indicated in Figure 39.7b. Thus, the signal from  $B'$  has already swept past  $O'$ , but the signal from  $A'$  has not yet reached  $O'$ . In other words,  $O'$  sees the signal from  $B'$  before seeing the signal from  $A'$ . According to Einstein, *the two observers must find that light travels at the same speed*. Therefore, observer  $O'$  concludes that the lightning strikes the front of the boxcar before it strikes the back.

This thought experiment clearly demonstrates that the two events that appear to be simultaneous to observer  $O$  do not appear to be simultaneous to observer  $O'$ . In other words,

two events that are simultaneous in one reference frame are in general not simultaneous in a second frame moving relative to the first. That is, simultaneity is not an absolute concept but rather one that depends on the state of motion of the observer.

### Quick Quiz 39.3

Which observer in Figure 39.7 is correct?

The central point of relativity is this: Any inertial frame of reference can be used to describe events and do physics. **There is no preferred inertial frame of reference.** However, observers in different inertial frames always measure different time intervals with their clocks and different distances with their meter sticks. Nevertheless, all observers agree on the forms of the laws of physics in their respective frames because these laws must be the same for all observers in uniform motion. For example, the relationship  $F = ma$  in a frame  $S$  has the same form  $F' = ma'$  in a frame  $S'$  that is moving at constant velocity relative to frame  $S$ . It is

the alteration of time and space that allows the laws of physics (including Maxwell's equations) to be the same for all observers in uniform motion.

### Time Dilation

We can illustrate the fact that observers in different inertial frames always measure different time intervals between a pair of events by considering a vehicle moving to the right with a speed  $v$ , as shown in Figure 39.8a. A mirror is fixed to the ceiling of the vehicle, and observer  $O'$  at rest in this system holds a laser a distance  $d$  below the mirror. At some instant, the laser emits a pulse of light directed toward the mirror (event 1), and at some later time after reflecting from the mirror, the pulse arrives back at the laser (event 2). Observer  $O'$  carries a clock  $C'$  and uses it to measure the time interval  $\Delta t_p$  between these two events. (The subscript  $p$  stands for *proper*, as we shall see in a moment.) Because the light pulse has a speed  $c$ , the time it takes the pulse to travel from  $O'$  to the mirror and back to  $O'$  is

$$\Delta t_p = \frac{\text{Distance traveled}}{\text{Speed}} = \frac{2d}{c} \quad (39.5)$$

This time interval  $\Delta t_p$  measured by  $O'$  requires only a single clock  $C'$  located at the same place as the laser in this frame.

Now consider the same pair of events as viewed by observer  $O$  in a second frame, as shown in Figure 39.8b. According to this observer, the mirror and laser are moving to the right with a speed  $v$ , and as a result the sequence of events appears entirely different. By the time the light from the laser reaches the mirror, the mirror has moved to the right a distance  $v \Delta t/2$ , where  $\Delta t$  is the time it takes the light to travel from  $O'$  to the mirror and back to  $O'$  as measured by  $O$ . In other words,  $O$  concludes that, because of the motion of the vehicle, if the light is to hit the mirror, it must leave the laser at an angle with respect to the vertical direction. Comparing Figure 39.8a and b, we see that the light must travel farther in (b) than in (a). (Note that neither observer "knows" that he or she is moving. Each is at rest in his or her own inertial frame.)

**Figure 39.8** (a) A mirror is fixed to a moving vehicle, and a light pulse is sent out by observer  $O'$  at rest in the vehicle. (b) Relative to a stationary observer  $O$  standing alongside the vehicle, the mirror and  $O'$  move with a speed  $v$ . Note that what observer  $O$  measures for the distance the pulse travels is greater than  $2d$ . (c) The right triangle for calculating the relationship between  $\Delta t$  and  $\Delta t_p$ .

According to the second postulate of the special theory of relativity, both observers must measure  $c$  for the speed of light. Because the light travels farther in the frame of  $O$ , it follows that the time interval  $\Delta t$  measured by  $O$  is longer than the time interval  $\Delta t_p$  measured by  $O'$ . To obtain a relationship between these two time intervals, it is convenient to use the right triangle shown in Figure 39.8c. The Pythagorean theorem gives

$$\left(\frac{c \Delta t}{2}\right)^2 = \left(\frac{v \Delta t}{2}\right)^2 + d^2$$

Solving for  $\Delta t$  gives

$$\Delta t = \frac{2d}{\sqrt{c^2 - v^2}} = \frac{2d}{c \sqrt{1 - \frac{v^2}{c^2}}} \quad (39.6)$$

Because  $\Delta t_p = 2d/c$ , we can express this result as

$$\Delta t = \frac{\Delta t_p}{\sqrt{1 - \frac{v^2}{c^2}}} = \gamma \Delta t_p \quad (39.7)$$

where

$$\gamma = (1 - v^2/c^2)^{-1/2} \quad (39.8)$$

Because  $\gamma$  is always greater than unity, this result says that **the time interval  $\Delta t$  measured by an observer moving with respect to a clock is longer than the time interval  $\Delta t_p$  measured by an observer at rest with respect to the clock.** (That is,  $\Delta t > \Delta t_p$ .) This effect is known as **time dilation**. Figure 39.9 shows that as the velocity approaches the speed of light,  $\gamma$  increases dramatically. Note that for speeds less than one tenth the speed of light,  $\gamma$  is very nearly equal to unity.

The time interval  $\Delta t_p$  in Equations 39.5 and 39.7 is called the **proper time**. (In German, Einstein used the term *Eigenzeit*, which means “own-time.”) In general, **proper time is the time interval between two events measured by an observer who sees the events occur at the same point in space.** Proper time is always the time measured with a single clock (clock  $C'$  in our case) at rest in the frame in which the events take place.

If a clock is moving with respect to you, it appears to fall behind (tick more slowly than) the clocks it is passing in the grid of synchronized clocks in your reference frame. Because the time interval  $\gamma(2d/c)$ , the interval between ticks of a moving

**Figure 39.9** Graph of  $\gamma$  versus  $v$ . As the velocity approaches the speed of light,  $\gamma$  increases rapidly.

clock, is observed to be longer than  $2d/c$ , the time interval between ticks of an identical clock in your reference frame, it is often said that a moving clock runs more slowly than a clock in your reference frame by a factor  $\gamma$ . This is true for mechanical clocks as well as for the light clock just described. We can generalize this result by stating that all physical processes, including chemical and biological ones, slow down relative to a stationary clock when those processes occur in a moving frame. For example, the heartbeat of an astronaut moving through space would keep time with a clock inside the spaceship. Both the astronaut's clock and heartbeat would be slowed down relative to a stationary clock back on the Earth (although the astronaut would have no sensation of life slowing down in the spaceship).

### Quick Quiz 39.4

A rocket has a clock built into its control panel. Use Figure 39.9 to determine approximately how fast the rocket must be moving before its clock appears to an Earth-bound observer to be ticking at one fifth the rate of a clock on the wall at Mission Control. What does an astronaut in the rocket observe?

Bizarre as it may seem, time dilation is a verifiable phenomenon. An experiment reported by Hafele and Keating provided direct evidence of time dilation.<sup>4</sup> Time intervals measured with four cesium atomic clocks in jet flight were compared with time intervals measured by Earth-based reference atomic clocks. In order to compare these results with theory, many factors had to be considered, including periods of acceleration and deceleration relative to the Earth, variations in direction of travel, and the fact that the gravitational field experienced by the flying clocks was weaker than that experienced by the Earth-based clock. The results were in good agreement with the predictions of the special theory of relativity and can be explained in terms of the relative motion between the Earth and the jet aircraft. In their paper, Hafele and Keating stated that “Relative to the atomic time scale of the U.S. Naval Observatory, the flying clocks lost  $59 \pm 10$  ns during the eastward trip and gained  $273 \pm 7$  ns during the westward trip . . . . These results provide an unambiguous empirical resolution of the famous clock paradox with macroscopic clocks.”

Another interesting example of time dilation involves the observation of *muons*, unstable elementary particles that have a charge equal to that of the electron and a mass 207 times that of the electron. Muons can be produced by the collision of cosmic radiation with atoms high in the atmosphere. These particles have a lifetime of  $2.2 \mu\text{s}$  when measured in a reference frame in which they are at rest or moving slowly. If we take  $2.2 \mu\text{s}$  as the average lifetime of a muon and assume that its speed is close to the speed of light, we find that these particles travel only approximately 600 m before they decay (Fig. 39.10a). Hence, they cannot reach the Earth from the upper atmosphere where they are produced. However, experiments show that a large number of muons do reach the Earth. The phenomenon of time dilation explains this effect. Relative to an observer on the Earth, the muons have a lifetime equal to  $\gamma\tau_p$ , where  $\tau_p = 2.2 \mu\text{s}$  is the lifetime in the frame traveling with the muons or the proper lifetime. For example, for a muon speed of  $v = 0.99c$ ,  $\gamma \approx 7.1$  and  $\gamma\tau_p \approx 16 \mu\text{s}$ . Hence, the average distance traveled as measured by an observer on the Earth is  $\gamma v\tau_p \approx 4800$  m, as indicated in Figure 39.10b.

In 1976, at the laboratory of the European Council for Nuclear Research

**Figure 39.10** (a) Muons moving with a speed of  $0.99c$  travel approximately 600 m as measured in the reference frame of the muons, where their lifetime is about  $2.2 \mu\text{s}$ . (b) The muons travel approximately 4800 m as measured by an observer on the Earth.

<sup>4</sup> J. C. Hafele and R. E. Keating, “Around the World Atomic Clocks: Relativistic Time Gains Observed,” *Science*, 177:168, 1972.

**Figure 39.11** Decay curves for muons at rest and for muons traveling at a speed of  $0.9994c$ .

(CERN) in Geneva, muons injected into a large storage ring reached speeds of approximately  $0.9994c$ . Electrons produced by the decaying muons were detected by counters around the ring, enabling scientists to measure the decay rate and hence the muon lifetime. The lifetime of the moving muons was measured to be approximately 30 times as long as that of the stationary muon (Fig. 39.11), in agreement

### EXAMPLE 39.1 What Is the Period of the Pendulum?

The period of a pendulum is measured to be 3.0 s in the reference frame of the pendulum. What is the period when measured by an observer moving at a speed of  $0.95c$  relative to the pendulum?

**Solution** Instead of the observer moving at  $0.95c$ , we can take the equivalent point of view that the observer is at rest and the pendulum is moving at  $0.95c$  past the stationary observer. Hence, the pendulum is an example of a moving clock.

The proper time is  $\Delta t_p = 3.0$  s. Because a moving clock

runs more slowly than a stationary clock by a factor  $\gamma$ , Equation 39.7 gives

$$\begin{aligned}\Delta t &= \gamma \Delta t_p = \frac{1}{\sqrt{1 - \frac{(0.95c)^2}{c^2}}} \Delta t_p = \frac{1}{\sqrt{1 - 0.902}} \Delta t_p \\ &= (3.2)(3.0 \text{ s}) = 9.6 \text{ s}\end{aligned}$$

That is, a moving pendulum takes longer to complete a period than a pendulum at rest does.

### EXAMPLE 39.2 How Long Was Your Trip?

Suppose you are driving your car on a business trip and are traveling at 30 m/s. Your boss, who is waiting at your destination, expects the trip to take 5.0 h. When you arrive late, your excuse is that your car clock registered the passage of 5.0 h but that you were driving fast and so your clock ran more slowly than your boss's clock. If your car clock actually did indicate a 5.0-h trip, how much time passed on your boss's clock, which was at rest on the Earth?

**Solution** We begin by calculating  $\gamma$  from Equation 39.8:

$$\gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}} = \frac{1}{\sqrt{1 - \frac{(3 \times 10^1 \text{ m/s})^2}{(3 \times 10^8 \text{ m/s})^2}}} = \frac{1}{\sqrt{1 - 10^{-14}}}$$

If you try to determine this value on your calculator, you will probably get  $\gamma = 1$ . However, if we perform a binomial expansion, we can more precisely determine the value as

$$\gamma = (1 - 10^{-14})^{-1/2} \approx 1 + \frac{1}{2}(10^{-14}) = 1 + 5.0 \times 10^{-15}$$

This result indicates that at typical automobile speeds,  $\gamma$  is not much different from 1.

Applying Equation 39.7, we find  $\Delta t$ , the time interval measured by your boss, to be

$$\begin{aligned}\Delta t &= \gamma \Delta t_p = (1 + 5.0 \times 10^{-15})(5.0 \text{ h}) \\ &= 5.0 \text{ h} + 2.5 \times 10^{-14} \text{ h} = 5.0 \text{ h} + 0.09 \text{ ns}\end{aligned}$$

Your boss's clock would be only 0.09 ns ahead of your car clock. You might want to try another excuse!

with the prediction of relativity to within two parts in a thousand.

### The Twins Paradox

An intriguing consequence of time dilation is the so-called *twins paradox* (Fig. 39.12). Consider an experiment involving a set of twins named Speedo and Goslo. When they are 20 yr old, Speedo, the more adventuresome of the two, sets out on an epic journey to Planet X, located 20 ly from the Earth. Furthermore, his spaceship is capable of reaching a speed of  $0.95c$  relative to the inertial frame of his twin brother back home. After reaching Planet X, Speedo becomes homesick and immediately returns to the Earth at the same speed  $0.95c$ . Upon his return, Speedo is shocked to discover that Goslo has aged 42 yr and is now 62 yr old. Speedo, on the other hand, has aged only 13 yr.

At this point, it is fair to raise the following question—which twin is the traveler and which is really younger as a result of this experiment? From Goslo's frame of reference, he was at rest while his brother traveled at a high speed. But from Speedo's perspective, it is he who was at rest while Goslo was on the high-speed space journey. According to Speedo, he himself remained stationary while Goslo and the Earth raced away from him on a 6.5-yr journey and then headed back for another 6.5 yr. This leads to an apparent contradiction. Which twin has developed signs of excess aging?

To resolve this apparent paradox, recall that the special theory of relativity deals with inertial frames of reference moving relative to each other at uniform speed. However, the trip in our current problem is not symmetrical. Speedo, the space traveler, must experience a series of accelerations during his journey. As a result, his speed is not always uniform, and consequently he is not in an inertial frame. He cannot be regarded as always being at rest while Goslo is in uniform motion because to do so would be an incorrect application of the special theory of relativity. Therefore, there is no paradox. During each passing year noted by Goslo, slightly less than 4 months elapsed for Speedo.

The conclusion that Speedo is in a noninertial frame is inescapable. Each twin observes the other as accelerating, but it is Speedo that actually undergoes dynamical acceleration due to the real forces acting on him. The time required to accelerate and decelerate Speedo's spaceship may be made very small by using large rockets, so that Speedo can claim that he spends most of his time traveling to Planet X

**Figure 39.12** (a) As one twin leaves his brother on the Earth, both are the same age. (b) When Speedo returns from his journey to Planet X, he is younger than his twin Goslo.

**Figure 39.13** (a) A stick measured by an observer in a frame attached to the stick (that is, both have the same velocity) has its proper length  $L_p$ . (b) The stick measured by an observer in a frame in which the stick has a velocity  $\mathbf{v}$  relative to the frame is shorter than its proper length  $L_p$  by a factor  $(1 - v^2/c^2)^{1/2}$ .

Length contraction

at  $0.95c$  in an inertial frame. However, Speedo must slow down, reverse his motion, and return to the Earth in an altogether different inertial frame. At the very best, Speedo is in two different inertial frames during his journey. Only Goslo, who is in a single inertial frame, can apply the simple time-dilation formula to Speedo's trip. Thus, Goslo finds that instead of aging 42 yr, Speedo ages only  $(1 - v^2/c^2)^{1/2}(42 \text{ yr}) = 13 \text{ yr}$ . Conversely, Speedo spends 6.5 yr traveling to Planet X and 6.5 yr returning, for a total travel time of 13 yr, in agreement with our earlier statement.

### Quick Quiz 39.5

Suppose astronauts are paid according to the amount of time they spend traveling in space. After a long voyage traveling at a speed approaching  $c$ , would a crew rather be paid according to an Earth-based clock or their spaceship's clock?

### Length Contraction

The measured distance between two points also depends on the frame of reference. **The proper length  $L_p$  of an object is the length measured by someone at rest relative to the object.** The length of an object measured by someone in a reference frame that is moving with respect to the object is always less than the proper length. This effect is known as **length contraction**.

Consider a spaceship traveling with a speed  $v$  from one star to another. There are two observers: one on the Earth and the other in the spaceship. The observer at rest on the Earth (and also assumed to be at rest with respect to the two stars) measures the distance between the stars to be the proper length  $L_p$ . According to this observer, the time it takes the spaceship to complete the voyage is  $\Delta t = L_p/v$ . Because of time dilation, the space traveler measures a smaller time of travel by the spaceship clock:  $\Delta t_p = \Delta t/\gamma$ . The space traveler claims to be at rest and sees the destination star moving toward the spaceship with speed  $v$ . Because the space traveler reaches the star in the time  $\Delta t_p$ , he or she concludes that the distance  $L$  between the stars is shorter than  $L_p$ . This distance measured by the space traveler is

$$L = v \Delta t_p = v \frac{\Delta t}{\gamma}$$

Because  $L_p = v \Delta t$ , we see that

$$L = \frac{L_p}{\gamma} = L_p \left(1 - \frac{v^2}{c^2}\right)^{1/2} \quad (39.9)$$

If an object has a proper length  $L_p$  when it is at rest, then when it moves with speed  $v$  in a direction parallel to its length, it contracts to the length  $L = L_p(1 - v^2/c^2)^{1/2} = L_p/\gamma$ .

where  $(1 - v^2/c^2)^{1/2}$  is a factor less than unity. This result may be interpreted as follows:

For example, suppose that a stick moves past a stationary Earth observer with speed  $v$ , as shown in Figure 39.13. The length of the stick as measured by an observer in a frame attached to the stick is the proper length  $L_p$  shown in Figure 39.13a. The length of the stick  $L$  measured by the Earth observer is shorter than  $L_p$  by the factor  $(1 - v^2/c^2)^{1/2}$ . Furthermore, length contraction is a symmetrical effect: If the stick is at rest on the Earth, an observer in a moving frame would

measure its length to be shorter by the same factor  $(1 - v^2/c^2)^{1/2}$ . Note that **length contraction takes place only along the direction of motion.**

It is important to emphasize that proper length and proper time are measured in different reference frames. As an example of this point, let us return to the decaying muons moving at speeds close to the speed of light. An observer in the muon reference frame measures the proper lifetime (that is, the time interval  $\tau_p$ ), whereas an Earth-based observer measures a dilated lifetime. However, the Earth-based observer measures the proper height (the length  $L_p$ ) of the mountain in Figure 39.10b. In the muon reference frame, this height is less than  $L_p$ , as the figure shows. Thus, in the muon frame, length contraction occurs but time dilation does not. In the Earth-based reference frame, time dilation occurs but length contraction does not. Thus, when calculations on the muon are performed in both

### EXAMPLE 39.3 The Contraction of a Spaceship

A spaceship is measured to be 120.0 m long and 20.0 m in diameter while at rest relative to an observer. If this spaceship now flies by the observer with a speed of  $0.99c$ , what length and diameter does the observer measure?

**Solution** From Equation 39.9, the length measured by the observer is

$$L = L_p \sqrt{1 - \frac{v^2}{c^2}} = (120.0 \text{ m}) \sqrt{1 - \frac{(0.99c)^2}{c^2}} = 17 \text{ m}$$

The diameter measured by the observer is still 20.0 m because the diameter is a dimension perpendicular to the motion and length contraction occurs only along the direction of motion.

**Exercise** If the ship moves past the observer with a speed of  $0.1000c$ , what length does the observer measure?

**Answer** 119.4 m.

### EXAMPLE 39.4 How Long Was Your Car?

In Example 39.2, you were driving at 30 m/s and claimed that your clock was running more slowly than your boss's stationary clock. Although your statement was true, the time dilation was negligible. If your car is 4.3 m long when it is parked, how much shorter does it appear to a stationary roadside observer as you drive by at 30 m/s?

**Solution** The observer sees the horizontal length of the car to be contracted to a length

$$L = L_p \sqrt{1 - \frac{v^2}{c^2}} \approx L_p \left(1 - \frac{1}{2} \frac{v^2}{c^2}\right)$$

where we have again used the binomial expansion for the factor

$\sqrt{1 - \frac{v^2}{c^2}}$ . The roadside observer sees the car's length as

having changed by an amount  $L_p - L$ :

$$\begin{aligned} L_p - L &\approx \frac{L_p}{2} \left(\frac{v^2}{c^2}\right) = \left(\frac{4.3 \text{ m}}{2}\right) \left(\frac{3.0 \times 10^1 \text{ m/s}}{3.0 \times 10^8 \text{ m/s}}\right)^2 \\ &= 2.2 \times 10^{-14} \text{ m} \end{aligned}$$

This is much smaller than the diameter of an atom!

### EXAMPLE 39.5 A Voyage to Sirius

An astronaut takes a trip to Sirius, which is located a distance of 8 lightyears from the Earth. (Note that 1 lightyear (ly) is the distance light travels through free space in 1 yr.) The astronaut measures the time of the one-way journey to be 6 yr. If the spaceship moves at a constant speed of  $0.8c$ , how can the 8-ly distance be reconciled with the 6-yr trip time measured by the astronaut?

**Solution** The 8 ly represents the proper length from the Earth to Sirius measured by an observer seeing both bodies

nearly at rest. The astronaut sees Sirius approaching her at  $0.8c$  but also sees the distance contracted to

$$\frac{8 \text{ ly}}{\gamma} = (8 \text{ ly}) \sqrt{1 - \frac{v^2}{c^2}} = (8 \text{ ly}) \sqrt{1 - \frac{(0.8c)^2}{c^2}} = 5 \text{ ly}$$

Thus, the travel time measured on her clock is

$$t = \frac{d}{v} = \frac{5 \text{ ly}}{0.8c} = 6 \text{ yr}$$

**Figure 39.14** The twins paradox on a space–time graph. The twin who stays on the Earth has a world-line along the  $t$  axis. The path of the traveling twin through space–time is represented by a world-line that changes direction.

frames, the effect of “offsetting penalties” is seen, and the outcome of the experiment in one frame is the same as the outcome in the other frame!

### Space–Time Graphs

It is sometimes helpful to make a *space–time graph*, in which time is the ordinate and displacement is the abscissa. The twins paradox is displayed in such a graph in Figure 39.14. A path through space–time is called a **world-line**. At the origin, the world-lines of Speedo and Goslo coincide because the twins are in the same location at the same time. After Speedo leaves on his trip, his world-line diverges from that of his brother. At their reunion, the two world-lines again come together. Note that Goslo’s world-line is vertical, indicating no displacement from his original location. Also note that it would be impossible for Speedo to have a world-line that crossed the path of a light beam that left the Earth when he did. To do so would require him to have a speed greater than  $c$ .

World-lines for light beams are diagonal lines on space–time graphs, typically drawn at  $45^\circ$  to the right or left of vertical, depending on whether the light beam is traveling in the direction of increasing or decreasing  $x$ . These two world-lines means that all possible future events for Goslo and Speedo lie within two  $45^\circ$  lines extending from the origin. Either twin’s presence at an event outside this “light cone” would require that twin to move at a speed greater than  $c$ , which, as we shall see in Section 39.5, is not possible. Also, the only past events that Goslo and Speedo could have experienced occurred within two similar  $45^\circ$  world-lines that approach the origin from below the  $x$  axis.

### Quick Quiz 39.6

How is acceleration indicated on a space–time graph?

### The Relativistic Doppler Effect

Another important consequence of time dilation is the shift in frequency found for light emitted by atoms in motion as opposed to light emitted by atoms at rest. This phenomenon, known as the Doppler effect, was introduced in Chapter 17 as it pertains to sound waves. In the case of sound, the motion of the source with respect to the medium of propagation can be distinguished from

the motion of the observer with respect to the medium. Light waves must be analyzed differently, however, because they require no medium of propagation, and no method exists for distinguishing the motion of a light source from the motion of the observer.

