Diagnostic laparoscopy—direct visualisation of corpus luteum, tubes; check tubal patency by insufflating blue dye from the cervix through the tubes to the peritoneal cavity.

Further investigations (if necessary)

Male

If azoospermia or severe oligospermia:

- serum FSH level (if 2.5 times normal, indicates irreversible testicular failure)—this is the most important endocrine test in the assessment of male infertility
- LH
- antisperm antibodies (in semen or serum)
- sperm function tests
- chromosome analysis: 46 XXY or 46 XXY/46 XY or microdeletion
- testosterone
- testicular ultrasound

Female

(Other investigations may be necessary.)

- Thyroid function tests: ? hypothyroidism
- Serum prolactin, FSH, LH androgen levels
- Sonohysterogram
- Endometrial biopsy
- Transvaginal ultrasound
- Hysteroscopy/laparoscopy
- CT of the pituitary fossa—if prolactin significantly elevated
- *Chlamydia* (cervical culture)

Note: Ovulation or its absence is best demonstrated by luteal progesterone.

Essential investigations are outlined in TABLE 117.3.

Table 117.3 Essential first-line investigations of the subfertile couple<sup>2</sup>

Basal body temperature chart and cervical mucus diary
Semen analysis
Serum progesterone (mid-luteal—day 21) in female
Transvaginal ultrasound
Rubella immune status (female)

Management principles<sup>5</sup>

- Both partners should be involved in management decisions since fertility is a couple's problem.
- Infertility can cause considerable emotional stress, including the taking or placing of blame by one partner or the other, and subsequent guilt feelings; hence sensitive and empathetic support is essential. This may include marital counselling.
- Since recent advances have helped this problem so much, there is no place for guesswork or for empirical therapy and early referral is necessary.

Fertility awareness

This education is helpful for couples:

- women always ovulate about 12–14 days before the period
- fertile mucus is copious, slippery and has the appearance of egg white (ovulation occurs within 24 hours)
- ova can survive up to 24 hours and sperm up to 5 days within the female genital tract
- the chance of fertilisation is best during days 10–16 of a 28-day cycle

## § Polycystic ovarian syndrome

PCOS is an ultrasound diagnosis—10 to 12 small cysts around the periphery of at least one ovary. About 50% of women have no other signs or symptoms.

PCOS is the above plus clinical symptoms—one of:

- oligomenorrhoea
- hirsutism
- acne
- obesity

PCOS has a strong hereditary basis and can begin in the pubertal years. There are variations of the syndrome, including normal menstruation (20%) and abnormal uterine bleeding (50%).

### General features<sup>8</sup>

Patients have some of the following (it is rare to have all):

- ovarian dysfunction—infertility, oligomenorrhoea, anovulation, tendency to miscarry, endometrial cancer
- androgen excess—hirsutism and acne
- obesity
- metabolic (insulin resistance) syndrome—upper truncal obesity, impaired glucose tolerance, hyperlipidaemia, hypertension, tendency towards type 2 diabetes
- ovarian abnormalities—multiple small follicles, stromal expansion

### Aetiology

The exact cause is unknown. There is a hereditary factor, and hormonal dysfunction resulting from several follicles failing to mature and release eggs, instead dying out on the ovarian surface. Some experts claim that the principal underlying disorder is insulin resistance with hyperinsulinaemia.

### Diagnosis/investigations

- Raised LH level with normal FSH levels (LH/FSH ratio >2)
- Raised serum testosterone level (not always)
- Transvaginal ultrasound (usually at least 12 follicles, small in size in an enlarged ovary)
- Possible endometrial biopsy

### Suggested screening for all women with PCOS<sup>8</sup>

- Smoking history
- Blood pressure

- Blood glucose levels
- Oral glucose tolerance test
- Fasting plasma insulin
- Fasting serum HDL and LDL levels

### Management strategies<sup>8</sup>

#### First-line<sup>4</sup>

- Lifestyle modification: weight reduction and exercise (the key—this alone may restore normal ovarian function)
- PCOS support group

#### Potential

- Screening and treat if necessary:
  - glucose intolerance and diabetes mellitus
  - hyperlipidaemia
  - hypertension
- Primary treatment of insulin resistance:
  - metformin
  - thiazolidinediones (glitazones)
- Ovulation induction—clomiphene/gonadotrophins
- Laparoscopic ovarian diathermy (failed medical treatment)
- Assisted conception

### Counselling the subfertile couple<sup>9</sup>

The counselling of subfertile couples has to be adapted to the level reached by the couple along the infertility pathway. The needs of each couple may be very different depending on their emotional nature, their lifestyle, and their moral, religious and ethical beliefs. However, their suffering can run very deep and deserves attention, time and opportunities for free expression of feelings and concerns.

The medical counselling model developed by Colagiuri and Craig<sup>9</sup> (see FIG. 5.1 in CHAPTER 5) is very useful as it empowers patients to make their own decision through facilitation as opposed to the directive and advisory medical model.

The couple are provided initially with accurate and appropriate information. Anxiety is alleviated by reassurance and by dispelling myths such as their problem being caused by an unfavourable position for intercourse, leakage of excess semen from the vagina or previous use of the pill.

The facilitation process enables the couple to ventilate any feelings of guilt, anxiety, fear, anger and sexuality. The style of questioning should aim to explore the influence that the problem has had on the

couple and then the influence they have over it. These processes then lead to decision making by the couple about further management strategies.

A graph of emotional responses to the infertility (see FIG. 117.3) can be used to help the couple explore their current and past emotional responses to their problem. Apart from helping them realise that their problem is not unique, it provides opportunities for ventilation of important feelings that can act as a basis for counselling.

## Treatment

If the problem has been identified, specific treatment needs to be prescribed by the consultant.

Treatable factors in female subfertility are tubular diseases, anovulation and endometriosis. In males the treatable causes are rare but include gonadotrophin deficiency, inherited congenital adrenal hyperplasia and simple occlusion of the vas deferens.

- Anovulation can be treated with ovulation induction drugs such as clomiphene, bromocriptine, gonadotrophins or GnRH.
- Endometriosis can be treated medically or surgically (peritubal adhesions).
- Male problems—little can be done (including testosterone and vitamins) to enhance semen quality. Corticosteroids may help if sperm antibodies are present. Consider in vitro

fertilisation (IVF) and related technology for male factor infertility, particularly intracytoplasmic sperm injection (ICSI) into the oocyte.

- Artificial insemination.
- Donor insemination.
- Severe tubal disease—use IVF and embryo transfer (IVF-ET).
- Unexplained subfertility—consider IVF, which depends on the woman's age and the couple's attitudes.

## Assisted conception<sup>10</sup>

This is the only option for subfertility/infertility due to azoospermia, anovulation and complete fallopian tube exclusion.

The main techniques are:

- assisted insemination (intra-uterine)
- ovulation
- IVF

## New NICE guidelines for fertility treatment

- NHS-funded IVF should be offered up to age 42 (in certain circumstances).
- Couples having conception difficulties should be offered treatment after 2 years of regular unprotected intercourse, instead of the current 3 years.

FIGURE 117.3 Emotional responses to infertility

Source: Reproduced with permission from Craig.<sup>9</sup>

- Those women under 40 also with 2 years of failure or 12 cycles of artificial insemination should be offered 3 full cycles of IVF with or without ICSI.
- Women aged 40–42 should be offered one full cycle of IVF with or without ICSI (with certain qualifications).
- Women with idiopathic subfertility should not be offered ovarian stimulation drugs such as clomifene, since they are considered ineffective.

Other guidelines can be accessed via the NICE website <[www.nice.org.uk/Guidance/CG156](http://www.nice.org.uk/Guidance/CG156)>.

## Evidence-based RCTs

The conclusion as published in *Clinical Evidence*<sup>11</sup> has summarised known benefits of infertility treatment (to date) as follows:

- ovarian disorders—clomiphene, laparoscopic ovarian ‘drilling’
- tubal infertility—IVF
- endometriosis—intra-uterine insemination with ovarian stimulation

## When to refer

A family doctor should perform the initial investigations of a couple with infertility, including

temperature chart, semen analysis and hormone levels, to determine whether it is a male or female problem and then organise the appropriate referral.

# 118 Sexual health

*The functional form of impotence fills the coffers of the quacks, and swells the list of suicides.*

RUTHERFORD MORRISON (1853–1939)

*Drink, sir, provokes the desire, but it takes away the performance.*

WILLIAM SHAKESPEARE (1564–1616), *MACBETH*, ACT 2, SCENE 1

Family doctors are often asked to provide advice and help for sexual concerns and are continually challenged to detect such problems presenting in some other guise. Since we deal with so much illness, including debilitating problems, and prescribe so many drugs, we must be aware of and sensitive to the possible implications of their various effects on sexual health.

Sexual disorders can be considered in three major groups: sexual dysfunction, sexual deviation and gender role disorders. This chapter largely confines itself to a discussion of sexual dysfunction.

## Sexual dysfunction

Sexual dysfunction in men refers to persistent inability to achieve normal sexual intercourse while in women it refers to a persistent lack of sexual satisfaction.<sup>1</sup>

Several studies have demonstrated that sexual concerns and problems are common, with a prevalence ranging from 10–70% of the population.<sup>2</sup> Difficult problems are summarised in **TABLE 118.1**. These studies have also indicated that patients are certainly willing to discuss their sexuality and wish their family doctors to become involved in counselling and management of their problems. Between 25% and 30% of sexual difficulties have an organic cause, while the remainder are emotional or psychogenic in origin.<sup>3</sup> The unique place of general practice and the family doctor provides ideal opportunities to address the sexual concerns of patients as the family doctor often has considerable insight into the family dynamics and first-hand perspective of the individuals involved.

The most common problem influencing an effective outcome is difficulty in communication between doctor and patient, which prejudices effective history taking and counselling. The problem is not content-related, much of which is based on commonsense, but the ubiquitous problem of communication.

**Table 118.1** Sexual dysfunction: difficult problems

Sexual desire:

- low libido

Sexual arousal:

- erectile impotence
- failure of arousal in women

Sexual orientation/activity:

- homosexuality
- fetishism

Orgasm:

- premature ejaculation
- retarded ejaculation
- orgasmic dysfunction in women

Male problems:

- low libido
- erectile difficulties
- premature ejaculation
- failure to ejaculate, or retarded ejaculation

Female problems:

- low libido
- failure of arousal
- vaginismus
- orgasmic difficulties
- dyspareunia

If, as a practitioner, you counsel on the assumption that astounding ignorance about sexuality still exists in our society, you will be amazed at the results and at how relatively simple it is to help so many confused people who often have unrealistic expectations of their partners and themselves.

## Opportunistic sexuality education

The family doctor has many opportunities to provide education in sexuality throughout the lifelong care of the patient and it is wise to have a strategy that matter of factly incorporates enquiries and information about sexual health.

Examples include:

- antenatal and postnatal care
- contraceptive requests
- parents concerned about their children's sex play
- serious illness—medical and surgical
- adolescent problems
- menopause problems

## Presentation of sexual concerns

Although some patients may present directly with a complaint of sexual dysfunction, many will be less direct and use some other pretext or complaint as a 'ticket of entry' for their sexual concerns (see TABLE 118.2). Despite a seemingly terse approach the issue must be recognised and treated with considerable importance. This may mean scheduling an appropriate time to discuss the concerns.

**Table 118.2** How sexual issues may present in family practice<sup>2</sup>

Minor non-sexual complaint—'entry ticket'
Specific sexual concern
Marital or relationship problem
Non-sexual problem (as perceived by the patient)
Sexual enquiry and counselling as part of illness management
Sexual enquiry as part of total health check-up
Infertility
Menopausal problems

Sometimes patients are unaware of an association between their medical problem and underlying sexual issues.<sup>2</sup> Doctors may recognise such an association and initiate a tactful psychosocial history that includes questions about sexuality. Examples are chronic backache, pelvic pain, vaginal discharge, tiredness, insomnia and tension headache.

## The effect of illness on sexual function

Doctors seldom enquire about the impact of an illness on the sexual function of patients and their

partners and tend to be unaware of the sexual needs of elderly people (see TABLE 118.3). It is most appropriate to enquire about these issues in our patients—e.g. the postmyocardial infarction patient,

**Table 118.3** Medical conditions affecting sexual performance

Cardiovascular:

- previous myocardial infarction
- angina pectoris
- peripheral vascular disease
- hypertension and its treatment

Respiratory:

- asthma
- COPD

Endocrine:

- diabetes mellitus
- hypothyroidism
- hyperthyroidism
- Cushing syndrome

Neurological:

- multiple sclerosis
- neuropathy
- spinal cord lesions
- Parkinson disease

Musculoskeletal:

- arthritis

Depression

Kidney:

- kidney failure

Urological problems:

- prostatectomy
- phimosis
- Peyronie disorder
- priapism

Hepatobiliary:

- cirrhosis

Surgical:

- vaginal repair
- hysterectomy
- others

Trauma:

- motor vehicle accidents

Cancer

Other:

- Klinefelter syndrome

the postprostatectomy patient, the patient taking antihypertensives or other drugs (see TABLE 118.4), and the post-mastectomy or post-hysterectomy patient. Diabetes deserves special attention as 27–55% of diabetic men reported some erectile difficulties.<sup>2</sup>

**Table 118.4** Drugs affecting sexual arousal and function

Male	Female
Alcohol	Alcohol
Anticholinergics	Anti-androgens
Anti-epileptics	Antidepressants (selected) e.g. SSRIs
Antihistamines	Anti-epileptics
Antihypertensives	Antihypertensives (selected)
Benzodiazepines	CNS depressants
Cytotoxic drugs	Hormone contraception e.g. combined oral contraceptive
Disulfiram	Marijuana
Marijuana	Narcotics
Narcotics	
Oestrogens	
Psychotherapeutic drugs	

## Taking a sexual history

It is important to be alert for psychiatric disorders and situational factors and not to predict a person's sexual disposition. Avoid being too formal or too familiar but aim to display a wise, matter-of-fact, empathic, commonsense rapport. Tactfully explore the patient's attitude to sexuality and examine the relationship. Ideally, it is best to see a couple together if the problem is occurring within a steady relationship. As a practitioner, you have to be comfortable with your own sexuality and learn to be relaxed, confident and understanding when dealing with sexual concerns.

Enquiry about possible child sexual abuse is an important part of the history.

## Probing questions for a suspected sexual problem

- Do you have any trouble passing urine or any vaginal discharge (women)?

- Are you sexually active?
- What is the physical side of your marriage/relationship like?
- Do you have any pain or discomfort during intercourse?
- Is your relationship good?
- Do you communicate well? Generally? Sexually?
- Do you have any difficulties in your sexual relationships?
- What is your sexual preference?
- Are you attracted to men, women or both?
- Have you experienced the 'coming out' process?
- What drugs are you taking?
- Do you take recreational drugs (e.g. alcohol, nicotine, marijuana, other illicit drugs)?

## Specific questions about sexuality

- Do you get aroused/turned on? What turns you on?
- Do you look forward to making love?
- Do you spend much time on love play?
- Does lovemaking make you feel happy and relaxed?
- Do you worry about getting pregnant (women)?
- What do you do about contraception?
- Do you worry about getting an STI?
- Do you worry about getting AIDS?
- How often do you reach a climax during lovemaking?
- How often do you have intercourse, or sexual activity without intercourse?
- Do you 'come' together?

## Female

- Do you have enough lubrication? Are you wet enough?
- Do you find intercourse uncomfortable or painful?

## Male

- Do you have trouble getting a full erection?
- How long does it take you to 'come' after you insert your penis?
- Do you 'come' too quickly?

## Background history for an admitted problem

- Can you think of any reasons why you have this problem?
- What sex education did you have as a child? At home or at school?
- Were your parents happily married?

- Were sexual matters something that could be discussed in the home?
- Did you come from a religious family?
- Did you receive warnings or prohibitions as a child?
- What was the family attitude to masturbation, extramarital sex, menstruation, contraception, etc.?
- What is your attitude to masturbation?
- Were you fondled or sexually abused by an adult, especially a member of the family?
- Were there healthy shows of affection such as touching or hugging between family members?
- Did you have any upsetting sexual experiences during childhood and adolescence?
- What was your first sexual experience like?

## Examination

The routine medical examination should include the basics such as urinalysis, BP measurement, genital examination and neurological where indicated. A careful vaginal and pelvic examination should be an opportune educational experience for the patient and an exercise in preventive medicine.

## Investigations

No particular routine tests are recommended. Tests for male erectile dysfunction (impotence) are outlined later in this chapter. Tests that may help exclude significant causes of low libido are those for diabetes, liver dysfunction, thyroid dysfunction and endocrine dysfunction. Endocrine dysfunction tests include prolactin, free testosterone, FSH, LH and oestradiol estimations. Other investigations may include pelvic ultrasonography, colposcopy or laparoscopy.

## Exploring sexual myths

The acceptance in part or in total of many sexual myths that have prevailed in our society may have affected the relationship of a couple, especially in the context of the modern trend towards openness in discussing sexuality. It is worthwhile to help patients identify whether any of these myths have influenced their concerns by exploring common myths and their significant consequences to the individual or couple.

Sexual myths that could be explored include:<sup>2</sup>

- men need sex, women need love
- men need more sex than women
- men must be the instigators
- men know all about it
- sex = intercourse
- in this enlightened age everyone understands sexual issues

## Sexual myths in the male<sup>4</sup>

- A hard erection is essential for good sex.
- A man should not show his feelings.
- A real man is always horny and ready for sex.
- As a person gets older there is no change in sexual interest, response or performance.
- As a person gets older there is a loss of interest in sex.
- Sexual performance is what really counts.
- Men are responsible for their partner's sexual pleasure.
- Sex must lead to orgasm.
- A man and his partner must reach orgasm simultaneously.

## Basic sexual counselling

The family doctor can learn to be an effective sex counsellor. Sex counselling can be emotionally demanding and, while good interviewing skills, interest, support and basic advice are important, additional skills are needed to be an effective counsellor.

The fundamental methods involve:<sup>5</sup>

- good communication and allowing a 'comfortable' exchange of information
- giving the patient 'permission' to talk openly about sexual matters
- providing basic 'facts of life' information
- dispelling sexual myths, correcting other misunderstandings
- gentle guidance for appropriate insight
- de-emphasising the modern-day obsession with performance and orgasm and emphasising the value of alternative forms of sexual expression (e.g. caressing, kissing, and manual and oral stimulation)
- reducing the patient's anxiety
- bolstering self-images affected by feelings of rejection, avoidance, guilt, resentment or incompetence
- reassuring the patient that he or she is normal (where appropriate)

Inappropriate doctor behaviour is presented in TABLE 118.5.

An interesting realisation after counselling families in sexuality is that most of the problems are not difficult and often spring from basic ignorance of normal sexual function; it's simply a matter of setting the record straight. The greatest hurdle is 'getting started' with delineating the problem. Once that barrier is crossed, satisfactory results appear to follow.

Table 118.5 Sexual counselling: inappropriate doctor behaviour

Overfamiliarity
Being too formal
Being too talkative
Blunt questioning
Being judgmental
Making assumptions about the other's sexuality
Imposing one's own beliefs and standards
Dogmatism
Tackling problems beyond one's experience

Another significant realisation is that sexual problems can be grossly underestimated. Human beings generally have a basic craving for intimacy, touching, stroking and loving sex. Apparently ‘good’ harmonious relationships can lack this type of intimacy, which may lead to various psychosomatic manifestations.

Ideally the family doctor should undertake a course in sexual counselling to promote confidence in the counselling process. Patients can be taught basic methods (where appropriate) such as sensate focus, squeeze or stop–start techniques for premature ejaculation, self-exploration using Kegel pelvic floor exercises, fantasy conditioning with DVDs, and behaviour modification. Complex problems, especially those involving erectile dysfunction, infertility and sexual deviations or perversions, demand referral to an expert.

### The PLISSIT counselling model

The PLISSIT counselling model developed by Annon<sup>5</sup> can be used to build the skills needed to deal with sexual problems, especially if there is a psychological element.<sup>3</sup>

The mnemonic PLISSIT stands for:

- P = Permission giving
- LI = Limited Information
- SS = Specific Suggestion
- IT = Intensive Therapy

‘Permission giving’ allows patients to talk about sex, ask questions, feel guilty and so on. Their problems are shared with a reflective listening confidant.

Most medically trained people can probably provide the limited information required about sexual physiology and behavioural patterns.<sup>3</sup> ‘Specific suggestion’ provides ideas for self-help and may include key reference books, and relevant audiotapes or VHS/DVDs (see box titled Further reading). DVDs can certainly arouse interest, ideas and motivation for a renewal of sexual activity. With a little support and permission, the patient can take simple action to remedy or improve a problem.

Intensive therapy, whether psychiatric or emotional, calls for deeper involvement and can be a dangerous area for the inexperienced. Referral to the appropriate practitioner is usually advisable.<sup>3</sup>

### Analogous roles of the penis and clitoris

An explanation of the analogous roles of the penis and clitoris (proposed by Cohen and Cohen) is a very useful strategy for educating patients and helping them to understand the relationship of intercourse and penile and clitoris stimulation with orgasm. The simple model (see FIG. 118.1) can be shown to patients to explain, for example, why some women are unable to achieve orgasm by intercourse alone, especially using the conventional missionary position.<sup>2,6</sup> It can readily be explained that clitoral stimulation in women is analogous to penile stimulation in men. Such information is very helpful for women and also

**FIGURE 118.1** Analogous structures in male and female genitalia

Source: Reproduced with permission from G and M Cohen, *Canadian Family Physician*, 852, 31: 767–71<sup>2</sup>

to men who may perceive themselves as inadequate lovers. The use of such explanatory aids greatly facilitates the educational process and makes it more 'comfortable' for all concerned.

## Female orgasmic difficulties

It is necessary to determine whether the woman has been anorgasmic or can experience orgasms from other activities such as masturbation, manual or oral stimulation, even though she is non-orgasmic during intercourse.

The use of the Cohen model (see FIG. 118.1) is very helpful in emphasising the importance of clitoral stimulation.

Therapy includes:

- sensate focus exercises<sup>7</sup>
- advice on the most appropriate positions for intercourse
- permission to use:
  - sexual aids: books, magazines
  - visual tapes
  - self-stimulation

## § Dyspareunia

Painful intercourse is a source of considerable distress both physically and psychologically for the sufferer

and also for her partner. It may be one of the 'hidden agenda' presentations with a vague complaint such as 'I am uncomfortable down below'. Tact and sensitivity is very important in management.

The patient needs to be encouraged to talk freely during history taking with an opportunity to express what they believe is the basic problem. Montgomery claims that most cases (about 80%) of dyspareunia have a physical cause and careful physical examination is mandatory. In particular it is helpful to keep in mind vulval vestibular syndrome, which has subtle physical signs (see CHAPTER 107). Important causes are listed in TABLE 118.6. A common problem encountered is the presence of painful scar tissue following an episiotomy, especially after the first vaginal delivery, so it is worth asking about this potential problem because some women are reluctant to raise the issue.

Management of dyspareunia involves treating the organic cause and giving appropriate advice about the use of lubricants, including oestrogen creams.

## § Vaginismus

Vaginismus is the involuntary contraction of muscles around the introitus (outer third of vagina) in response to and preventing the possibility of penetration. It can be classified as primary or secondary. In primary

**Table 118.6** Important causes of dyspareunia

Pain worse on insertion
Physiological—inadequate lubrication
Provoked vestibulodynia syndrome
Vaginitis in chronic candidiasis
Vulvar dermatoses
Postnatal perineal scarring
Incompletely ruptured hymen
Vulvovaginal atrophy (e.g. postmenopausal)
Vaginismus
Pain worse on deep penetration
Endometriosis
PID
Pelvic adhesions
Ovarian and uterine tumours
Postnatal

vaginismus tampons will probably never have been inserted. It is often related to provoked vestibulodynia (vestibular hypersensitivity—see **CHAPTER 107**). In some instances vaginismus may be voluntary.

It is not an uncommon cause of unconsummated marriages, usually associated with fears of internal damage, pregnancy, learned negative attitudes to sex and past sexual trauma. The problem usually responds well to brief therapy. This includes explanation of the anatomy and physiology with the use of a hand-held mirror during examination.

The patient or couple can use a lubricant such as baby oil, KY gel, Vaseline or oestrogen cream to make intercourse comfortable. The couple will benefit from a sensate focus program, which includes the most comfortable position for intercourse, controlled by the woman usually in a superior position. Otherwise, progressive vaginal dilation can be practised using lubricated fingers or graduated dilators.

## § Erectile dysfunction

Erectile dysfunction (impotence) is the inability to achieve or maintain an erection of sufficient quality for satisfactory intercourse. It doesn't refer to ejaculation, fertility or libido. Patients often use the term to refer to a problem of premature ejaculation, hence careful questioning is important.

Erectile dysfunction is a common problem. US data shows the prevalence to be 39% of males at 40 years and 67% of males aged 70.<sup>8</sup>

The most effective and practical approach to the man with erectile dysfunction is to determine the response to an intrapenile injection, where prostaglandin E<sub>1</sub> is preferred to papaverine.

## Causes<sup>9</sup>

- Psychogenic: related to stress, interpersonal or intrapsychic factors (e.g. depression, marital disharmony, performance anxiety)
- Neurogenic: disorders affecting the parasympathetic sacral spinal cord (e.g. multiple sclerosis); it usually develops gradually
- Vascular
- Diabetes
- Hypertension
- Chronic kidney disease
- Urological problems (e.g. Peyronie disorder, pelvic trauma and surgery)
- Hormone disorder
  - androgen deficiency (e.g. testicular disease)
  - hypothyroidism
  - hyperprolactinaemia (rare) → impotence and loss of libido due to secondary testosterone deficiency
- Drug-induced:
  - alcohol
  - cocaine, cannabis
  - nicotine (four times the risk by age 50)
  - antihypertensive agents
  - pharmaceutical preparations
- Ageing
- Unknown

## Practice tip

Erectile dysfunction may be the first symptom of atherosclerotic disease (e.g. CAD).

## History

The nature of the onset of erectile dysfunction is very important and this includes the nature of the relationship. Of particular importance is a drug history, including alcohol, nicotine, street drugs and pharmaceutical agents, particularly antihypertensives (beta blockers and thiazide diuretics), hypolipidaemic agents, anti-androgens (prostate cancer treatment), antidepressants, antipsychotics and H<sub>2</sub>-receptor antagonists. Ask about nocturnal and early morning erections.

## Examination

Genitourinary, cardiovascular and neurological examinations are important. This should include a

rectal examination and examination of the vascular and neurological status of the lower limbs and the genitalia, especially the testicles and penis. Check the cremasteric and bulbocavernosus reflexes.

## Investigations

First-line blood tests:

- free testosterone ? androgen deficiency
- thyroxine ? hypothyroidism
- prolactin ? hyperprolactinaemia
- luteinising hormone
- glucose

Other blood tests to consider:

- LFTs, especially GGT (alcohol effect)
- kidney function tests

## Nocturnal penile tumescence

This is an electronic computerised test used to detect and measure penile erections during REM sleep. Normally, there are 3–5 spontaneous erections lasting 20–35 minutes. The test helps to differentiate between psychogenic (normal studies) and organic (poor function). A very simple screening test is to use the snap gauge device.

## Dynamic tests of penile function<sup>7</sup>

These tests include injections of drugs into the corpus cavernosum (which is the simplest method) to assess function. If the patient does not have overt psychogenic erectile dysfunction and the diagnosis is uncertain, the response to intracavernosal injections of prostaglandin E (PGE) can be tested. A good response to PGE indicates that the patient has psychogenic or neurogenic impotence (e.g. due to pelvic nerve division during colon resection). Responses at higher doses indicate an incomplete organic disorder (e.g. partial arterial occlusion, venous leak, or diabetic neuropathy—early). Total failure to respond suggests arterial occlusion or an idiopathic disorder of the corpora cavernosa.

## Management

Address modifiable risk factors, including medications (if feasible), psychosocial issues and lifestyle (see NEAT, CHAPTER 7). Management should comprise appropriate patient education including a DVD of the specific recommended treatment and technique. The partner should be included in the discussions and general management process with an emphasis on bolstering the couple's self-image, which may have been affected by feelings of rejection or avoidance.

## Psychogenic disorders

These will involve psychotherapy and sex behavioural modification as outlined earlier in the chapter under Basic sexual counselling. Referral to a consultant may be appropriate.

## Hormonal disorders

- Testosterone for androgen deficiency: primary testicular disease (e.g. Klinefelter syndrome) or gonadotrophin deficiency

*Stepwise trial*

- 1 Oral: testosterone undecanoate (Andriol)
- 2 IM: testosterone enanthate (Primoteston Depot) or testosterone esters (Sustanon)
- 3 Subcutaneous implantation: testosterone implants (last 5–6 months)

- Thyroxine for hypothyroidism
- Bromocriptine for hyperprolactinaemia

## Oral medication

PDE-5 inhibitors: the phosphodiesterase type 5 (PDE-5) inhibitors are the first-line oral medication (see TABLE 118.7). They are about 70% effective but not very effective for neurogenic ED. They do not initiate an erection but enhance whatever erection the man is capable of having. Sexual stimulation is necessary. They are contraindicated if the patient has unstable angina, recent stroke or myocardial infarction. Use with nitrates should be avoided and a nitrate should never be taken within 24 hours of use. The interaction with nitrates can result in a severe and potentially fatal hypotensive response. PDE-5 inhibitors have the potential for side effects, especially headache. Treatment is not considered a failure until a full dose has been trialled 7–8 times.<sup>9</sup> In some cases combining them with alcohol or fatty foods can delay their onset of action.<sup>10</sup>

Four basic rules:

- sexual stimulation is necessary
- avoid fatty foods
- minimal or no alcohol
- no nitrates

## Intracavernosal injection

- Alprostadil intracavernosal injections:
  - self-administered after supervised teaching (use a penile model if available)
  - start with a lower dose, 2.5–5 mcg
  - maximum of three a week
  - spontaneous erection in 5 minutes
  - if prolonged erection > 2 hours take 120 mg pseudoephedrine orally—repeat at 3½ hours if necessary (provided not hypertensive)

Table 118.7 Phosphodiesterase type 5 inhibitors<sup>10</sup>

	Sildenafil (Viagra)	Tadalafil (Cialis)	Vardenafil (Levitra)
Dosage (mg)	25, 50, 100	5, 10, 20	5, 10, 20
Usual starting dose (1 hour pre i/c)	50 mg	10 mg	10 mg
Onset of action	30–60 min	1–2 hours	30–60 min
Alcohol effect	Possibly	Possibly	Possibly
Nitrate contraindication	Yes	Yes	Yes
Class side effects	Headache, nasal stuffiness, facial flushing, dyspepsia		
Specific side effects	Blue vision, diarrhoea	Myalgia, back pain	Visual disturbance

The cooperation of the partner is essential and urological back-up must be arranged.

Transurethral alprostadil (Muse)

Urethral pellet: initial dose 250 mcg

Vacuum constriction

Vacuum constriction devices may have a place in management, especially in men in long-term relationships and where pharmacological therapies are inappropriate. About 80% effective.<sup>9</sup>

Surgery

- Malleable penile prosthesis
- Inflatable penile prosthesis (see FIG. 118.2)
- Vascular surgery where appropriate

§ Premature ejaculation

Premature ejaculation is defined as ‘ejaculation that occurs sooner than desired’ or, more precisely, as ‘persistent or recurrent ejaculation, before, on or shortly after penetration and associated with significant personal distress’. For the latter the intravaginal ejaculatory time is <2 minutes.<sup>11,12</sup> It is a common problem with a prevalence of 24% in 16–60 year olds.<sup>11</sup> It may not be clearly described by the patient so a careful history is necessary to define the problem. Ensure that the person is not suffering from erectile dysfunction. Both patient and partner may complain about the problem.

There are many approaches to treatment but they are aimed either at prolonged ejaculatory control or at satisfactory sexual activity without preoccupation

FIGURE 118.2 An inflatable prosthesis, showing positioning of the components

with ejaculation and anticipation of better control with time and experience.

The standard management strategies to enhance ejaculatory control include a combination of three techniques:<sup>7</sup>

- graded sensate focus
- Semans' 'stop-start' technique<sup>12</sup>
- Masters and Johnson's squeeze technique<sup>13</sup>

### Pharmacological treatment

The tricyclic antidepressant, clomipramine, has been variously reported to be very effective (e.g. 25–50 mg/day).<sup>14</sup> The SSRIs have also been reported as effective—using dapoxetine 30 mg or sertraline 50 mg or paroxetine 20 mg, all once daily or about 3 hours before intercourse—but are still being evaluated. Trial the agents for 3–6 months and then slowly titrate down to cessation.

An alternative is to apply a local anaesthesia such as lignocaine 2.5% + prilocaine 2.5% cream thinly to the glans and distal shaft of the penis 10–20 minutes before intercourse.<sup>14</sup> Wash off any residual cream before contact and warn of hypersensitivity reactions.

## Sexual orientation and gender identity concerns

Sexual orientation or gender identity is a very important issue that GPs should handle competently and sensitively. It is incumbent on the general practitioner to be aware of the special health concerns of members of the gay, lesbian, bisexual and transsexual (GLBT) community and practise an empathic understanding of their specific organic and psychosocial concerns. It would be true to say that in the past we have been handicapped by ignorance, prejudice, physician homonegativity and social homophobia—an issue probably reinforced by the AIDS epidemic of the 1980s. Studies have revealed that significant numbers of gay men (approximately 40%) did not reveal their sexual orientation to their GP even when presenting with an STI.<sup>15,16</sup>

People experiencing uncertainty about their gender identity often present with high levels of distress, anxiety and guilt.

Gay men and women may have higher rates of depression, suicide, alcoholism, smoking and organic illness than their heterosexual counterparts.<sup>11</sup> They are also at increased risk of family rejection and being victims of violence.

DSM-5 refers to 'gender dysphoria' and outlines diagnostic criteria, including problems of 'discomfort'.<sup>17</sup>

### Definitions and facts

Sexual orientation refers to adult stable sexual attractions, desires and expression towards other men and women and which cannot be determined until emerging adulthood.<sup>15</sup> Homosexuality is the condition in which the libido is directed towards one of the same sex. Lesbians are women whose primary emotional and sexual relationships are with other women. The term is derived from a community of women living on the Greek island of Lesbos around 600 BC.

Gay is the comparable term for men but is generally used to describe both lesbians and gay men and perhaps bisexual people of both sexes. The term 'gay' is a more respectful and acceptable term, which seems to have gained more positive recognition from the 'mardi gras' gay festivals.

In response to the recognition that a description for behaviour, rather than an assertion of sexual identity was needed, the term 'men who have sex with men (MSM)' was coined. Some social researchers prefer the term 'male to male sexual practices', which acknowledges that practices rather than the person are at issue.<sup>18</sup>

The estimated incidence of homosexuality has varied from 2% to 13% over the past 60 years but the most recent general estimation lies between 3% and 10%, with a higher incidence in males.<sup>15,16</sup> At the present time there is no proven theory of causation although it is no longer considered to be one's conscious individual choice or preference but rather a complex, innate, sociobiological determinant. Genetic and hormonal hypotheses have not been verified to date. Interestingly, gender identity develops in the first four years of life.<sup>19</sup>

It is clear that no one factor causes an individual to become homosexual or heterosexual. In 1948 Kinsey concluded that sexual orientation fell on a continuum from exclusive homosexuality at one end to exclusive heterosexuality at the other end, and this perspective remains today. It is noteworthy that Freud determined that homosexual orientation appeared stable in most adults and resistant to modification through analysis.

It is also clear, based on information from GPs, that bisexuality is quite common in society. The Australian Study of Health and Relationships found that 0.9% of men were bisexual and that 6.0% reported sexual experience with other men including those identified as heterosexual.<sup>15</sup> In fact the numbers may be considerably higher.

### Recurring problems for gay people

- Health service providers often insensitive to their needs
- Prejudice and discrimination in rural communities
- The threat or reality of violence
- Isolation and loneliness
- Relationships, stress and anxiety
- Homophobia leading to reduced sense of self-esteem and self-worth
- Safety of sexual activity
- Concerns regarding infectious diseases: hepatitis A, B and C, HIV enteric infections, other STIs in gay men
- Concerns regarding fertility, safe insemination practices and raising children in lesbians

### Issues and concerns commonly raised

The following are typical of some of the questions and issues posed to the author over several years in family practice:

- How normal or freakish is it to feel like this?
- I hate to think of what my parents will think.
- How should I best approach them?
- How on earth can I tell my spouse (and kids)?
- Should I try out an opposite sex affair?
- Is it advisable to go ahead with the marriage?
- Can I be changed to be 'normal'?
- What about hypnosis or hormones or a little operation?
- My religious beliefs are a worry. The conflict is devastating.
- What can I do to be safe?
- Is there anyone or a group I can contact about this?

Managing this health area is difficult and highlights the value of sexual counselling courses, although a listening ear, an acceptance of our patient's natural feelings and commonsense supportive advice is the basis of counselling. The PLI component of the PLISSIT model works very well in general practice. As a rule it is wise to resist giving much specific advice but rather listen and then guide. The appropriate answers to the above questions are that it is important to accept oneself as one is, to let sexuality evolve, not to rush into experimental heterosexual affairs, be sceptical about treatments claiming to change orientation as there is no evidence that any are successful, to find close trusted friends to share concerns, and to inform the closest family members as soon as possible and then others. It is appropriate to refer to those with expertise for more intensive therapy.

### Developmental stages of the coming out process<sup>20</sup>

Coleman has proposed identifiable stages of homosexual identity formation, with each stage having unique health challenges for both the patient and the health provider, especially stress, depression and suicide risk in stage 1:

- 1 pre-coming out
- 2 coming out
- 3 exploration and experimentation
- 4 first relationships
- 5 integration

### Some guiding management principles<sup>15</sup>

- Don't assume that all patients, including those married with children, are heterosexually orientated—use neutral terms.
- Ask good opening questions:
  - 'How would you see your sexual orientation? Straight, gay or bisexual?'
  - 'What has been hard for you in your sexual development?'
- The great majority of openly gay men, lesbian women and bisexual persons will experience few or no problems with their sexual orientation.<sup>15</sup>
- A prime reason for dissatisfaction with being homosexual and desiring heterosexuality is feeling lonely and isolated. These people can be counselled successfully through training in social skills and assertiveness.
- Be aware of significant stress-related mental problems and somatisation disorders in people during the pre-coming out and coming out stages.
- Studies have shown that about 30–40% of gay teens have attempted or seriously considered suicide—many times above the national average.
- There is no evidence that reorientation strategies are successful.
- Don't assume stereotyped sexual behaviour and therefore unsafe sex or risk of STIs.
- Anal intercourse only occurs in about one-third of male homosexual encounters.
- It is necessary to differentiate homosexual orientation from transgender activities.
- In counselling it is important that the view of individuals as being either homosexual or heterosexual is not reinforced and that the person as an individual is the prime focus of attention.

- ‘In understanding and managing sexual orientation concerns, the central issue is to appreciate that homosexual individuals cover the same wide spectrum of humanity as heterosexual persons and the division of people into “heterosexual” or “homosexual” groups is arbitrary.’<sup>15</sup>

## § The small penis syndrome

In general practice it is not uncommon to counsel men and adolescent males for anxiety, sometimes pathological, about the relatively small size of their penis and its possible impact on sexual adequacy. Some males appear to be preoccupied with the size of their penis, especially when reaching the sexually active phase of their life. It is a manifestation of abnormal body image perception.

This attitude is related to the myth that a man’s sexual performance depends on the size of his penis. The patient may present with minor (often trivial) non-sexual complaints as a ‘ticket of entry’ into the consulting room or perhaps as a manifestation of anxiety or depression related to preoccupation with penile size.

### Measurement

Irrespective of physique or facial features, most men are concerned about penile size.<sup>18</sup> However, as for all parts of the body, there is considerable variation in size and shape of the penis.

The average adult penis measurements are summarised in TABLE 118.8.<sup>8,21</sup>

Table 118.8		Average penile size (symphysis pubis to meatus)	
		Flaccid	Erect
Length	centimetres	7.5–10.5	12–18
	inches	3–4	5–7
Circumference	centimetres	6–10	8–12
	inches	2.5–4	4–6

### Psychological factors

Virility and performance are not related to the size of the penis.<sup>21</sup> Orgasm in the female does not depend on deep vaginal penetration. Penile size was found to have little relationship to a partner’s satisfaction from sexual intercourse. The vagina, which is 10 cm (4 inches) long in the unstretched state, tended to accommodate itself to the size of the penis.

## Counselling

Counselling the male with fears about sexual inadequacy related to penis size is based on providing reassuring information about the preceding anatomical and physiological facts. The reasons for the patient’s concerns should be explored.

It should be explained that size generally has no relationship with physical serviceability or with the capacity to satisfy a partner.

## Sexuality in the elderly

The sexual needs of the elderly in our society tend to be ignored or misunderstood. While sexual activity and sexual interest generally decline with age, our elderly are not asexual and their sexuality has to be recognised and understood. They have the same needs as younger people—namely, the need for closeness, intimacy and body contact.<sup>22</sup> The same studies have shown that significant numbers of elderly people continue to enjoy both sexual interest and activity throughout their lives. Their activity is determined by factors such as marital status, knowledge about sexuality, prior patterns of sexual expression, privacy and physical health. Intercourse in the elderly may be difficult or not possible so it is appropriate to advise ‘outercourse’ which is an extension of foreplay and which provides loving body contact and reassuring intimacy.

A common problem is that termination of sexual activity stems from the belief that people feel they are ‘over the hill’ and have a performance anxiety. This applies particularly to people who have invariably experienced orgasm with intercourse and then start failing to maintain this pattern.

Many women require additional lubrication and need advice about the use of oestrogen cream or lubricating jelly. Testosterone cream has been reported to be beneficial for elderly women with vulvar dryness and fissuring.

The application of the PLISSIT model applies to the elderly with an emphasis initially on permission.

Sexually transmitted infections (STIs) are a group of communicable infections, usually transmitted by sexual contact. Their incidence has been of widespread significance during the past 30 years and they are a major public health problem in all countries.

The STIs have developed a high profile in modern society with the advent of HIV infection, hepatitis B, *Chlamydia trachomatis* as a major cause of PID, the emergence of penicillin-resistant gonorrhoea and the increasing frequency of the human papilloma (wart) virus infection with its association with cervical cancer. STIs are summarised in [TABLE 119.1](#).

- The presentation of STI in children, especially vaginitis, should alert practitioners to consider sexual abuse.
- HIV infection, which is predominantly sexually transmitted, should be considered in any person at risk of STI as well as IV drug users. It must be appreciated that it can present as an acute febrile illness (similar to Epstein–Barr mononucleosis) before going into a long asymptomatic ‘carrier’ phase.
- Nucleic acid amplification tests (NAAT) such as PCR on urine and other specimens have been a great advance in management of STIs.

## Key facts and guidelines

- In Western society most patients with STIs are in the 15–30 years age group.
- Gonorrhoea and syphilis are no longer the commonest STIs.
- Chlamydial infection, hepatitis B, human papillomavirus and genital herpes are now common infections.
- Not all STIs are manifest on the genitals.
- Not all genital lesions are STIs.
- The 5% rule:<sup>1</sup>
  - 5% of urethritis (STI) in males is lower UTI
  - 5% of lower UTI in females is urethritis (STI)
- *Chlamydia trachomatis* is now the commonest cause of urethritis.
- *Chlamydia* typically causes dysuria in men but may be asymptomatic. It usually causes no symptoms in women.
- Gonorrhoea may cause no symptoms, especially in women.
- STIs such as Donovanosis, lymphogranuloma venereum and chancroid occur mainly in tropical countries. Donovanosis is common in Indigenous Australians.

All sexually active young people aged 15–29 years who are at high risk and asymptomatic should be tested annually for *Chlamydia* with a first-catch urine or genital swab.<sup>2</sup>

## Who is at risk of STIs?<sup>2,3</sup>

- People aged 15–29 years, especially if:
  - under age 20 years
  - Aboriginal or Torres Strait Islander
  - inconsistent or no condom usage
- People with a past history of STIs
- Men who have sex with men (MSM), especially:
  - unprotected anal sex
  - >10 partners in past 6 months
  - participate in group sex
- Known contacts of a person with an STI
- People who have sex overseas
- Indigenous patients
- People who don’t use barrier forms of protection consistently with casual contacts
- People who have recently changed sexual partners
- Neonates born to infected mothers

**Table 119.1** Sexually transmitted or acquired infections: causative organisms and treatment<sup>2,4</sup>

STI	Causative organism/s	Treatment
<b>Bacterial</b>		
Gonorrhoea	<i>Neisseria gonorrhoeae</i>	Ceftriaxone IM + azithromycin
Chlamydia urethritis	<i>Chlamydia trachomatis</i>	Azithromycin (o)
Epididymo-orchitis	<i>Chlamydia trachomatis</i> (usual) Other	Azithromycin (o) then doxycycline + ceftriaxone (if gonorrhoea suspected)
Cervicitis and PID	<i>Neisseria gonorrhoeae</i> <i>Chlamydia trachomatis</i>	Mild: doxycycline + metronidazole + azithromycin (o) + ceftriaxone (IM) (if <i>N. gonorrhoeae</i> ) Severe: add cephalosporins (IV use in hospital)
Syphilis	<i>Treponema pallidum</i>	Benzathine penicillin: best to refer
Bacterial vaginosis	<i>Gardnerella vaginalis</i> Other anaerobes	Metronidazole or clindamycin 2% cream
Granuloma inguinale (Donovanosis)	<i>Calymmatobacterium granulomatis</i>	Azithromycin or doxycycline
Chancroid	<i>Haemophilus ducreyi</i>	Ciprofloxacin or azithromycin: best to refer
Lymphogranuloma venereum	<i>Chlamydia trachomatis</i>	Doxycycline or azithromycin: best to refer
<b>Viral</b>		
AIDS	HIV-1, HIV-2	Refer to Internet site and specialist
Genital herpes	Herpes simplex virus	Aciclovir, famciclovir or valaciclovir
Genital warts	Human papillomavirus	Podophyllotoxin paint or imiquimod cream
Hepatitis	HBV, HCV	Interferon, antiviral agent
Molluscum contagiosum	Pox virus	Various simple methods e.g. cryotherapy
<b>Fungal</b>		
Vaginal thrush (possible)	<i>Candida albicans</i>	Any antifungal preparation e.g. clotrimazole
<b>Protozoal</b>		
Vaginitis, urethritis	<i>Trichomonas vaginalis</i>	Metronidazole or tinidazole
<b>Balanoposthitis</b>		
<b>Arthropods</b>		
Genital scabies	<i>Sarcoptes scabiei</i>	Permethrin 5% cream
Pediculosis pubis	<i>Phthirus pubis</i>	Permethrin 1% lotion

## Asymptomatic STI testing

Since most STIs are asymptomatic, it is important to offer appropriate opportunistic testing to people at risk. A discrete history is also important—a detailed history and examination may serve as a barrier to proceeding to testing.

*Note:* Tests for STIs including HIV should be performed only with the patient's knowledge and consent and after adequate counselling

## Taking a sexual history<sup>3</sup>

(See also CHAPTER 118.) Doctors and patients alike usually find discussing sexual matters uncomfortable, even when STI testing is requested. A skilful approach will help overcome barriers or discomfort. A non-judgmental approach and appropriate body language will facilitate patient disclosures on sensitive sexual issues. It is important to use open questions with well-chosen words for sexual behaviour, practice and orientation.

## The full female STI check-up<sup>4</sup>

Family doctors may be consulted by a sex worker or other sexually active female requesting a thorough check-up. Such people require certificates from time to time and may not have access to a public STI clinic. The visit should provide an opportunity for counselling and education about her health risks.

The screening program includes:

- full sexual history
- physical examination: genital appearance, skin, breasts, oropharynx, lymph nodes, abdomen, careful anogenital examination
- investigations (guide only):
  - Pap test: 6–12 monthly
  - first-catch urine for NAAT (PCR)
  - endocervical swabs for *Chlamydia* and gonorrhoea 1–3 monthly (depending on risk)
  - high vaginal swab and ‘wet film prep’ for vaginal pathogens 1–3 monthly
  - HIV antibody test (with informed consent)—not ordered more often than every 3 months
  - syphilis screening test: RPR/VDRL (as for HIV)
  - hepatitis B screening: if negative, organise hepatitis B vaccination
  - rubella IgG as baseline test: if negative, advise rubella vaccination

Consider:

- throat swabs for gonorrhoea (if oral sex without condoms)
- urethral swab for gonorrhoea and *Chlamydia* if urinary symptoms
- anorectal swab for gonorrhoea if sexual history indicates need

## STI screening guidelines for MSM<sup>3</sup>

- First-catch urine for *Chlamydia* NAAT (PCR)
- Pharyngeal swab for gonorrhoea culture
- Anal swab for gonorrhoea culture and PCR and *Chlamydia* PCR
- Serology for HIV, syphilis, hepatitis A and B
- Hepatitis C (only if HIV positive or an injecting drug user)

Recommend 3–6 monthly tests for men at considerable risk (e.g. unprotected anal sex).

## Person of any age requesting ‘STI check-up’

- urine PCR or genital swab for *Chlamydia*
- serology for hepatitis B (if not vaccinated or immune)
- syphilis and HIV

## Presenting conditions<sup>1</sup>

Most STIs fit into one (or sometimes more) of the easily definable categories of clinical presentation:

- urethritis—discharge and/or dysuria
- vaginitis—discharge + irritation + odour + dyspareunia
- cervicitis/PID (possible symptoms):
  - pelvic pain/lower abdominal pain (PID)
  - backache (PID)
  - mild discharge
  - mucopurulent cervical discharge
  - dyspareunia (PID)
  - dysuria
- ulcer
- lump
- pruritus
- rash with:
  - secondary syphilis
  - HIV infection
  - hepatitis B

### § Vaginitis

Vaginitis is presented in more detail in [CHAPTER 106](#). The pathogens to consider are:

- *Candida albicans* → vaginal thrush
- *Gardnerella vaginalis* → bacterial vaginosis
- *Trichomonas vaginalis* (uncommon in Australia)
- *Chlamydia trachomatis*
- *Gonococcus*

### § Urethritis

The important STIs that cause urethritis are gonorrhoea and chlamydia, which is three times more common than gonorrhoea.<sup>1,4</sup> Non-specific urethritis (NSU) is commonly due to *C. trachomatis* but may also be caused by *Ureaplasma*, *Mycoplasma hominis* and other unknown organisms.

## Symptoms

### In males

The main symptoms (if present) are:

- a burning sensation when passing urine (dysuria)
- a penile discharge or leakage (clear, white or yellow)

Sometimes there is no discharge, just pain. Sometimes the infection is asymptomatic. Most often the symptoms are trivial with chlamydia. Although a creamy pus-like discharge is typical of gonorrhoea (see [FIG. 119.1](#)), and a less obvious milky-white or

clear discharge typical of chlamydia (see FIG. 119.2), it is often difficult to differentiate the causes from the discharge. In some males the only complaint is spots on the underpants or dampness under the foreskin. Epididymo-orchitis in the young male should be presumed to be a complication of an STI urethritis.

FIGURE 119.1 Gonococcal urethritis: typical purulent discharge

FIGURE 119.2 Chlamydia urethritis: the discharge is usually milky in colour but can also be yellow

### In females

Gonorrhoea often causes no symptoms but can produce vaginal discharge or dysuria or PID. Chlamydia usually causes no symptoms but may cause vaginal discharge, dysuria or PID. It is the commonest source of PID, which can result in infertility.

### Gonococcal infection of anus and throat

In both sexes, gonorrhoea may infect the anus or oropharynx. Anorectal gonorrhoea may be asymptomatic or may present as a mucopurulent anal discharge (a feeling of dampness) and anal discomfort.

Oropharyngeal gonorrhoea may be asymptomatic or present as a sore throat or dysphagia.

### Collection of specimens

Take swabs:

- standard swab for *Gonococcus* (from the urethral meatus and anus in males) and the endocervical canal in females: place into standard transport medium

In both sexes the NAAT tests (PCR or ligase chain reaction: LCR) are the tests that usually provide the diagnosis of chlamydial infection.<sup>1,5</sup> The PCR *Chlamydia* urine test (95% specific) is the preferred test (in both sexes) on the first-catch urine specimen (especially females) or at a later time (don't urinate for at least one hour after last void, then first 10 mL passed in ordinary MSU jar). These two tests are also used to diagnose gonorrhoea. However, urine PCR is less reliable in women for gonorrhoea than an endocervical specimen.

### Special notes

- Testing for *Chlamydia* and *Gonococcus* can be performed on a Pap test.
- It is possible for women to do self-collecting from tampons.
- Take an MSU in males who have dysuria but no discharge.  
or  
Take urethral swabs from females who have dysuria but not frequency. The presence of large numbers of coliform in a urethral swab culture is suggestive of bacterial cystourethritis (lower UTI).
- If there are gonococci on Gram stain, treat with azithromycin and doxycycline; if no gonococci on Gram stain, treat with azithromycin; and if microscopy unavailable give both antibiotics.

## § Chlamydia urethritis

### Incubation period

Symptoms appear 1–2 weeks after intercourse, although the incubation period can be as long as 12 weeks or as short as 5 days (compare with incubation period of gonorrhoea—about 2–3 days).

It is an underdiagnosed disorder since many cases are asymptomatic; hence the value of screening.<sup>6</sup> Woman can carry *Chlamydia* silently for 12 months or more.

**Treatment<sup>5,7</sup>**

azithromycin 1 g (o) single dose (preferred)  
 or  
 doxycycline 100 mg (o) 12 hourly for 7 days

A second course may be required if the symptoms persist or recur (about one in five cases).

Second-line treatment is erythromycin 500 mg qid for 7 days. All sexual partners, even if asymptomatic, need to be treated in the same way. If a female partner has proven cervicitis the treatment must be as for PID. Sexual intercourse must be avoided until 7 days after both partners have received treatment. The importance of compliance must be stressed.

Reinfection rates are high so retest after 3 months.

**Prevention**

Using condoms for vaginal and anal sex provides some protection.

**§ Gonococcal infection****Incubation period**

Gonorrhoea has a short incubation period of 2–3 days and symptoms usually appear 2–7 days after vaginal, anal or oral sex. The incubation period can be as long as 3 weeks.

**Other manifestations of gonorrhoea**

- Epididymo-orchitis and prostatitis (males)
- Urethral stricture is not uncommon in males

**Treatment**

If there is infection with penicillin-resistant gonococci (PPNG) due to  $\beta$ -lactamase (penicillinase) production (a problem prevalent in South-East Asia and eastern Australia), the following should be used.<sup>1,7</sup> The organism is becoming resistant to quinolone.

ceftriaxone 500 mg IM (dissolved in lignocaine 1–2 mL 1%) as a single dose (preferred)

plus either

azithromycin 1 g (o) as a single dose (to cover possible co-infection with chlamydia)

or

doxycycline 100 mg (o) bd for 10 days

Where PPNG prevalence is low:

amoxycillin 3 g (o) as a single dose + probenecid 1 g (o)

plus

azithromycin 1 g (o) as a single dose (if chlamydia has not been ruled out)

If the above antibiotics are inappropriate (e.g. pregnancy):

erythromycin 500 mg (o) bd for 10 days

or

roxithromycin 300 mg (o) daily for 10 days

Sexual partners must be examined and treated and sexual intercourse must be avoided until the infection has cleared. Follow-up culture (after 4 weeks) is advisable, especially in females.

**Prevention**

Using condoms for vaginal, anal and oral sex provides good protection. Sexually active men and women (especially those at risk) need at least annual checks.

**§ Cervicitis**

Cervicitis is often a forerunner to PID. If there is cervicitis only (mucopus at the cervix without uterine pain or tenderness) treat as for urethritis (the likely organisms are *C. trachomatis* or *N. gonorrhoeae*)—ceftriaxone IM + azithromycin (o).

**§ Pelvic inflammatory disease**

PID is covered in more detail in **CHAPTER 103**. It is not always an STI. The intra-uterine device is a possible cause. Often multiple pathogens are involved in the infection.

Common pathogens are *N. gonorrhoeae* and *C. trachomatis*. Swabs from the cervical os frequently underestimate the organisms involved and thus treatment needs to be directed to all possible pathogens.

Mucopurulent cervicitis is now known to be an early sign of PID, usually due to *Chlamydia*.<sup>1</sup>

**Specimen collection**

Cervical and urethral swabs for urethritis for *N. gonorrhoeae* and *C. trachomatis*

**Treatment**

Therapy for PID is deliberately vigorous because the major aim is to prevent infertility and the consequent need for IVF in the long term. The detailed treatment is outlined in **CHAPTER 102**.

**Summary<sup>1,7,8</sup>**

Mild to moderate infection:

ceftriaxone 500 mg IM or IV (as single dose)  
 plus

azithromycin 1 g as a single dose  
plus  
metronidazole or tinidazole  
Severe PID: hospitalise for IV therapy

**§ Ulcers**

STI causes of genital ulcers are presented in **TABLE 119.2**. Most genital ulcers are herpes—any small genital ulcer that is superficially ulcerated, scabbed, red-edged, multiple and painful is invariably herpes.

Syphilis rates have increased in recent years and may get overlooked, especially with anal chancres.

Chancroid is almost always an imported infection.

**Table 119.2** STI causes of anogenital ulcers

	Pain	Specimen collection
Common		
Herpes simplex virus	Yes	Swab for viral HSV PCR
Uncommon		
<i>Treponema pallidum</i> (primary chancre)	No	Dry swab for ulcer PCR Exudate for dark ground microscopy and serum for leutic screen (reagin or treponemal tests)
<i>Haemophilus ducreyi</i>	Yes	Scraping for Gram stain and special culture
<i>Calymmatobacterium granulomatis</i> (granuloma inguinale)	No	Scraping for special stains

**§ Genital herpes<sup>2</sup>**

The incubation period is usually 3–6 days but can be longer. A firm microbiological diagnosis is recommended. Swab for culture or PCR (very sensitive).

HSV 1 and 2 account for over 90% of cases. HSV 1 is becoming more common as a cause of a first episode of genital herpes, although recurrent genital herpes is usually caused by HSV 2.<sup>7</sup> Clinical diagnosis is unreliable. Many go unrecognised or are asymptomatic yet are chronic lifelong infections.

**Symptoms**

With the first attack there is a tingling or burning feeling in the genital area. A crop of small vesicles then

appears; these burst after 24 hours to leave small, red, painful ulcers. The ulcers form scabs and heal after a few days. The glands in the groin can become swollen and tender, and the patient might feel unwell and have a fever.

The first attack lasts about 2 weeks.

**Males**

The virus usually affects the shaft of the penis, but can involve the glans and coronal sulcus, and the anus (see **FIG. 119.3**).

**FIGURE 119.3** Usual sites of vesicles/ulcers in males

**Females**

Vesicles develop around the opening of, and just inside, the vagina and can involve the cervix and anus (see **FIG. 119.4**). Passing urine might be difficult, and there can be a vaginal discharge. In about 25%, the cervix is the only site of lesions and these cases may be asymptomatic. This occult presentation is a problem and a high index of suspicion is needed. The problem could be a simple tingling around the saddle area or a scratch-like lesion on epithelium.

In both sexes, it can affect the buttocks and thighs. A serious but uncommon complication, especially in females, is the inability to pass urine.

**FIGURE 119.4** Usual sites of vesicles/ulcers in females

### Specimen collection

Take a swab from a deroofed vesicle for culture, direct immunofluorescence or PCR (best test).<sup>4</sup> Blood tests for HSV are not recommended

### Transmission

It can be caught by direct contact through vaginal, anal or oral sex. Rarely is it transferred to the genitals from other areas of the body by the fingers. Sometimes in stable relationships it appears spontaneously. A new type-specific herpes serology (EIA) is available for testing partners of someone with known HSV 2 infection.<sup>5</sup>

### Recurrence

Half of those who have the first episode have recurrent attacks; the others have no recurrence. Fortunately, attacks gradually become milder and less frequent, last 5–7 days and usually stop eventually. Recurrences after many months or years can be precipitated by friction or rubbing as in sexual intercourse or tampon use in women. Emotional stress is a common trigger. Condom use reduces the risk by about 50%.

### Treatment (antimicrobial therapy)

Start with oral treatment as this is the most important since topical aciclovir is now considered ineffective.

#### Topical treatment<sup>2,7</sup>

Pain relief can be provided in some patients with topical lignocaine 2% gel but caution is needed since it may cause sensitisation with prolonged use.

#### Oral treatment—first episode

For the first episode of primary genital herpes (preferably within 24 hours of onset):

aciclovir 200 mg 6 hourly for 7–10 days or until resolution of infection<sup>5,8</sup>

or

valaciclovir 500 mg (o) bd for 7–10 days

This appears to reduce the duration of the lesions from 14 days to 5–7 days.<sup>1</sup> The drugs are not usually used for recurrent episodes, which last only 5–7 days.

#### Episodic genital herpes (within 24 hours)<sup>2</sup>

valaciclovir 500 mg (o) bd for 3 days

or

famciclovir 250 mg (o) 4 tablets statim, repeat in 12 hours

or

aciclovir 200 mg (o) 4 tablets tds for 2 days

### Suppressive treatment

Very frequent recurrences (six or more attacks annually) benefit from continuous low-dose therapy for 6 months (e.g. valaciclovir 500 mg (o) once daily). Interrupt at 6 months to evaluate.

### Supportive treatment (advice to the patient)

- Rest and relax as much as possible. Warm salt baths can be soothing.
- Icepacks or hot compresses can help.
- Painkillers such as paracetamol or paracetamol + codeine give relief.
- If urination is painful, pass urine under water in a warm bath.
- Keep the sores dry; dabbing with alcohol or using warm air from hairdryer can help.
- Leave the rash alone after cleaning and drying; do not poke or prod the sores.
- Wear loose clothing and cotton underwear. Avoid tight jeans.

### Counselling

'A chat beats medicine for herpes'. Since genital herpes is distressing and recurrent, patients are prone to feel stressed and depressed and can be assisted by appropriate counselling and support. Sexual abstinence should be practised while lesions are active.

### Syphilis

In Australia syphilis, which has re-emerged, usually presents either as a primary lesion or through chance finding on positive serology testing (latent syphilis).

It is important to be alert to the various manifestations of secondary syphilis. The classification and clinical features of syphilis are presented in **TABLE 119.3** (see also **CHAPTER 29**).

### Transmission

- Sexual intercourse (usual common mode)
- Transplacental to fetus
- Blood contamination: IV drug users
- Direct contact with open lesions

### Management

The management of syphilis has become quite complex and referral of the patient to a specialist facility for diagnosis, treatment and follow-up is recommended.

**Table 119.3** Classification and clinical features of syphilis

Type	Time period	Infectivity	Clinical features
Acquired			
Early (within first 2 years of infection)			
• Primary	10–90 days, average 21	Infectious	Hard chancre Painless Regional lymphadenopathy
• Secondary	6–8 weeks after chancre	Infectious	Coarse non-itchy maculopapular rash Constitutional symptoms (may be mild) Condylomata lata Mucous membrane lesions
• Early latent	Months to 2 years	Infectious	No clinical features but positive serology
Late (after the 2nd year of infection)			
• Late latent	2 years plus	Non-infectious	
• Tertiary (now rare)		Non-infectious	Late benign: gummas or Cardiovascular or Neurosyphilis
Congenital			
Early	Within first 2 years of life	Infectious	Stillbirth or failure to thrive Nasal infection: 'snuffles' Skin and mucous membrane lesions
Late	After second year of life	Non-infectious	Stigmata (e.g. Hutchinson teeth) Eye disease CNS disease Gummas

### Recommended antimicrobial therapy

Early syphilis (primary, secondary or latent) of not more than one year's duration:<sup>7</sup>

benzathine penicillin 1.8 g IM as a single dose  
or

procaine penicillin 1 g IM daily for 10 days

For patients hypersensitive to penicillin:

doxycycline 100 mg (o) 12 hourly for 14 days

For HIV-infected patients benzathine penicillin 1.8 g IM weekly for 3 doses.<sup>9</sup>

Note:

- sex should be avoided until ulcers healed
- sexual contacts in the past 3 months should have treatment
- repeat serology at 3 months and then 3 monthly

Late latent syphilis: more than 1 year or indeterminate duration:

benzathine penicillin 1.8 g IM once weekly for 3 doses, or procaine penicillin

Cardiovascular and neurosyphilis and congenital syphilis are also treated with penicillin but require special regimens.

### Lump

Common pathogens:

- wart (papilloma) virus—condylomata acuminata, venereal 'warts', anogenital warts

- *Molluscum contagiosum* (pox) virus

Uncommon:

- *Treponema pallidum*—condylomata lata

Physiological:

- Fordyce cysts, which are enlarged ectopic sebaceous glands in the mucosa, are a differential diagnosis of a genital lump

## Diagnosis

Warts and *Molluscum contagiosum* have a distinctive appearance and are readily diagnosed by inspection (see FIG. 119.5). Removal for diagnosis is usually not required. Condylomata lata are multiple lesions that resemble warts superficially but are covered by abundant exudate. They occur in secondary syphilis and leucic screen is positive.

FIGURE 119.5 *Molluscum contagiosum* on and around the penis. They were on the buttocks of his female partner.

## Treatment of warts<sup>7,10</sup>

Counselling and support are necessary. Not all genital warts are sexually transmitted.

Warts may be removed by chemical or physical means, or by surgery. Treatment needs to be individualised. For small numbers of readily accessible warts the simplest treatment is:<sup>6,7,10</sup>

cryotherapy weekly until resolved

or

podophyllotoxin 0.5% paint or 0.15% cream (a more stable podophyllin preparation):

- apply bd with plastic applicator for 3 days

- repeat in 4 days and then weekly for 4–6 cycles if necessary

*Note:* The normal surrounding skin should be spared as much as possible. Avoid this treatment in pregnancy and breastfeeding on cervical, meatal or anorectal warts.

or

topical imiquimod 5% (Aldara) cream applied to each wart by the patient three times a week at bedtime (wash off after 6 to 10 hours) until the warts disappear (usually 8–16 weeks)

All females (including partners of males with warts) should be referred to a specialised clinic where colposcopy is available, because of the causal link of warts to cervical cancer.

## Treatment of *Molluscum contagiosum*<sup>2</sup>

These lesions often resolve spontaneously. There are many treatment choices to provoke resolution. These include:

- cryotherapy with liquid nitrogen e.g. cryospray (for a few seconds)—can be repeated after several weeks
- application of 25% podophyllin in tincture of benzoin compound
- imiquimod 5% applied sparingly tds

Other destructive methods such as piercing with a needle, application of phenol or diathermy are seldom performed due to issues of pain and potential scarring.

## § Itch

Common pathogens:

- *Sarcoptes scabiei* (scabies)
- *Phthirus pubis* (pubic lice)
- *C. albicans*:
  - vulvovaginitis—females
  - balanitis—males

Non-STI itchy rashes on genitals include dermatitis and psoriasis.

## Diagnosis

*Scabies:* inspection on scraping and microscopy.

*Inspection:* scabies is diagnosed by a very itchy, lumpy rash. It is rare to find the tiny mites, but it may be possible to find them in the burrows, which look like small wavy lines.

*Pubic lice:* inspection for moving lice and nits (eggs) on hair shaft.

*C. albicans:* swab for Gram stain and *Candida* culture.

## Treatment

### Scabies<sup>5,10</sup>

permethrin 5% cream if >2 months of age. Apply to whole body from jawline down (include every flexure and area), leave overnight, then wash off. Wash clothing and linen after treatment and hang them in sun.

or

benzyl benzoate 25% emulsion left for 24 hours before washing off; repeat after 7 days

The whole family and close contacts must be treated, regardless of symptoms, which can take weeks to develop. One treatment is usually sufficient. It can be repeated in a week if necessary.

*Note:* Persistence of the itch after treatment is common. If the itch has not abated after 7 days, re-treat. After this, reassurance is usually all that is required. Also prescribe a topical antipruritic (e.g. crotamiton cream for 3–5 days or a topical corticosteroid or an oral antihistamine for the itch).

### Pubic lice

permethrin 1% lotion: apply to pubic hair and surrounding area, leave for 20 minutes and then wash off

or

pyrethrins 0.165% with piperonyl butoxide 2% in foam base; apply as above

Shaving pubic hair is also effective. Bed clothes and underwear should be washed normally in hot water after treatment and hung in the sun to dry. Repeat the treatment after 7 days. Sometimes a third treatment is necessary. Sexual contacts and the family must be treated (young children can be infested from heavily infested parents). Where the lice or the nits are attached to eyelashes, insecticides should not be used: apply white soft paraffin (e.g. Vaseline) liberally to the lashes bd for 8 days. Then remove the nits with forceps.

### Candidiasis

topical imidazole (e.g. clotrimazole 1% applied 2–3 times daily)

## Extragenital STIs

### § Viral hepatitis

Sexual activity is a factor in the transmission of hepatitis B (in particular), hepatitis A (where faecal–oral contact is involved), hepatitis C (probably occasionally) and hepatitis D.<sup>1</sup>

### § Hepatitis B

In Western societies, sexual transmission of HBV is a common mode of spread and there is a higher prevalence in homosexual men and prostitutes. HBV prevalence in homosexual men is correlated with insertive and receptive anogenital contact and oro–anal contact.

There is no specific therapy for hepatitis B, so prevention is important. Interferon  $\alpha$ -2 and lamivudine or tenofir can be used for complications such as chronic active hepatitis.

### Prevention<sup>4</sup>

Several prevention strategies are available; they include:

- immunisation
- prevention of infection in health care establishments
- management of exposure (needle stick injuries, etc.)
- management of infants of mothers who are hepatitis B carriers
- condoms, which offer some reduction of risk of sexual transmission
- personal hygiene

### Immunisation

Immunisation should be encouraged in hepatitis B marker-free people at risk of acquiring this infection. At-risk groups include sexual partners of carriers, institutional individuals, MSM, sex workers and drug addicts. Some health workers are exposed to risk.

### Management of exposure

Sexual partners of acute cases and chronic carriers who are negative for surface antigen (HBsAg) and antibody can be offered hepatitis B immunoglobulin, and routine hepatitis B immunisation should be commenced.

### § Hepatitis C

Although there have been doubts about the potential for sexual transmission of hepatitis C, Tedder et al. in 1991<sup>11</sup> demonstrated evidence for the sexual transmission of HCV but the epidemiological evidence is not strong.

### § HIV infection

HIV infection (colloquially called AIDS, although this represents only the severe end of the disease

spectrum) is predominantly transmitted by IV drug use in the community. In Australia about 80% of HIV cases are related to IV drug use and the rest are mainly sexually transmitted.<sup>12</sup> The important risk factors in infected men are receptive anal intercourse and multiple sexual partners.

### Sexual transmission to women<sup>4</sup>

Although the heterosexual partners of infected men are at risk of infection, spread to and from women has been relatively uncommon in developed countries, but now appears to be increasing significantly. In central Africa, heterosexual spread is an important means of transmission. Genital ulcerative diseases such as syphilis and genital herpes may be associated with an increased risk of heterosexual transmission.

HIV infection is considered in more detail in CHAPTER 27.

### When to refer<sup>13</sup>

- Syphilis:
  - probably all suspected or confirmed cases but certainly for suspected tertiary syphilis
  - HIV-positive patients, and
  - suspected treatment failure
- Pubic lice and scabies:
  - unresolved rash or itch despite apparently appropriate treatment
- Genital warts:
  - urethral or cervical warts
  - associated cervical HPV changes on cytology
  - refractory warts
- Gonorrhoea or non-specific urethritis:
  - if complications, pelvic spread or extragenital problems develop, or if symptoms persist after two courses of antibiotics

### Contact tracing

It is important to contact partners of those presenting with more serious STIs. Government guidelines recommend that for patients with asymptomatic infection (e.g. *Chlamydia*, gonorrhoea), partners in the previous 12 months should be contacted and they should refer sexual contact partners within 30 days of the onset of symptoms. A discreet letter sent to the contact is advisable.<sup>14</sup>

There are several helpful websites including <www.letthemknow.org.au>, which assist with sending anonymous emails or text messages to contacts.

### Practice tips

- Do not presume that the patient or his/her partner has acquired an STI outside their relationship.
- The itch of scabies or pubic lice can be distressing: prescribe the topical antipruritic (crotamiton cream) and/or an oral antihistamine.
- Reassure the patient that the itch will gradually subside over a few weeks (especially with scabies). This allays anxiety that may lead to overzealous self-medication.
- Make every attempt to confirm or exclude genital herpes, using the appropriate investigations.
- Use aciclovir or similar antivirals for first episodes of genital herpes and for all recurrences.
- Twelve golden rules of management are presented in TABLE 119.4.

**Table 119.4** STIs: Twelve golden rules of management (Sexual Health Society of Victoria)

- 1 An STI can only be diagnosed if the possibility is considered.
- 2 An adequate sexual history is paramount.
- 3 A proper history and careful examination must precede laboratory investigations.
- 4 Remember the sexual partner(s)!
- 5 Treatment consists of the appropriate antibiotic in correct dosage for an adequate period of time.
- 6 A patient concerned about STIs is probably an 'at risk' patient.
- 7 Counselling and education are fundamental to STI management.
- 8 Penicillin will not cure NSU.
- 9 *Not* all vaginal discharges are thrush.
- 10 Multiple, painful genital ulcers are most often due to herpes simplex.
- 11 Prompt, accurate treatment of PID is necessary to preserve fertility.
- 12 Remember the three Cs—Consent, Confidentiality and Counselling—of HIV antibody testing.

### Good communication

*Note:* Tests for STIs, including the HIV antibody test, should only be performed with the patient's knowledge and consent and after adequate counselling. An appointment should be made to give results person to person, irrespective of the results.

## Acknowledgment

Professor John Turnidge has given permission to adopt his categories of presenting conditions.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Chlamydial urethritis
- Gonorrhoea
- Hepatitis B
- Herpes: genital herpes
- HIV infection and AIDS
- Lice: pubic lice
- Pelvic inflammatory disease
- Warts: genital warts

# Intimate partner violence and sexual assault

120

*The root of Solomons seale when applied, taketh away in one or two nights, any bruise, blacke or blue spots gotten by falls or womens wilfulnesse, in stumbling upon their hasty husbands fists, or such like.*

John Gerard (1545–1612)

Intimate partner (or domestic) violence is defined by the World Health Organization as ‘any behaviour within an intimate relationship that causes physical, psychological or sexual harm to those in the relationship’. On the other hand, abuse can be of an elderly parent by the children or of some other member of the household to another member. It usually results from abuse and/or imbalance of power in close relationships. One person in the relationship consistently dominates or threatens with power and the abused victim gradually gives over more power.

A major problem in dealing with intimate partner violence (IPV) is that it is hidden and the victims are reluctant to divulge the cause of their injuries when visiting medical practitioners.

## Key facts and checkpoints<sup>1</sup>

- Between one-quarter and one-third of relationships experience violence at some time.
- In 90–95% of cases the victims are women.
- Ten per cent of women have been violently assaulted in the last year.
- Twenty-two per cent of homicides in Queensland in 1982–87 were spouse murders.
- In violent families with children, 90% of children witness the violence and 50% of children are victims of violence.
- Four per cent of relationships will experience chronic domestic violence (in 20% this occurs before marriage).
- Less than 20% of those who abuse their spouse abuse some other person.<sup>2</sup>
- Alcohol is a factor in 50% of IPV incidents (i.e. not the sole cause; it does make violence easier, and is used as an excuse). Other factors include work stress/pressure, financial stress and illness. However, there are no excuses for domestic violence.
- Pregnancy is a high-risk time for victims of domestic battering.

- Fifty per cent of people know someone affected by IPV, but one-third refuse to speak about it or get involved in any way because they regard it as a ‘private matter’.
- It is estimated that between 65% and 75% of women killed by abusive partners are killed while leaving or after leaving the relationship.<sup>3</sup>
- One in five people think that domestic violence is acceptable in certain circumstances.

