2-9

When the parallel load input = 1, the clock pulses go through the AND gate and the data inputs are loaded into the register. When the parallel load input = 0, the output of the AND gate remains at 0.

2-10

The buffer gate does not perform logic. It is used for signal amplification of the clock input.

4-4

Connect the 4-line common bus to the four inputs of each register.  
 Provide a "load" control input in each register.  
 Provide a clock input for each register.

To transfer from register C to register A:  
 Apply  $S_1, S_0 = 10$  (to select C for the bus.)  
 Enable the load input of A  
 Apply a clock pulse.

(c) Data: 32 bits; address: 18 bits.

5-2

A direct address instruction needs two references to memory: (1) Read instruction; (2) Read operand.

An indirect address instruction needs three references to memory: (1) Read instruction; (2) Read effective address; (3) Read operand.

5-3

(a) Memory read to bus and load to IR:  $IR \leftarrow M[AR]$

(b) TR to bus and load to PC:  $PC \leftarrow TR$

(c) AC to bus, write to memory, and load to DR:

$$DR \leftarrow AC, \quad M[AR] \leftarrow AC$$

(d) Add DR (or INPR) to AC:  $AC \leftarrow AC + DR$

(d) $DR \leftarrow AC$ $AC \leftarrow DR$	100 (AC)	DR and AC	—	Transfer DR to AC

5-5

(a)  $IR \leftarrow M[PC]$  PC cannot provide address to memory, Address must be transferred to AR first

(b)  $AC \leftarrow AC + TR$  Add operation must be done with DR, Transfer TR to DR first,

$DR \leftarrow TR$   
 $AC \leftarrow AC + DR$

(c)  $DR \leftarrow DR : AC$  Result of addition is transferred to AC (not DR). To save value of AC, its content must be stored temporary in DR (or TR).

Converts the ISZ instruction from a memory-reference instruction to a register-reference instruction. The new instruction ICSZ can be executed at time  $T_3$  instead of time  $T_6$ , a saving of 3 clock cycles.