If a light source and an observer approach each other with a relative speed  $v$ , the frequency  $f_{\text{obs}}$  measured by the observer is

$$f_{\text{obs}} = \frac{\sqrt{1 + v/c}}{\sqrt{1 - v/c}} f_{\text{source}} \quad (39.10)$$

where  $f_{\text{source}}$  is the frequency of the source measured in its rest frame. Note that this relativistic Doppler shift formula, unlike the Doppler shift formula for sound, depends only on the relative speed  $v$  of the source and observer and holds for relative speeds as great as  $c$ . As you might expect, the formula predicts that  $f_{\text{obs}} > f_{\text{source}}$  when the source and observer approach each other. We obtain the expression for the case in which the source and observer recede from each other by replacing  $v$  with  $-v$  in Equation 39.10.

The most spectacular and dramatic use of the relativistic Doppler effect is the measurement of shifts in the frequency of light emitted by a moving astronomical object such as a galaxy. Spectral lines normally found in the extreme violet region for galaxies at rest with respect to the Earth are shifted by about 100 nm toward the red end of the spectrum for distant galaxies—indicating that these galaxies are *receding* from us. The American astronomer Edwin Hubble (1889–1953) performed extensive measurements of this *red shift* to confirm that most galaxies are moving away from us, indicating that the Universe is expanding.

### 39.5 THE LORENTZ TRANSFORMATION EQUATIONS

We have seen that the Galilean transformation equations are not valid when  $v$  approaches the speed of light. In this section, we state the correct transformation equations that apply for all speeds in the range  $0 \leq v < c$ .

Suppose that an event that occurs at some point  $P$  is reported by two observers, one at rest in a frame  $S$  and the other in a frame  $S'$  that is moving to the right with speed  $v$ , as in Figure 39.15. The observer in  $S$  reports the event with space–time coordinates  $(x, y, z, t)$ , and the observer in  $S'$  reports the same event using the coordinates  $(x', y', z', t')$ . We would like to find a relationship between these coordinates that is valid for all speeds.

The equations that are valid from  $v = 0$  to  $v = c$  and enable us to transform coordinates from  $S$  to  $S'$  are the **Lorentz transformation equations**:

$$\begin{aligned} x' &= \gamma(x - vt) \\ y' &= y \end{aligned}$$

Lorentz transformation equations for  $S \rightarrow S'$

**Figure 39.15** An event that occurs at some point  $P$  is observed by two persons, one at rest in the  $S$  frame and the other in the  $S'$  frame, which is moving to the right with a speed  $v$ .

$$\begin{aligned} z' &= z \\ t' &= \gamma \left( t - \frac{v}{c^2} x \right) \end{aligned} \quad (39.11)$$

These transformation equations were developed by Hendrik A. Lorentz (1853–1928) in 1890 in connection with electromagnetism. However, it was Einstein who recognized their physical significance and took the bold step of interpreting them within the framework of the special theory of relativity.

Note the difference between the Galilean and Lorentz time equations. In the Galilean case,  $t = t'$ , but in the Lorentz case the value for  $t'$  assigned to an event by an observer  $O'$  standing at the origin of the  $S'$  frame in Figure 39.15 depends both on the time  $t$  and on the coordinate  $x$  as measured by an observer  $O$  standing in the  $S$  frame. This is consistent with the notion that an event is characterized by four space–time coordinates  $(x, y, z, t)$ . In other words, in relativity, space and time are not separate concepts but rather are closely interwoven with each other.

If we wish to transform coordinates in the  $S'$  frame to coordinates in the  $S$  frame, we simply replace  $v$  by  $-v$  and interchange the primed and unprimed coordinates in Equations 39.11:

Inverse Lorentz transformation equations for  $S' \rightarrow S$

$$\begin{aligned} x &= \gamma(x' + vt') \\ y &= y' \\ z &= z' \\ t &= \gamma \left( t' + \frac{v}{c^2} x' \right) \end{aligned} \quad (39.12)$$

When  $v \ll c$ , the Lorentz transformation equations should reduce to the Galilean equations. To verify this, note that as  $v$  approaches zero,  $v/c \ll 1$  and  $v^2/c^2 \ll 1$ ; thus,  $\gamma = 1$ , and Equations 39.11 reduce to the Galilean space–time transformation equations:

$$x' = x - vt \quad y' = y \quad z' = z \quad t' = t$$

In many situations, we would like to know the difference in coordinates between two events or the time interval between two events as seen by observers  $O$  and  $O'$ . We can accomplish this by writing the Lorentz equations in a form suitable for describing pairs of events. From Equations 39.11 and 39.12, we can express the differences between the four variables  $x, x', t,$  and  $t'$  in the form

$$\left. \begin{aligned} \Delta x' &= \gamma(\Delta x - v \Delta t) \\ \Delta t' &= \gamma \left( \Delta t - \frac{v}{c^2} \Delta x \right) \end{aligned} \right\} S \rightarrow S' \quad (39.13)$$

$$\left. \begin{aligned} \Delta x &= \gamma(\Delta x' + v \Delta t') \\ \Delta t &= \gamma \left( \Delta t' + \frac{v}{c^2} \Delta x' \right) \end{aligned} \right\} S' \rightarrow S \quad (39.14)$$

<sup>5</sup> Although relative motion of the two frames along the  $x$  axis does not change the  $y$  and  $z$  coordinates of an object, it does change the  $y$  and  $z$  velocity components of an object moving in either frame, as we shall soon see.

**EXAMPLE 39.6** Simultaneity and Time Dilation Revisited

Use the Lorentz transformation equations in difference form to show that (a) simultaneity is not an absolute concept and that (b) moving clocks run more slowly than stationary clocks.

**Solution** (a) Suppose that two events are simultaneous according to a moving observer  $O'$ , such that  $\Delta t' = 0$ . From the expression for  $\Delta t$  given in Equation 39.14, we see that in this case the time interval  $\Delta t$  measured by a stationary observer  $O$  is  $\Delta t = \gamma v \Delta x' / c^2$ . That is, the time interval for the same two events as measured by  $O$  is nonzero, and so the events do not appear to be simultaneous to  $O$ .

(b) Suppose that observer  $O'$  finds that two events occur at the same place ( $\Delta x' = 0$ ) but at different times ( $\Delta t' \neq 0$ ). In this situation, the expression for  $\Delta t$  given in Equation 39.14 becomes  $\Delta t = \gamma \Delta t'$ . This is the equation for time dilation found earlier (Eq. 39.7), where  $\Delta t' = \Delta t_p$  is the proper time measured by a clock located in the moving frame of observer  $O'$ .

**Exercise** Use the Lorentz transformation equations in difference form to confirm that  $L = L_p / \gamma$  (Eq. 39.9).

where  $\Delta x' = x'_2 - x'_1$  and  $\Delta t' = t'_2 - t'_1$  are the differences measured by observer  $O'$  and  $\Delta x = x_2 - x_1$  and  $\Delta t = t_2 - t_1$  are the differences measured by observer  $O$ . (We have not included the expressions for relating the  $y$  and  $z$  coordinates because they are unaffected by motion along the  $x$  direction.<sup>5</sup>)

**Derivation of the Lorentz Velocity Transformation Equation**

Once again  $S$  is our stationary frame of reference, and  $S'$  is our frame moving at a speed  $v$  relative to  $S$ . Suppose that an object has a speed  $u'_x$  measured in the  $S'$  frame, where

$$u'_x = \frac{dx'}{dt'} \quad (39.15)$$

Using Equation 39.11, we have

$$\begin{aligned} dx' &= \gamma(dx - v dt) \\ dt' &= \gamma\left(dt - \frac{v}{c^2} dx\right) \end{aligned}$$

Substituting these values into Equation 39.15 gives

$$u'_x = \frac{dx'}{dt'} = \frac{dx - v dt}{dt - \frac{v}{c^2} dx} = \frac{\frac{dx}{dt} - v}{1 - \frac{v}{c^2} \frac{dx}{dt}}$$

Lorentz velocity transformation equation for  $S \rightarrow S'$

But  $dx/dt$  is just the velocity component  $u_x$  of the object measured by an observer in  $S$ , and so this expression becomes

$$u'_x = \frac{u_x - v}{1 - \frac{u_x v}{c^2}} \quad (39.16)$$

If the object has velocity components along the  $y$  and  $z$  axes, the components as measured by an observer in  $S'$  are

The speed of light is the speed limit of the Universe. It is the maximum possible speed for energy transfer and for information transfer. Any object with mass must move at a lower speed.

Lorentz velocity transformation equations for  $S' \rightarrow S$

$$u'_y = \frac{u_y}{\gamma \left(1 - \frac{u_x v}{c^2}\right)} \quad \text{and} \quad u'_z = \frac{u_z}{\gamma \left(1 - \frac{u_x v}{c^2}\right)} \quad (39.17)$$

Note that  $u'_y$  and  $u'_z$  do not contain the parameter  $v$  in the numerator because the relative velocity is along the  $x$  axis.

When  $u_x$  and  $v$  are both much smaller than  $c$  (the nonrelativistic case), the denominator of Equation 39.16 approaches unity, and so  $u'_x \approx u_x - v$ , which is the Galilean velocity transformation equation. In the other extreme, when  $u_x = c$ , Equation 39.16 becomes

$$u'_x = \frac{c - v}{1 - \frac{cv}{c^2}} = \frac{c \left(1 - \frac{v}{c}\right)}{1 - \frac{v}{c}} = c$$

From this result, we see that an object moving with a speed  $c$  relative to an observer in  $S$  also has a speed  $c$  relative to an observer in  $S'$ —independent of the relative motion of  $S$  and  $S'$ . Note that this conclusion is consistent with Einstein's second postulate—that the speed of light must be  $c$  relative to all inertial reference frames. Furthermore, the speed of an object can never exceed  $c$ . That is, the speed of light is the ultimate speed. We return to this point later when we consider the energy of a particle.

### EXAMPLE 39.7 Relative Velocity of Spaceships

Two spaceships A and B are moving in opposite directions, as shown in Figure 39.16. An observer on the Earth measures the speed of ship A to be  $0.750c$  and the speed of ship B to be  $0.850c$ . Find the velocity of ship B as observed by the crew on ship A.

**Figure 39.16** Two spaceships A and B move in opposite directions. The speed of B relative to A is less than  $c$  and is obtained from the relativistic velocity transformation equation.

**Solution** We can solve this problem by taking the  $S'$  frame as being attached to ship A, so that  $v = 0.750c$  relative to the Earth (the  $S$  frame). We can consider ship B as moving with a velocity  $u_x = -0.850c$  relative to the Earth. Hence, we can obtain the velocity of ship B relative to ship A by using Equation 39.16:

$$u'_x = \frac{u_x - v}{1 - \frac{u_x v}{c^2}} = \frac{-0.850c - 0.750c}{1 - \frac{(-0.850c)(0.750c)}{c^2}} = -0.977c$$

The negative sign indicates that ship B is moving in the negative  $x$  direction as observed by the crew on ship A. Note that the speed is less than  $c$ . That is, a body whose speed is less than  $c$  in one frame of reference must have a speed less than  $c$  in any other frame. (If the Galilean velocity transformation equation were used in this example, we would find that  $u'_x = u_x - v = -0.850c - 0.750c = -1.60c$ , which is impossible. The Galilean transformation equation does not work in relativistic situations.)

### EXAMPLE 39.8 The Speeding Motorcycle

Imagine a motorcycle moving with a speed  $0.80c$  past a stationary observer, as shown in Figure 39.17. If the rider tosses a ball in the forward direction with a speed of  $0.70c$  relative

to himself, what is the speed of the ball relative to the stationary observer?

**Solution** The speed of the motorcycle relative to the stationary observer is  $v = 0.80c$ . The speed of the ball in the frame of reference of the motorcyclist is  $u'_x = 0.70c$ . Therefore, the speed  $u_x$  of the ball relative to the stationary observer is

$$u_x = \frac{u'_x + v}{1 + \frac{u'_x v}{c^2}} = \frac{0.70c + 0.80c}{1 + \frac{(0.70c)(0.80c)}{c^2}} = 0.96c$$

**Exercise** Suppose that the motorcyclist turns on the headlight so that a beam of light moves away from him with a speed  $c$  in the forward direction. What does the stationary observer measure for the speed of the light?

**Answer**  $c$ .

**Figure 39.17** A motorcyclist moves past a stationary observer with a speed of  $0.80c$  and throws a ball in the direction of motion with a speed of  $0.70c$  relative to himself.

**EXAMPLE 39.9** Relativistic Leaders of the Pack

Two motorcycle pack leaders named David and Emily are racing at relativistic speeds along perpendicular paths, as shown in Figure 39.18. How fast does Emily recede as seen by David over his right shoulder?

**Solution** Figure 39.18 represents the situation as seen by a police officer at rest in frame S, who observes the following:

David:  $u_x = 0.75c \quad u_y = 0$

Emily:  $u_x = 0 \quad u_y = -0.90c$

To calculate Emily's speed of recession as seen by David, we take  $S'$  to move along with David and then calculate  $u'_x$  and  $u'_y$  for Emily using Equations 39.16 and 39.17:

$$u'_x = \frac{u_x - v}{1 - \frac{u_x v}{c^2}} = \frac{0 - 0.75c}{1 - \frac{(0)(0.75c)}{c^2}} = -0.75c$$

$$u'_y = \frac{u_y}{\gamma \left(1 - \frac{u_x v}{c^2}\right)} = \frac{\sqrt{1 - \frac{(0.75c)^2}{c^2}} (-0.90c)}{\left(1 - \frac{(0)(0.75c)}{c^2}\right)} = -0.60c$$

Thus, the speed of Emily as observed by David is

$$u' = \sqrt{(u'_x)^2 + (u'_y)^2} = \sqrt{(-0.75c)^2 + (-0.60c)^2} = 0.96c$$

Note that this speed is less than  $c$ , as required by the special theory of relativity.

**Exercise** Use the Galilean velocity transformation equation to calculate the classical speed of recession for Emily as observed by David.

**Answer**  $1.2c$ .

**Figure 39.18** David moves to the east with a speed  $0.75c$  relative to the police officer, and Emily travels south at a speed  $0.90c$  relative to the officer.

To obtain  $u_x$  in terms of  $u'_x$ , we replace  $v$  by  $-v$  in Equation 39.16 and interchange the roles of  $u_x$  and  $u'_x$ :

$$u_x = \frac{u'_x + v}{1 + \frac{u'_x v}{c^2}} \quad (39.18)$$

### 39.6 RELATIVISTIC LINEAR MOMENTUM AND THE RELATIVISTIC FORM OF NEWTON'S LAWS

We have seen that in order to describe properly the motion of particles within the framework of the special theory of relativity, we must replace the Galilean transformation equations by the Lorentz transformation equations. Because the laws of physics must remain unchanged under the Lorentz transformation, we must generalize Newton's laws and the definitions of linear momentum and energy to conform to the Lorentz transformation equations and the principle of relativity. These generalized definitions should reduce to the classical (nonrelativistic) definitions for  $v \ll c$ .

First, recall that the law of conservation of linear momentum states that when two isolated objects collide, their combined total momentum remains constant. Suppose that the collision is described in a reference frame  $S$  in which linear momentum is conserved. If we calculate the velocities in a second reference frame  $S'$  using the Lorentz velocity transformation equation and the classical definition of linear momentum,  $\mathbf{p} = m\mathbf{u}$  (where  $\mathbf{u}$  is the velocity of either object), we find that linear momentum is *not* conserved in  $S'$ . However, because the laws of physics are the same in all inertial frames, linear momentum must be conserved in all frames. In view of this condition and assuming that the Lorentz velocity transformation equation is correct, we must modify the definition of linear momentum to satisfy the following conditions:

Definition of relativistic linear momentum

- Linear momentum  $\mathbf{p}$  must be conserved in all collisions.
- The relativistic value calculated for  $\mathbf{p}$  must approach the classical value  $m\mathbf{u}$  as  $\mathbf{u}$  approaches zero.

For any particle, the correct relativistic equation for linear momentum that satisfies these conditions is

$$\mathbf{p} \equiv \frac{m\mathbf{u}}{\sqrt{1 - \frac{u^2}{c^2}}} = \gamma m\mathbf{u} \quad (39.19)$$

where  $\mathbf{u}$  is the velocity of the particle and  $m$  is the mass of the particle. When  $u$  is much less than  $c$ ,  $\gamma = (1 - u^2/c^2)^{-1/2}$  approaches unity and  $\mathbf{p}$  approaches  $m\mathbf{u}$ . Therefore, the relativistic equation for  $\mathbf{p}$  does indeed reduce to the classical expression when  $u$  is much smaller than  $c$ .

The relativistic force  $\mathbf{F}$  acting on a particle whose linear momentum is  $\mathbf{p}$  is defined as

$$\mathbf{F} \equiv \frac{d\mathbf{p}}{dt} \quad (39.20)$$

where  $\mathbf{p}$  is given by Equation 39.19. This expression, which is the relativistic form of Newton's second law, is reasonable because it preserves classical mechanics in

**EXAMPLE 39.10** Linear Momentum of an Electron

An electron, which has a mass of  $9.11 \times 10^{-31}$  kg, moves with a speed of  $0.750c$ . Find its relativistic momentum and compare this value with the momentum calculated from the classical expression.

**Solution** Using Equation 39.19 with  $u = 0.750c$ , we have

$$p = \frac{m_e u}{\sqrt{1 - \frac{u^2}{c^2}}} = \frac{(9.11 \times 10^{-31} \text{ kg})(0.750 \times 3.00 \times 10^8 \text{ m/s})}{\sqrt{1 - \frac{(0.750c)^2}{c^2}}}$$

$$= 3.10 \times 10^{-22} \text{ kg} \cdot \text{m/s}$$

The (incorrect) classical expression gives

$$p_{\text{classical}} = m_e u = 2.05 \times 10^{-22} \text{ kg} \cdot \text{m/s}$$

Hence, the correct relativistic result is 50% greater than the classical result!

the limit of low velocities and requires conservation of linear momentum for an isolated system ( $\mathbf{F} = 0$ ) both relativistically and classically.

It is left as an end-of-chapter problem (Problem 63) to show that under relativistic conditions, the acceleration  $\mathbf{a}$  of a particle decreases under the action of a constant force, in which case  $a \propto (1 - u^2/c^2)^{3/2}$ . From this formula, note that as the particle's speed approaches  $c$ , the acceleration caused by any finite force approaches zero. Hence, it is impossible to accelerate a particle from rest to a speed  $u \geq c$ .

**39.7** RELATIVISTIC ENERGY

We have seen that the definition of linear momentum and the laws of motion require generalization to make them compatible with the principle of relativity. This implies that the definition of kinetic energy must also be modified.

To derive the relativistic form of the work–kinetic energy theorem, let us first use the definition of relativistic force, Equation 39.20, to determine the work done on a particle by a force  $F$ :

$$W = \int_{x_1}^{x_2} F dx = \int_{x_1}^{x_2} \frac{dp}{dt} dx \quad (39.21)$$

for force and motion both directed along the  $x$  axis. In order to perform this integration and find the work done on the particle and the relativistic kinetic energy as a function of  $u$ , we first evaluate  $dp/dt$ :

$$\frac{dp}{dt} = \frac{d}{dt} \frac{mu}{\sqrt{1 - \frac{u^2}{c^2}}} = \frac{m(du/dt)}{\left(1 - \frac{u^2}{c^2}\right)^{3/2}}$$

Substituting this expression for  $dp/dt$  and  $dx = u dt$  into Equation 39.21 gives

$$W = \int_0^t \frac{m(du/dt)u dt}{\left(1 - \frac{u^2}{c^2}\right)^{3/2}} = m \int_0^u \frac{u}{\left(1 - \frac{u^2}{c^2}\right)^{3/2}} du$$

where we use the limits 0 and  $u$  in the rightmost integral because we have assumed

that the particle is accelerated from rest to some final speed  $u$ . Evaluating the integral, we find that

Relativistic kinetic energy

$$W = \frac{mc^2}{\sqrt{1 - \frac{u^2}{c^2}}} - mc^2 \quad (39.22)$$

Recall from Chapter 7 that the work done by a force acting on a particle equals the change in kinetic energy of the particle. Because of our assumption that the initial speed of the particle is zero, we know that the initial kinetic energy is zero. We therefore conclude that the work  $W$  is equivalent to the relativistic kinetic energy  $K$ :

$$K = \frac{mc^2}{\sqrt{1 - \frac{u^2}{c^2}}} - mc^2 = \gamma mc^2 - mc^2 \quad (39.23)$$

This equation is routinely confirmed by experiments using high-energy particle accelerators.

At low speeds, where  $u/c \ll 1$ , Equation 39.23 should reduce to the classical expression  $K = \frac{1}{2}mu^2$ . We can check this by using the binomial expansion  $(1 - x^2)^{-1/2} \approx 1 + \frac{1}{2}x^2 + \dots$  for  $x \ll 1$ , where the higher-order powers of  $x$  are neglected in the expansion. In our case,  $x = u/c$ , so that

$$\frac{1}{\sqrt{1 - \frac{u^2}{c^2}}} = \left(1 - \frac{u^2}{c^2}\right)^{-1/2} \approx 1 + \frac{1}{2} \frac{u^2}{c^2}$$

Substituting this into Equation 39.23 gives

$$K \approx mc^2 \left(1 + \frac{1}{2} \frac{u^2}{c^2}\right) - mc^2 = \frac{1}{2} mu^2$$

Definition of total energy

which is the classical expression for kinetic energy. A graph comparing the relativistic and nonrelativistic expressions is given in Figure 39.19. In the relativistic case, the particle speed never exceeds  $c$ , regardless of the kinetic energy. The two curves are in good agreement when  $u \ll c$ .

The constant term  $mc^2$  in Equation 39.23, which is independent of the speed of the particle, is called the **rest energy**  $E_R$  of the particle (see Section 8.9). The term  $\gamma mc^2$ , which does depend on the particle speed, is therefore the sum of the kinetic and rest energies. We define  $\gamma mc^2$  to be the **total energy**  $E$ :

**Figure 39.19** A graph comparing relativistic and nonrelativistic kinetic energy. The energies are plotted as a function of speed. In the relativistic case,  $u$  is always less than  $c$ .

Total energy = kinetic energy + rest energy

$$E = \gamma mc^2 = K + mc^2 \quad (39.24)$$

or

$$E = \frac{mc^2}{\sqrt{1 - \frac{u^2}{c^2}}} \quad (39.25)$$

This is Einstein's famous equation about mass–energy equivalence.

The relationship  $E = K + mc^2$  shows that **mass is a form of energy**, where  $c^2$  in the rest energy term is just a constant conversion factor. This expression also shows that a small mass corresponds to an enormous amount of energy, a concept fundamental to nuclear and elementary-particle physics.

In many situations, the linear momentum or energy of a particle is measured rather than its speed. It is therefore useful to have an expression relating the total energy  $E$  to the relativistic linear momentum  $p$ . This is accomplished by using the expressions  $E = \gamma mc^2$  and  $p = \gamma mu$ . By squaring these equations and subtracting, we can eliminate  $u$  (Problem 39). The result, after some algebra, is<sup>6</sup>

$$E^2 = p^2c^2 + (mc^2)^2 \quad (39.26)$$

When the particle is at rest,  $p = 0$  and so  $E = E_R = mc^2$ . For particles that have zero mass, such as photons, we set  $m = 0$  in Equation 39.26 and see that

$$E = pc \quad (39.27)$$

This equation is an exact expression relating total energy and linear momentum for photons, which always travel at the speed of light.

Finally, note that because the mass  $m$  of a particle is independent of its motion,  $m$  must have the same value in all reference frames. For this reason,  $m$  is often called the **invariant mass**. On the other hand, because the total energy and linear momentum of a particle both depend on velocity, these quantities depend on the reference frame in which they are measured.