We usually think of domestic violence in terms of physical violence but it can take many forms.<sup>4</sup> These include:

- physical abuse
- psychological abuse
- economic abuse
- social abuse (e.g. isolation)
- sexual abuse

## Possible presentations<sup>3</sup>

- Physical injuries: usually bruising caused by punching, kicking or biting; also fractures, burns, genital trauma
- Physical symptoms (e.g. back pain, headache, abdominal pain, chronic diarrhoea, vague symptoms, sexual dysfunction, anxiety)
- Sleeping and eating disorders
- Psychological problems (in both the woman and her children, e.g. depression, somatiform disorders, anxiety disorders, stress syndrome, including panic attacks)
- Pregnancy and childbirth (e.g. unwanted pregnancy, miscarriages, antepartum haemorrhage, poor prenatal care)
- Suicide attempts

The physical injuries are rarely overlooked but the other symptoms are frequently overlooked.

A study by Stark et al.<sup>5</sup> defines a three-stage sequence to the battering syndrome:

- *Stage 1*: woman presents with injuries in the central anterior regions of the body (face, head and torso).
- *Stage 2*: multiple visits to clinics, often with vague complaints.
- *Stage 3*: development of psychological sequelae (alcohol, drug addiction, suicide attempts, depression).

## Diagnosis

It is important to have a high index of suspicion and recognise and manage the problem to prevent further violence. Diagnosing the problem, which is usually 'hidden', can be a challenge to the skill of the GP. If you suspect domestic violence—ASK! Talk to the woman alone:

- How are things at home?
- How are things with your spouse/children?
- Did anything unusual happen to bring about these injuries?
- Has there been any violence towards you?
- You seem to be having a hard time.

It is vital to believe the woman's story. Women are most likely to seek help from their family doctor in preference to any other agency.<sup>6</sup> The doctor has to take the initiative because patients rarely complain about the violence.<sup>3</sup> They may present up to 30 times before they take action to end the violence.<sup>4</sup>

### Barriers to communication about abuse<sup>7</sup>

- Concerns about confidentiality
- Perceptions about doctors:
  - do not ask directly
  - have no time
  - are not interested
- Embarrassment
- Fear of involving police/courts
- Fear of shaming family
- Fear of partner hurting or killing them

## Assessment

- Delineate the problem: pattern of violence; effect on the woman and her children; resources available to women; social/cultural environment.
- Examine and investigate presenting symptoms.

- Check for coexisting injuries (common target areas are breast, chest, abdomen and buttocks). Inspect the ears, teeth and jaw.
- Check the patient's general health status.
- Look for signs of alcohol or drug abuse.
- Keep accurate records and consider taking photographs.
- X-rays are helpful and may show old fractures.

## Victims

The victims come from all socioeconomic and cultural groups. As a rule they enter the relationship as normal, independent, competent women but gradually lose their coping ability and self-esteem and may become compliant victims.<sup>1</sup> This has been demonstrated by Hazelwood and colleagues in their investigations of sexual sadists.<sup>2</sup> Unfortunately, many victims believe that somehow they deserve their punishment.

Many would like to leave home but the move is not so simple. Some do love their husbands and live in hope that the marriage will eventually work. They may feel that they cannot cope with living alone or with the guilt and perceived failure of moving out. The victim may be at various stages of change in terms of taking action in accordance with Prochaska and Di Clemente's model of change (see CHAPTER 21, FIG. 21.4) and the counsellor should be aware of this process.

## Perpetrators

Perpetrators come from all walks of life and from all social and ethnic groups. They generally have inner drives to be strong, protective and powerful but can only achieve this at home through an inappropriate show of strength. However, they are basically insecure with poor self-esteem, poor communication skills, learned violence from family origins and an inability to express appropriate emotions, which tend to manifest as anger and violence.<sup>1</sup>

Although they usually control their violence outside the home, there is evidence that some perpetrators are guilty of violent behaviour in the community.

## Cycle of violence

A predictable pattern that is referred to as the 'cycle of violence' has been identified in many marriages. It is controlled by the perpetrator while the victim feels confused and helpless. The cycle repeats itself with a tendency for the violence to increase in severity (see FIG. 120.1).

FIGURE 120.1 The cycle of IPV

## Management

The key to successful management is initial recognition of the problem and establishment of empathic caring and support for the victim and family. Do not try to fit the victims into the disease model. It must be emphasised that the perpetrators (as in most criminal activity) do not readily change their behavioural pattern and thus there is minimal prospect of the violence decreasing unless there is a dramatic reason to change. As with an alcohol problem, the person has to admit that he has a problem before effective counselling can begin. A management strategy is presented in TABLE 120.1. The safety of women and children is always the prime working rule.

## Useful strategies

*Do believe her.*

- Talk openly and explicitly about it.
- Express concern for her safety.
- Give information (i.e. about the course of action available to her, contacts for legal advice).
- Respect her right to make her own decisions.

## Harmful strategies

*Don't:*

- deny domestic violence
- minimise the importance of domestic violence
- blame the victim

Table 120.1 Management strategy for domestic violence

Treat the physical injury and suspect domestic violence

↓

Establish the diagnosis

↓

Initiate crisis intervention:

- organise admission to a refuge
- ensure informed consent for all actions
- consider notifying police

↓

Establish an empathic, trusting relationship

↓

Build the victim's coping skills and self-esteem

↓

Make effective use of community resources:

- support services
- women's support group
- domestic violence resource centre (in each capital city)
- social services/police
- social workers
- private counsellors and psychologists

- treat with tranquillisers
- refer to a psychiatrist
- refer to marriage guidance if the husband isn't interested, but refer to specialist counsellors
- set explicit criteria/rules (takes away her power yet again)

It is uncommon to get the cooperation of the perpetrator in the management process. If they do seek help they require counselling by a skilled and experienced practitioner, as treatment will be prolonged and complex.

If an abusive incident develops or is imminent, the victim should have safety planning. One such plan is:

- Be aware of all exit routes and safety areas
- Have a plan that includes:
  - calling emergency services (000 or other)
  - safely exiting the house
  - seeking help
  - accessing a safety refuge
- Ask neighbours to call police if they hear any disturbance<sup>8</sup>

As a general rule the most effective intervention in arresting the violence is to arrest the violent person.<sup>3</sup>

## Sexual assault

Medical practitioners dealing with the difficult and distressing problem of alleged sexual assault should be trained in the subject and familiar with the laws applicable to sexual assault in their own state. Sexual assault is defined broadly as any unwanted sexual contact that occurs without a person's consent. The sexual act can range from touching to the penetration of an orifice. Rape involves considerable violence and physical injury in 5–10% of cases,<sup>9</sup> in which the victims fear for their lives. Apart from the inevitable psychological consequences, particularly acute stress disorder and PTSD, the possibility of pregnancy (overall rate is 5% per assault)<sup>9,10</sup> or acquired STI should be considered. The inexperienced practitioner should refer the patient to the nearest available resource but continue a caring involvement as the patient's GP. Survivors of sexual assault should be allowed to accept or decline various treatment options offered by the practitioner.

## Management of the victim<sup>8,10</sup>

What you should do for the patients first is to offer and provide privacy, safety, confidentiality and emotional support. Believe them, listen to them and be non-judgmental.

Five important things to say initially to any victim:

- You are safe now.
- I am sorry this happened to you.
- This is a crime—it was not your fault.
- It's good that you are seeing me.
- I will do what I can to help you

## Initial advice to the victim

If victim reporting to police:

- 1 Notify the police at once.
- 2 Take along a witness to the alleged assault (if there was a witness).
- 3 Do not wash or tidy yourself or change your clothing.
- 4 Do not take any alcohol or drugs.
- 5 Don't drink or wash out your mouth if there was oral assault.
- 6 Take a change of warm clothing.

If not reporting to police or unsure, contact any of the following:

- 1 a friend or other responsible person
- 2 Lifeline or Lifelink or a similar service

- 3 sexual assault referral/resource/forensic centre
- 4 a doctor
- 5 a counselling service

## Obtaining information—examining doctor

- 1 Obtain consent from the patient to record and release information.
- 2 Take a careful history and copious relevant notes.
- 3 Keep a record, have a protocol.
- 4 Obtain a kit for examination.
- 5 Have someone present during the examination (especially in the case of male doctors examining women).
- 6 Air-dry swabs (media destroy spermatozoa).
- 7 Hand specimens to police immediately.

## Examination

If possible the patient should be clothed when seen. Have the patient undress while standing on a white sheet to collect debris, and note any injuries as each item is removed. Each part of the body should be examined, under good illumination, and all injuries measured and recorded carefully on a diagram.

Injuries should be photographed professionally. Examine the body and genital area with a Wood's light to identify semen, which fluoresces. Perform a careful speculum examination. Palpate the scalp for hidden trauma. Collect appropriate swabs.

## Making reports

Remember that as a doctor you are impartial. Never make inappropriate judgments to authorities (e.g. 'This patient was raped' or 'Incest was committed'). Rather say: 'There is evidence (or no evidence) to support penetration of the vagina/anus' or 'There is evidence of trauma to \_\_\_\_\_'.

## Post-examination

After the medical examination a discussion of medical problems should take place with the patient. This should be done in private and kept totally confidential. A management plan for physical injuries and emotional problems is discussed.

Consider the possibility of STI and possible referral. Consider also the possibility of pregnancy and the need for postcoital hormone tablets. Organise follow-up counselling and STI screening.

**Table 120.2** STI prophylaxis (consider)<sup>11</sup>

Chlamydia	— 1 g azithromycin (o)
Gonorrhoea	— ceftriaxone 500 mg IM if high risk or azithromycin 1 g (o)
Hepatitis B	— Hepatitis B vaccine (dose 1) — immune globulin IM (if high risk)
Syphilis	— benzathine penicillin 1.8 g IM
Trichomonas	— metronidazole 1 g (o)
HIV	— consult appropriate physician

## Management issues

- Take swabs and/or first-void specimen for testing gonococcus and chlamydia (PCR).
- Take blood for HIV, syphilis, hepatitis B.
- Collect specimens—swab, aspirate of any fluid and keep for DNA analysis.
- Give prophylactic antibiotics (see **TABLE 120.2**)—depends on type of assault and assailant.
- Emergency contraception.
- Review in 3 weeks—check tests.
- Screen for HBV, HCV, syphilis and HIV in about 3 months.
- Refer to Rape Crisis centre.

## Drug-assisted sexual assault

Consider this when patient has no memory of events and time or other suspicious circumstances. Urine or blood testing may be appropriate.

# Part 9

## Problems of the skin

---

*The skilful doctor knows by observation, the mediocre doctor by interrogation, the ordinary doctor by palpation.*

Chang Chung-ching (c. AD 170–196)

The diagnosis of skin problems depends on astute clinical skills based on a systematic history and examination and, of course, experience. If the diagnosis is in doubt, it is appropriate to refer the patient to a skilled cooperative consultant, as the referral process is an excellent educational opportunity for the GP. Another opinion from a colleague/s in a group practice is also very educative. At least, cross-referencing the skin lesion with a colour atlas facilitates the learning process.

## Terminology of skin lesions

### Primary lesions

- **Macule.** Circumscribed area of altered skin colour (Latin for stain) without elevation <1 cm diameter (see FIG. 121.1).
- **Patch.** Macule of >1 cm diameter (see FIG. 121.1).
- **Papule.** Palpable mass on skin surface <0.5 cm diameter (see FIG. 121.2).
- **Maculopapule.** A raised and discoloured circumscribed lesion.
- **Nodule.** Circumscribed palpable mass >0.5 cm diameter (see FIG. 121.2).
- **Plaque.** A flat-topped palpable mass >1 cm diameter.
- **Wheal.** An area of dermal oedema (can be any size), which is pale and compressible.
- **Angio-oedema.** A diffuse area of oedema extending into subcutaneous tissue.
- **Vesicle.** A fluid-filled blister <0.5 cm in diameter (see FIG. 121.3).
- **Bulla.** A vesicle >0.5 cm diameter (see FIG. 121.3).
- **Pustule.** A visible collection of pus in the skin <1 cm diameter.
- **Abscess.** A localised collection of pus in a cavity >1 cm diameter.
- **Furuncle.** A purulent infected hair follicle; includes:
  - folliculitis (small furuncles)
  - boils (larger furuncles)
- **Carbuncle.** A cluster of boils discharging through several openings.
- **Purpura.** Bleeding into the skin (dermis) appearing as multiple haemorrhages. May be macular or papular.
- **Petechiae.** Purpuric lesions 2 mm or less in diameter.
- **Ecchymosis.** Larger purpuric lesion.
- **Haematoma.** A swelling from gross bleeding.
- **Telangiectasia.** Visible dilatation of small cutaneous blood vessels.
- **Comedo.** A plug of keratin and sebum in a dilated pilosebaceous gland.
- **'Blackhead'.** An open comedo.
- **'Whitehead'.** A closed comedo.
- **Erythema.** Redness of the skin due to increased vascularity.
- **Milium.** Tiny white cyst containing keratin, from occlusion of pilosebaceous gland.
- **Papilloma.** Warty projection above the skin surface.

### Secondary lesions

- **Scales.** An accumulation of excess keratin that presents as flaking.
- **Crusts (scabs).** Superficial dried secretions (serum and exudate).

FIGURE 121.1 Macule and patch

FIGURE 121.2 Papule and nodule

FIGURE 121.3 Vesicle and bulla

FIGURE 121.4 Ulcer, erosion and fissure

- **Ulcer.** A circumscribed deep defect with loss of all the epidermis and part or all of the dermis (see FIG. 121.4); they usually heal with scarring.
- **Erosion.** A skin defect with complete or partial loss of the epidermis; they heal without scarring (see FIG. 121.4).
- **Fissure.** A linear split in the epidermis and dermis (see FIG. 121.4).
- **Atrophy.** Thinning or loss of epidermis and/or dermis with loss of normal markings.
- **Sclerosis.** Thickening of the dermis with induration of subcutaneous tissue; resembles a scar but may arise spontaneously (e.g. scleroderma).
- **Scar.** A healed dermal lesion where normal structures are replaced by fibrous tissue.
- **Hypertrophic scar.** Rises above the skin surface.
- **Atrophic scar.** Settles below the skin surface.
- **Keloid.** Overgrowth of dense fibrous tissue extending beyond the original wound.
- **Excoriation.** Scratch marks causing an erosion or an ulcer (loss of epidermis).
- **Acanthosis.** Thickening of skin without accentuation of skin markings.
- **Lichenification.** Thickening secondary to chronic scratching or rubbing (in dermatitis).
- **Callus.** Localised hypertrophy of the stratum corneum.
- **Exfoliation.** Loss of epidermal keratin as large scales or sheets.
- **Keratoderma.** Thickening of skin especially stratum corneum.

## A diagnostic approach

The diagnostic approach of Robin Marks<sup>1</sup> presented here helps to achieve order in the midst of confusion. He describes the importance of simplifying the diagnostic process by being a 'lumper' rather than a 'splitter'. Most common dermatological problems fall into one of seven categories (see TABLE 121.1). A problem that does not fit into one of these seven groups is either an unusual condition or an unusual

presentation of a common condition and probably merits a consultant's opinion.

*Note:* TABLES 121.1 to 121.6 were prepared by Professor Robin Marks<sup>1</sup> and are reproduced with his permission.

## Defining terms

Terms that are continually referred to in skin disease include the following:

<b>Seborrhoeic</b>	Yellow-brown and waxy	} (interchangeable)
<b>Nummular</b>	Coin-like	
<b>Discoïd</b>	Disc-like	
<b>Annular</b>	Ring-like	
<b>Circinate</b>	Circular	
<b>Arcuate</b>	Curved	
<b>Reticulate</b>	Net-like	
<b>Pityriasis</b> ( <i>pityron</i> = bran)	Fine, bran-like scaly desquamation or powdery	
<b>Guttate</b>	'Dew drop'	
<b>Rosea</b>	Rose-coloured	
<b>Morbilloform</b>	Like measles	
<b>Morphoea</b>	Circumscribed scleroderma or skin infiltrate	
<b>Livido</b>	Cyanotic discolouration	
<b>Lichen</b>	Any papular skin disorder resembling lichens	
<b>Verrucous</b>	Rough and warty	

## History

The three basic questions are:<sup>1</sup>

- 1 Where is the rash and where did it start?
- 2 How long have you had the rash?

*Note:* The split into three time zone groups (see TABLE 121.2) is very useful. This question leads on to the next question regarding itch, as the patient is unlikely to tolerate an itchy eruption.

- 3 Is the rash itchy?

If so, is it mild, moderate or severe? The nature of the itch is very helpful diagnostically. A severe itch is one that wakes the patient at night and leads to marked excoriation of the skin, while

Table 121.1 Common dermatological conditions

<b>Infections</b>
Bacterial:
• impetigo
Viral:
• warts
• herpes simplex, herpes zoster
• pityriasis rosea
• exanthemata
Fungal:
• tinea
• candidiasis
• pityriasis versicolor
<b>Acne</b>
<b>Psoriasis</b>
<b>Atopic dermatitis (eczema)</b>
<b>Urticaria</b>
Acute and chronic
Papular:
• pediculosis
• scabies
• insect bites
<b>Sun-related skin cancer</b>
<b>Drug-related eruptions</b>

a mild itch is one that is only slightly upsetting for the patient and may not be noticeable for significant periods during the day.

Three questions the doctor must consider

- 1 Could this be a drug rash?
- 2 Has this rash been modified by treatment?
- 3 Do any contacts have a similar rash?

Further questions for the patient

- Do you have contact with a person with a similar eruption?
- What medicines are you taking or have you taken recently?
- Have you worn any new clothing recently?
- Have you been exposed to anything different recently?
- Do you have a past history of a similar rash or eczema or an allergic tendency (e.g. asthma)?
- Is there a family history of skin problems?

The nature of itching<sup>1</sup>

The characteristics of the itch are very useful in dividing up the diagnoses: an eruption that is not

Table 121.2 How long has the rash been present?

<b>Acute</b> (hours–days)	Urticaria Atopic dermatitis Allergic contact dermatitis Insect bites Drugs Herpes simplex/zoster Viral exanthemata
<b>Acute</b> → <b>chronic</b> (days–weeks)	Atopic dermatitis Impetigo Scabies Pediculosis Drugs Pityriasis rosea Psoriasis Tinea Candida
<b>Chronic</b> (weeks–months)	Psoriasis Atopic dermatitis Tinea Pityriasis versicolor Warts Cancers Skin infiltrations (such as granulomata, xanthomata)

Table 121.3 Is the rash itchy?

<b>Very</b>	Urticaria Atopic dermatitis Scabies, pediculosis Insect bites Chickenpox (adults) Dermatitis herpetiformis Grover disease
<b>Mild to moderate</b>	Tinea Psoriasis Drugs Pityriasis rosea Candida Stress itching/lichen simplex
<b>Often not</b>	Warts, tinea Impetigo, psoriasis Cancers Viral exanthemata Seborrhoeic dermatitis

itchy is unlikely to be scabies and one that is very itchy is unlikely to be a skin tumour (see TABLE 121.3). However, nothing is absolute and variations to the rule will occur—tinea, psoriasis and pityriasis versicolor are sometimes itchy and sometimes not.

Chickenpox can vary from being intensely itchy, especially in adults, to virtually no itching.

Relieving or aggravating factors of the itch provide useful diagnostic guidelines; for example, Whitfield's ointment applied to an itchy eruption for a provisional diagnosis of ringworm would make the itch worse if it were due to eczema.

Examination<sup>1</sup>

Examine the skin in good light, preferably natural light, and ensure that any make-up is removed.

There are two basic stages in the physical examination of a rash. The first is an assessment of the characteristics of the individual lesion and the second is the distribution or pattern of the lesions.

Characteristics of the individual lesion

The single most important discriminating feature is whether it involves the dermis alone or the epidermis as well (see TABLE 121.4). If the lesion involves the epidermis there will be scaling, crusting, weeping, vesiculation or a combination of these (see FIG. 121.5). If the dermis alone is involved, the lesion is by definition a lump, a papule or a nodule (see FIG. 121.6). No lesion ever involves the epidermis without involving the dermis as well.

Other characteristics of individual lesions that must be sought are the colour, the shape and the size. It is important to feel the skin during the physical examination and to note the consistency of the lesion. Is it firm or soft? The activity of the lesion may also be useful: does it have a clearing centre and an active edge?

Distribution of the lesions

The clinician must decide whether the lesions are localised or widespread. If they are widespread, are

they distributed centrally, peripherally, or both? (See TABLE 121.5.) Diagnosis is often helped when the skin lesions are in a specific area (see TABLE 121.6 and FIGS 121.7 and 121.8). Itchy papules on the penis associated with a widespread pruritus are likely to be scabies. However, care has to be taken because many misdiagnoses are made instinctively on the distribution (e.g. anything in the flexures is dermatitis or anything on the feet is tinea).

FIGURE 121.5 Epidermal skin lesion

FIGURE 121.6 Dermal skin lesion

Table 121.4 Appearance of individual lesions	
Epidermal	Atopic dermatitis Psoriasis Tinea Pityriasis rosea Impetigo, herpes, warts Cancers Scabies Solar keratoses
Dermal	Urticaria Insect bites, pediculosis, scabies Drugs Skin infiltrations Viral exanthemata

Table 121.5 Distribution of the rash	
Widespread	Atopic dermatitis Psoriasis Scabies Drugs Urticaria
Central trunk (initially at least)	Pityriasis versicolor Herpes zoster Seborrhoeic dermatitis Guttate psoriasis Pityriasis rosea Viral exanthemata
Peripheral	Atopic dermatitis Herpes zoster Tinea Psoriasis Warts Insect bites

Table 121.6 Specific areas affected

Face	Rosacea
	Impetigo
	Atopic dermatitis
	Psoriasis
	Photosensitive (e.g. drugs)
	Herpes simplex
	Acne vulgaris
	Cancers
Scalp	Viral exanthemata
	Psoriasis
	Seborrhoeic dermatitis
	Pediculosis
	Tinea
	Folliculitis
Flexures	Chickenpox
	Atopic dermatitis
	Psoriasis
	Seborrhoeic dermatitis
	Tinea
	Candida
Mouth	Pediculosis
	Aphthous ulcers
	Herpes simplex
	Candida
	Measles
Nails	Psoriasis
	Tinea
	Dermatitis
Penis	Scabies
	Genital herpes and warts
	Candida
	Psoriasis

Another feature of an eruption, which should be sought on examination, is whether the lesions are all at the same stage of evolution.

It is necessary to perform a complete physical examination as well. There is, after all, no such thing as a skin disease but rather disease affecting the skin. The clinician must always bear this in mind when managing patients complaining of a skin eruption. Disease does not affect the skin in isolation and it is unforgivable to look only at the skin and ignore the patient as a whole.

*Note:* In every case examine the mouth, scalp, nails, hands and feet.

### Diagnostic tools

Appropriate diagnostic tools include:

- a magnifying lens
- a diascope, which is a glass slide or clear plastic spoon that is used to blanch vascular lesions in order to determine their true colour

- a ‘Maggylamp’, which is a hand-held fluorescent light with an incorporated magnifier; the device allows shadow-free lighting and magnification
- a dermatoscope, which is very valuable in the diagnosis of pigmented tumours but it does require skill and familiarity to achieve effective use
- Wood’s light
- swabs for culture and NAAT test (PCR)
- skin biopsy (even with psoriasis, etc.)

### Office tests and diagnostic aids

#### Wood’s light

Wood’s light examination is an important diagnostic aid for skin problems in general practice. It has other uses, such as examination of the eye after fluorescein staining. (A low-cost, small ultraviolet light unit called ‘the black light’ is also available.)

#### Method

Simply hold the ultraviolet light unit above the area for investigation in a dark room.

#### Limitations of Wood’s light in diagnosis

Not all cases of tinea capitis fluoresce because some species that cause the condition do not produce porphyrins as a by-product. See TABLE 121.7 for a list of the skin conditions that do fluoresce. Wood’s light is really only useful for hair-bearing areas.

Porphyrins wash off with soap and water, and a negative result may occur in a patient who has shampooed the hair within 20 hours of presentation. Consequently, a negative Wood’s light reading may be misleading. The appropriate way of confirming the clinical diagnosis is to send specimens of hair and skin for microscopy and culture.

#### Skin scrapings for dermatophyte diagnosis

Skin scrapings are an excellent adjunct to diagnosis of fungal infections. Requirements are a scalpel blade, glass slide and cover slip, 20% potassium hydroxide

Table 121.7 Skin conditions that produce fluorescence in Wood’s light

Tinea capitis	Green/bright yellow (in hairs)
Erythrasma	Coral pink
Pityriasis versicolor	Pink–gold
<i>Pseudomonas</i> spp.	Yellowish-green
Porphyria cutanea tarda	Red (urine)

FIGURE 121.7 Typical sites on the face affected by the skin conditions indicated

FIGURE 121.8 Typical regional location of various skin conditions

\*Same conditions apply to chest and trunk

(preferably in dimethyl sulphoxide) and a microscope. Skin scrapings can also be sent for microscopy and culture.

Clinical indications:

- 1 tinea (superficial dermatophyte infection)
- 2 pityriasis versicolor
- 3 *Candida*

### Method

- Scrape skin from the active edge.
- Scoop the scrapings onto the glass microscope slide.
- Cover the sample with a drop of potassium hydroxide.
- Cover this with a cover slip and press down gently.
- Warm the slide and wait at least 5 minutes for 'clearing'.

### Microscopic examination

- Examine at first under low power with reduced light.
- When fungal hyphae are located, change to high power.
- Use the fine focus to highlight the hyphae (see FIG. 121.9).

*Note:* Some practice is necessary to recognise hyphae.

### Other uses of microscopy

Detection of the scabies mite: the burrow of the scabies mite is found (can be difficult!) and the epidermis is decisively scraped with a no. 15 scalpel blade, and transferred to a slide after adding a drop of liquid paraffin. The mite is very distinctive.

FIGURE 121.9 Diagrammatic representation of microscopic appearance of fungal hyphae

### Patch testing

Patch testing is used to determine allergens in allergic contact dermatitis. Read in 48 hours.

### Biopsies

Shave or punch biopsies can be useful (see FIGS 126.26 and 126.27 in CHAPTER 126).

### Hair<sup>2</sup>

Send hair samples for microscopy and root analysis. There are two main tests:

- 1 the hair pull test (refer CHAPTER 128)
- 2 the hair pluck test

In the hair pluck test (used for tinea capitis and hair shaft disorder), a tuft of about 20 hairs is drawn out, forceps applied close to the skin of the scalp and rotated slightly prior to sharp extraction. The hair should be collected on a glass slide for counting and analysis.

### Traditional chemicals used in extemporaneous preparations<sup>3</sup>

- *Salicylic acid*: produces painless destruction of epithelium, thereby facilitating absorption. Consider its use for psoriasis, neurodermatitis, tinea of palms and feet, seborrhoeic dermatitis.
- *Resorcinol*: a topical keratolytic with bactericidal and fungicidal properties. Consider its use for psoriasis, acne, rosacea, seborrhoeic dermatitis.
- *Coal tar*: the two commonly found tar preparations—crude tar and solution: liquor picis carbonis (LPC)—are used for their anti-inflammatory, soothing and antimitotic properties. Consider their use for psoriasis, atopic dermatitis, seborrhoeic dermatitis and neurodermatitis.
- *Menthol and phenol*: added to various preparations for their soothing and cooling effects. Consider for use in pruritic problems such as varicella, urticaria and atopic dermatitis.
- *Sulphur*: of benefit in dermatoses, due mainly to its keratolytic properties. The other actions of sulphur are scabidicidal, parasiticidal and fungicidal. Consider its use for acne, rosacea, seborrhoeic dermatitis, psoriasis and tinea.
- *Dithranol*: reduces the mitotic activity of a hyperplastic epidermis. Good for thick plaque psoriasis.
- *Calamine*: a mild astringent and antipruritic used as a soothing and protective agent in

various 'vehicles' (bases). It is zinc carbonate or zinc oxide powder mixed with a small amount of iron oxide. Has drying properties so avoid recommending calamine-based preparations for dry skin conditions.

- **Zinc oxide:** a mild astringent used in many preparations and combined with other ingredients. Used for soothing and protective functions.

### Common natural topical preparations<sup>4</sup>

- **Aloe vera:** the extract from aloe vera appears to have antiseptic, anaesthetic, anti-inflammatory, antipruritic and moisturising properties. It is used in a variety of products and promotes wound healing including those with mild burns.
- **Pawpaw:** papain extracted from the pawpaw plant is used as a moisturiser and antipruritic. It is used to treat discomfort and itching from bites and stings, minor burns and postsurgical wounds.
- **Teatree oil:** the oil from tea tree (*Melaleuca alternifolia*) has astringent and mild antibacterial and antifungal properties. It is commonly used as an antiseptic and for prevention of infection in areas prone to folliculitis and tinea (e.g. tinea pedis).
- **Honey:** especially manuka or 'jelly bush' unprocessed honey has been used as a non-antibiotic and protective treatment for chronic wound infections and wounds generally. Its properties include anti-oxidation, absorbance, hygroscopic, hypertonicity, anti-inflammatory and antibacterial. However the scientific evidence to support its use is not convincing and it should be used with care.
- **Colloidal oatmeal**
- **Wheat grass**

### Selection of corticosteroid preparations

- Class I and class II preparations are appropriate for most problems.
- Creams or lotions are used for 'weeping' lesions, the face, flexures and hair-bearing areas.
- Use ointments for dry and scaly skin.
- Use ointments and occlusive vehicles for dry and chronic skin surfaces.
- Ointments should not be used on weeping surfaces.
- Stubborn dermatoses such as psoriasis respond better to preparations under occlusion, such as plastic wrap applied overnight with appropriate securing in place.
- Use a gel or lotion for the scalp.

- For *Candida* infection (e.g. complicating seborrhoeic napkin dermatitis), mix 1% hydrocortisone in equal quantities with an antifungal preparation such as nystatin.
- Use the weakest strength for chronic dermatoses but treat severe acute dermatoses aggressively.
- Steroids not needed if no inflammation present.

### Terminology of topical skin preparations

See also TABLE 121.8.

**Antipruritic agent** One that relieves itching. Examples are:

- menthol (0.25%)
- phenol (0.5%)
- coal tar solution (2–10%)
- camphor (1 or 2%)

**Astringent** A topical agent that has styptic or binding properties with an ability to stop secretions from skin or tissues. An example is aluminium acetate solution (Burow's solution); the aluminium acetate acts as a protein precipitator and is a very effective soothing agent and antipruritic.

**Base or vehicle** A mixture of powders, water and greases (usually obtained from petroleum). The relative blending of these compounds determines the nature of the base (e.g. lotion, cream, ointment, gel or paste).

**Cream** A suspension of a powder in an emulsion of oil and water with the addition of an emulsifying agent. Usually applied to normal or moist skin.

**Emollient** A topical preparation of emulsified oils and fatty acids that is softening or soothing to the skin. It replaces natural oils in the stratum corneum. It also acts as a skin moisturiser and is therefore used on dry skin or dermatoses related to dry skin (e.g. atopic dermatitis). Examples are:

- mineral or vegetable oil (e.g. peanut oil 5% cream)
- sorbolene cream
- aqueous cream

**Emulsion** A mixture of two immiscible liquids, one being dispersed throughout the other in small droplets.

**Gel** A viscous substance with a greaseless, water-miscible base.

**Humectant** A chemical-containing agent that attracts and retains water due to its hygroscopic or osmotic properties. Examples are:

- urea 10% cream
- glycerol 10% cream

*continued*

continued

**Keratolytic** An agent that softens or breaks up keratin. Examples are:

- urea 10%—for xerosis or keratosis pilaris
- urea 20%—cracked palms and soles
- salicylic acid 2–10%
- benzoic acid alpha-hydroxy acids (e.g. lactic acid, propylene glycol)

**Lotion** A suspension of an insoluble powder in water. Modern lotions use an emulsifying agent, which eliminates the need to shake the lotion. An example is calamine lotion (zinc oxide 5, calamine 15, glycerine 5, water to 100).

**Moisturiser** An agent that increases the water content of the stratum corneum and reduces itching. Classified as:

- emollient
- humectant, and
- occlusive (e.g. white soft paraffin: Vaseline)

**Ointment** A suspension of a substance in an oily vehicle. Generally used for dry skin.

**Paint and tincture** A rapidly drying liquid preparation that is very useful for intertriginous areas, especially between the toes and natal cleft. ‘Tincture’ is the preparation when alcohol is the vehicle. Example: podophyllin in tinct. benz. co. (for genital warts).

**Paste** Similar to ointment in composition but is more viscid. A paste consists of an ointment to which another agent, such as starch, has been added. They dry and protect.

### Cautions

- Avoid high-potency preparations on the face, in flexures and on infants.
- Corticosteroids can mask or prolong an infection.
- Long-term use can cause striae and skin atrophy, peri-oral dermatitis, ‘steroid acne’ and rosacea.
- Excessive use of more potent preparations can cause adrenal suppression; predispositions include use >2 weeks, and use on thinner skin such as face, genitalia and intertriginous areas.
- Avoid sudden cessation: alternate with an emollient or a milder preparation.

The relative clinical potency of topical corticosteroids is given in TABLE 121.9.

### Skin tips

- Do no harm. Introduce the mildest possible preparation to alleviate the problem.
- Creams tend to be drying, lotions even more so.
- Ointments tend to reduce dryness and have greater skin penetration. If wet—use a wet dressing (wet soaks and a lotion). If dry—use an ointment (salve).
- Occlusive dressings with plastic wraps permit more rapid resolution of stubborn dermatoses.
- Most toilet soaps are alkaline and are very drying; they should not be used on dry skin or dermatitis with dry skin. Soap substitutes include neutral soaps (Dove, Neutrogena), superfatted soaps (Oilatum) and non-soap cleanser (Cetaphil).
- Soaps should be used only in the axillae and groin and on the feet of people with dry and irritated skin.
- Bath additives can be useful for dermatoses such as psoriasis, atopic dermatitis and for pruritus. For some people it may be better not to add it to the bath (diluting effect; accident from slipping) but to massage the oil into the dry itchy skin after the bath.
- Always give careful instructions to the patient regarding application of preparations: use a prepared handout if available.
- Alter the treatment according to the response.
- Explain the costs involved, especially where a preparation is expensive.
- Avoid combination creams unless clear evidence of secondary infection proven by culture and sensitivity.

121

Table 121.8 Guidelines for choosing a topical vehicle

Disorder	Topical vehicle
Acute inflammation: <ul style="list-style-type: none"><li>• erythema, weeping</li></ul>	Wet dressing Solution, lotions
Subacute inflammation: <ul style="list-style-type: none"><li>• erythema, scaling</li></ul>	Creams Gels (for hairy areas)
Chronic inflammation: <ul style="list-style-type: none"><li>• scaling, dryness, thickening</li></ul>	Ointments Impregnated tapes

### Topical corticosteroids for chronic dermatoses

Guidelines for long-term use (examples):<sup>4</sup>

- face—hydrocortisone 1%
- flexures—hydrocortisone 1%
- trunk—betamethasone valerate 0.2%  
— triamcinolone acetonide 0.02%
- elbows/knees—betamethasone dipropionate 0.05%
- palms/soles—methylprednisolone aceponate 0.1%

**Table 121.9** Potency ranking of the most commonly used topical corticosteroid preparations in Australia and New Zealand<sup>6</sup>

Generic name	Formulation
<b>Group I Mild</b>	
Hydrocortisone 0.5%	Cream
Hydrocortisone acetate 0.5%	Cream
Hydrocortisone 1%	Cream
Hydrocortisone acetate 1%	Cream, ointment
<b>Group II Moderately potent</b>	
Betamethasone valerate 0.02%	Cream, ointment
Betamethasone valerate 0.05%	Cream, ointment, gel
Clobetasone butyrate 0.05%*	Cream, ointment
Desonide 0.05%	Lotion
Triamcinolone acetonide 0.02%	Cream, ointment
Triamcinolone acetonide 0.05%	Cream, ointment
<b>Group III Potent</b>	
Betamethasone valerate 0.1%	Cream, ointment, scalp lotion
Betamethasone dipropionate 0.05%	Cream, ointment, lotion
Methylprednisolone aceponate 0.1%	Cream, ointment
Mometasone furoate 0.1%	Cream, ointment, lotion
Triamcinolone acetonide 0.1%	Cream, ointment
<b>Group IV Very potent</b>	
Betamethasone dipropionate 0.05% (enhanced)	Cream, ointment
Clobetasol propionate 0.05%*	Cream, ointment, scalp application
<b>Preparations containing other agents</b>	
Triamcinolone acetonide 0.01% + neomycin, gramicidin, nystatin	Cream, ointment
Betamethasone valerate 0.1% + gentamicin	Cream, ointment
Hydrocortisone 1% + clioquinol 1%	Cream
Hydrocortisone 1% + clioquinol 3%	Cream
Hydrocortisone 1% + clotrimazole	Cream

\*Not available in Australia.

## Rules for prescribing creams and ointments

### How much?<sup>5</sup>

On average, 30 g of cream will cover the body surface area of an adult. Ointments, despite being of thicker consistency, do not penetrate into the deeper skin layers so readily, and the requirements are slightly less. Pastes are applied thickly, and the requirements are at least 3–4 times as great as for creams.

**FIGURE 121.10** 'Rule of nines' for body surface area

The 'rule of nines', used routinely to determine the percentage of body surface area affected by burns (see FIG. 121.10), may also be used to calculate the amount of a topical preparation that needs to be prescribed.

For example:

- if 9% of the body surface area is affected by eczema, approximately 3 g of cream is required to cover it
- 9 g of cream is used per day if prescribed three times daily
- a 50 g tube will last 5–6 days

One gram of cream will cover an area approximately 10 cm × 10 cm (4 square inches), and this formula may be used for smaller lesions.

TABLE 121.10 provides guidelines for approximate weekly quantities of skin preparations required to cover specific areas of the body.

### Some general rules

Remember:

- to use cream or lotions for acute rashes
- to use ointments for chronic scaling rashes
- that a thin smear only is necessary
- that 30 g
  - will cover the adult body once
  - will cover hands twice daily for 2 weeks
  - will cover a patchy rash twice daily for 1 week
- that 200 g will cover a quite severe rash twice daily for 2 weeks

**Table 121.10** Suitable quantities of skin preparations for specific body areas<sup>7</sup> (twice daily application for 1 week)

	Creams and ointments		
	Corticosteroids	Others	Lotions
Face and neck	15–30 g	15–30 g	100 mL
Both hands	15–30 g	25–50 g	200 mL
Scalp	15–30 g	50–100 g	200 mL
Both arms	30–60 g	100 g	200 mL
Both legs	100 g	100–200 g	200 mL
Trunk	100 g	400 g	500 mL
Groin and genitalia	15–30 g	15–25 g	100 mL

*It is easy to stand a pain, but difficult to stand an itch.*

Chang Ch'a o 1676

Pruritus (the Latin word for itch) is defined simply as the desire to scratch.

It is one of the most important dermatological symptoms and is usually a symptom of primary skin disease with a visible rash. However, it is a subjective symptom and diagnostic difficulties arise when pruritus is the presenting symptom of a systemic disease with or without a rash—‘pruritus sine materia’. An associated rash may also be a manifestation of the underlying disease.

The broad differential diagnoses of pruritus are:

- skin disease
- systemic disease
- psychological and emotional disorders

## Physiology<sup>1</sup>

Itch arises from the same nerve pathway as pain, but pain and itch are distinct sensations. The difference is in the intensity of the stimulus. Unrelieved chronic itch, like unrelieved pain, can be intolerable and cause suicide. There are many similarities: both are abolished by analgesia and anaesthesia; subdued by counter-irritation, cold, heat and vibration; and referred itch occurs just like referred pain. Antihistamines that act on the H<sub>1</sub> receptor are often ineffective, suggesting that histamine is not the only mediator of itch.<sup>1</sup>

## Localised pruritus

Pruritus may be either localised or generalised. Localised itching is generally caused by common skin conditions such as atopic dermatitis (see TABLE 122.1). Scratch marks are generally presented. Pruritus is a feature of dry skin. An intense, localised itch is suggestive of scabies, also known as ‘the itch’.

Itching of the scalp, anal or vulval areas is a common presentation in general practice.

A careful examination is necessary to exclude primary skin disease; a detailed history and examination should be undertaken to determine if one of the various systemic diseases is responsible.

Notalgia paraesthetica is a common localised itch and/or paraesthesia (possibly also pain) in

**Table 122.1** Primary skin disorders causing significant pruritus

Atopic dermatitis (eczema)
Urticaria
Dermatitis herpetiformis
Grover disease
Scabies
Pediculosis
Asteatosis (dry skin)
Lichen planus
Chickenpox
Contact dermatitis
Insect bites

the interscapular area. It is considered to be due to pressure on spinal nerves from spinal dysfunction. It is usually relieved by physical therapy to the thoracic spine (see CHAPTER 24).<sup>2</sup> Pruritic rashes in children commonly include atopic dermatitis, varicella, urticaria (hives), insect bites and scabies.

## Generalised pruritus<sup>3</sup>

Pruritus may be a manifestation of systemic disease. It can accompany pregnancy, especially towards the end of the third trimester (beware of cholestasis), and disappear after childbirth. These women are then prone to pruritus if they take the contraceptive pill.<sup>4</sup>

Systemic causes are summarised in TABLE 122.2 and a summary of the diagnostic strategy model is given in TABLE 122.3.

The history may provide a lead to the diagnosis—the itching of polycythaemia may be triggered by a hot bath which can cause an unusual prickling quality that lasts for about an hour.<sup>4</sup> On the other hand, the itching may be caused by a primary irritant such as a ‘bubble bath’ preparation.

**Table 122.2** Systemic conditions that can cause pruritus

Pregnancy

Chronic kidney failure

Liver disorders:

- cholestatic jaundice, for example:
  - cancer of head of pancreas
  - primary biliary cirrhosis
  - drugs: chlorpromazine, antibiotics
- hepatic failure

Malignancy:

- lymphoma: Hodgkin lymphoma
- leukaemia, esp. chronic lymphatic leukaemia
- multiple myeloma
- disseminated carcinoma

Haematological disorders:

- polycythaemia rubra vera ('bath itch')
- iron-deficiency anaemia
- pernicious anaemia (rare)
- macroglobulinaemia

Endocrine disorders:

- diabetes mellitus
- hypothyroidism
- hyperthyroidism
- carcinoid syndrome
- hyperparathyroidism

Malabsorption syndrome:

- gluten sensitivity (rare)

Tropical infection/intestinal parasites:

- ascariasis
- filariasis
- hookworm

Drugs:

- alkaloids
- aspirin/other NSAIDs
- diuretics
- ACE inhibitors
- opiates
- cocaine
- antibiotics e.g. penicillin, sulfonamides
- quinidine
- chloroquine
- CNS stimulants

Senile pruritus

Autoimmune disorders:

- polyarteritis nodosa
- sicca syndromes (e.g. Sjögren syndrome)

Polyarteritis nodosa

Irritants:

- fibreglass
- others

Aquagenic pruritus

Xerosis (dry skin, winter itch)

HIV/AIDS

Psychological and emotional causes:

- anxiety/depression
- psychosis
- parasitophobia

**Table 122.3** Generalised pruritus: diagnostic strategy model

Q. Probability diagnosis

- A. Psychological/emotional<sup>3</sup>
- Old, dry skin (senile pruritus)
  - Atopic dermatitis (eczema)
  - Contact (allergic) dermatitis
  - Varicella (chickenpox)

Q. Serious disorders not to be missed

- A. Neoplasia:
- lymphoma/Hodgkin
  - leukaemia: CLL
  - other cancer
  - HIV/AIDS
- Chronic kidney failure
- Primary biliary cirrhosis

Q. Pitfalls (often missed)

- A. Pregnancy
- Tropical infection/infestation/scabies
  - Polycythaemia rubra vera
  - Polyarteritis nodosa
  - Lichen planus
  - Generalised sensitivity (e.g. fibreglass, bubble bath)

Q. Seven masquerades checklist

- A. Depression
- Diabetes
  - Drugs (several)
  - Anaemia (iron deficiency)
  - Thyroid disorders (hyper and hypo)
  - Spinal dysfunction (notalgia paraesthetica)

Q. Is the patient trying to tell me something?

- A. Quite likely: consider anxiety, parasitophobia.

## Guidelines

- The prevalence of itching in Hodgkin lymphoma is about 30%. The skin often looks normal but the patient will claim that the itch is unbearable.<sup>4</sup>
- Pruritus can be the presenting symptoms of primary biliary cirrhosis and may precede other

symptoms by 1–2 years.<sup>3</sup> The itch is usually most marked on the palms and soles.

- Pruritus can occur in both hyperthyroidism and hypothyroidism, especially in hypothyroidism where it is associated with the dry skin.

## Key history

Enquire about nature and distribution of itching. Consider pregnancy, liver disease and malignancy of the lymphatic system, particularly Hodgkin lymphoma. A careful review of any drug history is important. Note any associated general symptoms such as fever.

## Key examination

- General examination of the skin, abdomen and lymphopoietic systems

## Key investigations to consider

- Urinalysis
- Pregnancy test
- FBE ESR/CRP
- Iron studies
- Kidney function tests
- Liver function tests
- Thyroid function tests
- Random blood sugar
- Stool examination (ova and cysts)
- Chest X-ray
- Skin biopsy
- Skin testing
- Lymph node biopsy (if present)
- Immunological tests for primary biliary cirrhosis

## Treatment

The basic principle of treatment is to determine the cause of the itch and treat it accordingly. Itch of psychogenic origin responds to appropriate therapy, such as amitriptyline for depression.<sup>1</sup>

If no cause is found:

- apply cooling measures (e.g. air-conditioning, cool swims)
- avoid rough clothes; wear light clothing
- avoid known irritants
- avoid overheating
- avoid vasodilatation (e.g. alcohol, hot baths/showers—keep showers short and not too hot)
- treat dry skin with appropriate moisturisers (e.g. propylene glycol in aqueous cream)
- topical treatment
  - emollients to lubricate skin

- local soothing lotion such as calamine, including menthol or phenol (avoid topical antihistamines)
- pine tar preparations (e.g. Pinetarsol)
- crotamiton cream
- consider topical corticosteroids
- sedative antihistamines (not very effective for systemic pruritus)
- non-sedating antihistamines during day
- antidepressants or tranquillisers (if psychological cause and counselling ineffective)

## PRURITIC SKIN CONDITIONS

### § Scabies

Scabies is a highly infectious skin infestation caused by a tiny mite called *Sarcoptes scabiei* (see FIG. 122.1). It is common in school-aged children, in closed communities such as nursing homes and in some Indigenous communities. The female mite burrows just beneath the skin in order to lay her eggs. She then dies. The eggs hatch into tiny mites that spread out over the skin and live for only about 30 days. The mite antigen, in its excreta, causes a hypersensitivity rash. Diagnosis is by microscopic examination of skin scrapings. A new IgE diagnostic test is available.

### Clinical features

- Intense itching (worse with warmth and at night)
- Erythematous papular rash
- Usually on hands and wrists
- Common on male genitalia (see CHAPTER 119) (see FIG. 122.2)
- Also occurs on elbows, axillae, feet and ankles, nipples of females (see FIG. 122.3)

FIGURE 122.1 Scabies mite (*Sarcoptes scabiei*)

### Spread

The mites are spread from person to person through close personal contact (skin to skin), including sexual contact. They may also be spread through contact with infested clothes or bedding, although this is

**FIGURE 122.2** Genital scabies causing severe pruritus, showing bruising on the upper thighs from intense scratching

uncommon. Sometimes the whole family can get scabies. The spread is more likely with overcrowding and sexual promiscuity.

**FIGURE 122.3** Typical distribution of the scabies rash

### Crusted (Norwegian) scabies

While the majority of cases have a relatively small number of mites (as few as 15), infestation with thousands or millions will cause the crusted condition of Norwegian scabies. Diagnosis is made on a scraping which reveals vast numbers of lesions. It may be encountered in nursing homes. Treatment is with ivermectin 200 mcg/kg (o) as single dose plus topical treatment.<sup>5</sup>

### Treatment<sup>5</sup>

For all ages (except children under 6 months):

permethrin 5% cream (treatment of choice)

or

benzyl benzoate 25% emulsion (dilute with water if under 10 years)

best applied to clean, cool, dry skin

- Apply to entire body from jawline down (including under nails, in flexures and genitals).
- Leave permethrin overnight, then wash off thoroughly.
- Leave benzyl benzoate for 24 hours.
- Avoid hot baths or scrubbing before application.
- Treat the whole family at the same time even if they do not have the itch.
- Wash clothing, any soft toys and bedclothes as usual in hot water and hang in sun.
- One treatment is usually sufficient but repeat scabicide treatment in 1 week for moderate and severe infections.
- For children less than 2 months use sulphur 5% cream daily for 2–3 days or crotamiton 10% cream daily for 3–5 days.

### Dermatitis herpetiformis

This extremely itchy condition is a chronic subepidermal vesicular condition in which the herpes simplex-like vesicles erupt at the dermo-epidermal junction. The vesicles are so pruritic that it is unusual to see an intact one on presentation.

Some consider that it is always caused by a gluten-sensitive enteropathy. Most patients do have clinical coeliac disease.

### Clinical features

- Most common in young adults
- Vesicles mainly over elbows and knees (extensor surfaces)
- Also occurs on trunk, especially buttocks and shoulders (see FIG. 122.4)
- Vesicles rarely seen by doctors
- Presents as excoriation with eczematous changes

**FIGURE 122.4** Typical distribution of dermatitis herpetiformis

- Masquerades as scabies, excoriated eczema or insect bites
- Typically lasts for decades
- Associated with gluten-sensitive enteropathy
- Skin biopsy shows diagnostic features

### Treatment

- Gluten-free diet, which may suppress the condition
- Dapsone 100 mg (o) daily (usually dramatic response)

## § Lichen planus

Lichen planus is an epidermal inflammatory disorder of unknown aetiology characterised by pruritic, violaceous, flat-tipped papules, mainly on the wrists (see FIG. 122.5) and legs. If in doubt, diagnosis is confirmed by biopsy. One differential diagnosis is a lichen planus-like drug eruption (e.g. antihypertensives, anti-malarials).

### Clinical features

- Young and middle-aged adults
- 4Ps—papule, purple, polygonal, pruritic
- Small, shiny, lichenified plaques
- Symmetrical and flat-tipped
- Violaceous
- Flexor surfaces: wrists, forearms, groin, ankles
- Can affect oral mucosa—white streaks or papules or ulcers
- Can affect nails and scalp

**FIGURE 122.5** Lichen planus: thick, hypertrophic, reddish-purple papules

### Management

- Explanation and reassurance
- Usually resolves over 6–9 months, leaving discoloured marks without scarring
- Recurrence rare
- Asymptomatic lesions require no treatment
- Topical moderate to very potent corticosteroids (may use occlusive dressing)
- Oral prednisolone if not successful
- Intralesional corticosteroids for hypertrophic lesions

## § Pruritus ani

The generalised disorders causing pruritus may cause pruritus ani. However, various primary skin disorders such as psoriasis, dermatitis, contact dermatitis and lichen planus may also cause it, in addition to local anal conditions. It is covered in more detail in CHAPTER 36.

## § Pruritus capitis (itchy scalp)<sup>6</sup>

Scalp pruritus may be caused by several common skin conditions including seborrhoeic dermatitis, atopic dermatitis, psoriasis, tinea capitis, lichen simplex chronicus, contact dermatitis and pediculosis. Look for evidence of these conditions in the scalp and treat accordingly. The less severe form of seborrhoeic dermatitis is known as pityriasis capitis or dandruff.

## § Pruritus vulvae

Refer to CHAPTER 106.

## § Tinea cruris

Also known as Dhobie itch and jock itch, tinea cruris is a common infection of the groin area in young men (see FIG. 122.6), usually athletes, that is commonly caused by a tinea infection, although there are other causes of a groin rash (see TABLE 122.4). The dermatophytes responsible for tinea cruris (Dhobie itch) are *Trichophyton rubrum* (60%), *Epidermophyton floccosum* (30%) and *Trichophyton mentagrophytes*.<sup>7</sup> The organisms thrive in damp, warm, dark sites. The feet should be inspected for evidence of tinea pedis. It is transmitted by towels and other objects, particularly in locker rooms, saunas and communal showers.

FIGURE 122.6 Tinea cruris (also known as Dhobie itch and jock itch) in a young man caused by *Trichophyton rubrum*

Table 122.4 Common causes of a groin rash (intertrigo)

Simple intertrigo

Skin disorders:

- psoriasis
- seborrhoeic dermatitis
- dermatitis/eczema

Fungal:

- *Candida*
- tinea

Erythrasma

Contact dermatitis

### Clinical features

- Itchy rash
- More common in young males
- Strong association with tinea pedis (athlete's foot)

- Usually acute onset
- More common in hot months—a summer disease
- More common in physically active people
- Related to chafing in groin (e.g. tight pants, and especially synthetic jock straps)
- Scaling, especially at margin
- Well-defined border (see FIG. 122.7)

If left untreated, the rash may spread, especially to the inner upper thighs, while the scrotum is usually spared. Spread to the buttocks indicates *T. rubrum* infection.

FIGURE 122.7 Dermogram for tinea cruris

### Diagnostic aids

- Skin scrapings should be taken from the scaly area for preparation for microscopy (see CHAPTER 121).
- Wood's light may help the diagnosis, particularly if erythrasma is suspected.

### Management

- Soak the area in a warm bath and dry thoroughly.
- Apply topical terbinafine 1% cream or gel once daily for 7 days or an imidazole topical preparation (e.g. miconazole or clotrimazole cream); rub in a thin layer bd for 3–4 weeks on the rash and 2 cm beyond the border.
- Apply tolnaftate dusting powder bd when almost healed to prevent recurrence.
- If itch is severe, a mild topical hydrocortisone preparation (additional) can be used.<sup>7</sup>
- If weeping: Burow's solution 1 in 40 compresses to dry the area.
- For persistent or recurrent eruption, use oral terbinafine for 2–4 weeks or griseofulvin for 6–8 weeks.

## § **Candida intertrigo**

*Candida albicans* superinfects a simple intertrigo and tends to affect obese or bedridden patients, especially if incontinent.<sup>8</sup>

### **Clinical features**

- Occurs equally in men and women
- Erythematous scaly rash in groin
- Less well-defined margin than tinea (see FIG. 122.8)
- Associated satellite lesions
- Yeast may be seen on microscopy

indefinite border with satellite macular lesions at the edge

FIGURE 122.8 Dermogram for candidiasis of crural area

### **Treatment<sup>5,8</sup>**

- Treat underlying problem.
- Apply an imidazole preparation such as miconazole 2% or clotrimazole 1%.
- Continue treatment for 2 weeks after symptoms resolve.
- Use Burow's solution 1 in 40 compresses to dry a weeping area.
- Use short-term hydrocortisone cream for itch or inflammation (long-term aggravates the problem).

## § **Erythrasma**

Erythrasma, a common and widespread chronic superficial skin infection, is caused by the bacterium *Corynebacterium minutissimum*, which can be diagnosed by coral pink fluorescence on Wood's light examination. Itch is not a feature.

### **Clinical features**

- Superficial reddish-brown scaly patches
- Enlarges peripherally
- Mild infection but tends to chronicity if untreated

- Coral pink fluorescence with Wood's light
- Common sites: groin, axillae, submammary, toe webs (see FIG. 122.9)

### **Treatment**

- Topical imidazole e.g. miconazole or erythromycin 2% gel
- oral roxithromycin

FIGURE 122.9 Typical sites of erythrasma

## § **Asteatotic eczema (winter itch)**

This often unrecognised problem, which can be very itchy, is a disorder of the elderly. It is a form of eczema that typically occurs on the legs of the elderly (see FIG. 122.10), especially if they are subjected to considerable scrubbing and bathing. Other predisposing factors include low humidity (winter, central heating) and diuretics. The problem may be associated with a malabsorption state, hypothyroidism or drugs e.g. statins, diuretics.

### **Clinical features**

- Dry skin
- Fine scaling and red superficial cracking
- 'Crazy paving' appearance
- Occurs on legs, especially shins
- Also occurs on thighs, arms and trunk

### **Treatment**

- Avoid scrubbing with soaps
- Use aqueous cream and a soap substitute
- Apply topical steroid diluted in white soft paraffin

**FIGURE 122.10** Asteatotic eczema (winter itch) showing the 'crazy paving' pattern with a pruritic scaling erythematous eruption on the legs of a 74-year-old man

### § 'Golfer's vasculitis' (summer leg rash)<sup>9</sup>

This is a term used to describe an erythematous pruritic rash that appears on the legs after prolonged exercise such as golf or hiking, usually during summer months.

The rash is a red, blotchy, flat to slightly raised eruption on the lower leg. It is more common over age 50. It usually clears spontaneously within 3 days.

### § Brachioradialis pruritus

In this condition, itch and discomfort are limited to the outer surface of the upper limb above and below the elbow. It is often associated with sun damage, xerosis and nerve entrapment, hence the term 'golfer's itch'.<sup>2</sup>

### § Grover disease

Also known as transient acantholytic dermatosis, Grover disease produces small, firm, intensely pruritic, reddish-brown, warty papules with minimal scale, mainly on the upper trunk. It usually occurs in middle-aged to elderly men (typically 70–80 years). Trigger factors include heat, sweating, fever and occlusion, especially on photo-damaged skin. Diagnosis is by biopsy. Treatment is to relieve the itch until

spontaneous resolution occurs. Effective treatments include topical (preferable) or oral corticosteroids and ultraviolet light.<sup>3</sup>

### § Lichen simplex

Lichenification is a form of dermatitis caused by repeated scratching or rubbing, which results in epidermal thickening. Lichen simplex is the term used when no primary dermatological cause can be found.

### § Urticaria<sup>10</sup>

Urticaria is a common condition that mainly affects the dermis. It can be classified as acute (minutes to weeks) or chronic (lasting more than 6 weeks). It can also be classified as diffuse wheal-like or papular (hives).

The three characteristic features of diffuse urticaria are:

- transient erythema
- transient oedema
- transient itch

The most common causes are infections, especially viral URTIs, drug allergies and IgE-mediated food reactions.

### Classification according to site

- 1 *Superficial*: affecting superficial dermis = urticaria; occurs anywhere on body, especially the limbs and trunk.
- 2 *Deep*: affecting subcutaneous tissue = angio-oedema; occurs anywhere but especially peri-orbital region, lips and neck.

### Checklist of causes<sup>3</sup>

- Infections: viruses (the most common cause in children), bacteria (especially streptococcus infection), parasites, protozoa, yeasts
- C<sub>1</sub> esterase inhibitor deficiency (hereditary angio-oedema)—recurrent unexplained episodes of angio-oedema
- Allergies (acute allergic urticaria is dramatic and potentially very serious):
  - azo dyes
  - drugs: penicillin and other antibiotics
  - foods: eggs, fish, cheese, tomatoes, others
- Pharmacological:
  - drugs: penicillin, aspirin, codeine
  - foods: fish, shellfish, nuts, strawberries, chocolate, artificial food colourings, wheat, soy beans
  - plants: nettles, others

- Systemic lupus erythematosus
- Physical:
  - cholinergic: response to sweating induced by exercise and heat (e.g. young athletes)
  - heat, cold, sunlight
- Insect stings: bees, wasps, jellyfish, mosquitoes
- Pregnancy (last trimester), other hormonal
- Unknown (idiopathic)—80%; possible psychological factors

### Investigations

- Full blood examination—look for eosinophilia of parasites
- ANF and DNA binding tests—consider SLE
- Challenge tests

### Treatment<sup>5</sup>

- Avoid any identifiable causes.
- Avoid salicylates and related food preparations (e.g. tartrazine).
- Consider elimination diets.
- Use oral antihistamines (e.g. cyproheptadine) or a less sedating one (e.g. cetirizine, loratadine, fexofenadine).
- Consider adding an H<sub>2</sub> antagonist (e.g. ranitidine 150 mg bd).
- Give short course of systemic corticosteroids if severe (e.g. prednisolone 50 mg once daily for 3–5 days).<sup>11</sup>
- For severe urticaria with hypotension and anaphylaxis give IM adrenaline.<sup>5</sup>
- Use topical soothing preparation if relatively localised (e.g. crotonamiton 10%, or phenol 1% in oily calamine or menthol 1% cream).
- Lukewarm baths with Pinetarsol or similar soothing bath oil.

### Popular urticaria

This is a hypersensitivity to insect bites particularly seen in children aged 2–6 years. The lesions are grouped together as very itchy papules.

Common urticaria tends to come and go within hours but the lesions of papular urticaria persist.

### § Flea bites

Fleas (see FIG. 122.11) cause itchy erythematous maculopapular lesions. They are usually multiple or grouped in clusters, occurring typically on the arms, forearms, leg and waist (where clothing is tight). Treat the source of infestation, particularly domestic cats and dogs. The itchy bites can be treated with an application of simple agents such

as Stingose, alcohol, damp soap, anti-itch cream or a mild corticosteroid ointment.

FIGURE 122.11 Flea

### § Bed bug bites<sup>12</sup>

The common bed bug (*Cimex lectularius*, see FIG. 122.12) is now a major problem related to international travel. It travels in baggage and is widely distributed in hotels, motels and backpacker accommodation. The bugs hide in bedding and mattresses. Clinically bites are usually seen in children and teenagers. The presentation is a linear group of three or more bites (along the line of superficial blood vessels), which are extremely itchy. They appear as maculopapular red lesions with possible wheals. The lesions are commonly found on the neck, shoulders, arms, torso and legs. A bed bug infestation can be diagnosed by identification of rust-coloured specimens collected from the infested residence. In hotels and backpacker accommodation look for red specks in mattresses and check luggage.

FIGURE 122.12 Bed bug

### Management

- Clean the lesions with antiseptic soap.
- Apply a corticosteroid ointment.
- A simple antipruritic agent may suffice e.g. calamine lotion.
- Call in a licensed pest controller.

Control treatment is basically directed towards applying insecticides to the crevices in walls and furniture. Be careful of used furniture and insist that mattresses are delivered in plastic coverings.

## § Sandfly bites

Refer CHAPTER 130.

### When to refer

- Lichen planus
- Dermatitis herpetiformis
- Norwegian scabies

### Practice tip

An itchy non-specific rash worse at night? Think scabies.

### Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Bed bug bites
- Pruritus ani
- Scabies
- Urticaria

*The power of making a correct diagnosis is the key to all success in the treatment of skin diseases; without this faculty, the physician can never be a thorough dermatologist, and therapeutics at once cease to hold their proper position, and become empirical.*

Louis A Duhring (1845–1913)

Skin disorders are common. They account for 10.8% of all problems<sup>1</sup> encountered in general practice, the most common being contact dermatitis, malignant skin neoplasms, solar keratoses/sunburn, lacerations, warts and acne.

This chapter focuses on the common dermatoses.

## Dermatitis/eczema

The terms 'dermatitis' and 'eczema' are synonymous<sup>1</sup> and denote an inflammatory epidermal rash, acute or chronic, characterised by vesicles (acute stage), redness, weeping, oozing, crusting, scaling and itch. Dermatitis can be divided into *exogenous* causes (allergic contact, primary irritant contact, photo-allergic and phototoxic) and *endogenous*, which implies all forms of dermatitis not directly related to external causative factors. Endogenous types are atopic, nummular (discoid), vesicular hand/foot (dyshidrotic), pityriasis alba, lichen simplex chronicus and seborrhoeic.

Dermatitis is primarily due to an impairment of the barrier function of the skin, making it more susceptible to irritation by soap and other contact irritants, the weather, temperature and non-specific triggers.

## The meaning of atopy

The term 'atopic' refers to a hereditary background or tendency to develop one or more of a group of conditions, such as allergic rhinitis, asthma, eczema, skin sensitivities and urticaria. It is not synonymous with allergy.

An estimated 10% of the population are atopics, with allergic rhinitis being the most common manifestation.<sup>2</sup>

## § Atopic dermatitis

Features of classic atopic dermatitis:<sup>3</sup>

- itch
- usually a family history of atopy

- about 3% of infants are affected, signs appearing between 3 months and 2 years
- often known trigger factors (see TABLE 123.1) are evident

Table 123.1 Trigger factors for atopic dermatitis

Dust mite (common)
Sweating
Sand (e.g. in sandpits)
Extremes of hot and cold
Rapid temperature changes
Soap, shampoo and water/frequent washing, especially in winter
Chlorinated water
Bubble baths
Infection (viral, bacterial, fungal)
Allergy
Stress/emotional factors
Skin irritants:
• wool (e.g. sheepskin covers)
• brushed nylon or silk clothing
• rough clothing
• chemical disinfectants
• detergents
• petrochemical products
• pollens
Scratching and rubbing
Perfumes
Poor general health
Foodstuffs (consider):
• cow's milk
• beef
• chicken
• nuts
• eggs
• food colourants
• oranges and other citrus fruits
• tomatoes
• wheat

*Note:* The relationship to food is controversial and uncertain. RAST testing is misleading. Consider eliminating the foodstuffs and reintroducing one at a time. If sensitive, the child goes bright red a few minutes after feeding.

- dust mite allergy is not always obvious, especially for peri-orbital rash
- lichenification may occur with chronic atopic dermatitis
- flexures are usually involved (see FIG. 123.1)
- dryness is usually a feature

**FIGURE 123.1** Atopic dermatitis in the flexures of the knees—a typical location

### Criteria for diagnosis

- Itch
- Typical morphology and distribution
- Dry skin
- History of atopy
- Chronic relapsing dermatitis

### Distribution

The typical distribution of atopic dermatitis changes as the patient grows older. In infants the rash appears typically on the cheeks of the face, the folds of the neck and scalp and extensor surfaces of the limbs. It may then spread to the flexures of limbs and groins (see FIG. 91.10 in CHAPTER 91). The change from infancy through to adulthood is presented in FIGURE 123.2.

During childhood a drier and thicker rash tends to develop in the cubital and popliteal fossae and on the hands and feet, which may be dry, itchy, fissured and painful. The face often clears. Refer to CHAPTER 91.

### Prognosis

It is generally correct that children tend to 'grow out of' the problem as the function of their oil and sweat glands matures. The skin becomes less dry, less overheated and irritable.<sup>4</sup> About 60% of patients have virtually normal skin by 6 years and 90% by puberty.<sup>4</sup>

**FIGURE 123.2** Relative distribution of atopic dermatitis in (a) infants, (b) children, and (c) typical distribution of atopic dermatitis in adults

### Treatment

Advice to parents of affected children:

- Avoid soap and perfumed products. Use a bland bath oil in the bath and a cleansing bar (e.g. Cetaphil, DermaVeen) as a soap substitute. Choose cleansers and shampoos with low pH (4.5–6.0) e.g. DermaVeen, Ego or Hamilton body wash and shampoo.
- Apply an emollient soon after bathing.
- Older children should have short, tepid showers.
- Avoid rubbing and scratching—use gauze bandages with hand splints for infants.
- Keep fingernails short and clean.
- Avoid overheating, particularly at night.

- Avoid sudden changes of temperature, especially those that cause sweating.
- Wear light, soft, loose clothes, preferably made of cotton. Cotton clothing should be worn next to the skin.
- Avoid wool next to the skin.
- Avoid dusty conditions and sand, especially sandpits.
- Avoid contact with people with 'sores', especially herpes.
- Keep the skin moisturised.  
Consider dust mite strategies:
  - dust mite covers (premium grade) for bedding
  - wash linen in hot water  $>55^{\circ}\text{C}$
  - consider replacing fabric on chairs and changing carpet

### Education and reassurance

Explanation, reassurance and support are very important. Emphasise that atopic dermatitis is a superficial disorder and will not scar or disfigure under normal circumstances. The child should be treated normally in every respect. Counselling is indicated where family stress and psychological factors are contributing to the problem.

### Medication<sup>4,5</sup>

*Note:* Corticosteroid creams (for acute phase) and ointments (for chronic phase) in either a step-up or step-down strategy are the basis of treatment. Emollients are the key to preventing flares and steroids are used for the flares. For maintenance, especially if dry, consider coal tar (LPC) 3–6% with salicylic acid 2–6% in aqueous cream at night.

### Mild atopic dermatitis

- Soap substitutes
- Emollients apply bd to dry skin (choose from):
  - Ego skin cream
  - sorbolene alone or with 10% glycerol
  - paraffin creams (e.g. Dermeze)—good in infants
  - bath oils (e.g. Alpha Keri)
  - moisturising lotions (e.g. QV) in summer
- 1% hydrocortisone ointment (if not responding to above) once or twice daily:
  - short term for flares

### Moderate atopic dermatitis

- As for mild
- Topical corticosteroids (twice daily):
  - vital for active areas

- moderate strength (e.g. fluorinated) to trunk and limbs, once or twice daily
- weaker strength (e.g. 1% hydrocortisone) to face and flexures, once daily increasing to twice daily if inadequate response
- use as needed but should not be used for longer than 2 weeks, or use in cyclic fashion for chronic cases (e.g. 10 days on, 4 days off)
- Non-steroidal alternative: pimecrolimus (Elidel) cream bd for facial dermatitis; best used when eczema flares—then cease
- Oral antihistamines at night for itch

### Severe dermatitis

- As for mild and moderate eczema
- Potent topical corticosteroids to worse areas (consider occlusive dressings)
- Consider hospitalisation
- Systemic corticosteroids (rarely used)
- Allergy assessment if unresponsive
- Consider adding UV band therapy as back-up
- Systemic immunosuppressants may be used for recalcitrant cases

### Weeping dermatitis (an acute phase)

This often has crusts due to exudate. Burow's solution diluted to 1 in 20 or 1 in 10 can be made to soak affected areas. Saline (1 teaspoon to 500 mL water) dressings can also be used: soak old sheets till damp and lay on the areas. Infection is common.

### General points of dermatitis management

Acute weeping	→ wet dressings (saline or Burow's)
Acute	→ creams
Chronic	→ ointments, with or without occlusion
Lichenified	→ ointments under occlusion
Infection	→ antibiotics (e.g. mupirocin 2% topical or oral alone if unresponsive to topical)
Moisturising	→ use lotions not creams

### OTHER TYPES OF ATOPIC DERMATITIS

#### § Nummular (discoid) eczema

- Chronic, red, coin-shaped plaques
- Crusted, scaling and itchy
- Mainly on the legs, also buttocks and trunk
- Often symmetrical
- Common in middle-aged patients
- May be related to stress
- Tends to persist for months

Treatment as for classic atopic dermatitis.

### § Pityriasis alba

- These are white patches on the face of children and adolescents
- Very common mild condition
- More common around the mouth and on cheeks
- Can occur on the neck and upper limbs, occasionally on trunk
- It is a subacute form of atopic dermatitis
- Full repigmentation occurs eventually

#### Treatment

- Reassurance
- Simple emollients
- Restrict use of soap and washing
- May prescribe hydrocortisone ointment (rarely necessary)

### § Lichen simplex chronicus

- Circumscribed thick plaques of lichenification
- Often a feature of atopic dermatitis
- Caused by repeated rubbing and scratching of previously normal skin
- Due to chronic itch of unknown cause
- At sites within reach of fingers (e.g. neck, forearms, thighs, vulva, heels, fingers)
- May arise from habit

#### Treatment

- Explanation
- Refrain from scratching
- Potent fluorinated corticosteroid ointment with plastic occlusion

### § Dyshidrotic dermatitis (pompholyx)

- Typically in patients aged 20–40 years
- Itching vesicles usually on fingers (pompholyx, see FIG. 123.3)
- May be larger vesicles on palms and soles
- Commonly affects sides of digits and palms
- Lasts a few weeks
- Tends to recur
- Possibly related to stress
- Often triggered by high humidity

#### Treatment

- Wet dressings/soaks if severe
- As for atopic dermatitis
- Potent fluorinated corticosteroids
- Topically—use under occlusion (e.g. damp cotton gloves)
- Oral corticosteroids (3 weeks) may be necessary

**FIGURE 123.3** Pompholyx showing the typical vesicular dermatitis along the borders of the fingers. Look for associated inflammatory tinea of the feet which can precipitate it.

Photo courtesy Robin Marks

### § Asteatotic dermatitis

This is the common, very itchy dermatitis that occurs in the elderly, especially in the winter, with a dry 'crazy paving' pattern, especially on the legs (see CHAPTER 122). 'Asteatotic' means without moisture.

### § Cracked (fissured) hands/fingers

This common cause of disability is usually due to dermatitis of the hands, irritant contact dermatitis or very dry skin. It is usually part of the atopic dermatitis problem and it is important to consider allergic contact dermatitis.

#### Management (hand dermatitis)

Hand protection:

- avoid domestic or occupational duties that involve contact with irritants and detergents
- wear protective work gloves; cotton-lined PVC gloves
- avoid perfumed toilet soaps—use a substitute (e.g. Dove, Neutrogena, DermaVeen soap-free cleansing bar)
- Cetaphil lotion is a useful soap substitute
- apply emollients (e.g. 2% salicylic acid in white soft paraffin at night, or Neutrogena Norwegian Formula hand cream)

If necessary:

hydrocortisone 1% ointment (not cream)

or

stronger fluorinated preparation (e.g. Advantan fatty ointment)

## § Cracked heels

Cracked painful heels are a common problem, especially in adult women. It is a manifestation of very dry skin.

### Treatment

- Soak the feet for 15 minutes in warm water containing an oil such as Alpha Keri or Derma Oil.
- Pat dry, then apply an emollient foot cream (e.g. Nutraplus—10% urea).
- Can use tissue glue (with care) to hold edges together.

## CONTACT DERMATITIS

Acute contact (exogenous) dermatitis can be either *irritant* or *allergic* and it is estimated that at least 70% of patients have an irritant cause. It is difficult to separate these types on clinical or histological grounds. The presence of irritant dermatitis increases the risk of developing a contact allergy.

Features:

- itchy, inflamed skin
- red and swollen
- papulovesicular
- may be dry and fissured

## § Irritant contact dermatitis

This is caused by primary irritants such as acids, alkalis, detergents, soaps, oils, solvents. A reaction may result from either a once-only exposure to a very irritant chemical or, more commonly, repeated exposure to weaker irritants. This is irritation, not allergy.

## § Allergic contact dermatitis

Caused by allergens that provoke an allergic reaction in some individuals only—most people can handle the chemicals without undue effect. It is immunologically mediated. This allergic group also includes photo-contact allergens. Approximately 4.5% of the population is allergic to nickel, which is found in jewellery, studs on jeans, keys and coins

(see FIG. 123.4). Contact dermatitis is due to delayed hypersensitivity, sometimes with a long time of days to years. It is common in industrial or occupational situations, where it usually affects the hands and forearms.

FIGURE 123.4 Contact dermatitis due to nickel-containing underwire in brassiere in 17-year-old girl with a history of eczema

Common allergens:

- ingredients/fragrances in cosmetics (e.g. perfumes, preservatives)
- topical antibiotics (e.g. neomycin)
- topical anaesthetics (e.g. benzocaine)
- topical antihistamines
- plants: *Rhus*, *Grevillea*, *Primula*, poison ivy
- metal salts (e.g. nickel sulphate, chromate)
- dyes (especially clothing dyes)
- perfumes, cosmetics
- hairdressing chemicals
- rubber/latex
- epoxy resins and glues/acrylates
- glutaraldehyde (e.g. sterilising agents)
- toluene sulfonamide compound resins: nail polish
- coral

*Note:* The skin of mangoes cross-reacts with *Rhus* and *Grevillea*.

### Clinical features<sup>3</sup>

- Dermatitis ranges from faint erythema to 'water melon' face oedema
- Worse in peri-orbital region, genitalia and hairy skin; least in glabrous skin (e.g. palms and soles)

*Note:* Can be delayed onset.