5-11

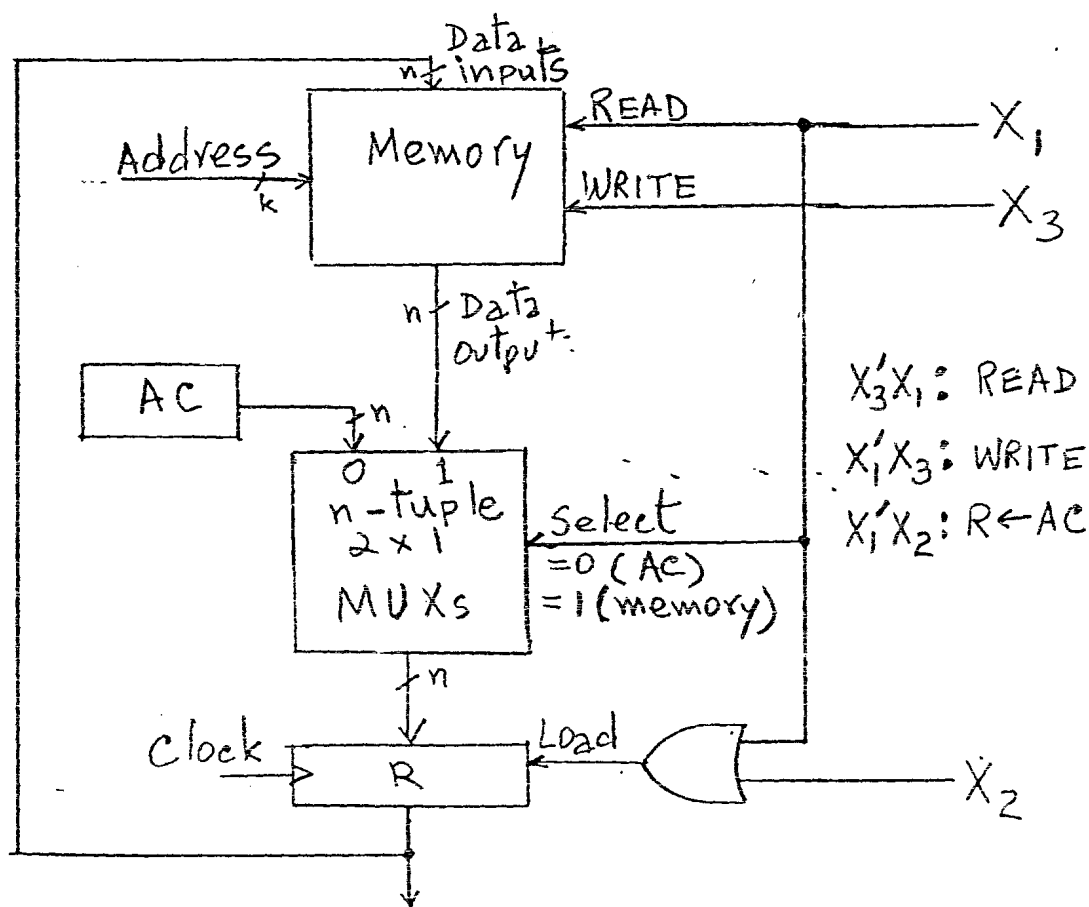

1. Read 40-bit double instruction from memory to IR and then increment PC,
2. Decode opcode 1.
3. Execute instruction 1 using address 1.
4. Decode opcode 2.
5. Execute instruction 2 using address 2.
6. Go back to step 1.

$$J_F = xT_3 + 3T_2 + wT_5G \quad K_F = yT_1 + 3T_2 + wT_5G'$$

5-21 From Table 5-6: ( $Z_{DR}=1$  if  $DR=0$  ;  $Z_{AC}=1$  if  $AC=0$ )

$$INR(PC) = R'T_1 + RT_2 + D_6T_6Z_{DR} + PB_9(FGI) + PB_8(FG0) \\ + YB_4(AC_{15})' + YB_3(AC_{15}) + YB_2Z_{AC} + YB_1E'$$

$$LD(PC) = D_4T_4 + D_5T_5$$

$$CLR(PC) = RT_1$$

The logic diagram is similar to the one in Fig. 5-16,

5-22 Write =  $D_3T_4 + D_5T_4 + D_6T_6 + RT_1$  ( $M[AR] \leftarrow xx$ )

5-23  $(T_0 + T_1 + T_2)'(IEN)(FGI + FG0) ; R \leftarrow 1$   
 $RT_2 ; R \leftarrow 0$

5-24

$\pi_2$  places PC onto the bus. From Table 5-6:

$$R'T_0 : AR \leftarrow PC$$

$$RT_0 : TR \leftarrow PC$$

$$D_5T_4 : M[AR] \leftarrow PC$$

$$\pi_2 = R'T_0 + RT_0 + D_5T_4 = (R' + R)T_0 + D_5T_4 = T_0 + D_5T_4$$

5-25

From Table 5-6:

$$\begin{aligned} \text{CLR}(SC) = & RT_2 + D_7T_3(I' + I) + (D_0 + D_1 + D_2 + D_5)T_5 \\ & + (D_3 + D_4)T_4 + D_6T_6 \end{aligned}$$

6-4 A line of code such as: LDA I is interpreted by the assembler (Fig. 6-2) as a two symbol field with I as the symbolic address. A line of code such as: LDA I I is interpreted as a three symbol field. The first I is an address symbol and the second I as the Indirect bit. Answer: Yes, it can be used for this assembler.

6-5

The assembler will not detect an ORG or END if the line has a label; according to the flow chart of Fig. 6-1. Such a label has no meaning and constitutes an error. To detect the error, modify the flow chart of Fig. 6-1:

## CHAPTER 7

7-1

A microprocessor is a small size CPU (computer on a chip).  
Microprogram is a program for a sequence of microoperations.  
The control unit of a microprocessor can be hardwired or microprogrammed, depending on the specific design.  
A microprogrammed computer does not have to be a microprocessor.

7-2

Hardwired control, by definition, does not contain a control memory.

7-3

Microoperation - an elementary digital computer operation.

Microinstruction - an instruction stored in control memory.

Microprogram - a sequence of microinstructions.

Microcode - same as microprogram.

7-4

frequency of each clock =  $\frac{1}{100 \times 10^{-9}} = \frac{1000}{100} \times 10^6 = 10 \text{ MHz}$

If the data register is removed, we can use a single phase clock with a frequency of  $\frac{1}{90 \times 10^{-9}} = 11.1 \text{ MHz}$

7-5 Control memory =  $2^{10} \times 32$

(b) 4 bits

(c) 2 bits

7-6 Control memory =  $2^{12} \times 24$

(a) 12 bits

(b) 12 bits

(c) 12 multiplexers, each of size 4-to-1 line.