Because  $m$  is a constant, we conclude from Equation 39.26 that the quantity  $E^2 - p^2c^2$  must have the same value in all reference frames. That is,  $E^2 - p^2c^2$  is invariant under a Lorentz transformation. (Equations 39.26 and 39.27 do not make provision for potential energy.)

When we are dealing with subatomic particles, it is convenient to express their

Energy–momentum relationship

### EXAMPLE 39.11 The Energy of a Speedy Electron

An electron in a television picture tube typically moves with a speed  $u = 0.250c$ . Find its total energy and kinetic energy in electron volts.

**Solution** Using the fact that the rest energy of the electron is 0.511 MeV together with Equation 39.25, we have

$$E = \frac{m_e c^2}{\sqrt{1 - \frac{u^2}{c^2}}} = \frac{0.511 \text{ MeV}}{\sqrt{1 - \frac{(0.250c)^2}{c^2}}}$$

$$= 1.03(0.511 \text{ MeV}) = 0.528 \text{ MeV}$$

This is 3% greater than the rest energy.

We obtain the kinetic energy by subtracting the rest energy from the total energy:

$$K = E - m_e c^2 = 0.528 \text{ MeV} - 0.511 \text{ MeV} = 0.017 \text{ MeV}$$

<sup>6</sup> One way to remember this relationship is to draw a right triangle having a hypotenuse of length  $E$  and legs of lengths  $pc$  and  $mc^2$ .

**EXAMPLE 39.12** The Energy of a Speedy Proton

(a) Find the rest energy of a proton in electron volts.

**Solution**

$$\begin{aligned} E_R &= m_p c^2 = (1.67 \times 10^{-27} \text{ kg})(3.00 \times 10^8 \text{ m/s})^2 \\ &= (1.50 \times 10^{-10} \text{ J})(1.00 \text{ eV}/1.60 \times 10^{-19} \text{ J}) \\ &= 938 \text{ MeV} \end{aligned}$$

(b) If the total energy of a proton is three times its rest energy, with what speed is the proton moving?

**Solution** Equation 39.25 gives

$$\begin{aligned} E &= 3m_p c^2 = \frac{m_p c^2}{\sqrt{1 - \frac{u^2}{c^2}}} \\ 3 &= \frac{1}{\sqrt{1 - \frac{u^2}{c^2}}} \end{aligned}$$

Solving for  $u$  gives

$$\begin{aligned} 1 - \frac{u^2}{c^2} &= \frac{1}{9} \\ \frac{u^2}{c^2} &= \frac{8}{9} \end{aligned}$$

$$u = \frac{\sqrt{8}}{3} c = 2.83 \times 10^8 \text{ m/s}$$

(c) Determine the kinetic energy of the proton in electron volts.

**Solution** From Equation 39.24,

$$K = E - m_p c^2 = 3m_p c^2 - m_p c^2 = 2m_p c^2$$

Because  $m_p c^2 = 938 \text{ MeV}$ ,  $K = 1880 \text{ MeV}$

(d) What is the proton's momentum?

**Solution** We can use Equation 39.26 to calculate the momentum with  $E = 3m_p c^2$ :

$$\begin{aligned} E^2 &= p^2 c^2 + (m_p c^2)^2 = (3m_p c^2)^2 \\ p^2 c^2 &= 9(m_p c^2)^2 - (m_p c^2)^2 = 8(m_p c^2)^2 \\ p &= \sqrt{8} \frac{m_p c^2}{c} = \sqrt{8} \frac{(938 \text{ MeV})}{c} = 2650 \text{ MeV}/c \end{aligned}$$

The unit of momentum is written  $\text{MeV}/c$  for convenience.

energy in electron volts because the particles are usually given this energy by acceleration through a potential difference. The conversion factor, as you recall from Equation 25.5, is

$$1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$$

For example, the mass of an electron is  $9.109 \times 10^{-31} \text{ kg}$ . Hence, the rest energy of the electron is

$$\begin{aligned} m_e c^2 &= (9.109 \times 10^{-31} \text{ kg})(2.9979 \times 10^8 \text{ m/s})^2 = 8.187 \times 10^{-14} \text{ J} \\ &= (8.187 \times 10^{-14} \text{ J})(1 \text{ eV}/1.602 \times 10^{-19} \text{ J}) = 0.5110 \text{ MeV} \end{aligned}$$

**Figure 39.20** (a) A box of length  $L$  at rest. (b) When a light pulse directed to the right is emitted at the left end of the box, the box recoils to the left until the pulse strikes the right end.

**39.8** EQUIVALENCE OF MASS AND ENERGY

To understand the equivalence of mass and energy, consider the following thought experiment proposed by Einstein in developing his famous equation  $E = mc^2$ . Imagine an isolated box of mass  $M_{\text{box}}$  and length  $L$  initially at rest, as shown in Figure 39.20a. Suppose that a pulse of light is emitted from the left side of the box, as depicted in Figure 39.20b. From Equation 39.27, we know that light of energy  $E$  carries linear momentum  $p = E/c$ . Hence, if momentum is to be conserved, the box must recoil to the left with a speed  $v$ . If it is assumed that the box is very mas-

sive, the recoil speed is much less than the speed of light, and conservation of momentum gives  $M_{\text{box}}v = E/c$ , or

$$v = \frac{E}{M_{\text{box}}c}$$

The time it takes the light pulse to move the length of the box is approximately  $\Delta t = L/c$ . In this time interval, the box moves a small distance  $\Delta x$  to the left, where

$$\Delta x = v \Delta t = \frac{EL}{M_{\text{box}}c^2}$$

The light then strikes the right end of the box and transfers its momentum to the box, causing the box to stop. With the box in its new position, its center of mass appears to have moved to the left. However, its center of mass cannot have moved because the box is an isolated system. Einstein resolved this perplexing situation by assuming that in addition to energy and momentum, light also carries mass. If  $M_{\text{pulse}}$  is the effective mass carried by the pulse of light and if the center of mass of the system (box plus pulse of light) is to remain fixed, then

$$M_{\text{pulse}}L = M_{\text{box}}\Delta x$$

Solving for  $M_{\text{pulse}}$ , and using the previous expression for  $\Delta x$ , we obtain

$$M_{\text{pulse}} = \frac{M_{\text{box}}\Delta x}{L} = \frac{M_{\text{box}}}{L} \frac{EL}{M_{\text{box}}c^2} = \frac{E}{c^2}$$

or

$$E = M_{\text{pulse}}c^2$$

the energy of a system of particles before interaction must equal the energy of the system after interaction, where energy of the  $i$ th particle is given by the expression

$$E_i = \frac{m_i c^2}{\sqrt{1 - \frac{u_i^2}{c^2}}} = \gamma m_i c^2$$

Conversion of mass–energy

Thus, Einstein reached the profound conclusion that “if a body gives off the energy  $E$  in the form of radiation, its mass diminishes by  $E/c^2$ , . . .”

Although we derived the relationship  $E = mc^2$  for light energy, the equivalence of mass and energy is universal. Equation 39.24,  $E = \gamma mc^2$ , which represents the total energy of any particle, suggests that even when a particle is at rest ( $\gamma = 1$ ) it still possesses enormous energy because it has mass. Probably the clearest experimental proof of the equivalence of mass and energy occurs in nuclear and elementary particle interactions, where large amounts of energy are released and the energy release is accompanied by a decrease in mass. Because energy and mass are related, we see that the laws of conservation of energy and conservation of mass are one and the same. Simply put, this law states that

The release of enormous quantities of energy from subatomic particles, accompanied by changes in their masses, is the basis of all nuclear reactions. In a conventional nuclear reactor, a uranium nucleus undergoes *fission*, a reaction that creates several lighter fragments having considerable kinetic energy. The com-

combined mass of all the fragments is less than the mass of the parent uranium nucleus by an amount  $\Delta m$ . The corresponding energy  $\Delta mc^2$  associated with this mass difference is exactly equal to the total kinetic energy of the fragments. This kinetic energy raises the temperature of water in the reactor, converting it to steam for the

### CONCEPTUAL EXAMPLE 39.13

Because mass is a measure of energy, can we conclude that the mass of a compressed spring is greater than the mass of the same spring when it is not compressed?

**Solution** Recall that when a spring of force constant  $k$  is compressed (or stretched) from its equilibrium position a distance  $x$ , it stores elastic potential energy  $U = kx^2/2$ . Ac-

cording to the special theory of relativity, any change in the total energy of a system is equivalent to a change in the mass of the system. Therefore, the mass of a compressed (or stretched) spring is greater than the mass of the spring in its equilibrium position by an amount  $U/c^2$ .

### EXAMPLE 39.14 Binding Energy of the Deuteron

A deuteron, which is the nucleus of a deuterium atom, contains one proton and one neutron and has a mass of 2.013 553 u. This total deuteron mass is not equal to the sum of the masses of the proton and neutron. Calculate the mass difference and determine its energy equivalence, which is called the *binding energy* of the nucleus.

**Solution** Using atomic mass units (u), we have

$$m_p = \text{mass of proton} = 1.007\,276\text{ u}$$

$$m_n = \text{mass of neutron} = 1.008\,665\text{ u}$$

$$m_p + m_n = 2.015\,941\text{ u}$$

The mass difference  $\Delta m$  is therefore 0.002 388 u. By defini-

tion,  $1\text{ u} = 1.66 \times 10^{-27}\text{ kg}$ , and therefore

$$\Delta m = 0.002\,388\text{ u} = 3.96 \times 10^{-30}\text{ kg}$$

Using  $E = \Delta mc^2$ , we find that the binding energy is

$$\begin{aligned} E = \Delta mc^2 &= (3.96 \times 10^{-30}\text{ kg})(3.00 \times 10^8\text{ m/s})^2 \\ &= 3.56 \times 10^{-13}\text{ J} = 2.23\text{ MeV} \end{aligned}$$

Therefore, the minimum energy required to separate the proton from the neutron of the deuterium nucleus (the binding energy) is 2.23 MeV.

generation of electric power.

In the nuclear reaction called *fusion*, two atomic nuclei combine to form a single nucleus. The fusion reaction in which two deuterium nuclei fuse to form a helium nucleus is of major importance in current research and the development of controlled-fusion reactors. The decrease in mass that results from the creation of one helium nucleus from two deuterium nuclei is  $\Delta m = 4.25 \times 10^{-29}\text{ kg}$ . Hence, the corresponding excess energy that results from one fusion reaction is  $\Delta mc^2 = 3.83 \times 10^{-12}\text{ J} = 23.9\text{ MeV}$ . To appreciate the magnitude of this result, note that if 1 g of deuterium is converted to helium, the energy released is about  $10^{12}\text{ J}$ ! At the current cost of electrical energy, this quantity of energy would be worth about \$70 000.

## 39.9 RELATIVITY AND ELECTROMAGNETISM

Consider two frames of reference S and S' that are in relative motion, and assume that a single charge  $q$  is at rest in the S' frame of reference. According to an ob-

**Figure 39.21** (a) In frame  $S$ , the positive charge  $q$  moves to the right with a velocity  $\mathbf{v}$ , and the current-carrying wire is stationary. A magnetic field  $\mathbf{B}$  surrounds the wire, and charge experiences a *magnetic* force directed away from the wire. (b) In frame  $S'$ , the wire moves to the left with a velocity  $-\mathbf{v}$ , and the charge  $q$  is stationary. The wire creates an electric field  $\mathbf{E}$ , and the charge experiences an *electric* force directed away from the wire.

server in this frame, an electric field surrounds the charge. However, an observer in frame  $S$  says that the charge is in motion and therefore measures both an electric field and a magnetic field. The magnetic field measured by the observer in frame  $S$  is created by the moving charge, which constitutes an electric current. In other words, electric and magnetic fields are viewed differently in frames of reference that are moving relative to each other. We now describe one situation that shows how an electric field in one frame of reference is viewed as a magnetic field in another frame of reference.

A positive test charge  $q$  is moving parallel to a current-carrying wire with velocity  $\mathbf{v}$  relative to the wire in frame  $S$ , as shown in Figure 39.21a. We assume that the net charge on the wire is zero and that the electrons in the wire also move with velocity  $\mathbf{v}$  in a straight line. The leftward current in the wire produces a magnetic field that forms circles around the wire and is directed into the page at the location of the moving test charge. Therefore, a magnetic force  $\mathbf{F}_B = q\mathbf{v} \times \mathbf{B}$  directed away from the wire is exerted on the test charge. However, no electric force acts on the test charge because the net charge on the wire is zero when viewed in this frame.

Now consider the same situation as viewed from frame  $S'$ , where the test charge is at rest (Figure 39.21b). In this frame, the positive charges in the wire move to the left, the electrons in the wire are at rest, and the wire still carries a cur-

rent. Because the test charge is not moving in this frame,  $\mathbf{F}_B = q\mathbf{v} \times \mathbf{B} = 0$ ; there is no magnetic force exerted on the test charge when viewed in this frame. However, if a force is exerted on the test charge in frame  $S'$ , the frame of the wire, as described earlier, a force must be exerted on it in any other frame. What is the origin of this force in frame  $S$ , the frame of the test charge?

The answer to this question is provided by the special theory of relativity. When the situation is viewed in frame  $S$ , as in Figure 39.21a, the positive charges are at rest and the electrons in the wire move to the right with a velocity  $\mathbf{v}$ . Because of length contraction, the electrons appear to be closer together than their proper separation. Because there is no net charge on the wire this contracted separation must equal the separation between the stationary positive charges. The situation is quite different when viewed in frame  $S'$ , shown in Figure 39.21b. In this frame, the positive charges appear closer together because of length contraction, and the electrons in the wire are at rest with a separation that is greater than that viewed in frame  $S$ . Therefore, there is a net positive charge on the wire when viewed in frame  $S'$ . This net positive charge produces an electric field pointing away from the wire toward the test charge, and so the test charge experiences an electric force directed away from the wire. Thus, what was viewed as a magnetic field (and a corresponding magnetic force) in the frame of the wire transforms into an electric field (and a corresponding electric force) in the frame of the test charge.

### Optional Section

## 39.10 THE GENERAL THEORY OF RELATIVITY

Up to this point, we have sidestepped a curious puzzle. Mass has two seemingly different properties: a *gravitational attraction* for other masses and an *inertial* property that resists acceleration. To designate these two attributes, we use the subscripts  $g$  and  $i$  and write

$$\begin{array}{ll} \text{Gravitational property} & F_g = m_g g \\ \text{Inertial property} & \Sigma F = m_i a \end{array}$$

The value for the gravitational constant  $G$  was chosen to make the magnitudes of  $m_g$  and  $m_i$  numerically equal. Regardless of how  $G$  is chosen, however, the strict proportionality of  $m_g$  and  $m_i$  has been established experimentally to an extremely high degree: a few parts in  $10^{12}$ . Thus, it appears that gravitational mass and inertial mass may indeed be exactly proportional.

But why? They seem to involve two entirely different concepts: a force of mutual gravitational attraction between two masses, and the resistance of a single mass to being accelerated. This question, which puzzled Newton and many other physicists over the years, was answered when Einstein published his theory of gravitation, known as his *general theory of relativity*, in 1916. Because it is a mathematically complex theory, we offer merely a hint of its elegance and insight.

In Einstein's view, the remarkable coincidence that  $m_g$  and  $m_i$  seemed to be proportional to each other was evidence of an intimate and basic connection between the two concepts. He pointed out that no mechanical experiment (such as dropping a mass) could distinguish between the two situations illustrated in Figure 39.22a and b. In each case, the dropped briefcase undergoes a downward acceleration  $g$  relative to the floor.

Einstein carried this idea further and proposed that *no* experiment, mechanical or otherwise, could distinguish between the two cases. This extension to in-

**Figure 39.22** (a) The observer is at rest in a uniform gravitational field  $\mathbf{g}$ . (b) The observer is in a region where gravity is negligible, but the frame of reference is accelerated by an external force  $\mathbf{F}$  that produces an acceleration  $\mathbf{g}$ . According to Einstein, the frames of reference in parts (a) and (b) are equivalent in every way. No local experiment can distinguish any difference between the two frames. (c) If parts (a) and (b) are truly equivalent, as Einstein proposed, then a ray of light should bend in a gravitational field.

clude all phenomena (not just mechanical ones) has interesting consequences. For example, suppose that a light pulse is sent horizontally across the elevator. During the time it takes the light to make the trip, the right wall of the elevator has accelerated upward. This causes the light to arrive at a location lower on the wall than the spot it would have hit if the elevator were not accelerating. Thus, in the frame of the elevator, the trajectory of the light pulse bends downward as the elevator accelerates upward to meet it. Because the accelerating elevator cannot be distinguished from a nonaccelerating one located in a gravitational field, Einstein proposed that a beam of light *should also be bent downward by a gravitational field*, as shown in Figure 39.22c. Experiments have verified the effect, although the bending is small. A laser aimed at the horizon falls less than 1 cm after traveling 6 000 km. (No such bending is predicted in Newton's theory of gravitation.)

The two postulates of Einstein's **general theory of relativity** are

- All the laws of nature have the same form for observers in any frame of reference, whether accelerated or not.

This Global Positioning System (GPS) unit incorporates relativistically corrected time calculations in its analysis of signals it receives from orbiting satellites. These corrections allow the unit to determine its position on the Earth's surface to within a few meters. If the corrections were not made, the location error would be about 1 km. (Courtesy of Trimble Navigation Limited)

- In the vicinity of any point, a gravitational field is equivalent to an accelerated frame of reference in the absence of gravitational effects. (This is the *principle of equivalence*.)

The second postulate implies that gravitational mass and inertial mass are completely equivalent, not just proportional. What were thought to be two different types of mass are actually identical.

One interesting effect predicted by the general theory is that time scales are altered by gravity. A clock in the presence of gravity runs more slowly than one located where gravity is negligible. Consequently, the frequencies of radiation emitted by atoms in the presence of a strong gravitational field are *red-shifted* to lower frequencies when compared with the same emissions in the presence of a weak field. This gravitational red shift has been detected in spectral lines emitted by atoms in massive stars. It has also been verified on the Earth by comparison of the frequencies of gamma rays (a high-energy form of electromagnetic radiation) emitted from nuclei separated vertically by about 20 m.

### Quick Quiz 39.7

Two identical clocks are in the same house, one upstairs in a bedroom and the other downstairs in the kitchen. Which clock runs more slowly?

The second postulate suggests that a gravitational field may be “transformed away” at any point if we choose an appropriate accelerated frame of reference—a freely falling one. Einstein developed an ingenious method of describing the acceleration necessary to make the gravitational field “disappear.” He specified a concept, the *curvature of space–time*, that describes the gravitational effect at every point. In fact, the curvature of space–time completely replaces Newton’s gravitational theory. According to Einstein, there is no such thing as a gravitational force. Rather, the presence of a mass causes a curvature of space–time in the vicinity of the mass, and this curvature dictates the space–time path that all freely moving objects must follow. In 1979, John Wheeler summarized Einstein’s general theory of relativity in a single sentence: “Space tells matter how to move and matter tells space how to curve.”

Consider two travelers on the surface of the Earth walking directly toward the

**Figure 39.23** Deflection of starlight passing near the Sun. Because of this effect, the Sun or some other remote object can act as a *gravitational lens*. In his general theory of relativity, Einstein calculated that starlight just grazing the Sun’s surface should be deflected by an angle of  $1.75''$ .

Einstein's cross. The four bright spots are images of the same galaxy that have been bent around a massive object located between the galaxy and the Earth. The massive object acts like a lens, causing the rays of light that were diverging from the distant galaxy to converge on the Earth. (If the intervening massive object had a uniform mass distribution, we would see a bright ring instead of four spots.)

North Pole but from different starting locations. Even though both say they are walking due north, and thus should be on parallel paths, they see themselves getting closer and closer together, as if they were somehow attracted to each other. The curvature of the Earth causes this effect. In a similar way, what we are used to thinking of as the gravitational attraction between two masses is, in Einstein's view, two masses curving space-time and as a result moving toward each other, much like two bowling balls on a mattress rolling together.

One prediction of the general theory of relativity is that a light ray passing near the Sun should be deflected into the curved space-time created by the Sun's mass. This prediction was confirmed when astronomers detected the bending of starlight near the Sun during a total solar eclipse that occurred shortly after World War I (Fig. 39.23). When this discovery was announced, Einstein became an international celebrity.

If the concentration of mass becomes very great, as is believed to occur when a large star exhausts its nuclear fuel and collapses to a very small volume, a **black hole** may form. Here, the curvature of space-time is so extreme that, within a certain distance from the center of the black hole, all matter and light become trapped.

---

## SUMMARY

The two basic postulates of the special theory of relativity are

- The laws of physics must be the same in all inertial reference frames.
- The speed of light in vacuum has the same value,  $c = 3.00 \times 10^8$  m/s, in all inertial frames, regardless of the velocity of the observer or the velocity of the source emitting the light.

Three consequences of the special theory of relativity are

- Events that are simultaneous for one observer are not simultaneous for another observer who is in motion relative to the first.
- Clocks in motion relative to an observer appear to be slowed down by a factor  $\gamma = (1 - v^2/c^2)^{-1/2}$ . This phenomenon is known as **time dilation**.
- The length of objects in motion appears to be contracted in the direction of

motion by a factor  $1/\gamma = (1 - v^2/c^2)^{1/2}$ . This phenomenon is known as **length contraction**.

To satisfy the postulates of special relativity, the Galilean transformation equations must be replaced by the **Lorentz transformation equations**:

$$\begin{aligned}x' &= \gamma(x - vt) \\y' &= y \\z' &= z \\t' &= \gamma\left(t - \frac{v}{c^2}x\right)\end{aligned}\tag{39.11}$$

where  $\gamma = (1 - v^2/c^2)^{-1/2}$ .

The relativistic form of the **velocity transformation equation** is

$$u'_x = \frac{u_x - v}{1 - \frac{u_x v}{c^2}}\tag{39.16}$$

where  $u_x$  is the speed of an object as measured in the S frame and  $u'_x$  is its speed measured in the S' frame.

The relativistic expression for the **linear momentum** of a particle moving with a velocity  $\mathbf{u}$  is

$$\mathbf{p} \equiv \frac{m\mathbf{u}}{\sqrt{1 - \frac{u^2}{c^2}}} = \gamma m\mathbf{u}\tag{39.19}$$

The relativistic expression for the **kinetic energy** of a particle is

## QUESTIONS

1. What two speed measurements do two observers in relative motion always agree on?
2. A spaceship in the shape of a sphere moves past an observer on the Earth with a speed  $0.5c$ . What shape does the observer see as the spaceship moves past?
3. An astronaut moves away from the Earth at a speed close to the speed of light. If an observer on Earth measures the astronaut's dimensions and pulse rate, what changes (if any) would the observer measure? Would the astronaut measure any changes about himself?
4. Two identical clocks are synchronized. One is then put in orbit directed eastward around the Earth while the other remains on Earth. Which clock runs slower? When the moving clock returns to Earth, are the two still synchronized?
5. Two lasers situated on a moving spacecraft are triggered simultaneously. An observer on the spacecraft claims to see the pulses of light simultaneously. What condition is necessary so that a second observer agrees?
6. When we say that a moving clock runs more slowly than a stationary one, does this imply that there is something physically unusual about the moving clock?
7. List some ways our day-to-day lives would change if the speed of light were only 50 m/s.
8. Give a physical argument that shows that it is impossible to accelerate an object of mass  $m$  to the speed of light, even if it has a continuous force acting on it.
9. It is said that Einstein, in his teenage years, asked the question, "What would I see in a mirror if I carried it in my hands and ran at the speed of light?" How would you answer this question?
10. Some distant star-like objects, called *quasars*, are receding from us at half the speed of light (or greater). What is the speed of the light we receive from these quasars?
11. How is it possible that photons of light, which have zero mass, have momentum?
12. With regard to reference frames, how does general relativity differ from special relativity?
13. Describe how the results of Example 39.7 would change if, instead of fast spaceships, two ordinary cars were approaching each other at highway speeds.
14. Two objects are identical except that one is hotter than the other. Compare how they respond to identical forces.