- Think of *Rhus*, *Grevillea* or poison ivy allergy if linear blisters on forearms and/or puffy eyes

### Diagnostic hallmarks<sup>3</sup>

- Site and shape of lesions suggest contact
- Linear lesions a feature
- Allergic causes may be found by patch testing
- Improvement when off work or on holiday

### Diagnosis

- Careful history and examination
- Consider occupation, family history, vacation or travel history, clothes (e.g. wetsuits, new clothes, Lycra bras), topical applications (e.g. medicines, cosmetics)
- Refer to a dermatologist for patch testing

### Management

- Determine cause with vigour and remove it
- Wash with water (only) and pat dry (avoid soap)
- If acute with blistering, apply Burow's compresses
- Oral prednisolone for severe cases<sup>4</sup> (start with 25–50 mg daily for adults for 1–2 weeks then gradually reduce over 1–2 weeks)
- Topical corticosteroid cream
- Oral antibiotics for secondary infection

## SEBORRHOEIC DERMATITIS

Seborrhoeic dermatitis is a very common skin inflammation that usually affects areas abundant in sebaceous glands or intertriginous areas. It is therefore common in hair-bearing areas of the body, especially the scalp and eyebrows. It can also affect the scalp, face, neck, axillae and groins, eyelids (blepharitis), external auditory meatus and nasolabial folds. The presternal area is often involved (see FIG. 123.5).

FIGURE 123.5 Seborrhoeic dermatitis in an adult showing a typical position on the chest

There are two distinct clinical forms: seborrhoeic dermatitis of infancy, and the adult form, which mainly affects young adults.

Studies have indicated that it may be caused by a reaction to the yeast *Malassezia* sp. It may be associated with HIV infection and Parkinson disease.

A feature of seborrhoeic dermatitis is that, unlike atopic dermatitis, it is not itchy. Seborrhoeic scale is greasy and yellowish unlike the silvery scale of psoriasis.

### Principles of treatment

- Topical sulphur, salicylic acid and tar preparations are first-line treatment: they lift the scale while sulphur kills the yeast.
- Ketoconazole cream is most effective.
- Ketoconazole shampoo for scalp twice weekly for 4 weeks.
- Topical corticosteroids are useful for inflammation and pruritus and best used in combination. Avoid corticosteroids if possible.

### § Seborrhoeic dermatitis of infancy

This rash may be known as 'cradle cap' if it affects the scalp, or nappy rash/diaper dermatitis if it involves the napkin area.

It can be difficult to differentiate the rash from that of atopic dermatitis but seborrhoeic dermatitis tends to appear very early (before atopic dermatitis), even in the first month of life and mostly within the first 3 months, when androgen activity is most prevalent.

The different features are summarised in TABLE 123.2 and the distribution is presented in FIGURE 123.6.

Seborrhoeic dermatitis usually appears as red patches or blotches with areas of scaling. This becomes redder when the baby cries or gets hot. Cradle cap may appear in the scalp. A flaky, scurf-like dandruff appears first, and then a yellowish, greasy, scaly crust forms. This scurf is usually associated with reddening of the skin. It may resolve spontaneously within a few months (see Cradle cap, CHAPTER 91).

The dermatitis can become infected, especially in the napkin area, and this may be difficult to treat. If untreated, it often spreads to many areas of the body. It is said that cradle cap and nappy rash 'may meet in the middle'.

### Treatment

Simple basic methods are:

- keep areas dry and clean

**Table 123.2** Differential diagnosis of seborrhoeic dermatitis and atopic dermatitis in infancy

	Seborrhoeic dermatitis	Atopic dermatitis (eczema)
<b>Age of onset</b>	Mainly within first 3 months	Usually after 2 months
<b>Itchiness</b>	Nil or mild	Usually severe
<b>Distribution</b>	Scalp, cheeks, folds of neck, axillae, folds of elbows and knees	Starts on face Elbow and knee flexures
<b>Typical features</b>	Cradle cap Red and yellow greasy scale	Vesicular and weeping Becomes dry and cracked
<b>Napkin rash</b>	Common Prone to infection with <i>Candida</i>	Less common
<b>Other features</b>	May become generalised	May become generalised

**FIGURE 123.6** Seborrhoeic dermatitis: typical distribution in infants

- bathe in warm water, pat areas dry with a soft cloth
- keep skin exposed to air as much as possible
- avoid toilet soaps for washing (use emulsifying ointment or cetaphil lotion)
- rub scales of cradle cap gently with baby oil or white soft paraffin then wash away loose scales
- change wet or soiled nappies often
- for mild areas on body, apply a thin smear of zinc cream

## Medication<sup>4</sup>

### Scalp

Infants:

1–2% sulphur and 1–2% salicylic acid in aqueous cream or same cream with 2% liquor picis carbonis added:

- apply overnight to scalp, shampoo off next day with a mild baby shampoo
- use 3 times a week until it clears

Egozite cradle cap lotion (6% salicylic acid)

Older children and adults:

zinc pyrithione 1% or selenium sulphide 2.5% shampoo

or

ketoconazole 1–2% or miconazole 2% shampoo

### Face, flexures and trunk

Select from (depending on severity):

- ketoconazole 2% cream, once or twice daily
- 2% salicylic acid ± 2% sulphur in aqueous or sorbolene cream
- if severe, hydrocortisone 1% (irritation on face and flexures)
- betamethasone 0.02–0.05% (if severe irritation on trunk)
- desonide 0.05% lotion, bd or tds for face/eyelids and for weeping areas

### Napkin area

- Mix equal parts 1% hydrocortisone with nystatin or ketoconazole 2% or clotrimazole 1% cream (or use Hydrozole Cream)

## Prognosis

Most children are clear by 18 months (rare after 2 years).

## Adult seborrhoeic dermatitis

### Clinical features

- Any age from teenage onwards
- The head is a common area: scalp and ears, face, eyebrows, eyelids (blepharitis), nasolabial folds (see FIG. 123.7)
- Other areas: centre of chest, centre of back, scapular area, intertriginous areas, especially perianal (see FIG. 123.8)
- Red rash with yellow greasy scale
- Secondary candidiasis infection common in flexures

**FIGURE 123.7** Seborrhoeic dermatitis: facial distribution in adults

**FIGURE 123.8** Seborrhoeic dermatitis: possible distribution in adults

- Dandruff a feature of scalp area
- Worse with stress and fatigue
- It is a chronic, recurring condition

## Treatment

### Scalp

Options:

- 1 salicylic acid 2% ± sulphur 2% (or LPC 3% plus salicylic acid 3%) in aqueous cream overnight—shampoo off next day using selenium sulphide or zinc pyrithione shampoo (apply 3 times a week)

- 2 ketoconazole shampoo; immediately after using medicated shampoo (leave 5 minutes), twice weekly
- 3 ciclopirox olamine shampoo, 2 or 3 times weekly
- 4 betamethasone dipropionate 0.5% lotion to scalp (if very itchy)

## Face and body

- Wash regularly using bland soap  
salicylic acid 2% + sulphur 2% (± tar) in aqueous cream  
or  
ketoconazole 2% cream (very effective); apply once daily for 4 weeks  
hydrocortisone 1% bd (if inflamed and pruritic)  
or  
combination hydrocortisone 1% + clotrimazole 1% cream topically, once or twice daily

*Note:* Oral antifungals are not recommended at all.

## PSORIASIS

Psoriasis (see FIG. 123.9) is a chronic, immune-mediated skin disorder of unknown aetiology which affects 2–4% of the population. It appears most often between the ages of 10 and 30 years, although its onset can occur any time from infancy to old age. It has a familial predisposition although its mode of inheritance is debatable. If one parent is affected there is a 25% chance of developing it; this rises to 65% if both parents are affected.<sup>2</sup>

Psoriasis is now regarded as a disorder involving activation of helper T cells in the skin. Cytokines are then released and cause skin cells to multiply faster, leading to thickening of the skin and overscaling. The new 'biological agents' intervene in this process.

Capillary dilatation explains the redness.

Be aware of association with cardiovascular disease, particularly heart disease, depressive illness, diabetes, arthritis, inflammatory bowel disease and lymphoma.<sup>6</sup>

## Factors that may worsen or precipitate psoriasis

- Infection, especially group A *Streptococcus*
- Trauma or other physical stress
- Emotional stress
- Sunburn
- Puberty/menopause
- Drugs:
  - antimalarials (e.g. chloroquine)
  - beta blockers
  - lithium
  - NSAIDs
  - oral contraceptives

**FIGURE 123.9** Psoriasis showing the typically raised pink plaques surmounted with a silvery scale

Types of psoriasis	Differential diagnosis
Infantile	Seborrhoeic dermatitis, atopic dermatitis
Plaque (commonest)	Seborrhoeic dermatitis, discoid eczema, solar keratoses, Bowen disorder
Guttate	Pityriasis rosea, secondary syphilis, drug eruption
Flexural	Tinea, candida intertrigo, seborrhoeic dermatitis
Scalp (sebopsoriasis)	Seborrhoeic dermatitis, tinea capitis
Nail	Tinea, idiopathic onycholysis
Pustular (palmoplantar)	Tinea, infected eczema
Exfoliative	Severe seborrhoeic dermatitis

### The typical patient

- Older teenager or young adult
- Possible family history
- Onset may follow stress, illness or injury
- Rash may appear on areas of minor trauma—the Koebner phenomenon

- Rash improves on exposure to sun but worse with sunburn
- Worse in winter
- Itching not a feature but is present sometimes
- Lesions are most unlikely to appear on the face

### Arthropathy

About 5% can develop a painful arthropathy (fingers, toes or a large joint) or a spondyloarthropathy (sacroiliitis).<sup>7</sup>

### The rash

The appearance depends on the site affected. The commonest form is plaque psoriasis, which begins with red lesions that enlarge and develop silvery scaling. The commonest sites are the extensor surfaces of the elbows and knees; then the scalp, sacral areas, genitals and nails are affected (see FIG. 123.10).

### Diagnosis

Psoriasis is a clinical diagnosis but biopsy may be needed for confirmation. No laboratory test (including blood testing) is available.

### Principles of management

While realising there is no cure for psoriasis, the aim of treatment is to relieve discomfort, slow down the rapid skin cell division and work in consultation with a specialist to achieve these aims.<sup>7</sup>

- Provide education, reassurance and support.
- Promote general measures such as rest, and holidays, preferably in the sun.

**FIGURE 123.10** Psoriasis: typical skin distribution

- Advise prevention, including avoidance of skin damage and stress if possible.
- Tailor treatment (including referral) according to the degree of severity and extent of the disease.
- Shared care with a consultant is advisable.

### Treatment options<sup>4,7</sup>

See TABLE 123.3.

Topical agents useful for mild psoriasis include tars, dithranol, salicylic acid, calcipotriol, corticosteroids and tazarotene (a retinoid).

**Table 123.3** Psoriasis treatment options

Therapy	Efficacy/notes
<b>1 Topical therapy</b>	
Dithranol (anthralin): concentrations range from 0.05 to 2% (max.)	Effective on difficult thick patches Facts: <ul style="list-style-type: none"> <li>• stains light-coloured hair purple so don't use on scalp</li> <li>• start in low concentration and build up according to tolerance and response</li> <li>• use in strengths 0.05% (children), 0.1%, 0.25%, 0.5% and 2.0% (max.)</li> <li>• can use a higher strength of 0.25% to start but only for short contact therapy (30 minutes before shower)</li> <li>• irritates skin, causing a burning sensation</li> <li>• don't use it on face, genitalia or flexures</li> </ul>
Tar preparations	Effective but messy to use
Corticosteroids	The mainstay of therapy for small plaques; use 1% hydrocortisone on more sensitive areas (genitals, groin, axillae, face) but use stronger types elsewhere (e.g. betamethasone dipropionate) <i>Note:</i> Avoid using corticosteroids alone as they promote instability—best to combine with tar or calcipotriol.
Calcipotriol 0.005% ointment	Facts: <ul style="list-style-type: none"> <li>• easy to use</li> <li>• apply twice daily for a minimum of 6 weeks</li> <li>• tends to irritate face and flexures</li> <li>• caution with hypercalcaemia</li> <li>• wash hands after use</li> <li>• used for chronic stable plaques (not for severe extensive rash)</li> <li>• good when combined with a potent corticosteroid (each applied once daily) e.g. Daivobet 50/500</li> </ul>
Bland preparations and emollients	These can be used for dryness, scaling and itching—liquor picis carbonis (LPC) and menthol (or salicylic acid) in sorbolene base
<b>2 Systemic therapy</b>	
Methotrexate	Can have dramatic results in severe cases
Cyclosporin	Hospital use only
Corticosteroids (for erythrodermic psoriasis only)	Oral use may unbalance psoriasis on withdrawal
Acitretin	A vitamin A derivative effective in severe intractable psoriasis (never use in females of child-bearing age)
<b>3 Biological agents</b>	
Monoclonal antibodies, anti-TNF agents, other agents	This new class of drugs is directed at the T cell dysfunction (i.e. immune response modifiers) (e.g. efalizumab, infliximab, ustekinumab, alefacept)
<b>4 Physical therapy</b>	
Phototherapy (ultraviolet light, narrowband or broadband, UV-B):	Needs careful supervision

UV-B plus coal tar (Goeckerman regimen):	Reserved for severe psoriasis: (a) tar bath (b) UV-B (c) 2–5% crude coal tar
Ingram regime	Also for severe psoriasis (best as inpatient): (a) tar bath (b) UV-B (c) 0.1%–0.5% dithranol in Lassar's paste
Photochemotherapy (PUVA = psoralen + UV-A)	Reserved for non-responders to UV-B treatment or other therapies.
Intralesional corticosteroids	An excellent and effective treatment for isolated small or moderate-sized plaques that can be readily given by the family doctor

### Recommended topical regimens

- Combined method for mild to moderate psoriasis (a good starting method):
  - dithranol 0.1%, salicylic acid 3%,  $\pm$  LPC (tar) 10% in white soft paraffin (preferable) or sorbolene cream
  - leave overnight (warn about dithranol stains—use old pyjamas and sheets)
  - review in 3 weeks then gradually increase strength of dithranol to 0.25%, then 0.5% then 1%. Can cut down frequency to 2–3 times per week
  - shower in the morning and then apply a topical fluorinated corticosteroid
- Short contact anthralin therapy (SCAT method):
  - apply dithranol 2% in sorbolene cream
  - wash off in shower after 10–15 minutes
- General adjunctive therapy:
  - tar baths (e.g. Pinetarsol or Polytar)
  - tar shampoo (e.g. Polytar, Ionil-T)
  - sunlight (in moderation)

### Other practice tips

#### Chronic stable plaque psoriasis

apply stronger fluorinated corticosteroid (II–III class) cover with DuoDERM Thin and leave for 7 days (other occlusive dressings can be used)  
*plus*  
 tar (as an alternative to dithranol) (e.g. crude coal tar 1–4% plus salicylic acid 3–5% in sorbolene cream)—it can be left on overnight and washed off in the morning  
*or*  
 calcipotriol 0.005% ointment or cream, apply bd  
*or*  
 calcipotriol once daily + corticosteroids once daily

### Resistant localised plaque

intralesional injection with corticosteroid diluted 50:50 with N saline or local anaesthetic

#### Method of injection

Mix equal parts of triamcinolone acetonide 10 mg/mL, or similar corticosteroid, and plain LA or N saline and, using a 25 gauge or 23 gauge needle, infiltrate the psoriatic plaque intradermally to cover virtually all the plaque. A small plaque can be covered by a single insertion while a larger plaque may require separate insertions (see FIG. 123.11).

FIGURE 123.11 Intralesional corticosteroid injection technique for psoriatic plaque (requiring double injection—small plaques need only one infiltration)

### Maintenance for milder stabilised plaque psoriasis

salicylic acid 3%, LPC 8% in sorbolene

#### Red scale

A traditional treatment is tar pomade, which is a preparation of various combinations of LPC (5–10%), salicylic acid  $\pm$  dithranol in liquid paraffin.

#### Scalp psoriasis

apply 20% urea cream for 4 days  
*then*

tar preparations for the scalp (shampoo with conditioner), steroid lotions or 5–10% salicylic acid in mineral oil; systemic therapy if severe.

or

intermittent use of mometasone furoate lotion or Daivobet gel

### Genital psoriasis

apply non-fluorinated corticosteroids

### Flexural psoriasis

Note that fissuring (e.g. inframammary, natal cleft) is a feature. It tends to have a silvery scale but is shiny and smooth.

apply topical steroids—mild to moderate fluorinated

### Nail psoriasis

Difficult but consider potent topical or intralesional corticosteroids and systemic therapy.

## NAPPY RASH<sup>4</sup>

Nappy rash (or diaper dermatitis) is an inflammatory contact dermatitis occurring in the napkin area and can be a common presentation of mild or moderate underlying skin disease. It is found in children up to 2 years old and has a peak incidence from 9–12 months.<sup>8</sup>

Most children will develop nappy rash at some stage of infancy with an estimated 50% having it to a significant extent. The commonest type is *irritant dermatitis*, but consider also:

- *Candida albicans* (invariably present although often not obvious)
- seborrhoeic dermatitis
- atopic dermatitis
- psoriasis

### § Irritant dermatitis

This is a type of contact dermatitis with the erythema and scaling conforming to the napkin area. The flexures are usually spared. It is related to the activity of faecal proteases and lipases and probably not to the activity of ammonia (from urea) as previously promoted. The problem can vary from mild erythema to a severe blistering eruption with ulceration. Ultrasorbent disposable nappies appear to be better than cloth nappies.<sup>9</sup> Diarrhoea, including spurious diarrhoea with constipation (check rectum) is a causative factor of irritant dermatitis. If the eruption extends further than the points of contact with the nappy an underlying skin disease such as seborrhoeic

or atopic dermatitis must be suspected. Psoriasis always involves the skin folds.

### § Seborrhoeic dermatitis

This affects mainly the flexures of the natal cleft and groin. It is important to look for evidence of seborrhoeic dermatitis elsewhere, such as cradle cap and lesions on the face and axillae.

### § Atopic dermatitis

Atopic dermatitis can involve the napkin area. Pruritus is a feature and the child may be observed scratching the area. There may be evidence of atopic dermatitis elsewhere, such as on the face.

### § Candidiasis (monilia nappy rash)

Superinfection of intertrigo or napkin dermatitis will result in a diffuse, red, raw, shiny rash that will involve the flexures and extend beyond the napkin area as 'satellite lesions'. *Candida* tends to invade the skin folds and the foreskin of male babies.

## Causes of nappy rash

The main predisposing factor in all types is dampness due to urine and faeces. It is far less common since the use of disposable nappies. Other causes or aggravating factors are:

- a tendency of the baby to eczema
- a tendency of the baby to seborrhoeic dermatitis
- infection, especially *Candida* (thrush)
- rough-textured nappies
- detergents and other chemicals in nappies
- plastic pants (aggravates wetness)
- excessive washing of the skin with soap
- too much powder over the nappy area (avoid talcum powders)
- teething aggravates (punched out lesions)

## Uncommon causes

### Psoriatic nappy rash

This presents as a non-scaling eruption, primarily on the napkin area, but can extend to the flexures, trunk and limbs. The edge of the rash is sharply demarcated. The typical psoriatic scale is absent. It tends to occur in the first weeks of life. There is usually a family history.

### Infections

Bacterial infections to consider include staphylococcal folliculitis, impetigo and perianal

streptococcal dermatitis. Culture of the lesion will reveal the cause.

### Impetigo

If there is *Staphylococcus* superinfection, bullae and pus-filled blisters will be present.

### Histiocytosis X (Letterer-Siwe syndrome)

There is a similar rash to seborrhoeic dermatitis but the lesions are purpuric. In this serious syndrome the child is very ill and usually lymphadenopathy and hepatosplenomegaly may be found.

### Zinc deficiency

May be more common than realised.

## Management

Basic care (instructions to patients):

- 1 Keep the area dry. Change wet or soiled nappies frequently and as soon as you notice them. Use highly absorbent disposable nappies.
- 2 After changing, gently remove any urine or moisture with diluted sorbolene cream or warm water.
- 3 Wash gently with warm water, pat dry (do not rub) and then apply any prescribed cream or ointment to help heal and protect the area. Vaseline or zinc cream applied lightly will do. Stoma adhesive powder is an excellent protector.
- 4 Expose the bare skin to fresh air wherever possible. Leave the nappy off several times a day, especially if the rash is severe.
- 5 Do not wash in soap or bathe too often—once or twice a week is enough.
- 6 Avoid powder and plastic pants.
- 7 Use special soft nappy liners that help protect the sensitive skin.
- 8 Thoroughly rinse out any bleach or disinfectants.

## Medical treatment

Some principles follow:

- The cornerstone of treatment is prevention.
- Emollients should be used to keep skin lubricated (act as a barrier), e.g. zinc oxide (best) or white soft paraffin or a mixture of zinc oxide and castor oil or Vaseline.
- A mild topical corticosteroid is the treatment of choice.
- It is usual to add an antifungal agent.
- Be careful of excessive use of corticosteroids, especially fluorinated steroids.

- If infection is suspected, confirm by swab or skin scraping.
- Consider a combined steroid and antifungal agent e.g. Hydrozole.

Treatment:

Atopic dermatitis	1% hydrocortisone
Seborrhoeic dermatitis	1% hydrocortisone + ketoconazole cream
<i>Candida</i>	topical nystatin at each nappy change
Widespread ( <i>Candida</i> present)	1% hydrocortisone cream mixed in equal quantities with nystatin or clotrimazole cream (apply tds or qid after changes)
Psoriatic dermatitis	tar preparation, or 1% hydrocortisone
Impetigo	topical mupirocin; oral antibiotics if severe

## FACIAL RASHES

Common facial skin disorders include acne, rosacea, peri-oral dermatitis and seborrhoeic dermatitis. These conditions must be distinguished from lupus erythematosus (discoid LE is more common).

### \$ Acne<sup>5</sup>

Acne is inflammation of the sebaceous (oil) glands of the skin (see FIG. 123.12). At first there is excessive sebum production due to the action of androgen. These glands become blocked (blackheads and whiteheads) due to increased keratinisation of the sebaceous duct. A secondary bacterial infection due to *Propionibacterium acnes* in the sebum produces lipases with the resultant free fatty acids, thus provoking inflammation characterised by red papules, pustules, nodules and cysts. Consider PCOS as a causative condition.

### Types<sup>10</sup>

- *Infantile*. Occurs in the first few months of life, mainly on the face. Affects mainly boys and is a self-limiting minor problem. Reassurance only is required in most cases. Some are severe and may scar.
- *Adolescent*. The most common type, occurring around puberty. Acne is rare under 10 years; ages 13–16 years are commonest and it is worse in males aged 18–19 years. It is slightly less common in girls and worse around 14 years with premenstrual exacerbations.

**FIGURE 123.12** Facial acne showing typical nodulocystic acne, a distressing problem which has been improved greatly by the development of isotretinoin

- *Cosmetica*. In females, associated with the prolonged use of skin care products (e.g. moisturiser, foundation cream and heavy make-up).
- *Oil*. Occurs mainly on the legs of workers exposed to petroleum products.
- *Drug-induced*. Especially steroids.

### History

Enquire about use of skin preparations—therapeutic or cosmetic, exposure to oils, possible diet relationships and drug intake.

Drugs that aggravate acne:<sup>11</sup>

- corticosteroids
- chloral hydrate
- iodides or bromides
- lithium
- anti-epileptics (e.g. phenytoin)
- quinine
- various oral contraceptives

### Management

#### Support and counselling

Adolescents hate acne; they find it embarrassing and require the sympathetic care and support not only of

their doctor but also of their family. It should not be dismissed as a minor problem.

### Education

People with acne should understand its pathogenesis and be given leaflets with appropriate explanations. Myths must be dispelled.

- It is not a dietary or infectious disorder.
- It is not caused by oily hair or hair touching the forehead.
- Ordinary chemicals (including chlorine in pools) do not make it worse.
- Blackheads are not dirt, and will not dissolve in hot, soapy water.

Reassure the patient that acne usually becomes less of a problem after the age of 25 years, although 15% of women and 5% of men continue to have acne as adults.

### General factors

- Diet is considered not to be a causative factor but a healthy diet is encouraged.
- Special soaps and overscrubbing are unhelpful. Use a normal soap and wash gently.
- Avoid oily or creamy cosmetics and all moisturisers. Use cosmetics sparingly.
- Avoid picking and squeezing blackheads.
- Exercise, hair washing and shampoos are not of proven value.
- Ultraviolet light such as sunlight may help improve acne but avoid overexposure to the sun.

### Principles of treatment<sup>5</sup>

- 1 Comedolysis: unblock the pores (follicular ducts) with keratolytics such as sulphur compounds, salicylic acid (5–10%); with benzoyl peroxide (2.5%, 5% or 10%) or retinoic acid (tretinoin) 0.01% gel, cream (0.025%, 0.05% or 0.1%), lotion or liquid; a tazarotene or adapalene (Differin) cream or gel.
- 2 Decrease bacteria in the sebum with systemic antibiotics—tetracyclines or erythromycin—or with topical antibiotics such as clindamycin and erythromycin.
- 3 Decrease sebaceous gland activity with oestrogens, spironolactone, cyproterone acetate, or isotretinoin.

*Note:* Oral isotretinoin is teratogenic.

Avoid concomitant use of oral and topical antibiotics.

## Recommended treatment regimens

### Topical regimens

Suitable for mild to moderate acne.

- Basic starting regimen is a retinoid (comedolytic) then a benzoyl peroxide (anti-bacterial) combination:
  - use tretinoin 0.01% gel or 0.05% cream or isotretinoin 0.05% gel cream or gel: apply each night (tretinoin is photosensitive)
  - if slow response after 6 weeks, add benzoyl peroxide 2.5% or 5% gel or cream once daily (in the morning). That is, maintenance treatment is:
    - tretinoin or isotretinoin at night
    - benzoyl peroxide gel mane
    - maintain for 3 months and review.

If a large area of mild truncal acne, consider topical salicylic acid 3% in ethanol 70%, once daily.

Alternative or add-on regimens, if persistent:

- clindamycin HCl 600 mg in 60 mL of 70% isopropyl alcohol (e.g. ClindaTech). Apply with fingertips twice daily.
- alternative bases for clindamycin, especially if the alcohol is too drying or irritating:
  - Cetaphil lotion 100 mL, or
  - ClindaTech solution 100 mL

Clindamycin is particularly useful for pregnant women and those who cannot tolerate antibiotics or exfoliants.<sup>10</sup> In more severe cases, combine with benzoyl peroxide (e.g. Duac).

Others:

- erythromycin 2% gel, apply bd
- azelaic acid, apply bd
- adapalene 0.1% cream or gel, apply once nocte
- tazarotene 0.1% cream, apply once nocte

### Oral antibiotics

Use for inflammatory acne: (moderate to severe papulopustular) ± trunk involvement

- doxycycline 100 mg per day or minocycline 100 mg per day
- use half this dose if mild
- reduce dosage according to response (e.g. doxycycline 50 mg per day)  
or  
minocycline 50 mg nocte (more adverse effects)
- erythromycin or cotrimoxazole are alternatives
- give a minimum 12 week trial; 6 months is standard. Avoid using antibiotics alone.

### Other therapies

Severe cystic or recalcitrant acne (specialist care):

- spironolactone
- isotretinoin (Roaccutane): outstanding agent
- Dapsone

Females not responding to first-line treatment:

- combined oral contraceptive pill with a third-generation progestogen (e.g. ethinylestradiol/cyproterone acetate: Diane-35 ED)

Avoid higher dose levonorgestrel formulations and progestogen-only preparations.

*Note:* Response to any acne treatment occurs in about 8 weeks or longer.

### Common mistakes with acne

- Not treating comedones with a comedolytic
- Monotherapy (e.g. antibiotics only)
- Not using recommended combinations
- Not using isotretinoin for cystic acne

### Rosacea

Rosacea is a common persistent eruption of unknown aetiology. It is typically chronic and persistent with a fluctuant course.

### Clinical features<sup>2</sup>

- Mainly 30–50 years
- Usually females of Celtic origin: ‘the curse of the Celts’
- On forehead, cheeks, nose and chin (see FIG. 123.13 and FIG. 123.14)
- ‘Flushing and blushing’ (often precedes the rash)
- Fluctuates from day to day
- Peri-orbital and peri-oral areas spared
- Vascular changes—erythema and telangiectasia
- Inflammation—papules and pustules

### Complications

- Blepharitis
- Conjunctivitis, rarely keratitis and corneal ulcer
- Associated rhinophyma in some cases

### Management<sup>4</sup>

- Apply cool packs if severe
- Avoid factors that cause facial flushings (e.g. excessive sun exposure, heat, wind, alcohol, excessive exercise, hot baths, spicy foods, hot drinks—tea and coffee)

**FIGURE 123.13** Rosacea: typical appearance with erythema, papules and pustules

**FIGURE 123.14** Rosacea: typical facial distribution

- Sun protection
- Use a gentle soap-free cleanser

### Systemic antibiotics

- Minocycline or doxycycline (first choice) 50 mg bd for a total of 8–10 weeks. Repeated for recurrences: avoid maintenance.

If using doxycycline, start with 50 mg bd then 50 mg daily, wean slowly.

- Erythromycin (second choice)
- Metronidazole 200 mg bd for 10 days for resistant cases

### Topical agents

For mild erythema and inflammatory lesions:

2% sulphur in aqueous cream tds (milder cases)  
or (for more severe cases)

metronidazole 0.75% gel bd

or

azelaic acid 15% gel bd

or

clindamycin 1% solution bd

or

erythromycin 2% gel bd

or

brimonidine 0.5% (a vasoconstrictor—helps red flush)

*Note:* Hydrocortisone 1% cream is effective, but steroids are best avoided and strong topical steroids should not be used because of severe rebound vascular changes.

### Laser therapy

Telangiectasia, erythema and rhinophymas respond to laser therapy.

### Rhinophyma

This is due to hypertrophy of the nasal sebaceous glands. There is no specific association with alcohol. May be associated with rosacea. Carbon dioxide laser therapy is the treatment of choice. Shave excision is also effective (see CHAPTER 59).

### § Peri-oral dermatitis

#### Clinical features

- Acne-like dermatitis of lower face
- Usually young women 20–50 years
- May be seen in children and adolescents
- 'Muzzle area' distribution around mouth and on chin, sparing adjacent peri-oral area (see FIG. 123.15 and 123.16); also in peri-orbital skin in men

**FIGURE 123.15** Peri-oral dermatitis: typical distribution

**FIGURE 123.16** Peri-oral dermatitis: this eruption (which has been linked with the use of fluorinated steroid creams on the face) frequently begins in the nasolabial fold. Papules and pustules occur on a background of erythema and scaling.

- Frequently begins at the nasolabial folds
- Multiple small red macules and papules
- On a background of erythema and scaling
- Burning and irritation
- May be associated seborrhoeic dermatitis on scalp and head
- May be related to pregnancy and oral contraception
- Related to the use of creamy cosmetic products
- May be related to repeated topical corticosteroid (especially fluorinated) use (may be a rebound on ceasing it)

### Treatment

- Doxycycline or minocycline for 6–8 weeks (e.g. doxycycline or minocycline 100 mg daily). Takes 10–14 days to respond. Use erythromycin if tetracyclines contraindicated. The rash sometimes recurs after the antibiotics are discontinued, even much later, but further courses can be used.
- Discontinue any topical corticosteroid therapy (tends to flare initially) and all 'creamy' preparations including cleansers, moisturisers and make-up.
- Topical: ketoconazole cream and shampoo for 10–14 days or metronidazole 0.75% gel twice daily or clindamycin 1% lotion twice daily.

## TINEA

Tinea (ringworm infections) is caused mainly by three major classes of dermatophytic organisms that have the ability to invade and proliferate in keratin of the skin, nails and hair.

It is most useful to perform skin scrapings and microscopy to look for encroaching septate hyphae.<sup>12</sup> Confirm the diagnosis by fungal culture. Tinea cruris is presented in [CHAPTER 124](#).

### § Tinea pedis (athlete's foot)

Tinea pedis is usually caused by *Trichophyton rubrum* and is the commonest type of fungal infection in humans. Candida intertrigo and interdigital maceration (alone without secondary tinea) in particular and also erythrasma, eczema and psoriasis, are important differential diagnoses.

### Symptoms

The commonest symptoms are itchiness and foot odour. Sweat and water make the top layer of skin white and soggy. There is scaling, maceration and fissuring of the skin between the fourth and fifth toes and also third and fourth toes.

### Advice to patients

- Keep your feet as clean and dry as possible.
- Carefully dry your feet after bathing and showering.
- After drying your feet, use an antifungal powder, especially between the toes.
- Remove flaky skin from beneath the toes each day with dry tissue paper or gauze.
- Wear light socks made of natural absorbent fibres, such as cotton and wool, to allow better circulation of air and to reduce sweating. Avoid synthetic socks.
- Change your shoes and socks daily. Spray shoes with an antifungal agent.
- If possible, wear open sandals or shoes with porous soles and uppers.
- Go barefoot whenever possible.
- Use thongs in public showers such as at swimming pools (rather than bare feet).

### Treatment

Clotrimazole 1%, ketoconazole 2%, terbinafine 1% cream or gel, or miconazole 2% cream or lotion or bifonazole 1% (daily), applied after drying, bd or tds for 2–3 weeks. Preferable to use terbinafine 1% daily for 1 week and review. If severe and spreading,

prescribe oral griseofulvin (see *Tinea corporis*) or terbinafine for up to 6 weeks after confirming the diagnosis by fungal culture.

Castellani paint may be helpful for macerated areas.

### § **Tinea corporis**<sup>10</sup>

*Tinea corporis* (ringworm infection of the body) is usually caused by *Trichophyton rubrum* (60%) or *Microsporum canis*.<sup>12</sup> Strongly related to exposure to cats and dogs, while the guinea pig is a potent source of facial tinea (can present as pustular folliculitis).

#### **Clinical features**

- Spreading circular erythematous lesions (see FIG. 123.17)
- Slight scaling or vesicles at the advancing edge
- Central areas usually normal
- Mild itch
- May involve hair, feet and nails

**FIGURE 123.17** Multiple ringworm (*tinea corporis*): this 12-year-old boy presented with a two-week history of an increasing number of pruritic scaling erythematous lesions on his face, neck and upper chest. Fungal scrapings confirmed the cause as *Microsporum canis*.

Photo courtesy Robin Marks

#### **Treatment**

- Clotrimazole 1% or miconazole 2% cream or bifonazole 1% cream or ketoconazole 2% cream, applied bd for 2–4 weeks or terbinafine 1% cream or gel once daily for 1 week
- Oral terbinafine or griseofulvin for up to 6 weeks if no response or if widespread

### § **Tinea manuum**

*Tinea manuum* is ringworm infection of the hand, usually presenting with scaling of the palms and

palmar aspects of the fingers. It also commonly presents on the dorsum of the hand and is typically unilateral. Differential diagnoses are atopic dermatitis and contact dermatitis of the hands.

#### **Clinical features**

- Usually unilateral
- Spreading edge
- Erythematous; fine scaling
- May be associated with *tinea pedis*

#### **Treatment**

- Topical clotrimazole 1%, ketoconazole 2% or miconazole 2% cream for 6 weeks or, if resistant, terbinafine 250 mg or griseofulvin 500 mg daily for 6 weeks.

### § **Tinea capitis**<sup>4</sup>

In Australia *tinea capitis* is usually due to *M. canis* acquired from cats and dogs.

#### **Clinical features**

- Usually in children (rare after puberty)
- Patches of partial alopecia
- Scaly patches
- Small broken-off hair shafts
- Hairs fluoresce yellow-green with Wood's light (not invariably, e.g. with *Trichophyton tonsurans* infection)

#### **Treatment**

griseofulvin (o): adults 500 mg daily; children 10 mg/kg/day (max. 500 mg) 4–8 week course  
or

ketoconazole (o): adults 200 mg/d, 4–8 weeks; children 5 mg/kg/d (max. 200 mg)

or

terbinafine: adults 250 mg/d, 4 weeks; children 62.5–125 mg

Also take hair plucking and scale for culture. Selsun or ketoconazole shampoo twice weekly.

### § **Kerion**

Kerion of the scalp and beard area may present like an abscess—tender and fluctuant. Usually occurs on the scalp, face or limbs. A fungal cause is possible if the hairs are plucked out easily and without pain (if painful and stuck, bacterial infection is likely).

### § Tinea incognita

This is the term used for unrecognised tinea infection due to modification with corticosteroid treatment. The lesions are enlarging and persistent, especially on the groins, hands and face.

The sequence is initial symptomatic relief of itching, stopping the ointment or cream and then relapse.

### § Tinea unguium (toenails and fingernails)

Refer to CHAPTER 129.

### § Pityriasis versicolor (tinea versicolor)<sup>12</sup>

Pityriasis versicolor is a superficial yeast infection of the skin (usually on the trunk) caused by *Malassezia* sp.). The old name, tinea versicolor, is inappropriate because the problem is not a dermatophyte infection. It occurs worldwide but is more common in tropical and subtropical climates.

There are two distinct presentations:

- 1 reddish brown, slightly scaly patches on upper trunk
- 2 hypopigmented area that will not tan, especially in suntanned skin

The term 'versicolor' means variable colours.

#### Clinical features

- Mainly young and middle-aged adults
- Brown on pale skin or white on tanned skin (see FIG. 123.18)
- Trunk distribution (see FIG. 123.19)

**FIGURE 123.18** Pityriasis versicolor showing the hypopigmented scaly patches on a suntanned skin mainly affecting the trunk

**FIGURE 123.19** Pityriasis versicolor: typical truncal distribution (corresponding area on back)

- Patches may coalesce
- May involve neck, upper arms, face and groin
- Slight scaling when scratched indicates active infection
- Scales removed by scraping show characteristic short stunted hyphae with spores on microscopy
- Often recurrent, especially in summer

#### Differential diagnosis

Seborrhoeic dermatitis of trunk (more erythematous), pityriasis rosea, vitiligo, pityriasis alba (affects face).

#### Treatment<sup>4,12</sup>

selenium sulphide (Selsun Yellow shampoo). Wash area, leaving on for 5–10 minutes, then wash off. Do this daily for 2 weeks (at night), then every second day for 2 weeks, then monthly for 12 months. Shampoo scalp twice weekly and/or econazole 1% solution to wet skin, leave overnight, for 3 nights or miconazole or ketoconazole shampoo, once daily for 10 minutes and wash off, for 10 days or terbinafine 1% cream twice daily for 2 weeks or sodium thiosulphate 25% solution bd for 4 weeks (wash off after 10 minutes) or (for persistent or recurrent problems)

ketoconazole 200 mg (o) daily for 7–10 days or 400 mg (o) single dose<sup>12</sup>

or

itraconazole 200 mg (o) once daily for 5 days or once every 30 to 90 days<sup>4</sup>

*Note:*

- Ketoconazole may be hepatotoxic. Always perform LFTs first (do not use long-term). Griseofulvin is inappropriate because the rash is not a fungal infection.
- Warn patients that the white patches will take a long time to disappear and that cure does not equate with disappearance.

## Dry skin

Disorders associated with scaling and roughness of the skin include:

- atopic dermatitis—all types (e.g. pityriasis alba, nummular eczema, asteatotic dermatitis)
- ageing skin
- psoriasis
- ichthyotic disorders
- keratosis pilaris

Itching may be a feature of dry skin (but is not inevitable).

Aggravating factors:

- low humidity (e.g. heaters, air-conditioners)
- frequent immersion in water
- heat/hot water
- toilet soaps
- swimming in chlorinated pools

## Management

- Avoid a dry home environment if possible.
- Reduce bathing.
- Bathe or shower in tepid water.
- Use a soap substitute (e.g. Dove or Neutrogena/Cetaphil lotion).
- Pat dry—avoid vigorous towelling.
- Rub in baby oil after bathing (better than adding oil to the bath).
- Avoid wool next to the skin (wear cotton).
- Use emollients/moisturisers (e.g. Alpha-Keri lotion, QV skin lotion, Nutraplus).

## § Sunburn

Sunburn is normally caused by UV-B radiation, which penetrates the epidermis and superficial dermis, releasing substances such as leucotrienes and histamines, which cause redness and pain. Severe

sunburn may develop on relatively dull days because thin clouds filter UV-B poorly. Beware of solariums and the midday sun.

Clinical presentations:

Minor sunburn:	Mild erythema with minimal discomfort for about 3 days.
Moderate:	Moderate to severe erythema within a few hours; worse the following day—red, hot and moderately painful. Settles in 3–4 days with some desquamation.
Severe:	Classic signs of inflammation—redness, heat, pain and swelling. Skin develops vesicles and bullae. Systemic features develop with very severe burns (e.g. fever, headache, nausea, delirium, hypotension). May require IV fluids.

## Differential diagnosis

- General photosensitivity: consider drugs (e.g. thiazide diuretics, tetracyclines, sulphonamides, phenothiazines, griseofulvin, NSAIDs, isotretinoin)
- Acute systemic lupus erythematosus may present as unexpectedly severe sunburn
- Photocontact dermatitis

## Treatment

Hydrocortisone 1% ointment or cream for severe sunburn on face, early. Use hydrocortisone 1% or 0.02% betamethasone valerate for other areas. Repeat in 2–3 hours and then the next day. Hydrocortisone is not useful after 24 hours and should be used for unblistered erythematous skin, not on broken skin.

Oral aspirin eases pain. Oil in water baths or bicarbonate of soda paste may help and wet applications such as oily calamine lotions or simply cool compresses may give relief.

## Prevention

Avoid direct exposure to summer sunlight during peak UV periods (10 am to 3 pm). Use natural shade—beware of reflected light from sand or water and light cloud. Use a sunscreen with a minimum of SPF 30. Wear broad-brimmed hats and protective clothing.

## § Photo-ageing/wrinkles

### Prevention

- Stop smoking.
- Avoid cold, dry and windy conditions.

- Avoid exposure to the sun.
- Use an SPF 30 or more sunscreen during the day.
- Avoid soaps with perfume and alcohol.
- Wash with a 'neutral' mild soap (e.g. Neutrogena, max. twice daily) and pat dry.
- Apply a simple moisturiser immediately after the bath.

### Treatment (options)

- Optimal nutrition—diet rich in fruit and vegetables
- Alpha hydroxy acid preparations (e.g. Elucent cream)
- Tretinoin (Retin-A) cream: apply once daily at bedtime (on dry skin) test for skin irritation by gradual exposure (e.g. 5 minutes at first, wash off, then 15 minutes until it can be left on overnight)
- Topical olive oil
- Lac-Hydrin (US): 12% solution may be effective alternative; other lactic acid preparations may be useful
- Botulinum toxin injections

## SWEATING AND ODOUR DISORDERS

### § Hyperhidrosis (excessive sweating)<sup>13</sup>

This problem is usually idiopathic and prolonged.

#### Clinical features

- Male = female incidence
- Affects axilla, groin, soles and palms
- Onset usually around puberty
- Tends to improve after age 25 years
- Family history
- ± Bromhidrosis (malodorous perspiration)
- Usually independent of climate
- Exacerbated by stress and heat; stops during sleep

#### Causes (secondary/pathological)

- Fever/sepsis
- Thyrotoxicosis
- Acromegaly
- Diabetes mellitus
- Pheochromocytoma
- Drugs: alcohol/narcotics/antidepressants
- Some neurological conditions (e.g. Parkinson)
- Malignancies especially lymphomas

#### Treatment<sup>5</sup>

- Reduce caffeine intake

- Avoid known aggravating factors
- First use:  
an aluminium chlorohydrate-containing antiperspirant deodorant (spray or roll on each morning) in axilla (suitable for palms and soles) *or*  
aluminium chloride hexahydrate 20% solution or spray—apply to affected areas at night when the area is dry (best for palms and soles). Irritation is a problem

### Additional treatments

- Iontophoresis (in specialist centres) to hands and feet
- Injection of botulinum toxin into dermis of affected area. Proven effectiveness for axilla and palms
- (Trial of) probanthine aluminium chloride 20% in alcohol solution to localised area
- Consider oral anticholinergics (e.g. oxybutynin) and beta blockers

### § Palmar hyperhidrosis

#### Treatment

- Aluminium chloride 20% in alcohol solution (Driclor)
- Iontophoresis
- Consider surgical sympathectomy

### § Axillary hyperhidrosis<sup>14</sup>

#### Treatment

- Explanation and reassurance
- See treatment of general hyperhidrosis
- Aluminium chloride 20% in alcohol solution (Driclor); apply nocte for 1 week, then 1–2 times weekly or as necessary
- Botulinum toxin injection

### Surgery

Wedge resection of a small block of skin and subcutaneous tissue from axillary vault. Define sweat glands with codeine starch powder. The area excised is usually about 4 × 2.5 cm.

### § Body odour/bromhidrosis

*Cause:* poor hygiene, excessive sweating and active skin bacteria

*Main focus:* axilla and groin

*Precautions:* consider uraemia, vaginitis

### Treatment

- Scrub body, especially groins and axillae, with deodorant soap at least morning and night
- Try an antibacterial surgical scrub
- Keep clothes clean, launder regularly
- Choose suitable clothes—natural fibres (e.g. cotton), not synthetics
- Use an antiperspirant deodorant
- Alternative soap—pine soap
- Diet: avoid garlic, fish, asparagus, onions, curry
- Reduce caffeine (coffee, tea and cola drinks), which stimulates sweat activity
- Consider a sugar-free diet
- Shave axillary hair
- Axillary wedge resection for excessive perspiration

### § Foot odour (smelly and sweaty feet)

Includes pitted keratolysis secondary to hyperhidrosis (common in teenagers).

### Treatment (with options)

- Education and reassurance
- Wear cotton or woollen socks
- Aluminium chloride 20% in alcohol solution (Driclor, Hydrosol) or Neat Feet—apply nocte for 1 week, then 1–2 times weekly as necessary
- Shoe liners (e.g. ‘Odor eaters’), charcoal inner soles
- Apply undiluted Burow’s solution after a shower or bath
- Formalin 1–5% soaks every second night
- Iontophoresis
- The teabag treatment (if desperate):
  - prepare 600 mL of strong hot tea (from two teabags left in water for 15 minutes)
  - pour the hot tea into a basin with 2 L of cool water
  - soak the feet in this for 20–30 minutes daily for 10 days, then as often as required

## SKIN DISORDERS OF FEET

Two conditions commonly seen in teenagers are pitted keratolysis and juvenile plantar dermatosis.

### § Pitted keratolysis

This common malodorous condition known as ‘stinky feet’ or ‘sneakers feet’, usually seen in 10–14 year olds, is related to sweaty feet. It is caused by an overgrowth of the bacterium *Kytococcus sedentarius* on the feet between the toes. It has a ‘honeycomb’ pitted appearance with maceration between the toes,

resembling tinea. For mild cases no specific treatment is needed other than attending to hyperhidrosis. Otherwise, treatment includes keeping the feet dry and using an ointment such as Whitfield’s (benzoic acid + salicylic acid) or benzoyl peroxide 5% gel or an imidazole or erythromycin 2% gel or clindamycin 1% lotion to remove the responsible organism. Try oral roxithromycin if topical therapy fails. Change to all-leather shoes with charcoal liners. Use a drying agent to decrease sweating.

### § Juvenile plantar dermatosis

‘Sweaty sock dermatitis’ is a painful condition of weight-bearing areas of the feet. The affected skin is red, shiny, smooth and often cracked. It is rare in adults. The treatment is to change to leather or open shoes and to cotton socks. A simple emollient cream gives excellent relief.

### § Prickly heat (miliaria/heat rash)

- Avoid sweating as much as possible.
- Keep the skin dry and cool (e.g. fan, air-conditioner).
- Dress in loose-fitting cotton clothing.
- Reduce activity.
- Avoid frequent bathing and overuse of soap.
- Dilute topical steroid cream bd.

### Treatment

lotion: salicylic acid 2%, menthol 1%, chlorhexidine 0.5% in alcohol or calamine lotion  
or  
Egozite (infants), Isophyl (adults)

If severe: hydrocortisone + clotrimazole cream (brief spells only).

### Prevention

- Ego Prickly Heat powder

## CHILBLAINS AND FROSTBITE

### § Chilblains (perniosis)

These are localised inflammatory reactions, caused by prolonged exposure to cold, usually on toes and fingers (see FIG. 123.20) but also on heels, nose, ears and thighs (horse riding).

### Precautions

- Think Raynaud phenomenon.
- Protect from trauma and secondary infection.
- Do not rub or massage injured tissues.

**FIGURE 123.20** Chilblains (perniosis) showing erythematous purplish swellings on fingers

- Do not apply heat or ice.
- Wear warm gloves and socks.

Differences between chilblains and Raynaud phenomenon:

- chilblains are intermittent without a pattern
- itchy at the onset
- patchy appearance (can be more generalised)
- Raynaud has two or three phases including a 'dead white' phase with line of demarcation
- it is significant if it extends to the MCP joints

### Treatment

- Elevate affected part
- Warm gradually to room temperature

### Drug treatment

- Potent topical corticosteroid (see **TABLE 121.9** in **CHAPTER 121**) twice daily
- If severe and recurrent, apply glyceryl trinitrate vasodilator spray or 0.2% ointment or patch sparingly once daily (use plastic gloves and wash hands for ointment)

### Other treatment

- Drink rum at night
- Nifedipine CR 30 mg (o) once daily (if very severe)
- UVB therapy weekly for 4–6 weeks prior to cold weather

### Frostbite

Treatment depends on severity.

### Precautions

- Watch for secondary infection, tetanus, gangrene.

### Treatment

- Elevate affected limb
- Rewarm in water just above body temperature 40°C (104°F) or use body heat (e.g. in axillae)
- Avoid thawing or refreezing
- Surgical debridement
- Don't debride early (wait until dead tissue dried)
- Don't drink alcohol or smoke
- For blistering, apply warm water compresses for 15 minutes every 2 hours

### Drug treatment

- Analgesics

### Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Atopic eczema
- Body odour
- Contact dermatitis
- Dry skin
- House dust mite management
- Nappy rash
- Pityriasis rosea
- Psoriasis
- Ringworm (tinea)
- Rosacea and perioral dermatitis
- Seborrhoea in infants
- Sunburn
- Tinea pedis

*They say love's like the measles—all the worse when it comes late in life.*

Douglas Jerrold (1803–57)

The sudden appearance of a rash, which is a common presentation in children (see [CHAPTER 93](#)), usually provokes patients and doctors alike to consider an infectious aetiology, commonly of viral origin. However, an important cause to consider is a reaction to a drug.

A knowledge of the relative distribution of the various causes of rashes helps with the diagnostic methodology. Many of the eruptions are relatively benign and undergo spontaneous remission. Fortunately, the potentially deadly rash of smallpox is no longer encountered.

A list of important causes of acute skin eruptions is presented in [TABLE 124.1](#).

Serious eruptions not to be missed and pitfalls are outlined in [TABLE 124.2](#).

## A diagnostic approach

The diagnostic approach to skin eruptions presupposes a basic knowledge of the causes; a careful history and physical examination should logically follow.

The history should include:

- site and mode of onset of the rash
- mode of progression
- drug history
- constitutional disturbance (e.g. pyrexia, pruritus)
- respiratory symptoms
- herald patch?
- diet—unaccustomed food
- exposure to irritants
- contacts with infectious disease
- bleeding or bruising tendency

The examination should include:

- skin of whole body
- nature and distribution of rash, including lesion characteristics
- soles of feet
- nails
- scalp
- mucous membranes

- oropharynx
- conjunctivae and the lymphopoietic system (? lymphadenopathy ? splenomegaly)

Laboratory investigations may include:

- a full blood examination
- syphilis serology
- Epstein–Barr mononucleosis test
- HIV test
- rubella haemagglutination tests (x 2)
- viral and bacterial cultures

## Dermatological manifestations of systemic disease

- Painful red nodules
    - erythema nodosum
  - Photosensitive rash
    - dermatomyositis (inflamed muscles + rash)—cause unknown, malignancy known association
  - Palpable purpura
    - vasculitis—primary or secondary (e.g. sepsis), various causes
  - Painful ulceration
    - pyoderma granulosum
- Causes
- inflammatory bowel disease
  - rheumatoid arthritis
  - haematological malignancies

## Acute skin eruptions in children

The following skin eruptions (some of which may also occur in adults) are outlined in [CHAPTER 93](#).

- Measles
- Rubella
- Viral exanthem (fourth disease)
- Erythema infectiosum (fifth disease)
- Roseola infantum (sixth disease)
- Kawasaki disorder
- Varicella
- Impetigo

**Table 124.1** Important causes of acute skin eruptions

Maculopapular
Measles
Rubella
Scarlet fever
Viral exanthem (fourth disease)
Erythema infectiosum (slapped cheek disease or fifth disease)
Roseola infantum (sixth disease)
EBM (primary or secondary to drugs)
Primary HIV infection
Secondary syphilis
Pityriasis rosea
Guttate psoriasis
Urticaria
Erythema multiforme (may be vesicular)
Drug reaction
Scabies
Ross River and Barmah Forest infection
Maculopapular vesicular
Varicella
Herpes zoster
Herpes simplex
Eczema herpeticum
Impetigo
Hand, foot and mouth disease
Drug reaction
Maculopapular pustular
<i>Pseudomonas</i> folliculitis
<i>Staphylococcus aureus</i> folliculitis
Impetigo
Purpuric (haemorrhagic) eruption
Purpura (e.g. drug-induced purpura, severe infection)
Vasculitis (vascular purpura):
• Henoch–Schönlein purpura
• polyarteritis nodosa

### Pityriasis rosea

Pityriasis rosea is a common but mild acute inflammatory skin disorder. Although a viral agent

**Table 124.2** Acute skin eruptions

Serious disorders not to be missed

Vascular:

- Henoch–Schönlein purpura
- Stevens–Johnson syndrome
- other vasculitides

Infection:

- purpura of meningococcus, typhoid, other sepsis
- primary HIV infection
- folliculitis (e.g. *pseudomonas*, *staphylococcus*)
- secondary syphilis
- scarlet fever

Other:

- erythema nodosum

Pifalls (often missed)

- guttate psoriasis
- Epstein-Barr virus (EBV) mononucleosis
- arbovirus infection (e.g. dengue, Ross River fever, Barmah Forest virus, Japanese encephalitis)
- scabies
- Kawasaki disease
- eczema herpeticum
- zoonoses (e.g. listeriosis, Q fever)

Rarities:

- filovirus diseases (e.g. Ebola, Marburg virus)
- erythema multiforme

(possibly human herpes virus 7) is suspected to be the cause, no infective agent has been demonstrated.

### Clinical features

- Any age, mainly young adults (aged 15–30 years)
- Preceding oval or round herald patch (1–2 weeks); can have 2–3, but none in 20% (can be mistaken for ringworm)
- Oval, salmon-pink or copper-coloured eruption 0.5–2 cm
- Coin-shaped patches with scaly margins 1–2 cm
- Follows cleavage lines of skin (see [FIGS 124.1](#) and [124.2](#)) with ‘fir tree’ pattern on back
- On trunk (‘T-shirt’ distribution)
- Occurs also on upper arms, upper legs, lower neck, face (rare) and axillae
- Patients not ill

**FIGURE 124.1** Pityriasis rosea in a 10-year-old child showing the salmon pink scaly eruption following skin cleavage lines—the 'Christmas tree' pattern

**FIGURE 124.2** Pityriasis rosea: typical distribution

- Itch varies from nil to severe (typically minor itching)
- Scale is on inner aspect of active border

### Differential diagnosis

Herald patch: tinea corporis/discoid eczema.

Generalised rash: seborrhoeic dermatitis (slower onset), guttate psoriasis, drug eruption (see TABLE 124.3), secondary syphilis.

**Table 124.3** Drugs that cause eruptions suggestive of pityriasis rosea<sup>1</sup>

Main drugs:

- captopril
- gold salts
- penicillamine

Others:

- arsenicals
- barbiturates
- bismuth
- clonidine
- metoprolol
- metronidazole

### Prognosis

A mild, self-limiting disorder with spontaneous remission in 2–10 weeks (average 2–5). It does not appear to be contagious. Recurrence is rare.

### Management

- Explain and reassure with patient education handout.<sup>2</sup>
- Bathe and shower as usual, using a neutral soap (e.g. Neutrogena).
- Use a soothing bath oil (e.g. QV Bath Oil).
- For a bothersome itch, apply mild topical corticosteroid ointment or calamine lotion with 1% phenol or menthol 1% in aqueous cream.
- For a severe itch, use a potent topical corticosteroid once or twice daily or oral corticosteroids.
- UV therapy is good but, like psoriasis, sunburn must be avoided. Expose the rash to sunlight or UV therapy (if flordid) three times a week, with care.

### Secondary syphilis

The generalised skin eruption of secondary syphilis varies and may resemble any type of eruption from

psoriasiform to rubelliform to roseoliform. The rash usually appears 6–8 weeks after the primary chancre.

### Clinical features (rash)

- Initially faint pink macules
- Then becomes maculopapular
- Can involve whole body (see FIG. 124.3)
- Palms and soles involved
- Dull red in colour and round
- More prolific on flexor surfaces
- Symmetrical and relatively coarse
- Asymptomatic

FIGURE 124.3 Secondary syphilis: typical features

### Associations (possible)

- Mucosal ulcers: 'snail track'
- Lymphadenopathy
- Patchy hair loss
- Condylomata lata

### Treatment

- As for primary syphilis (see CHAPTER 119)

## § Primary HIV infection

A common manifestation of the primary HIV infection is an erythematous, maculopapular rash, although other skin manifestations such as a roseola-like rash and urticaria can occur.

### Clinical features

- Symmetrical
- May be generalised
- Lesions 5–10 mm in diameter
- Common on face and/or trunk

- Can occur on extremities including palms and soles (see FIG. 124.4)
- Non-pruritic

Note: mimics glandular fever

FIGURE 124.4 Primary HIV infection: typical features

If such a rash accompanied by an illness like glandular fever occurs, HIV infection should be suspected and specific tests ordered.

## § Guttate psoriasis

Guttate psoriasis is the sudden eruption of small (2–10 mm in diameter), very dense, round, red papules of psoriasis on the trunk (see FIGS 124.5 and 124.6). The rash may extend to the proximal limbs.

It is usually seen in children and adolescents and often precipitated by a streptococcal throat infection.

FIGURE 124.5 Guttate psoriasis: small, drop-like lesions, mainly on trunk

**FIGURE 124.6** Guttate psoriasis in a child showing the small dense, round erythematous papules of psoriasis on the trunk

The rash soon develops a white silvery scale. It can persist for up to 6 months. It may undergo spontaneous resolution or enlarge to form plaques, which may become chronic.

Treatment includes UV light as well as tar preparations.

### § Epstein–Barr mononucleosis

The rash of EBM is almost always related to antibiotics given for tonsillitis (see FIG. 28.3 in CHAPTER 28). The primary rash, most often non-specific, pinkish and maculopapular (similar to that of rubella), occurs in about 5% of cases only. The secondary rash, which can be extensive and sometimes has a purplish-brown tinge, is most often precipitated by one of the penicillins (see FIG. 124.7):

- ampicillin 90–100% association
- amoxycillin 90–100% association
- penicillin up to 50%

**FIGURE 124.7** Epstein–Barr mononucleosis: typical rash induced by penicillin, amoxycillin or ampicillin

## DRUG ERUPTIONS

A rash is one of the most common side effects of drug therapy, which can precipitate many different types of rash; the most common is toxic erythema (see TABLE 124.4). Most drug-evoked dermatoses have an allergic basis with the eruption appearing approximately 10 days after administration, though much sooner if previously sensitised.<sup>3</sup> The most common drugs that cause skin eruptions are summarised in TABLE 124.5.

**Table 124.4** Most common types of drug eruptions (after Thomas)<sup>3</sup>

	Relative frequency (%)
Toxic erythema	45
Urticaria/angioedema	25
Erythema multiforme	7
Ecematous dermatitis	5
Fixed drug reaction	3
Photosensitivity	3

Others:

- acne form
- psoriasiform
- pigmentation
- erythema nodosum
- toxic epidermal necrolysis
- vasculitis/purpuric
- pigmentary
- exfoliative

Source: After Thomas<sup>3</sup>

**Table 124.5** The most common drugs that cause skin eruptions

Antimicrobials:	Penicillin/cephalosporins Sulphonamides Tetracyclines Nitrofurantoin Streptomycin Griseofulvin Metronidazole Antiretroviral agents Trimethoprim Dapsone
Diuretics:	Thiazides Frusemide
Anti-epileptics:	Carbamazepine Phenytoin Lamotrigine
Tranquillisers:	Phenothiazines Barbiturates Chlordiazepoxide
Anti-inflammatory and analgesics:	Gold salts Aspirin/salicylates Codeine/morphine Pyrazalones (e.g. BTZ) Other NSAIDs
Hormones:	Combined oral contraceptive Stillboestrol Testosterone
Others:	Phenolphthalein Serum Amiodarone Cytotoxic drugs Quinidine/quinine Bromides and iodides Sulphonylureas Allopurinol Warfarin Amphetamines

The most important fact to realise about drug reactions is that their appearances are so variable—they may mimic almost any cutaneous disease and, in addition, create unique appearances of their own.

When taking a history it is appropriate to enquire about medications or chemicals that may be overlooked such as aspirin, vitamins, toxins, laxatives and medicated toothpaste.

**Toxic erythema**

The maculopapular erythematous eruption is either morbilliform or scarlatiniform. It is more pronounced on the trunk than on the limbs and face but may become confluent over the whole body (see FIG. 124.8).

Drugs that typically cause toxic erythema include:

- antibiotics:
  - penicillin/cephalosporins
  - sulphonamides
- thiazides
- carbamazepine
- barbiturates
- allopurinol
- gold salts

**FIGURE 124.8** Toxic erythema: maculopapular erythematous scarlatiniform eruption caused by amoxicillin

## § Photosensitivity

Several antibiotics increase the sensitivity of the skin to UV light and may lead to a rash with a distribution according to sunlight exposure. The photosensitive rash may be erythematous, resembling sunburn; eczematous; or vesiculobullous.

Typical drugs:

- tetracyclines
- sulphonamides/sulphonylureas
- thiazides and frusemide
- phenothiazines
- retinoids
- amiodarone
- griseofulvin
- antihistamines, especially promethazine
- antimalarials
- psoralens

## § Fixed drug eruption

The mechanism of fixed drug eruption is unknown. The most commonly affected areas are the face, hands and genitalia. The lesions, which are usually bright red but can have other characteristics, are fixed in site and appearance within hours of the drug's administration.

Typical drugs:

- phenolphthalein
- tetracyclines
- penicillins
- sulphonamides
- salicylates
- oral contraceptive pill
- barbiturates
- quinine

## Treatment of any drug reaction

The important aspect of management is to recognise the offending agent and withdraw it. The rash should be treated according to its nature.

There is a therapeutic impulse to prescribe antihistamines but they should be reserved for the treatment of urticarial drug eruptions. They may actually delay healing in purpuric, erythematous and vesiculobullous reactions. Antihistamines may act as allergens and show cross-sensitivity with phenothiazines, sulphonamides and topical antihistamines.

TABLE 124.6 lists drugs with the highest skin reaction rates.

**Table 124.6** Drugs with the highest skin reaction rates<sup>4</sup>

Penicillin and derivatives
Sulphonamides*
Trimethoprim*
Thiazide diuretics
Allopurinol*
Dapsone*
NSAIDs, esp. piroxicam*
Nevirapine*, abacavir*
Barbiturates
Quinidine
Anti-epileptics (phenytoin, lamotrigine*)
Blood products
Gold salts

\* Severe reactions

## ERYTHEMA

### § Erythema multiforme

Erythema multiforme is an acute eruption affecting the skin and mucosal surfaces.

### Clinical features

- Mainly in children, adolescents, young adults
- Symmetric
- Erythematous papules
- Mainly backs of hands, palms and forearms (see FIG. 124.9)

FIGURE 124.9 Erythema multiforme: typical distribution

- Also on feet and toes, mouth
- Occasionally on trunk and genitalia
- Polymorphic
- Vesicles and bullae may develop
- Self-limiting (up to 2 weeks)

### § Stevens–Johnson syndrome

This is a very severe and often fatal variant. Sudden onset with fever and constitutional symptoms.

#### Causes and associations

Erythema multiforme is a vasculitis affecting the skin and mucosa. Herpes simplex virus (usually type 1) is the commonest known association.

Associations include:

- unknown 50%
- herpes simplex virus 33%
- other infections: *Mycoplasma pneumoniae*, tuberculosis, *Streptococcus*, HIV
- connective tissue disorders (e.g. SLE)
- neoplasia: Hodgkin lymphoma, myeloma, cancer
- deep X-ray therapy
- drugs:
  - barbiturates
  - penicillin
  - sulphonamides
  - phenothiazines
  - anti-epileptics e.g. phenytoin
  - NSAIDs
- Infections:
  - streptococcal infections e.g. strep throat
  - viral infections (e.g. hepatitis B)
  - tuberculosis
  - leprosy
  - chlamydia infection
  - fungal infections
  - bacterial gastroenteritis
- Inflammatory bowel disorders (e.g. Crohn)
- Drugs:
  - sulphonamides
  - tetracyclines
  - oral contraceptives
  - bromides and iodides
- Malignancy (e.g. lymphoma, leukaemia)
- Pregnancy
- Unknown (about 40%), perhaps autoimmune

#### Investigations

Tests include FBE, ESR/CRP, chest X-ray (the most important), streptococcal serology (e.g. ASOT) and Mantoux test.

#### Treatment

Identify the cause if possible. Rest, leg elevation and NSAIDs (e.g. ibuprofen 400 mg (o) bd) for the acute stage. Systemic corticosteroids speed resolution if severe episodes.

- prednisolone 0.75 mg/kg (o) once daily for 2 weeks, then reduce

#### Prognosis

There is a tendency to settle spontaneously over 3–8 weeks. The lesions may recur.

### HERPES ZOSTER

Herpes zoster (shingles) is caused by reactivation of varicella zoster virus (acquired from the primary infection of chickenpox) in the dorsal root ganglion. The term comes from the Greek *herpes* (to creep) and *zoster* (a belt or girdle). Shingles is from the Latin *cingere* (to gird) or *cingulum* (a belt). In most instances the reason for reactivation is unknown, but occasionally it is related to an underlying malignancy, usually leukaemia or a lymphoma, to immunosuppression, or to a local disease or disturbance of the spine or spinal cord, such as a tumour or radiotherapy.

The incidence is 3.4 cases per 1000 population per year. A person of any age can get herpes zoster but it is more common in people over 50 years.

#### Treatment

- Admit to hospital
- Identify and remove cause (e.g. withdraw drugs)
- Symptomatic treatment (e.g. antihistamines for itching)
- Refer severe cases

### § Erythema nodosum

Erythema nodosum is characterised by the relatively sudden onset of bright red, raised, tender nodules on the shins, knees and ankles (see FIG. 29.1, CHAPTER 29).

It is an acute, inflammatory, immunological reaction in the subcutaneous fat. The nodules may also appear on the thighs and the arms. Adult females are typically affected. An arthritic reaction can affect the ankles and knees. It is often associated with recent infection and illness.

#### Causes/associations

- Sarcoidosis (commonest known cause)

## Clinical features

The main features are:

- the condition is preceded by several days of radicular pain with hyperaesthesia
- unilateral patchy rash in one or two contiguous dermatomes (see FIG. 124.10)
- intense erythema with papules in affected skin
- later crusting and separation of scabs after 10–14 days, often with depigmentation
- regional lymphadenopathy

**FIGURE 124.10** Herpes zoster (shingles) involving the L2 nerve root in a 63-year-old woman presenting with low back and groin pain. Calamine lotion has been applied to soothe the discomfort.

## Distribution

Any part of the body may be affected, but thoracic and trigeminal dermatomes are the most common. It follows the distribution of the original varicella rash (worse on the face and trunk).

## Cranial nerve involvement

The trigeminal nerve—15% of all cases:

- ophthalmic branch—50% affects nasociliary branch with lesions on tip of nose and eyes (conjunctivae and cornea)
- maxillary and mandibular—oral, palatal and pharyngeal lesions

The facial nerve: lower motor neurone facial nerve palsy with vesicles in and around external auditory meatus (notably posterior wall)—the Ramsay–Hunt syndrome.

## Complications

- Rare: meningoencephalitis
- Uncommon: motor paralysis

- Common:
  - postherpetic neuralgia; increased incidence with age and debility, with duration greater than 6 months:
 

less than 50 years	1%
50–59 years	7%
60–69 years	21%
70–79 years	30–50%
  - the neuralgia resolves within 1 year in 70–80% of these patients but in others it may persist for years
  - eye complications of ophthalmic zoster including keratitis, uveitis and eyelid damage

## Management

- Provide appropriate detailed explanation and reassurance. Dispel myths: namely, that it is not a dangerous disease, the patient will not go insane nor die if the rash spreads from both sides and meets in the middle.
- Explain that herpes zoster is only mildly contagious but children can acquire chickenpox after exposure to a person with the disorder. It is advisable to avoid contact with infants and young children who have never had chickenpox and avoid contact with the immunocompromised and those undergoing chemotherapy. Consider giving varicella zoster immunoglobulin to those immunocompromised contacts who have no history of varicella.<sup>4</sup>
- *Treating the rash:* Instruct the patient to avoid overtreatment of the rash, which may become infected. Calamine lotion may be soothing but removal of the calamine can be painful. For a hot, painful rash, to remove crusts and exudate, bathe the lesions with saline three times daily. A drying lotion (e.g. menthol in flexible collodion) is most soothing and suitable. Cover the lesions in a light, non-adherent padded dressing.

## Oral medication<sup>5</sup>

Analgesics such paracetamol with or without codeine should be first-line therapy ± tricyclic antidepressants.

Antiviral therapy with a guanine analogue may reduce the duration of the disease in all people.

Optimal indications—patients:

- treated within 72 hours of onset of vesicles
- who are >50 years of age
- who are immunocompromised
- with acute severe pain
- with involvement of special areas (e.g. eye, perineum)

Dose (e.g. herpes ophthalmicus):<sup>5</sup>

aciclovir 800 mg (child: 20 mg/kg) (o) 5 times daily for 7 days

or

famciclovir 250 mg 8 hourly (o) for 7 days

or

valaciclovir 1000 mg 8 hourly (o) for 7 days

*Note:* increase dose in immunocompromised patients.

### Corticosteroids

For severe pain, consider prednisolone 50 mg (o) mane for 7 days then taper.

### Prevention<sup>5</sup>

- Varicella zoster vaccine (Zostavax).

### Postherpetic neuralgia<sup>6</sup>

This pain, mostly encountered in the elderly, is usually severe, varying in quality from paroxysmal stabbing pain to burning or aching. Spasms of pain upon light brushing of the skin are a feature.

Treatment is difficult and a careful 'trial and error' approach can be used until appropriate evidence from scientific trials establishes the optimal treatment.

### Treatment options<sup>5</sup>

- Basic analgesics: paracetamol 1.33 g (o) 6–8 hourly
- TENS as often as necessary (e.g. 16 hours/day for 2 weeks)<sup>5</sup>
- plus
- Oral medication:
  - tricyclic antidepressants, for example: amitriptyline 10–25 mg (o) nocte, increasing to a maximum 75–100 mg nocte
- or
- pregabalin (for lancinating pain) 75 mg (o) nocte initially, increasing the dose gradually to maximum tolerated dose (up to 150 mg bd)
- or
- gabapentin 300 mg (o) daily (nocte) initially, increasing as tolerated to maximum 2 400 mg
- Topical medication:
  - lignocaine 5% ointment or 10% gel
- or
- lignocaine 5% patch to painful area

### Evidence-based medicine

Systematic reviews confirm that oral antiviral agents (as above) are beneficial for preventing postherpetic

neuralgia while tricyclic antidepressants and gabapentin are beneficial for relieving the established condition.<sup>7</sup>

### Physical treatments

- Local corticosteroid and anaesthetic injections.
- Nerve blocks (e.g. supraorbital nerve).
- Excision of painful skin scar. If the neuralgia of 4 months or more is localised to a favourable area of skin, a most effective treatment is to excise the affected area, bearing in mind that the scar tends to follow a linear strip of skin. This method is clearly unsuitable for a large area.

### § Herpes simplex<sup>6</sup>

Herpes simplex is a common infection caused by the large DNA herpes simplex virus (HSV), which can cause a vesicular rash anywhere on the skin or mucous membranes (see FIG. 124.11). There are two major antigenic strains of HSV:

- HSV I, which commonly involves the lips and oral mucosa
- HSV II, which basically affects the genitalia (common in adolescents and young adults)

FIGURE 124.11 Acute eruption of herpes simplex on the face—a recurrent problem in this person

### Epidemiology

HSV has a worldwide distribution and is spread orally or genitally by infected secretions. Primary HSV infection is usually a disease of childhood, characteristically causing acute gingivostomatitis in a preschool child (see CHAPTER 72).

TABLE 124.7 summarises the major manifestations of HSV and the possible complications.

**Table 124.7** Herpes simplex virus: manifestations and complications

#### Examples of manifestations

Herpes labialis (synonyms: fever blisters, cold sores)

Keratoconjunctivitis, including dendritic ulcer

Genital infection

Other areas of skin such as buttocks

#### Complications

Eczema herpeticum

Erythema multiforme (3–14 days postinfection), often recurrent

Myeloradiculopathy with genital herpes

Pneumonia

Encephalitis

### Recurrent infection

Recurrences range from weeks to months and appear due to reactivation rather than re-infection. The cause is not clear but there are several known precipitating factors. These are fever, sunlight, respiratory infections, menstruation, emotional stress, local trauma and, with genital lesions, sexual intercourse.

### Fatalities

HSV infections can be potentially fatal. Reactivated HSV can cause a focal destruction encephalitis. The untreated case fatality rate is as high as 70%, but this can be greatly reduced with the use of aciclovir. Neonates exposed to HSV can develop fatal disseminated infection. In compromised patients the infection can be severe.

### Diagnosis

If the clinical picture is uncertain, immunofluorescence of, or PCR from, vesicle fluid can aid diagnosis.

### § Genital herpes

See CHAPTER 119 and CHAPTER 109.

### § Herpes labialis (classic cold sores)

The objective is to limit the size and intensity of the lesions.

### Treatment

At the first sensation of the development of a cold sore:

- apply an ice cube to the site for up to 5 minutes every 60 minutes (for first 12 hours)

- topical applications include:  
idoxuridine 0.5% preparations (e.g. Virasolve) applied hourly  
or  
saturated solution of menthol in SVR  
or  
povidone–iodine 10% cold sore paint: apply on swab sticks 4 times a day until disappearance  
or  
aciclovir 5% cream 5 times daily for 4 days  
or  
penciclovir 1% cream for 4 days  
*Note:* Corticosteroids are contraindicated.

### Oral medication

For a severe primary attack:

- aciclovir 400 mg (child: 10 mg/kg up to 400 mg) 8 hourly for 5 days or until resolution  
or  
famciclovir or valaciclovir

### Prevention

If exposure to the sun precipitates the cold sore, use an SPF 30 or more sun protection lip balm, ointment or Solastick. Zinc sulphate solution can be applied once a week for recurrences. Oral aciclovir 200 mg bd (6 months) can be used for severe and frequent recurrences.<sup>8</sup>

### Advice to the patient

Herpes simplex is contagious. It is present in saliva and can be spread in a family by the sharing of drinking and eating utensils and toothbrushes, or by kissing. It is most important not to kiss an infant if you have an active cold sore.

### FOLLICULITIS<sup>9</sup>

Folliculitis, which is infection in and around hair follicles, can be superficial or deep. Responsible organisms include bacteria (most common) but consider fungi, dermatophytes and *Candida albicans*.

### § Superficial folliculitis

This usually presents as mild itchy pustules on an erythematous base on any part of hair-bearing skin, particularly in hot weather in a patient who is often a chronic carrier of *S. aureus*. A swab supports diagnosis. Management involves removal of the cause and the application of an antiseptic wash, such as triclosan 1%, chlorhexidine or povidone–iodine. Occasionally oral flucloxacillin may also be required.

## Bacterial folliculitis<sup>3</sup>

A generalised acute erythematous maculopapular rash can be a manifestation of bacterial folliculitis, typically caused by *S. aureus*, *Pseudomonas aeruginosa*, or by fungal folliculitis due to *Pityrosporum orbiculare* or other dermatophytes.