7-7

(a) 0001000 = 8

(b) 0101100 = 44

(c) 0111100 = 60

7-8

opcode = 6 bits

control memory

address = 11 bits

7-9

The ROM can be programmed to provide any desired address for a given inputs from the instruction.

7-10

Either multiplexers, three-state gates, or gate logic (equivalent to a mux) are needed to transfer information from many sources to a common destination.

7-11

	F1	F2	F3

	DRTAC	$AC \leftarrow DR$	$F3 = 101$	
(b)	ACTDR	$DR \leftarrow AC$	$F2 = 101$	000 100 101
	DRTAC	$AC \leftarrow DR$	$F1 = 100$	
(c)	ARTPC	$PC \leftarrow AR$	$F3 = 110$	
	DRTAC	$AC \leftarrow DR$	$F1 = 100$	
	WRITE	$M[AR] \leftarrow DR$	$F1 = 111$	

Impossible.  
Both use F1

7-13

If  $I=0$ , the operand is read in the first microinstruction and added to AC in the second.

If  $I=1$ , the effective address is read into DR and control goes to INDR2. The subroutine must read the operand into DR.

INDR2: DRTAR U JMP NEXT

	61:	WRITE, READ	I	CALL	FETCH
	62:	ADD, SUB	S	RET	63 (NEXT)
	63:	DRTAC, INCDR	Z	MAP	60

(b)

60: Cannot increment and complement AC at the same time. With a JMP to INDRCT, control does not return to 61.

61: Cannot read and write at the same time. The CALL behaves as a JMP since there is no return from FETCH.

62: Cannot add and subtract at the same time. The RET will be executed independent of S.

63: The MAP is executed irrespective of Z or 60.

$$(d) S_{\max} = \frac{t_n}{t_p} = \frac{100}{50} = 2$$

9-6

(a) See discussion in Sec. 10-3 on array multipliers. There are  $8 \times 8 = 64$  AND gates in each segment and an 8-bit binary adder (in each segment).

(b) There are 7 segments in the pipeline

$$(c) \text{Average time} = \frac{k+n-1}{n} t_p = \frac{(n+6)30}{n}$$

$$\text{For } n=10 \quad t_{AV} = 48 \text{ ns}$$

$$\text{For } n=100 \quad t_{AV} = 31.8 \text{ ns}$$

$$\text{For } n \rightarrow \infty \quad t_{AV} = 30 \text{ ns}$$

To increase the speed of multiplication, a carry-save (Wallace tree) adder is used to reduce the propagation time of the carries.

9-7

$$(a) \text{Clock cycle} = 95 + 5 = 100 \text{ ns (time for segment 3)}$$

$$\text{for } n=100; k=4, t_p=100 \text{ ns.}$$

$$\text{Time to add 100 numbers} = (k+n-1)t_p = (4+99)100$$

$$= 10,300 \text{ ns} = 10.3 \mu\text{s}$$

(b) Divide segment 3 into two segments of  $50+5=55$  and  $45+5=50$  ns. This makes  $t_p=55$  ns;  $k=5$

$$(k+n-1)t_p = (5+99)55 = 5,720 \text{ ns} = 5.72 \mu\text{s}$$

9-8 Connect output of adder to input  $B \times 2^b$  in a feedback path and use input  $A \times 2^a$  for the data  $X_1$  through  $X_{100}$ . Then use a scheme similar to the one described in conjunction with the adder pipeline in Fig. 9-12.

9-9 One possibility is to use the six operations listed in the beginning of Sec. 9-4.

(b)  $40^3 = 64,000$

9-17

$8 + 60 + 4 = 72$  clock cycles for each inner product.

There are  $60^2 = 3600$  inner products. Product matrix takes  $3600 \times 72 = 259,200$  clock cycles to evaluate.

4.	$(-X) + (-Y)$	$(2^k + 2^k - X) + (2^k + 2^k - Y)$	$2^k + 2^k - (X+Y)$

It is necessary to show that the operations in column (b) produce the results listed in column (c).

case 1. column (b) = column (c)

case 2. If  $X \geq Y$  then  $(X-Y) \geq 0$  and consists of  $k$  bits.  
operation in column (b) gives:  $2^{2k} + (X-Y)$ . Discard  
carry  $2^{2k} = 2^n$  to get  $0 + (X-Y)$  as in column (c)