## PROBLEMS

 = paired numerical/symbolic problems

### Section 39.1 The Principle of Galilean Relativity

1. A 2 000-kg car moving at 20.0 m/s collides and locks together with a 1 500-kg car at rest at a stop sign. Show that momentum is conserved in a reference frame moving at 10.0 m/s in the direction of the moving car.
2. A ball is thrown at 20.0 m/s inside a boxcar moving along the tracks at 40.0 m/s. What is the speed of the ball relative to the ground if the ball is thrown (a) forward? (b) backward? (c) out the side door?
3. In a laboratory frame of reference, an observer notes that Newton's second law is valid. Show that it is also valid for an observer moving at a constant speed, small compared with the speed of light, relative to the laboratory frame.
4. Show that Newton's second law is *not* valid in a reference frame moving past the laboratory frame of Problem 3 with a constant acceleration.

### Section 39.2 The Michelson–Morley Experiment

### Section 39.3 Einstein's Principle of Relativity

### Section 39.4 Consequences of the Special Theory of Relativity

5. How fast must a meter stick be moving if its length is observed to shrink to 0.500 m?
6. At what speed does a clock have to move if it is to be seen to run at a rate that is one-half the rate of a clock at rest?
7. An astronaut is traveling in a space vehicle that has a speed of  $0.500c$  relative to the Earth. The astronaut measures his pulse rate at 75.0 beats per minute. Signals generated by the astronaut's pulse are radioed to Earth when the vehicle is moving in a direction perpendicular to a line that connects the vehicle with an observer on the Earth. What pulse rate does the Earth observer measure? What would be the pulse rate if the speed of the space vehicle were increased to  $0.990c$ ?
8. The proper length of one spaceship is three times that of another. The two spaceships are traveling in the same direction and, while both are passing overhead, an Earth observer measures the two spaceships to have the same length. If the slower spaceship is moving with a speed of  $0.350c$ , determine the speed of the faster spaceship.
9. An atomic clock moves at 1 000 km/h for 1 h as measured by an identical clock on Earth. How many nanoseconds slow will the moving clock be at the end of the 1-h interval?
10. If astronauts could travel at  $v = 0.950c$ , we on Earth would say it takes  $(4.20/0.950) = 4.42$  yr to reach Alpha

Centauri, 4.20 ly away. The astronauts disagree. (a) How much time passes on the astronauts' clocks? (b) What distance to Alpha Centauri do the astronauts measure?

- WEB 11. A spaceship with a proper length of 300 m takes  $0.750 \mu\text{s}$  to pass an Earth observer. Determine the speed of this spaceship as measured by the Earth observer.
12. A spaceship of proper length  $L_p$  takes time  $t$  to pass an Earth observer. Determine the speed of this spaceship as measured by the Earth observer.
  13. A muon formed high in the Earth's atmosphere travels at speed  $v = 0.990c$  for a distance of 4.60 km before it decays into an electron, a neutrino, and an antineutrino ( $\mu^- \rightarrow e^- + \nu + \bar{\nu}$ ). (a) How long does the muon live, as measured in its reference frame? (b) How far does the muon travel, as measured in its frame?
  14. **Review Problem.** In 1962, when Mercury astronaut Scott Carpenter orbited the Earth 22 times, the press stated that for each orbit he aged 2 millionths of a second less than he would have had he remained on Earth. (a) Assuming that he was 160 km above the Earth in a circular orbit, determine the time difference between someone on Earth and the orbiting astronaut for the 22 orbits. You will need to use the approximation  $\sqrt{1-x} \approx 1-x/2$  for small  $x$ . (b) Did the press report accurate information? Explain.
  15. The pion has an average lifetime of 26.0 ns when at rest. In order for it to travel 10.0 m, how fast must it move?
  16. For what value of  $v$  does  $\gamma = 1.01$ ? Observe that for speeds less than this value, time dilation and length contraction are less-than-one-percent effects.
  17. A friend passes by you in a spaceship traveling at a high speed. He tells you that his ship is 20.0 m long and that the identically constructed ship you are sitting in is 19.0 m long. According to your observations, (a) how long is your ship, (b) how long is your friend's ship, and (c) what is the speed of your friend's ship?
  18. An interstellar space probe is launched from Earth. After a brief period of acceleration it moves with a constant velocity, 70.0% of the speed of light. Its nuclear-powered batteries supply the energy to keep its data transmitter active continuously. The batteries have a lifetime of 15.0 yr as measured in a rest frame. (a) How long do the batteries on the space probe last as measured by Mission Control on Earth? (b) How far is the probe from Earth when its batteries fail, as measured by Mission Control? (c) How far is the probe from Earth when its batteries fail, as measured by its built-in trip odometer? (d) For what total time after launch are data

received from the probe by Mission Control? Note that radio waves travel at the speed of light and fill the space between the probe and Earth at the time of battery failure.

19. **Review Problem.** An alien civilization occupies a brown dwarf, nearly stationary relative to the Sun, several lightyears away. The extraterrestrials have come to love original broadcasts of *The Ed Sullivan Show*, on our television channel 2, at carrier frequency 57.0 MHz. Their line of sight to us is in the plane of the Earth's orbit. Find the difference between the highest and lowest frequencies they receive due to the Earth's orbital motion around the Sun.
20. Police radar detects the speed of a car (Fig. P39.20) as follows: Microwaves of a precisely known frequency are broadcast toward the car. The moving car reflects the microwaves with a Doppler shift. The reflected waves are received and combined with an attenuated version of the transmitted wave. Beats occur between the two microwave signals. The beat frequency is measured. (a) For an electromagnetic wave reflected back to its source from a mirror approaching at speed  $v$ , show that the reflected wave has frequency

$$f = f_{\text{source}} \frac{c + v}{c - v}$$

where  $f_{\text{source}}$  is the source frequency. (b) When  $v$  is much less than  $c$ , the beat frequency is much less than the transmitted frequency. In this case, use the approximation  $f + f_{\text{source}} \cong 2f_{\text{source}}$  and show that the beat frequency can be written as  $f_b = 2v/\lambda$ . (c) What beat fre-

Figure P39.20 (Trent Steffler/David R. Frazier Photolibrary)

quency is measured for a car speed of 30.0 m/s if the microwaves have frequency 10.0 GHz? (d) If the beat frequency measurement is accurate to  $\pm 5$  Hz, how accurate is the velocity measurement?

21. **The red shift.** A light source recedes from an observer with a speed  $v_{\text{source}}$ , which is small compared with  $c$ . (a) Show that the fractional shift in the measured wavelength is given by the approximate expression

$$\frac{\Delta\lambda}{\lambda} \approx \frac{v_{\text{source}}}{c}$$

This phenomenon is known as the red shift because the visible light is shifted toward the red. (b) Spectroscopic measurements of light at  $\lambda = 397$  nm coming from a galaxy in Ursa Major reveal a red shift of 20.0 nm. What is the recessional speed of the galaxy?

### Section 39.5 The Lorentz Transformation Equations

22. A spaceship travels at  $0.750c$  relative to Earth. If the spaceship fires a small rocket in the forward direction, how fast (relative to the ship) must it be fired for it to travel at  $0.950c$  relative to Earth?
- WEB 23. Two jets of material from the center of a radio galaxy fly away in opposite directions. Both jets move at  $0.750c$  relative to the galaxy. Determine the speed of one jet relative to that of the other.
24. A moving rod is observed to have a length of 2.00 m, and to be oriented at an angle of  $30.0^\circ$  with respect to the direction of motion (Fig. P39.24). The rod has a speed of  $0.995c$ . (a) What is the proper length of the rod? (b) What is the orientation angle in the proper frame?

Figure P39.24

25. A Klingon space ship moves away from the Earth at a speed of  $0.800c$  (Fig. P39.25). The starship *Enterprise* pursues at a speed of  $0.900c$  relative to the Earth. Observers on Earth see the *Enterprise* overtaking the Klingon ship at a relative speed of  $0.100c$ . With what speed is the *Enterprise* overtaking the Klingon ship as seen by the crew of the *Enterprise*?

Figure P39.25

26. A red light flashes at position  $x_R = 3.00$  m and time  $t_R = 1.00 \times 10^{-9}$  s, and a blue light flashes at  $x_B = 5.00$  m and  $t_B = 9.00 \times 10^{-9}$  s (all values are measured in the S reference frame). Reference frame S' has its origin at the same point as S at  $t = t' = 0$ ; frame S' moves constantly to the right. Both flashes are observed to occur at the same place in S'. (a) Find the relative velocity between S and S'. (b) Find the location of the two flashes in frame S'. (c) At what time does the red flash occur in the S' frame?

### Section 39.6 Relativistic Linear Momentum and the Relativistic Form of Newton's Laws

27. Calculate the momentum of an electron moving with a speed of (a)  $0.0100c$ , (b)  $0.500c$ , (c)  $0.900c$ .
28. The nonrelativistic expression for the momentum of a particle,  $p = mu$ , can be used if  $u \ll c$ . For what speed does the use of this formula yield an error in the momentum of (a) 1.00 percent and (b) 10.0 percent?
29. A golf ball travels with a speed of  $90.0$  m/s. By what fraction does its relativistic momentum  $p$  differ from its classical value  $mu$ ? That is, find the ratio  $(p - mu)/mu$ .
30. Show that the speed of an object having momentum  $p$  and mass  $m$  is

$$u = \frac{c}{\sqrt{1 + (mc/p)^2}}$$

- WEB 31. An unstable particle at rest breaks into two fragments of unequal mass. The mass of the lighter fragment is  $2.50 \times 10^{-28}$  kg, and that of the heavier fragment is  $1.67 \times 10^{-27}$  kg. If the lighter fragment has a speed of  $0.893c$  after the breakup, what is the speed of the heavier fragment?

### Section 39.7 Relativistic Energy

32. Determine the energy required to accelerate an electron (a) from  $0.500c$  to  $0.900c$  and (b) from  $0.900c$  to  $0.990c$ .
33. Find the momentum of a proton in MeV/ $c$  units if its total energy is twice its rest energy.
34. Show that, for any object moving at less than one-tenth the speed of light, the relativistic kinetic energy agrees with the result of the classical equation  $K = mu^2/2$  to within less than 1%. Thus, for most purposes, the classical equation is good enough to describe these objects, whose motion we call *nonrelativistic*.
- WEB 35. A proton moves at  $0.950c$ . Calculate its (a) rest energy, (b) total energy, and (c) kinetic energy.
36. An electron has a kinetic energy five times greater than its rest energy. Find (a) its total energy and (b) its speed.
37. A cube of steel has a volume of  $1.00$  cm<sup>3</sup> and a mass of  $8.00$  g when at rest on the Earth. If this cube is now given a speed  $u = 0.900c$ , what is its density as measured by a stationary observer? Note that relativistic density is  $E_R/c^2V$ .

38. An unstable particle with a mass of  $3.34 \times 10^{-27}$  kg is initially at rest. The particle decays into two fragments that fly off with velocities of  $0.987c$  and  $-0.868c$ . Find the masses of the fragments. (*Hint*: Conserve both mass-energy and momentum.)
39. Show that the energy-momentum relationship  $E^2 = p^2c^2 + (mc^2)^2$  follows from the expressions  $E = \gamma mc^2$  and  $p = \gamma mu$ .
40. A proton in a high-energy accelerator is given a kinetic energy of  $50.0$  GeV. Determine (a) its momentum and (b) its speed.
41. In a typical color television picture tube, the electrons are accelerated through a potential difference of  $25\,000$  V. (a) What speed do the electrons have when they strike the screen? (b) What is their kinetic energy in joules?
42. Electrons are accelerated to an energy of  $20.0$  GeV in the  $3.00$ -km-long Stanford Linear Accelerator. (a) What is the  $\gamma$  factor for the electrons? (b) What is their speed? (c) How long does the accelerator appear to them?
43. A pion at rest ( $m_\pi = 270m_e$ ) decays to a muon ( $m_\mu = 206m_e$ ) and an antineutrino ( $m_{\bar{\nu}} \approx 0$ ). The reaction is written  $\pi^- \rightarrow \mu^- + \bar{\nu}$ . Find the kinetic energy of the muon and the antineutrino in electron volts. (*Hint*: Relativistic momentum is conserved.)

### Section 39.8 Equivalence of Mass and Energy

44. Make an order-of-magnitude estimate of the ratio of mass increase to the original mass of a flag as you run it up a flagpole. In your solution explain what quantities you take as data and the values you estimate or measure for them.
45. When  $1.00$  g of hydrogen combines with  $8.00$  g of oxygen,  $9.00$  g of water is formed. During this chemical reaction,  $2.86 \times 10^5$  J of energy is released. How much mass do the constituents of this reaction lose? Is the loss of mass likely to be detectable?
46. A spaceship of mass  $1.00 \times 10^6$  kg is to be accelerated to  $0.600c$ . (a) How much energy does this require? (b) How many kilograms of matter would it take to provide this much energy?
47. In a nuclear power plant the fuel rods last 3 yr before they are replaced. If a plant with rated thermal power  $1.00$  GW operates at  $80.0\%$  capacity for the 3 yr, what is the loss of mass of the fuel?
48. A  $^{57}\text{Fe}$  nucleus at rest emits a  $14.0$ -keV photon. Use the conservation of energy and momentum to deduce the kinetic energy of the recoiling nucleus in electron volts. (Use  $Mc^2 = 8.60 \times 10^{-9}$  J for the final state of the  $^{57}\text{Fe}$  nucleus.)
49. The power output of the Sun is  $3.77 \times 10^{26}$  W. How much mass is converted to energy in the Sun each second?
50. A gamma ray (a high-energy photon of light) can produce an electron ( $e^-$ ) and a positron ( $e^+$ ) when

it enters the electric field of a heavy nucleus:  $\gamma \rightarrow e^+ + e^-$ . What minimum  $\gamma$ -ray energy is required to accomplish this task? (*Hint:* The masses of the electron and the positron are equal.)

### Section 39.9 Relativity and Electromagnetism

51. As measured by observers in a reference frame  $S$ , a particle having charge  $q$  moves with velocity  $\mathbf{v}$  in a magnetic field  $\mathbf{B}$  and an electric field  $\mathbf{E}$ . The resulting force on the particle is then measured to be  $\mathbf{F} = q(\mathbf{E} + \mathbf{v} \times \mathbf{B})$ . Another observer moves along with the charged particle and also measures its charge to be  $q$  but measures the electric field to be  $\mathbf{E}'$ . If both observers are to measure the same force  $\mathbf{F}$ , show that  $\mathbf{E}' = \mathbf{E} + \mathbf{v} \times \mathbf{B}$ .

### ADDITIONAL PROBLEMS

52. An electron has a speed of  $0.750c$ . Find the speed of a proton that has (a) the same kinetic energy as the electron; (b) the same momentum as the electron.
- WEB 53. The cosmic rays of highest energy are protons, which have kinetic energy on the order of  $10^{13}$  MeV. (a) How long would it take a proton of this energy to travel across the Milky Way galaxy, having a diameter of  $\sim 10^5$  ly, as measured in the proton's frame? (b) From the point of view of the proton, how many kilometers across is the galaxy?
54. A spaceship moves away from the Earth at  $0.500c$  and fires a shuttle craft in the forward direction at  $0.500c$  relative to the ship. The pilot of the shuttle craft launches a probe at forward speed  $0.500c$  relative to the shuttle craft. Determine (a) the speed of the shuttle craft relative to the Earth and (b) the speed of the probe relative to the Earth.
55. The net nuclear fusion reaction inside the Sun can be written as  $4^1\text{H} \rightarrow ^4\text{He} + \Delta E$ . If the rest energy of each hydrogen atom is 938.78 MeV and the rest energy of the helium-4 atom is 3728.4 MeV, what is the percentage of the starting mass that is released as energy?
56. An astronaut wishes to visit the Andromeda galaxy (2.00 million lightyears away), making a one-way trip that will take 30.0 yr in the spaceship's frame of reference. If his speed is constant, how fast must he travel relative to the Earth?
57. An alien spaceship traveling at  $0.600c$  toward the Earth launches a landing craft with an advance guard of purchasing agents. The lander travels in the same direction with a velocity  $0.800c$  relative to the spaceship. As observed on the Earth, the spaceship is 0.200 ly from the Earth when the lander is launched. (a) With what velocity is the lander observed to be approaching by observers on the Earth? (b) What is the distance to the Earth at the time of lander launch, as observed by the aliens? (c) How long does it take the lander to reach the Earth as observed by the aliens on the mother ship? (d) If the lander has a mass of  $4.00 \times 10^5$  kg, what is its kinetic energy as observed in the Earth reference frame?
58. A physics professor on the Earth gives an exam to her students, who are on a rocket ship traveling at speed  $v$  relative to the Earth. The moment the ship passes the professor, she signals the start of the exam. She wishes her students to have time  $T_0$  (rocket time) to complete the exam. Show that she should wait a time (Earth time) of
- $$T = T_0 \sqrt{\frac{1 - v/c}{1 + v/c}}$$
- before sending a light signal telling them to stop. (*Hint:* Remember that it takes some time for the second light signal to travel from the professor to the students.)
59. Spaceship I, which contains students taking a physics exam, approaches the Earth with a speed of  $0.600c$  (relative to the Earth), while spaceship II, which contains professors proctoring the exam, moves at  $0.280c$  (relative to the Earth) directly toward the students. If the professors stop the exam after 50.0 min have passed on their clock, how long does the exam last as measured by (a) the students? (b) an observer on the Earth?
60. Energy reaches the upper atmosphere of the Earth from the Sun at the rate of  $1.79 \times 10^{17}$  W. If all of this energy were absorbed by the Earth and not re-emitted, how much would the mass of the Earth increase in 1 yr?
61. A supertrain (proper length, 100 m) travels at a speed of  $0.950c$  as it passes through a tunnel (proper length, 50.0 m). As seen by a trackside observer, is the train ever completely within the tunnel? If so, with how much space to spare?
62. Imagine that the entire Sun collapses to a sphere of radius  $R_g$  such that the work required to remove a small mass  $m$  from the surface would be equal to its rest energy  $mc^2$ . This radius is called the *gravitational radius* for the Sun. Find  $R_g$ . (It is believed that the ultimate fate of very massive stars is to collapse beyond their gravitational radii into black holes.)
63. A charged particle moves along a straight line in a uniform electric field  $\mathbf{E}$  with a speed of  $u$ . If the motion and the electric field are both in the  $x$  direction, (a) show that the acceleration of the charge  $q$  in the  $x$  direction is given by
- $$a = \frac{du}{dt} = \frac{qE}{m} \left( 1 - \frac{u^2}{c^2} \right)^{3/2}$$
- (b) Discuss the significance of the dependence of the acceleration on the speed. (c) If the particle starts from rest at  $x = 0$  at  $t = 0$ , how would you proceed to find the speed of the particle and its position after a time  $t$  has elapsed?
64. (a) Show that the Doppler shift  $\Delta\lambda$  in the wavelength of light is described by the expression
- $$\frac{\Delta\lambda}{\lambda} + 1 = \sqrt{\frac{c - v}{c + v}}$$

where  $\lambda$  is the source wavelength and  $v$  is the speed of relative approach between source and observer.

(b) How fast would a motorist have to be going for a red light to appear green? Take 650 nm as a typical wavelength for red light, and one of 550 nm as typical for green.

65. A rocket moves toward a mirror at  $0.800c$  relative to the reference frame S in Figure P39.65. The mirror is stationary relative to S. A light pulse emitted by the rocket travels toward the mirror and is reflected back to the rocket. The front of the rocket is  $1.80 \times 10^{12}$  m from the mirror (as measured by observers in S) at the moment the light pulse leaves the rocket. What is the total travel time of the pulse as measured by observers in (a) the S frame and (b) the front of the rocket?

Figure P39.65 Problems 65 and 66.

66. An observer in a rocket moves toward a mirror at speed  $v$  relative to the reference frame labeled by S in Figure P39.65. The mirror is stationary with respect to S. A light pulse emitted by the rocket travels toward the mirror and is reflected back to the rocket. The front of the rocket is a distance  $d$  from the mirror (as measured by observers in S) at the moment the light pulse leaves the rocket. What is the total travel time of the pulse as measured by observers in (a) the S frame and (b) the front of the rocket?
67. Ted and Mary are playing a game of catch in frame  $S'$ , which is moving at  $0.600c$ , while Jim in frame S watches the action (Fig. P39.67). Ted throws the ball to Mary at  $0.800c$  (according to Ted) and their separation (measured in  $S'$ ) is  $1.80 \times 10^{12}$  m. (a) According to Mary,

Figure P39.67

how fast is the ball moving? (b) According to Mary, how long does it take the ball to reach her? (c) According to Jim, how far apart are Ted and Mary, and how fast is the ball moving? (d) According to Jim, how long does it take the ball to reach Mary?

68. A rod of length  $L_0$  moving with a speed  $v$  along the horizontal direction makes an angle  $\theta_0$  with respect to the  $x'$  axis. (a) Show that the length of the rod as measured by a stationary observer is  $L = L_0[1 - (v^2/c^2) \cos^2 \theta_0]^{1/2}$ . (b) Show that the angle that the rod makes with the  $x$  axis is given by  $\tan \theta = \gamma \tan \theta_0$ . These results show that the rod is both contracted and rotated. (Take the lower end of the rod to be at the origin of the primed coordinate system.)
69. Consider two inertial reference frames S and  $S'$ , where  $S'$  is moving to the right with a constant speed of  $0.600c$  as measured by an observer in S. A stick of proper length 1.00 m moves to the left toward the origins of both S and  $S'$ , and the length of the stick is 50.0 cm as measured by an observer in  $S'$ . (a) Determine the speed of the stick as measured by observers in S and  $S'$ . (b) What is the length of the stick as measured by an observer in S?
70. Suppose our Sun is about to explode. In an effort to escape, we depart in a spaceship at  $v = 0.800c$  and head toward the star Tau Ceti, 12.0 ly away. When we reach the midpoint of our journey from the Earth, we see our Sun explode and, unfortunately, at the same instant we see Tau Ceti explode as well. (a) In the spaceship's frame of reference, should we conclude that the two explosions occurred simultaneously? If not, which occurred first? (b) In a frame of reference in which the Sun and Tau Ceti are at rest, did they explode simultaneously? If not, which exploded first?
71. The light emitted by a galaxy shows a continuous distribution of wavelengths because the galaxy is composed of billions of different stars and other thermal emitters. Nevertheless, some narrow gaps occur in the continuous spectrum where light has been absorbed by cooler gases in the outer photospheres of normal stars. In particular, ionized calcium atoms at rest produce strong absorption at a wavelength of 394 nm. For a galaxy in the constellation Hydra, 2 billion lightyears away, this absorption line is shifted to 475 nm. How fast is the galaxy moving away from the Earth? (Note: The assumption that the recession speed is small compared with  $c$ , as made in Problem 21, is not a good approximation here.)
72. Prepare a graph of the relativistic kinetic energy and the classical kinetic energy, both as a function of speed, for an object with a mass of your choice. At what speed does the classical kinetic energy underestimate the relativistic value by 1 percent? By 5 percent? By 50 percent?
73. The total volume of water in the oceans is approximately  $1.40 \times 10^9$  km<sup>3</sup>. The density of sea water is 1 030 kg/m<sup>3</sup>, and the specific heat of the water is 4 186 J/(kg · °C). Find the increase in mass of the oceans produced by an increase in temperature of 10.0°C.