*Pseudomonas* folliculitis can cause confusion, the typical features being:

- rapidly spreading rash
- mainly on trunk, buttocks and thighs, especially axillae and groin
- itchy
- small pustules surrounded by circular red–purple halo
- follows immersion in a hot spa bath or tub

Treatment is based on the sensitivity of the cultured organisms (e.g. ciprofloxacin). Many cases resolve spontaneously in 1–2 weeks.

## Folliculitis of trunk from spa baths

‘Hot tub folliculitis’ is caused by *P. aeruginosa* (usually) in poorly chlorinated water maintained at temperatures 37–40°C.

Treatment is with ciprofloxacin 500 mg (o) bd for 7 days.

## Folliculitis of groin (pseudofolliculitis)

Folliculitis of the groin area is common in women who shave. It tends to recur.

### Management

- Use tea tree (melaleuca) lotion daily for folliculitis.
- Prior to shaving apply ‘tea tree wash’.
- Change shaving habits: avoid close shaving; shave less often; shave in direction of hair growth and use good quality blades.
- If persistent, use povidone–iodine or chlorhexidine (Hibiclens) solution or triclosan 1%.
- If severe, use mupirocin 2% (Bactroban) ointment.

## § Deep folliculitis

Deep forms are usually very tender and painful. Examples are styes, boils (furuncles) and carbuncles.

## Boil (furuncle)<sup>10</sup>

This is an *S. aureus* infection of a hair follicle and may occur in any hair-bearing site. The painful red

nodule enlarges, becomes fluctuant and develops a necrotic centre, which discharges a core of thick yellow pus tinged with blood (with associated relief of pain).

### Treatment (adults)

- (According to swabs) di(flucloxacillin 500 mg or cephalexin 500 mg (orally, 6 hourly for 5–7 days) or roxithromycin 300 mg (o) daily or erythromycin 500 mg (o) 12 hourly for 7 days

## Boils — recurrent

- Obtain swabs
- 3% hexachlorophene body wash daily
- Mupirocin to the lesions and nares
- Antibiotics (as above)—according to swabs

## Carbuncle

This is a cluster of small abscesses involving a group of adjoining hair follicles. Common sites are the back of the neck, the shoulders, buttocks or over the hips. Treatment is as for a boil.

## Stye of eye

- Apply heat with direct steam from a thermos onto the closed eye or by a hot compress (helps spontaneous discharge).
- Perform lash epilation to allow drainage (incise with a size 11 blade if epilation doesn’t work).
- Only use topical antibiotic ointment (e.g. chloramphenicol) if infection is spreading locally, and systemic antibiotics if distal spread noted by pre-auricular adenitis.

## Patient education resources

Hand-out sheets from *Murtagh’s Patient Education* 6th edition:

- Herpes simplex (cold sores)
- Herpes zoster (shingles)
- Pityriasis rosea

# 125 Skin ulcers

*An ulcer, which occurring at any of the vital parts of the body secretes a copious quantity of pus and blood, and refuses to be healed, even after a course of proper and persistent medical treatment, is sure to have a fatal determination.*

Sushrut a-Samhit a (5TH century BC)

An ulcer is a localised break in the epidermal tissue of the surface of the skin or mucous membrane as a result of trauma, pressure, infection; they are associated with an underlying pathology. This applies particularly to leg ulcers. Ulcers are commonly found on the legs and feet, on areas exposed to the sun, and over bony prominences on the sacrum and heels. They may be clean, sloughy or necrotic.

The national morbidity survey (UK) showed that 2–3 per 1000 patients per annum consulted their GP with ‘chronic ulcers of the skin’.

## Key facts and checkpoints<sup>1,2</sup>

- The great majority of leg ulcers are vascular in origin due to arterial insufficiency or venous hypertension or to a combination of the two i.e. mixed ulcers.
- If clinical findings don't provide the diagnosis, ordering the ankle-brachial index (ABI) is essential if pulses are not palpable to exclude arterial disease. Duplex Doppler ultrasound is the key investigation for both venous and arterial disease.
- Most ulcers are multifactorial:
  - 1 venous + obesity + immobility (often with osteoarthritis) + poor compliance, or
  - 2 venous + arterial + trauma + infection
- Identify and treat any intrinsic or extrinsic factors impairing wound healing.
- High-stretch compression bandages are better than short-stretch compression bandages, which are mainly used in lymphoedema, and multilayer is best.
- Elastic bandages are better than non-elastic bandages.
- Venous surgery can improve outcomes—newer methods use non-surgical foam injections and lasers.
- A moist environment delivered by modern dressings provides a physiological environment for wound healing.

- Adequate wound debridement is essential to remove necrotic material and slough, and enable healing to commence and progress.
- It is important to consider biopsy as hypergranulation that does not respond quickly to topical treatment with hypertonic saline, silver nitrate and compression bandaging may be an SCC.
- Diabetic ulcers may be either neuropathic, which are mostly caused by pressure damage due to sensory neuropathy, or ischaemic due to loss of peripheral arterial circulation.
- Autoimmune diseases are the underlying cause of vasculitic wounds. They result from damage caused by circulating antibodies often seen in RA, lupus and scleroderma. They are very painful and difficult to heal without the use of immunosuppressants.
- Accurate diagnosis of the ulcer is vitally important for management decisions.
- Bacterial swabs are unhelpful because all chronic ulcers will become colonised with both Gram-positive and Gram-negative bacteria.

## The clinical approach

It is useful to keep in mind the various causes of ulcers (see TABLE 125.1). The commonest causes or types are venous and ischaemic ulcers of the leg, pressure ulcers (decubitus) and trauma. It is important not to misdiagnose malignant ulcers, including ‘Marjolin ulcer’, which is SCC developing in unstable chronic scars or ulcers (e.g. burns, venous ulcers, tropical ulcers) of long-standing duration. Amelanotic melanoma is a specific trap.

## History

A careful history helps determine the cause of the ulceration. Relevant history includes previous deep venous thrombosis or pulmonary embolism, diabetes, rheumatoid arthritis, inflammatory bowel

**Table 125.1** Types and causes of skin ulcers**Traumatic**

Decubitus (related to trauma—pressure injury)

**Vascular**

- Venous:
  - varicose veins
  - post thrombophlebitis
- Arterial insufficiency
- Skin infarction (thrombolytic ulcer)
- Vasculitis
  - rheumatoid arthritis, SLE, scleroderma

**Infective**

- Tropical ulcer
- Tuberculosis
- *Mycobacterium ulcerans*
- Post cellulitis
- Chronic infected sinus

**Malignant**

- Squamous cell carcinoma
- Marjolin ulcer (SCC) in long-standing ulcer
- Basal cell carcinoma (rodent ulcer)
- Malignant melanoma
- Ulcerating metastases

**Neurotrophic**

- Peripheral neuropathy (e.g. diabetes)
- Peripheral nerve injuries (e.g. leprosy)

**Haematological**

- Polycythaemia
- Spherocytosis
- Sickle cell anaemia

**Miscellaneous**

- Artefactual
- Pyoderma gangrenosum inflammatory ulcer
- Insect and spider bites

disease, chronic skin ulcers and arterial insufficiency, including a history of intermittent claudication and ischaemic rest pain.

A drug history is important, considering especially beta blockers and ergotamine, which can compromise the arterial circulation, corticosteroids and NSAIDs, which affect healing, and nifedipine, which tends to aggravate ankle oedema.

**Examination<sup>3</sup>**

Any ulcer should be assessed for the following characteristics:

- site
- shape
- size

- edge—consider consistency
- floor
- base
- discharge
- surrounding skin:
  - colour (? signs of inflammation)
  - sensitivity
- mobility in relation to underlying tissue
- regional lymph nodes

**Site of ulcer**

Venous ulcers typically occur on the medial side of the leg in relation to incompetent perforating veins in the traditional gaiter area (see FIG. 125.1).

Ischaemic ulcers tend to occur on the lateral side and anterior part of the leg and the foot.

Trophic ulcers, which are associated with neuropathy, occur on parts subject to repeated pressure and trauma, such as the ball of the foot or the pulps of the fingers.

**FIGURE 125.1** Area typically affected by varicose eczema and ulceration (the 'gaiter' area)

**Postsolar keratoses**

Solar-induced ulcers, such as SCCs and BCCs, occur on such parts exposed to the sun. It should be noted if the ulcer is related to old scars, including burns and chronic ulcers.

**Size, shape and edge**

The classic appearances of various ulcers are presented in FIGURE 125.2. These are general guidelines only. Infective ulcers due to *Mycobacterium* species and pressure injury tend to have an undermined edge while a trophic ulcer is punched out and typically round in surface shape. A raised firm ulcer edge may indicate malignancy.

Floor of the ulcer

The floor or base of the ulcer provides useful clinical information. A dry or extended base or necrotic eschar in the floor implies ischaemia. Venous ulcers on the other hand are often superficial and tend to have fibrinous exudate and ooze, sometimes purulent fluid.

Colour guide:

- black—necrosis, ischaemia
- yellow—slough
- red—granulation
- pink—epithelium

Investigations

The following should be considered, according to the clinical findings:<sup>4</sup>

- full blood count
- ESR/CRP
- random blood sugar/HbA1c (known diabetes)
- kidney function tests
- rheumatoid factor tests
- duplex Doppler ultrasound
- swab for specific organisms
- biopsy, especially if SCC suspected (be careful of biopsy if melanoma: amelanotic melanomas are a trap); also accurately identify an infective organism

Lower limb ulceration

The most common causes of lower limb ulceration are venous disease, arterial disease, mixed venous and arterial, and diabetes.

Differentiating between leg ulcers (85%) and foot ulcers (15%) is very important since they present two very different problems.<sup>3</sup> According to the survey by Stacey, venous disease is present in two-thirds of leg ulcers, while arterial disease occurs in 28% (see TABLE 125.2). Ulceration on the foot frequently has an arterial aetiology (72%), with many of these patients also having diabetes, whereas venous disease is present in only 6%.<sup>5</sup>

The differential characteristics are presented in TABLE 125.3.

A general examination, including the leg, is very important. This includes examining the venous drainage (CHAPTER 66), the arterial pulses and the sensation of the leg, and checking for the presence of diabetes.

Appropriate investigations (if required) include:

- full blood count
- blood sugar
- duplex Doppler ultrasound for arterial circulation

Table 125.2	Causes of chronic ulceration of the leg and foot <sup>5</sup>	%

To swab or not to swab

A routine ulcer swab is not considered to be of significant value. If specific organisms such as *Mycobacterium ulcerans* are suspected, then cultures are necessary. Biopsy is considered to be accurate.

**Table 125.3** Comparison of typical features of venous and arterial ulceration of the leg

	Venous	Arterial
<b>Site</b>	Around ankle and lower third of leg (gaiter area) Just above medial and lateral malleoli	Distal to ankle Over pressure points on toes, side of foot, metatarsal heads
<b>Pain</b>	Nil to mild	Usually moderate to severe
<b>Oedema</b>	Pitting oedema usually present	Usually absent
<b>Ulcer features</b>	'Ragged' edge Often superficial Ooze + + +	'Punched out' Often deep, involving deep fascia Dry
<b>Associated limb features</b>	Varicosities Leg warm, red, oedematous Varicose dermatitis Haemosiderin deposits Atrophie blanche	'Cold' extremities Ischaemic changes Diminished or absent peripheral pulses Thin, shiny, dry skin Poor perfusion
<b>History</b>	Limb oedema Past DVT Failed graft	Peripheral vascular disease— claudication, rest pain Diabetes Smoker
<b>ABI</b>	>0.9	<0.5–0.7

## Measurement of ankle/brachial pressure index

To plan management of a leg ulcer, it is ideal to determine the blood flow with hand-held Doppler ultrasound. Measure ankle and brachial systolic pressures and then determine the ABI, which is the ankle pressure divided by the brachial pressure. Typical levels are:<sup>4</sup>

Normal range	0.91–1.3
Normal	>0.9 (venous ulcer)
Ischaemic	<0.5 (arterial ulcer)
Claudicant	0.5–0.9 (mixed arterial–venous ulcer, significant ischaemia if <0.8)

The ability to determine the cause of the ulceration and thus treat accordingly, especially with pressure dressings, has been a major advance in management. An ABI <0.8 warrants caution in applying any compression; <0.4 demands urgent referral.

*General rule:* Low compression 0.7–0.8; no compression <0.7.

## § Arterial (ischaemic) ulcers

Ischaemic ulcers are generally localised to the most peripheral areas below the ankle joint (see FIG. 125.3), such as the tips of the toes and the point of the heel, or to pressure points such as the heels, malleoli or head of the first metatarsal.

### Clinical features

- Painful
- Punched out
- Minimal granulation tissue

Management is directed towards reperfusion.

**FIGURE 125.3** Ischaemic 'arterial' ulcers in an elderly woman with a long history of intermittent claudication and a recent history of nocturnal ischaemic rest pain in the feet. The ulcers healed after reconstruction for arterial obstruction. Photo courtesy Terry Devine

## § Venous ulceration

Venous ulceration (synonyms: 'varicose', 'stasis' and 'gravitational' ulcers) accounts for the majority of leg ulcers. Chronic venous insufficiency is one of the most common medical problems in the elderly, with an estimated incidence of 5.9%.<sup>6</sup>

The problem is invariably secondary to deep venous thrombophlebitis. The subsequent chronic venous hypertension produces trophic changes such as hyperpigmentation (see FIG. 125.4), fibrotic thickening, induration and oedema. The end point of

**FIGURE 125.4** Venous ulceration in an elderly patient with postphlebotic varicose 'eczema'. Venous pigmentation, dermatitis, atrophy and calcification of the subcutaneous tissues are present.

Photo courtesy Terry Devine

this process is ulceration, which affects 3% of those with varicose veins and 30% of those with trophic changes.<sup>7</sup>

### Clinical features<sup>8</sup>

- Occur in same area as venous eczema
- Shallow (but can reach periosteum)
- More common medial than lateral
- Sometimes circumferential
- Granulating floor sometimes with surrounding inflammation—may be cellulitis
- Notoriously slow in healing without adequate compression
- Generally not tender but can be painful
- Associated pain is usually relieved by raising the leg

On examination, superficial varicosities are usually but not invariably present. Pitting oedema may be present early but with time fibrosis and firm induration develop. Other clinical features include dermatitis (eczema), punctate capillary proliferation, haemosiderin, hyperpigmentation and 'atrophie blanche' (porcelain white scar with rim of telangiectasia).<sup>8</sup>

### Management (venous leg ulcers)

A major advance in the management of venous ulcers has been the finding that wounds heal better in an occluded or semi-occluded state.<sup>9</sup> A moist environment also aids healing. The dressing will control the wound environment. The main treatment is graduated compression at 20–40 mmHg. See **TABLE 125.4**.

**Table 125.4** Wound management principles

The good	The bad
Hydration	Dryness
Washing with water or saline	Excess antiseptics
Insulation protection	Exposure to air
	Scabs, crust, slough
Dressings	
Compression (venous)	Dry dressings
Hydrogel	Gauze packing
Foams	Tulles
Minimal changes	Oedema/lymphoedema

### Principles of optimal management

- Explanation about the cause, and promotion of patient compliance
- Promoting clean granulation tissue to permit healing (see **TABLE 125.4**)
- Meticulous cleansing and dressing (avoid soaps and sensitising preparations)
- Prevention and control of infection—antibiotics indicated only if cellulitis (cephalexin or erythromycin): if infection is confirmed NOT where inflammation is present (as in most venous ulcers)
- Firm elastic compression bandage—use a minimal stretch bandage from base of toes to just below the knee. The degree of compression depends on the blood flow and is proportional to it
- Bed rest with elevation (if severe, 45–60 minutes twice a day and at night): ensure legs are elevated higher than the heart
- Encourage early ambulation and exercise
- Appropriate modification of lifestyle including weight reduction, smoking cessation (NB)
- Good nutrition includes a healthy balanced diet with ample protein and complex carbohydrates
- Be aware of drugs that can adversely affect healing (see **TABLE 125.5**)

*Note:* Firm compression is the single most important factor in the healing of venous ulcers.<sup>2,7</sup> Options include elastic stockings, elastic bandages, zinc paste bandages (Unna's boots) and legging orthoses.<sup>10</sup>

### Cleansing/debridement agents

There are many cleansing agents, including:

- N saline, surfactants e.g. QV wash and warm tap water

**Table 125.5** Drugs that can hamper healing<sup>11</sup>

Nicotine/smoking
Corticosteroids
Cytotoxic agents
Aspirin/NSAIDs
Antibiotics
Beta blockers
Hydrourea

As a rule, avoid antiseptics, which destroy cells, although cadexomer iodine, which is a slow-release form of iodine, is non-toxic to tissues, reduces bacterial load and clears odorous slough. However, wash off iodine solution after 5 minutes. Iodosorb is a low-dose iodine dressing appropriate for infected, contaminated wounds, particularly a diabetic wound. A good combination is normal saline cleansing followed by IntraSite Gel for debridement, covered with a foam dressing. Strong salt dressings (e.g. Mesalt or Curasalt) are very good for cleaning contaminated, infected wounds and hypergranulation but need changing daily and to be covered by a very absorbent overlying dressing.

Hydrogels such as IntraSite Gel, which have been found to be effective at debridement (including black necrotic areas), have generally replaced enzyme dressings.

### Lymphoedema<sup>12</sup>

This is not pitting oedema but a reduction in the function of the lymph vessels to drain extracellular fluid.

Primary lymphoedema is caused either by malformation of the lymph vessels or by damage from bacteria, fungi, parasites, insects, chemicals, radiotherapy or surgery. Secondary lymphoedema is caused by primary malignancy or intralymphatic propagation of a tumour. Lymphoedema results in major changes to the skin such as thickening of the skin, build-up of scale and keratin and worsening hyperkeratosis, producing a warty appearance.

Wounds are common in lymphoedema. They are managed by treating the wound environment with appropriate dressing, but the main treatment is significant compression with either specially developed garments or inelastic bandages. Difficult cases should be referred to a specialist lymphoedema clinic.

A simple clinical test for determining a lymphoedema component in a swelling of the lower leg is the Stemmer's sign test. This test is performed by lifting and pinching the skin at the dorsum of the second toe on each foot. A positive Stemmer's sign results when the skin cannot be lifted and pinched together. The test is negative for lymphoedema when the skin can be pinched and lifted. A positive Stemmer's sign *always* indicates lymphoedema, but a negative sign does not always rule out lymphoedema.

### Wound dressing<sup>9,13</sup>

There are six main types of modern wound dressings: films, hydrogels, hydrocolloids, alginates, foams and hydroactives (foam-like)—all expensive. Films, hydrogels and hydrocolloids increase the wound moisture whereas alginates and foams absorb exudate. The more traditional dressings such as tulle grass, non-adherent pad dressings and saline soaks have little use. A lightweight cohesive bandage or a lightweight tubular bandage can be used to hold non-adherent dressings in place.

General rules:<sup>11</sup>

- allow 2–3 cm of dressing greater than the wound
- place one-third above and two-thirds below the wound
- remove when 'strike-through' occurs
- remove with care in older patients
- remove under the shower if necessary
- when in doubt, DO NOT HARM: use foam and gel combinations

### Medicated occlusive bandages

There are several suitable occlusive paste bandages for ambulant patients, which ideally should be left on for 7–14 days. These contain zinc oxide. Examples include Flexi-Dress, Gelocast and Zipzoc (which are zinc paste bandages with no preservatives).

Patch testing for an allergic response should be performed for a few days beforehand.

### Bandages

Bandages have two main uses:

- retention: to keep a dressing in place
- compression: to assist venous return

High-stretch compression bandages are best.

Method of application:

- spiral application from toes with figure 8 around ankles, then spiral to knee
- 50% overlap
- constant tension provides graduated compression (Laplace's Law)

Pitfalls and other factors to be considered

- Treat the primary cause by surgery or other means (e.g. varicose veins, vascular insufficiency).
- If oedema, elevate legs and prescribe diuretics. An ulcer will not heal in the presence of significant ankle oedema.
- Clarify the cause of oedema, which may be due to medication e.g. calcium channel blockers.
- Be careful of allergy to local applications (e.g. zinc).
- Be careful of irritation from local applications (e.g. antibiotics). Antibiotic-impregnated dressings are not generally recommended.
- Avoid heavy packing of the wound.
- Consider grafting (pinch skin or split thickness).
- Consider oxpentifylline (Trental 400) for chronic occlusive arterial disease and venous disease.<sup>8</sup>

Post-healing and prevention of ulcers

- Encourage preventive measures, such as regular walking, good nutrition, no smoking, elevation of leg when resting, great care to avoid trauma.
- Apply emollients for varicose eczema.
- Wear a compression-grade elastic stocking for varicose ulcers (e.g. Jobst Fast-Fit, Jobst Venoscan).

A recommended treatment routine for a leg ulcer is presented in TABLE 125.6. It is desirable (for the outpatient) to leave the dressings and bandages in place for 1 week, perhaps 2 weeks, depending on the state of the dressing.

Principles of management for chronic ulcers are summarised in TABLE 125.7.

Decubitus ulcer (pressure injury)

Pressure injuries tend to occur in immobile patients, especially those who are unconscious, paralysed or debilitated. The cause is skin ischaemia from sustained pressure over a bony area, particularly the heels, sacrum, hips and buttocks. Poor general health, including anaemia, is a predisposing factor.

The classification of pressure injuries is based on the level of tissue damage and depths of the wound:

- Stage 1: non-blanching erythema
- Stage 2: partial thickness (superficial) ulceration
- Stage 3: full thickness ulceration
- Stage 4: deep full thickness—skin loss with extensive tissue loss
- Unstageable: deep tissue injury.

Table 125.6 A recommended leg ulcer treatment method

- Clean with normal saline
- If slough, apply IntraSite Gel
  - Dressing: non-adherent paraffin gauze
  - Padding bandage (e.g. Velband)
  - Occlusive paste bandage—Ichthaband or Viscopaste (7–14 days), from base of toe to just below knee, plus compression bandage
  - or
  - Compression bandage (e.g. Elastocrepe or Eloflex) to just below knee
  - Consider Tubigrip stockinette cover

Table 125.7 Principles of management of chronic ulcers<sup>14</sup>

Ulcer type	Major management principles
Venous	Control venous insufficiency: <ul style="list-style-type: none"><li>• compression bandage</li><li>• improve calf muscle pump action (ambulation, exercises)</li><li>• vertical leg drainage</li></ul>
Arterial	Vascular assessment for surgical intervention
Mixed venous/arterial	Vascular assessment for surgical intervention
Pressure	Eliminate or reduce pressure

Clinical features

- Preliminary area of fixed erythema at pressure site
- Relatively sudden onset of necrosis and ulceration
- Ulcer undermined at edges
- Possible rapid extension of ulcers
- Necrotic slough in base

Prevention

- Good nursing care including turning patient every 2 hours
- Regular skin examinations by the nursing and medical staff
- Special care of pressure areas, including gentle handling
- Special beds, mattresses (e.g. air-filled ripple) and sheepskin to relieve pressure areas
- Good nutrition and hygiene
- Control of urinary and faecal incontinence
- Avoid the donut cushion
- Avoid soaps

### Treatment<sup>13</sup>

The most important principle is early intervention including relief of pressure, friction and shear. Use above prevention measures, plus:

- clean base with warm water or saline solution and a surfactant (applied gently via a syringe)
- general guidelines for dressings:
  - deep ulcers—alginates (e.g. Algisite M, Kaltostat)
  - shallow ulcers—hydrocolloids (e.g. DuoDERM, CGF)
  - dry or necrotic ulcers—hydrogels (e.g. IntraSite, Purolin gel)
  - heavy exudative ulcers—foams (e.g. Lyofoam, Lyofoam extra, Allevyn, Cutinova Cavity)
- give vitamin C, 500 mg bd
- give antibiotics for spreading cellulitis (otherwise of little use)
- for non-healing large pressure wounds, apply negative pressure therapy
- review patient's nutritional status as it impacts on both formation of pressure injury and slow healing
- healing is usually satisfactory but, if not, surgical intervention with debridement of necrotic tissue and skin grafting may be necessary; this is very effective if the patient can cope

### Undressing wounds

Removal of dressings from ulcerated wounds is very important. The contact layer should be removed slowly to prevent detachment of fragile epithelial surface cells and trauma to healthy granulation tissue.<sup>15</sup>

### Role of honey

Honey has been advocated for centuries for healing ulcers. A particular type, Medihoney, is marketed. It provides moist healing and has antibacterial properties. Care has to be taken with over-moisturisation and maceration. Its role is still somewhat controversial as is the application of sugar, cromoglycate powder, maggots and hyperbaric oxygen.

### § Trophic ulcers

Trophic ulcers are due to neuropathy causing loss of sensation (invariably diabetic) and usually follow an injury of which the patient was unaware (see FIG. 125.5).

A feature is a deep, punched-out lesion (similar to ischaemic ulcers) over pressure points. A

FIGURE 125.5 Neuropathic ulcer under the third metatarsal of the right foot in a patient with diabetes

common site is the ball of the foot under the first metatarsal head, but the heel or a bunion may also be affected.

The ulcers may extend to the bone and into joints. They are prone to secondary infection.

Treatment is based on controlling the diabetes and clearing infection with appropriate antibiotics, but referral for surgical management is usually essential.

### DERMATITIS ARTEFACTA AND NEUROTIC EXCORIATIONS

These self-inflicted ulcerated or erosive skin lesions have a psychological basis.

### § Dermatitis artefacta

In this condition, patients deny self-trauma and may have deep-seated psychological problems, or they may be malingering or manipulative for secondary gain.

## § Neurotic excoriations

These lesions, which are usually identical to the artefactual lesions, are caused by patients who admit to scratching, picking or digging at their skin (FIG. 125.6). It occurs at times of stress and treatment is seldom successful. Treatment consists of counselling with CBT, a trial of antidepressants and topical antipruritics such as:

coal tar solution (liquor picis carbonis) and menthol in sorbolene cream  
or  
menthol (0.5%) or phenol (1.0%) in aqueous cream

### Practice tips

#### Principles of treatment<sup>11</sup>

- Occluded and moist wounds heal faster.
- Maintain moist wound environment.
- Control exudate and debris (remove excess—leave enough to allow cellular regeneration).
- Maintain/improve circulation.
- Insulate and protect.

# 126 Common lumps and bumps

*It will never get well if you pick it.*

American Proverb

Lumps and bumps are very common presentations and the skin a very common site for neoplastic lesions. Most of these lesions only invade locally, with the notable exception of malignant melanoma. Pigmented skin tumours thus demand very careful consideration, although only a very few are neoplastic. The optimum time to deal with the problem and cure any skin cancer is at its first presentation. The family doctor thus has an important responsibility to screen these tumours and is faced with two basic decisions: the diagnosis and whether to treat or refer.

Most skin lumps are benign and can be left in situ, but the family doctor should be able to remove most of these lumps if appropriate and submit them for histological verification. The main treatment options available in family practice are: biopsy, cryotherapy, curette and cautery, excision or intralesional injections of corticosteroid.<sup>1</sup> A list of common and important lumps is presented in **TABLE 126.1**.

## Skin cancer

The three main skin cancers are the non—melanocytic skin cancers—basal cell carcinoma (BCC) and squamous cell carcinoma (SCC)—and melanoma. The approximate relative incidence is BCC 80%, SCC 15–20%, and melanoma less than 5%.<sup>2</sup> The incidence of non-melanocytic skin cancer, which is increasing 2.5 times as fast as other cancers, is approximately 800 new cases per 100 000 population per year, and 25 per 100 000 for melanoma. About 80% of skin cancer deaths are due to melanoma and the rest mainly due to SCC.<sup>2</sup>

## A diagnostic approach to the lump

As with any examination, the routine of look, feel, move, measure, auscultate and transilluminate should be followed.

The lump or lumps can be described thus:

- number
- site
- shape—regular or irregular
- size (in metric units)

**Table 126.1**

Important lumps and their tissue of origin<sup>3</sup>

Skin and mucous membranes

Fibroepithelial polyp (skin tag)

Soft fibroma

Epidermoid (sebaceous) cyst

Implantation cyst

Sebaceous hyperplasia

Mucocele

Hypertrophic scar and keloid

Warts and papillomas

Pox virus lumps:

- molluscum contagiosum
- orf
- milker's nodules

Seborrhoeic keratoses

Granuloma annularae

Dermatofibroma

Solar keratosis/actinic keratosis

Keratoacanthoma

Malignant tumours:

- basal cell carcinoma
- squamous cell carcinoma
- Bowen disease
- malignant melanoma
- Kaposi sarcoma
- secondary tumour

Subcutaneous and deeper structures

Lipoma

Neurofibroma

Lymph node (see **CHAPTER 61**)

Pseudoaneurysm

Musculoskeletal:

- ganglion
- bursae

- position
- consistency (very soft, soft, firm, hard or stony hard)
- solid or cystic
- mobility
- surface or contour
- special features:
  - attachments (superficial/deep)
  - exact anatomical site
  - relation to anatomical structures
  - relation to overlying skin
  - colour
  - temperature (of skin over lump)
  - tenderness
  - pulsation (transmitted or direct)
  - impulse
  - reducibility
  - percussion
  - fluctuation (? contains fluid)
  - bruit
  - transilluminability
  - special signs: slipping sign, emptying sign of cavernous haemangioma
  - spread: local, lymphatic, haematogenous
  - regional lymph nodes
  - ? malignancy (is it primary or secondary?)

### Relation of the lump to anatomical structures<sup>3</sup>

The question 'In what tissue layer is the lump situated?' needs to be addressed.

- Is it in the skin? The lump moves when the skin is moved (e.g. epidermoid cyst).
- Is it in subcutaneous tissue? The skin can be moved over the lump. The slipping sign: if the edge of the lump is pushed, the swelling slips from beneath the finger (e.g. lipoma).
- Is it in muscle? The lump is movable when the muscle is relaxed but on contraction of the muscle this movement becomes limited.
- Is it arising from a tendon or joint? Movement of these structures may cause a change in the mobility or shape of the tumour.
- Is it in bone? The lump is immobile and best outlined with the muscles relaxed.

### LUMPS OF THE SKIN AND MUCOUS MEMBRANES

#### § Fibroepithelial polyps

Synonyms: skin tags, acrochordon, benign squamous papilloma, soft fibroma.

### Clinical features

- Benign skin overgrowth
- Pedunculated soft fibroma
- Increased incidence with age
- Commonest on neck, axillae, trunk, groins
- No malignant potential
- Can be irritating or unsightly to patient

### Management

- Can leave or remove
  - To remove:
    - snip off with scissors or bone forceps (see FIG. 126.1)
    - or
    - tie base with fine cotton or suture material
    - or
    - diathermy or electrocautery of base
    - or
    - apply liquid nitrogen (see FIG. 126.2)
- These methods do not require local anaesthetic.

FIGURE 126.1 Removal of skin tag using bone forceps

FIGURE 126.2 Removal of skin tag by liquid nitrogen: a cotton bud soaked in liquid nitrogen is applied to the forceps, which grasp the tag firmly

## § Epidermoid (sebaceous) cyst

Synonyms: 'pilar' cysts, keratinous cyst, wens, epidermoid cysts, sebaceous cysts (similar in appearance).

### Clinical features

- Firm to soft regular lump (usually round)
- Fixed to skin but not to other structures (see FIG. 126.3a)
- Move with the skin
- Found in hair-bearing skin mainly on scalp—then face, neck, trunk, scrotum
- Contains sebaceous material
- Usually fluctuant
- May be a central punctum containing keratin
- Tendency to inflammation

### Management

If before puberty—think of polyposis coli. Can leave if small and not bothersome.

### Surgical removal methods

There are several methods of removing epidermoid cysts after infiltrating local anaesthetic over and around the cyst. These include:

- *Method 1: Incision into cyst* Make an incision into the cyst to bisect it, squeeze the contents out with a gauze swab and then avulse the lining of the cyst with a pair of artery forceps or remove with a small curette.
- *Method 2: Incision over cyst and blunt dissection* Make a careful skin incision over the cyst, taking care not to puncture its wall. Free the skin carefully from the cyst by blunt dissection. When it is free from adherent subcutaneous tissue, digital pressure will cause the cyst to 'pop out'.
- *Method 3: Standard dissection* Incise a small ellipse of skin to include the central punctum over the cyst (see FIG. 126.3b). The objective is to avoid rupture of the cyst. Inserting curved scissors (e.g. McIndoe's scissors), free the cyst by gently opening and closing the blades (see FIG. 126.3c). Bleeding is not usually a problem. Send the cyst for histopathology.

### Treatment of infected cysts

Incise the cyst to drain purulent material. When the inflammation has resolved completely the cyst should be removed by method 1 or method 3 (see above).

FIGURE 126.3 (a) Configuration of a sebaceous cyst; (b), (c) standard dissection of a large sebaceous cyst

## § Implantation cyst

Synonym: implantation dermoid.

### Clinical features

- Small cystic swelling
- May be tender
- Usually follows puncture wounds
- Especially on finger pulp (e.g. hairdressers, sewers)
- Contains mucus

### Management

- Incision removal (similar to epidermoid cyst)

## § Mucocele

A mucous retention cyst.

### Clinical features

- A benign tumour
- Cyst containing mucus
- Appears spontaneously
- Common on lips and buccal mucosa
- Smooth and round
- Yellow or blue colour

### Management

- Incision removal

## § Hyperplastic scarring

### Hypertrophic scar

A hypertrophic scar is simply a lumpy scar caused by a nodular accumulation of thickened collagen fibres. It does not extend beyond the margins of the wound and regresses within a year but sometimes can be permanent.

### Keloid

A keloid is a special type of hyperplastic scar that extends beyond the margins of the wound.

### Clinical features

- Firm, raised, red–purple, skin overgrowth
- Common on ear lobes, chin, neck, shoulder, upper trunk
- Hereditary predisposition (e.g. dark-skinned person)
- Follows trauma, even minor (e.g. ear piercing)
- May be burning or itchy and tender

### Management of scarring

- Prevention (avoid procedures in keloid-prone individuals).
- Compression and silicone dressings
- Intradermal injection of corticosteroids in early stages (2–3 months) or intralesional cytotoxics (e.g. fluorouracil) or X-ray treatment of surgical wounds within 2 weeks of operation.<sup>4</sup>
- Consider re-excision of hypertrophic scarring

## § Warts and papillomas

Warts are skin tumours caused by the human papillomavirus (HPV). The virus invades the skin, usually through a small abrasion, causing abnormal skin growth. Warts are transmitted by direct or fomite contact and may be autoinoculated from one area to another.<sup>5</sup>

### Clinical features

- Average incubation period—4 months
- Increased incidence in children and adolescents
- Peak incidence around adolescence
- Occurs in all ethnicities at all ages
- About 25% resolve spontaneously in 6 months<sup>5</sup> and 70% in 2 years
- Present as various types

### Types of warts

These include common warts, plane warts, filiform warts (fine elongated growths, usually on the face and neck), digitate warts (finger-like projections, usually on scalp), genital and plantar warts (see FIG. 126.4).

### Common warts

These are skin-coloured tumours with a rough surface, found mainly on the fingers, elbows and knees.

### Plane warts

These are skin-coloured, small and flat, occurring in linear clusters along scratch lines (see FIG. 126.5). They mainly occur on the face and limbs. They are difficult to treat because they contain very few virus particles. They are prone to Koebner phenomenon, which is seeding when a scratch passes through a plane wart.

### Treatment options

Topical applications:<sup>5</sup>

- salicylic acid—for example: 5–20% in flexible collodion (apply daily or bd) or 16–17% salicylic acid + 16–17% lactic acid
- formaldehyde 2–4% alone or in combination
- podophyllotoxin 0.5% for anogenital warts—it is good on mucosal surfaces but does not penetrate normal keratin
- cytotoxic agents (e.g. 5-fluorouracil: very good for resistant warts such as plane warts and periungual warts)
- the immunomodulator, imiquimod

### Cryotherapy

Carbon dioxide (−56.5°C) or liquid nitrogen (−195.8°C) destroys the host cell and stimulates an immune reaction.

*Note:*

- excessive keratin must be pared before freezing
- the results are often disappointing

FIGURE 126.4 Configuration of various types of warts

### Curettage

A most common treatment; some plantar warts can be removed under LA with a sharp spoon curette. The problem is a tendency to scar, so avoid over a pressure area such as the sole of the foot.

### Electrodesiccation

A high-frequency spark under LA is useful for small, filiform or digitate warts. A combination of curettage and electrodesiccation is suitable for large and persistent warts.

FIGURE 126.5 Plane warts on the dorsum of the hand

### Vitamin A and the retinoids

- Topical retinoic acid (e.g. tretinoin 0.1% cream—Retin-A) is effective on plane warts
- Systemic oral retinoid, acitretin (Neotigason) for recalcitrant warts (with care)

### Medication

- Consider cimetidine

### Specific wart treatment

The method chosen depends on the type of wart, its site and the patient's age.

- *Plantar warts*: refer to **CHAPTER 68**
- *Genital warts*: podophyllotoxin 0.5% paint or imiquimod (best for penile warts, see **CHAPTER 119**)
- *Filiform and digitate warts*: liquid nitrogen or electrodissection
- *Plane warts*: liquid nitrogen; salicylic acid 20% co (e.g. Wartkil); consider 5-fluorouracil cream or tretinoin 0.05% cream (Retin-A)
- *Common warts*: a recommended method:
  - 1 Soak the wart/s in warm soapy water.
  - 2 Rub back the wart surface with a pumice stone.
  - 3 Apply keratolytic paint (only to the wart; protect the surrounding skin with Vaseline). The paints: formalin 5%, salicylic acid 12%, acetone 25%, collodion to 100%.<sup>4</sup>

Do this daily or every second day.

Carefully remove dead skin between applications

or (preferable applications)  
 (adult) 16% salicylic acid, 16% lactic acid in collodion paint (Dermatec, Duofilm), apply once daily  
 (children) 8% salicylic acid, 8% lactic acid in collodion  
 Combined method: salicylic acid 70% paste in linseed oil. Leave 1 week then pare and freeze (cryotherapy).

- *Periungual warts (fingernails)*: consider 5-fluorouracil or liquid nitrogen with care. Always use a paint rather than ointment or paste on fingers. Specialised treatment includes bleomycin, immunotherapy (e.g. topical diphencyprone—DPCP) and cantharidin

### § Pox virus lumps

Skin tumours can be caused by pox viruses, some of which result from handling infected sheep, cows and monkeys and other animals such as deer. Hence they are usually found in sheep shearers, farmers and zookeepers.

### Molluscum contagiosum

This common pox virus infection can be spread readily by direct contact, including sexual contact (see CHAPTER 119). The incubation period is 2–26 weeks.

#### Clinical features

- Common in school-aged children
- Single or multiple (more common)
- Shiny, round, pink-white papule (see FIG. 126.6)
- Hemispherical up to 5 mm

FIGURE 126.6 Molluscum contagiosum with the round, pink, pearly appearance and central punctum

- Central punctum gives umbilical look
- Can be spread by scratching

### Management

They are difficult to treat. Avoid using the bath—they spread to other body parts and those sharing the bath. Showering is preferable. There is a case for simply reassuring the family and waiting for spontaneous resolution.

### Treatment options

- Liquid nitrogen with care (a few seconds following topical anaesthetic) then dry dressings for 2 weeks
- Pricking the lesion with a pointed stick soaked in 1% or 2.5% phenol
- Application of 15% podophyllin in Friar's Balsam (compound benzoin tincture)
- Application of 30% trichloroacetic acid
- Application of imiquimod 0.1% cream tds for 6 weeks
- Destruction by electrocautery or diathermy
- Ether soap and friction method
- Lifting open the tip with a sterile needle inserted from the side (parallel to the skin) and applying 10% povidone–iodine (Betadine) solution (parents can be shown this method and continue to use it at home for multiple tumours)
- If more localised, covering with a piece of Micropore or Leucosilk tape—change every day after showering (may take a few months). This method also prevents spread
- For large areas, aluminium acetate (Burow's solution 1:30) applied bd can be effective

*Note:* The extract of the *Cantharis beetle* (cantharidin) (prepared as Cantharone) if available is reportedly very effective.

### Orf

Orf is due to a pox virus and presents as a single papule or group of papules on the hands of sheep-handlers after handling lambs with contagious pustular dermatitis. The papules change into pustular-like nodules or bullae with a violaceous erythematous margin. It clears up spontaneously in about 3–4 weeks without scarring and usually no treatment is necessary.

#### Practice tip for orf

Rapid resolution (days) can be obtained by an intralesional injection of triamcinolone diluted 50:50 in normal saline.<sup>6</sup>

### Milker's nodules (pseudo cowpox)

In humans 2–5 papules appear on the hands about 1 week after handling cows' udders or calves' mouths. It is caused by a parapoxvirus. The papules enlarge to become tender, grey nodules with a necrotic centre and surrounding inflammation (see FIG. 126.7). The patient can be reassured that the nodules are a self-limiting infection and spontaneous remission will occur in 5–6 weeks without residual scarring. One infection gives lifelong immunity.

FIGURE 126.7 Milker's nodule in a person who milks cows showing the grey nodule with the necrotic centre

#### Practice tip for milker's nodule

Rapid resolution (days) can be obtained by an intralesional injection of triamcinolone diluted 50:50 in normal saline.<sup>6</sup>

### § Seborrhoeic keratoses

Synonyms: seborrhoeic warts, senile warts, senile keratoses (avoid these terms).

#### Clinical features

- Very common
- There is a variety of subtypes
- Increasing number and pigmentation with age >40 years
- Sits on skin, appears in some like a 'sultana' pressed into the skin (i.e. well-defined border)
- Has a 'pitted' surface (see FIG. 126.8)
- May be solitary but usually multiple
- Common on face and trunk, but occurs anywhere
- Usually asymptomatic
- Usually causes patients some alarm (confused with melanoma)

FIGURE 126.8 Seborrhoeic keratosis in a 70-year-old man. The large pigmented warty mass appears to sit on top of the skin.

Photo courtesy Robin Marks

#### Management

- Usually nil apart from reassurance
- Does not undergo malignant change
- Can be removed for cosmetic reasons
- Light cautery to small facial lesions
- Freezing with liquid nitrogen (especially if thin) decolours the tumour
- 10% (or stronger) phenol solution applied carefully—repeat in 3 weeks
- Apply trichloroacetic acid to surface: instil gently by multiple pricks with a fine-gauge needle, twice weekly for 2 weeks
- May drop off spontaneously
- If diagnosis uncertain, remove for histopathology

### § Stucco keratoses

This subtype of seborrhoeic keratoses comprises multiple, non-pigmented (often white), small, friable keratoses over the lower legs. They can be treated with a topical keratolytic such as 3–5% salicylic acid in sorbolene.

### § Granuloma annularae

Granuloma annularae are a common benign group of papules arranged in an annular fashion.

#### Clinical features

- Most common among children and young adults
- Firm papules grouped in a 'string of pearls' pattern (see FIG. 126.9)
- Dermal nodules
- May be associated with minor trauma

**FIGURE 126.9** Granuloma annularae: this pearly papular tumour was longstanding on this finger. After taking a small biopsy, 20 mg of methylprednisolone acetate was injected into the tumour.

- Associated with diabetes
- Usually on dorsum or sides of fingers (knuckle area), backs of hands, the elbows and knees

### Management<sup>7</sup>

- Check urine/blood for sugar
- Give reassurance (they usually subside in a year or so)
- Cosmetic reasons:
  - first-line: potent topical corticosteroids  $\pm$  occlusion, apply bd for minimum of 4–6 weeks
  - if ineffective: intradermal injection into the extending outer margin of triamcinolone 10% or similar corticosteroid (dilute equal volume with N saline); can repeat at 6-weekly intervals if effective

### § Dermatofibroma

Synonyms: sclerosing haemangioma; histiocytoma.

This is a common pigmented nodule arising in the dermis due to a proliferation of fibroblasts, believed to develop as an abnormal response to minor trauma including insect bites. The nodule gives a characteristic button-like feel and dimpling when laterally compressed (pinched) from the side with the fingers.

### Clinical features

- Usually multiple
- Firm, well-circumscribed nodules
- Oval, 0.5–1 cm in diameter
- Freely mobile over deeper structures

- Slightly raised in relation to skin
- Mainly on limbs, especially legs
- May itch
- Mainly in women
- Variable colour, pink or brown, tan or grey or violaceous
- Characteristic 'dimple' sign on pinching margins

### Treatment

- Reassurance
- Simple excision if requested

### § Solar keratoses<sup>7</sup>

Solar keratoses (actinic keratoses) are reddened, adherent, scaly hyperkeratotic thickenings occurring on light-exposed areas. They represent intra-epidermal keratinocytic dysplasia with a potential for malignant change, especially on the ears.

### Clinical features

- Sun-exposed fair skin
- Mainly on face, ears, scalp (if balding), forearms, dorsum of hands (especially) (see FIG. 126.10)
- Vary in size from 2–20 mm in diameter
- Dry, rough, adherent scale
- Usually asymptomatic
- Discomfort on rubbing with towel
- Scale can separate to leave oozing surface
- A small proportion undergo malignant change

### Management<sup>7</sup>

- Reduced exposure to sunlight
- Can disappear spontaneously
- Liquid nitrogen if superficial (don't freeze unless inflamed, i.e. red)

**FIGURE 126.10** Solar keratoses showing the reddened, scaly thickenings on sun-exposed areas. Biopsy of one of the lesions proved SCC.

or

diclofenac 3% gel topical bd for 12 weeks

or

5-fluorouracil 5% cream daily for 3–4 weeks on face or 3–6 weeks on arms and legs

or

imiquimod, once daily 3 times a week for 3–4 weeks (for one to three cycles with 4-week spells between cycles)

- Surgical excision for suspicious and ulcerating lesions
- Biopsy if doubtful

## Terminology

**Solar keratoses** 'sun spots'

**Solar lentigines** 'age spots' or 'liver spots'

## § Keratoacanthoma

Keratoacanthomas (KA), which are rapidly evolving tumours of keratinocytes, occur singly on light-exposed areas. They are now considered a low-risk variant of SCC.<sup>7</sup> The major problem is differentiation from SCC, especially if on the lip or ear. The relative growth rates of three types of skin tumours are shown in FIGURE 126.11.

**FIGURE 126.11** Relative growth rates of three types of skin tumours: keratoacanthoma, squamous cell carcinoma and basal cell carcinoma

## Clinical features

- Rapidly growing lesion on sun-exposed skin
- Raised crater with central keratin plug (see FIGS 126.12 and 126.13)
- Grows to 2 cm or more
- Arises over a few weeks, remains static, then spontaneously disappears after about 4–6 months; can leave a big scar
- Can be confused with SCC

**FIGURE 126.12** Keratoacanthoma: this tumour, with its central plug, appeared suddenly on the face of a 63-year-old man. It may be confused with squamous cell carcinoma. Surgical excision is appropriate treatment.

**FIGURE 126.13** A typical keratoacanthoma

## Management

- Remove by excision—perform biopsy
- If clinically certain—curettage/diathermy
- Treat as SCC (by excision) if on lip/ear

The recommended treatment is surgical excision and histological examination. Ensure a 2–3 mm margin for excision. Most patients will not tolerate a tumour for 4–6 months on an exposed area such as the face while waiting for a spontaneous remission. Also, if it is an SCC, a potentially lethal cancer has remained in situ for an unnecessarily long period.

## § Sebaceous hyperplasia

Sebaceous hyperplasia presents as single or multiple nodules on the face, especially in older people. The nodules are small, yellow–pink, slightly umbilicated and are found in a similar distribution to BCCs, for which they may be mistaken. There is no need for surgical excision. Cryotherapy or fine wire diathermy achieves good results.

## § Basal cell carcinoma<sup>8</sup>

### Clinical features

- Most common skin cancer (80%)
- Age: usually >35 years
- More frequent in males
- Mostly on sun-exposed areas: face (mainly), neck, upper trunk, limbs (10%) (see FIG. 126.14)
- May ulcerate easily = 'rodent ulcer'
- Slow-growing over years
- Has various forms: nodular, pigmented, ulcerated, etc.
- Stretching the skin demarcates the lesion, highlights pearlyness and distinct margin
- Does not metastasise via lymph nodes or bloodstream
- Local spread is a problem (see FIG. 126.15)
- Can spread deeply if around nose, eye or ear

### Clinical types

- 1 Cystic nodular—translucent or pale grey
- 2 Ulcerated—nodular BCC that has necrosed centrally

FIGURE 126.14 Typical areas in which basal cell carcinomas occur

### Red flag pointer for BCC

FIGURE 126.15 Grossly neglected basal cell carcinoma on back

Photo courtesy Robin Marks

- 3 Pigmented—usually spotted, may be all black
- 4 Superficial—erythematous scaly patch, may be misdiagnosed as eczema or psoriasis
- 5 Morphoeic (fibrotic)—scar-like, poorly defined margin
- 6 Common: pearly edge, telangiectasia, ulcerated (see FIG. 126.16)
- 7 Basi-squamous—mixed BCC & SCC

FIGURE 126.16 Basal cell carcinoma showing a pearly nodular appearance with telangiectatic vessels

Photo courtesy Robin Marks

### Management<sup>8</sup>

- Simple elliptical excision (3–4 mm margin) is best.
- If not excision, do biopsy before other treatment.
- Radiotherapy is an option, especially in frail people.
- Mohs micrographic surgery—a form of surgical treatment suitable for large or recurrent tumours or those in a site when maximal normal tissue needs to be preserved.
- Photodynamic therapy—response rate is >90% for nodular and superficial BCCs.
- Cryotherapy is suitable for well-defined, histologically confirmed, superficial tumours at sites away from head and neck. Use judiciously and infrequently.

*Note:* For proven BCC but not on nose and around eyes, imiquimod may be an option. To biopsy a BCC, do a shave biopsy, not a punch biopsy.

## § Squamous cell carcinoma<sup>7</sup>

SCC is an important malignant tumour of the epidermis; it is also found on sun-exposed areas, especially in fair-skinned people. It tends to arise in premalignant areas such as solar keratoses, burns, chronic ulcers, leucoplakia and Bowen disease, or it can arise de novo. Keratoacanthoma is a variant.

*Note:* Although BCC and SCC are related to cumulative sun exposure, they are not always found in sun-exposed areas.

### Clinical features

- Usually >50 years
- Initially firm thickening of skin, especially in solar keratosis
- Surrounding erythema
- The hard nodules soon ulcerate (see FIG. 126.17)
- Occurs on the hands and forearms and the head and neck (see FIG. 126.18)
- Ulcers have a characteristic everted edge
- Capable of metastases and may involve regional nodes
- SCCs of ear, lip, oral cavity, tongue and genitalia are serious and need special management

**FIGURE 126.17** Squamous cell carcinoma. This recurrent, non-healing lesion on the index finger of a 58-year-old man had raised hard edges and was fixed to tendon and bone. Treatment was by surgical amputation of the finger.

### Management

- Early excision of tumours <1 cm with a 4 mm margin (in most cases), to deep fat level.
- Referral for specialised surgery and/or radiotherapy if large, in difficult site or lymphadenopathy.
- SCCs of the ear and lip, which have considerably more malignant potential, can be excised by wedge excision.

**FIGURE 126.18** Common sites of squamous cell carcinoma

- There is no alternative to surgery if the SCC is over cartilage—central nose or helix.

*Note:* Surgery is the treatment of choice for most tumours; cryotherapy, imiquimod and curettage are not.

Superficial X-ray therapy is an optional treatment in a biopsy-proven tumour where surgery is not feasible or will cause unacceptable morbidity.

### § Bowen disease<sup>7</sup>

Intra-epidermal carcinoma (Bowen disease) is SCC in situ of the skin. It begins as a slowly enlarging, sharply demarcated, thickened, red plaque, especially on the lower legs of females. It may resemble solar keratosis, dermatitis, or a patch of psoriasis. It remains virtually unchanged for months or years. It may become very crusty, ulcerate or bleed. It has a potential for malignant change since it is a full thickness SCC in situ.

### Management

- Biopsy first for diagnosis
- Wide surgical excision if small
- Skin grafting may be required
- Cryotherapy by double freeze thaw technique
- Imiquimod is considered promising (awaiting trials)

*Note:* Biopsy a single patch of suspected psoriasis or dermatitis not responding to topical steroids.

### LUMPS ON EARS

Lumps on ears, especially on the helix, demand close attention. SCCs that arise here have up to 17 times

the ability to metastasise and demand early wedge resection.

Causes of ear lumps include:

- solar keratosis
- BCC
- SCC
- keratoacanthoma
- gouty tophi
- chondrodermatitis nodularis helices

### § Chondrodermatitis nodularis helices<sup>9</sup>

This lump, which is not a neoplasm, presents as a painful nodule on the most prominent part of the helix or antihelix of the ear (see FIGS 126.19 and 126.20). It is seen more often in men while it is found more often on the antihelix in women. It is caused by sun damage. Histologically a thickened epidermis overlies inflamed cartilage. It looks like a small corn, is tender, and affects sleep if that side of the head lies on the pillow. It can be treated initially by cryotherapy or an intralesional injection of triamcinolone. Most resolve if the patient sleeps on the opposite side. If cryotherapy fails, wedge resection under local anaesthetic is an effective treatment.

FIGURE 126.19 Typical sites of chondrodermatitis nodularis helices

### § Malignant melanoma

These are usually enlarging pigmented lesions with an irregular, notched border. Refer to CHAPTER 127 on pigmented skin lesions.

### § Secondary tumour

These complex tumours may metastasise from the lung, melanoma or bowel and may arise in surgical scars (e.g. for breast cancer).

FIGURE 126.20 Chondrodermatitis nodularis helices on the right ear in a 44-year-old man

### § Kaposi sarcoma<sup>10</sup>

Kaposi sarcoma is a tumour of vascular and lymphatic endothelium that is related to human herpes virus type 8. There are three types:

- 'classic' or 'sporadic' form of primary tumour seen mostly in elderly males of central or eastern European origin
- 'endemic' form seen in males from Central Africa
- immunosuppressed-related form commonly associated with AIDS. Widespread lesions affect skin, bowel, oral cavity and lungs

Kaposi sarcoma presents as brownish-purple papules on the skin and mucosa (any organ).

Treatment is with radiotherapy, immunotherapy or chemotherapy.

## LUMPS OF SUBCUTANEOUS AND DEEPER STRUCTURES

### § Lipoma

Lipomas are common benign tumours of mature fat cells situated in subcutaneous tissue.

#### Clinical features

- Soft and may be fluctuant
- Well defined; lobulated (see FIG. 126.21)

**FIGURE 126.21** Lipoma: this 66-year-old woman had a long-standing soft, fluctuant, rubbery lump of 18 years. It was surgically removed for cosmetic reasons

- Rubbery consistency
- May be one or many
- Painless
- Most common on limbs (especially arms) and trunk
- Can occur at any site

### Management

- Reassurance about benign nature
- Removal for cosmetic reasons or to relieve discomfort from pressure. Use surgical excision or punch biopsy

### Surgical excision

Many lipomas can be enucleated using a gloved finger, but there are a few traps: some are deeper than anticipated, and some are adjacent to important structures such as large nerves and blood vessels. Others are tethered by fibrous bands, and can recur. Recurrence is also possible if excision is incomplete.

**Caution:** Lipomas on back (don't shell out easily). If >5 cm consider referral.

**Note:** Ultrasound is good at assessing depth of lipoma. CT scan or MRI will help diagnose and define.

### § Neurofibroma

These benign tumours are firm (sometimes soft), painless, subcutaneous lumps often aligned lengthwise in the long axis of a limb in relation to peripheral nerves (see FIG. 126.22). The lumps are more mobile from side to side than along the long axis. Some are tender to pressure with associated pain and paraesthesia on the nerve distribution.

**FIGURE 126.22** Neurofibroma. This mobile firm subcutaneous lump was tender to firm pressure.

### § Bursae

Bursae are cystic sacs between the skin and an underlying bony prominence or sacs of gelatinous fluid that separate and aid gliding of adjacent tendons and ligaments.

### § Pseudoaneurysm<sup>11</sup>

A pseudoaneurysm is a sac-like dilatation of the arterial wall (but not all three layers of the wall). It presents as an expanding subcutaneous nodule located close to a superficial artery. It can form after blunt or penetrating trauma that injures the vessel, leading to a haemorrhage into the vessel wall. Investigate with ultrasound and manage with caution. Refer to a vascular surgeon for surgical management.

### § Ganglion

Ganglia are firm cystic lumps associated with joints or tendon sheaths.

### Clinical features

- Deep subcutaneous lumps
- Around joints or tendon sheaths (see FIG. 126.23)
- Mostly around wrists, fingers, dorsum of feet
- Immobile, fixed to deep tissues
- Translucent
- Contain viscid gelatinous fluid
- Associated with arthritis and synovitis
- May disappear spontaneously
- Recurrences common

**FIGURE 126.23** Ganglion of wrist—firm, immobile and translucent. It was eventually treated by aspiration of gelatinous fluid followed by infusion of 40 mg methylprednisolone acetate.

### Management

- Can be left—wait and see
- Do not ‘bang with a Bible’
- Needle aspiration and steroid injection *or* surgical excision (can be difficult)
- Suture compression technique: a larger gauge catgut suture is inserted through the middle of the ganglion and firmly tied over it. Side pressure may express the contents through the needle holes. Remove the knot 12 days later.

### Injection treatment of ganglia

Ganglia have a high recurrence rate after treatment, with a relapse rate of 30% after surgery. A simple, relatively painless and more effective method is to use intralesional injections of long-acting corticosteroid, such as methylprednisolone acetate.<sup>12</sup>

### Method

- 1 Insert a 21 gauge needle attached to a 2 mL or 5 mL syringe into the cavity of the ganglion.

- 2 Aspirate some (not all) of its jelly-like contents, mainly to ensure the needle is in situ.
- 3 Keeping the needle exactly in place, swap the syringe for an insulin syringe containing up to 0.5 mL of steroid.
- 4 Inject 0.25–0.5 mL (see FIG. 126.24).
- 5 Rapidly withdraw the needle, pinch the overlying skin for several seconds and then apply a light dressing.
- 6 Review in 7 days and, if still present, repeat the injection using 0.25 mL of steroid.

Up to six injections can be given over a period of time, but 70% of ganglia will disperse with only one or two injections.<sup>9</sup>

**FIGURE 126.24** Injection treatment of ganglion

## Some preferred therapeutic options

### Liquid nitrogen therapy

Ideally, liquid nitrogen is stored in a special large container and decanted when required into a small thermos flask or spray device.

The easiest method of application to superficial skin tumours (see TABLE 126.2) is via a ball of cotton wool rolled rather loosely on the tip of a wooden applicator stick. The ball of cotton wool should be slightly smaller than the lesion, to prevent freezing of the surrounding skin.

### Method (basic steps)

- 1 Inform the patient what to expect.
- 2 Pare excess keratin with a scalpel.
- 3 Use a cotton wool applicator slightly smaller (not larger—see FIG. 126.25a) than the lesion.

**Table 126.2** Superficial skin tumours suitable for cryotherapy

Warts (plane, periungual, plantar, anogenital)

Skin tags

Seborrhoeic keratoses

Molluscum contagiosum

Sebaceous hyperplasia

Solar keratoses

- 4 Immerse it in nitrogen until bubbling ceases.
- 5 Gently tap it on the side of the container to remove excess liquid.
- 6 Hold the lesion firmly between thumb and forefinger.
- 7 Place applicator vertically (see FIG. 126.25b and FIG. 126.25c) on tumour surface.
- 8 Apply with firm pressure: do not dab.
- 9 Freeze until a 2 mm white halo appears around the lesion.

**FIGURE 126.25** Application of liquid nitrogen with cotton wool applicator: (a) applicator too large, (b) correct size and approach of applicator, (c) correct size but wrong position of applicator

Explain likely reaction to patient, such as the appearance of blisters (possibly blood blisters). The optimal time for retreatment of warts is in 2–3 weeks (not longer than 3 weeks).

## Biopsies

There are various methods for taking biopsies from skin lesions. These include scraping, shaving and punch biopsies, all of which are useful but not as effective or safe as excisional biopsies.

### Shave biopsies

This simple technique is generally used for the tissue diagnosis of premalignant lesions and some malignant tumours, but not melanoma.

#### Method

- 1 Infiltrate with LA.
- 2 Holding a number 10 or 15 scalpel blade horizontally, shave off the tumour just into the dermis (see FIG. 126.26).
- 3 Diathermy may be required for haemostasis.

The biopsy site usually heals with minimal scarring.

**FIGURE 126.26** Shave biopsy

### Punch biopsy

This biopsy (see FIG 126.27) has considerable use in general practice where full-thickness skin specimens are required for histological diagnosis. (Good quality disposable biopsy punches are available from Dermatech Laboratories.)

### Steroid injections into skin lesions

Suitable lesions for steroid injections are:

- plaque psoriasis
- granuloma annularae
- hypertrophic scars (early development)
- keloid scars (early development)

FIGURE 126.27 Punch biopsy

- alopecia areata
- lichen simplex chronicus
- necrobiosis lipoidica
- hypertrophic lichen planus
- orf and milker's nodules

Triamcinolone is the appropriate long-acting corticosteroid (10 mg/mL). It may be diluted in equal quantities with saline.

### Method

- 1 The steroid should be injected into the lesion (not below it).
- 2 Insert a 25 or (preferably) 27 gauge needle, firmly locked to a small insulin-type 1 mL syringe, into the lesion at the level of the middle of the dermis (see FIG. 126.28).
- 3 High pressure is required with some lesions (e.g. keloid).
- 4 Inject sufficient steroid to make the lesion blanch.
- 5 Several sites will be needed for larger lesions, so preceding LA may be required in some instances. Avoid infiltration of steroid in larger lesions: use multiple injections.

### Elliptical excisions

Small lesions are best excised as an ellipse. Generally, the long axis of the ellipse should be along the skin tension lines identified by natural wrinkles.

The intended ellipse should be drawn on the skin (see FIG. 126.29). The placement will depend on such factors as the size and shape of the lesion, the margin required (usually 3 mm) and the skin tension lines.

FIGURE 126.28 Injection of corticosteroid into mid-dermis

FIGURE 126.29 Ellipse excision

### General points<sup>9</sup>

- The length of the ellipse should be three times the width.
- This length should be increased (say, to four times) in areas with little subcutaneous tissue (dorsum of hand) and high skin tension (upper back).
- A good rule is to obtain an angle at each end of the excision of 30° or less.
- These rules should achieve closure without 'dog ears'.

### Excisions on the face

It is important to select optimal sites for elliptical excisions of tumours of the face. As a rule it is best for incisions to follow wrinkle lines and the direction of hair follicles in the beard area. Therefore, follow the natural wrinkles in the glabella area, the 'crow's

feet' around the eye, and the nasolabial folds (see FIG. 126.30). To determine non-obvious wrinkles, gently compress the relaxed skin in different directions to demonstrate the lines.

**FIGURE 126.30** Recommended lines for excisions on face  
Source: Adapted from JS Brown, *Minor Surgery: A Text And Atlas*. London: Chapman & Hall, 1986

For tumours of the forehead make horizontal incisions, although vertical incisions may be used for large tumours of the forehead. Ensure that you keep your incisions in the temporal area quite superficial, as the frontal branch of the facial nerve is easily cut.

## When to refer<sup>9</sup>

Referral should be considered for:

- uncertainty of diagnosis
- suspicion of melanoma
- tumours larger than 1 cm
- recurrent tumours, despite treatment
- incomplete excised tumours, especially with poor healing
- doubts about appropriate treatment
- recommended treatment beyond skills of practitioner
- frequent multiple tumours (e.g. organ transplant patients)
- SCC on the lip or ear
- infiltrating or scar-like morphoeic BCC, particularly those on the nose or around the nasal labial fold

- cosmetic concerns, such as lesions in the upper chest and upper arms where keloid scarring is a potential problem

## Key points

- Uncomplicated small tumours are best removed by an elliptical excision with a 3 mm margin for BCC and a 4 mm margin for SCC.
- Caution should be used in the management of tumours on the face, including the ears and lips.

## Resource

Hayes M. *Skin Cancer, Melanoma and Mimics*. Brisbane: Skin Cancer Books, 2013.

*The skin calls for the faculty of close observation and attention to detail.*

Louis A Duhring (1845–1913), valedictory address, University of Pennsylvania Medical School

The management of pigmented skin lesions is a constant concern for all practitioners and requires careful evaluation based on the natural history of these lesions and the increasing incidence of malignant melanoma in particular.

Most pigmented lesions are benign and include simple moles or melanocytic naevi, seborrhoeic keratoses, freckles and lentigines. Reassurance is all that is necessary in the management of these problems.

However, one-third of all melanomas arise in pre-existing naevi, many of which are dysplastic, and it is the recognition and removal of such naevi that is so important in the prevention of melanoma.<sup>1</sup>

Malignant melanoma is doubling in incidence each decade, which is an alarming statistic considering the public education programs about the hazards of sun exposure. Of equal interest is the fact that the cure rate for melanoma is also increasing, reflecting earlier diagnosis and treatment. The most important factor in management is early detection. It is most appropriate for GPs to acquire skills in dermoscopy.<sup>2</sup>

A classification of pigmented skin lesions is given in TABLE 127.1.

## Key facts and checkpoints

- The incidence of melanoma is greatest in white Caucasians and increases with proximity to the equator.
- The early diagnosis and treatment of melanoma profoundly affects the prognosis.
- Melanoma is extremely rare before puberty.
- Currently the greatest rate of increase is in men >55 years.
- Most people have 5–10 melanocytic naevi on average.
- Multiple dysplastic naevi carry a higher risk of malignant change, which may occur in young adults. Such patients require regular observation (with photography).

## § Pyogenic granuloma

Synonyms: granuloma, granuloma telangiectaticum, acquired haemangioma.

**Table 127.1** Classification of pigmented skin lesions

Non-melanocytic
Pigmented basal cell carcinoma
Seborrhoeic keratoses
Solar keratoses
Dermatofibroma
Pyogenic granuloma
Foreign body granuloma
Talon noir (black heel)
Tinea nigra
Becker naevus
Melanocytic
Non-melanoma
Freckles
Lentigines
Naevi:
1 congenital
2 acquired:
— junctional → compound → intradermal
— halo
— blue
— Spitz
— dysplastic
Melanoma
1 Lentigo maligna (Hutchinson melanotic freckle)
2 Superficial spreading melanoma
3 Nodular melanoma
4 Acral lentiginous melanoma

A pyogenic granuloma is a 5–10 mm soft vascular lesion (without pus) due to a proliferation of capillary vessels. It is considered to be an abnormal reaction to minor trauma (see FIG. 127.1).

## Clinical features

- Common in children and young adults
- Usually on hands and face
- Bright red ‘raspberry’-like lesion
- Raised, sometimes pedunculated
- Friable—bleeds easily

Beware of misdiagnosing pyogenic granuloma for a nodular melanoma.

**FIGURE 127.1** Pyogenic granuloma showing bright red, friable tumour on face. It followed a puncture from a spiky plant in the garden.

Photo courtesy Robin Marks

### Management

It must be distinguished from amelanotic melanoma or anaplastic SCC. Shave biopsy or curettage with electrocautery of base. The specimen must be sent for histological examination. They are prone to recur.

### § Talon noir ('black heel')

Talon noir is a black spotted appearance on the heel and is common in sportspeople. A similar lesion (probably smaller) is often found on the other heel.

'Black heel' is formed by small petechiae caused by the trauma of the sharp turns required in sport: shearing stress on the skin of the heel produces superficial bleeding. The diagnosis can be confirmed by gentle paring of the callus to reveal the multiple small petechial spots in the epidermis; these are then pared away. If there is doubt about the diagnosis (malignant melanoma is the main differential diagnosis), the lesion should be excised.

### § Tinea nigra

Tinea nigra is characterised by solitary black macular lesions on the palm or sole. The simple technique of taking skin scrapings to reveal fungal elements will allow easy differentiation from malignant melanoma.

### § Becker naevus

Becker naevus is a faint, brown, diffuse pigmented area with a component of coarse hairs and is usually found on the shoulder and upper trunk. It occurs mainly in boys around puberty. It is not a birthmark, it is benign and reassurance is appropriate.

### § Freckles

Freckles are small, brown flat macules (usually <0.5 cm), coloured by excessive epidermal melanin without any increase in the number of naevus cells (melanocytes). They occur mainly on light-coloured skin and tend to darken in summer and fade in winter. Cosmetic improvement can be achieved through the use of sunscreens.

### § Lentigines

Lentigines are small, rounded, brown to black macular areas ranging from 1 mm to 1 cm or more across. They are very common and may appear in childhood as a few scattered lesions, often on areas not exposed to the sun. In the elderly, lentigines often develop on sun-damaged skin, usually on the backs of the hands (so-called 'liver spots') and on the face.

Unlike freckles they have increased numbers of melanocytes.

### Management

- Treatment is usually unnecessary. Liquid nitrogen or excision can be used for cosmetically unacceptable lesions. Sunscreens are needed to prevent further darkening of existing lesions.
- Otherwise, rather than use 'fade cream', use fresh lemon juice. Squeeze lemon juice (½ lemon) into a small bowl and apply the juice to the spots daily. Continue for 8 weeks.
- Apply tretinoin 0.05% cream daily at night, if necessary.
- Laser for severe cases.

### § Congenital melanocytic naevi

These moles are present at birth and are sometimes large.

### Clinical features

- Variable colour—brown to black
- Sometimes hairy and protruding
- Increased risk of malignant change (especially in larger ones)

### § Common acquired naevi

These are the common moles for which an opinion is so often sought. The moles are localised, benign proliferations of naevus cells. There may be a sharp increase in numbers during pregnancy. New lesions appear less frequently after the age of 20 years. The types are junctional, compound and intradermal.

**FIGURE 127.2** Comparison of melanocyte (naevus cell) distribution in various common acquired naevi

Naevi in children are usually the junctional type with proliferating naevus cells clumped at the dermo-epidermal junction. With time the naevus cells ‘move’ into the dermis. A compound naevus has both junctional and dermal elements. With maturation all the naevus cells move into the dermis. Refer to **FIGURE 127.2**.

## Clinical features

### Junctional

- Usually <5 mm
- Circular-shaped macules
- May be slightly elevated
- Colour usually brown to black
- May be ‘fuzzy’ border

Most naevi of the palms, soles and genitals are junctional but there is no evidence to support the traditional view that naevi in these sites have more malignant potential.<sup>2</sup>

### Compound

- Dome-shaped, slightly raised pigmented nodules
- Up to 1 cm in diameter
- Colour varies from light to dark brown/black, but lighter than junctional naevi (see **FIG. 127.3**)
- Most are smooth but surface can be rough or verrucoid
- Larger ones may be hairy, especially after puberty
- Become ‘flesh’-coloured in time

### Intradermal

- Look like compound but less pigmented
- Often skin-coloured

**FIGURE 127.3** Compound naevus. This pigmented lesion, which was benign, has been present since birth. At puberty there is often a rapid increase in size and colour.

Photo courtesy Robin Marks

- May evolve to pink or brown senile nodules or to soft, pedunculated tags

## Malignant potential of common acquired melanocytic naevi

- *Junctional*: have significant potential to undergo malignant change (as long as junctional activity is present)
- *Compound*: very rarely undergo malignant change
- *Intradermal*: these are totally benign lesions

## Management

- Provide appropriate reassurance.
- Observe.

**FIGURE 127.4** Halo naevus in a child. The central lesion is usually a benign pigmented naevus.

Photo courtesy Robin Marks

- If lesion is changing or there is uncertainty, perform surgical excision (2 mm margin) for histopathology.

### § Halo naevus

A halo naevus consists of a depigmented halo around a central melanocytic naevus (see FIG. 127.4). It is the result of an autoimmune reaction. The central naevus gradually involutes. It tends to occur around puberty. Multiple halo naevi are often seen on the trunk of adolescents.

*Caution:* A halo can occur around a melanoma.

### Management

Measure the lesion. Reassure and do nothing, as it usually disappears over the next few years; if doubtful at all, remove and obtain histological diagnosis.

### § Blue naevus

A blue naevus presents as a solitary, slate-grey–blue dermal lesion. Blue naevi usually present in childhood and adolescence on the lower back and buttocks and the limbs, especially dorsa of the hands and feet. Malignant change is rare. They are often excised for cosmetic reasons.

### § Spitz naevus (benign juvenile melanoma)

Spitz naevi are also called benign juvenile melanomas or spindle cell naevi.

### Clinical features

- Solitary pigmented or erythematous nodules
- Often appear in children, usually 4–8 years

**FIGURE 127.5** Dysplastic melanocytic naevi. These lesions may have ill-defined borders and irregular pigmentation.

Photo courtesy Robin Marks

- Develop over 1–3 months
- Well-circumscribed, dome-shaped lesions

### Management

Surgical excision is treatment of choice (because of rapid growth and best ‘reassurance’ policy).

### § Dysplastic melanocytic naevi

These are large, irregular moles that appear predominantly on the trunk in young adults (see FIG. 127.5). They can be familial or sporadic and are markers of an increased risk of melanoma, rather than necessarily being premalignant lesions. Even so, melanoma may arise within these lesions more frequently than would be expected by random chance.<sup>3</sup>

They are considered to be intermediate between benign naevi and melanoma.

### Clinical features

- Age: adolescence onwards
- Large >5 mm (variable size)
- Most common on trunk
- Irregular and ill-defined border
- Irregular pigmentation
- Background redness
- Variable colours—brown, tan, black, pink, red
- Variation of colours within the naevus
- Most are stable and do not progress to melanoma

### Dysplastic naevus syndrome

The presence of multiple, large, irregular pigmented naevi, mainly on the trunk, presents a difficult management problem, especially if there is a family history of melanoma. The lifetime risk of melanoma may approach 100% for such patients.

## Management

Use a follow-up program (similar to excised early melanoma) of 6 monthly review for 2 years (3-monthly if family history of melanoma) and yearly thereafter, provided no lesions become malignant during the first 2 years. During this time the patient and family should become well versed in surveillance. Apart from measurement, good professional-quality photographs of areas of the body including total body photography or specific lesions of concern may also be helpful.

Any suspicious lesions should be excised for histological examination.

## Advice to patients

To decrease your chances of getting a melanoma, you should protect yourself from the sun. These rules should be followed.

- Try to avoid direct sunlight when the sun is at its strongest (from 10 am to 3 pm).
- Always wear a broad-brimmed hat and long-sleeved shirt in the sun.
- Use an SPF 30 or more sunscreen on exposed skin and renew the sunscreen regularly.
- Sunbaking might give you a good tan but it is also going to increase your chances of getting a melanoma, so you should avoid it.

## § Melanoma

Melanomas are malignant tumours derived from melanocytes, with the skin being the most common site.

The early diagnosis of melanoma is vital to outcome. Thickness of a melanoma when it is removed is the major factor determining prognosis: it is vital to detect melanomas when they are in the thin stage and look like an unusual freckle.

In Australia, only about 30% of melanomas develop in pre-existing melanocytic naevi (moles).<sup>2,3</sup> The majority arise in apparently normal skin. Initially the tumour tends to spread laterally in many cases and it should be removed at this stage when it is easily cured. An irregular border or margin is suggestive of the tumour.

## Risk factors

- History of previous melanoma (fivefold)
- Presence of many moles (50 or more), especially atypical dysplastic naevi
- Family history (one or more members)
- History of many sunburns
- Sun sensitive skin/fair complexion

- Patient age and sex: increasing age and male
- Tanning (including solarium) treatments

## Clinical features

- Typical age range 30–50 years (average 40 years)
- Can occur anywhere on the body—more common:
  - lower limbs in women
  - upper back in men
- Often asymptomatic
- Can bleed or itch

## Change

The sign of major importance is a recent change in a 'freckle' or mole:

- change in size—at edge or thickening
- change in shape
- change in colour—brown, blue, black, red, violet, white, including combinations
- change in surface
- change in the border
- bleeding or ulceration
- other symptoms (e.g. itching)
- development of satellite nodules
- lymph node involvement

## Red flag pointers for melanoma<sup>4</sup>

- New or changing lesion (see preceding change list)
- Rapidly growing nodule of any colour
- Non-healing lump or ulcer
- The 'ugly duckling' syndrome: a prominent pigment lesion that stands out from any other
- A lesion that concerns the patient
- Dermoscopic changes on follow-up or poor dermoscopic-clinical correlation

## Types

### Lentigo maligna<sup>3</sup>

Lentigo maligna (Hutchinson melanotic freckle) is a slow-growing form of intra-epidermal melanoma that occurs on areas exposed to light (usually the face), predominantly in the elderly (see FIG. 127.6). If allowed to remain it may become invasive and the prognosis will be similar to that for other invasive melanomas. These lesions have all the variations in size, shape and colour of superficial melanomas. Lentigo maligna should be excised.