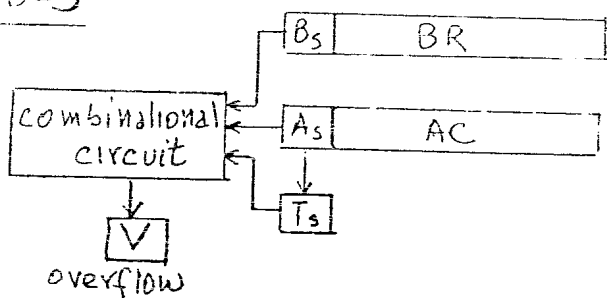

If  $X < Y$  then  $(Y-X) > 0$ . Operation gives  
 $2^k + 2^k - (Y-X)$  as in column (c).

case 3. is the same as case 2 with  $X$  and  $Y$  reversed

case 4. Operation in column (b) gives:  $2^{2k} + 2^k + 2^k - (X+Y)$

Discard carry  $2^{2k} = 2^n$  to obtain result of (c):  
 $2^k + (2^k - X - Y)$

(b) The procedure  $V \leftarrow E \oplus F$  is valid for 1's complement numbers provided we check the result  $0 \ 1111 \dots 11$  when  $V=1$ . Algorithm

10-7 Add algorithm flowchart is shown above (Prob. 10-6b)

10-8 Maximum value of numbers is  $r_{n-1}$ . It is necessary to show that maximum product is less than or equal to  $r_{2n-1}$ . Maximum product is:

$$(r^n - 1)(r^n - 1) = r^{2n} - 2r^n + 1 \leq r^{2n} - 1$$

which gives :  $2 \leq 2r^n$  or  $1 \leq r^n$

This is always true since  $r \geq 2$  and  $n \geq 1$

 remove end-carry  $2^n$  to obtain A.

10-12

To correspond with correct result. In general:

$$\frac{A}{B} = Q + \frac{R}{B}$$

Where A is dividend, Q the quotient and R the remainder.  
 Four possible signs for A and B:

$$\frac{+52}{+5} = +10 + \frac{+2}{+5} = +10.4 \quad \frac{-52}{+5} = -10 + \frac{-2}{+5} = -10.4$$

10-16 The algorithm for square-root is similar to division with the radicand being equivalent to the dividend and a "test value" being equivalent to the divisor.

Let  $A$  be the radicand,  $Q$  the square-root, and  $R$  the remainder such that  $Q^2 + R = A$  or:

$$\sqrt{A} = Q \text{ and a remainder}$$

General comments:

1. For  $k$  bits in  $A$  ( $k$  even),  $Q$  will have  $k/2$  bits:

$$Q = q_1 q_2 q_3 \dots q_{k/2}$$

2. The first test value is 01

The second test value is 09, 01

The third test value is 009, 92, 01

The fourth test value is 0009, 9293, 01 etc.

3. Mark the bits of  $A$  in groups of two starting from left.

4. The procedure is similar to the division restoring method as shown in the following example:

$\begin{array}{cccc} q_1 & q_2 & q_3 & q_4 \\ 1 & 1 & 0 & 1 \end{array}$	$= Q = 13$

(b) The biased exponent follows the same algorithm as a magnitude comparator. See Sec. 9-2

(c)  $(e_1+64) + (e_2+64) = (e_1+e_2+64) + 64$   
subtract 64 to obtain biased exponent sum

(d)  $(e_1+64) - (e_2-64) = e_1+e_2$   
add 64 to obtain biased exponent difference.

## 11-19

If an interrupt is recognized in the middle of an instruction execution, it is necessary to save all the information from control registers in addition to processor registers. The state of the CPU to be saved is more complex.

(2) Before CPU responds with acknowledge, device 1 sends interrupt request:	PI=0; PD=0; RF=1	PI=0; PD=0; RF=1
(3) After CPU sends an acknowledge, device 1 has priority:	PI=1; PD=0; RF=1 VAD enable=1	PI=0; PD=0; RF=1 VAD enable=0

Set the mask bit belonging to the interrupt source so it can interrupt again.

At the beginning of the service routine, check the value of the return address in the stack. If it is an address within the source service program, then the same source has interrupted again while being serviced.

# 11-21

The service routine checks the flags in sequence to determine which one is set. The first flag that is checked has the highest priority level. The priority level of the other sources corresponds to the order in which the flags are checked.

11-27

When the CPU communicates with the DMA controller, the read and write lines are used as inputs from the CPU to the DMA controller.

When the DMA controller communicates with memory, the read and write lines are used as outputs from the DMA to memory.