## ANSWERS TO QUICK QUIZZES

- 39.1** They both are because they can report only what they see. They agree that the person in the truck throws the ball up and then catches it a bit later.
- 39.2** It depends on the direction of the throw. Taking the direction in which the train is traveling as the positive  $x$  direction, use the values  $u'_x = +90$  mi/h and  $v = +110$  mi/h, with  $u_x$  in Equation 39.2 being the value you are looking for. If the pitcher throws the ball in the same direction as the train, a person at rest on the Earth sees the ball moving at  $110$  mi/h  $+ 90$  mi/h  $= 200$  mi/h. If the pitcher throws in the opposite direction, the person on the Earth sees the ball moving in the same direction as the train but at only  $110$  mi/h  $- 90$  mi/h  $= 20$  mi/h.
- 39.3** Both are correct. Although the two observers reach different conclusions, each is correct in her or his own reference frame because the concept of simultaneity is not absolute.
- 39.4** About  $2.9 \times 10^8$  m/s, because this is the speed at which  $\gamma = 5$ . For every 5 s ticking by on the Mission Control clock, the Earth-bound observer (with a powerful telescope!) sees the rocket clock ticking off 1 s. The astronaut sees her own clock operating at a normal rate. To her, Mission Control is moving away from her at a speed of  $2.9 \times 10^8$  m/s, and she sees the Mission Control clock as running slow. Strange stuff, this relativity!
- 39.5** If their on-duty time is based on clocks that remain on the Earth, they will have larger paychecks. Less time will have passed for the astronauts in their frame of reference than for their employer back on the Earth.
- 39.6** By a curved line. This can be seen in the middle of Speedo's world-line in Figure 39.14, where he turns around and begins his trip home.
- 39.7** The downstairs clock runs more slowly because it is closer to the Earth and hence experiences a stronger gravitational field than the upstairs clock does.

# Answers to Odd-Numbered Problems

## Chapter 1

1.  $2.15 \times 10^4 \text{ kg/m}^3$
3. 184 g
5. (a)  $7.10 \text{ cm}^3$  (b)  $1.18 \times 10^{-29} \text{ m}^3$  (c) 0.228 nm  
(d)  $12.7 \text{ cm}^3$ ,  $2.11 \times 10^{-29} \text{ m}^3$ , 0.277 nm
7. (a)  $4.00 \text{ u} = 6.64 \times 10^{-24} \text{ g}$  (b)  $55.9 \text{ u} = 9.29 \times 10^{-23} \text{ g}$  (c)  $207 \text{ u} = 3.44 \times 10^{-22} \text{ g}$
9. (a)  $9.83 \times 10^{-16} \text{ g}$  (b)  $1.06 \times 10^7 \text{ atoms}$
11. (a)  $4.01 \times 10^{25} \text{ molecules}$  (b)  $3.65 \times 10^4 \text{ molecules}$
13. no
15. (b) only
17.  $0.579t \text{ ft}^3/\text{s} + 1.19 \times 10^{-9}t^2 \text{ ft}^3/\text{s}^2$
19.  $1.39 \times 10^3 \text{ m}^2$
21. (a) 0.071 4 gal/s (b)  $2.70 \times 10^{-4} \text{ m}^3/\text{s}$  (c) 1.03 h
23.  $4.05 \times 10^3 \text{ m}^2$
25.  $11.4 \times 10^3 \text{ kg/m}^3$
27.  $1.19 \times 10^{57} \text{ atoms}$
29. (a) 190 y (b)  $2.32 \times 10^4 \text{ times}$
31.  $151 \mu\text{m}$
33.  $1.00 \times 10^{10} \text{ lb}$
35.  $3.08 \times 10^4 \text{ m}^3$
37. 5.0 m
39. 2.86 cm
41.  $\sim 10^6 \text{ balls}$
43.  $\sim 10^7 \text{ or } 10^8 \text{ rev}$
45.  $\sim 10^7 \text{ or } 10^8 \text{ blades}$
47.  $\sim 10^2 \text{ kg}$ ;  $\sim 10^3 \text{ kg}$
49.  $\sim 10^2 \text{ tuners}$
51. (a)  $(346 \pm 13) \text{ m}^2$  (b)  $(66.0 \pm 1.3) \text{ m}$
53.  $(1.61 \pm 0.17) \times 10^3 \text{ kg/m}^3$
55. 115.9 m
57. 316 m
59.  $4.50 \text{ m}^2$
61. 3.41 m
63. 0.449%
65. (a) 0.529 cm/s (b) 11.5 cm/s
67.  $1 \times 10^{10} \text{ gal/yr}$
69.  $\sim 10^{11} \text{ stars}$

## Chapter 2

1. (a) 2.30 m/s (b) 16.1 m/s (c) 11.5 m/s
3. (a) 5 m/s (b) 1.2 m/s (c) -2.5 m/s (d) -3.3 m/s  
(e) 0
5. (a) 3.75 m/s (b) 0

7. (a)

(b) 1.60 m/s

9. (a) -2.4 m/s (b) -3.8 m/s (c) 4.0 s
11. (a) 5.0 m/s (b) -2.5 m/s (c) 0 (d) 5.0 m/s
13.  $1.34 \times 10^4 \text{ m/s}^2$
15. (a)

(b)  $1.6 \text{ m/s}^2$  and  $0.80 \text{ m/s}^2$

17. (a) 2.00 m (b) -3.00 m/s (c) -2.00 m/s<sup>2</sup>
19. (a)  $1.3 \text{ m/s}^2$  (b)  $2.0 \text{ m/s}^2$  at 3 s (c) at  $t = 6 \text{ s}$  and for  $t > 10 \text{ s}$  (d)  $-1.5 \text{ m/s}^2$  at 8 s
21.  $2.74 \times 10^5 \text{ m/s}^2$ , which is  $2.79 \times 10^4 g$
23. (a) 6.61 m/s (b) -0.448 m/s<sup>2</sup>
25. -16.0 cm/s<sup>2</sup>
27. (a) 2.56 m (b) -3.00 m/s
29. (a) 8.94 s (b) 89.4 m/s
31. (a) 20.0 s (b) no
33.  $x_f - x_i = v_{xf}t - a_x t^2/2$ ;  $v_{xf} = 3.10 \text{ m/s}$

35. (a) 35.0 s (b) 15.7 m/s  
 37. (a)  $-202 \text{ m/s}^2$  (b) 198 m  
 39. (a) 3.00 m/s (b) 6.00 s (c)  $-0.300 \text{ m/s}^2$   
 (d) 2.05 m/s  
 41. (a)  $-4.90 \text{ m}$ ,  $-19.6 \text{ m}$ ,  $-44.1 \text{ m}$  (b)  $-9.80 \text{ m/s}$ ,  
 $-19.6 \text{ m/s}$ ,  $-29.4 \text{ m/s}$   
 43. (a) 10.0 m/s up (b) 4.68 m/s down  
 45. No. In 0.2 s the bill falls out from between David's fingers.  
 47. (a) 29.4 m/s (b) 44.1 m  
 49. (a) 7.82 m (b) 0.782 s  
 51. (a) 1.53 s (b) 11.5 m (c)  $-4.60 \text{ m/s}$ ,  $-9.80 \text{ m/s}^2$   
 53. (a)  $a_x = a_{xi} + Jt$ ,  $v_x = v_{xi} + a_{xi}t + \frac{1}{2}Jt^2$ ,  
 $x = x_i + v_{xi}t + \frac{1}{2}a_{xi}t^2 + \frac{1}{6}Jt^3$   
 55. 0.222 s  
 57. 0.509 s  
 59. (a) 41.0 s (b) 1.73 km (c)  $-184 \text{ m/s}$   
 61.  $v_{xi}t + at^2/2$ , in agreement with Equation 2.11  
 63. (a)  $5.43 \text{ m/s}^2$  and  $3.83 \text{ m/s}^2$  (b) 10.9 m/s and 11.5 m/s  
 (c) Maggie by 2.62 m  
 65. (a) 45.7 s (b) 574 m (c) 12.6 m/s (d) 765 s  
 67. (a) 2.99 s (b)  $-15.4 \text{ m/s}$  (c) 31.3 m/s down and  
 34.9 m/s down  
 69. (a) 5.46 s (b) 73.0 m (c)  $v_{\text{Stan}} = 22.6 \text{ m/s}$ ,  $v_{\text{Kathy}} =$   
 $26.7 \text{ m/s}$   
 71. (a) See top of next column.  
 (b) See top of next column.  
 73.  $0.577v$

### Chapter 3

1.  $(-2.75, -4.76) \text{ m}$   
 3. 1.15; 2.31  
 5. (a) 2.24 m (b) 2.24 m at  $26.6^\circ$  from the positive  $x$  axis.  
 7. (a) 484 m (b)  $18.1^\circ$  north of west  
 9. 70.0 m  
 11. (a) approximately 6.1 units at  $112^\circ$  (b) approximately  
 14.8 units at  $22^\circ$   
 13. (a) 10.0 m (b) 15.7 m (c) 0  
 15. (a) 5.2 m at  $60^\circ$  (b) 3.0 m at  $330^\circ$  (c) 3.0 m at  $150^\circ$   
 (d) 5.2 m at  $300^\circ$   
 17. approximately 420 ft at  $-3^\circ$   
 19. 5.83 m at  $59.0^\circ$  to the right of his initial direction  
 21. 1.31 km north and 2.81 km east  
 23. (a) 10.4 cm (b)  $35.5^\circ$   
 25. 47.2 units at  $122^\circ$  from the positive  $x$  axis.  
 27.  $(-25.0\mathbf{i})\text{m} + (43.3\mathbf{j})\text{m}$   
 29. 7.21 m at  $56.3^\circ$  from the positive  $x$  axis.  
 31. (a)  $2.00\mathbf{i} - 6.00\mathbf{j}$  (b)  $4.00\mathbf{i} + 2.00\mathbf{j}$  (c) 6.32 (d) 4.47  
 (e)  $288^\circ$ ;  $26.6^\circ$  from the positive  $x$  axis.  
 33. (a)  $(-11.1\mathbf{i} + 6.40\mathbf{j}) \text{ m}$  (b)  $(1.65\mathbf{i} + 2.86\mathbf{j}) \text{ cm}$   
 (c)  $(-18.0\mathbf{i} - 12.6\mathbf{j}) \text{ in.}$   
 35. 9.48 m at  $166^\circ$   
 37. (a) 185 N at  $77.8^\circ$  from the positive  $x$  axis  
 (b)  $(-39.3\mathbf{i} - 181\mathbf{j}) \text{ N}$   
 39.  $\mathbf{A} + \mathbf{B} = (2.60\mathbf{i} + 4.50\mathbf{j}) \text{ m}$

Chapter 2, Problem 71(a)

Chapter 2, Problem 71(b)

41. 196 cm at  $-14.7^\circ$  from the positive  $x$  axis.  
 43. (a)  $8.00\mathbf{i} + 12.0\mathbf{j} - 4.00\mathbf{k}$  (b)  $2.00\mathbf{i} + 3.00\mathbf{j} - 1.00\mathbf{k}$   
 (c)  $-24.0\mathbf{i} - 36.0\mathbf{j} + 12.0\mathbf{k}$   
 45. (a) 5.92 m is the magnitude of  $(5.00\mathbf{i} - 1.00\mathbf{j} - 3.00\mathbf{k}) \text{ m}$   
 (b) 19.0 m is the magnitude of  $(4.00\mathbf{i} - 11.0\mathbf{j} + 15.0\mathbf{k}) \text{ m}$   
 47. 157 km  
 49. (a)  $-3.00\mathbf{i} + 2.00\mathbf{j}$  (b) 3.61 at  $146^\circ$  from the positive  
 $x$  axis. (c)  $3.00\mathbf{i} - 6.00\mathbf{j}$   
 51. (a) 49.5i + 27.1j (b) 56.4 units at  $28.7^\circ$  from the positive  
 $x$  axis.  
 53.  $1.15^\circ$   
 55. (a) 2.00, 1.00, 3.00 (b) 3.74 (c)  $\theta_x = 57.7^\circ$ ,  $\theta_y = 74.5^\circ$ ,  
 $\theta_z = 36.7^\circ$   
 57. 240 m at  $237^\circ$   
 59. 390 mi/h at  $7.37^\circ$  north of east  
 61.  $\mathbf{R}_1 = a\mathbf{i} + b\mathbf{j}$ ;  $R_1 = \sqrt{a^2 + b^2}$  (b)  $\mathbf{R}_2 = a\mathbf{i} + b\mathbf{j} + c\mathbf{k}$

Chapter 4

1. (a) 4.87 km at 209° from east (b) 23.3 m/s  
(c) 13.5 m/s at 209°
3. (a)  $(18.0t)\mathbf{i} + (4.00t - 4.90t^2)\mathbf{j}$   
(b)  $18.0\mathbf{i} + (4.00 - 9.80t)\mathbf{j}$  (c)  $-9.80\mathbf{j}$   
(d)  $(54.0\mathbf{i} - 32.1\mathbf{j})$  m  
(e)  $(18.0\mathbf{i} - 25.4\mathbf{j})$  m/s (f)  $(-9.80\mathbf{j})$  m/s<sup>2</sup>
5. (a)  $(2.00\mathbf{i} + 3.00\mathbf{j})$  m/s<sup>2</sup>  
(b)  $(3.00t + t^2)\mathbf{i}$  m,  $(1.50t^2 - 2.00t)\mathbf{j}$  m
7. (a)  $(0.800\mathbf{i} - 0.300\mathbf{j})$  m/s<sup>2</sup> (b) 339°  
(c)  $(360\mathbf{i} - 72.7\mathbf{j})$  m,  $-15.2^\circ$
9. (a)  $(3.34\mathbf{i})$  m/s (b)  $-50.9^\circ$
11. (a) 20.0° (b) 3.05 s
13.  $x = 7.23$  km  $y = 1.68$  km
15. 53.1°
17. 22.4° or 89.4°
19. (a) The ball clears by 0.889 m (b) while descending
21.  $d \tan \theta_i - gd^2 / (2v_i^2 \cos^2 \theta_i)$
23. (a) 0.852 s (b) 3.29 m/s (c) 4.03 m/s (d) 50.8°  
(e) 1.12 s
25. 377 m/s<sup>2</sup>
27. 10.5 m/s, 219 m/s<sup>2</sup>
29. (a) 6.00 rev/s (b) 1.52 km/s<sup>2</sup> (c) 1.28 km/s<sup>2</sup>
31. 1.48 m/s<sup>2</sup> inward at 29.9° behind the radius
33. (a) 13.0 m/s<sup>2</sup> (b) 5.70 m/s (c) 7.50 m/s<sup>2</sup>
35. (a)

- (b) 29.7 m/s<sup>2</sup> (c) 6.67 m/s at 36.9° above the horizontal
37.  $2.02 \times 10^3$  s; 21.0% longer
  39. 153 km/h at 11.3° north of west
  41. (a) 36.9° (b) 41.6° (c) 3.00 min
  43. 15.3 m
  45.  $2v_i t \cos \theta_i$
  47. (b)  $45^\circ + \phi/2$ ;  $v_i^2(1 - \sin \phi) / g \cos^2 \phi$
  49. (a) 41.7 m/s (b) 3.81 s (c)  $(34.1\mathbf{i} - 13.4\mathbf{j})$  m/s; 36.6 m/s
  51. (a) 25.0 m/s<sup>2</sup> (radial); 9.80 m/s<sup>2</sup> (tangential)  
(b)

- (c) 26.8 m/s<sup>2</sup> inward at 21.4° below the horizontal
53. 8.94 m/s at  $-63.4^\circ$  relative to the positive  $x$  axis.
55. 20.0 m
57. (a) 0.600 m (b) 0.402 m (c) 1.87 m/s<sup>2</sup> toward center  
(d) 9.80 m/s<sup>2</sup> down
59. (a) 6.80 km (b) 3.00 km vertically above the impact point (c) 66.2°
61. (a) 46.5 m/s (b)  $-77.6^\circ$  (c) 6.34 s
63. (a) 1.53 km (b) 36.2 s (c) 4.04 km
65. (a) 20.0 m/s, 5.00 s (b)  $(16.0\mathbf{i} - 27.1\mathbf{j})$  m/s (c) 6.54 s  
(d)  $(24.6\mathbf{i})$  m
67. (a) 43.2 m (b)  $(9.66\mathbf{i} - 25.5\mathbf{j})$  m/s
69. Imagine you are shaking down the mercury in a fever thermometer. Starting with your hand at the level of your shoulder, move your hand down as fast as you can and snap it around an arc at the bottom.  $\sim 100$  m/s<sup>2</sup>  $\approx 10g$

Chapter 5

1. (a) 1/3 (b) 0.750 m/s<sup>2</sup>
3.  $(6.00\mathbf{i} + 15.0\mathbf{j})$  N; 16.2 N
5. 312 N
7. (a)  $x = vt/2$  (b)  $F_g v\mathbf{i} / gt + F_g\mathbf{j}$
9. (a)  $(2.50\mathbf{i} + 5.00\mathbf{j})$  N (b) 5.59 N
11. (a)  $3.64 \times 10^{-18}$  N (b)  $8.93 \times 10^{-30}$  N is 408 billion times smaller.
13. 2.38 kN
15. (a) 5.00 m/s<sup>2</sup> at 36.9° (b) 6.08 m/s<sup>2</sup> at 25.3°
17. (a)  $\sim 10^{-22}$  m/s<sup>2</sup> (b)  $\sim 10^{-23}$  m
19. (a) 0.200 m/s<sup>2</sup> forward (b) 10.0 m (c) 2.00 m/s
21. (a) 15.0 lb up (b) 5.00 lb up (c) 0
23. 613 N

27. (a) 49.0 N (b) 98.0 N (c) 24.5 N
29. 8.66 N east
31. 100 N and 204 N
33. 3.73 m
35.  $a = F / (m_1 + m_2)$ ;  $T = Fm_1 / (m_1 + m_2)$
37. (a)  $F_x > 19.6$  N (b)  $F_x \leq -78.4$  N  
(c) See top of next page.
39. (a) 706 N (b) 814 N (c) 706 N (d) 648 N
41.  $\mu_s = 0.306$ ;  $\mu_k = 0.245$
43. (a) 256 m (b) 42.7 m
45. (a) 1.78 m/s<sup>2</sup> (b) 0.368 (c) 9.37 N (d) 2.67 m/s
47. (a) 0.161 (b) 1.01 m/s<sup>2</sup>
49. 37.8 N

Chapter 5, Problem 37(c)

Chapter 5, Problem 55(a)

51. (a)

(b) 27.2 N, 1.29 m/s<sup>2</sup>

53. Any value between 31.7 N and 48.6 N

55. (a) See top of next column.

(b) 0.408 m/s<sup>2</sup> (c) 83.3 N

57. 1.18 kN

59. (a)  $Mg/2$ ,  $Mg/2$ ,  $Mg/2$ ,  $3Mg/2$ ,  $Mg$  (b)  $Mg/2$

61. (b) $\theta$	0	15.0°	30.0°	45.0°	60.0°
$P(N)$	40.0	46.4	60.1	94.3	260

63. (a) 19.3° (b) 4.21 N

65. (a) 2.13 s (b) 1.67 m

67. (a) See next column.

Static friction between the two blocks accelerates the upper block. (b) 34.7 N (c) 0.306

69.  $(M + m_1 + m_2)(m_2g/m_1)$

Chapter 5, Problem 67(a)

71. (a)

(b) 113 N (c) 0.980 m/s<sup>2</sup> and 1.96 m/s<sup>2</sup>

73. (a) 0.087 1 (b) 27.4 N

75. (a) 30.7° (b) 0.843 N

77. (a) 3.34 (b) Either the car would flip over backwards, or the wheels would skid, spinning in place, and the time would increase.

### Chapter 6

1. (a) 8.00 m/s (b) 3.02 N

3. Any speed up to 8.08 m/s

5.  $6.22 \times 10^{-12}$  N  
 7. (a)  $1.52 \text{ m/s}^2$  (b)  $1.66 \text{ km/s}$  (c) 6 820 s  
 9. (a) static friction (b) 0.085 0  
 11.  $v \leq 14.3 \text{ m/s}$   
 13. (a) 68.6 N toward the center of the circle and 784 N up  
 (b)  $0.857 \text{ m/s}^2$   
 15. No. The jungle lord needs a vine of tensile strength  
 1.38 kN.  
 17. (a)  $4.81 \text{ m/s}$  (b) 700 N up  
 19.  $3.13 \text{ m/s}$   
 21. (a)  $2.49 \times 10^4 \text{ N up}$  (b)  $12.1 \text{ m/s}$   
 23. (a)  $0.822 \text{ m/s}^2$  (b) 37.0 N (c) 0.0839  
 25. (a)  $17.0^\circ$  (b) 5.12 N  
 27. (a) 491 N (b) 50.1 kg (c)  $2.00 \text{ m/s}^2$   
 29.  $0.0927^\circ$   
 31. (a)  $32.7 \text{ s}^{-1}$  (b)  $9.80 \text{ m/s}^2$  (c)  $4.90 \text{ m/s}^2$   
 33. 3.01 N  
 35. (a)  $1.47 \text{ N}\cdot\text{s/m}$  (b)  $2.04 \times 10^{-3} \text{ s}$  (c)  $2.94 \times 10^{-2} \text{ N}$   
 37. (a)  $0.0347 \text{ s}^{-1}$  (b)  $2.50 \text{ m/s}$  (c)  $a = -cv$   
 39.  $\sim 10^1 \text{ N}$   
 41. (a)  $13.7 \text{ m/s down}$

(b)

$t$ (s)	$x$ (m)	$v$ (m/s)
0	0	0
0.2	0	-1.96
0.4	-0.392	-3.88
...	...	...
1.0	-3.77	-8.71
... 2.0	-14.4	-12.56
... 4.0	-41.0	-13.67

43. (a)  $49.5 \text{ m/s}$  and  $4.95 \text{ m/s}$

(b)

$t$ (s)	$y$ (m)	$v$ (m/s)
0	1 000	0
... 1	995	-9.7
... 2	980	-18.6
... 10	674	-47.7
... 10.1	671	-16.7
... 12	659	-4.95
... 145	0	-4.95

45. (a)  $2.33 \times 10^{-4} \text{ kg/m}$  (b)  $53 \text{ m/s}$  (c)  $42 \text{ m/s}$ . The second trajectory is higher and shorter. In both, the ball attains maximum height when it has covered about 57% of its horizontal range, and it attains minimum speed somewhat later. The impact speeds also are both about  $30 \text{ m/s}$ .

47. (a)  $mg - mv^2/R$  (b)  $\sqrt{gR}$   
 49. (a)  $2.63 \text{ m/s}^2$  (b) 201 m (c)  $17.7 \text{ m/s}$   
 51. (a) 9.80 N (b) 9.80 N (c)  $6.26 \text{ m/s}$   
 53. (b) 732 N down at the equator and 735 N down at the poles  
 59. (a)  $1.58 \text{ m/s}^2$  (b) 455 N (c) 329 N (d) 397 N upward and  $9.15^\circ$  inward

61. (a)  $5.19 \text{ m/s}$  (b) Child + seat:

$T = 555 \text{ N}$

63. (b) 2.54 s; 23.6 rev/min  
 65. 215 N horizontally inward  
 67. (a) either  $70.4^\circ$  or  $0^\circ$  (b)  $0^\circ$   
 69. 12.8 N  
 71. (a)

$t$ (s)	$d$ (m)
0	0
1	4.9
2	18.9
...	...
5	112.6
... 10	347.0
11	399.1
... 15	611.3
... 20	876.5

- (c) The graph is straight for  $11 \text{ s} < t < 20 \text{ s}$ , with slope  $53.0 \text{ m/s}$ .