### Superficial spreading melanoma

Like lentigo maligna, the initial growth is in a lateral or radial intra-epidermal manner, rather than in

**FIGURE 127.6** Lentigo maligna in a 72-year-old man. Excision is recommended as it is a form of intra-epidermal melanoma.  
Photo courtesy Robin Marks

**FIGURE 127.7** Superficial spreading melanoma with an irregular border which has altered and variable colours. Requires excision.  
Photo courtesy Robin Marks

an invasive downward or vertical manner (see FIG. 127.7). It exhibits a striking colour variation. It accounts for 70% of melanomas. It can be detected early by biopsy—shave is preferred to punch (less sampling error). Excisional biopsy is preferable.

### Nodular melanoma

Nodular melanoma, which accounts for 20% of melanomas, has no radial growth phase. It is typically found on the trunk and limbs of young to middle-aged individuals (see FIG. 127.8). It may have a 'blueberry'-like nodule. Prognosis is determined by thickness at the time of excision.

### The early nodular melanoma problem<sup>4,5</sup>

Nodular melanoma can present a diagnostic dilemma since the ABCD rule (see later in this chapter) often does not apply. The mnemonic EFG, standing for

**FIGURE 127.8** Nodular melanoma on the back. It has no radial growth phase and because it grows vertically can be readily misdiagnosed. The ABCD rule often does not apply but this lesion shows variable colours and an irregular border.  
Photo courtesy Robin Marks

**FIGURE 127.9** Acral lentiginous melanoma. A 30-year-old man presented with a 'mole' on his toe that had become 'lumpier'. This type of melanoma, which occurs on the distal areas of the limbs, begins as a spreading pigmented, macule before developing into a nodule surrounded by a pigmented halo (as shown).  
Photo courtesy Robin Marks

'Elevated', 'Firm' and 'Growing for more than 1 month', is more appropriate. Early melanomas tend to be symmetrical, non-pigmented, even in colour, of small diameter and to grow vertically.

They are often mistaken for a haemangioma or a pyogenic granuloma. If one is suspicious, refer early to a specialist/specialist clinic.

### Acral lentiginous melanoma

These typically occur on palms, soles and distal phalanges (see FIG. 127.9). They have a poorer prognosis than other types. They occur mainly in dark-skinned races.

## Desmoplastic melanoma<sup>4</sup>

This is a rare and aggressive subtype of melanoma. They are often subtle clinically and sometimes scar-like. Most are non-pigmented.

## Variations

Amelanotic melanomas are flesh-coloured papules that increase in size or change shape. These lesions can be extremely difficult to diagnose and the poor prognosis associated with them is due to late diagnosis rather than an increased malignancy.

The features and associations of melanoma subtypes are presented in TABLE 127.2.

## Prognosis

Determinants of prognosis include:<sup>3</sup>

- thickness (Breslow classification)
- level or depth (worse in level IV or V) (see FIG. 127.10)
- site (worse on head and neck, trunk)
- sex (worse for men)

- age (worse >50 years)
- amelanotic melanoma
- ulceration

Vertical growth is associated with invasion and the prognosis worsens with depth. The chance of cure is greater than 90% if a melanoma is removed when it is less than 0.75 mm thick.<sup>3</sup> If the lesion is allowed to invade to a thickness of 4 mm or more, the likelihood of a cure is reduced to less than 30%.<sup>3</sup>

The influence of tumour thickness on 5-year survival rates is shown in TABLE 127.3.

Staging is based on the tumour level (depth) shown in FIGURE 127.10:

- level I—confined to the epidermis (in situ)
- level II—tumour cells extend into the superficial (papillary) dermis
- level III—tumour cells fill up the superficial dermis
- level IV—tumour cells extend into the deeper (reticular) dermis
- level V—invasion of subcutaneous tissue

**Table 127.2** Features and associations of melanoma subtypes<sup>5,6</sup>

Melanoma subtype	Frequency %	Radial growth phase	Location	Average age	Occupation profile
Superficial spreading	70	+	Trunk (back), limbs (legs)	Middle-aged	Indoor worker
Nodular	20	—	Trunk, limbs	Middle-aged	Indoor worker
Lentigo maligna	7.5	+	Head, neck	Elderly	Outdoor worker
Acral lentiginous	2.5	+	Palms, soles mucosae	Not known	Not known

### Differential diagnosis

There are several common skin lesions that may be mistaken for melanoma.<sup>1</sup> They are:

- haemangioma (thrombosed)
- dermatofibroma (sclerosing haemangioma)
- pigmented seborrheic keratosis
- pigmented BCC
- junctional and compound naevi
- blue naevi
- dysplastic naevi
- lentigines

### Facilitating early diagnosis of melanoma

An adequate light source without shadows is essential. Refer to **CHAPTER 121** for use of the 'Maggylamp' and the dermatoscope, which is a very important and useful adjunct to diagnosis.

### Clinical examination of the skin<sup>1</sup>

It is important to examine the entire skin and not just the lesion presented by the patient. Comparison of pigmented skin lesions is very helpful in differentiating between benign and malignant. One satisfactory routine is:

- Starting at the head, examine the hairline, backs of ears, neck, back, and backs of the arms. Pull down the underwear to expose the buttocks; examine the backs of the legs.
- With the patient facing you, examine the anterior hairline, the front of the ears, the forehead, cheeks and neck, moving downwards to the anterior chest. Move bra straps as required to achieve complete coverage. Then examine the abdomen, pulling down the underwear to examine as far as the pubic hairs.

- Then examine the anterior surfaces of the legs. The 'Maggylamp' is very useful for this examination.

After scanning the entire skin surface and comparing and contrasting naevi, specific lesions may be examined with the dermatoscope. Compare suspicious lesions with similar lesions elsewhere on the patient's skin.

### Applying the ABCDE system<sup>1</sup>

#### A = Asymmetry

Melanoma is almost always asymmetrical. Most non-melanoma lesions are symmetrical, oval or round.

#### B = Border

The border of the melanoma is usually well defined, especially in the more malignant, compared with the dysplastic naevus, which is almost always indistinct with a fading-out 'shoulder' effect. The border of the melanoma is irregular while most benign lesions have a regular edge.

#### C = Colour

The classic blue-black colour is helpful but the *variety* of colours present in most melanomas is the most helpful. Magnification usually visualises greys, whites, violets, reds, oranges and shades of brown interspersed in the darker blue-black pigmentation. Early melanomas developing in dysplastic naevi tend not to have this deep pigmentation.

#### D = Diameter

The majority of melanomas when first seen are at least 7 mm in diameter, especially if arising from a pre-existing naevus. However, it is possible to diagnose small nodular melanomas <5 mm.

#### E = Evolution and/or Elevation

Elevation indicates invasion and is a sign of more advanced disease and a flat lesion may become raised.

#### Practice tip

Not all melanomas are black and black may not be present in some melanomas.

### Diagnosis by exclusion

In the diagnostic process consider the lesions outlined in the differential diagnosis and check out the various characteristics. Haemangiomas may have an emptying sign when pressed with a finger. Pigmented BCCs can be difficult if they are fully pigmented but this is uncommon. The characteristic pearly-grey look and the telangiectasia are usually still visible on magnification with the 'Maggylamp'. The most useful

feature of dysplastic naevi is that they are usually multiple and lesions for comparison can generally be found elsewhere. Dysplastic naevi also have greater breadth and height and often a darker nodule in the centre—the 'target' sign. A small but significant number of melanomas are undiagnosable.

### Pitfalls in diagnosis of melanoma

- Nodular melanoma
- Small melanoma
- Amelanotic melanoma
- Regressing melanoma
- Rapidly growing melanoma

### Management points for naevi and melanomas

- Do not inject local anaesthetic directly into the lesion.
- Incisional biopsy of a melanoma or suspicious mole is best avoided.
- Accurate clinical diagnosis, with the definitive treatment performed in one stage, is optimal, rather than excision biopsy with follow-up surgery.

### Management tips<sup>1</sup>

- The solitary dysplastic naevus has no significant malignant potential.
- Multiple excision of naevi is not justified.
- If in doubt, perform excision biopsy with a margin of 2 mm. Refer to **FIGURE 127.11** for the protocol for a suspicious lesion.

- If melanoma is strongly suspected, referral to a consultant is necessary.
- Beware of the pigmented BCC—it is easily missed but it usually has a shiny surface.
- Do not freeze a pigmented lesion—take a biopsy.

### Guidelines for excision margins<sup>4,7</sup> (Breslow thickness)

- Suspicious lesion—margin 2 mm
- Melanoma *in situ*—margin 5 mm
- Melanoma <1 mm thick—margin 1 cm
- Melanoma 1–4 mm thick, minimum margin 1 cm and maximum 2 cm
- Melanoma >4 mm thick, margin 2 cm (minimum)

### Counselling

An encouragingly positive and supportive approach can realistically be taken for most patients, as the overall survival for melanoma in Australia is around 90%.<sup>8</sup>

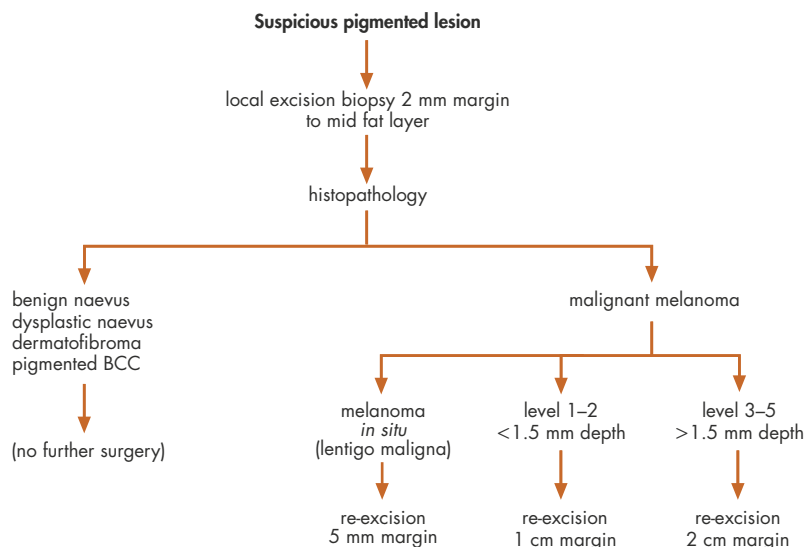

Even with tumours greater than 4 mm thickness, 50% of patients will survive.

### Follow-up

Follow-up tends to be based on the tumour thickness:<sup>1</sup>

- 1 mm—6 monthly review for 2 years
- 1–2 mm—4 monthly for 2 years, 6 monthly for next 2 years, then yearly for 10 years
- >2 mm—review by both specialist and GP, regularly, for 10 years

The first site of metastasis is usually the lungs, so a yearly chest X-ray is advisable.

**FIGURE 127.11** Plan for management of a suspicious pigmented lesion

### Practice tips<sup>9</sup>

- Excision biopsy with 2 mm margin is appropriate whenever possible.
- Wider excision is then based on the Breslow thickness.
- Sentinel lymph node biopsy for tumours >1 mm thickness provides accurate prognostic information.

*Look it's only death. It's not like losing your hair.*

Harold Brod key upon le arning he had AIDS, *New Yorker Magazine* 1994

The hair of our scalp is referred to as our crowning glory and the threat of hair loss in both sexes provokes extraordinary anxiety bordering on grief in some people. It behoves us as medical practitioners to treat the patient presenting with 'I'm losing my hair' with appropriate support and understanding. Likewise, the problem of hirsutism provokes similar anxiety and concerns about body image. Interestingly, women present with hair loss more than men.

## Key facts and checkpoints

- There are two types of hair: terminal hair, which is coarse and well pigmented, and vellus hair, which is fine, soft and relatively unpigmented.
- Alopecia is a generic term for hair loss.
- Hair loss (alopecia) generates considerable anxiety and the fear of total hair loss should be addressed with the patient and a realistic prognosis given.
- Androgenic alopecia is the most common cause of human hair loss, affecting 50% of men by age 40 and up to 50% of women by age 60.<sup>2</sup> Other common causes are alopecia areata, seborrhoeic dermatitis and tinea capitis (see TABLE 128.1).
- In telogen effluvium, the traumatic event has preceded the hair loss by about 2 months (peak loss at 4 months).
- Although severe stress could precipitate alopecia areata, day-to-day stressors are not considered to be a trigger. Stress seems to be a consequence of alopecia rather than the cause of it.<sup>3</sup>
- Hair loss can be patchy or diffuse where it involves the entire scalp.
- Patchy loss—alopecia areata and trichotillomania.
- Generalised loss—telogen effluvium, systemic disease, drugs (see TABLE 128.2).
- Alopecia areata has a poor prognosis if it begins in childhood, if there are several patches and there is loss of eyebrows or eyelashes.
- Scarring alopecia can be an indicator of lupus erythematosus or lichen planus.

**Table 128.1** Hair loss: diagnostic strategy model

Q. Probability diagnosis
A. Androgenetic alopecia (male pattern baldness)
Alopecia areata (diffuse type)
Telogen effluvium (incl. postpartum)
Anagen effluvium (esp. cytotoxic therapy)
Seborrhoeic dermatitis
Q. Serious disorders not to be missed
A. Infection:
• tinea capitis
• bacterial folliculitis
• secondary syphilis
• post-febrile state
Cancer:
• treatment for cancer
Other:
• systemic disease (e.g. lupus)
Q. Pitfalls (often missed)
A. <i>Rarities:</i>
Heavy metal poisoning
Nutritional:
• severe dieting
• malnutrition
• zinc/iron deficiency
Q. Masquerades checklist
A. Drugs (cytotoxics, anticoagulants, antiepileptics, amphetamines, anti-thyroid agents, various hormones, cessation OCP)
Thyroid/other endocrine (hypothyroidism)
Q. Is the patient trying to tell me something?
A. Emotional stress → telogen effluvium; trichotillomania

## The normal hair growth cycle

An understanding of the process of normal hair growth is necessary to comprehend and evaluate hair disorders. Each follicle progresses quite independently through regular cycles of growth and shedding (see FIG. 128.1).

FIGURE 128.1 The normal hair cycle

**Table 128.2** Causes of diffuse hair loss

Androgenetic alopecia

Telogen effluvium

Postpartum telogen effluvium

Alopecia areata (diffuse type)

Drugs—cytotoxics and others

Hypothyroidism

Nutritional:

- iron deficiency
- severe dieting
- zinc deficiency
- malnutrition

Post-febrile state

Anagen effluvium

The three phases of follicular activity are:<sup>1</sup>

- 1 Anagen phase—the active growth phase of hair production.
  - The dermal papilla stimulates division of epithelial cells that produce the hair shaft.
  - The hair shaft grows 1 cm per month.
  - It lasts for about 2.5–5 years on the scalp (average 1000 days).
  - It lasts 1–2 months on eyebrows and eyelashes and 6–9 months in the axilla and pubis.
  - It varies between individuals.
- 2 Catagen phase—a short transition phase from active growth to inactivity (the involutional stage).

- The base of the hair becomes club-shaped.
- It lasts for only about 2 weeks.

- 3 Telogen phase—the resting (dormant) phase of the cycle at the end of which the club hair with its non-pigmented bulb is shed.
  - This lasts 2–4 months (average 100 days).
  - The percentage of hairs in telogen varies from site to site—10% in scalp to 60–80% in pubic hair.<sup>2</sup>
  - The hair is anchored in the follicle but does not grow longer.
  - The follicle then re-enters anagen.

Thus every 3–5 years every hair on the scalp is shed and replaced.

### Some facts on hair numbers<sup>1</sup>

- Hair growth is asynchronous (i.e. continuous production and shedding).
- Humans produce 1 km of hair a month.
- About 50–100 hairs are shed daily without a reduction in density.
- The scalp contains, on average, 100 000 hair follicles.
- The hair follicle is subject to melanocytic activity.
- At least 25% of hair must be shed before a noticeable loss of density occurs.
- Hair loss counts consistently above 100 per day indicate excessive hair loss.
- Significant hair loss tends to block the shower drain or be visible all over the pillow.

### Key history

- Onset, duration, quantity and rate of loss
- Localised or generalised loss
- Associated symptoms (e.g. pruritus, scaling, pustules)
- Systems review including fever, acute illness, surgery, stressors
- Endocrine features
- Past history including skin disorders, cancer, thyroid disorders
- Family history of hair loss

### Key examination

- General review with emphasis on endocrine system and examination of scalp
- Look for exclamation mark hair, 'white bulb' hair, state of bald patch (clean, scaly, scarred or inflamed) and the unusual pattern of trichotillomania

### Key investigations

Consider:

- FBE/ESR
- pituitary hormones (FSH/LH/prolactin/FSH)
- hair pull test
- trichogram
- scalp biopsy
- skin scrapings and hair sample for fungal microscopy and culture

## § Alopecia areata, alopecia totalis and alopecia universalis

Alopecia areata is a disorder of the hair follicle causing a sudden onset of localised or diffuse hair loss. It is thought to be an autoimmune disorder that has a genetic susceptibility (20% have a positive family history). The hairs are affected during the growth phase, resulting in cessation of anagen.

**DxT** patch of complete hair loss + clean scalp + exclamation-mark hairs → alopecia areata

### Clinical features

- Complete hair loss (small patch or diffuse)
- Pigmented hairs often lost first
- Clean normal scalp
- No or minimal inflammation
- Exclamation-mark hairs, especially around the periphery (see FIG. 128.2)

### Associations

- Loss of facial (beard in men) or body hair
- Nail changes—dystrophy or pitting

## Alopecia areata<sup>3</sup>

The course taken may be as follows.

### Localised patches

Small patches may recover spontaneously (usually 80%), while others depend on the extent of loss and general factors. Treatment (options) includes:

- topical potent class III steroids (especially in children) bd, 12 weeks
- topical irritants (e.g. dithranol 0.5% ointment initially, increasing in strength to 2% applied once daily)
- intralesional steroids—triamcinolone 10 mg/mL or betamethasone acetate/phosphate 5.7 mg/mL bd (caution needed on face—risk of cutaneous atrophy). Multiple injections required.
- topical minoxidil 5%—1 mL bd (for 4 or more months) only when hair growing
- topical immunotherapy with DNCB antigen

### Extensive area (>50% loss)

- Treatment
- Counselling
- Alopecia areata support group
- Use of cosmetic aids (e.g. wigs, hair pieces, scarves) and camouflage

FIGURE 128.2 Exclamation-mark hair (a feature of alopecia areata)

- Topical steroids not recommended—ineffective
- Topical immunotherapy under specialist care may help
- Psoralen and ultraviolet A (PUVA) phototherapy may also help
- Systemic steroids only for active and progressive cases: prednisolone 0.75 mg/kg (o) daily for 3–4 weeks, then taper off over 2 months

A solitary patch of hair loss will recover within 6 months in 33% of cases, while 50% of cases will recover over a year and 33% will never recover. Unfortunately, most patients (86% in one study) relapse.<sup>3</sup>

### Alopecia totalis

- This is where the alopecia extends over the total scalp.
- There is, at best, a 50% chance of hair recovery in a fit adult but only a very small chance in childhood.

### Alopecia universalis

- This is where the alopecia involves the eyebrows and eyelids as well. Recovery is rare.

### § Scarring alopecia<sup>1</sup>

In this condition, the hair follicles are damaged and if the follicular openings cannot be seen with a magnifying lens, regrowth of hair cannot be expected. Thus, the process is irreversible and a scalp biopsy is essential to determine the diagnosis. Apart from obvious causes such as trauma, severe burns, a carbuncle and scalp ringworm with kerion, the causes of scarring alopecia are as follows.

- Lichen planopilaris—this is a variant of lichen planus that produces small follicular papules in the scalp that tend to heal with scarring and destruction of hair follicles; treatment, which is difficult, includes corticosteroids, antimalarials and etretinate<sup>1</sup>
- Discoid lupus erythematosus—this gives a similar picture to the former and tends to be treated in a similar manner
- Folliculitis decalvans—a chronic folliculitis of the scalp, probably as a response to staphylococci on the scalp; treated with long-term tetracyclines
- Pseudopelade—a slowly progressive, non-inflammatory, scarring condition causing patchy areas of hair loss without any obvious preceding skin disease

### § Telogen effluvium<sup>4</sup>

Telogen effluvium, which is increased shedding of hairs in the telogen phase, is one of the most common causes of diffuse hair loss and can be triggered by a variety of stressors.

It is worth noting that follicular matrix cells have a high metabolic rate second only to haematological tissue and stress can result in shunting into premature telogen with cessation of anagen.<sup>1</sup>

An obligatory delay occurs between the ‘insult’ or precipitating event and the onset of hair shedding because the hair follicle cycles through catagen and telogen—approximately 2–3 months when the club hairs with white bulbs of telogen are shed.

Greater than 25% of hair must be lost before there is a perceptible thinning and in this disorder up to 50% loss is common.

**DxT** stressful event + 2–3 month gap to diffuse hair loss + ‘white bulbs’ → telogen effluvium

Patients usually complain of large clumps of hairs with white bulbs coming out with gentle tugging on combing or shampooing (this can exceed 150 hairs per day compared with the normal average of 50–100 hairs).

### Stress precipitants of acute telogen effluvium

- Any severe stress
- Childbirth (common)
- High fever
- Weight loss, especially crash dieting
- Trauma—surgical or accidental
- Oral contraceptive pill (OCP) cessation
- Malnutrition
- Haemorrhage

### Course of telogen effluvium

If uncomplicated, spontaneous recovery can be expected in 6 months so reassurance with explanation is all that is required. If it persists longer than 6 months, consider the chronic idiopathic form or an unmasked androgenetic alopecia. However, if there is concern about non-recovery and the stress factors are corrected, topical minoxidil 5% lotion (2% if too irritant) twice daily for a minimum of 4 months is an option.<sup>3</sup> Referral to a specialist is advised for relapsing episodes or incomplete recovery.

## Chronic telogen effluvium<sup>5</sup>

This occurs usually in perimenopausal and postmenopausal women. It may be primary and idiopathic or secondary to hypothyroidism, hyperthyroidism, malnutrition or cancer. The feature is episodes of dramatic hair shedding that recover but recur weeks to months later and last up to several days. It does not result in obvious balding—it is self-limiting and does not usually need treatment.

## § Anagen effluvium

This is hair loss during the anagen phase and is typically seen in association with cancer chemotherapy and radiotherapy to the scalp, which results in immediate metabolic arrest. Hair loss is diffuse, involving the whole scalp. Anagen hair shafts are identified by their long and pigmented hair bulb. The follicle may remain in anagen, leading to a quick recovery, or move into telogen, thus delaying growth by about 3 months.<sup>3</sup>

## § Drug-induced alopecia

Drugs are a very important cause of alopecia (see TABLE 128.3). They may cause telogen effluvium, anagen effluvium or accelerate androgenetic alopecia.

Drugs tend to cause telogen effluvium but cancer chemotherapy, radiation to the scalp, thallium/mercury/arsenic and colchicine in high dosage cause anagen effluvium. Acceleration of androgenetic alopecia is caused by hormone therapy, namely the OCP, danazol, testosterone and anabolic steroids.

## § Androgenetic alopecia (male pattern baldness)

This is the most common form of alopecia, which is age related and is genetically determined in addition to being androgen dependent. The key androgen is dihydrotestosterone, which is produced from testosterone by 5 $\alpha$  reductase. The hair loss is reasonably predictable, with some men losing hair quickly and others more slowly in a familial pattern. In others it is unpredictable. The diffuse pattern loss seen in women tends to progress slowly. About 50% of women have significant hair loss by the age of 60. The typical male pattern is shown in FIGURE 128.3.

Alopecia affects 30% of men by age 30 and 50% by age 50.

**Table 128.3** Drug-induced causes of alopecia generally from prolonged use<sup>2,3</sup>

Cytotoxic agents/thallium
Amphetamines
Anticoagulants: heparin, warfarin
Anti-epileptics: phenytoin, sodium valproate, carbimazole
Antigout agents: allopurinol, colchicine
Anthelmintic agents: albendazole/mebendazole
Anti-inflammatories: indomethacin, gold, penicillamine, salicylate
Antiparkinson: levodopa, bromocriptine
Antithyroid agents/thyroxine/iodine
Cardiovascular agents:
• amiodarone
• statins, clofibrate
• selected ACE inhibitors
• selected $\beta$ -blockers
Cimetidine
Gentamicin
Hormones: OCP, androgens, danazol
Interferon
Lithium
Methysergide
Vitamin A derivatives/retinoids: Roaccutane

**FIGURE 128.3** Typical male pattern baldness

## Androgenetic alopecia in women

- In women, the pattern of hair loss is different from men.
- Diffuse thinning occurs, usually on the top of the head (the crown). The front hairline usually remains but in some women this can recede with bitemporal loss (see FIG. 128.4).

FIGURE 128.4 Typical female pattern baldness

- Although hair loss can appear in men and women as early as the 20s, it may not appear before the age of 50 in women.
- Some women notice a short period of considerable hair loss but this may be followed by a long stable period of no loss. Total loss of hair rarely occurs in women.
- It may be unmasked after an episode of diffuse hair loss such as after childbirth or an acute illness.

### Treatment (men)

It is appropriate to counsel men to accept their balding as part of a natural ageing process. This includes cutting the hair short to make it look better cosmetically. If baldness is not acceptable, some options include wearing a toupee, a wig or other hair substitute or having a hair transplant operation. However, with hair transplantation, the new hair is often just as likely to disappear as the original hair. The use of medicated oils and shampoos should be discouraged. The androgen receptor antagonists such as spironolactone and cyproterone acetate are unsuitable for men because of adverse effects.<sup>3</sup>

### Available medications<sup>3</sup>

- Minoxidil 2% and 5%, 1 mL applied bd to the dry scalp for a minimum of 12 months. The results vary from good to no change. One study showed that one-third of men using 2% minoxidil for 12 months experienced 'cosmetically significant hair growth'. However, a lifetime of expensive treatment is required in these people and hair loss resumes, with loss of that being maintained by the treatment, when it is ceased.
- Finasteride 1 mg tablet taken daily for a minimum of 2 years. This can halt the balding process in over 85% of men and may initiate some modest regrowth in 65% over a 12-month period, with further improvement if it is continued over a longer period. However, it is

expensive, is not a cure and balding resumes when it is discontinued.

### Treatment (women)

#### Physical treatments/hair styling

This includes the use of wigs, hair transplantation and camouflage. Wigs can be worn on the whole head or on the bald spot, or fibres can be interwoven into the remaining hairs.

Camouflage can be used either by having the existing hair bleached by a skilled hairdresser or by colouring the scalp the same colour as the hair. Mascara can be lightly brushed into the roots of the hair at receding hairlines or along gaps.

#### Medications<sup>2</sup>

minoxidil 2% and 5% topical application bd for minimum of 12 months (to assess efficacy) although one large trial has approved its effectiveness generally in women<sup>6</sup>

or

spironolactone 100 mg increasing to 200 mg daily for 6 months

or

cyproterone acetate 100 mg (o) daily (course of 10 tablets a month) usually with OCP (coinciding with 10 active pill days)

- If postmenopausal, cyproterone acetate 50 mg (o) daily in consultation with an endocrinologist

As for men, these drugs tend to prevent further loss and, if effective, need long-term use.

### § Trichotillomania (hair pulling)

This is patchy hair loss caused by deliberate plucking or twisting of hair shafts. It is reasonably common in young children, where it may be of little significance, simply being a 'habit'. In older children and adults it may be an obsessive compulsive disorder often associated with stress.<sup>1</sup>

### Clinical features

- Incomplete patchy alopecia
- Hairs of different length
- Hairs broken and twisted
- Strange pattern of loss
- Tends to occur on side of dominant hand
- Eyelashes or eyebrows may be involved

## Hair disorders in children

### Loose anagen (growing hair) syndrome<sup>7</sup>

This is a disorder of the hair follicle characterised by the ability to pluck anagen hairs painlessly from the scalp by gentle pulling. It presents as very thin, wispy new hair growth. It is an autosomal dominant trait.

### Clinical features

- Thin wispy hair with tatty ends
- More common in girls; can affect boys
- Onset in early childhood—usually <5 years
- Large clumps easily pulled out at play
- Light microscopy of hair shafts aids diagnosis

**DxT** fair females under 5 + thin wispy hair  
+ easy loss with pulling → loose anagen  
syndrome

### Outcome

- Spontaneous improvement with age
- Usually normal hair by teens

### Treatment

- Reassurance and explanation
- Gentle hair care

### Traction alopecia

Traction alopecia is thinning of the hair seen in female children and young women due to very tight hairstyles, as with ponytails, excessive hair rolling and hair braiding in particular. The bald areas that show short broken hairs and sometimes scarring are found in areas of maximal tug. The most common type is 'marginal alopecia' found in the forehead and sides at the hair edges (see FIG. 128.5). Patients should be advised to cease the procedure. Rollers that cause traction can be replaced by those that heat.

### Trichotillomania<sup>7</sup>

This occurs in children typically between 4 and 10 years, usually as a nocturnal habit; parents may be unaware of the hair pulling. The affected areas

are usually on the anterior and temporal areas of the head (see FIG. 128.6). The areas are never completely bald. A characteristic feature is an irregular-shaped area of incomplete patchy alopecia containing hairs of different length. The variable length is due to the fact that some hairs will not break with pulling while others will break at varying distances from the scalp surface. There may be associated follicular pustules. However, scrapings should be taken to exclude a particular type of tinea capitis (black dot ringworm) caused by *Trichophyton tonsurans*. The management is similar to thumb sucking or nail biting with a low-key approach. It does not imply a significant psychological problem.

**FIGURE 128.5** Traction alopecia in an adult from pulling the hair up in a tight bun

**FIGURE 128.6** Trichotillomania in an 11-year-old boy. Note the incomplete patchy hair loss and unusual pattern.

128

Localised alopecia areata

This can also occur in children. Most childhood cases resolve spontaneously but it can progress to total hair loss or recurrent alopecia can occur. Regrowth decades later is a possibility. Treatment with moderate-potency topical steroids for 12 weeks or so may help.

Tinea capitis

This is a dermatophyte infection that produces an area of incomplete, ‘unclean’ alopecia with various degrees of scaling and inflammation of the scalp surface. A boggy swelling (kerion) can develop in severe cases. Wood’s light examination will be positive in only 50% of cases. Confirm diagnosis with scalp scrapings for microscopy and culture.

Office procedures

The following procedures can be useful in determining diagnosis and prognosis.

The hair-pull test<sup>1</sup>

In this simple method, 50–100 hairs are grasped between thumb and forefinger and gently pulled proximal to distal. This is repeated 6–8 times and should yield a total of 2–5 telogen hairs, which can be analysed. More than eight hairs per pull is abnormal.

Trichogram

Twenty to 50 hairs are extracted by a short, sharp pull with artery forceps. The anagen-to-telogen ratio is calculated. The ratio is decreased in telogen effluvium because of the increased numbers of hairs in telogen.

Scalp biopsy

This differentiates between scarring and non-scarring alopecia and also between alopecia areata and trichotillomania.

Light microscopy of hair shafts

Light and/or electron microscopy is indicated if a hair shaft defect is suspected. Skin scrapings and hair samples are taken for fungal microscopy and culture.

Hirsutism

Hirsutism is growth in the female of excess, coarse, terminal pigmented hair in androgen-dependent

sites, namely in a male sexual pattern (e.g. upper lip, beard area and back; see FIG. 128.7).

Most cases are due to idiopathic hirsutism, which may follow ethnic or familial factors, or to a variant of the polycystic ovarian syndrome. Other causes include adrenal hyperplasia, virilising adrenal tumours, Cushing syndrome, virilising ovarian tumours and iatrogenic causes, particularly drugs.

The diagnostic strategy model is presented in TABLE 128.4 and followed by the key features.

Table 128.4	Hirsutism in women: diagnostic strategy model
Q.	Probability diagnosis
A.	Constitutional (physiological or familial) Polycystic ovarian syndrome (PCOS)
Q.	Serious disorders not to be missed
A.	Cancer/tumour: <ul style="list-style-type: none"><li>• virilising ovarian tumour</li><li>• adrenal tumours (cancer and adenoma)</li><li>• ectopic (paraneoplastic) hormone production (e.g. lung cancer, carcinoid)</li></ul>
Q.	Pitfalls (often missed)
A.	Postmenopausal Rarities: <ul style="list-style-type: none"><li>• porphyria cutanea tarda</li><li>• congenital adrenal hyperplasia</li><li>• gonadal dysgenesis</li></ul>
Q.	Masquerades checklist
A.	Drugs (many incl. phenytoin, danazol, minoxidil, anabolic steroids, cyclosporin, corticosteroids, OCP, phenothiazines, interferon α, penicillamine) Thyroid/other endocrine (prolactinaemia, Cushing syndrome, acromegaly, hypothyroidism)

Key history

History of age of onset, extent and activity of the hair. Family history and past medical history including endocrine disorders and drugs, especially those listed above.

Key examination

- General inspection including distribution and character of the hair growth, endocrine abnormalities (e.g. Cushing syndrome), skin, abdomen and breasts

### Key investigations

- Consider pituitary hormones (e.g. FSH, LH, ACTH, TSH, prolactin)
- Serum thyroxine, testosterone, DHEAS
- Pelvic ultrasound (? PCOS)
- Urinary porphyrins
- Imaging of pituitary and adrenal regions

Routine investigation is not required unless there are other features of virilisation.

It is important to exclude adrenal or ovarian pathology.

Hirsutism of reasonably sudden onset is an important marker for serious underlying pathology.

Appropriate investigations include pelvic ultrasound to diagnose polycystic ovaries and serum testosterone and dehydroepiandrosteredione (DHEA), which indicates an adrenal cause of androgen excess if elevated.

For patients with severe hirsutism and regular menses, serum testosterone, DHEA and early morning 17-hydroxyprogesterone levels should be measured. If menses are irregular, measure follicle stimulating hormone, luteinising hormone and serum prolactin.

### Principles of management

- Exclude underlying adrenal or ovarian pathology.
- Support the patient to achieve an acceptable body image through appropriate advice and referral.
- Recommend appropriate cosmetic measures, which include bleaching (a good option), waxing or depilatory creams, or shaving.
- Do not pluck hairs, especially around the lips and chin—plucking stimulates hair growth but shaving appears to have no effect.
- Electrolysis may help for hair removal but it is expensive and requires multiple treatments from an experienced therapist (beware of scarring).

FIGURE 128.7 Areas prone to hirsutism

It achieves temporary hair removal—significant regrowth can occur within 3 months.

- Laser epilation may also help but seems to be most suitable for dark hair on a light skin and provides temporary removal, lasting up to 6 months.

### Pharmaceutical options

These include either inhibition of androgen action at the hair follicles (spironolactone and cyproterone acetate) or suppression of ovarian and/or adrenal androgen production (dexamethasone or oral contraception).

The following are options:<sup>2</sup>

spironolactone 100–200 mg (o) daily (takes 6–12 months to respond)

or

cyproterone acetate 10–100 mg (o) daily for 10 days of each menstrual cycle plus an OCP

Topical eflornithine HCl 11.5% (Vaniqa) cream for topical use on facial hair and hair under the chin is a newer preparation. Apply thinly twice a day.

### § Hypertrichosis

Hypertrichosis is the increased growth of fine vellus or downy hair over the entire body. It is non-androgen dependent hair and does not respond to anti-androgen therapy. The cause is generally unknown—it may be primary or constitutional where it is usually apparent prior to puberty and where it is evenly distributed over the back and limbs. Prepubertal hypertrichosis is commonly familial but a positive family history is not always determined.

An important cause of secondary hypertrichosis is drugs. Drugs that are implicated include phenytoin, minoxidil, cyclosporin, corticosteroids, including topicals, diazoxide and anabolic steroids.

It is also associated with an underlying neoplasia, such as stomach cancer, when it is termed hypertrichosis lanuginosa acquisita or ‘malignant down’.

Other causes include anorexia nervosa, the menopause, starvation and a few rare syndromes (e.g. Cornelia de Lange syndrome).

## SCALY SCALP DISORDERS

### § Dandruff

Dandruff (pityriasis capitis) is mainly a physiological process, the result of normal desquamation of scale from the scalp. It is most prevalent in adolescence and worse around the age of 20.

If it is persistent with heavy scaling, seborrhoeic dermatitis and scalp psoriasis, which is distinguished by palpable plaques, are likely causes.

Dandruff and seborrhoeic dermatitis are related conditions on a continuum of severity. They are caused mainly by the fungal genus *Malassezia*, such as *M. globosa*, which produces lipases that break down sebum. They both have a common pathogenesis and are chronic recurring conditions presenting with scaling and a varying degree of itch. More importantly, they all respond to similar treatments.

### Treatment

Shampoos:

- zinc pyrithione (e.g. Dan-Gard, Head and Shoulders)

or

- selenium sulphide (e.g. Selsun)

Method: massage into scalp, leave for 5 minutes, rinse thoroughly—twice weekly.

Treatment of persistent or severe dandruff:

- coal tar plus salicylic acid compound (Sebitar) shampoo

or

- Ionil T plus shampoo

Method: as above, followed by Sebi Rinse or ketoconazole (Nizoral) shampoo. If persistent, especially itching, and Nizoral shampoo is ineffective, use a corticosteroid (e.g. betamethasone scalp lotion).

### § Dry hair

#### Advice to patients

- Don't shampoo every day.
- Use a mild shampoo (labelled for 'dry or damaged hair').
- Use a conditioner.
- Snip off the split or frayed ends.
- Avoid heat (e.g. electric curlers, hair dryers).
- Wear head protection in hot winds.
- Wear a rubber cap when swimming.

### § Oily hair

#### Advice to patients

- Shampoo daily with a 'shampoo for oily hair'.
- Massage the scalp during the shampoo process.
- Leave the shampoo on for at least 5 minutes.
- Avoid hair conditioners.
- Avoid overbrushing.
- Attend to lifestyle factors: relaxation and balanced diet are important.

# 129 Nail disorders

*A physician should wear white garments, put on a pair of shoes, carry a stick and an umbrella in his hand, and walk about with a mild and benignant look as a friend of all created beings. He should be cleanly in his habits and well shaved, and should not allow his nails to grow.*

Sushrut a-Samhit a (5th century BC)

Making a diagnosis of abnormal nails for a concerned patient can be quite simple for a few obvious conditions. However, in many cases the diagnosis can be elusive when we are not familiar with classic patterns that are seen so infrequently. The diagnostic process can be facilitated by learning the basic anatomy and function of the nail, as well as characteristic patterns, which are presented with the aid of diagrams in this chapter. There are, in fact, only a limited number of ways in which injury, infection and inflammation can present in a nail.<sup>1</sup>

The main nail problems encountered in general practice are trauma, onychomycosis, infection, ingrowing toenails, paronychia and psoriasis. Fungal nail infection and psoriasis are the commonest causes of nail dystrophy. Damage to the nail from trauma or disease results in nail dystrophy. The problem of nail changes due to onychotillomania, be it from excessive nail biting, picking or cleaning, should be suspected from the history and examination.

The examination should include a general inspection of the skin including in the webbing of the toes, looking for evidence of a skin disorder such as psoriasis, atopic eczema, lichen planus and tinea.

## Key facts and checkpoints

- The growth rate of nails varies between individuals: fingernails average 0.5–1.2 mm per week while toenails grow more slowly.<sup>2</sup>
- An avulsed or totally dystrophic nail will take up to 9 months to regrow.
- It takes approximately 6 weeks to grow a new cuticle.
- Beau's lines associated with a severe acute illness take about 3 months to appear.
- Do not confuse chronic paronychia with onychomycosis. The former affects the nail folds, the latter mainly affects the distal nail.
- Nail clippings for culture and histology may be the only way to differentiate between nail dystrophy and onychomycosis.

- Not all white crumbly nails are caused by a fungus.
- Suspect melanoma in any subungual pigmented lesion. Do not confuse with subungual haematomas, which 'grow out' with the nail. They usually present as a longitudinal pigmented streak. Beware of amelanotic melanoma, which may mimic chronic paronychia or a pyogenic granuloma.<sup>2,3</sup> Any suspicion necessitates early referral.
- Various dermatoses and connective tissue disorders can affect the nails—psoriasis, lichen planus, lupus erythematosus, scleroderma, bullous pemphigoid, Darier disease (keratosis follicularis).<sup>4</sup>
- Clubbing of the fingers is basically an abnormality of the fingertips—look for evidence of major pulmonary or cardiac disease.
- Significantly bitten or traumatised nails may be a symptom of a major anxiety disorder—explore psychogenic issues.

A summary of causes of abnormal nails is presented in **TABLE 129.1**.

**Table 129.1** Abnormal nails: diagnostic strategy model (modified)

Q. Probability diagnosis
A. Fungal infection: onychomycosis
Onycholysis
• trauma to nail bed
• trauma from biting
• trauma from habit picking
Onychogryphosis
Paronychia
Psoriasis
Q. Serious disorders not to be missed
A. Melanoma
Iron deficiency: koilonychia
Liver disease: leuconychia
Endocarditis: splinter haemorrhages
Chronic kidney failure: white bands, half-and-half nail

Glomus tumour  
Bowen disorder/scc

- Q. Pitfalls (often missed)  
A. Atopic dermatitis  
Lichen planus  
Pyogenic granuloma (usually with ingrowing toenails)<sup>3</sup>  
Drug effects (e.g. tetracycline)  
*Pseudomonas* infection  
Connective tissue disorders (e.g. SLE)  
Arsenic (Mees stripes)

## Key history

Enquire about a history of severe stress or illness and possible onychotillomania, be it excessive nail biting, picking or cleaning. Ask whether the hands are frequently in wet work (e.g. dishwashing, soaps and detergents) or dirt.

## Key examination

Careful examination of nails: look for associated skin disease (e.g. psoriasis, atopic dermatitis, tinea pedis, lichen planus).

## Key investigations

- Nail clippings for culture and histology
- FBE and ESR
- Consider LFTs and CXR

## Anatomy and function of the nail

The basic nail unit (apparatus) consists of the nail matrix, the proximal and lateral nail folds, the cuticle and the nail plate (see FIG. 129.1). The hard keratin of the nail plate is formed in the nail matrix. The matrix, which contains germinal epithelium, lies in an invagination of the epidermis (the nail fold) and is protected by a waterproof seal formed by the cuticle. The matrix runs from the proximal end of the nail fold to the cuticle.

The nail bed closely approximates the distal phalanx. The nail has an important functional and cosmetic role. It enhances fine touch and motor skills for picking up fine objects, such as a pin from a flat surface, not possible without fingernails.

## Nail disorders and their causes<sup>1</sup>

### Lifting of the nail plate (onycholysis)

See FIGURE 129.2.

#### Causes

- Trauma
- Factitious (self-induced)

FIGURE 129.1 Normal anatomy of the nail. Diagram of the nail apparatus: (a) lateral section view, (b) dorsal surface view

- Tinea
- Psoriasis
- Photosensitivity, usually tetracyclines
- Others (e.g. warts, lichen planus)
- Hyperthyroidism
- Nail destruction:
  - squamous cell carcinoma
  - melanoma
  - lichen planus

FIGURE 129.2 Lifting of the nail plate (onycholysis)

## Thickening of the nail plate

### Causes

- Developmental
- Trauma
- Tinea
- Psoriasis (see FIG. 129.3)
- Onychogryphosis
- Age-related changes

FIGURE 129.3 Psoriasis

## Thinning of the nail plate

### Causes

- Trauma—wear and tear (repeated water immersion)
- Artificial fingernails—application and removal
- Lichen planus
- Peripheral vascular disease (impaired peripheral circulation)
- Twenty-nail dystrophy, usually children
- Brittle nails

## Pitting of the nail plate

See FIGURE 129.4.

### Causes

- Psoriasis
- Alopecia areata
- Atopic dermatitis

FIGURE 129.4 Pitting of the nail plate

## Longitudinal marks in the nail plate

See FIGURE 129.5.

### Causes (grooved)

- Myxoid cyst
- Angiofibroma
- Ageing

### Causes (central single stripe)

- Darier disease
- Hereditary/congenital
- Mechanical trauma

FIGURE 129.5 Longitudinal marks in the nail plate

## Horizontal grooves in nail plate

### Causes

- Beau's lines (from acute illness) (see FIG. 129.6)
- Habit tic (picking cuticle of thumb nail) (see FIG. 129.7)
- Atopic dermatitis
- Raynaud phenomenon

Beau's line

FIGURE 129.6 Beau's lines in nails following an episode of acute cholecystitis a few months earlier

habit tic

FIGURE 129.7 Habit tic: horizontal grooves on thumb nails

## Horizontal single white lines or band

### Causes

- Chemotherapy
- Arsenic poisoning
- Kidney failure

## Lamellar splitting

See FIGURE 129.8.

### Causes

- Trauma—repeated wetting and drying (e.g. housework)

FIGURE 129.8 Lamellar splitting

## Abnormal curvature

### Causes

#### Spoon nails: koilonychia

See FIGURE 129.9.

- Idiopathic (most cases)
- Hereditary
- Trauma
- Iron deficiency
- Haemochromatosis

FIGURE 129.9 Spoon nails (koilonychia)

### Overcurvature

- Hereditary pincer nail

## Clubbing

See FIGURE 129.10.

- Hereditary/congenital
- Lung disease (e.g. cancer, pulmonary fibrosis), sepsis
- Heart disease (e.g. congenital cyanotic, SBE)
- Liver disease (e.g. cirrhosis)
- Gastrointestinal disorders (e.g. Crohn disease)

FIGURE 129.10 Clubbing

## Splinter haemorrhages

See FIGURE 129.11.

### Causes

- Minor trauma (e.g. manual workers)
- Bacterial endocarditis

FIGURE 129.11 Splinter haemorrhages

## Discolouration of the nail plate

- White:
  - striate leuconychia (usually trauma)
  - liver cirrhosis
  - hypoalbuminaemia (total whiteout)
- Red:
  - splinter haemorrhages
  - kidney failure
  - polycythaemia
  - CO poisoning
  - glomus tumour
- Brown:
  - fungal infection
  - cigarette staining
  - drugs—gold, chlorpromazine
  - Addison disease
  - psoriasis ('oil stain' patches)
  - melanoma
- Black:
  - haematoma
  - melanoma
  - racial pigmentation
  - naevus
  - minocycline
  - cytotoxic drugs (transverse bands)
- Green:
  - *Pseudomonas* infection
  - *Aspergillus* infection

- Blue:
  - antimalarials
  - argyria
- Yellow:
  - yellow nail dystrophy (? respiratory illness)
  - fungal infections
  - psoriasis
  - slow growth
  - tetracyclines
- Half (pale proximal) and half (brown or red distal) (i.e. half-and-half nails)
  - kidney failure (chronic)
  - liver cirrhosis
  - trauma (biting, splits, splinters)

### Swelling of the proximal nail folds (paronychia)

- Trauma (e.g. biting)
- Manicure (retracting the cuticles)
- *Candida* infection
- Staphylococcal infection
- Herpetic whitlow

### Swelling of the lateral nail folds

- Ingrowing toenails
- Retinoids
- Overcurvature of the nail plate

### Tumours of the nail fold

Benign:

- myxoid (mucus) cyst
- warts
- periungual fibroma

Malignant:

- squamous cell carcinoma
- melanoma

### Destruction of the nail apparatus

- Trauma
- Lichen planus
- Melanoma
- Bowen disorder
- Squamous cell carcinoma

### § Onycholysis<sup>1</sup>

Onycholysis refers to the separation of the nail plate from the underlying nail bed and is a sign rather than a disease. This separation creates a subungual space with an air interface that gathers unwanted debris, such as dirt and keratin. It is usually seen in

fingernails but it can develop in toenails from rubbing against shoes. Adverse local reactions to agents such as formaldehyde and resins in polishes or nail glues can distort nails.

Self-induced trauma is a common cause from obsessive manipulation, including meticulous cleaning and frequent manicuring.

The band of discolouration at the end of the separated nail is usually in a straight line compared with other causes such as psoriasis and tinea. Tinea may be distinguished from other causes by white or yellow streaks or 'spears' travelling proximally in the nail.

Greenish discolouration indicates invasion by *Pseudomonas pyocyanea* or *Aspergillus*.

### Management<sup>5</sup>

First exclude psoriasis, tinea (check toe webbing) and trauma (check history).

### Fingernails

- Keep nails as short as possible
- Avoid insertion of sharp objects under nails for cleaning out debris
- Apply tape (Micropore or similar) over free edge for months, until healed
- Avoid unnecessary soaps and detergents—wear gloves for housework, gardening, etc.
- Keep hands out of water
- Use a mild soap and shampoo
- First-line treatment especially if mild infection is vinegar soaks—10 minutes two times daily

### Toenails

- Exclude fungal infection (clinical tinea pedis)—culture
- Improve footwear to avoid any rubbing

### Pharmaceutical treatment

- Daily application of an imidazole (e.g. clotrimazole) or terbinafine
- Potent topical corticosteroids in lotion form may be useful
- For *Pseudomonas* infection soak the nails in vinegar or Milton's solution and/or gentamicin sulphate cream

Refer difficult and unresponsive cases to a dermatologist.

### § Psoriasis of nails

Psoriasis can have many manifestations, such as pitting, onycholysis, discolouration, splinter haemorrhages, distal subungual hyperkeratosis

(which can resemble warts) and severe total nail dystrophy (often with arthropathy). Psoriasis can closely mimic onychomycosis, which should be excluded by fungal culture and histology before commencing presumed tinea therapy.

There is no effective topical therapy for psoriasis of the nails but a trial of a potent corticosteroid lotion may help selected cases. Intralesional steroid injections, which are painful and require multiple treatments, can help. Successful treatment of the skin does not help the nails.

## § Onychomycosis (fungal nail infection)

### Key facts and checkpoints

- Affects 3–5% of population and 40% over 60 years<sup>1</sup>
- Classified as superficial, distal or proximal
- Toenails affected more commonly than fingernails
- The most common form is distal lateral subungual caused by *Trichophyton mentagrophytes* var. *interdigitale* (typical of toe web space tinea and responds well to terbinafine) or by *Trichophyton rubrum* (common on sole of foot and more resistant)
- Superficial white onychomycosis is also common, and is usually confined to the toenails with small superficial white plaques with distinct edges and caused by *Trichophyton mentagrophytes* var. *interdigitale*
- Total dystrophic onychomycosis—whole nail affected, thickened, opaque and yellow brown (caused by *Trichophyton* sp.)
- *Candida albicans* and other fungi are not a common factor
- Diagnosis—always confirm by culture and histology of the distal nail plate clippings placed in formalin. Positive in 60–80% of cases

### Treatment<sup>5,6</sup>

Regular nail clipping is important. The antifungal treatment of choice for all types of toenail tinea is:

terbinafine 250 mg (o) daily for 12 weeks (cures 70–80% of cases); 6 weeks for fingernails

An alternative is itraconazole 200 mg (o) bd for the first week of each month for 2 months for fingernails; 3–4 months for toenails.

### Tips

No improvement apart from the proximal part of the nail will be noticed after months because it takes 12 months or more for the toenail to grow.

Mark the base of the dystrophic nail with a scalpel blade or black ink to assess progress.

## Topical treatment for superficial or distal nail involvement

amorolfine 5% (Loceryl) nail lacquer 1–2 times weekly after filing (fingernails: 6 months; toenails: 9–12 months)

A systematic review found poor evidence for the effectiveness of topical therapy for onychomycosis.<sup>7</sup>

Consider twice-daily applications of tea-tree oil indefinitely for tinea pedis and tinea unguium.

## PARONYCHIA

### § Acute paronychia

This is a painful condition that is mainly due to bacterial infection, especially *Staphylococcus aureus*.

### Management

Uncomplicated with localised pus:

- simple elevation of nail fold or puncture the fold—close to drain pus
- advice on hygiene
- antibiotics not usually necessary
- if not responding to drainage, use (di)flucloxacillin
- exclude diabetes

Complicated with subungual extension:

- small vertical incision alongside the nail, or
- removal of nail in part or totally
- exclude diabetes

### § Chronic paronychia

### Clinical features

- Painless
- A form of traumatic nail dystrophy
- Loss of cuticle fundamental to diagnosis

### Causes

- Excessive manipulation of cuticles (e.g. by manicurists)
- Occupational (e.g. chefs, housewives, nurses, fishmongers)
- Frequent contact with water, detergents and chemicals
- Habit tic—picking the nail fold

Note:

- Secondary infection with *Candida* common but not basic cause.

- The damaged cuticle permits access of water and grit to the nail matrix and causes inflammation of the proximal nail fold.

### Management<sup>4,5</sup>

- Culture organisms
- Exclude diabetes
- Basic nail care advice:
  - keep hands dry (avoid wet work if possible)
  - wear cotton-lined gloves when washing dishes (for max. of 15 minutes)
  - minimise contact with water, soap, detergents, lipid solvents and other irritants
  - never pick, push back or manicure cuticles
  - never insert anything beneath cuticle for cleaning
  - wear cotton gloves in garden
  - use a mild soap and shampoo

### Medications<sup>5</sup>

For *Candida* (if cultured):

tincture miconazole 2% bd for 7 days  
or  
clotrimazole topical preparations

For *Staphylococcus* (if cultured):

Bactroban topical ointment

Topical medications to nail folds (especially if persistent exudate):

4% thymol in alcohol (SVR) qid  
or  
10% sulphacetamide in alcohol

Vaseline (to waterproof) can be applied frequently (5–10 times daily) when it is dry and without exudate. Very potent topical corticosteroids are helpful. Refer unresponsive cases.

### Atopic dermatitis

- Avoid irritants: special soaps, wear gloves for dishwashing
- Good nail hygiene
- Apply potent topical steroids to proximal nail fold

### Lichen planus

This commonly presents in the nail with atrophy of one or more nails. The nail plate is predisposed to breaking and splitting as it thins. If advanced, a pterygium arising from the proximal nail fold grows as the nail matrix is destroyed and eventually total loss of the nail may occur.

Biopsy of the nail matrix is recommended before treatment.

Intralesional steroids into the proximal nail fold are the treatment of choice if seen prior to destruction of the nail unit. Otherwise a trial of prednisolone 25 mg (o) daily for 4 weeks, reducing the dose gradually over 1–2 weeks, may induce temporary remission.

### § Twenty-nail dystrophy

This is an uncommon disorder seen in preschool or pre-adolescent children with thinning and roughening of all or almost all 20 nails. It may be a prodrome to psoriasis, lichen planus or alopecia areata but it tends to be a self-limiting condition and most cases resolves over 2–3 years.<sup>4</sup>

It is reported to respond well to the very potent topical steroid, clobetasol.

### § Brittle nails

The nails break easily, usually at their distal end. Brittle nails are age related and are usually caused by local physical factors, such as repeated water immersion, and exposure to chemicals, such as detergents, alkalis and nail polish removers and also hypothyroidism and digital ischaemia. Systemic causes such as deficiency of iron and vitamins are not considered to be a common factor.

Calcium does not contribute to the hardness of nails and calcium deficiency does not cause brittle nails.<sup>4</sup> No cosmetic applications appear to be helpful.

### Management<sup>4</sup>

- Avoid excessive hydration and trauma
- Wear rubber gloves with cotton liners for wet work
- Massage Vaseline or nail creams (e.g. Eulactol or NeoStrata) into the nail several times daily
- Nail polishes and hardeners (preferably without formalin) may give a good cosmetic result

### § Nail apparatus melanoma

#### Clinical features<sup>5</sup>

- Rare but potentially fatal
- Responsible for 2–3% of all melanoma
- All age groups but especially in seventh decade
- Affects all ethnic groups in all climates
- Presents as a longitudinal pigmented streak in the nail (see FIG. 129.12)
- Hutchinson sign (pigmentation of the proximal nail fold) may be present

**FIGURE 129.12** Longitudinal pigmented streak: sign of nail apparatus melanoma

- Usually diagnosed late
- Mortality >50%
- Median survival <12 months after diagnosis
- Early recognition and referral may result in a cure

### Management

- All cases require a longitudinal nail biopsy for diagnosis
- If confirmed, treatment is based on Breslow thickness and level of invasion
- Level 1 or in situ—removal of whole nail apparatus
- Invasive melanoma—amputation of distal phalanx

### § Glomus tumours

Glomus tumours are those mysterious little tumours that occur beneath the nail plate and can give paroxysms of sharp pain.

They are small purplish lesions that are exquisitely tender to touch and activate with changes in temperature. They may not be visible but may be revealed when the nail bed is blanched with gentle pressure. Imaging may be needed for diagnosis. Treatment is surgical.

### § Onychogryphosis

Onychogryphosis, or irregular thickening and overgrowth of the nail, is commonly seen in the big toenails of the elderly and appears to be related to pressure from footwear (see FIG. 129.13). It is really a permanent condition. Simple removal of the nail by avulsion is followed by recurrence some months later. Softening and burring of the nail gives only temporary relief, although burring sometimes provides a good result.

The powder from burring can be used as culture for fungal organisms. Permanent cure requires ablation of the nail bed after removal of nail.

**FIGURE 129.13** Onychogryphosis

Two methods of nail ablation are:<sup>6</sup>

- 1 total surgical excision
- 2 cauterisation with phenol (with care)

### Ingrowing toenails

Refer to section in CHAPTER 68.

### § Periungual warts

These are similar to other warts and fortunately rarely spread under the nail to the nail bed. Caution is needed with treatment.

Cryotherapy must be used with caution to avoid damage to the nail matrix—otherwise it is usually safe but often ineffective. Consider wart paints under occlusion.

### SUBUNGUAL HAEMATOMA<sup>8</sup>

#### § The small, localised haematoma

There are several methods of decompressing a small localised haematoma under the fingernail or toenail that causes considerable pain. The objective is to release the blood by drilling a hole in the overlying nail with a hot wire or a drill/needle.

### Treatment

#### Method 1: the sterile needle

Simply drill a hole by twisting a standard disposable hypodermic needle (21 or 23 gauge) into the selected site. Some practitioners prefer drilling two holes to facilitate the release of blood.

#### Method 2: the hot paper clip

Take a standard, large paper clip and straighten it. Heat one end (until it is red hot) in the flame of a

spirit lamp. Immediately transfer the hot wire to the nail, and press the point lightly on the nail at the centre of the haematoma. After a small puff of smoke, an acrid odour and a spurt of blood, the patient will experience immediate relief (see FIG. 129.14).

129

**FIGURE 129.14** Treatment of subungual haematoma. The point of a heated end of a paper clip is pressed lightly on the nail at the centre of the haematoma.

### Method 3: electrocautery

This is the best method. Simply apply the hot wire of the electrocautery unit to the selected site (see FIG. 129.15). It is very important to keep the wire hot at all times and to be prepared to withdraw it quickly, as soon as the nail is pierced. It should be painless.

**FIGURE 129.15** Electrocautery to subungual haematoma

### Important precautions

- Reassure patients that the process will not cause pain; they may be alarmed by the preparations.
- The hot point must quickly penetrate, so go no deeper than the nail. The blood under the nail insulates the underlying tissues from the heat and, therefore, from pain.
- The procedure is effective for a recent traumatic haematoma under tension. Do not attempt this procedure on an old, dried haematoma as it will be painful and ineffective.

- Advise the patient to clean the nail with spirit or an antiseptic and cover with an adhesive strip to prevent contamination and infection.
- Advise the patient that the nail will eventually separate and a normal nail will appear in 6–9 months.

## § The large haematoma

Where blood occupies the total nail area, a relatively large laceration is present in the nail bed.

### Treatment

To permit a good, long-term functional and cosmetic result it is imperative to remove the nail and repair the laceration (see FIG. 129.16).

**FIGURE 129.16** Treating the diffuse haematoma: (a) the diffuse haematoma, (b) sutures to laceration, (c) fingernail as splint

### Method

- Apply digital nerve block to the digit.
- Remove the nail.
- Repair the laceration with 4/0 plain catgut.
- Replace the fingernail, which acts as a splint, and hold this in place with a suture for 10 days.

## § Myxoid pseudocyst

There are two types of digital myxoid pseudocysts (also known as mucous cysts) appearing in relation to the distal phalanx and nail in either fingers or toes (more common) (see FIG. 129.17). One type occurs in relation to, and often connecting with, the distal interphalangeal joint and the other occurs at the site of the proximal nail fold. The latter (more common) is translucent and fluctuant, and contains

thick clear gelatinous fluid, which is easily expressed after puncture of the cyst with a sterile needle. Osteoarthritis of the DIP is associated with leakage of myxoid fluid into the surrounding tissue to form the cyst.

**FIGURE 129.17** Myxoid pseudocyst: typical position of the cyst

Some pseudocysts resolve spontaneously. If persistent and symptomatic attempt:<sup>8</sup>

repeated aspiration (aseptically) at 4–6 weekly intervals

or

cryosurgery

or

puncture, compression, then infiltration intralesionally with triamcinolone acetonide (or similar steroid)

They tend to persist and recur; if so, refer to surgery for total excision of the proximal nail fold and/or ligation of the communicating stalk to the DIP or (preferably) microscopic dissection to the capsule defect and capsule repair.

# Part 10

## Accident and emergency medicine

---

# 130 Emergency care

*When Elisha arrived, he went alone into the room and saw the boy lying dead on the bed. He closed the door and prayed to the Lord. Then he lay down on the boy, placing his mouth, eyes and hands on the boy's mouth, eyes and hands. As he lay stretched out over the boy, the boy's body started to get warm—the boy sneezed seven times and then opened his eyes.*

II Kings 4: 32–5 (A miracle or successful artificial resuscitation?)

## Definition of the emergency

**Emergency:** 'An event demanding immediate medical attention'.

The GP must be available and organised to cope with the medically defined emergency when it comes. Emergency care outside the hospital represents one of the most interesting and rewarding areas of medical practice. City doctors will have to modify their degree of availability, equipment and skills according to paramedical emergency services, while others, especially remote doctors, will need total expertise and equipment to provide optimal circumstances to save their patients' lives.

In dealing with a specific emergency, the doctor adopts a different approach. Instead of taking a history and performing an examination in the usual way, he or she replaces this with a technique of rapid assessment and immediate management. In fact, the diagnosis may be possible on the information available over the telephone.

An important yet obvious concept is that of 'time criticality', which implies that certain patients are at high risk of a critical outcome of deterioration if there is significant delay in appropriate management. This applies particularly to acute coronary syndromes.

Refer also to childhood emergencies (see **CHAPTER 96**).

## Key facts and checkpoints

- The commonest emergency calls in a survey of a typical community<sup>1</sup> were accidents and violence (50.7%), abdominal pain (9.9%), dyspnoea (7.2%), chest pain (5.8%), syncope/blackout (5.2%), other acute pain (5.0%).
- The prevalence of emergency calls was 2.6 per 1000 population per week.
- The commonest specific conditions in this study<sup>1</sup> were lacerations 19%, fractures 11%, injuries from

transport accidents 11%, bronchial asthma 4%, ischaemic heart pain 3.5%, appendicitis 3%.

- The commonest causes of sudden death were myocardial infarction 67%, accidents 10%, cerebrovascular accidents 7%, pulmonary embolism 6%, suicide 4%.
- The main vital emergency procedures were cardiopulmonary resuscitation, intubation and ventilation, intravenous access including cutdown, intravenous (or rectal) dextrose and arrest of haemorrhage.

## Principles of management

The important principles of management of the emergency call can be summarised as follows:

- 1 The practitioner must be aware of life-threatening conditions.
- 2 The practitioner should be prepared mentally and physically:  
PLAN, EQUIP and PRACTISE
- 3 Chest pain/collapse/myocardial infarction (collectively) represents *the* premium emergency call.
- 4 Beware of children with respiratory distress and traumatic injuries.
- 5 The most saveable patients are those with blood loss. Hence IV fluids for intravascular volume expansion are essential.
- 6 The necessary basic skills to cope with most emergencies involve ABC—airway, breathing, circulation.
- 7 Have the equipment and the skills to handle potentially HIV-contaminated body fluids.<sup>2</sup>
- 8 Seventy per cent of cardiac arrests occur in the home so the availability of a portable defibrillator is important.

## Vital basic skills

- 1 Rapid intravenous access
- 2 Cardiopulmonary resuscitation, including upper airway relief, intubation and ventilation, treatment of cardiac arrhythmias and defibrillation
- 3 Cricothyroidotomy
- 4 Arrest of haemorrhage
- 5 Knowledge of usage of common emergency drugs

## Alarming symptoms and signs

- unconsciousness
- convulsions
- chest pain in an adult, especially associated with pallor and sweating
- pallor and sweating in any patient with pain, collapse or injury
- collapse, especially at toilet
- significant haemorrhage
- breathlessness, including bronchial asthma
- the agitated patient threatening homicide or suicide (take a police officer for company)
- asthmatic patients

## Don't forget the value of oxygen

Ideally, the doctor who attends emergency calls should carry an oxygen delivery unit or at least rely on the simultaneous arrival of an ambulance with resuscitation equipment. Most cases require a high flow rate of 8–10 L/minute.

Typical medical emergencies requiring oxygen:

- bronchial asthma
- acute pulmonary oedema
- acute anaphylaxis
- myocardial infarction
- cardiopulmonary arrest
- collapse

## Twelve golden rules

Here are twelve important rules for the diagnostic approach to the emergency call.

- 1 Always consider the possibility of hypoglycaemia and opioid overdose in the unconscious patient.
- 2 Consider intra-abdominal bleeding first and foremost in a patient with abdominal pain who collapses at toilet.
- 3 Acute chest pain represents myocardial infarction until proved otherwise.
- 4 Exclude meningitis and septicaemia in a child with a rather sudden onset of drowsiness and pallor.

- 5 Consider the possibility of a ruptured intra-abdominal viscus in any person, especially a child, with persistent post-traumatic abdominal pain.
- 6 Always consider the possibility of acute anaphylaxis in patients with a past history of allergies.
- 7 Always consider the possibility of depression in a postpartum woman presenting with undifferentiated illness or problems in coping with the baby.
- 8 Always consider ectopic pregnancy in any woman of child-bearing age presenting with acute abdominal pain.
- 9 If a patient is found cyanosed, always consider upper airway obstruction first.
- 10 Beware of the asthmatic who is cyanosed with a 'silent chest' and tachycardia.
- 11 Consider ventricular fibrillation or other arrhythmia foremost in an adult with sudden collapse or dizziness.
- 12 The sudden onset of severe headache adds up to subarachnoid haemorrhage.

## IMPORTANT MEDICAL EMERGENCIES IN ADULTS

This section includes summarised protocols for management of emergencies.

### § Acute anaphylaxis and anaphylactic reactions

Common causes: bee stings, wasp stings, other bites (e.g. imported red fire ants, jack jumper ants), parenteral antibiotics, especially penicillin, food reactions (e.g. peanuts, fish). See FIG. 130.1.

Other causes: allergic extracts, blood products, antivenom, radiological contact materials, anaesthetic agents.

The onset of anaphylaxis from exposure is usually rapid—typically 10–20 minutes. The diagnosis is basically a clinical one.<sup>3</sup>

### Symptoms

- Skin: pruritus—generalised, palate, hands, feet, urticaria, angio-oedema
- Respiratory: wheeze, stridor
- Nausea and vomiting, abdominal pain
- Hypotension: syncope, collapse
- Palpitations
- Sense of impending doom

*Note:* The early danger symptom is itching of the palms of hands and soles of the feet.

FIGURE 130.1 Acute anaphylaxis with respiratory difficulty caused by a European wasp sting

### Differential diagnosis: syncope

Refer to the adult anaphylaxis kit in CHAPTER 80.

### First-line treatment (adults)<sup>3,4</sup>

- Oxygen 8 L/min (by face mask)
- Adrenaline 0.3–0.5 mg (1:1000) IM best given in mid antero-lateral thigh (mg = mL of 1:1000 adrenaline)  
Remove cause (e.g. bee sting) if possible.  
Set up IV access.
- If no rapid improvement:
  - repeat IM adrenaline every 3–5 minutes
  - set up adrenaline infusion: 1 mg adrenaline to 1000 mL N saline (i.e. 1 mL = 1 mcg adrenaline) bolus of 50 mcg (= 50 mL) can be given as required (best with ECG monitor)
- Set up additional IV line (preferably two 'wide bore' lines) and infuse crystalloid solution (e.g. N saline 1–2 L) with bolus (20 mL/kg) over 1–2 min

- Salbutamol aerosol inhalation (or nebulisation if severe), especially if wheeze/stridor
- If very severe add glucagon 1 mg IM or IV
- Admit to hospital (observe at least 4 hours)
- Discharge on diphenhydramine 25 mg qid or promethazine 25 mg tds + prednisolone 50 mg/day for 3 days. Provide an adrenaline autoinjector

### § Angioedema and acute urticaria

Acute urticaria and angioedema are essentially anaphylaxis limited to the skin, subcutaneous tissues and other specific organs. They can occur together.

#### Treatment

- Uncomplicated cutaneous swelling—antihistamines  
e.g. diphenhydramine or promethazine 50 mg (o) or  
25 mg IM if more severe or prednisolone 25–50 mg (o) as a single dose
- Upper respiratory involvement  
adrenaline 0.3 mg SC or IM or 5 mg nebulised

### § Acute cardiogenic pulmonary oedema

Keep in mind the mnemonic LMNOP (lasix, morphine, nitrates, O<sub>2</sub>, CPAP).

- Keep the patient propped up in bed with legs over side
- Oxygen by mask or intranasally (8 L/min)
- Glyceryl trinitrate (nitroglycerin) 300–600 mcg tablet sublingual; can use IV nitrates in preference to morphine (if BP >100 mmHg)
- Insert IV line (large bore cannula)
- Frusemide 40 mg IV, increasing to 80 mg IV as necessary (or twice normal oral dose)
- Morphine 1–2.5 mg IV—usually reserved for chest pain and anxiety
- CPAP (continuous positive airway pressure)—for unresponsive cases or BiPAP (if available)—in ambulance, ED or CCU

Give amiodarone 3–5 mg/kg loading dose IV infusion if rapid atrial fibrillation.

An intravenous infusion of glyceryl trinitrate is superseding morphine use in hospitals.

Note: Keep in mind underlying cause e.g.:

- myocardial infarction (? silent)
- arrhythmia
- cardiomyopathy
- anaemia

## § Severe asthma<sup>4</sup>

Severe asthma is a life-threatening condition that is resistant to standard treatment. It requires intensive medication because of marked obstruction to the air passages, due to severe smooth muscle spasm and inflammation, producing mucosal oedema and mucous impaction. (Refer CHAPTER 82.)

### Initial treatment (summary)

- Oxygen 8 L/min by mask to maintain SpO<sub>2</sub> >95%
- Salbutamol 12 puffs (adult) in a spacer (4 × 4 × 4 rule)  
or
- Continuous nebulised 0.5% salbutamol by face mask, using compressed (8 L/min) oxygen for nebulisation  
↓ insert IV line
- hydrocortisone 250 mg IV or IM  
↓ if poor response
- magnesium sulphate 25–100 mg/kg IV over 20 minutes
- adrenaline 0.5 mg 1:1000 SC or IM or 1:10 000 IV

If not responding, exhausted and moribund:

- intubation with intermittent positive pressure ventilation (IPPV)
- hydration with IV fluids

## § Opioid respiratory depression<sup>4</sup>

- Attend to airway (e.g. pocket mask and bag)
- naloxone 0.1–0.2 mg IV boluses titrated to clinical effect

Beware of recurrence of respiratory depression or neurogenic pulmonary oedema from excess naloxone.

## § Severe hypoglycaemia (confirm by blood glucose)

glucagon 1 mL IM or SC (most practical option)  
then oral glucose—can repeat glucagon

or

50% dextrose 20 mL IV through securely positioned canula (if IV line difficult, administer rectally by pressing the nozzle of a large syringe into the anus and injecting slowly)

## § Myocardial infarction/unstable angina

Refer to CHAPTER 40.

### First-line management

- Oxygen (face mask) 6 L/min
- Insert IV line
- Glyceryl trinitrate (nitroglycerin) 300 mcg (1/2 tab) SL, or spray if BP >100 mmHg
- Aspirin 300 mg (1/2 or 1 tab)
- Morphine 1 mg per minute IV until pain relief (up to 15 mg)—usually 2.5–10 mg (lower dose if elderly/frail)
- ECG (set up by an assistant)
- Arrange ambulance and hospitalisation

## § Hyperventilation

Rebreathe slowly from a paper (not plastic) bag or into cupped hands.

## § Status epilepticus and serial seizures

*Status epilepticus* = repeated convulsions without regaining consciousness after initial tonic-clonic seizure.

*Serial seizures* = repeated convulsions after regaining consciousness.

### Management

(Refer CHAPTER 84.)

- Lie patient on side
- Ensure adequate oxygenation: attend to airway (e.g. Guedel tube); give oxygen 8 L/min (check blood sugar)

If persisting >5 minutes: (summarised)

midazolam 5–10 mg IM or IV over 2–5 minutes

or

midazolam 5–10 mg buccally (tear top off plastic ampoule,<sup>5</sup> slowly drip into patient's mouth between gums and cheek—with syringe or from ampoule)

or

midazolam 5–10 mg intranasal—1–3 drops at a time into alternate nostrils

repeat once in 15 minutes (if necessary)

or

diazepam 0.05 mg/kg/minute IV until the seizures cease or respiratory depression begins (beware of respiratory depression and other vital parameters): usually 10–20 mg bolus in adult

When seizures cease, follow immediately with:

- phenytoin 15–20 mg/kg IV over 30 minutes
- or
- sodium valproate 10 mg/kg by slow IV infusion

Other drugs to consider:

- phenobarbitone, thiopentone

## BITES AND STINGS

Bites and stings from animals, spiders and insects are common in Australia and the US but fatal bites are uncommon.

### Snake bites

Snake bites are more common and severe in those handling snakes and in those trying to kill the snake. Snakes are more aggressive when mating or sloughing their skin (about four times a year). They strike for one-third of their length at 3.5 metres/second. Over 70% of bites are on the legs. Sea snakes are not a major problem in Australian waters.

#### First aid

- 1 Keep the patient as still as possible.
- 2 Do not wash, cut, manipulate the wound, apply ice or use a tourniquet.
- 3 Immediately bandage the bite site very firmly (not too tight). A 15 cm crepe bandage is ideal: it should extend above the bite site for 15 cm (e.g. if bitten around the ankle the bandage should cover the leg to the knee).
- 4 Splint the limb to immobilise it: a firm stick or slab of wood would be ideal.
- 5 Transport to a medical facility for definitive treatment. Do not give alcoholic beverages or stimulants.

*Note:* A venom detection kit is used to examine a swab of the bitten area or a fresh urine specimen but only to identify the snake species involved.

The bandage can be removed when the patient is safely under medical observation. Observe for symptoms and signs of envenomation.

Antivenom for most venomous Australian snakes in addition to a polyvalent vaccine is available <[www.toxicology.com/generic-antivenom.html](http://www.toxicology.com/generic-antivenom.html)>.

#### Envenomation

Not all patients become envenomated and the antivenom should not be given unless there is evidence of this. Envenomation is more likely when the snake has a clear bite, such as in snake handlers or barefooted people or hands placed in burrows.

Apart from non-specific systemic effects (as listed) there may be major organ effects according to the type of snake and its toxin. These include coagulopathy, neurotoxicity, myolysis and kidney damage.

Important early symptoms of snake bite envenomation include:

- nausea and vomiting (a reliable early symptom)
- abdominal pain
- excessive perspiration
- severe headache
- dizziness, blurred vision
- difficulty speaking or swallowing
- coagulation defects (e.g. haematuria)
- tender lymphadenopathy

The greatest danger is respiratory obstruction and failure or unexpected catastrophic bleeding (e.g. intracerebral haemorrhage).