11-28

- (a) CPU initiates DMA by transferring:
- 256 to the word count register.
  - 1230 to the DMA address register.
  - Bits to the control register to specify a write operation.

(b)

1. I/O device sends a "DMA request".
2. DMA sends BR (bus request) to CPU.
3. CPU responds with a BG (bus grant).
4. Contents of DMA address register are placed in address bus.
5. DMA sends "DMA acknowledge" to I/O device and enables the write control line to memory.
6. Data word is placed on data bus by I/O device.
7. Increment DMA address register by 1 and decrement DMA word count register by 1.
8. Repeat steps 4-7 for each data word transferred.

11-29

CPU refers to memory on the average once (or more) every  $1 \mu\text{sec}$ , ( $1/10^6$ ). Characters arrive one every  $1/2400 = 416.6 \mu\text{sec}$ . Two characters of 8 bits each are packed into a 16-bit word every  $2 \times 416.6 = 833.3 \mu\text{sec}$ . The CPU is slowed down by no more than  $(1/833.3) \times 100 = 0.12\%$ .

11-30

The CPU can wait to fetch instructions and data from memory without any damage occurring except loss of time. DMA usually transfers data from a device that cannot be stopped since information continues to flow so loss of data may occur.

11-32 There are 26 letters and 10 numerals.

$$26 \times 26 + 26 \times 10 = 936 \text{ possible addresses.}$$

11-33

The processor transmits the address of the terminal followed by ENQ (enquiry) code 0000 0101. The terminal responds with either ACK (acknowledge) or NAK (negative acknowledge) or the terminal does not respond during a timeout period. If the processor receives an ACK, it sends a block of text.

The processor selects the external register with an address 8000 hexadecimal. Each bank of 32K bytes are selected by addresses 0000-7FFF. The processor loads an 8-bit number into the register with a single 1 and 7 0's. Each output of the register selects one of the 8 banks of 32K bytes through a chip-select input. A memory bank can be changed by changing the number in the register.

12-7 Average time =  $T_s$  + time for half revolution +  
+ time to read a sector.

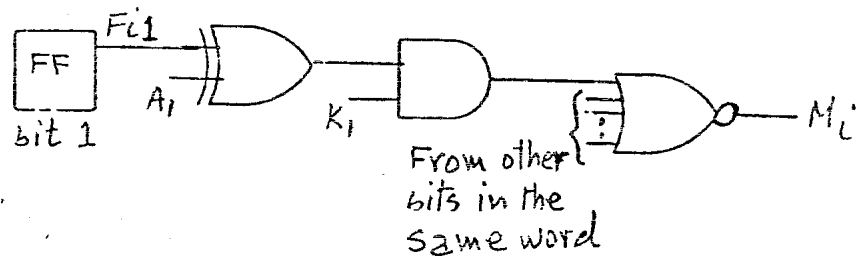

$$T_2 = T_s + \frac{1}{2R} + \frac{N_s}{N_t} \times \frac{1}{R}$$

12-8 An eight-track tape reads 8 bits (one character)  
at the same time. Transfer rate =  $1600 \times 120 = 192,000$   
characters/s

12-9

From Sec. 12-4:  $M_i = \prod_{j=1}^n [(A_j \oplus F_{ij})' + K_j']$

$$M_i' = \sum_{j=1}^n (A_j \oplus F_{ij}) K_j$$

12-10

A match occurs if  $T_i = 1$

$$\text{match} = M_i T_i$$

12-11

$$M_i = \left( \prod_{j=1}^n A_j F_{ij} + A_j' F_{ij}' + K_j' \right) \cdot (K_1 + K_2 + K_3 + \dots + K_n)$$

At least one key bit  $K_i$  must be equal to 1

12-12(c)

12-13

A  $d$ -bit counter drives a  $d$ -to- $m$  line decoder where  $2^d = m$  ( $m$  = No. of words in memory). For each count, the  $M_i$  bit is checked and if 1, the corresponding read signal for word  $i$  is activated.