 31. 3.74 m/s  
 33. (a) -160 J (b) 73.5 J (c) 28.8 N (d) 0.679  
 35. 489 kJ  
 37. (a) 1.40 m/s (b) 4.60 cm after release (c) 1.79 m/s  
 39. 1.96 m  
 41.  $(A/r^2)$  away from the other particle  
 43. (a)  $r = 1.5$  mm, stable; 2.3 mm, unstable; 3.2 mm, stable;  
 $r \rightarrow \infty$  neutral (b)  $-5.6$  J  $< E < 1$  J  
 (c)  $0.6$  mm  $< r < 3.6$  mm (d) 2.6 J (e) 1.5 mm  
 (f) 4 J  
 45. (a) + at Ⓑ, - at Ⓓ, 0 at Ⓐ, Ⓒ, and Ⓔ (b) Ⓒ stable;  
 Ⓐ and Ⓔ unstable  
 (c)

47. (b)

- Equilibrium at  $x = 0$  (c)  $v = \sqrt{0.800J/m}$   
 49. (a)  $1.50 \times 10^{-10}$  J (b)  $1.07 \times 10^{-9}$  J (c)  $9.15 \times 10^{-10}$  J  
 51. 48.2° Note that the answer is independent of the pumpkin's mass and of the radius of the dome.  
 53. (a) 0.225 J (b)  $\Delta E_f = -0.363$  J (c) No; the normal force changes in a complicated way.  
 55.  $\sim 10^2$  W sustainable power  
 57. 0.327  
 59. (a) 23.6 cm (b) 5.90 m/s<sup>2</sup> up the incline; no.  
 (c) Gravitational potential energy turns into kinetic energy plus elastic potential energy and then entirely into elastic potential energy.  
 61. 1.25 m/s

63. (a) 0.400 m (b) 4.10 m/s (c) The block stays on the track.  
 65. (b) 2.06 m/s  
 67. (b) 1.44 m (c) 0.400 m (d) No. A very strong wind pulls the string out horizontally (parallel to the ground). The largest possible equilibrium height is equal to  $L$ .  
 71. (a) 6.15 m/s (b) 9.87 m/s  
 73. 0.923 m/s

### Chapter 9

1. (a)  $(9.00\mathbf{i} - 12.0\mathbf{j})$  kg·m/s (b) 15.0 kg·m/s at  $307^\circ$   
 3. 6.25 cm/s west  
 5.  $\sim 10^{-23}$  m/s  
 7. (b)  $p = \sqrt{2mK}$   
 9. (a) 13.5 N·s (b) 9.00 kN (c) 18.0 kN  
 11. 260 N normal to the wall  
 13. 15.0 N in the direction of the initial velocity of the exiting water stream  
 15. 65.2 m/s  
 17. 301 m/s  
 19. (a)  $v_{gx} = 1.15$  m/s (b)  $v_{px} = -0.346$  m/s  
 21. (a) 20.9 m/s east (b) 8.68 kJ into internal energy  
 23. (a) 2.50 m/s (b) 37.5 kJ (c) Each process is the time-reversal of the other. The same momentum conservation equation describes both.  
 25. (a) 0.284 (b) 115 fJ and 45.4 fJ  
 27. 91.2 m/s  
 29. (a) 2.88 m/s at  $32.3^\circ$  north of east (b) 783 J into internal energy  
 31. No; his speed was 41.5 mi/h.  
 33. 2.50 m/s at  $-60.0^\circ$   
 35.  $(3.00\mathbf{i} - 1.20\mathbf{j})$  m/s  
 37. Orange:  $v_i \cos \theta$ ; yellow:  $v_i \sin \theta$   
 39. (a)  $(-9.33\mathbf{i} - 8.33\mathbf{j})$  Mm/s (b) 439 fJ  
 41.  $\mathbf{r}_{CM} = (11.7\mathbf{i} + 13.3\mathbf{j})$  cm  
 43. 0.006 73 nm from the oxygen nucleus along the bisector of the angle  
 45. (a) 15.9 g (b) 0.153 m  
 47. 0.700 m  
 49. (a)  $(1.40\mathbf{i} + 2.40\mathbf{j})$  m/s (b)  $(7.00\mathbf{i} + 12.0\mathbf{j})$  kg·m/s  
 51. (a) 39.0 MN up (b)  $3.20$  m/s<sup>2</sup> up  
 53. (a) 442 metric tons (b) 19.2 metric tons  
 55. (a)  $(1.33\mathbf{i})$  m/s (b)  $(-235\mathbf{i})$  N (c) 0.680 s  
 (d)  $(-160\mathbf{i})$  N·s and  $(+160\mathbf{i})$  N·s (e) 1.81 m  
 (f) 0.454 m (g)  $-427$  J (h)  $+107$  J  
 (i) Equal friction forces act through different distances on person and cart to do different amounts of work on them. The total work on both together,  $-320$  J, becomes  $+320$  J of internal energy in this perfectly inelastic collision.  
 57. 1.39 km/s  
 59. 240 s  
 61. 0.980 m  
 63. (a) 6.81 m/s (b) 1.00 m  
 65.  $(3Mgx/L)\mathbf{j}$

67. (a)  $3.75$  kg·m/s<sup>2</sup> (b) 3.75 N (c) 3.75 N (d) 2.81 J  
 (e) 1.41 J (f) Friction between sand and belt converts half of the input work into internal energy.  
 69. (a) As the child walks to the right, the boat moves to the left and the center of mass remains fixed. (b) 5.55 m from the pier (c) No, since 6.55 m is less than 7.00 m.  
 71. (a) 100 m/s (b) 374 J  
 73. (a)  $\sqrt{2} v_i$  for  $m$  and  $\sqrt{2/3} v_i$  for  $3m$  (b)  $35.3^\circ$   
 75. (a) 3.73 km/s (b) 153 km

### Chapter 10

1. (a) 4.00 rad/s<sup>2</sup> (b) 18.0 rad  
 3. (a) 1 200 rad/s (b) 25.0 s  
 5. (a) 5.24 s (b) 27.4 rad

### Chapter 11

1. (a) 500 J (b) 250 J (c) 750 J  
 3.  $\frac{7}{10}Mv^2$   
 5. (a)  $\frac{2}{3}g \sin \theta$  for the disk, larger than  $\frac{1}{2}g \sin \theta$  for the hoop  
 (b)  $\frac{1}{3} \tan \theta$   
 7.  $1.21 \times 10^{-4} \text{ kg} \cdot \text{m}^2$ . The height is unnecessary.  
 9.  $-7.00\mathbf{i} + 16.0\mathbf{j} - 10.0\mathbf{k}$   
 11. (a)  $-17.0\mathbf{k}$  (b)  $70.5^\circ$   
 13. (a) 2.00 N·m (b)  $\mathbf{k}$   
 15. (a) negative z direction (b) positive z direction  
 17.  $45.0^\circ$   
 19.  $(17.5\mathbf{k}) \text{ kg} \cdot \text{m}^2/\text{s}$   
 21.  $(60.0\mathbf{k}) \text{ kg} \cdot \text{m}^2/\text{s}$   
 23.  $mvR[\cos(vt/R) + 1]\mathbf{k}$   
 25. (a) zero (b)  $(-mv_i^3 \sin^2 \theta \cos \theta/2g)\mathbf{k}$   
 (c)  $(-2mv_i^3 \sin^2 \theta \cos \theta/g)\mathbf{k}$  (d) The downward force of gravity exerts a torque in the  $-z$  direction.  
 27.  $-m\ell g t \cos \theta \mathbf{k}$   
 29. 4.50 kg·m<sup>2</sup>/s up  
 31. (a) 0.433 kg·m<sup>2</sup>/s (b) 1.73 kg·m<sup>2</sup>/s  
 33. (a)  $\omega_f = \omega_i I_1 / (I_1 + I_2)$  (b)  $I_1 / (I_1 + I_2)$   
 35. (a) 1.91 rad/s (b) 2.53 J, 6.44 J  
 37. (a) 0.360 rad/s counterclockwise (b) 99.9 J  
 39. (a)  $mv\ell$  down (b)  $M/(M + m)$   
 41. (a)  $\omega = 2mv_i d / (M + 2m)R^2$  (b) No; some mechanical energy changes into internal energy.  
 43. (a)  $2.19 \times 10^6 \text{ m/s}$  (b)  $2.18 \times 10^{-18} \text{ J}$   
 (c)  $4.13 \times 10^{16} \text{ rad/s}$   
 45.  $[10Rg(1 - \cos \theta)/7r^2]^{1/2}$   
 51. (a) 2.70R (b)  $F_x = -\frac{20}{7}mg$ ,  $F_y = -mg$   
 53. 0.632  
 55. (a)  $v_i r_i / r$  (b)  $T = (mv_i^2 r_i^2) r^{-3}$  (c)  $\frac{1}{2}mv_i^2(r_i^2/r^2 - 1)$   
 (d) 4.50 m/s, 10.1 N, 0.450 J  
 57.  $54.0^\circ$   
 59. (a) 3 750 kg·m<sup>2</sup>/s (b) 1.88 kJ (c) 3 750 kg·m<sup>2</sup>/s  
 (d) 10.0 m/s (e) 7.50 kJ (f) 5.62 kJ  
 61.  $(M/m)[3ga(\sqrt{2} - 1)]^{1/2}$   
 63. (c)  $(8Fd/3M)^{1/2}$

67. (a) 0.800 m/s<sup>2</sup>, 0.400 m/s<sup>2</sup> (b) 0.600 N backward on the plank and forward on the roller, at the top of each roller; 0.200 N forward on each roller and backward on the floor, at the bottom of each roller.

### Chapter 12

1. 10.0 N up; 6.00 N·m counterclockwise  
 3.  $[(m_1 + m_b)d + m_1\ell/2]/m_2$   
 5.  $-0.429 \text{ m}$   
 7. (3.85 cm, 6.85 cm)  
 9.  $(-1.50 \text{ m}, -1.50 \text{ m})$   
 11. (a) 859 N (b) 1 040 N left and upward at  $36.9^\circ$   
 13. (a)  $f_s = 268 \text{ N}$ ,  $n = 1 300 \text{ N}$  (b) 0.324  
 15. (a) 1.04 kN at  $60.0^\circ$  (b)  $(370\mathbf{i} + 900\mathbf{j}) \text{ N}$   
 17. 2.94 kN on each rear wheel and 4.41 kN on each front wheel  
 19. (a) 29.9 N (b) 22.2 N  
 21. (a) 35.5 kN (b) 11.5 kN (c)  $-4.19 \text{ kN}$   
 23. 88.2 N and 58.8 N  
 25. 4.90 mm  
 27. 0.023 8 mm  
 29. 0.912 mm  
 31.  $\frac{8m_1 m_2 g L_i}{\pi d^2 Y (m_1 + m_2)}$   
 33. (a)  $3.14 \times 10^4 \text{ N}$  (b)  $6.28 \times 10^4 \text{ N}$   
 35.  $1.80 \times 10^8 \text{ N/m}^2$   
 37.  $n_A = 5.98 \times 10^5 \text{ N}$ ,  $n_B = 4.80 \times 10^5 \text{ N}$   
 39. (a) 0.400 mm (b) 40.0 kN (c) 2.00 mm (d) 2.40 mm  
 (e) 48.0 kN  
 41. (a)

- (b) 69.8 N (c) 0.877L  
 43. (a) 160 N right (b) 13.2 N right (c) 292 N up  
 (d) 192 N  
 45. (a)  $T = F_g(L + d)/\sin \theta(2L + d)$   
 (b)  $R_x = F_g(L + d)\cot \theta/(2L + d)$ ;  $R_y = F_g L/(2L + d)$   
 47. 0.789 L  
 49. 5.08 kN,  $R_x = 4.77 \text{ kN}$ ,  $R_y = 8.26 \text{ kN}$   
 51.  $T = 2.71 \text{ kN}$ ,  $R_x = 2.65 \text{ kN}$   
 53. (a)  $\mu_k = 0.571$ ; the normal force acts 20.1 cm to the left of the front edge of the sliding cabinet. (b) 0.501 m

55. (b)  $60.0^\circ$   
 57. (a)  $M = (m/2)(2\mu_s \sin \theta - \cos \theta)(\cos \theta - \mu_s \sin \theta)^{-1}$   
 (b)  $R = (m + M)g(1 + \mu_s^2)^{1/2}$ ,  
 $F = g[M^2 + \mu_s^2(m + M)^2]^{1/2}$   
 59. (a) 133 N (b)  $n_A = 429$  N and  $n_B = 257$  N  
 (c)  $R_x = 133$  N and  $R_y = -257$  N  
 61. 66.7 N  
 65. 1.09 m  
 67. (a) 4 500 N (b)  $4.50 \times 10^6$  N/m<sup>2</sup> (c) yes.  
 69. (a)  $P_y = (F_g/L)(d - ah/g)$  (b) 0.306 m  
 (c)  $\mathbf{P} = (-306\mathbf{i} + 553\mathbf{j})$  N  
 71.  $n_A = n_E = 6.66$  kN;  $F_{AB} = 10.4$  kN =  $F_{BC} = F_{DC} = F_{DE}$ ;  
 $F_{AC} = 7.94$  kN =  $F_{CE}$ ;  $F_{BD} = 15.9$  kN

**Chapter 13**

1. (a) 1.50 Hz, 0.667 s (b) 4.00 m (c)  $\pi$  rad (d) 2.83 m  
 3. (a) 20.0 cm (b) 94.2 cm/s as the particle passes through equilibrium (c) 17.8 m/s<sup>2</sup> at the maximum displacement from equilibrium  
 5. (b) 18.8 cm/s, 0.333 s (c) 178 cm/s<sup>2</sup>, 0.500 s (d) 12.0 cm

(b)  $y = (8.00 \text{ cm}) \sin(7.85x + 6\pi t - 0.785)$
- 33. (a) 0.500 Hz, 3.14 rad/s (b) 3.14 rad/m  
(c)  $(0.100 \text{ m}) \sin(3.14x/\text{m} - 3.14t/\text{s})$

Chapter 16, Problem 23(a)

- (d)  $(0.100 \text{ m}) \sin(-3.14t/s)$   
 (e)  $(0.100 \text{ m}) \sin(4.71 \text{ rad} - 3.14t/s)$  (f)  $0.314 \text{ m/s}$
35. 2.00 cm, 2.98 m, 0.576 Hz, 1.72 m/s  
 37. (b) 3.18 Hz  
 41. 55.1 Hz  
 43. (a) 62.5 m/s (b) 7.85 m (c) 7.96 Hz (d) 21.1 W  
 45. (a)  $A = 40.0$  (b)  $A = 7.00$ ,  $B = 0$ ,  $C = 3.00$ . One can take the dot product of the given equation with each one of  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$ . (c) By inspection,  $A = 0$ ,  $B = 7.00 \text{ mm}$ ,  $C = 3.00/\text{m}$ ,  $D = 4.00/\text{s}$ ,  $E = 2.00$ . Consider the average value of both sides of the given equation to find  $A$ . Then consider the maximum value of both sides to find  $B$ . You can evaluate the partial derivative of both sides of the given equation with respect to  $x$  and separately with respect to  $t$  to obtain equations yielding  $C$  and  $D$  upon chosen substitutions for  $x$  and  $t$ . Then substitute  $x = 0$  and  $t = 0$  to obtain  $E$ .

<sup>a</sup> The masses in the sixth column are atomic masses, which include the mass of Z electrons. Data are from the National Nuclear Data Center, Brookhaven National Laboratory, prepared by Jagdish K. Tuli, July 1990. The data are based on experimental results reported in *Nuclear Data Sheets* and *Nuclear Physics* and also from *Chart of the Nuclides*, 14th ed. Atomic masses are based on those by A. H. Wapstra, G. Audi, and R. Hoekstra. Isotopic abundances are based on those by N. E. Holden.

## APPENDIX B • Mathematics Review

These appendices in mathematics are intended as a brief review of operations and methods. Early in this course, you should be totally familiar with basic algebraic techniques, analytic geometry, and trigonometry. The appendices on differential and integral calculus are more detailed and are intended for those students who have difficulty applying calculus concepts to physical situations.

### **B.1** SCIENTIFIC NOTATION

Many quantities that scientists deal with often have very large or very small values. For example, the speed of light is about 300 000 000 m/s, and the ink required to make the dot over an *i* in this textbook has a mass of about 0.000 000 001 kg. Obviously, it is very cumbersome to read, write, and keep track of numbers such as these. We avoid this problem by using a method dealing with powers of the number 10:

$$10^0 = 1$$

$$10^1 = 10$$

$$10^2 = 10 \times 10 = 100$$

$$10^3 = 10 \times 10 \times 10 = 1000$$

$$10^4 = 10 \times 10 \times 10 \times 10 = 10\,000$$

$$10^5 = 10 \times 10 \times 10 \times 10 \times 10 = 100\,000$$

and so on. The number of zeros corresponds to the power to which 10 is raised, called the **exponent** of 10. For example, the speed of light, 300 000 000 m/s, can be expressed as  $3 \times 10^8$  m/s.

In this method, some representative numbers smaller than unity are

$$10^{-1} = \frac{1}{10} = 0.1$$

$$10^{-2} = \frac{1}{10 \times 10} = 0.01$$

$$10^{-3} = \frac{1}{10 \times 10 \times 10} = 0.001$$

$$10^{-4} = \frac{1}{10 \times 10 \times 10 \times 10} = 0.000\,1$$

$$10^{-5} = \frac{1}{10 \times 10 \times 10 \times 10 \times 10} = 0.000\,01$$

In these cases, the number of places the decimal point is to the left of the digit 1 equals the value of the (negative) exponent. Numbers expressed as some power of 10 multiplied by another number between 1 and 10 are said to be in **scientific notation**. For example, the scientific notation for 5 943 000 000 is  $5.943 \times 10^9$  and that for 0.000 083 2 is  $8.32 \times 10^{-5}$ .

When numbers expressed in scientific notation are being multiplied, the following general rule is very useful:

$$10^n \times 10^m = 10^{n+m} \quad (\text{B.1})$$

where  $n$  and  $m$  can be *any* numbers (not necessarily integers). For example,  $10^2 \times 10^5 = 10^7$ . The rule also applies if one of the exponents is negative:  $10^3 \times 10^{-8} = 10^{-5}$ .

When dividing numbers expressed in scientific notation, note that

$$\frac{10^n}{10^m} = 10^n \times 10^{-m} = 10^{n-m} \quad (\text{B.2})$$

## EXERCISES

With help from the above rules, verify the answers to the following:

1.  $86\,400 = 8.64 \times 10^4$
2.  $9\,816\,762.5 = 9.816\,762\,5 \times 10^6$
3.  $0.000\,000\,039\,8 = 3.98 \times 10^{-8}$
4.  $(4 \times 10^8)(9 \times 10^9) = 3.6 \times 10^{18}$
5.  $(3 \times 10^7)(6 \times 10^{-12}) = 1.8 \times 10^{-4}$
6.  $\frac{75 \times 10^{-11}}{5 \times 10^{-3}} = 1.5 \times 10^{-7}$
7.  $\frac{(3 \times 10^6)(8 \times 10^{-2})}{(2 \times 10^{17})(6 \times 10^5)} = 2 \times 10^{-18}$

## B.2 ALGEBRA

### Some Basic Rules

When algebraic operations are performed, the laws of arithmetic apply. Symbols such as  $x$ ,  $y$ , and  $z$  are usually used to represent quantities that are not specified, what are called the **unknowns**.

First, consider the equation

$$8x = 32$$

If we wish to solve for  $x$ , we can divide (or multiply) each side of the equation by the same factor without destroying the equality. In this case, if we divide both sides by 8, we have

$$\frac{8x}{8} = \frac{32}{8}$$

$$x = 4$$

Next consider the equation

$$x + 2 = 8$$

In this type of expression, we can add or subtract the same quantity from each side. If we subtract 2 from each side, we get

$$\begin{aligned} x + 2 - 2 &= 8 - 2 \\ x &= 6 \end{aligned}$$

In general, if  $x + a = b$ , then  $x = b - a$ .

Now consider the equation

$$\frac{x}{5} = 9$$

If we multiply each side by 5, we are left with  $x$  on the left by itself and 45 on the right:

$$\begin{aligned} \left(\frac{x}{5}\right)(5) &= 9 \times 5 \\ x &= 45 \end{aligned}$$

In all cases, *whatever operation is performed on the left side of the equality must also be performed on the right side.*

The following rules for multiplying, dividing, adding, and subtracting fractions should be recalled, where  $a$ ,  $b$ , and  $c$  are three numbers:

	Rule	Example
<b>Multiplying</b>	$\left(\frac{a}{b}\right)\left(\frac{c}{d}\right) = \frac{ac}{bd}$	$\left(\frac{2}{3}\right)\left(\frac{4}{5}\right) = \frac{8}{15}$
<b>Dividing</b>	$\frac{(a/b)}{(c/d)} = \frac{ad}{bc}$	$\frac{2/3}{4/5} = \frac{(2)(5)}{(4)(3)} = \frac{10}{12}$
<b>Adding</b>	$\frac{a}{b} \pm \frac{c}{d} = \frac{ad \pm bc}{bd}$	$\frac{2}{3} - \frac{4}{5} = \frac{(2)(5) - (4)(3)}{(3)(5)} = -\frac{2}{15}$

## EXERCISES

In the following exercises, solve for  $x$ :

### Answers

- $a = \frac{1}{1+x}$        $x = \frac{1-a}{a}$
- $3x - 5 = 13$        $x = 6$
- $ax - 5 = bx + 2$        $x = \frac{7}{a-b}$
- $\frac{5}{2x+6} = \frac{3}{4x+8}$        $x = -\frac{11}{7}$

## Powers

When powers of a given quantity  $x$  are multiplied, the following rule applies:

$$x^n x^m = x^{n+m} \quad \text{(B.3)}$$

For example,  $x^2x^4 = x^{2+4} = x^6$ .

When dividing the powers of a given quantity, the rule is

$$\frac{x^n}{x^m} = x^{n-m} \quad (\text{B.4})$$

For example,  $x^8/x^2 = x^{8-2} = x^6$ .

A power that is a fraction, such as  $\frac{1}{3}$ , corresponds to a root as follows:

$$x^{1/n} = \sqrt[n]{x} \quad (\text{B.5})$$

For example,  $4^{1/3} = \sqrt[3]{4} = 1.5874$ . (A scientific calculator is useful for such calculations.)

Finally, any quantity  $x^n$  raised to the  $m$ th power is

$$(x^n)^m = x^{nm} \quad (\text{B.6})$$

Table B.1 summarizes the rules of exponents.

**TABLE B.1**  
Rules of Exponents

$$\begin{aligned} x^0 &= 1 \\ x^1 &= x \\ x^n x^m &= x^{n+m} \\ x^n / x^m &= x^{n-m} \\ x^{1/n} &= \sqrt[n]{x} \\ (x^n)^m &= x^{nm} \end{aligned}$$

## EXERCISES

Verify the following:

- $3^2 \times 3^3 = 243$
- $x^5 x^{-8} = x^{-3}$
- $x^{10} / x^{-5} = x^{15}$
- $5^{1/3} = 1.709\ 975$  (Use your calculator.)
- $60^{1/4} = 2.783\ 158$  (Use your calculator.)
- $(x^4)^3 = x^{12}$

## Factoring

Some useful formulas for factoring an equation are

$$\begin{aligned} ax + ay + az &= a(x + y + z) && \text{common factor} \\ a^2 + 2ab + b^2 &= (a + b)^2 && \text{perfect square} \\ a^2 - b^2 &= (a + b)(a - b) && \text{differences of squares} \end{aligned}$$

## Quadratic Equations

The general form of a quadratic equation is

$$ax^2 + bx + c = 0 \quad (\text{B.7})$$

where  $x$  is the unknown quantity and  $a$ ,  $b$ , and  $c$  are numerical factors referred to as **coefficients** of the equation. This equation has two roots, given by

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad (\text{B.8})$$

If  $b^2 \geq 4ac$ , the roots are real.

**EXAMPLE 1**

The equation  $x^2 + 5x + 4 = 0$  has the following roots corresponding to the two signs of the square-root term:

$$x = \frac{-5 \pm \sqrt{5^2 - (4)(1)(4)}}{2(1)} = \frac{-5 \pm \sqrt{9}}{2} = \frac{-5 \pm 3}{2}$$

$$x_+ = \frac{-5 + 3}{2} = -1 \quad x_- = \frac{-5 - 3}{2} = -4$$

where  $x_+$  refers to the root corresponding to the positive sign and  $x_-$  refers to the root corresponding to the negative sign.

