Triangulating Polygons

Definitions

- Simple polygon: Regions enclosed by a single closed polygonal chain that does not intersect itself.
- Question: How many cameras do we need to guard a simple polygon?
Answer: Depends on the polygon.
- One solution: Decompose the polygon to parts which are simple to guard.

Guarding a triangulated polygon

- $\mathcal{T}_P$: A triangulation of a simple polygon P .
- Select $S \subseteq$ the vertices of P , such that any triangle in $\mathcal{T}_P$ has at least one vertex in S , and place the cameras at vertices in S .
- To find such a subset: find a 3-coloring of a triangulated polygon.
- In a 3-coloring of $\mathcal{T}_P$, every triangle has a blue, a red, and a black vertex. Hence, if we place cameras at all red vertices, we have guarded the whole polygon.
- By choosing the smallest color class to place the cameras, we can guard P using at most $\lfloor n/3 \rfloor$ cameras.

Does a 3-coloring always exist?

Dual graph:

- This graph $\mathcal{G}(\mathcal{T}_P)$ has a node for every triangle in $\mathcal{T}_P$.
- There is an arc between two nodes ν and μ if $t(\nu)$ and $t(\mu)$ share a diagonal.
- $\mathcal{G}(\mathcal{T}_P)$ is a tree.

Does a 3-coloring always exist?

For 3-coloring:

- Traverse the dual graph (DFS).
- Invariant: so far everything is nice.
- Start from any node of $\mathcal{G}(\mathcal{T}_P)$; color the vertices.
- When we reach a node ν in $\mathcal{G}$, coming from node μ . Only one vertex of $t(\nu)$ remains to be colored.

Art Gallery Theorem

We will show:

How to compute a triangulation in $\mathcal{O}(n \log n)$ time.

Therefore:

Theorem 3.3

Let P be a simple polygon with n vertices. A set of $\lfloor n/3 \rfloor$ camera positions in P such that any point inside P is visible from at least one of the cameras can be computed in $\mathcal{O}(n \log n)$ time.

Triangulation algorithms

- A really naive algorithm: check all $\binom{n}{2}$ choices for a diagonal, each takes $\mathcal{O}(n)$ time. Time complexity: $\mathcal{O}(n^3)$.
- A better naive algorithm: find an ear in $\mathcal{O}(n)$ time, then recurse. Total time: $\mathcal{O}(n^2)$.
- First non-trivial algorithm: $\mathcal{O}(n \log n)$ (1978).
- A long series of papers and algorithms in 80s until Chazelle produced an optimal $\mathcal{O}(n)$ algorithm in 1991.
- Linear time algorithm insanely complicated; there are randomized, expected linear time that are more accessible.
- Here we present a $\mathcal{O}(n \log n)$ algorithm.

Data Structure:

For this approach, we need to find the edge to the left of each vertex. To do that:

- 1 We store the edges of P intersecting the sweep line in the leaves of a dynamic binary search tree $\mathcal{T}$.
- 2 Because we are only interested in edges to the left of split and merge vertices we only need to store edges in $\mathcal{T}$ that have the interior of P to their right.
- 3 With each edge in $\mathcal{T}$ we store its helper.
- 4 We store P in DCEL form and make changes such that it remains valid.

Make Monotone Algorithm:

Yazd Univ.

Algorithm MAKEMONOTONE($\mathcal{P}$)

Input. A simple polygon $\mathcal{P}$ stored in a doubly-connected edge list $\mathcal{D}$.

Output. A partitioning of $\mathcal{P}$ into monotone subpolygons, stored in $\mathcal{D}$.

1. Construct a priority queue $\mathcal{Q}$ on the vertices of $\mathcal{P}$, using their y -coordinates as priority. If two points have the same y -coordinate, the one with smaller x -coordinate has higher priority.
2. Initialize an empty binary search tree $\mathcal{T}$.
3. **while** $\mathcal{Q}$ is not empty
4. **do** Remove the vertex v_i with the highest priority from $\mathcal{Q}$.
5. Call the appropriate procedure to handle the vertex, depending on its type.