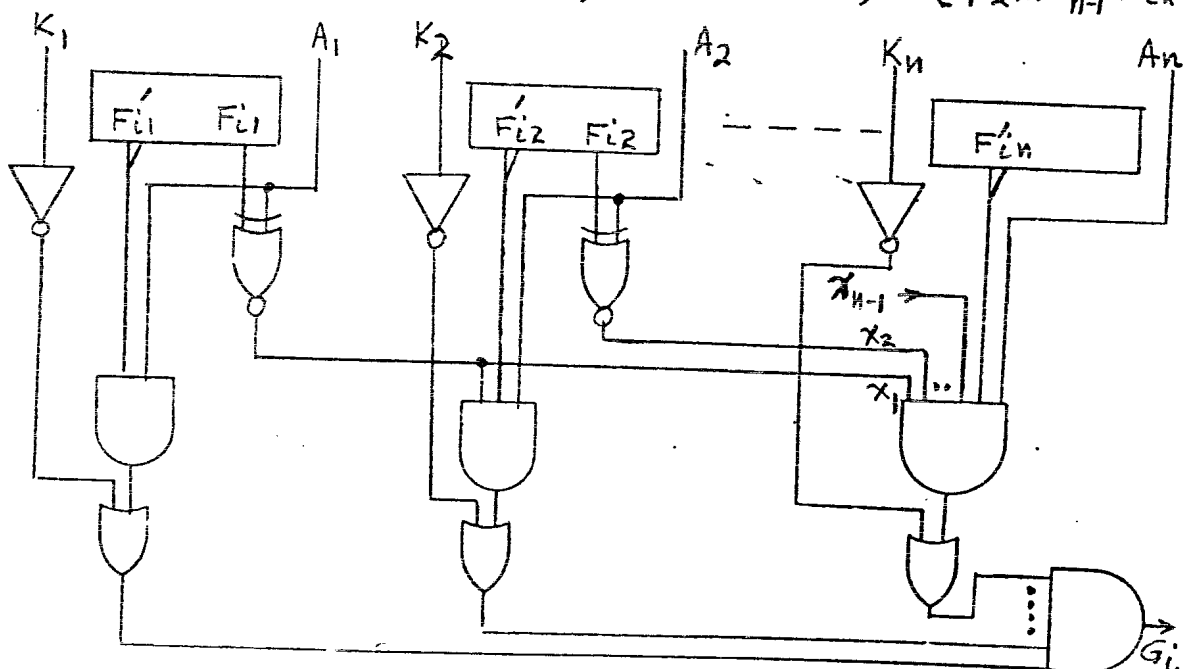

12-14

Let  $x_j = A_j F_{ij} + A'_j F'_{ij}$  (argument bit = memory word bit)

(a) Address space = 24 bits  $2^{24} = 16$  M words

(b) Memory space = 16 bits  $2^{16} = 64$  K words

(c)  $\frac{16 \text{ M}}{2 \text{ K}} = 8 \text{ K pages}$   $\frac{64 \text{ K}}{2 \text{ K}} = 32 \text{ blocks}$

## CHAPTER 13

13-1

Tightly coupled multiprocessors require that all processors in the system have access to a common global memory. In loosely coupled multiprocessors, the memory is distributed and a mechanism is required to provide message-passing between the processors. Tightly coupled systems are easier to program. Since no special steps are required to make shared data available to two or more processors, A loosely coupled system required that sharing of data be implemented by the messages.

13-2

The address assigned to common memory is never assigned to any of the local memories. The common memory is recognized by its distinct address.

13-3

$P \times M$  switches

13-4

$\log_2 n$  stages with  $\frac{n}{2}$  switches in each stage.

13-5

Inputs 0, 2, 4, and 6 will be disconnected from outputs 2 and 3.

13-11

As explained in the text, connect output PO from arbitrator 4 into input PI of arbitrator 1. Once the line is disabled, the arbitrator that releases the bus has the lowest priority.

13-12

Memory access needed to send data from one processor to another must be synchronized with test-and-set instructions. Most of the time would be taken up by unsuccessful test by the receiver. One way to speed the transfer would be to send an interrupt request to the receiving processor.

13-13

(a) Mutual exclusion implies that each processor claims exclusive control of the resources allocated to it.

(b) Critical section is a program sequence that must be completely executed without interruptions by other processors.

(Continued in next page)

### 13-13 (Continued)

- (c) Hardware lock is a hardware signal to ensure that a memory read is followed by a memory write without interruption from another processor.
- (d) Semaphore is a variable that indicates the number of processes attempting to use the critical section.
- (e) Test and set instruction causes a read-modify-write memory operation so that the memory location cannot be accessed and modified by another processor.

### 11-14

Cache coherence is defined as the situation in which all cache copies of shared variables in a multiprocessor system have the same value at all times. A snoop cache controller is a monitoring action that detects a write operation into any cache. The cache coherence problem can be resolved by either updating or invalidating all other cache values of the written information.