**EXERCISES**

Solve the following quadratic equations:

**Answers**

1.  $x^2 + 2x - 3 = 0$       $x_+ = 1$       $x_- = -3$
2.  $2x^2 - 5x + 2 = 0$       $x_+ = 2$       $x_- = \frac{1}{2}$
3.  $2x^2 - 4x - 9 = 0$       $x_+ = 1 + \sqrt{22}/2$       $x_- = 1 - \sqrt{22}/2$

**Linear Equations**

A linear equation has the general form

$$y = mx + b \tag{B.9}$$

where  $m$  and  $b$  are constants. This equation is referred to as being linear because the graph of  $y$  versus  $x$  is a straight line, as shown in Figure B.1. The constant  $b$ , called the **y-intercept**, represents the value of  $y$  at which the straight line intersects the  $y$  axis. The constant  $m$  is equal to the **slope** of the straight line and is also equal to the tangent of the angle that the line makes with the  $x$  axis. If any two points on the straight line are specified by the coordinates  $(x_1, y_1)$  and  $(x_2, y_2)$ , as in Figure B.1, then the slope of the straight line can be expressed as

$$\text{Slope} = \frac{y_2 - y_1}{x_2 - x_1} = \frac{\Delta y}{\Delta x} = \tan \theta \tag{B.10}$$

Note that  $m$  and  $b$  can have either positive or negative values. If  $m > 0$ , the straight line has a *positive* slope, as in Figure B.1. If  $m < 0$ , the straight line has a *negative* slope. In Figure B.1, both  $m$  and  $b$  are positive. Three other possible situations are shown in Figure B.2.

Figure B.1

Figure B.2

**EXERCISES**

1. Draw graphs of the following straight lines:
  - (a)  $y = 5x + 3$
  - (b)  $y = -2x + 4$
  - (c)  $y = -3x - 6$
2. Find the slopes of the straight lines described in Exercise 1.

**Answers** (a) 5 (b) -2 (c) -3

3. Find the slopes of the straight lines that pass through the following sets of points:

(a)  $(0, -4)$  and  $(4, 2)$ , (b)  $(0, 0)$  and  $(2, -5)$ , and (c)  $(-5, 2)$  and  $(4, -2)$

**Answers** (a)  $3/2$  (b)  $-5/2$  (c)  $-4/9$

### Solving Simultaneous Linear Equations

Consider the equation  $3x + 5y = 15$ , which has two unknowns,  $x$  and  $y$ . Such an equation does not have a unique solution. For example, note that  $(x = 0, y = 3)$ ,  $(x = 5, y = 0)$ , and  $(x = 2, y = 9/5)$  are all solutions to this equation.

If a problem has two unknowns, a unique solution is possible only if we have *two* equations. In general, if a problem has  $n$  unknowns, its solution requires  $n$  equations. In order to solve two simultaneous equations involving two unknowns,  $x$  and  $y$ , we solve one of the equations for  $x$  in terms of  $y$  and substitute this expression into the other equation.

#### EXAMPLE 2

Solve the following two simultaneous equations:

$$(1) \quad 5x + y = -8$$

$$(2) \quad 2x - 2y = 4$$

**Solution** From (2),  $x = y + 2$ . Substitution of this into (1) gives

$$5(y + 2) + y = -8$$

$$6y = -18$$

$$y = -3$$

$$x = y + 2 = -1$$

**Alternate Solution** Multiply each term in (1) by the factor 2 and add the result to (2):

$$10x + 2y = -16$$

$$\underline{2x - 2y = 4}$$

$$12x = -12$$

$$x = -1$$

$$y = x - 2 = -3$$

Figure B.3

Two linear equations containing two unknowns can also be solved by a graphical method. If the straight lines corresponding to the two equations are plotted in a conventional coordinate system, the intersection of the two lines represents the solution. For example, consider the two equations

$$x - y = 2$$

$$x - 2y = -1$$

These are plotted in Figure B.3. The intersection of the two lines has the coordinates  $x = 5, y = 3$ . This represents the solution to the equations. You should check this solution by the analytical technique discussed above.

### EXERCISES

Solve the following pairs of simultaneous equations involving two unknowns:

#### Answers

1.  $x + y = 8$        $x = 5, y = 3$   
 $x - y = 2$

$$\begin{aligned}
 2. \quad 98 - T &= 10a & T &= 65, a = 3.27 \\
 & T - 49 &= 5a \\
 3. \quad 6x + 2y &= 6 & x &= 2, y = -3 \\
 & 8x - 4y &= 28
 \end{aligned}$$

## Logarithms

Suppose that a quantity  $x$  is expressed as a power of some quantity  $a$ :

$$x = a^y \quad (\text{B.11})$$

The number  $a$  is called the **base** number. The **logarithm** of  $x$  with respect to the base  $a$  is equal to the exponent to which the base must be raised in order to satisfy the expression  $x = a^y$ :

$$y = \log_a x \quad (\text{B.12})$$

Conversely, the **antilogarithm** of  $y$  is the number  $x$ :

$$x = \text{antilog}_a y \quad (\text{B.13})$$

In practice, the two bases most often used are base 10, called the *common* logarithm base, and base  $e = 2.718 \dots$ , called Euler's constant or the *natural* logarithm base. When common logarithms are used,

$$y = \log_{10} x \quad (\text{or } x = 10^y) \quad (\text{B.14})$$

When natural logarithms are used,

$$y = \ln_e x \quad (\text{or } x = e^y) \quad (\text{B.15})$$

For example,  $\log_{10} 52 = 1.716$ , so that  $\text{antilog}_{10} 1.716 = 10^{1.716} = 52$ . Likewise,  $\ln_e 52 = 3.951$ , so  $\text{antiln}_e 3.951 = e^{3.951} = 52$ .

In general, note that you can convert between base 10 and base  $e$  with the equality

$$\ln_e x = (2.302\,585) \log_{10} x \quad (\text{B.16})$$

Finally, some useful properties of logarithms are

$$\begin{aligned}
 \log(ab) &= \log a + \log b \\
 \log(a/b) &= \log a - \log b \\
 \log(a^n) &= n \log a \\
 \ln e &= 1 \\
 \ln e^a &= a \\
 \ln\left(\frac{1}{a}\right) &= -\ln a
 \end{aligned}$$

## B.3 GEOMETRY

The **distance**  $d$  between two points having coordinates  $(x_1, y_1)$  and  $(x_2, y_2)$  is

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (\text{B.17})$$

Figure B.4

**Radian measure:** The arc length  $s$  of a circular arc (Fig. B.4) is proportional to the radius  $r$  for a fixed value of  $\theta$  (in radians):

$$\begin{aligned} s &= r\theta \\ \theta &= \frac{s}{r} \end{aligned} \tag{B.18}$$

Table B.2 gives the areas and volumes for several geometric shapes used throughout this text:

**TABLE B.2 Useful Information for Geometry**

Shape	Area or Volume	Shape	Area or Volume
<p>Rectangle</p>	Area = $\ell w$	<p>Sphere</p>	Surface area = $4\pi r^2$ Volume = $\frac{4\pi r^3}{3}$
<p>Circle</p>	Area = $\pi r^2$ (Circumference = $2\pi r$ )	<p>Cylinder</p>	Lateral surface area = $2\pi r\ell$ Volume = $\pi r^2\ell$
<p>Triangle</p>	Area = $\frac{1}{2}bh$	<p>Rectangular box</p>	Area = $2(\ell h + \ell w + hw)$ Volume = $\ell wh$

Figure B.5

The equation of a **straight line** (Fig. B.5) is

$$y = mx + b \tag{B.19}$$

where  $b$  is the  $y$ -intercept and  $m$  is the slope of the line.

The equation of a **circle** of radius  $R$  centered at the origin is

$$x^2 + y^2 = R^2 \tag{B.20}$$

The equation of an **ellipse** having the origin at its center (Fig. B.6) is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \tag{B.21}$$

Figure B.6

where  $a$  is the length of the semi-major axis (the longer one) and  $b$  is the length of the semi-minor axis (the shorter one).

The equation of a **parabola** the vertex of which is at  $y = b$  (Fig. B.7) is

$$y = ax^2 + b \tag{B.22}$$

The equation of a **rectangular hyperbola** (Fig. B.8) is

$$xy = \text{constant} \tag{B.23}$$

Figure B.7

## B.4 TRIGONOMETRY

That portion of mathematics based on the special properties of the right triangle is called trigonometry. By definition, a right triangle is one containing a  $90^\circ$  angle. Consider the right triangle shown in Figure B.9, where side  $a$  is opposite the angle  $\theta$ , side  $b$  is adjacent to the angle  $\theta$ , and side  $c$  is the hypotenuse of the triangle. The three basic trigonometric functions defined by such a triangle are the sine (sin), cosine (cos), and tangent (tan) functions. In terms of the angle  $\theta$ , these functions are defined by

$$\sin \theta \equiv \frac{\text{side opposite } \theta}{\text{hypotenuse}} = \frac{a}{c} \tag{B.24}$$

$$\cos \theta \equiv \frac{\text{side adjacent to } \theta}{\text{hypotenuse}} = \frac{b}{c} \tag{B.25}$$

$$\tan \theta \equiv \frac{\text{side opposite } \theta}{\text{side adjacent to } \theta} = \frac{a}{b} \tag{B.26}$$

The Pythagorean theorem provides the following relationship between the sides of a right triangle:

$$c^2 = a^2 + b^2 \tag{B.27}$$

From the above definitions and the Pythagorean theorem, it follows that

$$\sin^2 \theta + \cos^2 \theta = 1$$

$$\tan \theta = \frac{\sin \theta}{\cos \theta}$$

The cosecant, secant, and cotangent functions are defined by

$$\csc \theta \equiv \frac{1}{\sin \theta} \quad \sec \theta \equiv \frac{1}{\cos \theta} \quad \cot \theta \equiv \frac{1}{\tan \theta}$$

The relationships below follow directly from the right triangle shown in Figure B.9:

$$\sin \theta = \cos(90^\circ - \theta)$$

$$\cos \theta = \sin(90^\circ - \theta)$$

$$\cot \theta = \tan(90^\circ - \theta)$$

Some properties of trigonometric functions are

$$\sin(-\theta) = -\sin \theta$$

$$\cos(-\theta) = \cos \theta$$

$$\tan(-\theta) = -\tan \theta$$

The following relationships apply to *any* triangle, as shown in Figure B.10:

$$\alpha + \beta + \gamma = 180^\circ$$

Figure B.8

$a$  = opposite side  
 $b$  = adjacent side  
 $c$  = hypotenuse

Figure B.9

Figure B.10

Law of cosines

$$a^2 = b^2 + c^2 - 2bc \cos \alpha$$

$$b^2 = a^2 + c^2 - 2ac \cos \beta$$

$$c^2 = a^2 + b^2 - 2ab \cos \gamma$$

Law of sines

$$\frac{a}{\sin \alpha} = \frac{b}{\sin \beta} = \frac{c}{\sin \gamma}$$

Table B.3 lists a number of useful trigonometric identities.

**TABLE B.3** Some Trigonometric Identities

$\sin^2 \theta + \cos^2 \theta = 1$	$\csc^2 \theta = 1 + \cot^2 \theta$
$\sec^2 \theta = 1 + \tan^2 \theta$	$\sin^2 \frac{\theta}{2} = \frac{1}{2}(1 - \cos \theta)$
$\sin 2\theta = 2 \sin \theta \cos \theta$	$\cos^2 \frac{\theta}{2} = \frac{1}{2}(1 + \cos \theta)$
$\cos 2\theta = \cos^2 \theta - \sin^2 \theta$	$1 - \cos \theta = 2 \sin^2 \frac{\theta}{2}$
$\tan 2\theta = \frac{2 \tan \theta}{1 - \tan^2 \theta}$	$\tan \frac{\theta}{2} = \sqrt{\frac{1 - \cos \theta}{1 + \cos \theta}}$
$\sin(A \pm B) = \sin A \cos B \pm \cos A \sin B$	
$\cos(A \pm B) = \cos A \cos B \mp \sin A \sin B$	

**EXAMPLE 3**

Consider the right triangle in Figure B.11, in which  $a = 2$ ,  $b = 5$ , and  $c$  is unknown. From the Pythagorean theorem, we have

$$c^2 = a^2 + b^2 = 2^2 + 5^2 = 4 + 25 = 29$$

$$c = \sqrt{29} = 5.39$$

To find the angle  $\theta$ , note that

$$\tan \theta = \frac{a}{b} = \frac{2}{5} = 0.400$$

From a table of functions or from a calculator, we have

$$\theta = \tan^{-1}(0.400) = 21.8^\circ$$

where  $\tan^{-1}(0.400)$  is the notation for “angle whose tangent is 0.400,” sometimes written as  $\arctan(0.400)$ .

Figure B.11

Figure B.12

**EXERCISES**

1. In Figure B.12, identify (a) the side opposite  $\theta$  and (b) the side adjacent to  $\phi$  and then find (c)  $\cos \theta$ , (d)  $\sin \phi$ , and (e)  $\tan \phi$ .

**Answers** (a) 3, (b) 3, (c)  $\frac{4}{5}$ , (d)  $\frac{4}{5}$ , and (e)  $\frac{4}{3}$

2. In a certain right triangle, the two sides that are perpendicular to each other are 5 m and 7 m long. What is the length of the third side?

**Answer** 8.60 m

3. A right triangle has a hypotenuse of length 3 m, and one of its angles is  $30^\circ$ . What is the length of (a) the side opposite the  $30^\circ$  angle and (b) the side adjacent to the  $30^\circ$  angle?

**Answers** (a) 1.5 m, (b) 2.60 m

## B.5 SERIES EXPANSIONS

$$(a + b)^n = a^n + \frac{n}{1!} a^{n-1}b + \frac{n(n-1)}{2!} a^{n-2}b^2 + \dots$$

$$(1 + x)^n = 1 + nx + \frac{n(n-1)}{2!} x^2 + \dots$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$$

$$\ln(1 \pm x) = \pm x - \frac{1}{2}x^2 \pm \frac{1}{3}x^3 - \dots$$

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \dots$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \dots$$

$$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \dots \quad |x| < \pi/2$$

}  $x$  in radians

For  $x \ll 1$ , the following approximations can be used<sup>1</sup>:

$$(1 + x)^n \approx 1 + nx \quad \sin x \approx x$$

$$e^x \approx 1 + x \quad \cos x \approx 1$$

$$\ln(1 \pm x) \approx \pm x \quad \tan x \approx x$$

## B.6 DIFFERENTIAL CALCULUS

In various branches of science, it is sometimes necessary to use the basic tools of calculus, invented by Newton, to describe physical phenomena. The use of calculus is fundamental in the treatment of various problems in Newtonian mechanics, electricity, and magnetism. In this section, we simply state some basic properties and “rules of thumb” that should be a useful review to the student.

First, a **function** must be specified that relates one variable to another (such as a coordinate as a function of time). Suppose one of the variables is called  $y$  (the dependent variable), the other  $x$  (the independent variable). We might have a function relationship such as

$$y(x) = ax^3 + bx^2 + cx + d$$

If  $a$ ,  $b$ ,  $c$ , and  $d$  are specified constants, then  $y$  can be calculated for any value of  $x$ . We usually deal with continuous functions, that is, those for which  $y$  varies “smoothly” with  $x$ .

<sup>1</sup>The approximations for the functions  $\sin x$ ,  $\cos x$ , and  $\tan x$  are for  $x \leq 0.1$  rad.

Figure B.13

The **derivative** of  $y$  with respect to  $x$  is defined as the limit, as  $\Delta x$  approaches zero, of the slopes of chords drawn between two points on the  $y$  versus  $x$  curve. Mathematically, we write this definition as

$$\frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{y(x + \Delta x) - y(x)}{\Delta x} \quad (\text{B.28})$$

where  $\Delta y$  and  $\Delta x$  are defined as  $\Delta x = x_2 - x_1$  and  $\Delta y = y_2 - y_1$  (Fig. B.13). It is important to note that  $dy/dx$  does not mean  $dy$  divided by  $dx$ , but is simply a notation of the limiting process of the derivative as defined by Equation B.28.

A useful expression to remember when  $y(x) = ax^n$ , where  $a$  is a constant and  $n$  is any positive or negative number (integer or fraction), is

$$\frac{dy}{dx} = nax^{n-1} \quad (\text{B.29})$$

If  $y(x)$  is a polynomial or algebraic function of  $x$ , we apply Equation B.29 to each term in the polynomial and take  $d[\text{constant}]/dx = 0$ . In Examples 4 through 7, we evaluate the derivatives of several functions.

**EXAMPLE 4**

Suppose  $y(x)$  (that is,  $y$  as a function of  $x$ ) is given by

$$y(x) = ax^3 + bx + c$$

where  $a$  and  $b$  are constants. Then it follows that

$$\begin{aligned} y(x + \Delta x) &= a(x + \Delta x)^3 \\ &\quad + b(x + \Delta x) + c \\ y(x + \Delta x) &= a(x^3 + 3x^2\Delta x + 3x\Delta x^2 + \Delta x^3) \\ &\quad + b(x + \Delta x) + c \end{aligned}$$

so

$$\begin{aligned} \Delta y = y(x + \Delta x) - y(x) &= a(3x^2\Delta x + 3x\Delta x^2 + \Delta x^3) \\ &\quad + b\Delta x \end{aligned}$$

Substituting this into Equation B.28 gives

$$\begin{aligned} \frac{dy}{dx} &= \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \rightarrow 0} [3ax^2 + 3x\Delta x + \Delta x^2] + b \\ \frac{dy}{dx} &= 3ax^2 + b \end{aligned}$$

**EXAMPLE 5**

$$y(x) = 8x^5 + 4x^3 + 2x + 7$$

$$\frac{dy}{dx} = 40x^4 + 12x^2 + 2$$

**Solution** Applying Equation B.29 to each term independently, and remembering that  $d/dx(\text{constant}) = 0$ , we have

$$\frac{dy}{dx} = 8(5)x^4 + 4(3)x^2 + 2(1)x^0 + 0$$

**Special Properties of the Derivative**

**A. Derivative of the product of two functions** If a function  $f(x)$  is given by the product of two functions, say,  $g(x)$  and  $h(x)$ , then the derivative of  $f(x)$  is defined as

$$\frac{d}{dx} f(x) = \frac{d}{dx} [g(x)h(x)] = g \frac{dh}{dx} + h \frac{dg}{dx} \quad (\text{B.30})$$

**B. Derivative of the sum of two functions** If a function  $f(x)$  is equal to the sum of two functions, then the derivative of the sum is equal to the sum of the derivatives:

$$\frac{d}{dx} f(x) = \frac{d}{dx} [g(x) + h(x)] = \frac{dg}{dx} + \frac{dh}{dx} \quad (\text{B.31})$$

**C. Chain rule of differential calculus** If  $y = f(x)$  and  $x = g(z)$ , then  $dy/dz$  can be written as the product of two derivatives:

$$\frac{dy}{dz} = \frac{dy}{dx} \frac{dx}{dz} \quad (\text{B.32})$$

**D. The second derivative** The second derivative of  $y$  with respect to  $x$  is defined as the derivative of the function  $dy/dx$  (the derivative of the derivative). It is usually written

$$\frac{d^2y}{dx^2} = \frac{d}{dx} \left( \frac{dy}{dx} \right) \quad (\text{B.33})$$

### EXAMPLE 6

Find the derivative of  $y(x) = x^3/(x+1)^2$  with respect to  $x$ .

**Solution** We can rewrite this function as  $y(x) = x^3(x+1)^{-2}$  and apply Equation B.30:

$$\frac{dy}{dx} = (x+1)^{-2} \frac{d}{dx} (x^3) + x^3 \frac{d}{dx} (x+1)^{-2}$$

$$= (x+1)^{-2} 3x^2 + x^3(-2)(x+1)^{-3}$$

$$\frac{dy}{dx} = \frac{3x^2}{(x+1)^2} - \frac{2x^3}{(x+1)^3}$$

### EXAMPLE 7

A useful formula that follows from Equation B.30 is the derivative of the quotient of two functions. Show that

$$\frac{d}{dx} \left[ \frac{g(x)}{h(x)} \right] = \frac{h \frac{dg}{dx} - g \frac{dh}{dx}}{h^2}$$

**Solution** We can write the quotient as  $gh^{-1}$  and then apply Equations B.29 and B.30:

$$\frac{d}{dx} \left( \frac{g}{h} \right) = \frac{d}{dx} (gh^{-1}) = g \frac{d}{dx} (h^{-1}) + h^{-1} \frac{d}{dx} (g)$$

$$= -gh^{-2} \frac{dh}{dx} + h^{-1} \frac{dg}{dx}$$

$$= \frac{h \frac{dg}{dx} - g \frac{dh}{dx}}{h^2}$$

Some of the more commonly used derivatives of functions are listed in Table B.4.

## B.7 INTEGRAL CALCULUS

We think of integration as the inverse of differentiation. As an example, consider the expression

$$f(x) = \frac{dy}{dx} = 3ax^2 + b \quad (\text{B.34})$$

which was the result of differentiating the function

$$y(x) = ax^3 + bx + c$$

**TABLE B.4**  
**Derivatives for Several Functions**

$$\frac{d}{dx} (a) = 0$$

$$\frac{d}{dx} (ax^n) = nax^{n-1}$$

$$\frac{d}{dx} (e^{ax}) = ae^{ax}$$

$$\frac{d}{dx} (\sin ax) = a \cos ax$$

$$\frac{d}{dx} (\cos ax) = -a \sin ax$$

$$\frac{d}{dx} (\tan ax) = a \sec^2 ax$$

$$\frac{d}{dx} (\cot ax) = -a \csc^2 ax$$

$$\frac{d}{dx} (\sec x) = \tan x \sec x$$

$$\frac{d}{dx} (\csc x) = -\cot x \csc x$$

$$\frac{d}{dx} (\ln ax) = \frac{1}{x}$$

Note: The letters  $a$  and  $n$  are constants.

in Example 4. We can write Equation B.34 as  $dy = f(x) dx = (3ax^2 + b) dx$  and obtain  $y(x)$  by “summing” over all values of  $x$ . Mathematically, we write this inverse operation

$$y(x) = \int f(x) dx$$

For the function  $f(x)$  given by Equation B.34, we have

$$y(x) = \int (3ax^2 + b) dx = ax^3 + bx + c$$

where  $c$  is a constant of the integration. This type of integral is called an *indefinite integral* because its value depends on the choice of  $c$ .

A general **indefinite integral**  $I(x)$  is defined as

$$I(x) = \int f(x) dx \tag{B.35}$$

where  $f(x)$  is called the *integrand* and  $f(x) = \frac{dI(x)}{dx}$ .

For a *general continuous function*  $f(x)$ , the integral can be described as the area under the curve bounded by  $f(x)$  and the  $x$  axis, between two specified values of  $x$ , say,  $x_1$  and  $x_2$ , as in Figure B.14.

The area of the blue element is approximately  $f(x_i)\Delta x_i$ . If we sum all these area elements from  $x_1$  and  $x_2$  and take the limit of this sum as  $\Delta x_i \rightarrow 0$ , we obtain the *true area* under the curve bounded by  $f(x)$  and  $x$ , between the limits  $x_1$  and  $x_2$ :

$$\text{Area} = \lim_{\Delta x_i \rightarrow 0} \sum_i f(x_i) \Delta x_i = \int_{x_1}^{x_2} f(x) dx \tag{B.36}$$

Integrals of the type defined by Equation B.36 are called **definite integrals**.