Refer to **FIGURE 130.2** for detailed effects.

#### Investigations and observation

- Careful observations (e.g. vital signs, conscious state)
- Test all urine for blood and protein
- FBE, serum electrolytes, LFTs, KFTs
- Watch for coagulopathy (e.g. spitting and coughing blood, bleeding from wounds/IV site, haematuria)
- Serial whole blood clotting time (a plain glass tube): normal <5–8 min, >15 min significant
- Coagulation screen—APTT and PT or INR
- Venom detection kit: wound site (best) or urine (not always indicator)

#### Treatment of envenomation

See note 2 (below).

- Reassure patient at all times
- Set up a slow IV infusion of N saline
- Keep adrenaline on standby
- Dilute the specific antivenom (1 in 10 in N saline) and infuse slowly over 30 minutes via the tubing of the saline solution
- Have adrenaline, antihistamines, oxygen, and steroids on standby
- Monitor vital signs
- Provide basic life support as necessary

*Note 1:* The use of prophylactic adrenaline is controversial and some authorities reserve it for a reaction to the antivenom. It is best avoided with brown snake envenomation and with coagulopathy.

*Note 2:* Do not give antivenom unless clinical signs of envenomation or biochemical signs (e.g. positive urine, or abnormal clotting profile).

*Note 3:* One ampoule may be sufficient but three or more may be needed, especially if coagulopathy.

FIGURE 130.2 How to recognise snake bite envenomation

## § Spider bites<sup>4</sup>

The toxin of most species of spider causes only localised pain, redness and swelling, but the toxin of some, notably the deadly Sydney funnel-web spider (*Atrax robustus*), can be rapidly fatal.

**Rule:** a bite from a large black spider should be managed initially as for a funnel-web spider.

### First aid

- Sydney funnel-web: as for snake bites
- Other spiders: apply an ice pack, do not bandage

## Treatment

### 1 Sydney funnel-web

Signs of envenomation (in order):

- muscle fasciculation—limb  $\rightarrow$  tongue/lip
- marked salivation or lacrimation
- piloerection
- dyspnoea
- neurological symptoms (e.g. disorientation, coma)

Treatment of envenomation

- specific antivenom (usually 4–8 vials)
- admit to a hospital critical care area
- resuscitation and other supportive measures

## 2 Other spider bites

The toxins of most species of spiders cause only localised symptoms but the venom of a selected few, namely the red-back spider of Australia (*Latrodectus hasseltii*) and the related black widow spider of the US (*Latrodectus mactans*), can cause envenomation. This is rarely fatal but is more serious in the young, the frail and the elderly. The bite wounds are prone to infection.

Treatment of envenomation (rarely needed):

- antivenom given IM or diluted IV injection

130

## § Bee stings

### First aid

- 1 Scrape the sting off sideways with a fingernail or knife blade. Do not squeeze it with the fingertips.
- 2 Apply 20% aluminium sulphate solution (Stingose) or methylated spirits.
- 3 Apply ice to the site.
- 4 Rest and elevate the limb that has been stung.

If anaphylaxis, treat as outlined earlier.

### Preventive measures (if hypersensitive)

- Avoid bees (and wasps) if possible.
- Immunotherapy to honey bee (or wasp) venom. There is no cross-allergy between the honey bee, the 'yellow jacket wasp' and the paper wasp. Specific hyposensitisation against the *Vespula* species is required. For the bee, use pure venom antigen.
- Immunotherapy should be offered to those:
  - with a history of asthma who have had a single severe reaction to a bee sting
  - who have had a minimum of three stings with serial crescendo reactions
  - occupationally exposed who manifest severe reactions
  - with elevated venom-specific IgE (RAST) antibodies, or positive venom prick tests

## § Centipede and scorpion bites

The main symptom is pain, which can be very severe and prolonged. Usually minor systemic symptoms.

### First aid

- 1 Apply local heat (e.g. hot water with ammonia—household bleach).
- 2 Clean site.
- 3 Local anaesthetic (e.g. 1–2 mL of 1% lignocaine) infiltrated around the site.

- 4 Consider opioids—morphine or fentanyl—for pain.
- 5 Consider promethazine injection.
- 6 Check tetanus immunisation status.

## § Box jellyfish or sea wasp (*Chironex fleckeri*)<sup>4</sup>

This is the most dangerous jellyfish in Australian waters and has been responsible for at least 80 extremely painful and sudden deaths.<sup>4</sup> Death can occur in minutes due to cardiopulmonary failure, especially in children. There can be up to 180 metres of stinging tentacles. The sting gives a 'frosted ladder' appearance. The jellyfish is limited to tropical waters north of the Tropic of Capricorn (Exmouth in west to Gladstone in east) and is found in coastal waters during the summer.

### Prevention

- Avoid swimming, paddling and wading in 'jellyfish alert' areas in unsafe months.
- Otherwise, use a 'stinger suit'.

### Treatment<sup>4</sup>

- The victim should be removed from the water to prevent drowning.
- Immediately remove tentacles.
- Pour vinegar liberally to sting site and surrounding area—use up to 2 L of vinegar at a time.
- Use a cold pack for small stings and ice massage for large areas.
- Check respiration and the pulse.
- Start immediate cardiopulmonary resuscitation if necessary.
- Gain IV access and give magnesium sulphate 50%; give oxygen and up to 5 mL inotropes if necessary.
- Give box jellyfish antivenom by IV injection for major stings (may need at least 6 ampoules if patient remains in cardiac arrest).
- Provide pain relief if required (ice, lignocaine and analgesics—fentanyl or morphine).

*Note:* A delayed reaction can occur—the stings can cause pain after weeks (oral steroids are used).

Pressure immobilisation bandaging is no longer recommended for *Chironex* stings.

## § Irukandji syndrome<sup>4</sup>

This is caused by *Carukia barnesi*, a tiny box jellyfish that can penetrate safety nets for *Chironex*, and

possibly other species of box jellyfish. Initially a mild sting with a delayed severe syndrome (usually after 30 minutes):

- severe generalised back, abdominal and muscle pain and muscle cramps
- chest pain, sweating and anxiety
- anxiety, restlessness, 'impending doom' feeling
- headache, nausea, vomiting
- tachycardia, hypertension

There is no specific first aid or antivenom but resuscitation measures may be needed as death can occur from pulmonary oedema or cardiac arrest. Measures include morphine or fentanyl 5 mg IV every 5 minutes as required, blood pressure control (e.g. phentolamine, CPAP and oxygen for pulmonary oedema) and possibly IV magnesium.

### § Common jellyfish stings<sup>4</sup>

These include bluebottle (*Physalia* species) and others that cause intense local pain (up to an hour or more) and linear skin redness. Systemic effects are uncommon.

#### Treatment

- Wash the sting site with sea water.
- Remove any tentacles with gloved hands or water.
- Immerse affected site in hot water at 45°C for 20 minutes. This is quite hot so check tolerance to temperature on other limb.
- Vinegar is not helpful.

### § Stinging fish<sup>4</sup>

The sharp spines of the stinging fish have venom glands that can produce severe pain if they spike or even graze the skin. The best known of these is the stonefish. Others include bullrout, catfish, sea-urchins and crown of thorns (may need an X-ray). The toxin is usually heat-sensitive. Stingrays cause a gash wound with possible superinfection.

#### Envenomation

- Intense pain
- Localised swelling
- Bluish discolouration

#### Treatment

- Clean the wound—consider exploration.
- Bathe or immerse the affected part in very warm to hot (not scalding, 45°C) water—this may give instant relief.<sup>4</sup>
- Give simple analgesics.

- If pain persists, give a local injection/infiltration of lignocaine 1% or even a regional block. If still persisting, consider morphine IV or fentanyl IV.
- A specific antivenom is available for the sting of the stonefish. Best given IV by slow infusion in CCU.

### § Mollusc bite (blue-ringed octopus, cone shell)<sup>4</sup>

Mollusc venoms usually cause numbness or paraesthesia but can be rapidly fatal because of prolonged muscular weakness leading to respiratory paralysis.

#### Treatment

- Compression bandage to bite site (usually hand/arm)
- Immobilise the limb
- Arrange transport (preferably by ambulance) to a medical facility
- Observe (and manage) for respiratory paralysis—ensure adequate ABC

### § Sandfly bites

For some reason, possibly the nature of body odour, the use of oral thiamine may prevent sandfly bites.

*Dose:* thiamine 100 mg orally, daily

### § Other bites and stings

This includes bites from ants, wasps and mosquitoes.

#### First aid

- 1 Wash the site with large quantities of cool water.
- 2 Apply vinegar (liberal amount) or aluminium sulphate 20% solution (Stingose) to the wound for about 30 seconds.
- 3 Apply ice for several minutes.
- 4 Use soothing anti-itch cream or 5% lignocaine cream or ointment if very painful.

Medication is not usually necessary unless an acute allergic reaction develops.

### § The embedded tick<sup>4</sup>

Some species of ticks can be very dangerous to human beings, especially to children. In Australia, tick paralysis is confined to the eastern seaboard. Be careful in children 1–5 years—they are usually found in the scalp behind the ears. If they attach themselves to the head or neck, usually behind the ear, a serious problem

exists. As it is impossible to distinguish between dangerous and non-dangerous ticks, early removal is mandatory. The tick should be totally removed—and the mouthparts of the tick must not be left behind. Do not attempt to grab the tick by its body and tug. This is rarely successful in dislodging the tick, and more toxin is thereby injected into the host.

As an office procedure, many practitioners grasp the tick's head as close to the skin as possible with fine forceps or tweezers, and pull the tick out sideways with a sharp rotatory action. This is acceptable, but not as effective as the methods described here.

130

### First aid outdoor removal method

- Loop a strong thin thread (as a half-hitch lasso) around the tick's head as close to the skin as possible, and pull sharply with a twisting motion. Suitable materials include strong silk sutures or dental floss.
- A pyrethrin-based spray is often used.

### Office procedure

- Infiltrate a small amount of local anaesthetic into the skin around the site of embedment.
- With a number 11 or 15 scalpel blade, make the necessary very small excision, including the mouthparts of the tick, to ensure total removal (see FIG. 130.3).
- The small defect can usually be closed with a bandaid (or Steri-Strips).
- Careful observation is needed after removal.

FIGURE 130.3 Removing the embedded tick

### Human bites and animal bites

These bites can cause problems of suppurative infection and management in general. They are outlined in CHAPTER 134.

## A POTPOURRI OF EMERGENCY CALLS

### Electric shock

#### Facts

- Direct current (DC) from welding machines or lightning produces more electrolyte tissue damage and burns than AC (domestic supply).
- Injuries occur at sites distant from entry or exit.
- Severe muscle contractions can cause bone fracture or posterior dislocation of the shoulder.
- Household shocks tend to cause cardiac arrest (ventricular fibrillation) and myocardial damage is common.
- Ischaemic necrosis of a limb or digit is possible.
- Apparently minor initial injuries may be very misleading (see FIG. 130.4).
- Neurological deficits and psychoneurotic sequelae are common in survivors.

FIGURE 130.4 Effect of electric shock passing through the body

### Principles of management

- Make the site safe: switch off the electricity. Use dry wool to insulate rescuers.
- 'Treat the clinically dead'.
- Attend to ABC.
- Give a precordial thump in a witnessed arrest.
- Consider a cervical collar (? cervical fracture).

Bystander CPR and prolonged respiratory support for electric shocks and lightning strike can be lifesaving.

- Provide basic cardiopulmonary resuscitation, including defibrillation (as required).
- Investigate and consider:
  - careful examination of all limbs
  - X-ray of limbs or spine as appropriate
  - check for myoglobinuria and kidney failure
  - give tetanus and clostridial prophylaxis
- Get expert help—intensive care unit, burns unit.

## § Lightning strike

### Prevention (during an electrical storm)

- Don't shelter under trees or tall objects (splash phenomenon—see FIG. 130.5).<sup>6</sup>
- Stay indoors—shelter in a building or closed car.
- Avoid using telephone.
- Avoid holding metal objects (e.g. golf clubs).
- Keep as low to ground as possible (e.g. curl up in a ditch).
- Avoid being in a group.

FIGURE 130.5 'Splash effect' where current is reflected from tree

### Clinical effects

- Burn injury (90%): the 'flashover' phenomenon—clothing disintegrates
- Blast injury (e.g. ruptured spleen, subdural, ruptured eardrum)
- Electrical injury as for household shock (uncommon)

## § Petrol and solvent sniffing

Substances commonly sniffed include petrol, glues, spirit-based paints, paint spray cans and other aerosols.

The three main acute problems are:

- 1 shaking and fitting: give midazolam IV or IM or diazepam IV (as for convulsions)
- 2 agitation/aggressive behaviour, self-harm: try to calm patient in a well-lit room; give sedation with diazepam; give haloperidol for hallucinations or delusions
- 3 general debilitation: this may include acute infections (e.g. chest infection) or anaemia; investigation and referral for breaking the habit is necessary

## § Near-drowning<sup>4</sup>

Near-drowning is survival after asphyxia from submersion in a liquid medium. Hypoxia is the final common pathway in drowning or near-drowning, whether by water aspiration (wet drowning) or by glottic closure (dry drowning).

The rule to remember is that victims can respond to resuscitation after considerable immersion time (up to 30 minutes) and that mouth-to-mouth resuscitation should always be attempted even if pulseless or with fixed dilated pupils. The usual routine of basic life support and CPR apply. All symptomatic patients should receive high-flow oxygen and ideally CPAP or BiPAP. Those requiring intubation should receive positive end expiratory pressure (PEEP) in an in-patient facility.

Artificial surfactant given via an endotracheal tube has been used successfully in the UK.

There is no significant difference in outcome and management between salt water and fresh water drowning. Hypothermia should be attended to with warming, such as a hot-air blanket if available and warm fluids.

## § Epistaxis

Refer to CHAPTER 59.

## § Opioid (heroin) overdose

Refer to CHAPTER 75 and earlier in this chapter.

§

Migraine

Refer to CHAPTER 56.

### Vital emergency skills

#### Cardiopulmonary resuscitation

**Cardiopulmonary arrest (CPA)** It is essential that all doctors are familiar with the protocol for instituting basic life support in such an eventuality. Sick patients do visit our offices daily and the potential for sudden collapse, including a cardiac arrest, is ever present. About 75% of arrests are due to ventricular fibrillation and more than 75% of victims have severe coronary artery disease.<sup>7</sup> After 3 minutes of CPA (unconsciousness, no pulse, no respiration) there is an increasing risk of permanent cerebral dysfunction.

Important causes of sudden death are outlined in TABLE 130.1.<sup>8</sup>

The ABC basic life support for cardiac arrest should be followed, but DRABCD is best (defibrillation first if a defibrillator is available—the outcome appears to be directly related to the speed of defibrillation). The ‘chain of survival’ principle for a victim of out-of-hospital cardiac arrest is presented in FIGURE 130.6.

#### Basic life support<sup>9</sup>

The following represents a logical DRSABCD plan for the adult patient who collapses or is found apparently unconscious.

- D = assess Danger
- R = assess Response
- S = Send for help
- A = Airway open

Table 130.1 Causes of sudden death

- Cardiac arrhythmias:
- ventricular fibrillation (75%)
  - ventricular tachycardia
  - torsade de pointes VT (? drugs)
  - sick sinus syndrome
  - severe bradycardia
- Sudden pump failure:
- acute myocardial infarction
  - cardiomyopathy
- Cardiovascular rupture:
- myocardial rupture
  - dissecting aneurysm of aorta
  - subarachnoid haemorrhage
- Acute circulatory obstruction:
- pulmonary embolism
- Others:
- aortic stenosis
  - pulmonary hypertension
  - mitral valve prolapse
  - electrolyte abnormalities
  - glue sniffing

- B = Breathing  
C = Circulation/CPR  
D = Defibrillation

- 1 Shake and shout at the patient.
- 2 Check breathing.
- 3 Check pulse (feel carotid adjacent to thyroid cartilage).
- 4 Call for help (if no pulse). Ring 000 (or 112 from mobile services) or 911.
- 5 Finger sweep oropharynx (clear it).
- 6 Place victim on back on firm surface.
- 7 Thump precordium (if arrest witnessed).
- 8 Tilt head back (to maximum).

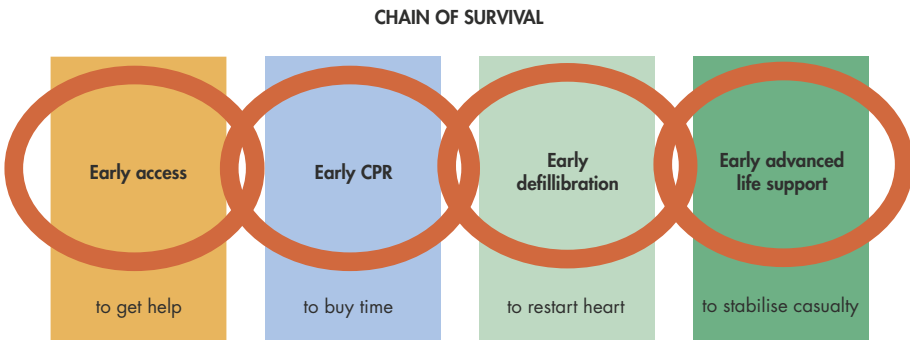

FIGURE 130.6 The chain of survival for a victim of out-of-hospital cardiac arrest

**Table 130.2** Basic schedule for CPR

	Infant <1 year	Child	Adult
Compression (rate per min)	100	100 (large) 100 (small)	100
Depth of compression (cm)	2–3	3–4	4–5
Position of compression	Centre sternum	Centre sternum	4 cm above xiphisternum
Method	2 fingers	1 hand	2 hands
Ventilation (rate per minute)	20	16	12
Head tilt	Nil	Mid	Full

- 9 Lift chin (use airway if available).
- 10 Commence basic life support:
- rescue breaths (RBs)—2 strong breaths
  - external chest compressions (no pause)—30 compressions
  - continue alternating 30 compressions (at rate of 100 beats/min) with 2 strong breaths

Attach automated external defibrillator (if necessary).

*Note:* The ratio of 30:2 with one or two rescuers is favoured. Some authorities recommended continuous compression only. This is most appropriate for the untrained resuscitator.

The basic schedule for cardiopulmonary resuscitation is presented in **TABLE 130.2** and a flow chart for basic life support in **FIGURE 130.7**.

*Note:* Check the International Liaison Committee on Resuscitation (ILCOR) guidelines <www.ilcor.org>.

## Method of rescue breathing/ventilation

With the victim's head in the 'sniffing the morning air' position (head totally tilted back and chin pulled forward) the rescuer takes a deep breath and seals his or her lips around the mouth or nose of the victim. Pinch the victim's nose if using mouth-to-mouth resuscitation. Two full puffs are given within a few seconds (see **FIG. 130.8** and **130.9**). Rescue breathing/ventilation is the only method of artificial respiration that successfully ventilates the patient.<sup>7</sup> If the chest does not move easily, obstruction is present. If available a sucker should be used to clear the oropharynx. Firmly fitting dentures should be left in place as they make artificial respiration easier. A Resuscitube or Laerdal pocket mask (which should be in the doctor's bag) is ideal for EAR; it saves mouth-to-mouth contact and probably improves the efficacy of ventilations.

**FIGURE 130.7** Basic life support algorithm

Source: Adapted from Australian Resuscitation Council material

## External chest compression

Evidence supports the need to maintain cardiac compression following a cardiac arrest. This should be commenced on any person who is not responsive and not breathing normally.

Compressions are safely performed by finding the xiphisternal notch then placing the broad heel of one hand over the lower half of the sternum (in adults) with the heel of the second hand placed over the first with the fingers interlocked. Remember to keep the arms and elbows straight as the sternum is rhythmically depressed for 4–5 cm. Try to keep to this position as 'wandering' causes fractured ribs or worse. The fingers must be kept off the chest.

For optimal airway patency:

- 1 Clear foreign matter from mouth: use finger sweep from airway; blow between shoulder blades consider a Heimlich manoeuvre
- 2 Lay patient supine on flat, firm surface (A). Note how the soft tissue of the pharynx can obstruct the airway by falling backwards.

- 3 In order to overcome this, apply a head lift (B) plus a chin lift (C) or jaw thrust manoeuvre. (Note: avoid excessive movement of the neck if spinal injury is suspected, but clearing the airway has first priority.)

Slight flexion of the neck with small cushion

FIGURE 130.8 Basic life support: A = Airway

Maintain the compression for 0.5 seconds, then relax—compressions should be smooth, regular and uninterrupted.

Check pupil size and reaction to light and the carotid or femoral pulse. The compressions should ideally produce an impulse in the femoral pulse. Another person can check for carotid or femoral pulsation during CPR (see FIG. 130.10).

### Maintenance of CPR

Consider ceasing CPR if there is no improvement in 30 minutes. Exceptions where prolonged CPR can be successful are cold water drowning, marine envenomation, snake bite, and certain poisonings (e.g. cyanide and organophosphate).

Rescue breathing:

- 1 Five full breaths within 10 seconds.
- 2 Observe rise of chest, not of abdomen.
- 3 Look, listen and feel for exhalation.
- 4 Check the carotid pulse.
- 5 If no pulse, commence full cardiopulmonary resuscitation.

FIGURE 130.9 Basic life support: B = Breathing

### Advanced cardiac life support

Advanced life support depends on the availability of skilled personnel and appropriate equipment.

Optimal initial support involves:

- airway management
- endotracheal intubation (otherwise bag and oxygen)
- ECG monitoring
- intravenous access (large peripheral or central vein)

Optimal initial therapy involves:

- defibrillation
- oxygen
- cardioactive drugs, especially adrenaline

If an ECG recording is unavailable the best course of action is:

- defibrillation if unsuccessful
- adrenaline IV, repeat every 3 minutes

Consider anti-arrhythmic agents—amiodarone, lignocaine, magnesium.

### Advanced life support: defibrillation<sup>9,10</sup>

- Minimise interruptions to chest compressions.
- Give a single shock instead of stacked shocks (single shock strategy) for ventricular fibrillation/pulseless ventricular tachycardia.
- Where the arrest is witnessed by a health care professional and a manual defibrillator is

(a)

- 1 If carotid or femoral pulse is absent, immediately commence external cardiac compression
- 2 See FIGURE 130.7 for rhythm.

(b)

External cardiac compression with fingers locked (a), and with fingers extended (b). Heel of one hand placed on lower sternum 2 finger breadths above the xiphoid sternal junction. Heel of second hand placed on first. Ensure fingers don't exert pressure. The patient should be lying on a firm surface, the operator level with shoulder.

130

FIGURE 130.10 Basic life support: C = Circulation

available, then up to three shocks may be given (stacked shock strategy) at the first defibrillation attempt.

- Biphasic defibrillation (usually biphasic at 360 joules)—where specific devices have been identified to be efficacious at other energy levels these should be used if known. *However*, where the health care professional is unsure of the energy level recommended for a specific device, a default energy level of 200 J should be used without delay.
- After each defibrillation attempt give 2 minutes of CPR before checking rhythm and pulse.

For defibrillation, two paddles or pads should be placed correctly on the chest wall, using one of two positions:

- one to right of upper sternum (under right clavicle) and the other over the apex of the heart (see FIG. 130.11)
- one over anterior wall of chest and the other under tip of left scapula

Hairs on the chest should be shaved to accommodate the paddles.

### Urgent intravenous access

It is preferable to aim for transcutaneous cannulation of veins initially so a peripheral line should be

FIGURE 130.11 Standard position of two paddles for defibrillation: A under right clavicle, B under left breast

introduced into a vein in the cubital fossa. Several lines may be required with massive blood loss.

Alternative routes:

- central venous cannulation: most doctors should be able to cannulate the external jugular vein with a standard cannula
- peripheral venous cutdown
- intraosseous infusion (see CHAPTER 96)

## Disaster medicine

The frequency of disasters and the number of people affected by them are increasing. This is due to a number of factors, including increased media coverage, global movement of populations, and human habitation in more disaster-prone areas.

Disaster management is a crucial, rapidly expanding discipline in the world of general practice. 'The World Medical Association recommends that disaster medicine training be included in the curricula of university and postgraduate courses in medicine.'<sup>11</sup>

Disaster situations 'from the medical standpoint . . . are characterised by an acute and unforeseen *imbalance* between the capacity and *resources* of the medical profession and the *needs* of survivors who are injured, or whose health is threatened, over a given period of time'.<sup>12</sup>

Disaster management differs relative to the time of disaster impact with four phases to be considered: prevention, preparedness (disaster impact), response and recovery (PPRR). Management may also vary depending on the hazard that caused the disaster such as bushfire, flood, heat wave, drought, nuclear accident or terrorism.

### Key facts and checkpoints

- Preparedness:
  - Evidence shows that preparedness helps in recovery.<sup>13</sup>

- Response:
  - It is valuable for GPs to maintain an up-to-date vulnerable patients list.
  - Maintenance of business-as-usual is the most crucial GP response.
- Recovery:
  - May take days, weeks, months, years or decades.
  - Most people recover with limited to no assistance.
- Self-care:
  - GPs could be considered a vulnerable group during a disaster in their community.

### A systematic approach

It is useful to consider a GP's role according to the four phases of disaster, PPRR. In order to do this a general practice would benefit from an emergency response plan or disaster plan.<sup>14</sup>

During the acute event there are emergency response systems, including fire, ambulance and police services. It is important that GPs recognise these systems and work with them to provide the most benefit, and to avoid the risk of potential harm to themselves, the patients or other responders.

In an isolated area, the GP may be the only respondent for a considerable time. In this situation triage and improvisation are important.

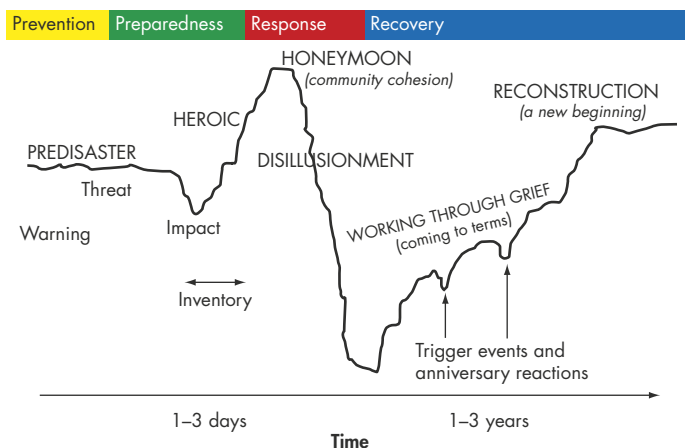

FIGURE 130.12: Phases of disaster: a storyline of disasters over time shows both the phases of disasters (B&W) and prevention/preparedness/response/recovery (PPRR) (colour)<sup>12</sup>

Source: Reproduced in adapted form after modification from RJ Ursano et al;<sup>12</sup> *Training Manual for Human Services Workers in Major Disasters* (2nd edn). Washington DC: Department of Health and Human Services, Substance Abuse and Mental Health Services Administration, 2000; and RJ Ursano et al.: page 8<sup>12</sup>

## Recovery

### In the first weeks

There is distress, denial and disbelief, lasting days to weeks. Most people will recover. Some will require minimal support; a few will require greater support.

In order to reduce distress due to a traumatic experience, psychological first aid (PFA) aims to improve short-term and long-term functioning. It is evidence-informed and endorsed by the World Health Organization (WHO) and the Australian Red Cross.<sup>15</sup>

### Psychological first aid (PFA)

PFA requires no psycho-education. It involves:

- ensuring individuals are physically safe, with shelter and basic human needs
- comforting and quietly listening to what individuals want to say. It is *not* asking individuals to talk about what happened, or telling them it is good for them to talk about it
- connecting individuals with loved ones or friends
- orientating individuals to goals to improve the sense of efficacy—small, practical, achievable tasks assist the return to normal routine<sup>15</sup>

PFA is not *critical incident stress debriefing*, which has not been shown to be useful, and may even be harmful to some individuals.

### In the following weeks, months and years

As mentioned above, most patients and families will recover unassisted. Physical and mental health effects of a disaster may coexist in the aftermath.<sup>16</sup> A key element is surveillance for deterioration of chronic conditions, emerging mental and physical health conditions,<sup>16</sup> and for increased substance use in the aftermath.

Supporting children is best done by supporting their parents<sup>17</sup> and by assisting them to return to a normal routine.<sup>18</sup> Recurrent viewing of the event on media is not recommended.

Disasters divide lives in two; for some the effects may endure for decades, or span generations, depending on the characteristics of the individuals, the families and the disaster.<sup>19</sup>

*Almost everyone who goes to bed counts upon a full night's rest: like a picket at the outposts, the doctor must be ever on call.*

Karl F Marx (1796–1877)

GPs who perform home visits and nursing home visits require the traditional doctor's bag that includes the basic tools of trade, drugs (including those for emergency use), stationery and various miscellaneous items. Country doctors will by necessity use their bag for more emergency home and roadside calls. These recommended contents are simply a guide for cross-checking.

## Essential requirements for the bag

- Sturdiness
- Lockable (e.g. combination lock)
- Ready interior access
- Uncluttered
- Disposable single-use items
- Light, portable equipment
- Regular checks to ensure non-expired drugs
- Storage in a cool place (not boot of car)

## Stationery (checklist)

- Practice letterhead and envelopes
- Prescription pads
- Hospital admission forms
- Sickness/off-work certificates
- X-ray, pathology referral forms
- Accounting forms
- Dangerous drugs record books
- Continuation notes
- Large adhesive labels to record visit (attach later to patient's history)
- Tie-on labels for emergencies
- Recommendation forms (to psychiatric/mental hospitals)
- Pens

## Miscellaneous items

- Quick reference cards:
  - the doctor's bag checklist<sup>1,2</sup>
  - dosage details of drugs, all age groups
  - important telephone numbers

- Local map
- Phonecard or coins for public telephone use
- Handbook of emergency medicine

## Equipment

- Sphygmomanometer (aneroid)
- Stethoscope
- Pulse oximeter
- Diagnostic set (auriscope + ophthalmoscope)
- Tongue depressors
- Tourniquet
- Small needle-disposal bottle
- Scissors
- Syringes 2, 5, 10 mL
- Needles 19, 21, 23, 25 gauge
- Scalp veins (butterfly) needles
- IV cannulae 16, 18, 20 gauge
- Alcohol swabs
- Micropore tape
- Thermometer
- Spacer (e.g. Volumatic, for asthma)
- Artery forceps
- Urine testing sticks
- Pathology specimen bottles
- Skin swabs, throat swabs
- Torch
- Patellar hammer
- Oral airway (e.g. Revivatube, Resuscitube—[FIG. 131.1](#), Guedel)
- Laerdal pocket mask ([FIG. 131.2](#))
- Scalpel (disposable)
- File (for glass ampoules)
- Examination glove

## Drugs

### Drugs (oral)

- Samples of commonly used:
  - analgesics
  - antibiotics
  - antidiarrhoeal agents

FIGURE 131.1 The two-way Resuscitube

- anti-emetics
- antihistamines
- sedatives
- Glyceryl trinitrate (nitroglycerin)
- Soluble aspirin (for myocardial infarction)
- Sumatriptan (Imigran)

### Drugs (sprays)

- Glyceryl trinitrate
- Salbutamol aerosol (see Spacer)

### Drugs (topical)

- Anaesthetic eyedrops

### Drugs (injectable)

Refer to TABLE 131.1.

A study conducted by Johnston et al.<sup>3</sup> of 512 Queensland GPs revealed the range of emergency equipment and essential drugs carried with indications of those items considered essential. The most common emergencies were acute asthma, psychiatric emergencies, seizures, hypoglycaemia, anaphylaxis, impaired consciousness, shock, poisoning and overdose. Most GPs stocked at least 15 of the 16 emergency doctor's bag drugs. The drugs used most were adrenaline, benzotropine, diazepam, glucagon, haloperidol, hydrocortisone, naloxone and salbutamol (inhaler).

The issue of what drugs to carry is always an interesting intellectual exercise. It could reduce to just a few items such as adrenaline, diazepam, naloxone and morphine. It is advisable not to carry pethidine

FIGURE 131.2 The Laerdal pocket mask

as morphine can be used for kidney and biliary colic since it does not aggravate spasm. An alternative injectable analgesic to the traditional opioids is tramadol (available as 100 mg/2 mL injection).<sup>4</sup>

### Drugs (suppositories)

- Indomethacin

## The country doctor's bag

Country doctors, especially in isolated areas, usually carry additional equipment in their motor vehicles when called to the scene of an accident or other emergency. The equipment will vary according to geographic factors, the ambulance service and the special interests and enthusiasm of the practitioner.

FIGURE 131.3 Home visit to a 25-year-old woman with acute urticaria caused by an upper respiratory viral infection. Given 25 mg promethazine IM for severe pruritus and vomiting.

**Table 131.1** Drugs available on PBS (except those marketed #) <www.pbs.gov.au/browse/doctorsbag><sup>5,6</sup>

Drug	Presentation	Indications
Adrenaline*	1 mg/mL (1:1000)	Hypersensitivity reactions and anaphylactic shock, bronchial asthma <sup>†</sup> , ventricular asystole, croup, ventricular fibrillation (to assist CPR)
Atropine sulphate	0.6 mg/1 mL	Bradycardia (after myocardial infarction), 2nd or 3rd degree heart block, ureteric colic <sup>†</sup> , organophosphate poisoning
Benztropine mesylate*	Cogentin 2 mg/2 mL	Acute dystonic reactions
Benzylpenicillin*	3 g with 10 mL water	Meningococcaemia, pneumonia (adults)
Ceftriaxone#	2 g powder with 10 mL solvent	Meningococcaemia, septicaemia
Dexamethasone	4 mg/1 mL	Severe asthma (esp. elderly), moderate to severe croup, anaphylaxis, acute Addisonian crisis
Diazepam*	10 mg/2 mL	Status epilepticus and other convulsions such as eclampsia, sedation in acute anxiety and severe tension headache, psychiatric emergencies including acute alcohol withdrawal
Dihydroergotamine	1 mg/mL	Severe migraine, cluster headache
Ergometrine maleate	0.25 mg/1 mL	Uterine bleeding, abortion or postpartum haemorrhage
Frusemide*	Lasix 20 mg/2 mL	Left ventricular failure, acute pulmonary oedema
Glucagon*	1 mg + 1 mL solvent	Hypoglycaemia (insulin or oral therapy)
Glucose#	50% (500 mg/mL in 50 mL)	Hypoglycaemia
Glyceryl trinitrate	Inhaler 400 mcg/dose	Acute coronary syndrome
Haloperidol*	Serenace 5 mg/1 mL	Psychiatric emergencies such as severe agitation, psychoses; migraine
Hydrocortisone sodium succinate*	Solu-Cortef 100 mg/2 mL 250 mg/2 L	Anaphylaxis, severe asthma, Addisonian crisis, thyrotoxic crisis, acute allergies
Methoxyflurane	3 mL pack with inhaler	Analgesia for acute pain
Midazolam#	5 mg/1 mL	As for diazepam
Metoclopramide* or	Maxolon 10 mg/2 mL	Severe vomiting (e.g. Meniere syndrome, gastritis), acute labyrinthitis, migraine
Prochlorperazine	Stemetil 12.5 mg/mL	
Morphine sulphate*	15 mg/1 mL or 30 mg/1 mL	Acute pulmonary oedema, relief of severe pain (e.g. cardiac pain, colics)
Naloxone (more than one ampoule)*	Narcan 0.4 mg/mL	Opiate respiratory depression

Drug	Presentation	Indications
Promethazine*	Phenergan 50 mg/2 mL	Acute allergic conditions (see FIG. 131.3), anti-emetic†
Salbutamol*	MD Inhaler and/or nebuliser solution	Bronchial asthma, other bronchospasm
Tramadol	100 mg/2 mL	Moderate to severe pain
Water	5 mL	diluent

\*Essential drugs

† May be useful as an alternative drug

# Drugs not supplied as PBS doctor's bag items

All drugs listed are injectable except salbutamol inhaler

Note: The author recommends the MIN-IJET syringe packs for ideal emergency use. The range includes naloxone 5 mL, aminophylline, atropine, adrenaline, dextrose, lignocaine, isoprenaline, sodium bicarbonate

## Storage of drugs

The main issues are safe storage of opioid drugs, avoidance of overheating (keep <25°C), accessibility in emergencies and careful recording of Schedule 8 drugs in a register. Diphtheria and tetanus vaccines should be stored in a refrigerator.

## Emergency drugs

The value of emergency drugs for the doctor's bag continues to be debated. Essential drugs are highlighted in TABLE 131.1. One challenging paper<sup>5</sup> suggest that drugs such as benzyl penicillin, procaine penicillin, diazepam, haloperidol, chlorpromazine, frusemide and tramadol be replaced. The recommended more appropriate options would be ceftriaxone or cefotaxime (for severe infections), midazolam, olanzapine and amiodarone, while CPAP or BIPAP is preferable to frusemide for acute ventricular failure.

### Medical emergencies in general practice—a management proposal

Note: Using basic equipment and doctor's bag (mainly adult dosages)

#### Don't forget:

- Secure IV line (may need rapid bolus N saline)
- Oxygen
- Measure vital signs

#### Acute cardiogenic pulmonary oedema (ventricular failure)

Frusemide 40–80 mg IV (or twice usual dose)  
Glyceryl trinitrate 1 dose (spray)  
Consider (especially if chest pain)—morphine 2.5–5 mg IV

#### Acute anaphylaxis

Adrenaline 0.3–0.5 mg (1:1000) IM, repeat every minutes as necessary or set up adrenaline infusion (see CHAPTER 130)

If no rapid improvement:

- salbutamol inhalation
- IV fluids
- ? hydrocortisone/glucagon

#### Angio-oedema and acute urticaria

Promethazine 25 mg IM

#### Asthma

Salbutamol 6 (<6 years)–12 (adults) puffs by spacer

Hydrocortisone 200 mg IV

If severe:

- adrenaline 0.3–0.5 mg 1:1000 IM or SC or infusion

#### Croup (severe)

Dexamethasone 0.15 mg/kg IM or prednisolone 1 mg/kg (o)

#### Epilepsy (seizure)

Diazepam 5–20 mg IV or midazolam 0.2 mg/kg IM

#### Opiate respiratory depression

Naloxone HCl 0.4 (or 0.2) mg IV + 0.4 mg IM

#### Acute coronary syndrome

Aspirin 300 mg soluble tab  
Glyceryl trinitrate spray or tablets (max. 3)

If pain, morphine sulphate 2.5–5 mg IV + metoclopramide

#### Hypoglycaemia

Glucagon 1 mg/mL SC, IM or IV, then sweet drink or 20–30 mL 50% glucose IV

#### Migraine (severe)

Prochlorperazine 12.5 mg IV or

continued

<b>Cluster headache</b>	Metoclopramide 10 mg IV $\pm$ dihydroergotamine IV or IM
	or
<b>Movement disorders (from antipsychotic medication)</b>	Haloperidol 5 mg IM or IV
	100% oxygen 6 L/min for 15 minutes
<b>Meningococcaemia</b>	Metoclopramide 10 mg IV
	Benztrapine 1–2 mg IV or IM
<b>Ureteric colic</b>	Benzylpenicillin 60 mg/kg IV
	Morphine 10–15 mg IM or IV $\pm$ metoclopramide
<b>Vertigo (acute)</b>	Indomethacin suppository
	Prochlorperazine 12.5–25 mg IM or promethazine 25 mg IM
<b>Vomiting</b>	Prochlorperazine 12.5 mg IM or IV or metoclopramide 10 mg

### Practice tips

- Check your doctor's bag every month for drugs that may be expired, damaged or in short supply (your practice nurse can do this).<sup>6</sup>
- Replace any used drugs or materials the day after use.

- Always have your bag handy but don't carry it in the car in hot weather. It is best to be able to grab it from a safe, accessible spot when you leave for an emergency.
- Security is an issue. Drugs of addiction (tramadol and morphine) may be kept separate and then taken from their secure place when their use is anticipated (e.g. myocardial infarction, severe biliary or kidney colic). Tramadol appears to be a satisfactory alternative but beware of the serotonin syndrome.
- Keep a spare kit in your surgery if you or your assistants or locums perform a lot of emergency work.
- Familiarise yourself with the layout of your bag (including ampoule files) so that using it in urgent circumstances is efficient.
- Use a large intravenous cannula wherever possible if rapid infusion is required.

## Glossary of terms

**Stroke** A focal neurological deficit lasting longer than 24 hours caused by intracerebral haemorrhage or infarction.

**Stroke in evolution** An enlarging neurological deficit, presumably due to infarction, which increases over 24–48 hours.

**Transient cerebral ischaemic attack (TIA)** A transient episode of neurological dysfunction caused by focal brain or retinal ischaemia without infarction.<sup>1</sup>

## Key facts and checkpoints

- A stroke or TIA must be considered a medical emergency.
- One in 10 patients with a TIA is likely to have a stroke shortly afterwards—usually within 2 weeks and most within 48 hours. The risk is greatest if older than 60, symptoms last more than 10 minutes and there is weakness or a speech impediment with the TIA.<sup>2</sup>
- Clinical assessment (including neurological examination) investigations and treatment should be commenced quickly.
- The best approach to stroke management is aggressive attention to primary and secondary prevention.
- The main risk factors for stroke are atrial fibrillation, hypertension, smoking, age and diabetes.
- Cardiac disease is now a more recognised source of emboli.
- Most patients with a stroke or TIA require urgent imaging to find the cause and guide treatment.
- Ideally patients should be referred to a stroke unit ASAP—within 3 hours.
- Consider the possibility of a cryptogenic stroke,<sup>1</sup> especially from a patent foramen ovale (PFO) (in 20–25% of population and responsible for 50% of these strokes) in relatively young people presenting

with a stroke: this leads to paradoxical emboli (from veins to the brain). PFOs may be detected by echocardiography and sealed with a percutaneous closure device.

- Consider the possibility of endocarditis if there is a heart murmur.
- Order a CT or MRI scan on all patients with suspected TIAs and strokes (if not referring to a stroke unit): if normal repeat in 7 days (CT scans unreliable after 7 days). Such imaging is required to differentiate between ischaemia and haemorrhage.
- Keep in mind atherosclerotic disease of aortic arch as a source of cerebral embolism.
- The place of carotid endarterectomy for asymptomatic carotid stenosis remains controversial. It should be seriously considered if the stenosis is severe, the risk of surgery is low (3% risk of major stroke), the team has proven expertise and the patient is medically fit with a good life expectancy.<sup>1</sup>
- Carotid artery stenting for the treatment and prevention of stroke is an evolving procedure.

## Modifiable risk factors for cerebrovascular disease<sup>2</sup>

**Major:** hypertension, smoking, cardiovascular disease, atrial fibrillation (especially valvular), diabetes.

**Others:** cardiac failure, dyslipidaemia, obesity, alcohol excess, oral contraception, migraine, stress.

Control of risk factors is the key approach to management. Control of hypertension, including systolic hypertension in the elderly, and smoking cessation are vital factors for reduction of the incidence of stroke. A meta-analysis of 14 randomised trials showed that a reduction of blood pressure of 5–6 mmHg is associated with about 40% reduction in stroke incidence.<sup>1</sup> There is a 3-hour time window of opportunity for optimal management.

## § Stroke

### Facts<sup>1</sup>

- Stroke is the third most common cause of death in Australia.
- About one-third of victims will die within 1 month.
- About 50% of ischaemic strokes are preceded by TIAs.
- Symptomatic carotid artery stenosis is the major risk factor for stroke.
- Thromboembolism from vascular disease outside the brain causes 70% of strokes and 90% of TIAs.
- Such sources are atheromatous plaques within the carotid or vertebral systems or cardiac causes (e.g. postmyocardial infarction).
- Echocardiography is an important investigation with TIAs since LV dysfunction and the size of the left atrium are the strongest independent predictors of thromboembolism.

### Pathophysiological groups of cerebral infarction

The three main groups are:

- single penetrator or small vessel disease (lacunar syndrome)—probably due to in situ small vessel disease
- cardio-emboli (heart to artery embolism)
- large vessel artery-to-artery embolic infarcts (see TABLE 132.1)

### Differential diagnosis ('stroke mimics')

- Syncope
- Seizure (and subsequent Todd paresis)
- Migraine
- Cerebral tumour and other space-occupying lesions

Table 132.1 Types and incidence of stroke<sup>2</sup>

Stroke subtype	Frequency (%)
Haemorrhagic stroke:	
• primary intracerebral	10
• subarachnoid	5
Ischaemic stroke:	
• large vessel (artery-to-artery embolism)	30
• cardio-embolic	20
• small vessels (lacunar infarcts)	15
• uncertain type	15
• rare (e.g. venous infarction)	5

- Hypoglycaemia
- Hyponatraemia
- Delirium
- Head injury
- Medically unexplained (e.g. somatisation)

### Diagnostic guidelines

- Sudden stroke is typical of embolism.
- The clinical picture depends on the vessel involved.
- In young people <50 years consider PFO.
- With cerebral haemorrhage the stroke evolves steadily, often over hours: the putamen (50%) is the commonest site.
- Lacunar CVAs:
  - small, deep infarcts
  - pure motor hemiplegia most common effect
  - lack of cortical signs
  - the neurological deficit may progress over 24–36 hours
  - outcome usually good
- Investigate all, including SAH, with CT scans or MRI (may need a lumbar puncture for SAH diagnosis). MRI is preferred if available.
- Carotid duplex Doppler ultrasound scan can accurately determine atherosclerotic narrowing of the extracranial carotid circulation.

### Pitfalls

- Mistaking visual or sensory migraine equivalents in young adults for TIAs
- Mistaking a CVA for labyrinthitis (rare over 50 years)
- Failure to perform carotid duplex Doppler ultrasound or CT scan before starting aspirin for TIA or small stroke (because of missing small haemorrhage, unsuspected tumour or a subdural)
- Diagnosing small stroke as a lacuna (may be a stroke in evolution)

### Management

The development of an acute stroke or TIA is a medical emergency and admission to a stroke unit (if available) as soon as possible is advised. The evidence that care in a stroke unit gives the patient the greatest chance of independent survival is proven.<sup>3</sup>

### Immediate

- Stabilise ventilation—consider intubation and oxygen.
- Exclude head trauma.
- Obtain urgent CT or MRI scan (non-contrast CT scan is emerging investigation of choice).

- Treat any seizures.
- Treat any hypoglycaemia.

### General

- Carry out investigations, including carotid duplex Doppler ultrasound (for carotid territory symptoms).
- Treat hypertension (systolic >140) vigorously—it carries a six times increased risk of stroke.
- Give IV fluid, electrolyte and nutritional support (nil orally until swallowing has been assessed).
- Good nursing care is the cornerstone of management.
- Physiotherapy and speech therapy.
- Vigorous rehabilitation.
- Intracerebral haemorrhage: consider urgent surgical evacuation for haematomas of the posterior fossa (cerebellum) and cerebral white matter.<sup>1</sup> Shunt insertion may be needed. No medical therapy is of proven value.
- SAH: requires urgent referral (vasospasm and rebleeding are the main causes of morbidity and mortality):
  - nimodipine ± surgery
- Ischaemic stroke: give aspirin 150–300 mg (o) daily within 48 hours if CT scan/MRI has excluded cerebral haemorrhage or other blood-thinning agents are not used. Early intervention within 3–4.5 hours (ideally) of onset with tissue plasminogen activator (rtPA). Recent trials indicate improved outcomes with rtPA (but not

with streptokinase). However, there appears to be a 5–7% risk of intracerebral haemorrhage.<sup>1</sup>

The usual thrombolytic rtPA therapy is alteplase 0.9 mg/kg up to 90 mg IV over 1 hour, with 10% of the dose given as an initial bolus.<sup>1</sup> Withhold aspirin for 24 hours.

*Note:* Avoid steroids, mannitol, haemodilution and anticoagulation in acute stroke.<sup>4</sup>

## § Transient ischaemic attacks

### Clinical features

- Sudden onset
- Complete clinical recovery in less than 24 hours
- Average duration is 5 minutes
- Consciousness usually preserved
- Ninety per cent usually in anterior circulation
- Carotid TIAs—unilateral features
- Vertebrobasilar TIAs—often have bilateral or crossed features

A comparison of the main clinical features of carotid (anterior circulation) ischaemia and vertebrobasilar (posterior circulation) ischaemia is presented in **FIGURE 132.1**. The carotid circulation accounts for 80% of TIAs.

Differential diagnoses of TIAs are presented in **TABLE 132.2**.

### Some ischaemic syndromes

- Transient monocular blindness (amaurosis fugax)
- Transient hemisphere attacks

**FIGURE 132.1** Cerebral arterial circulation with some important clinical features of carotid and vertebrobasilar ischaemia

Source: Reproduced with permission from C Kenna and J Murtagh, *Back Pain and Spinal Manipulation*, Sydney: Butterworth, 1989

**Table 132.2** Differential diagnosis of TIAs

Classic migraine (with aura)
Unusual migraine variants:
• hemiplegic
• ophthalmoplegic
• retinal
Focal epileptic seizures:
• complex partial
• simple partial
Multiple sclerosis
Transient global amnesia
Intracranial structural lesions:
• arteriovenous malformation
• tumour
Vestibular disorders:
• acute labyrinthitis
Benign paroxysmal positional vertigo
Meniere syndrome
Hypoglycaemia
Adverse drug reactions
Toxic reactions
Peripheral nerve lesions:
• carpal tunnel syndrome
• Bell palsy
Psychological conditions:
• hyperventilation
• panic attacks
• somatisation
• The 'locked-in' syndrome
• Vertebrobasilar:
— bilateral motor loss
— crossed sensory and motor loss
— diplopia
— bilateral blurring or blindness

### Amaurosis fugax

This is the sudden transient loss of vision in one eye (like a 'curtain or shade' coming from above or below) due to the passage of an embolus through the retinal vessels from ipsilateral carotid vessel disease. It is a feature of a TIA in the carotid artery circulation and is often the first clinical evidence of carotid stenosis.<sup>5</sup> About 20% of all TIAs present as amaurosis fugax.<sup>7</sup> Amaurosis fugax may forewarn of the development of hemiparesis or blindness and should be considered a matter for urgent attention and rectification. Give aspirin immediately. Carotid endarterectomy may be required for high grade stenosis.

### Differential diagnosis of transient amaurosis fugax

- thromboembolic phenomena
- vasospasm
- temporal arteritis
- blood—sickle cell, polycythaemia
- retinal—haemorrhage, venous thrombosis, detachment
- optic neuritis
- vitreous floaters

### Transient hemisphere attack (usually middle cerebral artery)

- Affects motor or sensory or both
- Usually face and arm (more than leg)
- Dysphasia common

### The 'locked-in' syndrome

In this syndrome, which may be transient or persistent, patients remain conscious and aware of their dilemma but are unable to speak or move the limbs, particularly the arms. It may be possible to communicate with patients using eye responses to commands. The cause is invariably a lesion in the brain stem.

### Significance of TIAs

- Five years after a TIA, 22–51% (average 1 in 3) patients (without treatment) will have a stroke.<sup>5,6</sup> This figure may be higher for those with ipsilateral high-grade (70% or more) carotid stenosis.
- The highest risk is in the first 6 months.
- A carotid artery TIA has more serious prognostic significance. Such patients are at high risk of developing a stroke that is potentially preventable.
- Referral for investigation is appropriate.
- All patients should have a carotid duplex Doppler ultrasound and CT scan or MRI at presentation.
- Cardiac status should be addressed because of an association with myocardial infarction.
- association with myocardial infarction.

### ABCD stroke risk tool<sup>7</sup>

This screening tool is useful as a predictor for risk of stroke in the first 7 days of a TIA.

**A** = Age  $\geq 60$  years (1 point)

**B** = BP  $\geq 140$  systolic or  $\geq 90$  diastolic (1 point)

**C** = Clinical features: any unilateral limb weakness (2 points), speech impairment without weakness (1 point)

**D** = Duration:  $\geq 60$  minutes (2 points), 10–59 minutes (1 point)

**D** = Diabetes: 1 point

Maximum 7 points

$>4$  = high risk

$\leq 4$  = low risk

### Investigations<sup>8</sup>

- CT scans, 12 lead ECG and carotid imaging are essential investigations in the first hours of a suspected TIA
- Blood tests, echocardiography, MRI and Holter or bedside cardiac monitoring are likely to improve diagnosis
- Carotid duplex Doppler ultrasound for carotid territory symptoms
- ECG
- Transoesophageal echocardiography

### Management

- All high-risk patients admitted to a stroke unit or specialist TIA clinic
- Aim to minimise the risk of a major stroke
- Determine cause and correct (if possible)
- Early neurorehabilitation
- Advise cessation of smoking and treat hypertension (if applicable)
- Anti-platelet therapy (especially for carotid ischaemia):

aspirin 100–300 mg (o) daily (gives 30% protection from stroke or death after TIA)<sup>9</sup>

or

clopidogrel 75 mg (o) daily

or

dipyridamole CR + aspirin 200 mg/25 mg (o) bd

(proven better outcomes than aspirin alone)<sup>10</sup>

or

ticlopidine (only if others unsuitable)

Antiplatelet therapy reduces the relative risk of stroke, myocardial infarction or vascular death by 22% (95% confidence interval 14–30%) in people with an ischaemic stroke or TIA due to arterial disease, compared with no treatment.<sup>2</sup>

- Anticoagulation therapy: warfarin:
  - for vertebrobasilar ischaemia (with increasing frequency of TIAs)
  - for failed anti-platelet therapy

— atrial fibrillation (selected cases)  $>65$  years of age

- Carotid endarterectomy has been proven to have a place in the management of carotid artery stenosis and the decision depends on the expertise of the unit. There is no evidence that surgery is appropriate for the asymptomatic patient with a stenosis  $<60\%$  (antiplatelet therapy proved to be as effective) or the symptomatic patient with a stenosis less than 30%, but there is a significant benefit for a stenosis greater than 70% (and possibly  $>60\%$  in asymptomatic patients).<sup>11,12</sup> If the stenosis is  $>90\%$  refer immediately. Greater than 75% stenosis is associated with a 2% per annum rate of ipsilateral ischaemic stroke.<sup>1</sup>
- Percutaneous transluminal angioplasty (stenting). Carotid artery stenting for the treatment and prevention of stroke is now employed in stroke units as an alternative to surgery.

### Guiding rules for carotid artery stenosis

70–99%—intervention

50–69%—‘grey area’: refer

$<50\%$ —observe

### § Atrial fibrillation<sup>1,13</sup>

- The main source of cardio-embolic infarction
- Increased with risk factors—hypertension, previous embolism and recent CHF (previous 3 months)
- With non-valvular AF, annual risk of CVA is 2.5% (no risk factors) to 17.6% (2 + risk factors)
- Risk of stroke about 6 times that of other people
- Intermittent AF can also be a risk

### Management

- Valvular disease: warfarin—target INR 2–3
- Non-valvular AF:
  - no risk factors: aspirin 100–300 mg/day or NOACs
  - high risk: warfarin INR 2–3
  - if warfarin contraindicated: aspirin or NOACs

Selecting antithrombotic therapy in non-valvular AF is assisted by the CHADS<sub>2</sub> index, a well-validated tool (see TABLE 132.3).

**Table 132.3** CHADS<sub>2</sub> criteria and stroke risk<sup>13</sup> (for carotid and vertebral arteries)

CHADS <sub>2</sub> criteria	Points	Stroke risk	Recommended therapy
Previous stroke or TIA	2	High (2–6)	Warfarin (INR 2–3) or NOACs
Age ≥75 years	1	Moderate (1)	Warfarin or aspirin or NOACs
Hypertension	1	Low (0)	Aspirin (100–300 mg daily)
Diabetes mellitus	1		
Heart failure	1		

## § Cerebral venous thrombosis<sup>2</sup>

This rare cause of stroke may present as an acute or chronic cerebrovascular disorder. It should be suspected particularly in women in the postpartum period presenting with severe headache or focal neurological defects. Diagnosis is by MRI. In the acute phase treatment is by anticoagulation with heparin followed by warfarin for approximately 6 months.

## Indications for carotid duplex Doppler ultrasound

- Bruit in neck
- TIAs if diagnosis uncertain
- Crescendo TIAs (two or more in 1 week and longer lasting)
- Internal carotid artery symptoms
- Hemispheric stroke
- Prior to major vascular surgery (e.g. CABG)

## Stroke in children

Stroke in children is relatively uncommon. Causes include paradoxical embolus (e.g. PFO), cerebral vasculopathy (e.g. vasculitis), arterial dissection and metabolic disease. The most common clinical presentation of stroke in childhood is acute hemiparesis due to involvement of the carotid distribution.<sup>1</sup> Investigation includes immediate brain MRI or CT scan, transthoracic echocardiography, thrombophilia factors (e.g. V Leiden) and urine homocysteine. Consider also sickle-cell disease. Initial treatment within 48 hours and after imaging is aspirin 2–5 mg/kg up to 300 mg orally daily.

## When to refer

- Refer immediately to a stroke unit
- Suspicion of SAH
- Carotid artery stenosis on carotid duplex Doppler ultrasound scan

- Cerebellar haemorrhage on CT scan
- Stroke in a young patient <50 years (consider PFO and other, less common causes)

## Key checkpoints

## Proven strategies

Three proven strategies to improve outcome of acute stroke (level I evidence):

- management in a stroke unit
- giving IV tPA within 3 hours of ischaemic stroke
- giving antiplatelet agents ASAP and within 48 hours of ischaemic stroke

## First aid for stroke

Is it a stroke?

Think **FAST**

↓

**Face** (ask person to smile)

**Arms** (raise both arms)

**Speech** (speak a simple sentence)

**Time** (within 3 hours)

*then, if yes*

Refer to stroke unit ASAP

Don't give aspirin

National Stroke Foundation, Australia. *Clinical Guidelines for Stroke Management*, 2013. <[www.strokefoundation.com.au](http://www.strokefoundation.com.au)>  
European Society of Cardiology Guidelines <[www.escardio.org](http://www.escardio.org)>

*Thrombosis is an ugly thought;  
Dicumarol and heparin,  
Statistics show, prevent most ills  
Like thrombus of the coronary, infarction of the heart  
And tests are made so many times  
That arms turn blue and blood runs thin*

David Litman, 'The Good Old Days', N Engl J Med, 1965

A thrombus is defined as a clot formed in the circulation from the constituents of the blood, whereas emboli are fragments of thrombus that break off and block vessels downstream. Almost half of adult deaths in Western countries are due to thrombosis of coronary arteries or cerebral arteries and to pulmonary embolism.<sup>1</sup> A thrombus is the result of a cascade of events involving platelets, RBCs, coagulation factors and the vessel wall.

Conditions predisposing to thrombosis:

- thrombophilia
- thrombocytosis (platelets)
- polycythaemia rubra vera

### § Thrombophilia<sup>2</sup>

Thrombophilia refers to a disorder of haemostasis in the form of a primary coagulopathy leading to a tendency to thrombosis. This should be considered in patients with major unprecipitated venous thromboembolism with or without a strong family history of venous thrombosis. There are several causes that can be tested. The factors are both inherited and acquired:

- inherited:
  - factor V Leiden gene mutation (activated protein C resistance)
  - prothrombin gene mutation
  - protein C deficiency
  - protein S deficiency
  - antithrombin deficiency
- acquired:
  - antiphospholipid antibodies (anticardiolipin or anti- $\beta_2$  GPI)
  - elevated homocysteine level
  - lupus anticoagulant

The above factors can all be measured in the laboratory with specific genetic tests, coagulation or antibody-based tests. Other acquired causes (regarded as risk factors) include malignancy, OCP, HRT, immobilisation, obesity, smoking, pregnancy and major surgery. Consideration should be given to screening patients with a DVT, especially in travellers at possible risk. Referral to a haematologist if thrombophilia is proved or suspected is advisable. Of particular interest is factor V Leiden, which occurs in about 5% of Caucasians, and the risk of venous thrombosis is increased three to seven times in heterozygotes and 80 times in homozygotes.<sup>2</sup>

### Indications for investigation

- Recurrent or unusual thrombosis
- Venous thromboembolism <40 years
- Arterial thrombosis <30 years
- Skin necrosis, especially on warfarin
- Recurrent fetal loss
- Familial thromboembolism

### § Venous thromboembolism

A feature of venous thrombosis is that it develops in normal vessels, with key factors being stasis and increased coagulability including thrombophilia. The classic example is deep venous thrombosis of the leg veins. Another poorly recognised thrombosis is axillosubclavian venous thrombosis, which is associated with pulmonary embolism in 30% of cases.<sup>3</sup>

Other sites of deep vein thrombosis are the pelvic/ovarian veins, which should be suspected in a person at risk with pelvic pain and swollen upper thighs, mesenteric venous thrombosis and cerebral sinus thrombosis, which are usually due to thrombophilia.

## § Deep venous thrombosis

Past history is very important.

### Risk factors

- Family history
- Thrombophilia
- History of previous thromboembolism
- Drugs (e.g. OCP, tamoxifen, HRT)
- Malignancy (watch idiopathic DVT)
- Increasing age; age >40
- Varicose veins
- Significant illness, esp. heart failure and cancer
- Other chronic illness
- Recent surgery
- Major/orthopaedic surgery
- Immobility
- Long flights
- Pregnancy/puerperium
- Obesity
- Dehydration

There is an up to 20% association with pulmonary emboli, of which 30% may be fatal. DVT may be asymptomatic, but usually causes tenderness in the calf. DVT may present with painless unilateral leg swelling. Because of the potentially serious consequences from untreated thromboembolism, it is essential to objectively confirm or exclude clinically suspected disease.

### Examination

May be low-grade fever.

Examine both legs. Look for:

- swelling of calf and thighs
- asymmetry
- erythema
- superficial veins

Feel for:

- warmth
- tenderness (gently squeeze calves)
- pitting oedema

Don't test Homan's sign (pain on sharp dorsiflexion of foot) as it may dislodge a thrombus.

Refer to Wells criteria (e.g. <[www.nice.org.uk/guidance/cg144/chapter/guidance#terms-used-in-this-guidance](http://www.nice.org.uk/guidance/cg144/chapter/guidance#terms-used-in-this-guidance)> or <[www.mdcalc.com/wells-criteria-for-dvt/](http://www.mdcalc.com/wells-criteria-for-dvt/)>).

### Investigations

- Duplex ultrasound: accurate for above-knee thrombosis; improving for distal calf

- Should be repeated in 1 week if initial test normal
- Contrast venography: reserved if ultrasound doubtful

Note:

- MRI appears to be very accurate for DVT, but is not yet available generally.
- The plasma D-dimer can be helpful. Where the clinical probability of venous thrombosis is low, a normal D-dimer effectively excludes the diagnosis. Where clinical probability is high, appropriate imaging with Doppler ultrasound or lung scan should be performed. A raised D-dimer is non-specific and does not help with diagnosis.

### Treatment<sup>3,4</sup>

Provide education and counselling. Admit to hospital (usually 5–7 days)—can treat as an outpatient. Drugs used in the treatment of thromboembolism are summarised in general format in **TABLE 133.1**.

- Collect blood for APTT, international normalised ratio (INR), and platelet count
- Check renal function
- LMW heparin e.g. enoxaparin or dalteparin  
or  
unfractionated heparin (UFH) 330 U/kg, SC loading dose then 250 U/kg bd SC (or monitor with APTT)  
or  
UFH 5000 U bolus IV then infusion in N saline (12 500 U over 12 hours)  
— monitor with APTT after 4–8 hours then for 5–7 days  
or  
fondaparinux SC, according to weight e.g. 50–100 kg: 7.5 mg SC daily
- Oral anticoagulant (warfarin) for 6 months depending on relative risk  
commence on day 1 or 2, usually 5 mg nocte for 2 nights and then according to INR monitoring (max. 30 mg in 3 days)
- Do not give aspirin
- Mobilisation within the limits of pain, tenderness and swelling
- Class II graded compression stocking to affected leg in proximal DVT associated with significant swelling. The stocking may be above or below the knee depending on the extent of the swelling.

Long term: complete resolution 50–80% at 6 months and almost 100% by 12 months.

**Table 133.1** Drugs employed in thrombotic disorders

## Antiplatelet

Aspirin  
 Clopidogrel  
 Dipyridamole  
 Ticlopidine  
 Glycoprotein IIb/IIIa inhibitors (e.g. abciximab)

## Anticoagulants

## Heparin:

- unfractionated/standard
- low molecular weight
  - dalteparin
  - enoxaparin
  - danaparoid

## Vitamin K antagonists:

- phenindione
- warfarin

## Clotting factor inhibitors:

- Direct thrombin inhibitors<sup>5</sup>
  - bivalirudin (IV use)
  - dabigatran (oral)
  - lepirudin (IV use)
- Factor Xa inhibitors
  - apixaban (oral)
  - fondaparinux (SC use)
  - rivaroxaban (oral)

## Thrombolytics

Alteplase  
 Reteplase  
 Streptokinase  
 Tenecteplase  
 Urokinase

**Prevention****Surgery**

- Early ambulation
- LMW heparin for orthopaedic or other high-risk surgery or new anticoagulants e.g. fondaparinux SC or oral agents (as in TABLE 133.1) for 28 to 35 days
- Graded pressure elastic stockings
- Physiotherapy
- Pneumatic compression (especially in high-risk patients where heparin is contraindicated)
- Electrical calf muscle stimulation during surgery

**Prolonged travel/immobilisation**

- Keep hydrated—ample water.
- Avoid or restrict alcohol and coffee.
- Exercises—3–4 minutes per hour (e.g. walking, calf contraction—e.g. foot pumps, see FIG. 133.1, ankle circles, knee lifts)
- Injections LMWH just prior to flying and on arrival for those at high risk. Use a prophylactic dose (e.g. enoxaparin 40 mg or dalteparin 5000 U—both SC injections twice daily)

**§ Pulmonary embolism<sup>6</sup>**

Refer to CHAPTER 40 for more detail on the clinical features and management of pulmonary embolism. CT pulmonary angiography is very specific and appears to be as sensitive as V/Q scanning for embolism, and is currently the preferred first-line investigation. The basis of treatment is LMW heparin and warfarin, as for DVT.

**FIGURE 133.1** Foot pump exercises to prevent DVT during prolonged air travel

- 1 Start with the feet flat and both heels on the floor, lift the feet (toes up) as high as you can.
  - 2 Return the feet to the flat position, pressing them firmly on the floor.
  - 3 Lift the heels high, keeping the balls of the feet on the floor.
- Continue this up-and-down movement for at least 30 seconds. Repeat often.

## § Arterial thromboembolism

The common serious manifestations of this are myocardial infarction, stroke, occlusion of the arterial system of the lower limbs and 'eye' embolism (e.g. central retinal artery thrombosis). Emboli originate from the left side of the heart, the carotid arteries or the iliac arteries. Atrial fibrillation is an important predisposing factor.

### Preventing systemic embolism in atrial fibrillation<sup>6</sup>

Atrial fibrillation (AF) accounts for about 15% of ischaemic strokes caused by systemic embolism of cardiac thrombi. This risk gradually increases with age. Use of warfarin reduces the annual incidence of stroke during AF from 4.5% to 1.4%—a risk reduction of almost 70%. The decision to use it or an antiplatelet agent is a difficult one and should be made in consultation with a cardiologist. Although aspirin reduces stroke rate by about 20% in patients with AF when compared with no treatment, it has half the effectiveness of warfarin and is less able to prevent severe strokes. As a general rule all patients with AF should start on warfarin (or an appropriate NOAC) unless <65 years old or have a major contraindication to its use. It is not indicated in patients with lone AF who are less than 60 years of age with no risk factors. If using warfarin, start with a low dose (e.g. 2–4 mg) and maintain an INR of 2–3 with regular checks. Anticoagulant therapy is also required to prevent embolism after cardioversion.

## Drug treatment of thrombotic disorders

### The new oral anticoagulants (NOACs)<sup>5</sup>

The NOACs, which can be used as an alternative to warfarin, are currently indicated for thromboprophylaxis in non-valvular atrial fibrillation and post hip and knee replacement surgery. Rivaroxaban is also approved for treatment and secondary prevention of DVT and PE. They need less monitoring than warfarin but so far have no effective antidote. Intracranial bleeding is less likely with NOACs compared with warfarin. Caution for use is required in renal impairment and they are contraindicated in patients with renal failure. This requires measurement of creatinine clearance (not a GFR, which does not allow for weight).

### Warfarin

Warfarin is an oral agent used in the treatment and prevention of venous thromboembolism, unlike the

antiplatelet drugs which have little or no benefit and are recommended in arterial disease. Before prescribing warfarin, the risk of bleeding should be evaluated and discussed with each patient. Indications for warfarin treatment are outlined in TABLE 133.2.

Table 133.2 Warfarin anticoagulation

#### Indications

Prosthetic cardiac valves  
Deep venous thrombosis, pulmonary thromboembolism  
Atrial fibrillation (selected cases)  
Postoperatively in lower limb orthopaedic surgery (low dose)  
Postcoronary bypass surgery (selected cases)  
Thrombosis in antiphospholipid antibody syndrome

#### Contraindications

Active bleeding  
History of intracranial haemorrhage  
Uncontrolled hypertension  
Liver disease with impaired synthetic function—based on INR  
Pregnancy

### Actions<sup>4</sup>

- Antagonises vitamin K.
- Depresses factors VII, IX and X (half-life of 30–40 hours) and prothrombin.
- Achieves full anticoagulation effect after 5–7 days.
- Prothrombin time (INR ratio) of 2–3 times normal control indicates therapeutic effect.
- The INR is a good indicator of effectiveness and risk of bleeding.
- Duration of effect is 4–5 days after cessation.
- It can cause thrombocytopenia.
- Antidote is vitamin K  $\pm$  plasma or prothrombin complex concentrate.

### Initiation of warfarin treatment<sup>7,8</sup>

An estimate of the patient's final steady dose is made. The patient is commenced on this dose and the INR monitored daily and the dose altered accordingly.

- Measure INR first to establish baseline.
- Generally warfarin is commenced on same day or day after heparin is commenced.
- Heparin can be ceased when INR >2 for 2 consecutive days.
- Typical loading dose is 5–10 mg (o) daily (usually 5 mg) for 2 days (avoid dose >30 mg over 3 days without INR).

- Adjust the dosage according to an INR table (eTG Complete: Therapeutic Guidelines Ltd <www.tg.org.au>) and your pathology laboratory, from the third day.
- Establish the INR in the therapeutic range, usually 2–3 (average 2.5).
- Maintenance dose is usually reached by day 5.
- The INR reflects the warfarin dose given 48 hours earlier.
- It is best taken in the evening and the INR measured in the morning.

*Note:*

- Warfarin should be continued for 3 to 6 months and longer if major risk factors are present.
- Watch for potential drug interactions.

Recommended target INR values are given in the box.

### Recommended INR target values

Prevention of DVT	2.0–3.0
Treatment of DVT or PE	2.0–3.0
Preventing systemic embolism:	2.0–3.0
• atrial fibrillation	
• post myocardial infarction	
• tissue heart valve	
• valvular heart disease	
Mechanical prosthetic heart valve	2.5–3.5
Prevent recurrence of MI	2.0–3.0
Antiphospholipid antibody syndrome thrombosis	2.0–3.0

### Overdosage of warfarin

Signs of warfarin overdosage include:

- unexpected bleeding after minor trauma
- epistaxis
- spontaneous bruising
- unusually heavy menstrual bleeding
- gastrointestinal bleeding

### Management of overdosage<sup>9</sup>

- 1 Urgent measurement of INR is required.
- 2 If the only evidence of overdosage is a small increase of the INR above the therapeutic range, cessation of warfarin for 1 to 2 days followed by a continuation at a lower dose is appropriate.
- 3 If the INR is markedly elevated (>5.0) consider giving oral vitamin K e.g. 10 mg tablet.
- 4 If bleeding is minor, transient action as in point 2 is still appropriate.

- 5 If bleeding is persistent, or severe, or involves closed body cavities (such as pericardium, intracranial, fascial compartment), urgent admission to hospital is essential. The anticoagulation may need to be reversed by administering oral or parenteral vitamin K. Infusion of fresh frozen plasma and/or prothrombin complex concentrate (best option) may also be necessary.

### Drug interactions

There are so many potential interactions between warfarin and other drugs that the following general principles should be applied:

- 1 Maintain the simplest possible drug regimens. Avoid polypharmacy.
- 2 Aspirin is contraindicated while the patient is on warfarin because of the combined antiplatelet and anticoagulation effects. The risk of gastrointestinal bleeding is also increased. Other NSAIDs should also be avoided (see TABLE 133.3).
- 3 If the patient's drug regimen must be altered during warfarin therapy, then the INR should be followed closely until stable.

### Advice to the patient

- Keep to a consistent diet.
- Do not take aspirin or liquid paraffin.
- Always mention that you take warfarin to any doctor, dentist or chemist you are consulting.
- Remember to take tablets strictly as directed and have your blood tests.
- Report signs of bleeding, such as black motions, blood in urine, easy bruising, unusual nose bleeds, heavy periods, 'purple toes'.

*Note:* Give the patient the information sheet about risks, especially if ceasing warfarin.

### Bleeding on heparin

- Recheck APTT
- Cease or reduce heparin
- Admit patient—alert laboratory and haematologist

Antidotes:

- protamine sulfate will reverse (use with caution)
- fresh frozen plasma
- clotting factors (as guided by consultant)

**Table 133.3** Some important drug interactions with warfarin

Effects on warfarin activity	Drug
↑ Increased	<p>Allopurinol</p> <p>Amiodarone</p> <p>Anabolic steroids</p> <p>Antibiotics (broad spectrum)</p> <p>Antifungals</p> <p>Aspirin—salicylates (high doses)</p> <p>Chloral hydrate</p> <p>Cimetidine</p> <p>Clofibrate</p> <p>Gemfibrozil</p> <p>Metronidazole</p> <p>Miconazole</p> <p>NSAIDs, including COX-2 inhibitors</p> <p>Paracetamol (large doses)</p> <p>Phenytoin</p> <p>Proton-pump blockers</p> <p>Quinidine/quinine</p> <p>Ranitidine</p> <p>SSRIs</p> <p>Sulphonamides</p> <p>Tamoxifen</p> <p>Thyroxine</p> <p>Herbal medicines:</p> <ul style="list-style-type: none"> <li>• dong quai</li> <li>• papaya</li> <li>• St John's wort</li> </ul>
↓ Decreased	<p>Antacids</p> <p>Antihistamines</p> <p>Barbiturates</p> <p>Anti-epileptics (e.g. carbamazepine)</p> <p>Cholestyramine (reduced absorption)</p> <p>Griseofulvin</p> <p>Haloperidol</p> <p>Oestrogen/oral contraceptives</p> <p>Rifampicin</p> <p>Vitamin C</p>
Increased or decreased	<p>Alcohol</p> <p>Chloral hydrate</p> <p>Diuretics</p> <p>Ranitidine</p>

## Practice tips for warfarin<sup>10</sup>

- Consider avoiding use if patient compliance is likely to be poor.
- The INR result reflects the warfarin dose administered 48–72 hours earlier.
- Advise and encourage patients to keep a record in an 'anticoagulant diary' of drug dosage and INR results.
- An unacceptable INR is >5.0.
- Discontinue therapy if skin necrosis or 'purple toes syndrome' occurs.

Injuries to the skin, including simple lacerations, abrasions, contusions and foreign bodies, are among the commonest problems encountered in general practice. To manage these cosmetically important injuries well is one of the really basic and enjoyable skills of our profession.

## Key facts and checkpoints

- A well-prepared treatment room with good sterilisation facilities, instruments, sterile dressings and an assistant facilitates management.
- With lacerations, check carefully for nerve damage, tendon damage and arterial damage.
- Beware of slivers of glass in wounds caused by glass—explore carefully and X-ray (especially with high-resolution ultrasound) if in doubt.
- Beware of electrical or thermal wounds because marked tissue necrosis can be hidden by slightly injured skin.
- Beware also of roller injuries such as car wheels.
- Beware of pressure gun injuries such as oil and paint. The consequences can be disastrous.
- Avoid suturing the tongue, and animal and human bites, unless absolutely necessary.
- Keep drawings or photographs of wounds in your medical records.
- Have a management plan for puncture wounds, including medical needle-stick injuries.
- Gravel rash wounds are a special problem because retained fragments of dirt and metal can leave a 'dirty' tattoo-like effect in the healed wound.