HANDLEREGULARVERTEX(v_i)

1. **if** the interior of $\mathcal{P}$ lies to the right of v_i
2. **then if** $\text{helper}(e_{i-1})$ is a merge vertex
3. **then** Insert the diagonal connecting v_i to $\text{helper}(e_{i-1})$ in $\mathcal{D}$.
4. Delete e_{i-1} from $\mathcal{T}$.
5. Insert e_i in $\mathcal{T}$ and set $\text{helper}(e_i)$ to v_i .
6. **else** Search in $\mathcal{T}$ to find the edge e_j directly left of v_i .
7. **if** $\text{helper}(e_j)$ is a merge vertex
8. **then** Insert the diagonal connecting v_i to $\text{helper}(e_j)$ in $\mathcal{D}$.
9. $\text{helper}(e_j) \leftarrow v_i$

Lemma 3.5

Algorithm MAKEMONOTONE adds a set of non-intersecting diagonals that partitions P into monotone subpolygons.

Proof. (For split vertices) (other cases are similar)

- No intersection between $v_i v_m$ and edges of P .
- No intersection between $v_i v_m$ and previous edges.

Triangulating a Monotone
Polygon

Running time:

- Constructing the priority queue Q : $\mathcal{O}(n)$ time.
- Initializing $\mathcal{T}$: $\mathcal{O}(1)$ time.
- To handle an event, we perform:
 - 1 one operation on Q : $\mathcal{O}(\log n)$ time.
 - 2 at most one query on $\mathcal{T}$: $\mathcal{O}(\log n)$ time.
 - 3 one insertion, and one deletion on $\mathcal{T}$: $\mathcal{O}(\log n)$ time.
 - 4 we insert at most two diagonals into D : $\mathcal{O}(1)$ time.

Space Complexity:

The amount of storage used by the algorithm is clearly linear: every vertex is stored at most once in Q , and every edge is stored at most once in $\mathcal{T}$.

Theorem 3.6

A simple polygon with n vertices can be partitioned into y -monotone polygons in $\mathcal{O}(n \log n)$ time with an algorithm that uses $\mathcal{O}(n)$ storage.

Triangulation Algorithm:

- 1 The algorithm handles the vertices in order of decreasing y -coordinate. (Left to right for points with same y -coordinate).
- 2 The algorithm requires a stack S as auxiliary data structure. It keeps the points that handled but might need more diagonals.
- 3 When we handle a vertex we add as many diagonals from this vertex to vertices on the stack as possible.
- 4 Algorithm invariant: the part of P that still needs to be triangulated, and lies above the last vertex that has been encountered so far, looks like a funnel turned upside down.

Algorithm TRIANGULATEMONOTONEPOLYGON($\mathcal{P}$)

Input. A strictly y -monotone polygon $\mathcal{P}$ stored in a doubly-connected edge list $\mathcal{D}$.

Output. A triangulation of $\mathcal{P}$ stored in the doubly-connected edge list $\mathcal{D}$.

1. Merge the vertices on the left chain and the vertices on the right chain of $\mathcal{P}$ into one sequence, sorted on decreasing y -coordinate. If two vertices have the same y -coordinate, then the leftmost one comes first. Let $u_1, \dots, u_n$ denote the sorted sequence.
2. Initialize an empty stack $\mathcal{S}$, and push u_1 and u_2 onto it.
3. **for** $j \leftarrow 3$ **to** $n - 1$
4. **do if** u_j and the vertex on top of $\mathcal{S}$ are on different chains
5. **then** Pop all vertices from $\mathcal{S}$.
6. Insert into $\mathcal{D}$ a diagonal from u_j to each popped vertex, except the last one.
7. Push u_{j-1} and u_j onto $\mathcal{S}$.
8. **else** Pop one vertex from $\mathcal{S}$.
9. Pop the other vertices from $\mathcal{S}$ as long as the diagonals from u_j to them are inside $\mathcal{P}$. Insert these diagonals into $\mathcal{D}$. Push the last vertex that has been popped back onto $\mathcal{S}$.
10. Push u_j onto $\mathcal{S}$.
11. Add diagonals from u_n to all stack vertices except the first and the last one.

Polygon Triangulation

Theorem 3.8

A simple polygon with n vertices can be triangulated in $\mathcal{O}(n \log n)$ time with an algorithm that uses $\mathcal{O}(n)$ storage.

Theorem 3.9

A planar subdivision with n vertices in total can be triangulated in $\mathcal{O}(n \log n)$ time with an algorithm that uses $\mathcal{O}(n)$ storage.