Figure B.14

One common integral that arises in practical situations has the form

$$\int x^n dx = \frac{x^{n+1}}{n+1} + c \quad (n \neq -1) \tag{B.37}$$

This result is obvious, being that differentiation of the right-hand side with respect to  $x$  gives  $f(x) = x^n$  directly. If the limits of the integration are known, this integral becomes a *definite integral* and is written

$$\int_{x_1}^{x_2} x^n dx = \frac{x_2^{n+1} - x_1^{n+1}}{n+1} \quad (n \neq -1) \tag{B.38}$$

**EXAMPLES**

1.  $\int_0^a x^2 dx = \frac{x^3}{3} \Big|_0^a = \frac{a^3}{3}$
2.  $\int_0^b x^{3/2} dx = \frac{x^{5/2}}{5/2} \Big|_0^b = \frac{2}{5} b^{5/2}$
3.  $\int_3^5 x dx = \frac{x^2}{2} \Big|_3^5 = \frac{5^2 - 3^2}{2} = 8$

**Partial Integration**

Sometimes it is useful to apply the method of *partial integration* (also called “integrating by parts”) to evaluate certain integrals. The method uses the property that

$$\int u dv = uv - \int v du \quad (\text{B.39})$$

where  $u$  and  $v$  are *carefully* chosen so as to reduce a complex integral to a simpler one. In many cases, several reductions have to be made. Consider the function

$$I(x) = \int x^2 e^x dx$$

This can be evaluated by integrating by parts twice. First, if we choose  $u = x^2$ ,  $v = e^x$ , we get

$$\int x^2 e^x dx = \int x^2 d(e^x) = x^2 e^x - 2 \int e^x x dx + c_1$$

Now, in the second term, choose  $u = x$ ,  $v = e^x$ , which gives

$$\int x^2 e^x dx = x^2 e^x - 2x e^x + 2 \int e^x dx + c_1$$

or

$$\int x^2 e^x dx = x^2 e^x - 2x e^x + 2e^x + c_2$$

**The Perfect Differential**

Another useful method to remember is the use of the *perfect differential*, in which we look for a change of variable such that the differential of the function is the differential of the independent variable appearing in the integrand. For example, consider the integral

$$I(x) = \int \cos^2 x \sin x dx$$

This becomes easy to evaluate if we rewrite the differential as  $d(\cos x) = -\sin x dx$ . The integral then becomes

$$\int \cos^2 x \sin x dx = -\int \cos^2 x d(\cos x)$$

If we now change variables, letting  $y = \cos x$ , we obtain

$$\int \cos^2 x \sin x dx = -\int y^2 dy = -\frac{y^3}{3} + c = -\frac{\cos^3 x}{3} + c$$

Table B.5 lists some useful indefinite integrals. Table B.6 gives Gauss's probability integral and other definite integrals. A more complete list can be found in various handbooks, such as *The Handbook of Chemistry and Physics*, CRC Press.

**TABLE B.5** Some Indefinite Integrals (An arbitrary constant should be added to each of these integrals.)

$\int x^n dx = \frac{x^{n+1}}{n+1}$ (provided $n \neq -1$ )	$\int \ln ax dx = (x \ln ax) - x$
$\int \frac{dx}{x} = \int x^{-1} dx = \ln x$	$\int xe^{ax} dx = \frac{e^{ax}}{a^2} (ax - 1)$
$\int \frac{dx}{a+bx} = \frac{1}{b} \ln(a+bx)$	$\int \frac{dx}{a+be^{cx}} = \frac{x}{a} - \frac{1}{ac} \ln(a+be^{cx})$
$\int \frac{xdx}{a+bx} = \frac{x}{b} - \frac{a}{b^2} \ln(a+bx)$	$\int \sin ax dx = -\frac{1}{a} \cos ax$
$\int \frac{dx}{x(x+a)} = -\frac{1}{a} \ln \frac{x+a}{x}$	$\int \cos ax dx = \frac{1}{a} \sin ax$
$\int \frac{dx}{(a+bx)^2} = -\frac{1}{b(a+bx)}$	$\int \tan ax dx = \frac{1}{a} \ln(\cos ax) = \frac{1}{a} \ln(\sec ax)$
$\int \frac{dx}{a^2+x^2} = \frac{1}{a} \tan^{-1} \frac{x}{a}$	$\int \cot ax dx = \frac{1}{a} \ln(\sin ax)$
$\int \frac{dx}{a^2-x^2} = \frac{1}{2a} \ln \frac{a+x}{a-x}$ ( $a^2-x^2 > 0$ )	$\int \sec ax dx = \frac{1}{a} \ln(\sec ax + \tan ax) = \frac{1}{a} \ln \left[ \tan \left( \frac{ax}{2} + \frac{\pi}{4} \right) \right]$
$\int \frac{dx}{x^2-a^2} = \frac{1}{2a} \ln \frac{x-a}{x+a}$ ( $x^2-a^2 > 0$ )	$\int \csc ax dx = \frac{1}{a} \ln(\csc ax - \cot ax) = \frac{1}{a} \ln \left( \tan \frac{ax}{2} \right)$
$\int \frac{xdx}{a^2 \pm x^2} = \pm \frac{1}{2} \ln(a^2 \pm x^2)$	$\int \sin^2 ax dx = \frac{x}{2} - \frac{\sin 2ax}{4a}$
$\int \frac{dx}{\sqrt{a^2-x^2}} = \sin^{-1} \frac{x}{a} = -\cos^{-1} \frac{x}{a}$ ( $a^2-x^2 > 0$ )	$\int \cos^2 ax dx = \frac{x}{2} + \frac{\sin 2ax}{4a}$
$\int \frac{dx}{\sqrt{x^2 \pm a^2}} = \ln(x + \sqrt{x^2 \pm a^2})$	$\int \frac{dx}{\sin^2 ax} = -\frac{1}{a} \cot ax$
$\int \frac{xdx}{\sqrt{a^2-x^2}} = -\sqrt{a^2-x^2}$	$\int \frac{dx}{\cos^2 ax} = \frac{1}{a} \tan ax$
$\int \frac{xdx}{\sqrt{x^2 \pm a^2}} = \sqrt{x^2 \pm a^2}$	$\int \tan^2 ax dx = \frac{1}{a} (\tan ax) - x$
$\int \sqrt{a^2-x^2} dx = \frac{1}{2} \left( x\sqrt{a^2-x^2} + a^2 \sin^{-1} \frac{x}{a} \right)$	$\int \cot^2 ax dx = -\frac{1}{a} (\cot ax) - x$
$\int x\sqrt{a^2-x^2} dx = -\frac{1}{3} (a^2-x^2)^{3/2}$	$\int \sin^{-1} ax dx = x(\sin^{-1} ax) + \frac{\sqrt{1-a^2x^2}}{a}$
$\int \sqrt{x^2 \pm a^2} dx = \frac{1}{2} [x\sqrt{x^2 \pm a^2} \pm a^2 \ln(x + \sqrt{x^2 \pm a^2})]$	$\int \cos^{-1} ax dx = x(\cos^{-1} ax) - \frac{\sqrt{1-a^2x^2}}{a}$
$\int x(\sqrt{x^2 \pm a^2}) dx = \frac{1}{3} (x^2 \pm a^2)^{3/2}$	$\int \frac{dx}{(x^2+a^2)^{3/2}} = \frac{x}{a^2\sqrt{x^2+a^2}}$
$\int e^{ax} dx = \frac{1}{a} e^{ax}$	$\int \frac{xdx}{(x^2+a^2)^{3/2}} = -\frac{1}{\sqrt{x^2+a^2}}$

**TABLE B.6** Gauss's Probability Integral and Other Definite Integrals

$$\int_0^{\infty} x^n e^{-ax} dx = \frac{n!}{a^{n+1}}$$

$$I_0 = \int_0^{\infty} e^{-ax^2} dx = \frac{1}{2} \sqrt{\frac{\pi}{a}} \quad (\text{Gauss's probability integral})$$

$$I_1 = \int_0^{\infty} xe^{-ax^2} dx = \frac{1}{2a}$$

$$I_2 = \int_0^{\infty} x^2 e^{-ax^2} dx = -\frac{dI_0}{da} = \frac{1}{4} \sqrt{\frac{\pi}{a^3}}$$

$$I_3 = \int_0^{\infty} x^3 e^{-ax^2} dx = -\frac{dI_1}{da} = \frac{1}{2a^2}$$

$$I_4 = \int_0^{\infty} x^4 e^{-ax^2} dx = \frac{d^2 I_0}{da^2} = \frac{3}{8} \sqrt{\frac{\pi}{a^5}}$$

$$I_5 = \int_0^{\infty} x^5 e^{-ax^2} dx = \frac{d^2 I_1}{da^2} = \frac{1}{a^3}$$

Atomic mass values given are averaged over isotopes in the percentages in which they exist in nature.

† For an unstable element, mass number of the most stable known isotope is given in parentheses.

†† Elements 110, 111, 112, and 114 have not yet been named.

## APPENDIX D • SI Units

**TABLE D.1** SI Units

Base Quantity	SI Base Unit	
	Name	Symbol
Length	Meter	m
Mass	Kilogram	kg
Time	Second	s
Electric current	Ampere	A
Temperature	Kelvin	K
Amount of substance	Mole	mol
Luminous intensity	Candela	cd

**TABLE D.2** Some Derived SI Units

Quantity	Name	Symbol	Expression in Terms of Base Units	Expression in Terms of Other SI Units
Plane angle	radian	rad	m/m	
Frequency	hertz	Hz	s <sup>-1</sup>	
Force	newton	N	kg·m/s <sup>2</sup>	J/m
Pressure	pascal	Pa	kg/m·s <sup>2</sup>	N/m <sup>2</sup>
Energy; work	joule	J	kg·m <sup>2</sup> /s <sup>2</sup>	N·m
Power	watt	W	kg·m <sup>2</sup> /s <sup>3</sup>	J/s
Electric charge	coulomb	C	A·s	
Electric potential	volt	V	kg·m <sup>2</sup> /A·s <sup>3</sup>	W/A
Capacitance	farad	F	A <sup>2</sup> ·s <sup>4</sup> /kg·m <sup>2</sup>	C/V
Electric resistance	ohm	Ω	kg·m <sup>2</sup> /A <sup>2</sup> ·s <sup>3</sup>	V/A
Magnetic flux	weber	Wb	kg·m <sup>2</sup> /A·s <sup>2</sup>	V·s
Magnetic field intensity	tesla	T	kg/A·s <sup>2</sup>	
Inductance	henry	H	kg·m <sup>2</sup> /A <sup>2</sup> ·s <sup>2</sup>	T·m <sup>2</sup> /A

## APPENDIX E • Nobel Prizes

All Nobel Prizes in physics are listed (and marked with a P), as well as relevant Nobel Prizes in Chemistry (C). The key dates for some of the scientific work are supplied; they often antedate the prize considerably.

- 1901** (P) *Wilhelm Roentgen* for discovering x-rays (1895).
- 1902** (P) *Hendrik A. Lorentz* for predicting the Zeeman effect and *Pieter Zeeman* for discovering the Zeeman effect, the splitting of spectral lines in magnetic fields.
- 1903** (P) *Antoine-Henri Becquerel* for discovering radioactivity (1896) and *Pierre* and *Marie Curie* for studying radioactivity.
- 1904** (P) *Lord Rayleigh* for studying the density of gases and discovering argon. (C) *William Ramsay* for discovering the inert gas elements helium, neon, xenon, and krypton, and placing them in the periodic table.
- 1905** (P) *Philipp Lenard* for studying cathode rays, electrons (1898–1899).
- 1906** (P) *J. J. Thomson* for studying electrical discharge through gases and discovering the electron (1897).
- 1907** (P) *Albert A. Michelson* for inventing optical instruments and measuring the speed of light (1880s).
- 1908** (P) *Gabriel Lippmann* for making the first color photographic plate, using interference methods (1891). (C) *Ernest Rutherford* for discovering that atoms can be broken apart by alpha rays and for studying radioactivity.
- 1909** (P) *Guglielmo Marconi* and *Carl Ferdinand Braun* for developing wireless telegraphy.
- 1910** (P) *Johannes D. van der Waals* for studying the equation of state for gases and liquids (1881).
- 1911** (P) *Wilhelm Wien* for discovering Wien's law giving the peak of a black-body spectrum (1893). (C) *Marie Curie* for discovering radium and polonium (1898) and isolating radium.
- 1912** (P) *Nils Dalén* for inventing automatic gas regulators for lighthouses.
- 1913** (P) *Heike Kamerlingh Onnes* for the discovery of superconductivity and liquefying helium (1908).
- 1914** (P) *Max T. F. von Laue* for studying x-rays from their diffraction by crystals, showing that x-rays are electromagnetic waves (1912). (C) *Theodore W. Richards* for determining the atomic weights of sixty elements, indicating the existence of isotopes.
- 1915** (P) *William Henry Bragg* and *William Lawrence Bragg*, his son, for studying the diffraction of x-rays in crystals.
- 1917** (P) *Charles Barkla* for studying atoms by x-ray scattering (1906).
- 1918** (P) *Max Planck* for discovering energy quanta (1900).
- 1919** (P) *Johannes Stark*, for discovering the Stark effect, the splitting of spectral lines in electric fields (1913).

- 1920** (P) *Charles-Édouard Guillaume* for discovering invar, a nickel-steel alloy with low coefficient of expansion.  
(C) *Walther Nernst* for studying heat changes in chemical reactions and formulating the third law of thermodynamics (1918).
- 1921** (P) *Albert Einstein* for explaining the photoelectric effect and for his services to theoretical physics (1905).  
(C) *Frederick Soddy* for studying the chemistry of radioactive substances and discovering isotopes (1912).
- 1922** (P) *Niels Bohr* for his model of the atom and its radiation (1913).  
(C) *Francis W. Aston* for using the mass spectrograph to study atomic weights, thus discovering 212 of the 287 naturally occurring isotopes.
- 1923** (P) *Robert A. Millikan* for measuring the charge on an electron (1911) and for studying the photoelectric effect experimentally (1914).
- 1924** (P) *Karl M. G. Siegbahn* for his work in x-ray spectroscopy.
- 1925** (P) *James Franck* and *Gustav Hertz* for discovering the Franck-Hertz effect in electron-atom collisions.
- 1926** (P) *Jean-Baptiste Perrin* for studying Brownian motion to validate the discontinuous structure of matter and measure the size of atoms.
- 1927** (P) *Arthur Holly Compton* for discovering the Compton effect on x-rays, their change in wavelength when they collide with matter (1922), and *Charles T. R. Wilson* for inventing the cloud chamber, used to study charged particles (1906).
- 1928** (P) *Owen W. Richardson* for studying the thermionic effect and electrons emitted by hot metals (1911).
- 1929** (P) *Louis Victor de Broglie* for discovering the wave nature of electrons (1923).
- 1930** (P) *Chandrasekhara Venkata Raman* for studying Raman scattering, the scattering of light by atoms and molecules with a change in wavelength (1928).
- 1932** (P) *Werner Heisenberg* for creating quantum mechanics (1925).
- 1933** (P) *Erwin Schrödinger* and *Paul A. M. Dirac* for developing wave mechanics (1925) and relativistic quantum mechanics (1927).  
(C) *Harold Urey* for discovering heavy hydrogen, deuterium (1931).
- 1935** (P) *James Chadwick* for discovering the neutron (1932).  
(C) *Irène* and *Frédéric Joliot-Curie* for synthesizing new radioactive elements.
- 1936** (P) *Carl D. Anderson* for discovering the positron in particular and antimatter in general (1932) and *Victor F. Hess* for discovering cosmic rays.  
(C) *Peter J. W. Debye* for studying dipole moments and diffraction of x-rays and electrons in gases.
- 1937** (P) *Clinton Davisson* and *George Thomson* for discovering the diffraction of electrons by crystals, confirming de Broglie's hypothesis (1927).
- 1938** (P) *Enrico Fermi* for producing the transuranic radioactive elements by neutron irradiation (1934–1937).
- 1939** (P) *Ernest O. Lawrence* for inventing the cyclotron.
- 1943** (P) *Otto Stern* for developing molecular-beam studies (1923), and using them to discover the magnetic moment of the proton (1933).
- 1944** (P) *Isidor I. Rabi* for discovering nuclear magnetic resonance in atomic and molecular beams.  
(C) *Otto Hahn* for discovering nuclear fission (1938).
- 1945** (P) *Wolfgang Pauli* for discovering the exclusion principle (1924).
- 1946** (P) *Percy W. Bridgman* for studying physics at high pressures.
- 1947** (P) *Edward V. Appleton* for studying the ionosphere.

- 1948** (P) *Patrick M. S. Blackett* for studying nuclear physics with cloud-chamber photographs of cosmic-ray interactions.
- 1949** (P) *Hideki Yukawa* for predicting the existence of mesons (1935).
- 1950** (P) *Cecil F. Powell* for developing the method of studying cosmic rays with photographic emulsions and discovering new mesons.
- 1951** (P) *John D. Cockcroft* and *Ernest T. S. Walton* for transmuting nuclei in an accelerator (1932).  
(C) *Edwin M. McMillan* for producing neptunium (1940) and *Glenn T. Seaborg* for producing plutonium (1941) and further transuranic elements.
- 1952** (P) *Felix Bloch* and *Edward Mills Purcell* for discovering nuclear magnetic resonance in liquids and gases (1946).
- 1953** (P) *Frits Zernike* for inventing the phase-contrast microscope, which uses interference to provide high contrast.
- 1954** (P) *Max Born* for interpreting the wave function as a probability (1926) and other quantum-mechanical discoveries and *Walther Bothe* for developing the coincidence method to study subatomic particles (1930–1931), producing, in particular, the particle interpreted by Chadwick as the neutron.
- 1955** (P) *Willis E. Lamb, Jr.*, for discovering the Lamb shift in the hydrogen spectrum (1947) and *Polykarp Kusch* for determining the magnetic moment of the electron (1947).
- 1956** (P) *John Bardeen*, *Walter H. Brattain*, and *William Shockley* for inventing the transistor (1956).
- 1957** (P) *T.-D. Lee* and *C.-N. Yang* for predicting that parity is not conserved in beta decay (1956).
- 1958** (P) *Pavel A. Čerenkov* for discovering Čerenkov radiation (1935) and *Ilya M. Frank* and *Igor Tamm* for interpreting it (1937).
- 1959** (P) *Emilio G. Segrè* and *Owen Chamberlain* for discovering the antiproton (1955).
- 1960** (P) *Donald A. Glaser* for inventing the bubble chamber to study elementary particles (1952).  
(C) *Willard Libby* for developing radiocarbon dating (1947).
- 1961** (P) *Robert Hofstadter* for discovering internal structure in protons and neutrons and *Rudolf L. Mössbauer* for discovering the Mössbauer effect of recoilless gamma-ray emission (1957).
- 1962** (P) *Lev Davidovich Landau* for studying liquid helium and other condensed matter theoretically.
- 1963** (P) *Eugene P. Wigner* for applying symmetry principles to elementary-particle theory and *Maria Goeppert Mayer* and *J. Hans D. Jensen* for studying the shell model of nuclei (1947).
- 1964** (P) *Charles H. Townes*, *Nikolai G. Basov*, and *Alexandr M. Prokhorov* for developing masers (1951–1952) and lasers.
- 1965** (P) *Sin-itiro Tomonaga*, *Julian S. Schwinger*, and *Richard P. Feynman* for developing quantum electrodynamics (1948).
- 1966** (P) *Alfred Kastler* for his optical methods of studying atomic energy levels.
- 1967** (P) *Hans Albrecht Bethe* for discovering the routes of energy production in stars (1939).
- 1968** (P) *Luis W. Alvarez* for discovering resonance states of elementary particles.
- 1969** (P) *Murray Gell-Mann* for classifying elementary particles (1963).
- 1970** (P) *Hannes Alfvén* for developing magnetohydrodynamic theory and *Louis Eugène Félix Néel* for discovering antiferromagnetism and ferrimagnetism (1930s).

- 1971** (P) *Dennis Gabor* for developing holography (1947).  
(C) *Gerhard Herzberg* for studying the structure of molecules spectroscopically.
- 1972** (P) *John Bardeen*, *Leon N. Cooper*, and *John Robert Schrieffer* for explaining superconductivity (1957).
- 1973** (P) *Leo Esaki* for discovering tunneling in semiconductors, *Ivar Giaever* for discovering tunneling in superconductors, and *Brian D. Josephson* for predicting the Josephson effect, which involves tunneling of paired electrons (1958–1962).
- 1974** (P) *Anthony Hewish* for discovering pulsars and *Martin Ryle* for developing radio interferometry.
- 1975** (P) *Aage N. Bohr*, *Ben R. Mottelson*, and *James Rainwater* for discovering why some nuclei take asymmetric shapes.
- 1976** (P) *Burton Richter* and *Samuel C. C. Ting* for discovering the J/psi particle, the first charmed particle (1974).
- 1977** (P) *John H. Van Vleck*, *Nevill F. Mott*, and *Philip W. Anderson* for studying solids quantum-mechanically.  
(C) *Ilya Prigogine* for extending thermodynamics to show how life could arise in the face of the second law.
- 1978** (P) *Arno A. Penzias* and *Robert W. Wilson* for discovering the cosmic background radiation (1965) and *Pyotr Kapitsa* for his studies of liquid helium.
- 1979** (P) *Sheldon L. Glashow*, *Abdus Salam*, and *Steven Weinberg* for developing the theory that unified the weak and electromagnetic forces (1958–1971).
- 1980** (P) *Val Fitch* and *James W. Cronin* for discovering CP (charge-parity) violation (1964), which possibly explains the cosmological dominance of matter over antimatter.
- 1981** (P) *Nicolaas Bloembergen* and *Arthur L. Schawlow* for developing laser spectroscopy and *Kai M. Siegbahn* for developing high-resolution electron spectroscopy (1958).
- 1982** (P) *Kenneth G. Wilson* for developing a method of constructing theories of phase transitions to analyze critical phenomena.
- 1983** (P) *William A. Fowler* for theoretical studies of astrophysical nucleosynthesis and *Subramanyan Chandrasekhar* for studying physical processes of importance to stellar structure and evolution, including the prediction of white dwarf stars (1930).
- 1984** (P) *Carlo Rubbia* for discovering the W and Z particles, verifying the electroweak unification, and *Simon van der Meer*, for developing the method of stochastic cooling of the CERN beam that allowed the discovery (1982–1983).
- 1985** (P) *Klaus von Klitzing* for the quantized Hall effect, relating to conductivity in the presence of a magnetic field (1980).
- 1986** (P) *Ernst Ruska* for inventing the electron microscope (1931), and *Gerd Binnig* and *Heinrich Rohrer* for inventing the scanning-tunneling electron microscope (1981).
- 1987** (P) *J. Georg Bednorz* and *Karl Alex Müller* for the discovery of high temperature superconductivity (1986).
- 1988** (P) *Leon M. Lederman*, *Melvin Schwartz*, and *Jack Steinberger* for a collaborative experiment that led to the development of a new tool for studying the weak nuclear force, which affects the radioactive decay of atoms.
- 1989** (P) *Norman Ramsay* (U.S.) for various techniques in atomic physics; and *Hans Dehmelt* (U.S.) and *Wolfgang Paul* (Germany) for the development of techniques for trapping single charge particles.

- 1990** (P) *Jerome Friedman, Henry Kendall* (both U.S.), and *Richard Taylor* (Canada) for experiments important to the development of the quark model.
- 1991** (P) *Pierre-Gilles de Gennes* for discovering that methods developed for studying order phenomena in simple systems can be generalized to more complex forms of matter, in particular to liquid crystals and polymers.
- 1992** (P) *George Charpak* for developing detectors that trace the paths of evanescent subatomic particles produced in particle accelerators.
- 1993** (P) *Russell Hulse* and *Joseph Taylor* for discovering evidence of gravitational waves.
- 1994** (P) *Bertram N. Brockhouse* and *Clifford G. Shull* for pioneering work in neutron scattering.
- 1995** (P) *Martin L. Perl* and *Frederick Reines* for discovering the tau particle and the neutrino, respectively.
- 1996** (P) *David M. Lee, Douglas C. Osheroff,* and *Robert C. Richardson* for developing a superfluid using helium-3.
- 1997** (P) *Steven Chu, Claude Cohen-Tannoudji,* and *William D. Phillips* for developing methods to cool and trap atoms with laser light.
- 1998** (P) *Robert B. Laughlin, Horst L. Störmer,* and *Daniel C. Tsui* for discovering a new form of quantum fluid with fractionally charged excitations.