## Contusions and haematomas

A contusion (bruise or ecchymosis) is the consequence of injury causing bleeding in subcutaneous or deeper

tissue while leaving the skin basically intact. It might take weeks to resolve, especially if extensive.

A haematoma is a large collection of extravasated blood that produces an obvious and tender swelling or deformity. The blood usually clots and becomes firm, warm and red; later (about 10 days) it begins to liquefy and becomes fluctuant.

## Principles of management

- Explanation and reassurance
- **RICE** (for larger bruises/haematomas) for 48 hours  
R = Rest  
I = Ice (for 20 minutes every 2 waking hours)  
C = Compression (firm elastic bandage)  
E = Elevation (if a limb)
- Analgesics: paracetamol/acetaminophen
- Avoid aspiration (some exceptions)
- Avoid massage
- Heat may be applied after 72 hours as local heat or whirlpool baths
- Consider possibility of bleeding disorder if bleeding is out of proportion to the injury

## PROBLEMATIC HAEMATOMAS

Some haematomas in certain locations can cause deformity and other problems.

### \$ Haematoma of nasal septum<sup>1</sup>

Refer CHAPTER 59.

### \$ Haematoma of the pinna<sup>1</sup>

When trauma to the pinna causes a haematoma between the epidermis and the cartilage, a permanent deformity known as 'cauliflower ear' may result.

The haematoma, if left, becomes organised and the normal contour of the ear is lost.

The aim is to evacuate the haematoma as soon as practical and then to prevent it reforming. One can achieve a fair degree of success even on haematomas that have been present for several days.

### Method

Under aseptic conditions insert a 25 gauge needle into the haematoma at its lowest point and aspirate the extravasated blood (see FIG. 134.1a). Apply a padded test tube clamp to the haematoma site and leave on for 30–40 minutes (see FIG. 134.1b). Generally, daily aspiration and clamping are sufficient to eradicate the haematoma completely.

FIGURE 134.1 Treatment of haematoma of the pinna

### § Pretibial haematoma

A haematoma over the tibia (shin bone) can be persistently painful and slow to resolve. An efficient method is, under very strict asepsis, to inject 1 mL lignocaine 1% and 1 mL hyaluronidase and follow

with immediate ultrasound. This may disperse or require drainage.

### § Subungual haematomas

These important haematomas are discussed in CHAPTER 129.

## Abrasions

Abrasions vary considerably in degree and potential contamination. They are common with bicycle or motorcycle accidents and skateboard accidents. Special care is needed over joints such as the knee or elbow.

### Rules of management

- Clean meticulously, remove all ground-in dirt, metal, clothing and other material.
- Scrub out dirt with sterile normal saline under anaesthesia (local infiltration or general anaesthesia for deep wounds).
- Treat the injury as a burn.
- When clean, apply a protective dressing (some wounds may be left open).
- Use paraffin gauze and non-adhesive absorbent pads such as Melolin.
- Ensure adequate follow-up.
- Immobilise a joint that may be affected by a deep wound.

## Lacerations

Lacerations vary enormously in complexity and reparability. Very complex lacerations and those involving nerves or other structures should be referred to an expert.

### Principles of repair

- Good approximation of wound edges minimises scar formation and healing time.
- Pay special attention to debridement.
- Avoid deep layers of suture material in a contaminated wound—consider drainage.
- Inspect all wounds carefully for damage to major structures such as nerves and tendons and for foreign material:
  - shattered glass wounds require careful inspection and perhaps plain X-ray or ultrasound
  - high-energy wounds (e.g. motor mowers) are prone to have metallic foreign bodies and associated fractures

- Be ready to take X-rays of wounds to look for foreign objects or fractures (compound fractures).
- Trim jagged or crushed wound edges, especially on the face.
- All wounds should be closed in layers.
- Avoid leaving dead space.
- Do not suture an 'old' wound (greater than 8 hours) if it is contaminated with primary closure: leave 4 days before suturing if not infected.
- Take care in poor healing areas, such as backs, necks, calves and knees, and in areas prone to hypertrophic scarring, such as over the sternum of the chest and the shoulder.
- Use atraumatic tissue-handling techniques.
- Everted edges heal better than inverted edges.
- Practise minimal handling of wound edges.
- A suture is too tight when it blanches the skin between the thread—it should be loosened.
- Avoid tension on the wound, especially in fingers, lower leg, foot or palm.
- The finest scar and best result is obtained by using a large number of fine sutures rather than fewer thicker sutures more widely spread.
- Avoid haematoma.
- Apply a firm pressure dressing when appropriate, especially with swollen skin flaps.
- Consider appropriate immobilisation for wounds. Many wound failures are due to lack of immobilisation from a volar slab on the hand or a back slab on the leg.

- Monofilament nylon sutures are generally preferred for skin repair.
- Use the smallest calibre compatible with required strains.
- The synthetic, absorbable polyglycolic acid or polyglactin sutures (Dexon, Vicryl) are stronger than catgut of the same gauge, but do not use these (use catgut instead) on the face or subcuticularly.

Instruments

Examples of good-quality instruments:

- locking needle holder (e.g. Crile–Wood 12 cm)
- skin hooks
- iris scissors
- toothed forceps

Holding the needle

The needle should be held in its middle; this will help to avoid breakage and distortion, which tend to occur if the needle is held near its end (see FIG. 134.2).

FIGURE 134.2 Correct and incorrect methods of holding the needle

Dead space

Dead space should be eliminated to reduce tension on skin sutures. Use buried, absorbable sutures to approximate underlying tissue. This is done by starting suture insertion from the fat to pick up the fat/dermis interface so as to bury the knot (see FIG. 134.3).

FIGURE 134.3 Eliminating dead space

Practical aspects

Suture material

See TABLE 134.1.

Table 134.1	Selection of suture material (guidelines)	
Skin	Nylon 6/0	Face
	Nylon 3/0	Back, scalp
	Nylon 5/0	Elsewhere
Deeper tissue (dead space)	Catgut 4/0	Face
	Dexon/Vicryl 3/0 or 4/0	Elsewhere
Subcuticular	Catgut 4/0	
Small vessel ties	Plain catgut 4/0	
Large vessel ties	Chromic catgut (CCG) 4/0	

## Everted wounds

Eversion is achieved by making the 'bite' in the dermis wider than the bite in the epidermis (skin surface) and making the suture deeper than it is wide. Shown are:

- simple suture (see FIG. 134.4a)
- vertical mattress suture (see FIG. 134.4b)

FIGURE 134.4 Everted wounds: (a) correct and incorrect methods of making a simple suture, (b) making a vertical mattress suture

The mattress suture is the ideal way to evert a wound.

## Number of sutures

One should aim to use a minimum number of sutures to achieve closure without gaps but sufficient sutures to avoid tension. Place the sutures as close to the wound edge as possible.

## SPECIAL TECHNIQUES FOR VARIOUS WOUNDS

### § The three-point suture

In wounds with a triangular flap component, it is often difficult to place the apex of the flap accurately. The three-point suture is the best way to achieve this while minimising the chance of strangulation necrosis at the tip of the flap.

## Method

- 1 Pass the needle through the skin of the non-flap side of the wound.
- 2 Pass it then through the subcuticular layer of the flap tip at exactly the same level as the reception side.
- 3 Finally, pass the needle back through the reception side so that it emerges well back from the V flap (see FIG. 134.5).

FIGURE 134.5 The three-point suture

### § Triangular flap wounds on the lower leg

Triangular flap wounds below the knee are a common injury and are often treated incorrectly. Similar wounds in the upper limb heal rapidly when sutured properly, but lower limb injury will not usually heal at first intention unless the apex of the flap is given special attention.

### Proximally based flap

A fall through a gap in flooring boards will produce a proximally based flap; a heavy object (such as the tailboard of a trailer) striking the shin will result in a distally based flap.

Often the apex of the flap is crushed and poorly vascularised; it will not survive to heal after suture.

### Treatment methods (under infiltration with LA)

- 1 Preferred method: to attempt to salvage the distal flap, scrape away the subcutaneous tissue on the flap and use it as a full-thickness graft.
- 2 An alternative is to excise the apex of the flap, loosely suture the remaining flap and place a small split-thickness graft on the raw area (see FIG. 134.6).

FIGURE 134.6 Triangular flap wound repair: proximally based flap

134

For both methods apply a suitable dressing and strap firmly with a crepe bandage. The patient should rest with the leg elevated for 3 days.

### Distally based flap

See FIG. 134.7. This flap, which is quite avascular, has a poorer prognosis. The same methods as for the proximally based flap can be used. Trimming the flap and using it as a full thickness graft has a good chance of repair in a younger person but a poor chance in the elderly.

FIGURE 134.7 Triangular flap wound repair: distally based flap

### Repair of cut lip

While small lacerations of the buccal mucosa of the lip can be left safely, more extensive cuts require careful repair. Local anaesthetic infiltration may be adequate, although a mental nerve block is ideal for larger lacerations of the lower lip.

For wounds that cross the vermilion border, meticulous alignment is essential. It may be advisable to premark the vermilion border with gentian violet or a marker pen. It is desirable to have an assistant.

### Method

- 1 Close the deeper muscular layer of the wound using 4/0 CCG. The first suture should carefully appose the mucosal area of the lip, followed by one or two sutures in the remaining layer.
- 2 Next, insert a 6/0 monofilament nylon suture to bring both ends of the vermilion border together. The slightest step is unacceptable (see FIG. 134.8). This is the key to the procedure.
- 3 Close the inner buccal mucosa with interrupted 4/0 plain catgut sutures.
- 4 The outer skin of the lip (above and below the vermilion border) is closed with interrupted nylon sutures.

FIGURE 134.8 The lacerated lip: ensuring meticulous suture of the vermilion border

### Post repair

- 1 Apply a moisturising lotion along the lines of the wound.
- 2 Remove nylon sutures in 3–4 days (in a young person) and 5–6 days (in an older person).

## § Repair of lacerated eyelid

### General points

- Preserve as much tissue as possible.
- Do not shave the eyebrow.
- Do not invert hair-bearing skin into the wound.
- Ensure precise alignment of wound margins.
- Tie suture knots away from the eyeball.

### Method

- 1 Place an intermarginal suture behind the eyelashes if the margin is involved.
- 2 Repair conjunctiva and tarsus with 6/0 catgut.
- 3 Then repair skin and muscle (orbicularis oculi) with 6/0 nylon (see FIG. 134.9).

FIGURE 134.9 The lacerated eyelid

## § Repair of tongue wound

Wherever possible, it is best to avoid repair to wounds of the tongue because these heal rapidly. However, large flap wounds to the tongue on the dorsum or the lateral border may require suturing. The best method is to use buried catgut sutures.

### Method

- 1 Get patient to suck ice for a few minutes, then infiltrate with 1% lignocaine and leave 5–10 minutes.
- 2 Use 4/0 or 3/0 catgut sutures to suture the flap to its bed, and bury the sutures (see FIG. 134.10).

It should not be necessary to use surface sutures. If it is, 4/0 silk sutures will suffice.

The patient should be instructed to rinse the mouth regularly with salt water until healing is satisfactory.

FIGURE 134.10 Repair of tongue wound

## § The amputated finger

In this emergency situation, instruct the patient to place the severed finger directly into a fluid-tight sterile container, such as a plastic bag or sterile specimen jar. Then place this 'unit' in a bag containing iced water with crushed ice.

*Note:* Never place the amputated finger directly in ice or in fluid such as saline. Fluid makes the tissue soggy, rendering microsurgical repair difficult.

### Care of the finger stump

Apply a simple, sterile, loose, non-sticky dressing and keep the hand elevated.

## § Bite wounds

### Human bites and clenched fist injuries

Human bites and clenched fist injuries can present a serious problem of infection.  $\beta$ -lactamase producing anaerobic organisms in the oral cavity (e.g. Vincent's) can penetrate the damaged tissue and form a deep-seated infection. *Streptococcus* species, staphylococcal organisms and *Eikenella corrodens* are common

pathogens. Complications of the infected wounds include cellulitis, wound abscess and lymphangitis. A Cochrane review of antibiotic prophylaxis concluded that it significantly reduces the risk of infection.<sup>2</sup>

### Principles of treatment

- Clean and debride the wound carefully (e.g. aqueous antiseptic solution or hydrogen peroxide).
- Give prophylactic penicillin if a severe or deep bite.
- Avoid suturing if possible.
- Tetanus toxoid (although minimum risk).
- Consider rare possibility of HIV and hepatitis B or C infections.
- For high-risk wounds, give procaine penicillin 1.5 g IM statim and/or amoxycillin/clavulanate 875/125 mg bd for 5 days.<sup>3</sup>
- If established infection in a deep wound, take a swab and give metronidazole 400 mg (o) bd for 14 days plus either cefotaxime 1 g IV 8 hourly or ceftriaxone 1 g IV daily for 14 days.

## Dog bites

### Non-rabid

Dog bites typically have poor healing and carry a risk of infection with anaerobic organisms, including tetanus, staphylococci and streptococci. Puncture and crush wounds are more prone to infection than laceration. Up to 25% of dog bite wounds become infected with the first signs appearing in about 24 hours.<sup>4</sup>

Principles of treatment (see FIG. 134.11):

- Clean and debride the wound with aqueous antiseptic, allowing it to soak for 10–20 minutes.
- Aim for open healing—avoid suturing if possible (except in ‘privileged’ sites with an excellent blood supply such as the face and scalp).
- Apply non-adherent, absorbent dressings (paraffin gauze and Melolin) to absorb the discharge from the wound.
- Tetanus prophylaxis: immunoglobulin or tetanus toxoid.
- Give prophylactic penicillin for a severe or deep bite: 1.5 million units procaine penicillin IM statim, then orally for 5–10 days. An alternative is amoxycillin/clavulanate for 5–7 days. Use this antibiotic for 7–10 days for an established infection (depending on swab).<sup>4</sup>
- Inform the patient that slow healing and scarring are likely.

FIGURE 134.11 Dog bite treated by antibiotics, sterile dressing and anti-tetanus vaccination

### Rabid or possibly rabid dog (or other animal)

Not currently applicable in Australia (see CHAPTER 15).

- Wash the site immediately with detergent or saline (preferable) or hydrogen peroxide or soap (if no other option).
- Do not suture.
- If rabid:
  - human rabies immune globulin (passive)
  - antirabies vaccine (active)
- Uncertain: capture and observe animal, consider vaccination.

### Cat bites

Cat bites have the greatest potential for suppurative infection with *Pasteurella multocida* being the most common organism. The same principles apply as for the management of human or dog bites. Use amoxycillin + clavulanate for prophylaxis for 5 days. For infection, swab the wound but start with metronidazole + doxycycline or ciprofloxacin.<sup>3</sup> It is important to clean a deep and penetrating wound. Another problem is cat-scratch disease, presumably caused by a Gram-negative bacterium, *Bartonella henselae*.

### Clinical features of cat-scratch disease

- An infected ulcer or papule pustule at bite site (30–50% of cases) after 3 days or so<sup>5</sup>

- 1–3 weeks later: fever, headache, malaise regional lymphadenopathy (may suppurate)
- Intradermal skin test positive
- Benign, self-limiting course
- Sometimes severe symptoms for weeks, especially in immunocompromised
- Treat with erythromycin or roxithromycin for 10 days<sup>3</sup>

### § Water-related wound infections<sup>3</sup>

These complex infections may require expert advice.

#### Coral cuts

Wounds from coral cuts are at risk of serious infection with *Vibrio* organisms (marine pathogens) or *Streptococcus pyogenes*. Such wounds require cleaning with antiseptics, debridement, dressing and antibiotic cover with doxycycline 100 mg bd or cephalexin 500 mg bd for 7 days.

#### Fish tank/swimming pool granuloma

Due to *Mycobacterium marinum*, which causes a localised papular or nodular skin lesion in people who usually clean aquaria or swimming pools. Diagnosis is by biopsy and culture (acid-fast bacilli).

Treatment: single lesion excision (may suffice). May need antibiotic therapy e.g. clarithromycin (o) bd for 3–4 months plus rifampicin for severe or unresponsive infection.

#### Aeromonas species wound infections

From fresh or brackish water or mud exposure to open wounds. Treat with ciprofloxacin.

#### Shewanella putrefaciens

From salt or brackish water contact, infecting legs with vascular compromise. Causes severe cellulitis with necrosis, even sepsis. Treat with ciprofloxacin or meropenem/imipenem.

### Scalp lacerations in children

If lacerations are small but gaping use the child's hair for the suture, provided it is long enough.

#### Method

Make a twisted bunch of the child's own hair on each side of the wound. Tie a reef knot and then an extra holding knot to minimise slipping. Ask an assistant to drop compound benzoin tincture solution (Friar's Balsam) on the hair knot. Leave the hair suture long and get the parent to cut the knot in 5 days.

### Forehead and other lacerations in children

Despite the temptation, avoid using reinforced paper adhesive strips (Steri-Strips) for children with open wounds. They will merely close the dermis and cause a thin, stretched scar. They can be used only for very superficial epidermal wounds in conjunction with sutures.

#### Adhesive glue for wound adhesion

A tissue adhesive glue can be used successfully to close superficial smooth and clean skin wounds, particularly in children. Commercial preparations such as Histoacryl, Dermabond and Epiglu (active ingredient enbucrilate) are available. SuperGlue also serves the purpose although sterility and toxicity have to be considered. The glue should be used only for superficial, dry, clean and fresh wounds. No gaps are permissible with this method. Avoid glues if possible.

#### Wound anaesthesia in children

New topical preparations that provide surface anaesthesia are being used for wound repair in children. They include lignocaine and prilocaine mixture (EMLA cream) and adrenaline and cocaine (AC) liquid. Use the latter with caution.

Some practitioners use an ice block to freeze the lacerated site. The child is asked to hold the ice while a suture is rapidly inserted.

### Removal of skin sutures

Suture marks are related to the time of retention of the suture, its tension and position. The objective is to remove the sutures as early as possible, as soon as their purpose is achieved. The timing of removal is based on commonsense and individual cases. Nylon sutures are less reactive and can be left for longer periods. After suture removal it is advisable to support the wound with Micropore skin tape/Steri-Strips for 1–2 weeks, especially in areas of skin tension.

#### Method

- 1 Use good light and have the patient lying comfortably.
- 2 Use fine, sharp scissors that cut to the point or the tip of a scalpel blade, and a pair of fine, non-toothed dissecting forceps that grip firmly.
- 3 Cut the suture close to the skin below the knot with scissors or a scalpel tip (see FIG. 134.12a).
- 4 Gently pull the suture out towards the side on which it was divided—that is, always towards the wound (see FIG. 134.12b).

**FIGURE 134.12** Removal of skin sutures: (a) cutting the suture, (b) removal by pulling towards wound

When to remove non-absorbable sutures

For removal of sutures after non-complicated wound closure in adults, see TABLE 134.2.

*Note:* Decisions need to be individualised according to the nature of the wound and health of the patient and healing. In general, take sutures out as soon

as possible. One way of achieving this is to remove alternate sutures a day or two earlier and remove the rest at the usual time. Steri-Strips can then be used to maintain closure and healing.

Additional aspects

In children, tend to remove 1–2 days earlier. Allow additional time for backs and legs, especially the calf. Nylon sutures can be left longer because they are less reactive. Alternate sutures may be removed earlier (e.g. face in women).

Burns<sup>5,6</sup>

Management depends on extent and depth (burns are classified as superficial or deep—otherwise first, second or third degree).

*First degree* burns are superficial and involve only the epidermis, causing pain, redness and swelling. A scald, which is a burn caused by moist heat, is an example. Healing proceeds quickly.

*Second degree* or partial skin thickness burns cause the epidermis to blister and become necrotic with subsequent serous ooze.

In *third degree* or full thickness burns, there is deep necrosis and perhaps anaesthesia from destroyed nerve endings. If extensive (>9% of body surface area) and deep there is a possibility of hypovolaemia and shock.

A major burn, which is a medical emergency, is an injury of more than 20% of the total body surface for an adult and 10% for a child.

First aid

The immediate treatment of burns, especially for smaller areas, is immersion in cool to cold, running water such as tap water, for a minimum of 20 minutes. Do not disturb charred adherent clothing but remove wet clothing.

Chemical burns should be liberally irrigated with water. Apply 1 in 10 diluted vinegar to alkali burns and sodium bicarbonate solution for acid burns.

Refer the following burns to hospital:

- >9% surface area, especially in a child (see ‘rule of nines’, CHAPTER 121)
- >5% in an infant
- all deep burns
- burns of difficult or vital areas (e.g. face, hands, perineum/genitalia, feet)
- burns with potential problems (e.g. electrical, chemical, circumferential)
- suspicion of inhalational injury

Always give adequate pain relief. During transport, continue cooling by using a fine-mist water spray.

Table 134.2	Time after insertion for removal of sutures
Area	Days later
Scalp	6
Face	3 (or alternate at 2, rest 3–4)
Ear	5
Neck	4 (or alternate at 3, rest 4)
Chest	8
Arm (including hand and fingers)	8–10
Abdomen	8–10 (tension 12–14)
Back	12
Inguinal and scrotal	7
Perineum	2
Legs	10
Knees and calf	12
Foot (including toes)	10–12

## Treatment

- 1 *Very superficial—intact skin.* Can be left with application of a mild antiseptic only (e.g. aqueous chlorhexidine). Review if blistering.
- 2 *Superficial—blistered skin.* Apply a dressing to promote epithelialisation (e.g. hydrocolloid sheets, hydrogel sheets) covered by an absorbent dressing or (best option) a retention adhesive material (e.g. Fixomull, Mefix, Hypafix) with daily or twice daily cleaning of the serous ooze and reapplication of outer stretch bandage. Fixomull can be left in place for up to 2 weeks.

## Guidelines to patient for retention dressings

- First 24 hours: keep dry. If there is any ooze coming through the dressing, pat dry with a clean tissue.
- From day 2: wash over dressing twice daily. Use gentle soap and water, rinse then pat dry. Do not soak. Rinse only. Do not remove the dressing as it may cause pain and damage to the wound. If the wound becomes red, hot or swollen, or if pain increases, return to the clinic.
- From day 7: return to the clinic for removal of the dressing. Two hours prior to coming into the clinic, soak the dressing with olive oil then cover with plastic wrap (e.g. Glad Wrap).

*Note:* Dressing must be soaked off with oil (e.g. olive, baby, citrus or peanut). Debride 'popped blisters'. Only pop blisters that interfere with dermal circulation.

- 3 *Deep burns.* If considerable ooze, apply the following in order:
  - SoloSite gel, Solugel or similar
  - non-adherent neutral dressing (e.g. Melolin)
  - layer of absorbent gauze or cotton wool (larger burns)

Change every 2–4 days with analgesic cover. Surgical treatment, including skin grafting, may be necessary.

## Exposure (open method)

- Keep open without dressings (good for face, perineum or single surface burns)
- Renew coating of antiseptic cream every 24 hours

## Dressings (closed method)

- Suitable for circumferential wounds
- Cover area with non-adherent tulle (e.g. paraffin gauze)

- Dress with an absorbent, bulky layer of gauze and wool
- Use a plaster splint if necessary

## Burns to hands

For superficial blistered burns to the hand or similar 'complex' shaped parts of the body apply strips of the retention stretch adhesive dressings as described above. They conform well to digits. Apply an outer bandage. At 7 days soak the dressings in oil for 2 hours prior to coming in to the clinic.

## FOREIGN BODIES

### Penetrating gun injuries

Injuries to the body from various types of guns present decision dilemmas for the treating doctor. The following information represents guidelines, including special sources of danger to tissues from various foreign materials discharged by guns.

## Gunshot wounds

### Airgun

The rule is to remove subcutaneous slugs but to leave deeper slugs unless they lie within and around vital structures (e.g. the wrist). A special common problem is that of slugs in the orbit. These often do little damage and can be left alone, but referral to an ophthalmologist would be appropriate.

### 0.22 rifle (the pea rifle)

The same principles of management apply but the bullet must be localised precisely by X-ray. Of particular interest are abdominal wounds, which should be observed carefully, as visceral perforations can occur with minimal initial symptoms and signs.

### 0.410 shotgun

The pellets from this shotgun are usually only dangerous when penetrating from a close range. Again, the rule is not to remove deep-lying pellets—perhaps only those superficial pellets that can be palpated.

## Pressure gun injuries

Injection of grease, oil, paint and similar substances from pressure guns (see FIG. 134.13) can cause very serious injuries, requiring decompression and removal of the substances.

FIGURE 134.13 Dangerous accidental injections into the hand

### Grease gun and paint gun

High-pressure injection of paint or grease into the hand requires urgent surgery if amputation is to be avoided. There is a deceptively minor wound to show for this injury, and after a while the hand feels comfortable. However, ischaemia,<sup>1</sup> chemical irritation and infection can follow, with gangrene of the digits, resulting in, at best, a claw hand due to sclerosis. Treatment is by immediate decompression and meticulous removal of all foreign material and necrotic tissue.

### Oil injection

Accidental injection of an inoculum in an oily vehicle into the hand also creates a serious problem with local tissue necrosis. If injected into the digital pulp, this may necessitate amputation. Such injections are common on poultry farms, where many fowl-pest injections are administered.

### § Splinters under the skin

The splinter under the skin is a common and difficult procedural problem. Instead of using forceps or making a wider excision, use a disposable hypodermic needle to 'spear' the splinter (see FIG. 134.14) and then use it as a lever to ease the splinter out through the skin.

A 'buried' wooden foreign body can be detected by ultrasound.

### § Embedded fish hooks

Two methods of removing fish hooks are presented here, both requiring removal in the reverse direction, against the barb. Method 2 is recommended as first-line management.

FIGURE 134.14 Removal of splinters in the skin

### Method 1

- 1 Inject 1–2 mL of LA around the fish hook.
- 2 Grasp the shank of the hook with strong artery forceps.
- 3 Slide a D11 scalpel blade in along the hook, sharp edge away from the hook, to cut the tissue and free the barb (see FIG. 134.15).
- 4 Withdraw the hook with the forceps.

FIGURE 134.15 Removal of fish hook by cutting a path in the skin

### Method 2

This method, used by some fishermen, relies on a loop of cord or fishing line to forcibly disengage and extract the hook intact. It requires no anaesthesia and no instruments—only nerves of steel, especially for the first attempt.

- 1 Take a piece of string about 10–12 cm long and make a loop. One end slips around the hook, the other hooking around one finger of the operator.
- 2 Depress the shank with the other hand in the direction that tends to disengage the barb.
- 3 At this point give a very swift, sharp tug along the cord.
- 4 The hook flies out painlessly in the direction of the tug (see FIG. 134.16).

*Note:* You must be bold, decisive, confident and quick—half-hearted attempts do not work.

For difficult cases, some local anaesthetic infiltration may be appropriate. Instead of a short loop of cord, a long piece of fishing line double looped around the hook and tugged by the hand, or flicked with a thin ruler in the loop, will work.

FIGURE 134.16 Fisherman's method of removing a fish hook intact

## Needle-stick and sharps injuries

Accidental skin puncture by contaminated 'sharps', including needles (with blood or bloodstained body fluids), is of great concern to all health care workers. Another problem that occurs occasionally is the deliberate inoculation of people such as police by angry, sociopathic individuals. A needle-stick accident is the commonest incident with the potential to transmit infections such as HIV and hepatitis B, C or D. The part of the venipuncture that is most likely to cause the accident is the recapping or resheathing of the needle. This practice should be discouraged.

Infections transmitted by needle-stick accidents are summarised in TABLE 134.3. The risk from a contaminated patient is greatest with hepatitis (10–30%), while the risk of seroconversion or clinical infection after a needle-stick injury with HIV-positive blood is very low (probably about 1 in 300).<sup>7</sup> The risk of tetanus, especially for outdoor injuries, is significant and should be addressed.

Table 134.3 Infections transmitted by needle-stick accidents

### Viruses

#### HIV

Hepatitis B, C, D

Herpes simplex

Herpes varicella zoster

### Bacteria

Streptococcal infections

Staphylococcal infections

Syphilis

Tetanus

Tuberculosis

### Other

Malaria

## Prevention

- Avoid physically struggling with overdose victims or high-risk patients for lavage or venipuncture.
- Needles should not be recapped.
- Dispose of needles immediately and directly into a leak-proof, puncture-proof sharps container.
- Avoid contact with blood.
- Wear protective gloves (does not prevent sharps injury).

## Postexposure prophylaxis

Postexposure prophylaxis (PEP) must be considered for high-risk exposure such as hollow blood-containing needles, deep injury and high viral load or late-stage HIV infection of the source.<sup>3</sup> Although in most instances of sharps injuries PEP is not justified, do seek expert advice.

## Management<sup>8</sup>

- Wash affected site with soap and water without scrubbing. Also wash or irrigate any areas of skin, eye/conjunctiva or other mucous membrane exposed to blood or body fluids.
- Do not suck or squeeze wound.
- Encourage bleeding.
- Reassure the patient that the risk of viral infection is very low.
- Obtain information about and blood from the sharps victim and the source person (source of body fluid). A known carrier of hepatitis B surface antigen or an HIV-positive source person will facilitate early decision making.

*Note:* It takes 3 months to seroconvert with HIV so the patient may be infected but negative on initial tests.

Consider the exposed person's wishes after discussing the risks/benefits of treatment including adverse effects.

### Known hepatitis B carrier source person

- If injured person immune—no further action
- If non-vaccinated and non-immune:
  - give hyperimmune hepatitis B gammaglobulin (within 48 hours)
  - commence course of hepatitis B vaccination, within 24 hours

### Known hepatitis C carrier source person<sup>8</sup>

- The recipient needs to have follow-up HCV antibody tests at 1 and 6 weeks and ALT levels at 4–6 months.
- There is no effective immunoprophylaxis available. Consider early therapy should seroconversion occur.

### Known HIV-positive source person<sup>8</sup>

Refer to consultant about relative merits of drug prophylaxis (ART) and serological monitoring. A case control study by the US Centers for Disease Control and Prevention indicated that giving zidovudine following a needle-stick injury decreases the rate of HIV seroconversion by 79%.<sup>9</sup>

### Options (best to start within 1–2 hours)

- low risk  
emtricitabine + tenofovir, daily for 4 weeks  
or  
zidovudine + lamivudine 12-hourly for 4 weeks
- high risk  
*add*  
lopinavir + ritonavir 400 + 100 mg (o) 12 hourly for 4 weeks prophylaxis within 8 hours, preferably within 1–2 hours,<sup>10</sup> for 6 weeks  
*or*  
serological monitoring 0, 4, 6, 12, 24 and 52 weeks<sup>11</sup> (check with consultant and refer to national guidelines; WHO guidelines: <whqlibdoc.who.int/publications/>)

### Unknown risk source person

Take source person's blood (if consent is given) and sharps victim's blood for hepatitis B (HBsAg and anti-HBs) and hepatitis C and (if high risk for HIV)

HIV status tests. Commence hepatitis B vaccination if not vaccinated.

*Note:* Informed consent for testing and disclosure of test results for involved person should be obtained.

## Tetanus prophylaxis

Tetanus is a very serious disease but completely preventable by active immunisation. Protection should be universal, especially if the childhood immunisation program is followed. However, all patients with wounds should be assessed for their tetanus status and managed on their merits. For severe wounds the possibility of gas gangrene should also be considered.

Tetanus-prone wounds:

- compound fractures
- penetrating injuries
- foreign bodies
- extensive crushing
- delayed debridement
- severe burns
- pyogenic infection

For the primary immunisation of adults, tetanus toxoid (singly or combined with diphtheria if primary childhood course not given) is given as two doses 6 weeks apart with a third dose 6 months later. Booster doses of tetanus toxoid are given every 10 years or at the time of major injury occurring 5 years after previous dose.

## Passive immunisation

Passive immunisation, in the form of tetanus immunoglobulin 250 units by IM injection, is reserved for non-immunised individuals or those of uncertain immunity wherever the wound is contaminated or has devitalised tissue. Wounds at risk include those contaminated with dirt, faeces/manure, soil, saliva or other foreign material; puncture wounds; and wounds from missiles, crushes and burns.

The guide is outlined in **TABLE 134.4**.

## Practice tips

- Have the patient lying down for suturing and parents of children sitting down.
- Avoid using antibiotic sprays and powders in simple wounds—resistant organisms can develop.
- Consider tetanus and gas gangrene prophylaxis in contaminated and deep necrotic wounds.

**Table 134.4** Guide to tetanus prophylaxis in wound management<sup>3</sup>

Time since vaccination	Type of wound	Tetanus toxoid	Tetanus immunoglobulin
History of 3 or more doses of tetanus toxoid			
<5 years	All wounds	No	No
5 to 10 years	Clean minor wounds	No	No
	All other wounds	Yes	No
>10 years	All wounds	Yes	No
Uncertain vaccination history or less than 3 doses of tetanus toxoid			
	Clean minor wounds	Yes	No
	All other wounds	Yes	Yes

- Give a tetanus booster if patient has not had one within 5 years for dirty wounds or within 10 years with clean wounds.
- Give tetanus immunoglobulin if patient is not immunised or if the wound is grossly contaminated.
- Never send head-wound patients home before thoroughly washing their hair and carefully examining for other lacerations.
- Any laceration in the cheek, mandible or lower eyelid may damage the facial nerve, parotid duct or lacrimal duct respectively.
- When a patient falls onto glass it takes bone to halt its cutting path. Assume all structures between skin and bone are severed.

*The broken bone, once set together, is stronger than ever.*

John Lyly (1554–1606)

Common fractures and dislocations usually apply to the limbs, the shoulder girdle and the pelvic girdle and their management requires an early diagnosis to ensure optimum treatment and to prevent complications. Early diagnosis depends on the physician being vigilant and on having knowledge of the less common conditions so that a careful search for the diagnosis can be made.

The diagnosis is dependent on a good history followed by a careful examination, good-quality X-rays appropriate to the injury (e.g. stress view) and, if necessary, special investigations. The golden rule is: if in doubt—X-ray. The family doctor should develop the habit of looking at a patient's X-rays. Such a back-up to the radiologist's report can help avoid missed diagnoses.

There are many pitfalls involved in managing fractures and dislocations. Many injuries, such as fractures of the arm and hand, may seem trivial but they can lead to long-term disability. This chapter presents guidelines to help avoid these pitfalls.

### Key facts and checkpoints

- A fracture usually causes deformity but may cause nothing more than local tenderness over the bone (e.g. scaphoid fracture, impacted fractured neck of femur).
- The classic signs of fracture are:
  - pain
  - tenderness
  - loss of function
  - deformity
  - swelling/bruising
  - crepitus
- X-ray examination of the affected area of the upper limb should include views of joints proximal or distal to the site of the injury, and X-rays in both AP and lateral planes.
- If an X-ray is reported as normal but a fracture is strongly suspected, an option is to splint the affected limb for about 10 days and then repeat the X-ray.
- As a rule, displaced fractures must be reduced whereby bone ends should be placed in proper alignment and then immobilised until union occurs.
- Fractures should be monitored radiologically for loss of position, particularly in the first 1–2 weeks following reduction.
- Bone union is assessed clinically by reduced pain at the fracture site and reduced fracture mobility. It is assessed radiologically by X-ray features such as trabecular continuity across the fracture site and bridging callus.
- Non-union is caused by such factors as inadequate immobilisation, excessive distraction, loss of healing callus, infection or avascular necrosis.
- Stiffness of joints is a common problem with immobilisation in plaster casts and slings so the joints must be moved as early as possible. Early use is possible if the fracture is stable.
- A dislocation is a complete disruption of one bone relative to another at a joint.
- A subluxation is a partial displacement such that the joint surfaces are still in partial contact.
- A sprain is a partial disruption of a ligament or capsule of a joint.
- Always consider associated soft-tissue injuries such as neuropraxia to adjacent nerves, vascular injuries and muscle compartment syndromes.
- A stress fracture is an incomplete fracture resulting from repeated small episodes of trauma, which individually would be insufficient to damage the bone. Stress fractures, especially in the foot, are most likely to result from sport, ballet, gymnastics and aerobics. Their incidence rises sharply at times of increased activity.<sup>1</sup>
- Typical stress fractures (with their usual cause) include:
  - navicular (sprinting sports, football)
  - metatarsal neck (running, walking, basketball, jumping)
  - base of fifth metatarsal (dancing)
  - femur—neck or shaft (distance running)
  - ulna (weight-lifting)
  - distal radial and ulnar epiphyses (gymnastics)
  - talus (running)

- proximal tibia (running, football)
- lumbar spine
- medial tibia (running, football)
- distal phalanges (guitar playing)
- cervical spinous process (gardening)
- lumbar vertebrae—pars interarticularis (fast bowling)
- spiral humerus (throwing sports)
- rib fractures—1st (weight-lifting)
- rib fractures—8th (tennis)
- The key strategy of most reduction manoeuvres is traction, especially for dislocations. This may be supplemented with translation or leverage.

### Red flag pointers for fractures

- Supracondylar fracture in children
- Elbow fractures in children, especially lateral humeral condyle
- Trampoline injuries in children
- Scaphoid fracture
- Scapholunate dislocation
- Skull fractures, especially temporal
- Talar dome fractures
- All intra-articular fractures
- Avascular heads of humerus and femur

### Testing for fractures<sup>2</sup>

This method describes the simple principle of applying axial compression for the clinical diagnosis of fractures of bones of the forearm and hand, but also applies to bones of the limbs.

Many fractures are obvious when applying the classic methods of diagnosis but it is sometimes more difficult if there is associated soft-tissue injury from a blow or if there is only a minor fracture such as a greenstick fracture of the distal radius.

If the bone suspected of fracture is compressed gently from end to end, the patient will feel pain. A soft-tissue injury of the forearm will show pain, tenderness, swelling and possibly loss of function. It will, however, not be painful if the bone is compressed axially—that is, in its long axis.

Walking is another method of applying axial compression, and this is very difficult (because of pain) in the presence of a fracture in the weight-bearing axis or pelvis.

### Method

- 1 Grasp the affected area both distally and proximally with your hands.

- 2 Compress along the long axis of the bones by pushing in both directions, so that the forces focus on the affected area (fracture site, see FIG. 135.1a). Alternatively, compression can be applied from the distal end with stabilising counterpressure applied proximally (see FIG. 135.1b).
- 3 The patient will accurately localise the pain at the fracture site.

FIGURE 135.1 Testing for fractures: (a) axial compression to detect a fracture of the radius or ulna bones, (b) axial compression to detect a fracture of the metacarpal

### Principles of treatment of limb fractures

To reduce any fracture properly, the following steps must be taken (see FIG. 135.2a).<sup>3</sup>

- 1 Disimpact the fragments, usually by increasing the deformity.
- 2 Re-establish the correct length of the bone.
- 3 Re-establish the correct alignment by proper reduction of the fracture.
- 4 Stabilise the bone in an acceptable position for as long as it takes to heal.

(a) fracture (impacted)

Step 1. Disimpaction

Step 2. Establish length

Step 3. Establish alignment

**FIGURE 135.2** (a) Principles of reduction of fractured bones, (b) Principles of moulding to maintain reduction: the arrows indicate the three point pressure areas required to maintain reduction

The above steps will only be achieved with adequate anaesthesia, analgesia and relaxation. Maintenance of the reduction depends upon the moulding, which utilises the intact periosteal bridge to hold the fracture fragments in a reduced position. **FIGURE 135.2b** illustrates the principle of moulding to maintain reduction.<sup>3</sup>

## INJURIES OF THE SKULL AND FACE

### § Skull fractures

Closed fractures without any neurological symptoms do not require active intervention. Depressed fractures

may require elevation of the depressed fragment. Compound fractures of the vault require careful evaluation and referral. Special care is required over the midline as manipulation (usually by elevation) of any depressed fragment can tear the sagittal sinus, causing profuse and fatal bleeding.<sup>4</sup> Beware of the associated extradural or subdural haematoma (see **CHAPTER 75**).

### § Base of skull fractures

These fractures are difficult to diagnose on radiography but their presence is indicated by bleeding from the nose, throat or ears. CSF may be observed escaping, especially through the nose, if the dura is also torn.

Treatment of basal fractures is based on prevention of intracranial infection and avoidance of excessive interference with the nose or ear, such as with packing and nasogastric tubes. An appropriate antibiotic is cotrimoxazole.<sup>4</sup>

### § Malar fracture

A fractured zygomaticomaxillary complex (malar) is a common body contact sports injury or injury resulting from a fight. See **FIGURE 135.3**.

### Clinical features

- Swelling of cheek
- Circumocular haematoma
- Subconjunctival haemorrhage
- Palpable step in infraorbital margin
- Flat malar eminence when viewed from above
- Paraesthesia due to infraorbital nerve injury
- Loss of function (i.e. difficulty opening mouth)

### Management

- Head injury assessment
- Exclude 'blow-out' fracture of the orbit
- Exclude ocular trauma:
  - remove contact lenses if worn
  - check visual acuity
  - check for diplopia
  - check for hyphaema
  - check for retinal haemorrhage
- Persuade patient not to blow nose (can cause surgical emphysema)
- If fracture displaced, refer for reduction under general anaesthesia

### Reduction methods

- Elevation by temporal or intraoral approach—healing can be expected in 3–4 weeks
- Some require interosseous wiring or plating or pinning

**FIGURE 135.3** Fractured malar showing circumocular haematoma and depression of the infraorbital margin

### § Fracture of mandible

A fracture of the mandible follows a blow to the jaw. The patient may have swelling (which can vary from virtually none to severe), pain, deformity, inability to chew, malalignment of the jaw and teeth and drooling of saliva. Intraoral examination is important as submucosal ecchymosis in the floor of the mouth is a pathognomonic sign.

A simple office test for a suspected fractured mandible is to ask patients to bite on a wooden tongue depressor (or similar firm object). Ask them to maintain the bite as you twist the spatula. If they have a fracture they cannot hang onto the spatula because of pain.<sup>5</sup>

X-rays:

- AP views and lateral obliques
- an orthopantomogram provides a global view

### First aid management

- Check the patient's bite and airway
- Remove any free-floating tooth fragments and retain them
- Replace any avulsed or subluxed teeth in their sockets

*Note:* Never discard teeth.

- First aid immobilisation with a four-tailed bandage (see FIG. 135.4)

**FIGURE 135.4** Immobilisation of a fractured mandible in a four-tailed bandage

### Treatment

Refer for possible internal fixation.

A fracture of the body of the mandible will usually heal in 6–12 weeks (depending on the nature of the fracture and fitness of the patient).

### § Dislocated jaw

The patient may present with unilateral or bilateral dislocation. The jaw will be 'locked' and the patient unable to articulate or close the mouth.

### Method of reduction

- Get the patient to sit upright with the head against the wall.
- Wrap a handkerchief or cloth around both thumbs and place the thumbs over the lower molar teeth, with the fingers firmly grasping the mandible on the outside.
- Firmly thrusting with the thumbs, push downwards towards the floor (see FIG. 135.5).

**FIGURE 135.5** Method of reduction of a dislocated jaw by downward traction on the mandible

This action invariably reduces the dislocation, but the reduction can be reinforced by the fingers rotating the mandible upward as the thumbs thrust downwards.

## INJURIES OF THE SPINE

Cervical fractures, especially atlas (C1), axis (C2) and odontoid process, require early referral with the neck immobilised in a cervical collar, in a supine position. A hard collar is preferred but a soft collar with sandbags either side of the head to prevent movement will suffice.

### § Thoracolumbar fractures

Fractures or fracture dislocations of the thoracic and lumbar vertebrae, without neurological deficit, are classified as either stable or unstable.

#### Stable fractures

- Compression fractures of vertebral body with <50% loss of vertical height
- Minor fractures
- Laminar fractures

Treatment: rest on firm-to-hard bed for 10–28 days depending on symptoms, followed by a brace.

Special problems:

- retroperitoneal haematoma
- paralytic ileus
- associated kidney rupture with L1 fractures
- underlying vertebral body pathology in the elderly (e.g. myeloma or metastases)

#### Unstable fractures

Burst fractures and shearing fractures are usually unstable. They are often associated with partial or complete paraplegia and require urgent referral.

### § Fractures of sacrum and coccyx

No treatment apart from symptomatic treatment is required. Manual reduction per rectum can be attempted for significant forward displacement of the coccyx. Advise the use of a rubber ring or special cushion (such as a Sorbo cushion) when sitting. Excision of the coccyx may be considered for persistent discomfort.

## INJURIES OF THE THORACIC CAGE

### § Fractured rib

#### Clinical features

- Pain over the fracture site, especially with deep inspiration and coughing

- Localised tenderness and swelling
- Pain in the site upon whole-chest compression
- X-ray confirms diagnosis and excludes underlying lung damage (e.g. pneumothorax). There is a high incidence of false negative fractures on X-ray, so caution is necessary.
- Suspect splenic, hepatic and kidney trauma with lower rib fractures

#### Treatment

A simple rib fracture can be extremely painful. The first treatment strategy is to prescribe analgesics, such as paracetamol, and encourage breathing within the limits of pain. If pain persists in cases of single or double rib fracture with no complication, application of a rib support is most helpful.

#### The universal rib belt

A special elastic rib belt can provide thoracic support and mild compression for fractured ribs (see FIG. 135.6). Despite its flexibility it gives excellent support and symptom relief while permitting adequate lung expansion. The elastic belt is 15 cm wide and has a Velcro grip fastening, so it can be applied to a variety of chest sizes.

#### Healing time

Healing may take 3–6 weeks; local discomfort may persist much longer.

### § Fractures of the clavicle

There is a history of a fall onto the outstretched hand or elbow although this fracture may also occur

FIGURE 135.6 Method of application of a universal rib belt

with a direct blow to the clavicle or the point of the shoulder. The patient has pain aggravated by shoulder movement and usually supports the arm at the elbow and clasped to the chest. The most common fracture site is at the junction of the outer and middle thirds, or in the middle third. Consider the possibility of neurovascular injury.

### Treatment

- St John's elevated sling to support arm—for 3 weeks
- Figure-of-eight bandage (used mainly for severe discomfort)
- Early active exercises to elbow, wrist and fingers
- Active shoulder movements as early as possible

### Special problem

Type II fracture at the lateral end of the clavicle that is displaced: this fracture, which usually occurs in elderly patients following low energy injuries,<sup>6</sup> is often subject to delayed or non-union. The line of fracture passes through the conoid and trapezoid ligaments. Consider referral for open reduction.

### Healing time

Healing time is 4–8 weeks.

The appropriate use of slings for fracture-dislocations is presented in [TABLE 135.1](#).

**Table 135.1** Appropriate use of slings for fracture-dislocations

<b>Collar and cuff</b>	Fractured shaft of humerus
<b>Broad arm sling</b>	Fractured forearm Fractured scapula
<b>St John's high sling</b>	Fractured clavicle Fractured neck of humerus Subluxed acromioclavicular joint Dislocated acromioclavicular joint Subluxed sternoclavicular joint

### § Fractures of the scapula

Fractures of the scapula may include:

- body of scapula: due to a crushing force, considerable blood loss, may be rib fractures
- neck of scapula (may involve joint)
- acromion process (due to a blow or fall on the shoulder)
- coracoid process (due to a blow or fall on the shoulder)

### Treatment

- Broad-based triangular sling for comfort
- Early active exercises for shoulder, elbow and fingers as soon as tolerable
- A large glenoid fragment usually requires surgical reduction because of potential glenohumeral joint instability

### Healing time

Healing takes several weeks to months.

### § Fractures of the sternum

These are treated symptomatically with analgesics but careful evaluation of thoracic injuries, including cardiac tamponade or myocardial contusion, is essential. A significantly depressed fracture should be referred. An ECG is advisable.

## DISLOCATIONS OF THE SHOULDER AND CLAVICLE

### § Acromioclavicular joint dislocation/subluxation

A fall on the shoulder, elbow or outstretched arm can cause varying degrees of separation of the acromioclavicular (AC) joint, causing the lateral end of the clavicle to be displaced upwards (see [FIG. 135.7](#)).

- Grades I, II: partial separation, involving tearing of the AC capsule and ligaments
- Grade III: complete tearing, also affecting the coracoclavicular ligaments

**FIGURE 135.7** Subluxation of the acromioclavicular joint: typical appearance

## Treatment

- Analgesics
- St John's arm sling (suitable for all injuries)
- Mobilisation exercises as soon as possible
- For Grade III, a compression bandage (or long straps of adhesive low-stretch strapping) with padding at pressure points—elbows, clavicle and coracoid. The clavicle should be manipulated into its correct position and the forearm elevated: applying pressure from above (clavicle) and below (elbow) to achieve compression, apply a bandage over the outer end of the clavicle and round the elbow joint which is flexed to 90°. The bandage or strapping is worn for 2–3 weeks.<sup>6</sup> Many patients are unable to tolerate this method of treatment. Skin irritation or blisters are common. This occurs particularly with adhesive strapping and the deformity commonly requires correction after the removal of bandage or strapping. The same effect may be achieved with an orthotic device known as a Kenny-Howard sling or brace.
- The issue of internal fixation versus conservative treatment for a complete dislocation is controversial in that the bulk of patients treated conservatively have minimal residual symptoms. However, a significant proportion have residual symptoms in the form of AC joint pain and traction effects on the brachial plexus due to loss of scapular suspension. The patients most likely to have these symptoms are those with high grades of separation, involvement of the dominant shoulder and participation in employment or sports that place heavy physical demands on the shoulder girdle. If there is disruption of the suspensory ligaments of the clavicle, surgical reduction and stabilisation is the preferred option.<sup>6</sup> If in doubt, referral within the first few weeks of injury for consideration of the pros and cons of conservative versus surgical treatment would be appropriate.

## § Sternoclavicular joint dislocation/subluxation

This uncommon injury is caused by a fall or very heavy impact on the shoulder, causing the medial end of the clavicle to move forwards or anterior (making it prominent) or backwards.<sup>7</sup> Plain X-rays are difficult to interpret and a CT scan is the ideal diagnostic method.

## Special problem

A special problem is backward (inward) displacement of the clavicular end with danger to major blood vessels and trachea. This is one of the few potentially life-threatening orthopaedic injuries. Urgent referral for reduction is essential, especially if stridor or venous obstruction is present. A first aid measure is to place a sandbag between the shoulders with the patient supine and extending the abducted arm on the affected side.<sup>8</sup> Closed reduction can usually be achieved under anaesthesia. The reduction is nearly always stable.

## Treatment

Forward subluxation or dislocation, unlike posterior dislocation, is nearly always unstable and resists attempts at maintaining closed reduction. Despite the persistence of a medial clavicular swelling, most patients need a sling for only 1–2 weeks and the bulk of their pain settles over the following months. Surgery is generally only indicated for an unusually painful and chronic anterior sternoclavicular dislocation.

## § Dislocation of the shoulder

Dislocations of the shoulder joint can be caused by an impact on the arm by falling directly on the outer aspect of the shoulder, or by a direct violent impact, or by a forceful wrenching of the arm outwards and backwards.

## Types of dislocation

- Anterior (forward and downward)—95% of dislocations
- Posterior (backward)—diagnosis often overlooked
- Recurrent anterior dislocation (recurrent posterior dislocation extremely rare)

## Anterior dislocation of the shoulder

### Management

AP and lateral X-rays should be undertaken to check the position and exclude an associated fracture. The arm should be assessed for the presence of neurological injury before reduction. Reduction can be achieved under general anaesthesia (easier and more comfortable) or with intravenous pethidine ± diazepam. The following methods can be used for anterior dislocation. Satisfactory analgesia and patient relaxation are vital to the success of any of the methods.

## Kocher method

(See FIG. 135.8.)

- Elbow flexed to 90° and held close to the body
- Slowly rotate arm laterally (externally)
- Adduct humerus across the body by carrying point of elbow while simultaneously applying longitudinal traction along the line of the humerus
- Rotate arm medially (internally)

FIGURE 135.8 Kocher method for a dislocated shoulder

## Hippocratic method

Apply traction to the outstretched arm by a hold on the hand with countertraction from stockinged foot in the medial wall of the axilla. This levers the head of the humerus back. It is a good method if there is an associated avulsion fracture of the greater tuberosity.

## Postreduction

- Reduction is complete if the hand can rest comfortably on the opposite shoulder.
- Confirm reduction by X-ray in two planes and again assess for unsuspected fractures (e.g. glenoid rim or greater tuberosity fractures).
- Keep the arm in a sling for 2 weeks.
- Apply a swathe bandage to the chest wall.
- After immobilisation, begin pendulum and circumduction exercises.
- Combined abduction and lateral rotation should be avoided for 3 weeks.

## Posterior dislocation of the shoulder

This is the most commonly misdiagnosed major joint dislocation.<sup>9</sup> Posterior dislocation most often follows an epileptic seizure or electrical shock. The postictal patient with a painful shoulder has a posterior dislocation of the shoulder until proven otherwise. Less often this injury is caused by a fall onto the outstretched hand with the arm internally rotated or by a direct blow to the front of the shoulder. If any doubt persists about the diagnosis, a CT scan is appropriate.

The shoulder contour may look normal but the major clinical sign is painful restriction of external rotation, which is usually completely blocked. Beware of the problem of pain in the shoulder after a convulsion. An 'axillary shoot through' X-ray view should be routinely ordered following shoulder trauma.

## Reduction of posterior dislocation

Using appropriate analgesia or anaesthesia, apply traction to the shoulder in 90° of abduction (with the elbow at right angles) and laterally (externally) rotate the limb. Referral for reduction is advisable.

## Recurrent anterior dislocation

Acute anterior shoulder dislocation may tear or stretch the anterior capsular ligaments from their bony origin. This may predispose to recurrent anterior dislocation or subluxation. (Recurrent posterior instability is rare.)

A simple procedure for reducing recurrent anterior dislocation is as follows.

- Get the patient to sit comfortably on a chair with legs crossed.
- The patient then interlocks hands and elevates the upper knee so that the hands grip the knee.
- The knee is gradually lowered until its full weight is taken by the hands. At the same time the patient has to concentrate on relaxing the muscles of the shoulder girdle. This method usually effects reduction without the use of force.

Recurrent dislocation often requires definitive surgery, depending on the frequency of dislocations and the degree of apprehension between episodes.

## The Bankart lesion

Teenagers and young adults who sustain a traumatic dislocation of the shoulders tend to have the Bankart lesion, which is avulsion of the anteroinferior capsulolabral complex, leading to a high rate of recurrent dislocation. This should be considered for an arthroscopic anterior stabilisation.

## Pitfalls

- Nerve injury, especially axillary (circumflex) nerve
- A fractured neck of the humerus, especially in the elderly, may mimic a dislocation
- Associated fractures (greater tuberosity, head of radius, glenoid) may require internal fixation
- Great difficulty with some reductions (this is often related to inadequate analgesia; the use of excessive force may result in fracture)

- Failing to X-ray all suspected dislocations before and after reduction; failing to obtain an axillary view to show posterior displacement or fractures of the humerus or glenoid

Orthopaedic problems that cause difficulties in diagnosis and management are outlined in **TABLE 135.2**.

**Table 135.2** Important orthopaedic problems that cause difficulties in diagnosis and management<sup>9</sup>

FRACTURES OF THE HUMERUS

§ Fractured greater tuberosity of humerus

Treat with a combination of immediate mobilisation and rest in a sling unless grossly displaced, when

surgical reduction is advisable. Shoulder stiffness can be a disabling problem, so early movement is encouraged with review in 7 days. This fracture should be monitored by X-ray within 2 weeks after injury. Undetected displacement may lead to mechanical impingement against the acromion. This fracture may also be an indication of the patient having had a transient glenohumeral dislocation.

§ Fractured surgical neck of humerus

This usually occurs in the elderly due to a fall onto the outstretched hand. The fragments may be impacted. The greater tuberosity may also be fractured. Watch out for associated dislocation. In adolescents, fracture–separation of the upper humeral epiphysis occurs.

Treatment (no displacement or impaction)

- Triangular sling
- When pain subsides (10–14 days) encourage pendulum exercises in the sling
- Aim at full activity within 8–12 weeks postinjury

Displaced fractures may require internal fixation. Severely comminuted fractures may predispose to post-traumatic osteoarthritis or humeral head avascular necrosis. Referral with a view to prosthetic hemiarthroplasty should be considered.

Healing

Union usually occurs in 4 weeks and consolidation at 6 weeks.

Pitfalls with fractures of the surgical neck

Minimally displaced fractures of the surgical neck of the humerus are usually managed conservatively, but overzealous early mobilisation can lead to non-union.<sup>8</sup> If there is a communication of this fracture with joint fluid, movement washes away the fracture haematoma and leads to the development of true pseudoarthrosis. Judicious early immobilisation will avert this complication.

Always remember the cardinal fracture management rule: ‘First ensure that stability of the fracture is sufficient to allow healing before prescribing rehabilitation exercises or early use of the extremity’.<sup>9</sup>

The management of various humeral fractures is summarised in **FIGURE 135.9**.

FIGURE 135.9 Various fractures of the humerus in adults

### § Fracture of shaft of humerus

Humeral shaft fractures may be:

- spiral—due to a fall on the hand
- transverse or slightly oblique—fall on elbow with arm abducted
- comminuted—heavy blow

Caution: watch for radial nerve palsy.

#### Treatment

- Perfect bony opposition is not necessary; some overriding is acceptable but distraction of the fragments is not.
- Undisplaced fracture: collar and cuff with elbow flexed to 60–70°.
- Significantly displaced humeral shaft fractures may require manipulation under anaesthetic. However, the vast majority of shaft fractures realign to a satisfactory extent under gravitational effects in a sling once muscle spasm and oedema have subsided. A U-shaped hanging cast or slab enhances the gravitational effect and assists splintage.

### Intercondylar fractures in adults

Intercondylar fractures, which may be T-shaped or Y-shaped, are usually caused by a fall on the point of the elbow, which drives the olecranon process upwards, splitting the condyles apart. Fractures involving the joint can cause long-term problems of post-traumatic osteoarthritis and joint stiffness. Referral for reduction (closed or open) is appropriate.

### INJURIES OF THE ELBOW AND FOREARM

#### § Fractures and avulsion injuries around the elbow joint in children

Potentially severe deforming injuries include:

- supracondylar fractures
- fracture of the lateral humeral condyle
- fracture of medial humeral epicondyle (see FIG. 135.10)
- fracture of neck of radius

Fractures around the elbow in children require referral to consultants experienced in radiology and fracture management.

#### Supracondylar fractures with forearm ischaemia

Supracondylar fractures represent about half of all elbow fractures in children and most are extension fractures following falls onto the outstretched arm.

FIGURE 135.10 Fractures and avulsion injuries around the elbow joint in children

Pressure of the displaced bony fragments causing impingement on the brachial artery leads to impending forearm flexor compartment ischaemia and muscle death. Severe forearm pain is the most significant and important sign of ischaemia. Neuropraxia of the median, radial or ulnar nerves is common. These injuries almost invariably recover.

This diagnosis must always be assumed in displaced supracondylar fractures in children. Thus, it is the GP's responsibility to ensure treatment is expedited. The brachial and radial pulses should be assessed carefully.

The fracture is reduced by hyperflexion of the elbow during traction (after lateral displacement has been corrected) and then immobilised in collar and cuff and stockinet vest. The fully flexed elbow with the usually intact posterior periosteal hinge provides fracture stability. Plaster casting is unnecessary and some would suggest contraindicated because of the significant risk of ischaemic contracture. Circulatory status requires monitoring in the first 24 hours following injury. The collar and cuff should be used for 6 weeks. The invariably stiff elbow quickly resolves without a need for formal therapy.

### Fracture of the lateral humeral condyle

Fractures of the lateral humeral condyle also result from a fall onto the outstretched arm in children (see FIG. 135.10). The fracture line passes vertically or obliquely through the lateral condyle and thus crosses the distal humeral growth plate. It occurs in an age group prior to the appearance of the epiphysis of the lateral epicondyle. Pain and swelling over the lateral elbow, but without the gross deformity of a supracondylar fracture of the humerus, could make one suspect this injury. The fracture is commonly overlooked on X-ray. Comparison views of the opposite elbow are particularly helpful in diagnosing this injury.

Recognition of the fracture and early open reduction and internal fixation with wires is vital to reduce the risk of premature plate closure. Such growth plate disturbance may result in a progressive valgus deformity of the elbow and the late development of an ulnar nerve palsy.

The Salter–Harris classification of epiphyseal injuries (FIG. 135.11), which is widely used, has therapeutic and prognostic implications. Most of these injuries heal well but some have the potential for growth arrest or asymmetrical bone growth, leading to deformity and permanent disability, especially type V. Types I and II (the most common) have an excellent prognosis but type III and IV require precise reduction.<sup>10</sup>

FIGURE 135.11 Salter–Harris classification of growth plate fractures. V represents compression of the growth plate (green in the figure) as shown by the region arrowed  
Source: *Brunker and Khan's Clinical Sports Medicine*, 4th edn McGraw-Hill, Sydney, 2009.

### Fracture of the medial humeral epicondyle

This problem occurs typically in adolescents following a fall onto the outstretched hand. The medial epicondyle may be avulsed by massive flexor pronator muscle contraction together with abduction stresses on the forearm. Avulsion of the epicondyle occurs in the young patient before the epiphysis is united. If displaced, this fracture is best treated by open reduction and internal fixation. Untreated injuries commonly result in non-union, elbow pain and restricted elbow extension.

### Fractured neck of radius

This fracture is caused by a child falling on to the outstretched hand. The fracture line is transverse and is situated immediately distal to the epiphysis.

The degree of tilt is critical. Up to 15° of tilt is acceptable but, beyond that, reduction (preferably closed) will be necessary. The head of the radius must never be excised in children.

### § Dislocated elbow

A dislocated elbow is caused by a fall onto the outstretched hand, forcing the forearm backwards

**FIGURE 135.12** Dislocated elbow: uncomplicated posterior dislocation

**FIGURE 135.13** Dislocated elbow showing posterior displacement of the ulna and radius, with the typical deformity

to result in posterior and lateral displacement (see **FIGS 135.12** and **135.13**). The peripheral pulses and sensation in the hand must be assessed carefully. It may result in vascular injury to the brachial artery or injury to the median and ulnar nerves. Check the function of the ulnar nerve before and after reduction.

### Treatment

Attempt reduction with patient fully relaxed under anaesthesia. It is important to apply traction to the flexed elbow but allowing it to extend approximately 20–30° to enable correction of the lateral displacement and then the posterior displacement.

### Follow-up

Encourage early mobilisation with gentle exercises in between resting the elbow for 2–3 weeks in a collar and cuff with the elbow flexed above 90°, avoiding passive movements. A plaster cast should not be used because of the risk of ischaemic necrosis of

muscle. This will minimise the possibility of myositis ossificans. Recurrent dislocation of the elbow is uncommon.

### A simple method of reduction

This method reduces an uncomplicated posterior dislocation of the elbow without the need for anaesthesia or an assistant. The manipulation must be gentle and without sudden movement.

#### Method

- 1 The patient lies prone on a stretcher or couch, with the forearm dangling towards the floor.
- 2 Grasp the wrist and slowly apply traction in the direction of the long axis of the forearm (see **FIG. 135.14**).
- 3 When the muscles feel relaxed (this might take several minutes), use the thumb and index finger of the other hand to grasp the olecranon and guide it to a reduced position, correcting any lateral shift.

#### Pitfalls

- Incomplete reduction: ulna articulates with capitellum and not the trochlea
- Injury to ulnar nerve (spontaneous recovery usually occurs after 6–8 weeks)
- Associated fractures (e.g. coronoid process), which may cause instability

**FIGURE 135.14** Dislocated elbow: method of reduction by traction on the dependent arm

## § 'Pulled' elbow

See CHAPTER 64.

## § Fractured head of radius (adults)

If the fracture is very slight and undisplaced, treat conservatively with the elbow at right angles in a collar and cuff until pain subsides sufficiently to allow flexion/extension and pronation/supination exercises.

Elbow stiffness is a major problem even after apparently trivial radial head fractures. Early mobilisation is vital. Excision of the radial head should be considered for highly comminuted fractures that limit the ability to mobilise the elbow early or predispose to post-traumatic osteoarthritis. Associated distal radioulnar joint or wrist injuries are often overlooked.

## § Fractured olecranon

- Comminuted fracture (with little displacement): sling for 3 weeks and active movements
- Transverse (gap) fracture: open reduction with screw or wire

## § Monteggia fracture–dislocation of the radial head

Fractures of the proximal third of the ulna with dislocation of the radial head (Monteggia fracture–dislocation) (see FIG. 135.15) has a history of mismanagement during treatment. The radial head dislocation is easily overlooked.

Redislocation or subluxation of the radial head is common.

Since surgical intervention is advisable, referral of displaced forearm fractures for early surgery is recommended. Surgical plating of the ulnar shaft maintains the radial head in a reduced position. Follow-up X-rays are mandatory to ensure that there has not been a late redislocation of the radial head.

**FIGURE 135.15** Monteggia fracture–dislocation of the radial head; it is important not to miss a dislocated head of radius with a fracture of the proximal third of the ulna

## § Fracture–dislocation in the lower forearm (Galeazzi injury)

This injury is usually caused by a fall on to the hand and is a combination of a fractured radius (at the junction of its middle and distal thirds) and subluxation of the distal radioulnar joint. The patient should be referred, as open reduction is often required.

## § Fractures of the radius and ulna shafts

### General features

It is more common to have both bones broken. Displaced fractures of both forearm bones in the adult require perfect reduction, which can generally only be achieved by surgical reduction and plating. Less-than-satisfactory reduction interferes with normal pronation and supination. A fracture of one bone alone is uncommon and usually caused by a direct blow. For a fracture of one bone alone look for evidence of an associated dislocation of the other forearm bone. In children, greenstick fractures are common. Fractured radial shafts tend to slip and ulna fractures heal slowly. Dislocation of the head of the radius or inferior radioulnar joint can be missed if X-rays do not include the elbows and wrist joints.

### Reduction

- A greenstick fracture is readily straightened by firm pressure.
- A complete fracture (spiral or transverse) is reduced by traction and rotation.
- A slight overlap and angulation is permissible in children but perfect reduction is essential in adults.
- A plaster cast should include both the elbow and the wrist joints.

Healing time: (adults) spiral fracture—6 weeks; transverse fracture—12 weeks.

## INJURIES OF THE WRIST

## § Colles fracture of lower end of radius

A Colles fracture, probably the most common of all fractures, is a supination fracture of the distal 3 cm of the radius, caused by a fall onto the outstretched hand.

### Clinical features

- Usually an elderly woman
- Osteoporosis is common
- Fall on dorsiflexed hand

- Fracture features:
  - impaction
  - posterior displacement and angulation
  - lateral displacement and angulation
  - supination
  - dinner fork deformity (see FIG. 135.16)

**FIGURE 135.16** Dinner fork deformity of Colles fracture: a fracture of the distal head of the radius showing impaction and posterior displacement and angulation

### Treatment

- If minimal displacement—below-elbow plaster for 4 weeks, then a crepe bandage
- If displaced: meticulous reduction under anaesthesia:
  - set in flexion 10°, ulnar deviation 10° and pronation (see FIG. 135.17)
  - below-elbow plaster 4–6 weeks (6 weeks maximum time)
  - unstable fractures may require an above-elbow cast initially with the forearm in pronation
  - check X-ray at 10–14 days; position may be lost as swelling subsides and plaster becomes loose

Problems associated with Colles fracture:

- watch for ruptured extensor pollicus longus tendon
- stiffness of the elbow, MCP joints and IP joints
- discomfort at inferior radioulnar joint due to disruption
- regional pain syndrome

**FIGURE 135.17** Ideal position of the forearm in a Colles plaster: note ulnar deviation, slight flexion and pronation

### Pitfall: the unstable Colles fracture<sup>9</sup>

With the advent of modern imaging techniques and power equipment it has become a simple procedure to pin unstable Colles fractures percutaneously, even in the elderly. Thus, severe deformities are now unacceptable. An early percutaneous pin is much simpler than a late osteotomy. Colles fractures deserve more respect than they received in the past.

Remember the basic classification into intra-articular and extra-articular fractures. Restoring reasonable joint surface alignment is an important part of the treatment and fortunately is usually relieved with simple traction under local or general anaesthesia.

### § Smith fracture of lower end of radius

This is often referred to as a 'reverse Colles'. It is caused by a fall on to the back of the hand. The lower fragment is flexed and impacted on the upper fragment. It is reduced and immobilised for 6 weeks in a cast as for Colles fracture but with the wrist extended. Unstable fractures may require an above-elbow cast initially with the forearm in supination.

### § Ulna styloid fracture

Treat symptomatically. Delayed union or non-union is common, but rarely symptomatic.

### § Radial styloid fracture

Undisplaced: plaster slab for 3 weeks.

Displaced: closed reduction and plaster slab for 6 weeks. If this fails—open reduction.

### § Scaphoid fractures

Scaphoid fractures account for almost 75% of all carpal injuries (see FIG. 135.18), but are rare in children and the elderly.<sup>10</sup> A scaphoid fracture is caused typically by a fall onto the outstretched hand.

### Features

- Pain on lateral aspect of wrist
- Tenderness in the anatomical snuffbox (the key sign)
- Swelling in and around the snuffbox
- Pain or clicking on movement of the wrist
- Pain on axial compression of the thumb towards the radius

There is a 20% rate of false positive reporting of scaphoid radiographs and clinical confirmation of the diagnosis is mandatory.<sup>11</sup>

If a scaphoid fracture is highly suspected in the presence of a normal X-ray of wrist, immobilise the

FIGURE 135.18 Typical appearance of a fractured scaphoid

wrist in a scaphoid plaster for 10 days (ensure 1st MCP joint is immobilised), remove it and then re-X-ray. Isotopic bone scan may be indicated in cases where suspicion of fracture is high despite normal X-rays. For undisplaced and stable fractures, 6–8 weeks in a below-elbow scaphoid cast usually suffices (see FIG. 135.19). Displaced fractures of the scaphoid require reduction (either open or closed) and, if unstable, internal fixation.

All scaphoid fractures require late X-ray evaluation of treatment to diagnose non-union before they become symptomatic from late degenerative changes. Early bone grafting of a non-union can prevent fragment collapse and radioscapoid degenerative changes.

135

### Pitfall

The fracture may not be apparent on routine wrist X-rays. Lateral, antero-posterior and specific scaphoid views should be requested.

FIGURE 135.19 Appearance of the scaphoid plaster

## § Scapholunate dissociation

This not uncommon carpal injury results from disruption of the scapholunate interosseous ligament and palmar radiocarpal ligaments. It results in a gap appearing between the scaphoid and lunate bones (the so-called 'Terry Thomas' sign on plain AP X-rays of the wrist) and the scaphoid rotating into a vertical position on lateral X-rays. It is associated with pain in the wrist on dorsiflexion. Median nerve compression may occur after wrist or carpal dislocations.

Early diagnosis with referral simplifies treatment. This injury has only been recognised in recent times.

## INJURIES OF THE HAND

### § Thumb fractures

The thumb's special function renders injuries more difficult than other digits. Fractures well clear of the joints in the proximal and distal phalanges are treated in a similar way to other digits. However, intra-articular injuries are more common and internal fixation is more likely on the thumb than other digits.<sup>12</sup>

### Bennett fracture

This is a fracture–dislocation of the first carpometacarpal joint. The larger fragment of the first metacarpal dislocates proximally and laterally (see FIG. 135.20).

FIGURE 135.20 Method of reduction of a Bennett fracture–dislocation of the first carpometacarpal joint

## Treatment

Under anaesthesia the thumb is reduced using the forces indicated (see FIG. 135.20). A scaphoid plaster is applied with the thumb in the open grasp position. If anatomical reduction cannot be achieved by closed means, then open reduction and internal fixation is indicated. Percutaneous pinning with wires under X-ray control is also commonly used to hold an anatomical reduction.

## Gamekeeper's (or skier's) thumb

This problematic injury of the metacarpophalangeal joint is presented in more detail in CHAPTER 136.

## § Metacarpal fractures

Metacarpal fractures can be stable or unstable, intra-articular or extra-articular, and closed or open. They include the 'knuckle' injuries resulting from a punch, which is prone to cause a fracture of the neck of the fifth metacarpal. As a general rule, most metacarpal (shaft and neck) fractures are treated by correcting marked displacements with manipulation (under anaesthesia) and splinting with a below-elbow, padded posterior plaster slab that extends up to the dorsum of the proximal phalanx and holds the metacarpophalangeal joints in a position of function (see FIG. 135.21).<sup>4</sup>

FIGURE 135.21 Fracture of the metacarpal: showing position of function with posterior plaster slab and the hand gripping a roll of felt padding

There is often a tendency for metacarpal fractures to rotate and this must be prevented. This is best achieved by splinting the metacarpophalangeal joints at 90°, which corrects any tendency to malrotation. If there is gross displacement, shortening or rotation then surgical intervention is indicated. A felt pad acts as a suitable grip. The patient should exercise free fingers vigorously. Remove the splint after 3 weeks and start active mobilisation.

## § Phalangeal fractures

These fractures result from either direct trauma causing a transverse or a comminuted fracture or a torsional force causing an oblique fracture. The tendency to regard fractures of phalanges (especially middle and

proximal phalanges) as minor injuries (with scant attention paid to management and particularly to follow-up care) is worth highlighting. These fractures require as near-perfect reduction as possible, careful splintage and, above all, early mobilisation once the fracture is stable—usually in 2–3 weeks.

Nevertheless, overzealous mobilisation can be as dangerous as prolonged immobilisation. Early operative intervention should be considered if the fracture is unstable.

Angulation is usually obvious but it is most important to check for rotational malalignment, especially with torsional fracture. A simple method is to get the patient to make a fist of the hand and check the direction in which the nails are facing. Furthermore each finger can be flexed in turn and checked to see if the fingertips point towards the tubercle of the scaphoid (palpable halfway along the base of the thenar eminence and 1.5 cm distal to the distal wrist crease).

## The phalanges

- *Distal phalanges*: usually crush fractures; generally heal simply unless intra-articular. Disturbance of nail growth is common.
- *Middle phalanges*: tend to be displaced and unstable—beware of rotation.
- *Proximal phalanges*: of the greatest concern, especially of the little finger; intra-articular fractures usually need internal fixation.

## Treatment

*Non-displaced phalanges with no rotational malalignment.* Strap the injured finger to the adjacent normal finger with an elastic garter or adhesive tape for 2–3 weeks (i.e. 'buddy strapping') (see FIG. 135.22). Start the patient on active exercises.

or

If pain and swelling is a problem, splint the finger with a narrow dorsal or anterior slab (a felt-lined strip of malleable aluminium can be used) (see FIG. 135.23).

An alternative is to bandage the hand while the patient holds a tennis ball or appropriate roll of bandage in order to maintain appropriate flexion of all interphalangeal joints.

*Displaced phalangeal fractures (usually proximal and middle).* With suitable anaesthesia correct the deformity by traction and direct digital pressure. Maintain correction by splintage for 2–3 weeks. Ensure flexion at the interphalangeal joints with a dorsal padded plaster slab from above the wrist to the base of the fingernail (see FIG. 135.23).

**FIGURE 135.22** Treatment of non-displaced phalanges by 'buddy strapping': the fractured finger is strapped to an adjacent healthy finger

**FIGURE 135.23** Method of splinting a phalangeal fracture of the index finger by a posterior plaster slab<sup>4</sup>

135

### § Intra-articular phalangeal fractures

Intra-articular phalangeal fractures are a great problem in management as subsequent stiffness of even a single interphalangeal joint can be a significant disability. Subsequent degenerative changes are common.

These fractures often occur in association with subluxation or dislocation of the joint. Reduction and fixation of the fracture may be an integral part of restoring joint stability. Displaced intra-articular phalangeal fractures, especially with joint instability, require referral.

### Mallet finger

Refer to **CHAPTER 136**.

### § Penetrating injuries to the hand

Assessing these injuries requires a careful history and examination. The pugilist who sustains a seemingly minor cut over a 'knuckle' may have a tooth-penetrating injury to the metacarpophalangeal

joint. In the flexed position the dorsal hood is drawn over the joint. The point of penetration of the hood retracts as the finger extends and 'locks' saliva into the joint. This injury invariably results in a severe septic arthritis unless aggressively treated with surgical debridement and high-dose antibiotics. Given the common occurrence of oral pathogens, antibiotic cover should include anaerobic organisms.

Refer to **CHAPTER 134**.

### § Dislocated fingers

In most cases the distal part dislocates dorsally.

For dislocated fingers immediate reduction is advisable. Test for an associated fracture and X-ray if appropriate. General anaesthesia may be necessary for reduction of a dislocated thumb.

### Simple reduction of a dislocated interphalangeal joint

This method employs the principles of using the patient's body weight as the distracting force to achieve reduction of the dislocation. It is relatively painless and very effective.

#### Method

- 1 Face the patient, both in standing positions.
- 2 Firmly grasp the distal part of the dislocated finger. A better grip is achieved by wrapping simple adhesive tape around the end of the finger.
- 3 Request the patient to lean backward, while maintaining the finger in the fixed position (see **FIG. 135.24**).
- 4 As the patient leans back, sudden, painless reduction should spontaneously occur. Otherwise under a ring block or sedation apply traction and push the proximal phalangeal head dorsally. Splint the joint for 3 weeks to allow soft-tissue healing.

#### Pitfalls

- Instability—torn collateral ligaments: unstable in lateral direction
- Interposed volar plate—postreduction full flexion absent
- Fractures of base of phalanx
- Extensor mechanism rupture (e.g. buttonhole deformity at PIP joint or mallet finger deformity at DIP joint)

These problems may need surgical reduction.

FIGURE 135.24 Reduction of a dislocated finger

## INJURIES TO THE PELVIS AND HIP

### § Fractures of the pelvis

Fractures of the pelvic ring are either:

- 1 stable: a single fracture
- 2 unstable: a break at two sites or association with disruption of the symphysis pubis or sacroiliac articulation

### Treatment

Stable pelvic fracture:

- symptomatic, especially analgesics
- bed rest as pain symptoms dictate
- attempt walking with an aid as soon as comfortable

Unstable fractures: these are usually serious with possible associated visceral damage or blood loss. Patients should be referred for expert help.

### § Femoral fractures

Femoral neck fractures include:

- subcapital fractures
- intertrochanteric fractures
- stress fractures in the young

Subcapital fractures are usually treated by pinning. Greatly displaced subcapital fractures in the elderly have a high risk of femoral head vascular necrosis. Thus, prosthetic replacement of the femoral head may be considered as a primary option.

A trap can be the impacted subcapital fracture that may allow partial weight-bearing, thus making radiological investigation essential in elderly patients complaining of hip pain. The fracture may not be evident on plain X-rays. If suspicion of fracture is still high, a bone scan should be performed.

Beware of the teenage athlete who complains of hip pain after running. Exclude a slipped upper femoral epiphysis and then a stress fracture. A technetium-99m bone scan will detect the fracture. A stress fracture may displace without warning, posing a serious risk of femoral head avascular necrosis. Thus, stress fractures must be considered for prophylactic pinning.

A summary of the management of other femoral fractures is presented in FIGURE 135.25.

FIGURE 135.25 Management of basic fractures of the femur

## § Posterior dislocation of the hip

This causes a very painful shortened leg which is held adducted, medially rotated and slightly flexed. Be careful of sciatic nerve damage. Early reduction within hours minimises the risk of avascular necrosis of the femoral head.

### Management

- Adequate analgesia (e.g. IM pethidine)
- X-rays to confirm diagnosis and exclude associated fracture
- Reduction of the dislocated hip under relaxant anaesthesia
- Follow-up X-ray to confirm reduction and exclude any fracture not visible on the first X-ray
- Intra-articular bone fragments need to be excluded by CT scanning

*Note:* Femoral neurovascular injury may occur in the rare cases of anterior dislocation of the hip.

## INJURIES OF THE LOWER LIMBS

### § Patella dislocation and subluxation

An acute dislocation needs to be reduced as a medical emergency.

The dislocated patella, which occurs mainly in children and young adults, especially girls, is always displaced laterally (see FIG. 135.26), often following a rotational and valgus force. The patient may feel the patella dislocate and it may sometimes reduce spontaneously. It may be associated with an osteochondral injury on the medial facet of the patella or the lateral femoral condyle. There is often a tense joint effusion, especially in the presence of an osteochondral fracture. Predisposing factors include

FIGURE 135.26 Dislocated patella showing lateral displacement

valgus knees, a small mobile patella, a laterally placed tibial tuberosity, a shallow patellofemoral groove and ligamentous laxity. Immediate reduction can be attempted by gently flexing the hip to relax the quadriceps, placing the thumb under the lateral edge of the patella and pushing it medially as the knee is extended. This may be attempted without anaesthesia or by using pethidine and intravenous diazepam as a relaxant.

X-rays with anteroposterior, lateral, skyline and intracondylar views should be taken to exclude an associated osteochondral fracture.

The usual RICE treatment should be given initially and crutches provided. Rest of the injured knee is achieved using a knee splint with the knee held in extension and crutches for 4 weeks.

Weight-bearing is permitted when the swelling has subsided and the patient is gradually taken off the crutches. Introduce quadriceps exercises with the knee in extension.

Patellar subluxation is when the patella is mobile and does not actually dislocate, but results in episodic pain and feelings of instability. Physiotherapy and appropriate splinting for sporting activities is helpful before surgical stabilisation is considered.

Recurrent dislocation/subluxations in young females (14–18 years) require surgery—combined tibial tubercle transfer with lateral release of the capsule. Immediate surgery in the acute phase is undertaken only in the presence of haemarthrosis with an osteochondral fracture.

### § Fractures of the patella

- Fractures without displacement: walking plaster cylinder 4 weeks
- Displaced single transverse fracture: surgical reduction with Kirschner wires
- Displaced and comminuted fracture: refer for patellectomy

### § Fractures of both tibia and fibula

The nature and management of these fractures vary considerably. Some fractures are caused by blunt injuries, such as a blow from a motor car bumper, while twisting forces cause a spiral fracture of both bones at different levels. As a general rule, referral of patients to a specialist is necessary, especially where soft-tissue damage is significant. Management of fractures with minimal soft-tissue damage can be summarised thus:

- no or minimal displacement: full-length cast as for isolated fracture of tibia
- displacement: reduction under general anaesthesia, then application of cast as above (meticulous alignment essential)
- period of immobilisation: adults 16 weeks, children 8 weeks

### § Fracture of fibula<sup>10</sup>

An isolated fracture of the fibula is usually due to stress or to a direct blow. The patient is generally able to stand and move the knee and ankle joints. However, most spiral fractures are associated with injuries of the ankle or knee. The ankle in particular should be examined and X-rayed.

Treatment is usually with analgesics to control the pain and no more than a crepe bandage or a walking stick is necessary. A below-knee walking plaster for about 3 weeks will help those with severe discomfort.

### § Fracture of the tibial shaft

A fracture of the tibia alone is uncommon in adults but more common in children, due to a twisting injury. Reduction may not be necessary in some patients. Many can be reduced to a satisfactory position in the anaesthetised patient by letting the fractured leg hang over the edge of the table with the knee at a right angle.

A padded cast from the groin to the metatarsal necks is applied with the knee joint at 10° of flexion, and the ankle at a right angle. This should be maintained for 3–4 months.

### § Toddler's fracture<sup>13</sup>

Toddler's fracture is a hairline spiral fracture of the tibia that is common in children aged 1–2 years. They may present with failure to weight-bear after minimal or no known trauma. The fracture may not be seen on X-ray. A backslab for 4 weeks may relieve discomfort.

### § Fracture around the ankle

The ankle is one of the areas liable to fractures. The commonest mechanism is forceful inversion of the foot, which can cause fracture of the fibula on a level with the joint line and tearing of the lateral collateral ligament. Other injuries can also occur, such as fracture of the medial malleolus and tearing of the tibiofibular syndesmosis. At least three views on X-ray are needed: AP, lateral and a half oblique 'mortise' view.

Undisplaced, uncomplicated fractures are treated with a plaster cast from just below the knee to the

toes for 6–8 weeks. The foot must be plantigrade (i.e. with the foot at 90° to the leg and neither in varus nor in valgus).<sup>10</sup> Fractures treated in plaster need X-ray monitoring. Unsuspected displacement may occur as swelling subsides and the plaster loosens. Occult displacement of the fracture leading to mal-union will predispose to ankle osteoarthritis. Fractures that are displaced or cause instability of the ankle joint require surgery to achieve stability followed by a longer period of immobilisation.

### § Ankle/talus/subtalar joint dislocations

These dislocations may result in vascular compromise. The stretched overlying skin may rapidly necrose. Refer early.<sup>8</sup>

### § Stress fractures of the foot

Stress fractures of the navicular, calcaneus and metatarsal bones can be found in otherwise healthy people from the age of 7 onwards. Long-distance runners and high-performance athletes are also susceptible.

#### Clinical features

- Localised pain during weight-bearing activity
- Localised tenderness and swelling (not inevitable)
- Plain X-rays are necessary but show no fracture in about 50% of cases;<sup>6</sup> X-rays can be repeated in 2–3 weeks if a fracture is suspected
- A nuclear bone scan may confirm the diagnosis

#### Navicular

This hitherto unrecognised stress fracture has become apparent with the advent of CT scanning, which shows up the fracture better than nuclear scanning. It is seen in athletes involved with running sports and presents as poorly localised mid-foot pain. Plain X-ray is usually normal. The fracture, like the scaphoid fracture, is difficult to manage since delayed union and non-union are common. Cast immobilisation for 8 weeks may avoid the need for an operation.

#### Metatarsal bones

The second metatarsal is probably the most common site of all for stress fracture because it is invariably the largest metatarsal and absorbs a greater load than the others.<sup>1</sup>

### Treatment

- Rest is the basis of treatment
- Resting the foot with crutches for 6 weeks provides optimal healing
- Healing usually takes 6–8 weeks
- Gradual slow resumption of activity

### Lisfranc joint injury (midfoot sprain)<sup>14</sup>

This is basically a dislocation of the tarsometatarsal joints of the foot. The spectrum ranges from partial strains with no displacement to complete tears with separation of the first and second metatarsal bones (FIG. 135.27). Causes range from low-energy compression and twisting to high-energy crush forces. Diagnosis is usually confirmed by weight-bearing plain X-rays. Treatment depends on the degree of stability. Surgical reduction and fixation is required if there is evidence of instability.

### § Fractures of the toes

Most toe injuries are easy to treat but, like the fingers, the great and little toes demand special attention. Intra-articular injuries of the great toe (unless undisplaced) should be treated by internal fixation.

'Buddy strapping' can be used for many uncomplicated fractured phalanges of the toes,

which tend to angulate and rotate more readily and are often harder to control than finger fractures. Strapping them to their adjacent toes on both sides simultaneously tends to counteract this problem.

Like the little finger, the little toe is injured by forceful abduction and if allowed to heal in that position may leave difficulties in wearing shoes.<sup>10</sup>

Approximate average immobilisation times for various fractures are given in TABLE 135.3.

### § Dislocation of toes

Dislocations occur mainly at the metatarsophalangeal joint and are rare; they require special care because of the strong tendons crossing the joint. Perfect reduction of the dislocated great toe is essential and it should be supported by a below-knee plaster cast extending beyond the toes. Temporary internal fixation with a Kirschner wire or open ligamentous repair may be required.<sup>11</sup>

### Analgesia and relaxation

For the reduction of dislocations, analgesia and relaxation are appropriate. Resuscitation facilities and an experienced practitioner are required to handle this procedure. All drugs should be given intravenously and titrated to achieve the desired effect. Adverse effects include respiratory depression and hypotension.<sup>8</sup> The choice of agents is presented in TABLE 135.4.

### Plastering tips

#### Plaster of Paris

##### The bucket of water

- Line the bucket with a plastic bag for easy cleaning.
- The water should be deep enough to allow complete vertical immersion.
- Use cold water for slow setting.
- Use tepid water for faster setting.
- Do not use hot water: it produces rapid-setting and brittle plaster.

##### The plaster rolls

- Do not use plaster rolls if water has been splashed on them.
- Hold the roll loosely but with the free end firm and secure (see FIG. 135.28).
- Ensure that the centre of the plaster is fully wet.
- Drain surface water after removal from the bucket.
- Gently squeeze the roll in the middle: do not indent.

FIGURE 135.27 Lisfranc dislocation at midfoot joints—this severe case shows fracture of the base of the second metatarsal.

**Table 135.3** Healing of uncomplicated fractures (adults)

Fracture	(Approximate) average immobilisation time (weeks)
Rib	3–6 (healing time)
Clavicle	4–8 (2 weeks in sling)
Scapula	weeks to months
Humerus:	
• neck	3–6
• shaft	8
• condyles	3–4
Radius:	
• head of radius	3
• shaft	6
• Colles	4–6
Radius and ulna (shafts)	6–12
Ulna—shaft	8
Scaphoid	8–12
Metacarpals:	
• Bennett fracture	6–8
Other MCs	3–4
Phalanges (hand):	
• proximal	3
• middle	2–3
• distal	2–3
Pelvis	rest in bed 2–6
Femur:	
• femoral neck	according to surgery
• shaft	12–16
• distal	8–12
Patella	3–4
Tibia	12–16
Fibula	0–6
Both tibia and fibula	16
Pott fracture	6–8
Lateral malleolus avulsion	3
Calcaneus:	
• minor	4–6
• compression	14–16
Talus	12
Tarsal bones (stress fracture)	8
Metatarsals	4
Phalanges (toes)	0–3
Vertebrae	
• spinous process	3
• transverse process	3
• stable vertebrae	3
• unstable vertebrae	9–14
• sacrum/coccyx	3

**Important principles:**

- children under 8 years usually take half the time to heal
- have a check X-ray in 1 week (for most fractures)
- radiological union lags behind clinical union

**Note:** There can be considerable variation in immobilisation times depending on factors such as trauma degree and soft-tissue injuries.

**Table 135.4** Analgesic and relaxant/sedative agents

	IV dose	Antidote
Relaxant/sedative agent		
Diazepam	0.1–0.2 mg/kg (5–10 mg)	Flumazenil
Midazolam	0.05–0.1 mg/kg (2–5 mg)	Flumazenil
Analgesic agent		
Fentanyl	1–2 mcg/kg (50–100 mcg)	Naloxone
Morphine	0.1–0.2 mg/kg (5–15 mg)	Naloxone

**FIGURE 135.28** Holding the plaster roll**Padding**

- Use Velband or stockinet under the plaster.
- With Velband, moisten the end of the roll in water to allow it to adhere to the limb.
- For legs, make extra padding around the ankle and heel.
- Avoid multiple layers of padding.

**Method**

- Use an assistant to support the limb where possible (e.g. hold the arm up with fingers of stockinet).

- Lay the bandage on firmly but do not pull tight.
- Lay it on quickly.
- Overlap the bandage by about 25% of its width.

*Note:* It is good practice to review the patient the next day.

Cicero (106–43 BC)

Although there is considerable overlap between injuries occurring during everyday activities and those of sporting and recreational activities, many injuries are characteristic to sportspeople. A large proportion of these injuries are the result of trauma of various degrees and include the many varieties of fractures, dislocations and soft-tissue injuries.

On the other hand ‘runner’s anaemia’—an iron deficiency—is considered to be multifactorial, including mild haemolysis and blood loss from the bladder, kidney and gastrointestinal tract (see [CHAPTER 76](#)).

## INJURIES TO THE EYE

Blunt injuries to the eye are common in sport. Examples include tennis and squash balls, cricket balls and baseballs, and fists and fingers associated with body contact sports. Haemorrhage is the most common problem and occurs throughout the eye: subconjunctivally, in the anterior chamber (hyphaema), into the vitreous, and underneath the retina or choroid.

Another common problem is a corneal abrasion, where a small wound can be caused by a foreign body, a fingernail or a contact lens. It needs to be treated with great respect (see [CHAPTER 51](#)).

### § Hyphaema

With hyphaema, bleeding from the iris collects in the anterior chamber of the eye (see [FIG. 136.1](#)). The danger is that, with exertion, a secondary bleed from the ruptured vessel could fill the anterior chamber with blood, blocking the escape of aqueous humour and causing a severe secondary glaucoma. Loss of the eye can occur with a severe haemorrhage. It is likely to happen between the second and fourth day after the injury.

### Management

- First, exclude a penetrating injury.
- Avoid unnecessary movement: vibration will aggravate bleeding. (For this reason, do not use a helicopter if evacuation is necessary.)
- Avoid smoking and alcohol.

**FIGURE 136.1** Hyphaema of the eye showing blood in the anterior chamber; this occurred in a 29-year-old man who was struck in the eye by a squash ball

- Do not give aspirin (can induce bleeding).
- Prescribe complete bed rest for 5 days and review the patient daily.
- Apply padding over the injured eye for 4 days.
- Administer sedatives as required.
- Beware of ‘floaters’, ‘flashes’ and field defects.

Arrange ophthalmic consultation after 1 month to exclude glaucoma and retinal detachment. No sport before this time.

Generally, recovery runs an uneventful course. If secondary bleeding occurs (usually the second, third or fourth day) the patient should be transported immediately to the nearest eye hospital. Evacuate by air (not by helicopter) only if the cabin altitude can be kept below 1300 metres (4000 feet). It is important to prevent vomiting and expansion of air within the eye.

Protective spectacles should always be worn when playing squash. People with monocular vision should be advised not to participate in this sport.

## KNOCKED-OUT OR BROKEN TEETH

If a permanent (second) tooth is knocked out it can be saved by immediate proper care. Likewise, a broken tooth should be saved and urgent dental attention sought.

### § The knocked-out tooth

- Place the tooth in its original position, preferably immediately (see FIG. 136.2): if dirty, put it in milk before replacement or, better still, place it under the tongue and 'wash it' in saliva. Do not use water, and do not wipe or touch the root.
- Fix the tooth by moulding strong silver foil (e.g. cooking foil) over it and the adjacent teeth.
- Refer the patient to his or her dentist or dental hospital as soon as possible.

*Note:* Teeth replaced within half an hour have a 90% chance of successful re-implantation.

FIGURE 136.2 Replacement of a knocked-out tooth

### INJURIES TO THE NOSE

Common injuries to the nose include epistaxis and fractures of the nasal bones.

#### § Epistaxis

First aid is simple tamponade, which is invariably effective. The soft, cartilaginous part of the nose should be pinched between the finger and thumb for 5–10 minutes. The head should be kept bent slightly forward. Packing of the nose may be required (see CHAPTER 59).

#### § Fracture of the nose

If deformity is present the patient should be referred for reduction within 7 days. Refer to CHAPTER 59.

#### § Septal haematoma

Special care has to be taken of a septal haematoma, which has a tendency to become infected (see CHAPTER 59).

### SHOULDER INJURIES

Common shoulder injuries acquired in sporting activities include:

- dislocated or subluxed acromioclavicular joint (see CHAPTER 135)
- fractured clavicle (see CHAPTER 135)
- dislocated shoulder (see CHAPTER 135)
- supraspinatus tendonopathy (see CHAPTER 63)

#### § Swimmer's shoulder

Painful shoulders occur in about 60% of elite level swimmers during their career. The basic disorder is rotator cuff tendonopathy, particularly supraspinatus tendonopathy, which is considered to be associated with abnormal scapular positioning and spinal dysfunction. The best treatment is prevention, which aims at rotator cuff strengthening exercises, better scapulothoracic control, including correction of thoracic extension if it is decreased, and scapular stabilisation exercises.<sup>1</sup>

### ELBOW INJURIES

Soft-tissue disorders of the elbow are extremely common. Two types of tennis elbow are identifiable: 'backhand' tennis elbow or lateral epicondylitis (see CHAPTER 64) and 'forehand' tennis elbow or medial epicondylitis, which is also known as golfer's elbow or baseball pitcher's elbow. These common problems, often unrelated to sporting activity, are presented in more detail in CHAPTER 64.

### HAND INJURIES

Hand and finger injuries are very important in sporting activities and include fractures and dislocations of phalanges and metacarpals. A mallet finger is a common injury and can result from overuse.

Ligamentous disruption of finger joints can cause instability and require early referral. An example is 'gamekeeper's' (or 'skier's') thumb, where there is complete tearing of the medial ligament of the metacarpophalangeal joint.

#### § Mallet finger

A mallet finger is a common sports injury caused by the ball (football, cricket ball or baseball) unexpectedly hitting the finger tip and forcing the finger to flex. Such a forced hyperflexion injury to the distal phalanx can rupture or avulse the extensor insertion into its dorsal base. The characteristic swan-neck deformity (see FIG. 136.3) is due to retraction of

**FIGURE 136.3** Mallet finger with the 'swan-neck' deformity following rupture of the extensor tendon to the distal phalanx

the lateral bands and hyperextension of the proximal interphalangeal joint.

### The 45° guideline

Without treatment, the eventual disability will be minimal if the extensor lag at the distal joint is less than 45°; a greater lag will result in functional difficulty and cosmetic deformity.

### Treatment

Maintain hyperextension of the distal interphalangeal joint for 6 weeks, leaving the proximal interphalangeal joint free to flex.

### Equipment

- Friar's Balsam (will permit greater adhesion of tape)
- Non-stretch adhesive tape, 1 cm wide: two strips approximately 10 cm in length

### Method

- 1 Paint finger with Friar's Balsam (compound benzoin tincture).
- 2 Apply the first strip of tape in a figure-of-eight configuration. The centre of the tape must engage and support the pulp of the finger. The tapes must cross dorsally at the level of the distal interphalangeal joint and extend to the volar aspect of the proximal interphalangeal joint without inhibiting its movement (see FIG. 136.4a).
- 3 Apply the second piece of tape as a 'stay' around the midshaft of the middle phalanx (see FIG. 136.4b).

Reapply the tape wherever extension of the distal interphalangeal joint drops below the neutral

**FIGURE 136.4** Mallet finger: (a) application of first tape, (b) application of 'stay' tape

position (usually daily, depending on the patient's occupation). Maintain extension for 6 weeks.

### Surgery

Open reduction and internal fixation are reserved for those cases where the avulsed bony fragment is large enough to cause instability, leading to volar subluxation of the distal interphalangeal joint.

### \$ Tenpin bowler's thumb

Tenpin bowler's thumb is a common stress syndrome in players. It usually presents as a soft-tissue swelling at the base of the thumb web, with associated pain and stiffness of the digits used for bowling. It may cause a traumatic neuroma of the digital nerve at this site with associated hypaesthesia.

### Management

- Rest
- Massage
- Bevel the bowling ball holes to reduce friction
- An intralesional injection (see FIG. 136.5) of 0.25 mL of long-acting corticosteroid mixed with local anaesthetic (resistant cases)

### SNOW SKIING INJURIES

The most common injuries encountered in snow skiing are soft-tissue injuries and fractures and dislocations.

A study by Robinson showed that the six most common skiing injuries were strains to the medial collateral ligament of the knee 24.3%; contusions of soft tissue (excluding head and neck) 17.6%; lacerations 15.5%; neck and back injuries 7.8%; fractures 7.6%; and dislocations.<sup>2</sup>

FIGURE 136.5 Tenpin bowler's thumb

There has been a large decrease in injuries relative to participation in the past decade because of improved equipment and attention to safety. The most common fractures in skiers are those involving the tibia and fibula, especially spiral fractures. Other common fractures are of the clavicle, wrist and humerus. Dislocation of the shoulder region (glenohumeral joint and acromioclavicular joint) are due to falls on hard impacted snow.

### § Ulnar collateral ligament injury ('gamekeeper's thumb')<sup>3,4</sup>

A special injury is gamekeeper's thumb (also known as skier's thumb) in which there is ligamentous disruption of the metacarpophalangeal joint with or without an avulsion fracture of the base of the proximal phalanx at the point of ligamentous attachment. This injury is caused by the thumb being forced into abduction and hyperextension by the ski pole as the skier pitches into the snow.

Diagnosis is made by X-ray with stress views of the thumb. Incomplete tears are immobilised in a scaphoid type of plaster for 3 weeks, while complete tears (the Stener lesion) and avulsion fractures should be referred for surgical repair.

## SPINAL PROBLEMS

Spinal dysfunction, particularly of the neck and low back, are very common problems in sport, as for the general population.

Serious problems include pars interarticularis fractures, spondylolisthesis, disc disruptions with

prolapse and, rarely, vertebral body fracture. The common problems are the various facet joint syndromes and musculoskeletal strains, which are managed conservatively as outlined in CHAPTERS 37, 38 and 62. The key to management is a conservative approach with a back education and exercise program.

## INJURIES TO THE LOWER LIMBS

Injuries due to trauma and overuse of the lower limbs comprise the most frequent group of sports-related disorders requiring medical attention.

The three main causes of overuse trauma are:

- friction (e.g. peritendonopathy)
- stress or overload (e.g. hamstring tear, tibial stress fracture)
- ischaemia (e.g. anterior compartment syndrome)

### § Overuse leg syndromes

Increased community participation in physical activity, including running and jogging, has resulted in a concomitant increase in overuse leg injuries, especially in the lower leg with its weight-bearing load. The common cause is repetitive trauma where the forces involved overwhelm the tissue's ability to repair adequately. Common causes of chronic leg pain include hamstring injuries and injuries to the lower leg.

### Principles of management

Prevention:

- maintain ideal weight
- good nutrition
- adequate preparation
- warm-up exercises for the legs
- proper footwear
- proper activity planning

### Treatment of injury

- Rest, or relative rest: the patient is allowed to perform activities that do not aggravate the injury.
- Ice: apply an ice pack for 20–30 minutes every 2 hours while awake during the first 48–72 hours post injury.
- Compression: keep the injured muscle or tissue firmly bandaged for at least 48 hours.
- Elevation: rest the leg on a stool or chair until the swelling subsides.
- Correction of predisposing factors (intrinsic or extrinsic)—orthotics for malalignment, correction of training errors.

- NSAIDs for painful inflammatory response.
- Physical therapy (e.g. stretching, mobilisation when acute phase settled).

## GROIN PAIN

Groin pain is a particularly common condition among athletes.

### § Acute groin pain

Acute conditions such as muscle and musculotendinous strains,<sup>5</sup> and overuse injuries such as tendinopathy and tendoperiostitis, are generally readily diagnosed and treated.<sup>6</sup> Diagnostic difficulties can arise because of referred pain from the lumbosacral spine, hip and pelvis, including hip labral injuries and a stress fracture of the femoral neck. More common acute groin injuries include injuries to the following muscles and their tendons (see FIG. 136.6):

- adductor longus (e.g. musculotendinous strains)
- rectus femoris
- sartorius
- iliopsoas

### § Adductor muscle or tendon injury

Features: upper inner thigh pain, local tenderness, resisted hip adduction and a history of twisting, catching or slipping. Initial management is with RICE therapy followed by an adductor strengthening program. Persistent adductor pain will require

investigation with ultrasound or MRI to confirm the diagnosis and management (possible steroid injection).

### § Iliopsoas problems

The typical feature is pain on stretching the hip flexor or with resisted hip flexion. Bursitis may be present. Treatment includes avoidance of aggravating activity and stretching, followed by a graduated re-strengthening program.

Other injuries include:

- SCFE in adolescents
- avulsion fractures in adolescents (e.g. rectus femoris and sartorius on the iliac spines)

### § Chronic groin pain

There are many causes of chronic groin pain, with bone and joint abnormalities being more likely causes. Important causes include:

- muscle and musculotendinous lesions (e.g. adductor longus tendoperiostitis)
- bursitis (e.g. iliopsoas bursitis)
- osteitis pubis (pubic symphysis)
- stress fractures (e.g. femoral neck and pubic rami)
- sacroiliac and hip joint disorders (e.g. osteoarthritis hip/tumour)
- lumbar spine—L1–2 or L2–3 disc
- 'occult' inguinal or femoral hernia

### Investigations

- X-ray of pelvis (AP, lateral, oblique)
- Tomography of pubic symphysis (to detect osteitis pubis and pubic instability)
- Bone scan to detect stress fractures or osteitis pubis
- Herniography
- CT scan or MRI or ultrasound (increasing potential)

### § Osteitis pubis

This is considered to be inflammation on each side of the periosteal bone of the symphysis pubis that usually develops insidiously in sportspeople and is associated with pubic bone stress. It often presents in a football player or other athlete involved in sports that involve sudden twisting or turning movements.<sup>5</sup> It may follow injuries of the adductor longus muscle origin.

### Clinical features

- Pain in groin (i.e. low anterior pelvis)
- Radiation of pain into adductor muscles of both thighs

FIGURE 136.6 Muscles in the groin region subject to musculotendinous injuries in the athlete

- Tendency to 'duck waddling' gait
- Pain aggravated by exercise, especially twisting and turning and kicking
- Local 'pinpoint' tenderness to palpation over the symphysis
- Positive squeeze test:<sup>5</sup> the patient lies supine with the hips flexed to 45°, the knee flexed to 90° and the feet on the bed. The examiner places a fist between the medial aspects of the patient's knees and the patient is asked to adduct the hips bilaterally against the fist
- MRI scanning is the most sensitive imaging technique<sup>5</sup>

### Management

- NSAIDs
- Relative rest from provoking activity
- Conservative rehabilitation program
- Activity modification
- Change to a low impact sport for 3–6 months (e.g. cycling)
- Regular stretching—physiotherapy supervision
- Graduated strengthening program of the adductors and lower abdominal musculature over 10–12 weeks
- Surgery has a place for specific cases

### § Jock itch

Jock itch, or *tinea cruris*, is a common infection in the groin area of young men, especially athletes, who are subjected to chafing in the groins from tight shorts and synthetic jock straps. The feet should be inspected for evidence of *tinea pedis*. The dermatophyte is transmitted by towels and other objects, particularly in change rooms and communal showers (see CHAPTER 122).

### HAMSTRING INJURIES

Hamstring strains are common in athletes. The short head of biceps femoris is the most commonly strained component of the hamstring group.

#### Clinical features

- A history of a 'pull', 'twinge', 'tear' or 'twang' in the back of the thigh
- A soreness and lump develops (with a severe tear a person can collapse)
- Localised tenderness
- Limitation of straight leg raising
- Pain on resisted or active knee flexion or hip extension
- Bruising (usually in popliteal fossa) may be present

The injury is classified as:

- grade I—a mild strain
- grade II—a moderate strain with tearing of the musculotendinous complex
- grade III—a complete muscular tear

### Management

The immediate goals of treatment of the acute injury are to relieve pain and minimise swelling.

- RICE for 72 hours
- NSAIDs (e.g. aspirin or indomethacin)
- stretching exercises:
  - passive stretching after ice treatment
  - then active stretching
  - then isometric contraction exercises

Surgical repair is used sometimes for a complete grade III tear.

### HAEMATOMAS IN MUSCLE ('CORKED THIGH')

Haematomas can be intramuscular, intermuscular or interstitial. They usually result from a sharp blow (e.g. knee to the thigh or kick in the anterior compartment of the leg).

An intramuscular haematoma can cause an acute compartment syndrome that may require urgent decompression. One objective of treatment is to prevent excessive scarring. Other complications include infection, cyst formation, thrombophlebitis and myositis ossificans.

### Management

- RICE treatment with emphasis on cooling
- Non-weight-bearing, using crutches initially
- Consider admission to hospital or a day surgical unit to check progress
- Referral for expert advice may be appropriate because of the potentially serious nature of the injury

### INJURIES TO THE KNEE

Knee injuries are common, have multiple clinical disorders and are potentially disastrous to the athlete. The various injuries and overuse syndromes are presented in considerable detail in CHAPTER 67, on the painful knee. Any twisting or pivoting knee injury resulting in pain or swelling should be considered an anterior cruciate ligament disruption until proved otherwise. Often the person is involved in a ball sport and describes a loud 'pop' or 'crack' at the time of injury.

## § Acute injuries

Acute injuries (see CHAPTER 67) include:

- meniscal tears
- ligamentous tears and strains (of varying degrees):
  - anterior cruciate ligament (ACL)
  - posterior cruciate ligament (PCL)
  - medial collateral ligament
  - lateral collateral ligament

## § Overuse syndromes

The knee is very prone to overuse disorders (see CHAPTER 67). The pain develops gradually without swelling, is aggravated by activity and relieved with rest. It can usually be traced back to a change in the sportsperson's training schedule, footwear, technique or related factors. It may also be related to biomechanical abnormalities, ranging from hip disorders to disorders of the feet.

Overuse injuries include:

- patellofemoral pain syndrome (jogger's knee/runner's knee)
- patellar tendonopathy (jumper's knee)
- synovial plica syndrome
- infrapatellar fat-pad inflammation
- anserinus bursitis/tendonopathy
- biceps femoris tendonopathy
- semimembranous bursitis/tendonopathy
- quadriceps tendonopathy/rupture
- popliteus tendonopathy
- iliotibial band friction syndrome (runner's knee)
- the hamstrung knee

A careful history followed by systematic anatomical palpation around the knee joint will pinpoint the specific overuse syndrome.

## Overuse injuries to lower leg

A summary of the clinical and management aspects of various injuries is presented in TABLE 136.1 and FIGURE 136.7.

Common causes of chronic lower leg pain in sportspeople include:<sup>7</sup>

- medial tibial stress syndrome (previously called shin splints)
- stress fractures (see FIG. 136.8)
- exertional compartment syndrome, especially anterior compartment
- tibialis anterior tenosynovitis (see FIG. 136.9)
- chronic muscle strains

FIGURE 136.7 Common sites of overuse injuries in the lower leg

FIGURE 136.8 Typical sites of stress fractures in athletes in the tibia and fibula

These problems are invariably due to excessive physical demands in athletes striving for the ultimate performance or in the occasional athletes who have made inadequate preparation for their activity. Training errors contribute to a large proportion (60%) of overuse injuries.<sup>7</sup>

### Principles of treatment

- Rest or relative rest
- Exercise program (where appropriate)

Table 136.1 Clinical comparisons of overuse syndromes in lower leg

Syndrome	Symptoms	Cause	Treatment
<b>Anterior compartment syndrome</b>	Pain in the anterolateral muscular compartment of the leg, increasing with activity Difficult dorsiflexion of foot, which may feel floppy	Persistent fast running (e.g. squash, football, middle-distance running)	Modify activities Surgical fasciotomy is the only effective treatment
<b>Iliotibial band tendinopathy</b>	Deep aching along lateral aspect of knee or lateral thigh Worse running downhill, eased by rest Pain appears after 3–4 km running	Running up hills by long-distance runners and increasing distance too quickly	Rest from running for 6 weeks Special stretching exercises Correct training faults and footwear ?Injection of LA and corticosteroids deep into tender areas
<b>Tibial stress syndrome or shin splints</b>	Pain and localised tenderness over the distal posteromedial border of the tibia Bone scan for diagnosis	Running or jumping on hard surfaces	Relative rest for 6 weeks Ice massage Calf (soleus stretching) NSAIDs Correct training faults and footwear
<b>Tibial stress fracture</b>	Pain, in a similar site to shin splints, noted after running Usually relieved by rest Bone scan for diagnosis	Overtraining on hard (often bitumen) surfaces Faulty footwear	Rest for 6–10 weeks Casting not recommended Graduated training after healing
<b>Tibialis anterior tenosynovitis</b>	Pain, over anterior distal third of leg and ankle Pain at beginning and after exercise $\pm$ swelling, crepitus Pain on active or resisted ankle dorsiflexion	Overuse—excessive downhill running	Rest, even from walking Injection of LA and corticosteroid within tendon sheath
<b>Achilles tendonopathy</b>	Pain in the Achilles tendon aggravated by walking on the toes Stiff and sore in the morning after rising but improving after activity	Repeated toe running in sprinters or running uphill in distance runners	Relative rest Ice at first and then heat 10 mm heel wedge Correct training faults and footwear NSAIDs

- Correction of predisposing factors:
  - training errors
  - unsuitable footwear
  - inadequate warm-up
  - malalignment
- Analgesics: use NSAIDs only if it is true inflammatory pain (pain at rest)

## § Stress fractures

Stress fractures are an important cause of lower leg pain and foot pain in sport, accounting for 5–15% of injuries.<sup>7</sup> Stress fractures occur in the tibia and fibula and in the foot (navicular, calcaneus and metatarsals). The important clinical factor is to keep

stress fractures in mind and X-ray the tender area. If the X-ray is negative and there is a high index of suspicion, a radionuclide scan should be ordered.

In the tibia, stress fractures occur mainly in the proximal metaphysis and the junction of the middle and distal thirds of the shaft (see FIG. 136.10). In the fibula they usually occur 5–7 cm above the tip of the lateral malleolus (see FIG. 136.8).

These stress fractures usually occur after prolonged and repeated heavy loading such as long-distance running or repeated jumping.

## § Torn 'monkey muscle'

The so-called torn 'monkey muscle', or 'tennis leg', is actually a rupture of the medial head of gastrocnemius

FIGURE 136.9 Site of tibialis anterior tenosynovitis

FIGURE 136.10 Site of pain in tibial stress syndrome

at the musculotendinous junction where the Achilles tendon merges with the muscle (see FIG. 136.11).

It is not a torn plantaris muscle as commonly believed. This painful injury is common in middle-aged tennis and squash players who play infrequently and are unfit.

FIGURE 136.11 'Tennis leg' or 'monkey muscle'—illustrating typical site of rupture of the medial head of gastrocnemius at the junction of muscle and tendon (left leg)

### Clinical features

- A sudden sharp pain in the calf (the person thinks he/she has been struck from behind, e.g. a thrown stone)
- Unable to put heel to ground
- Walks on tiptoes
- Localised tenderness and hardness
- Dorsiflexion of ankle painful
- Bruising over site of rupture

### Management

- RICE treatment for 48 hours
- Ice packs immediately for 20 minutes and then every 2 hours when awake (can be placed over the bandage)
- A firm elastic bandage from toes to below the knee
- Crutches can be used if severe
- A raised heel on the shoe aids mobility. Women should wear high heels
- Commence mobilisation after 48 hours rest, with active exercises
- Physiotherapist supervision for gentle stretching massage and then restricted exercise

### § Sprained ankle

There are two main ligaments that are subject to heavy inversion or eversion stresses, namely the lateral ligaments and the medial ligaments respectively.

Most of the ankle ‘sprains’ or tears involve the lateral ligaments (up to 90%), while the stronger tauter (deltoid) ligament is less prone to injury.

The lateral ligament complex involves three main bands: the anterior talofibular (ATFL), the calcaneofibular (CFL) and the posterior talofibular ligament (PTFL) (see FIG. 136.12). The ATFL and CFL are usually partially or completely torn.

Mechanism of injury to lateral ligaments<sup>8</sup>

Forced inversion causes about 90% of all ankle injuries.

Most sprains occur when the ankle is plantar-flexed and inverted, such as when landing awkwardly after jumping or stepping on uneven ground.

Inversion

- Foot in plantar-flexion: ATFL injury likely (50–60%)
  - Foot in neutral: CFL injury likely (10%)
  - Foot in dorsiflexion: PTFL injury likely (5%)
- Note: Combined ATFL and CFL injury (15–25%).

Eversion

- Foot in plantar-flexion or neutral: medial ligament (mainly anterior part)
- The classification of ankle injuries is presented in TABLE 136.2.

Clinical features (sprained lateral ligaments)

- Common features:
- ankle ‘gives way’
  - difficulty in weight-bearing

FIGURE 136.12 Lateral ligaments of the ankle

- discomfort varies from mild to severe
- bruising (may take 12–24 hours) indicates more severe injury (see FIG. 136.13)
- may have functional instability: ankle gives way on uneven ground

Examination

- Perform as soon as possible:
- note swelling and bruising
  - palpate over bony landmarks and three lateral ligaments
  - test general joint laxity and range of motion

Table 136.2 Classification of injuries to ankle ligaments (adapted from Litt)

Grade	Functional/clinical	Ligamentous stability	Stress X-rays
I (mild)	Minimal pain and swelling Minimal bleeding Full range of motion heel and toe walking	Minor ligamentous injury with only a partial tear of the ligament Stable ankle joint	Normal
II (moderate)	Moderate to severe pain and swelling Considerable bleeding Decreased range of motion Difficulty in weight-bearing and ambulation	Similar to grade I only more severe Partially unstable joint Anterior draw 4–14 mm Talar tilt 5–10°	Anterior draw 4–14 mm Talar tilt 5–10°
III (severe)	Minimal to severe pain and swelling Pronounced bleeding Minimal range of motion Unable to weight-bear	Complete ligamentous rupture with unstable joint	Anterior draw >15 mm Talar tilt >20°

**FIGURE 136.13** Sprained ankle with tearing of the lateral ligament complex with obvious haematoma

- a common finding is rounded swelling in front of lateral malleolus ('signe de la coquille d'oeuf')
- test stability in AP plane (anterior draw sign)
- talar tilt test (inversion stress test)

### Is there an underlying fracture?<sup>9</sup>

For a severe injury the possibility of a fracture—usually of the lateral malleolus or base of fifth metatarsal—must be considered. If the patient is able to walk without much discomfort straight after the injury, a fracture is unlikely.

Indications for X-ray include:<sup>9</sup>

- inability to weight-bear immediately after injury
- marked swelling and bruising soon after injury
- marked tenderness over the bony landmarks
- marked pain on movement of the ankle
- crepitus on palpation or movement
- point tenderness over the base of the fifth metatarsal
- special circumstances (e.g. litigation potential)

### Ottawa rules for ankle and foot X-ray<sup>10</sup>

These rules are a quick and reliable method of selecting which patients with ankle and foot injuries need X-rays to exclude a fracture.

### Ankle injury

An X-ray of the ankle is necessary when the patient has pain over the medial or lateral malleolar zone *and* any one of the following findings:

- there is bone tenderness on palpation of the distal 6 cm of the fibula (posterior tip of lateral malleolus)
- there is bone tenderness on palpation of the distal 6 cm of the tibia (posterior tip of medial malleolus)

- there was an inability to bear weight (walk four steps) *both* immediately after injury and during the clinical examination

### Foot injury

Refer for a foot X-ray (suspected midfoot fracture) if there is pain in the midfoot and any one of:

- bone tenderness at fifth metatarsal base
- bone tenderness at the navicular bone
- inability to weight-bear immediately after injury and when seen

### Management

The treatment of ankle ligament sprains depends on the severity of the sprain. Most grade I and II sprains respond well to standard conservative measures and regain full, pain-free movement in 1–6 weeks, but controversy surrounds the most appropriate management of grade III sprains.

A 2002 Cochrane Systematic Review revealed that functional recovery for grade III strains was quicker in those treated by rehabilitation compared with surgery.<sup>11</sup>

### Grade I sprain

- R** = Rest the injured part for 48 hours, depending on disability
- I** = Ice pack for 20 minutes every 3–4 hours when awake for the first 48 hours
- C** = Compression bandage (e.g. crepe bandage)
- E** = Elevate to hip level to minimise swelling
- A** = Analgesics (e.g. paracetamol ± codeine)
- R** = Review in 48 hours, then 7 days
- S** = Special strapping

Use partial weight-bearing with crutches for the first 48 hours or until standing is no longer painful, then encourage early full weight-bearing and a full range of movement. This can be followed by isometric exercises.<sup>7</sup> Use warm soaks, dispense with ice packs after 48 hours. Walking in sand (e.g. along the beach) is excellent rehabilitation. Aim towards full activity by 2 weeks.

### Special strapping

A firm support for partial tears in the absence of gross swelling provides excellent symptomatic relief and early mobilisation.

Method:

- maintain the foot in a neutral position (right angles to leg) by getting patient to hold the foot in that position by a long strap or sling
- apply small protective pads over pressure points

**FIGURE 136.14** Supportive strapping for a sprained ankle: (a) apply protective pads and stay tape, (b) apply stirrups to hold foot in slight eversion and (c) apply an ankle lock tape

- apply one or two stirrups of adhesive low-stretch 6–8 cm strapping from halfway up medial side, around the heel and then halfway up the lateral side to hold foot in slight eversion (see FIG. 136.14)
- apply an adhesive bandage (e.g. Acrylastic, 6–8 cm) which can be rerolled and reused
- reapply in 3–4 days
- after 7 days, remove the bandage and use a non-adhesive tubular elasticised support until full pain-free movement is achieved

### Grade II sprain

RICE treatment (as above) for 48 hours but ice (e.g. ACE wrap) should be used every 2–3 hours and no weight-bearing (use crutches) for 48 hours. Then permit partial weight-bearing with crutches and begin the active exercise program. Follow-up and supportive strapping as for grade I. Note that the ice packs can be placed over the strapping.

### Grade III sprain

It would be appropriate to refer this patient with a complete tear (see FIG. 136.15). Initial management includes RICE and analgesics and an X-ray to exclude an associated fracture. The three main treatment approaches appear to be equally satisfactory.

#### Surgical repair

Some specialists prefer this treatment but it is usually reserved for the competitive athlete who demands absolute stability of the ankle.

**FIGURE 136.15** Complete (grade III) tear of lateral ligaments of the ankle in a netball player; note excessive movement in inversion and anterior draw

#### Plaster immobilisation

This is usually reserved for patients who are unable actively to dorsiflex their foot to a right angle and those who need to be mobile and protected in order to work. The plaster is maintained until the ligament repairs, usually 4–6 weeks. The patient can walk normally when comfortable with a rockered sole or open cast walking shoe.

### Strapping and physiotherapy

This approach is generally recommended. After the usual treatment for a grade II repair, including the strapping as described, a heel lock (see FIG. 136.14c) should be used.

The patient continues on crutches and appropriate physiotherapy is given with care so that the torn ends are not distracted. Strengthened balance is achieved by the use of elastic bands, swimming and cycling.

### Non-response to treatment

There are some patients who, despite an apparently straightforward ankle sprain, do not respond to therapy and do not regain a full range of movement. In such patients alternative diagnoses in addition to ligament tearing must be considered (see TABLE 136.3).

**Table 136.3** Unstable ankle injuries to be considered in delayed healing (after Brukner)<sup>9</sup>

Osteochondral fracture of the talar dome
Dislocation of the peroneal tendons
Sinus tarsi syndrome
Anteroinferior tibiofibular ligament (syndesmosis) injury
Post-traumatic synovitis
Anterior impingement syndrome
Posterior impingement syndrome
Anterior lateral impingement
Rupture of posterior tibial tendon
Regional pain syndrome
Other fractures:
• base fifth metatarsal (avulsion)
• lateral process of talus
• anterior process of the calcaneus
• tibial plafond
• stress fracture navicular

These require careful clinical assessment and further investigation such as bone scans.

### Rocker board 'aeroplane' technique for ankle dysfunction

This involves proprioception exercises for injured ankle ligaments. The ligaments and leg muscles can be strengthened by the use of a rocker (wobble) board. The patient stands on the board and shifts his or her weight from side to side in neutral (first), forward (after 2–3 days) or extended (later) body positions, to improve proprioception and balance.

### § Tibiofibular syndesmosis injury<sup>5</sup>

The syndesmosis of the ankle joint comprises the anterior and posterior tibiofibular ligaments and the interosseous membrane. It is injured commonly in football codes by a dorsiflexion–eversion mechanism. The injury is not commonly recognised and can present as an ankle sprain that is slow to recover. Tenderness is found anteriorly over the ligament, and pain (which can radiate proximally between the tibia and fibula) can be produced by forced external rotation in dorsiflexion. An X-ray may determine a widened ankle mortise. More severe cases leading to tibiofibular diastasis require an orthopaedic opinion.

### § Talar dome injury<sup>12</sup>

Talar dome lesions represent chip fractures of cartilage or bone from the articular surface of the talus. These occur in about 4–5% of ankle sprains and are usually detected by MRI and/or bone scan. It should be suspected with an inability to weight-bear after an ankle sprain and persistent severe pain. Symptomatic lesions are usually treated best with arthroscopic surgery.

## HEEL DISORDERS

Important causes of heel pain and other disorders resulting from overuse sporting activities include:

- Achilles tendon disorders (see CHAPTER 68)
  - tendonopathy/peritendonopathy
  - tear: partial or complete
- bruised heel
- 'pump bumps'/bursitis
- calcaneal apophysitis
- plantar fasciitis (see CHAPTER 68)
- talon noir
- blisters

### § Achilles tendonopathy/peritendonopathy<sup>13</sup>

The inflammation that occurs as a combination of degenerative and inflammatory changes due to overuse may appear either in the tendon itself or in the surrounding paratendon. The latter is called peritendonopathy rather than tenosynovitis because there is no synovial sheath.

### Clinical features

- History of unaccustomed running or long walk
- Common in runners who change routine

- Usually young to middle-aged males
- Aching pain on using tendon
- Tendon feels stiff, especially on rising
- Tender thickened tendon
- Palpable crepitus on movement of tendon

### Ultrasound examination

This is very useful in differentiating between tendonopathy, peritendonopathy, focal degeneration and a partial tear.

### Preventive measures

- Warm-up and stretching exercises in athletes
- Good quality shoes
- 1 cm heel raise

### Treatment

- Rest: ? crutches in acute phase, plaster cast if severe
- Cool with ice in acute stage, then heat
- NSAIDs
- 1–2 cm heel raise under the shoe
- Ultrasound and deep friction massage
- Mobilisation, then graduated stretching exercises

*Note:* Ensure adequate rest and early resolution because chronic tendonopathy is persistent and very difficult to treat.

Avoid corticosteroid injection in acute stages and never give into tendon: can be injected *around* the tendon if localised and very tender.

## § Partial rupture of Achilles tendon

### Clinical features

- A sudden sharp pain at the time of injury
- Sharp pain when stepping off affected leg
- Usually males >30 years sporadically engaged in sport
- History of running, jumping or hurrying up stairs
- A tender swelling palpable about 2.5 cm above the insertion
- May be a very tender defect about the size of the tip of little finger

### Treatment

If palpable gap—early surgical exploration with repair.

If no gap, use conservative treatment:

- initial rest (with ice) and crutches
- 1–2 cm heel raise inside shoe

- ultrasound and deep friction massage
- graduated stretching exercises

Convalescence is usually 10–12 weeks. A poor response to healing manifests as recurrent pain and disability, indicates surgical exploration and possible repair.

## § Complete rupture of Achilles tendon

This common problem in athletes occurs in a possibly degenerated tendon subjected to a sudden increased load (e.g. a skier with foot anchored and ankle dorsiflexed).

### Clinical features

- Sudden onset of intense pain
- Patient usually falls over
- Feels more comfortable when acute phase passes
- Development of swelling and bruising
- Some difficulty walking, especially on tiptoe

### Diagnosis

- Palpation of gap (best to test in first 2–3 hours as haematoma can fill gap)
- Positive Thompson test (see FIGS 136.16 and 136.17)

*Note:* The injury may be missed because the patient is able to plantar-flex the foot actively by means of the deep long flexors to the foot.

### Treatment

- Early surgical repair (within 3 weeks)

## § 'Pump bumps'

A 'pump bump' is a tender bursa over a bony prominence lateral to the attachment of the Achilles tendon. This is caused by inflammation related to poorly fitting footwear irritating a pre-existing enlargement of the calcaneus. Treatment is symptomatic and attention to footwear.

## § Talon noir

Talon noir or 'black heel', which has a black spotted appearance on the posterior end of the heel, is common in sportspeople, especially squash players. It tends to be bilateral and is caused by the shearing stresses of the sharp turns required in sport. The diagnosis is confirmed by gentle paring away of the hard skin containing old blood.

**FIGURE 136.16** Rupture of the left Achilles tendon. This 31-year-old woman injured her heel snow skiing. Examination by firmly compressing the gastrocnemius soleus complex of both legs shows an absent plantar reflex on the left side (positive Thompson test).

Photo courtesy Bryan Walpole

**FIGURE 136.17** Thompson calf squeeze test for ruptured Achilles tendon: (a) intact tendon, normal plantar-flexion, (b) ruptured tendon, foot remains stationary

**FIGURE 136.18** Black nails ('soccer toe'), due to subungual haematoma caused by chronic trauma to the great toes; in this case a netball player was wearing new, ill-fitting shoes

136

## DISORDERS OF THE FEET AND TOES

Common problems include:

- fractures of toes
- foot strain
- ingrowing toenails
- 'black' nails
- bony outgrowth under the nail (subungual exostosis)
- calluses
- athlete's foot (tinea pedis)
- plantar warts
- turf toe

### § Black nails ('soccer toe')

Black or 'bruised' nails are due to subungual haematoma caused by trauma (see FIG. 136.18). The

problem can be acute or chronic and is seen in the great toes. Acute cases are usually the result of the toe being trodden on, while chronic cases are the result of wearing ill-fitting shoes (too narrow or loose) or the toenails being left too long.

The problem is encountered commonly in sports that involve deceleration forces and include running (especially cross-country with downhill running), netball, basketball, tennis, football and skiing.

## Treatment

An acute subungual haematoma should be decompressed with a hot needle or other procedure through the nail. A chronic non-painful problem should be left to heal. The toenails will become dystrophic and be replaced by 'new' nails.

Attention should be paid to the footwear either by changing it or by placing protective padding in the toes of the running shoes or boots.

## § 'Turf toe'

This is a sprain of the first metatarsophalangeal joint caused by a forced hyperextension (occasionally hyperflexion) injury to the joint. It is common in football player and athletes e.g. jamming or stubbing the great toe.<sup>14</sup> There is pain, swelling and limitation of movement. Plain X-rays are unhelpful but isotopic scans and MRI may help.

Treatment is conservative with RICE, NSAIDs and relative rest. Surgical intervention may be required.

## Injuries in adolescents

If an adolescent engaged in sport presents with pain in the leg it is important to consider the following problems.

- SCFE (see CHAPTER 65)
- Avulsion of epiphyses (e.g. ischial tuberosity—hamstring)
- Stress fracture
- Osgood–Schlatter disorder
- Scheuermann disorder
- Idiopathic scoliosis

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Calf muscle injury
- Hamstring muscle injury

- Sports injuries: first aid
- Sprained ankle
- Tennis elbow
- Warm-up exercises for the legs

## Health of specific groups

---

# 137 The health of Indigenous peoples

*'Closing the Gap' is a long-term ambitious framework that builds on the foundation of respect and unity provided by the 2008 National Apology to the Aboriginal and Torres Strait Islander Peoples. It acknowledges that improving opportunities for Indigenous Australians requires intensive and sustained effort from all levels of government, as well as private and not-for-profit sectors, communities and individuals.'*

Council of Australian Governments (COAG) 2008

The major health challenge in Australia (and several other developed countries) is the health status of Indigenous peoples, which continues to be significantly worse than that of other people. In some cases, it appears that the gap may be widening for women and narrowing for men.<sup>1</sup>

However, at the end of 2013 the average life expectancy for Aboriginal and Torres Strait Islanders was 69.1 years for men and 73.7 years for women (compared with others—79.9 years and 84.3 years, respectively).<sup>2</sup>

The commonest cause of death is cardiovascular disease, especially ischaemic heart disease which causes about 57% of these deaths.<sup>3</sup> The contrast with other Australians is most marked at 25–54 years. Diseases of the circulatory system, injury and poisoning, respiratory illness and neoplasms continue to be important causes of death. Deaths from infectious diseases and genitourinary disorders continue to occur at much higher rates than among other Australians.

The increasing incidence of diabetes is of great concern, especially in those changing from a traditional diet to inappropriate Westernised diets. It is four times higher than for other Australians.<sup>4</sup>

The estimated lifespan prior to white settlement was 40 years, with the commonest cause of death being injury, particularly from warfare and murder. Thirteen per cent of all children died within the first year of life and 25% by the end of the fifth year.<sup>5</sup> Records written by early settlers indicated that the Indigenous people appeared to be in good health and free from disease. It is estimated that the total Indigenous population was 750 000 in 1788. It had fallen to about 70 000 in the 1930s after 150 years of exposure to white civilisation. Significant causes were killing by the settlers (recorded as approximately 20 000) and disease predominantly.

The main diseases that decimated the population were smallpox (two severe epidemics: 1789 and 1829–30), influenza, TB (very severe), pneumonia, measles, varicella, whooping cough, typhoid and diphtheria. The Indigenous population is now estimated to be 670 000.

The level of infant and maternal mortality continues to be a concern. After great reductions in infant mortality rates in the 1970s there has been a levelling off, with rates remaining 3–5 times higher than those of other Australians. Despite some improvement, we all need to work to close the gap, and general practice is an ideal service to embrace this.<sup>6,7</sup>

It is important to understand that Indigenous people and culture must not be seen as homogeneous but rather as diverse, with each group needing a special understanding of its cultural issues.

Practitioners working in primary health care in rural and remote areas in Central and Northern Australia are advised to use the *CARPA Standard Treatment Manual*.<sup>8</sup>

## Key facts and checkpoints

- Consider the importance of cultural issues in a consultation with an Indigenous person.
- If assistance is required with a cultural issue, consider involving an Aboriginal health worker in the consultation. Such health workers are a vital part of the team.
- Always consider multiple medical conditions in the sick person.
- Remember the importance of opportunistic screening in Indigenous patients for relatively common conditions:
  - type 2 diabetes (20–50% incidence)
  - hypertension
  - kidney function

- other cardiovascular risk factors (e.g. hypercholesterolaemia)
- hepatitis B
- STI urine screening (men and women)
- Pap tests
- anaemia in children
- hearing in children
- Screening investigations to consider include:
  - blood sugar (finger-prick test)
  - serum lipids
  - urea and electrolytes
  - hepatitis B serology
  - BMI
  - urinalysis
- Cervical cancer is 6–8 times more common in Indigenous Australian women.
- Other common cancers are lung and liver.
- Approximately 50% of Indigenous children have chronic tympanic membrane perforations, with very significant consequences for language development and school achievement.
- The Indigenous Australian population has an incidence of end-stage kidney failure 10 times greater than that of other Australians.
- In some regions BCG vaccination is recommended for newborn Indigenous children.
- Influenza and pneumococcal vaccines are recommended for adults over 50 years.
- The prevalence of asthma is higher (16.5%) compared with other Australians (10.2%).
- Depressive illness, like in the general community, is a significant concern.
- Alcohol use is a serious health and community problem. Another drinking problem is kava, a drink made from a plant native to the Pacific Islands. Its effects are similar to alcohol and benzodiazepines with marked muscle relaxation.<sup>6,8</sup> Excessive use causes acute and long-term problems.

## National survey

The first national survey of the health of Indigenous Australians, completed in 1994, highlighted considerable differences in reported health status according to place of residence.<sup>1</sup> Interestingly, most survey participants (88%) considered themselves to be in good to excellent health.

The survey highlighted the following disorders:

- asthma
- ear and hearing problems
- diabetes
- hypertension
- kidney disorders
- heart disease
- skin disorders
- eye problems, including trachoma
- nutritional status (especially obesity)
- substance abuse (e.g. alcohol, marijuana, petrol sniffing)
- dental problems (a reversed trend of dental caries)<sup>9</sup>
- pneumococcal respiratory disease

According to the BEACH data, the six most common problems managed at encounters with Indigenous Australians were (in order) diabetes, hypertension, URTI, asthma, chronic bronchitis, bronchiolitis.<sup>10</sup>

The many reasons for the lower health status of Indigenous Australians include poverty, dispossession, geographical isolation, high population mobility, unemployment, poor housing, low education attainment, temperature extremes in central Australia, increased exposure to infectious diseases, especially in subtropical areas, and lack of appropriate service deliveries.

Poor living conditions including overcrowding contribute to poor health outcomes, such as substance abuse, domestic violence, other social dysfunction and child malnutrition. Other environmental health issues, such as lack of adequate shelter, lack of basic amenities such as clean running water and adequate sewage disposal facilities, and often lack of refrigeration in hot climates all impact on Aboriginal health.

Associated comorbidities of children admitted to the infectious diseases ward of the Royal Darwin Hospital<sup>11</sup> included dehydration (50%), malnutrition (60%), hypokalaemia (70%), iron deficiency (90%), anaemia (25%), pneumonia (24–32%), chronic suppurative otitis media (37%), urinary tract infection (10%) and scabies (25%).

Priority health problems have been identified by the National Aboriginal Health Strategy and are summarised in TABLE 137.1.

## Indigenous culture and the doctor–patient relationship

An understanding of Indigenous cultural issues is fundamental to successful management outcomes. Doctors should realise that, while examining Indigenous patients, they are themselves being examined. When Indigenous Australians visit the doctor they bring their own cultural expectations with them. 'A poster or coffee table book on Indigenous culture in the waiting room may form a

 Unemployment

simple bridge to acceptance.<sup>12</sup> Indigenous people are often rather shy and communicate more indirectly than Europeans on important sensitive issues. They may use silence while waiting for answers and this could be a cue for the doctor to use a new line of approach.<sup>13</sup> It is important for doctors working in Indigenous communities (see FIG. 137.1) to have an appreciation of and respect for Indigenous culture and be aware of its significance in health and behaviour.

An Indigenous patient may feel more relaxed if accompanied by a relative, who can witness what the doctor said and reinforce it later.

137

## Women's business

The Indigenous concept of 'women's business' can be defined as the range of experience and knowledge that is the exclusive preserve and domain of Indigenous women. It encompasses issues about menstruation, pregnancy, childbirth and contraception.<sup>14</sup> Such matters are traditionally not discussed directly but are conveyed indirectly through stories, ceremonies and songs. For more traditional women it is taboo to talk about women's health issues to male doctors or male health workers, or to be physically examined by them. Apart from the sense of shame and embarrassment, it represents a transgression of their natural law.<sup>15</sup>

**FIGURE 137.1** Doctor on an outback home visit in Central Australia

Courtesy Alice Springs Rural District Department of Health and Community Services

## Men's business

Similarly, the cultural issue of men's business needs to be understood and respected. This applies to manhood initiation rites, circumcision, sexuality and sexually transmitted infections.

## Sorry business

Sorry business is the process of grieving, and this needs to be clearly understood. There is a cultural obligation for mourners to grieve the death of a relative in a special way. This involves changing their appearance and a deliberate avoidance of any mention of the deceased person's name or any portrayal of his or her likeness.<sup>12</sup> The place where the person died is deserted for a certain time and then smoked out.

## Common problems in children<sup>16</sup>

Indigenous children suffer the same spectrum of health problems as children in developing countries

and communities throughout the world, and the infant mortality rate remains high. The major problems are malnutrition, diarrhoeal disease, skin infections and respiratory tract infection. Common problems are presented in **TABLE 137.2**.

**Table 137.2** Common clinical problems in children

Perinatal
Low birthweight
Asphyxia
Infections
Preschool
Failure to thrive
Malnutrition
Anaemia
Respiratory infection
Diarrhoeal disease
Hepatitis B
Skin infection/infestation
Urinary tract infection
Meningitis
Joint and bone infection
Chronic suppurative otitis media
Later childhood and adolescence
Bacterial and viral infections
Parasitic infestation
Streptococcal infection:
• rheumatic fever
• glomerulonephritis
Trauma
Substance abuse
Chronic suppurative otitis media

Acute respiratory tract infections are a common reason for admission to hospital. Bacterial pneumonias occur more commonly than in non-Indigenous children and usually present late. Chronic upper respiratory tract disease is typical in younger children and mucopurulent nasal discharge is present in most preschool children.<sup>13</sup> Inappropriate treatment of respiratory tract infection will predispose to a high incidence of low-grade lower respiratory tract disease in later childhood and classic bronchiectasis.

Chronic suppurative otitis media, which is almost universal in preschool children, is often refractory to treatment and can lead to significant hearing impairment in many children. It can develop without apparent preceding acute otitis media and may be related to poor nutrition and anaemia. The basic treatment is ear toilet with povidone-iodine solution,

followed by dry mopping with rolled toilet paper/tissue 'spears', or initial use of the 'spears' followed by acetic acid drops.

Skin infection and infestation are almost as prevalent as respiratory tract disease. Scabies is endemic and occasionally reaches epidemic proportions. It can be a very debilitating problem and can present in very young infants, in the first few weeks of life.<sup>16</sup>

Anaemia, usually iron deficiency, is found in at least 25% of children. Apart from reduced intake, intestinal loss from hookworm and other parasitic infection is an important factor. Treatment includes deworming in addition to iron supplements.

Diarrhoeal disease is a very common reason for hospital admission. Causes of infective gastroenteritis include rotavirus, bacteria including *Shigella*, *Salmonella* and *Campylobacter*, and parasites such as *Giardia lamblia*, *Strongyloides* and *Cryptosporidium*.

Other important and serious problems encountered more frequently in Indigenous children include bacterial meningitis (especially due to *Haemophilus influenzae*), septic arthritis and osteomyelitis, pyomyositis, *Streptococcus pyogenes* infections with associated glomerulonephritis and rheumatic fever, urinary tract calculi, urinary tract infection (especially at 6–18 months of age), hepatitis B and petrol sniffing (see **CHAPTER 130**).

The ability to achieve appropriate levels of immunisation in these communities will have enormous health benefits. Poliomyelitis, diphtheria, pertussis and tuberculosis are now rare and it is hoped that hepatitis B and *H. influenzae* infections will be drastically reduced.

## Specific disorders requiring attention

The GP attending Indigenous patients has to develop special skills in the diagnosis and management of the following health concerns:

- diabetes mellitus, frequently with associated hypertension and kidney disease
- trauma
- substance abuse, including alcohol and smoking
- ear and eye infections
- respiratory disorders—URTIs and LRTIs, asthma
- skin disorders (e.g. fungal infections, impetigo, leg ulcers, cellulitis, boils)
- parasitic infestations (e.g. scabies, lice)
- gastrointestinal infections (e.g. *Campylobacter* enteritis, giardiasis, *Shigella*)

- sexually transmitted infections
- psychosocial dysfunction
- bites and stings
- severe infections (e.g. meningitis, rheumatic fever, septicaemia)
- hepatitis B
- tropical diseases (where applicable)
- worm infestation e.g. strongyloides

However, the general management of medical disorders follows the principles and treatment guidelines outlined in this book. Antibiotic guidelines for use by Indigenous health workers in rural Indigenous communities are available.<sup>8,17</sup>

## Cardiovascular disease<sup>3,18</sup>

Cardiovascular disease, especially ischaemic heart disease, is a major cause of continuing high rates of mortality and morbidity and includes ischaemic and rheumatic heart disease and stroke. Mortality from ischaemic heart disease is almost twice that in the non-Indigenous population overall and 6–8 times higher in those aged 25–64 years. Reasons for this include high smoking rates (twice the rate for others), type 2 diabetes (two to four times higher), obesity and low rates of physical activity. Rheumatic heart disease is 11 times more common in the Indigenous population.

Targets for secondary prevention of cardiovascular disease and diabetes mellitus are as presented in CHAPTER 20, FIGS 20.7 and 20.8).

## Ear infections<sup>8,17</sup>

Otitis externa and otitis media with its acute and chronic complications are major health problems in rural Indigenous children. Acute otitis media should be treated early and aggressively with antibiotics to prevent chronic suppurative otitis media, which is very difficult to cure once established. Check carefully for a perforation, which may affect management.

## Treatment guidelines

- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li>• Acute otitis media</li> </ul>             | Amoxycillin (o) or clotrimazole (o) or procaine penicillin (IM) for 5 days; if no response, consider amoxycillin/clavulanate or cefaclor. Review in 4–6 weeks |
| <ul style="list-style-type: none"> <li>• Acute suppurative otitis media</li> </ul> | Antibiotics (as above) + dry mop ear  |

- |  |  |
|--|--|
| <ul style="list-style-type: none"> <li>• Chronic suppurative otitis media</li> </ul> | Wash with povidone–iodine 5% solution using a 20 mL syringe with plastic tubing 1, 2 or 3 times daily, then dry mop with rolled toilet paper ‘spears’. Teach this method to family members. If available, suction kits are useful. Then instil ciprofloxacin with hydrocortisone drops 12 hourly, especially in the presence of a perforation of the tympanic membrane |
| <ul style="list-style-type: none"> <li>• Otitis externa</li> </ul>                   | Gently clean out debris with toilet paper ‘spears’ followed by acetic acid 0.25%; insert Kenacomb or Sofradex drops or ointment 12 hourly on a gauze wick (if no perforation), otherwise ciprofloxacin with hydrocortisone drops 12 hourly   |
| <ul style="list-style-type: none"> <li>• Acute mastoiditis</li> </ul>                | Parenteral IM or IV flucloxacillin/dicloxacillin ± gentamicin IM or IV and hospitalisation   |

## Eye infections<sup>8,17</sup>

### Treatment guidelines

- *Peri-orbital cellulitis and penetrating eye trauma.* Arrange evacuation to hospital; if critically ill or delay in transfer give empirical treatment with ceftriaxone IM or IV once daily. Add gentamicin IM or IV as single dose for a child <3 months or patients with other risk factors such as diabetes.
  - *Conjunctivitis.* Take two swabs (one for microculture and one for *Chlamydia*). Apply topical chloramphenicol eyedrops plus ointment.
  - *Neonatal gonococcal ophthalmia and Chlamydia infection.* Refer to CHAPTER 51.
  - *Gonococcal conjunctivitis.* Procaine penicillin (IM) statim or single dose oral therapy with amoxycillin plus probenecid (e.g. 3 g + 1 g in adult). Use ceftriaxone IM if penicillin-resistant.
  - *Trachoma.* These patients have ‘scratchy’ eyes and watery discharge ± red eye (see FIG. 137.2):
    - if over 6 kg and not pregnant: azithromycin (o) as single dose
    - if under 6 kg or pregnant: erythromycin or roxithromycin (o) for 21 days
- or
- oily tetracycline eyedrops 1 bd for 3–6 weeks
- check and treat household contacts
  - check routinely for ‘follicles’ of trachoma

**FIGURE 137.2** Trachoma showing conjunctival follicles and papillae, subconjunctival scarring, including conjunctivalisation of the meibomian orifices, paramarginal sulcus formation and, on the cornea, a 2 mm vascular pannus and Herbert's pits

Photo taken from the 1980 grading manual prepared by Fred Hollows and Hugh Taylor for workers in the National Trachoma and Eye Health Program (courtesy Dr David Tamblyn)

## Skin and soft-tissue infections

Skin infections are the commonest presenting problem in many clinics.<sup>19,20</sup> These include a high incidence of scabies and tinea corporis (ringworm), boils and carbuncles, infected wounds, impetigo and cellulitis. The most serious complication of skin infections is post-streptococcal glomerulonephritis secondary to *S. pyogenes* infection. Scabies is the most common skin infestation and commonly starts as an itchy rash with pinhead papules in the web spaces of the fingers.

### Recommended treatment (in summary)<sup>8,17,20</sup>

#### Impetigo and other skin sores

- Soak and remove crusts with saline or soap and water or povidone-iodine or sodium permanganate (Condy's crystals) solution
- Antibiotic treatment (if required)  
Bicillin All-Purpose IM, statim dose  
or  
erythromycin (o) 12 hourly or roxithromycin (o) daily for 10 days

#### Cellulitis (mild-moderate) and erysipelas

Bicillin All-Purpose IM on days 1 and 3 or daily for 3–5 days  
or

procaine penicillin IM daily for 5 days

If no improvement: flucloxacillin/dicloxacillin plus probenecid (as below)

### Boils, carbuncles, abscesses, bullous impetigo (*Staphylococcus aureus* infections)

Flucloxacillin/dicloxacillin (o) 6 hourly for 5–10 days

### Suppurative wound infections

- Use local measures such as aseptic dressings and topical antiseptics
- If necessary, add flucloxacillin/dicloxacillin (as above); consider clindamycin

### Tinea corporis (ringworm)

- Use benzoic acid ointment, Whitfield's ointment or one of the imidazole preparations: apply 1–3 times daily for 4–6 weeks or for 1 week after rash resolves
- Systemic agents may be necessary

### Scabies

- Apply permethrin 5% cream or benzyl benzoate 25% emulsion (see CHAPTERS 119 and 122)
- For children less than 2 months use:  
sulphur 5% cream for 2–3 days  
or  
crotamiton 10% cream daily for 3–5 days
- For infected scabies use flucloxacillin/dicloxacillin or erythromycin

### Pityriasis versicolor (white spot)

Refer to CHAPTER 123.

## GABHS INFECTIONS

Group A beta-haemolytic *Streptococcus* (GABHS) infections are a significant problem, causing diseases such as pharyngotonsillitis, impetigo, cellulitis, otitis media and scarlet fever. Two important immunological reactions to the streptococcus toxin are acute rheumatic fever and post-streptococcal glomerulonephritis (PSGN).<sup>3</sup>

### § Acute rheumatic fever

Rheumatic fever and its effects are a serious cause of cardiovascular morbidity and mortality in Indigenous people. It is a classic hallmark of overcrowding, poverty and lack of hygiene, all of which facilitate streptococcal infection. The Australian Indigenous

population has the highest rate of acute rheumatic fever of any ethnic group in the world, with an incidence of 250–300 per 100 000 children<sup>21</sup> (see **CHAPTER 35** for clinical features).

Treatment is with benzathine penicillin.

## § Acute glomerulonephritis

There is an association between PSGN (see **CHAPTER 76**) and streptococcal skin and throat infections. Impetigo is the more frequent antecedent to PSGN. A study based on the fact that the Indigenous population has an incidence of end-stage kidney failure 10 times greater than the general population found that people with a history of PSGN in childhood had a risk of overt albuminuria more than six times that in a control group.<sup>22</sup> There is no simple treatment of PSGN and preventing streptococcal infection remains the most important control strategy. Penicillin is beneficial in preventing spread during epidemics.

## COMMUNICABLE DISEASES

Communicable diseases remain a problem with up to a 10-fold increase over the non-Indigenous population for diseases such as hepatitis A, hepatitis B, meningococcal disease, *Salmonella*, *Chlamydia* and tuberculosis.<sup>1,2</sup>

## § Tuberculosis

The rate of TB in Indigenous Australians is 10–15 times higher than for other people in the Northern Territory.<sup>3</sup> It is related to poverty, overcrowding, malnutrition and homelessness. Early diagnosis and treatment is the key to its control. This includes detection of latent TB infection in those at risk and strategies to prevent transmission in acute cases. BCG immunisation in high-risk groups is a key preventive strategy and is recommended for newborns from high-risk communities (see **CHAPTER 29**).

## § Leprosy (Hansen disease)

Leprosy (see **CHAPTER 15**) has been endemic in Northern Australia for over 100 years, with the Indigenous population being mainly affected, although the incidence is reducing. Control strategies include early diagnosis of new cases, treatment with multidrug therapy, monitoring of treatment to ensure its completion and prevention of nerve function impairment (NFI). NFI is monitored by a brief voluntary muscle and sensory test. If detected

early it responds to anti-inflammatory medication such as prednisolone.

BCG vaccination, used to prevent TB, has probably had a protective efficacy against leprosy of approximately 50%.<sup>3</sup>

## Worm infestations

Intestinal helminths are common in tropical northern Australia. Symptoms may include diarrhoea and abdominal pain with or without distension. Anaemia is common with hookworm infestation. Refer to **CHAPTER 15** for more information.

## Treatment<sup>8,17</sup>

- Hookworm, roundworm, threadworm—pyrantel embonate or mebendazole or albendazole
- Whipworm—mebendazole or albendazole
- Strongyloidiasis—albendazole or thiabendazole
- Cutaneous larva migrans—albendazole or thiabendazole

*Community worm program.* In selected communities a worm eradication program is recommended for children between the ages of 6 months and 12 years with either pyrantel embonate or albendazole.

## Sexually transmitted infections

In the management of STIs it is important to be aware of the significance of men's and women's 'business'; that is, the cultural sensitivities regarding men's and women's special gender feelings and issues, which need to be observed when discussing STIs with Indigenous patients. For some women it is inappropriate for a male doctor to discuss such issues with them but appropriate for a female doctor, nurse or health worker to do so. Similarly, it may be inappropriate for a female health worker to discuss STIs with a male patient.

Always undertake a full STI screen in patients presenting with an STI. Screening consists of counselling, taking blood for RPR, hepatitis B, hepatitis C and HIV, urethral and cervical swabs for *Gonococcus* and *Chlamydia*, ulcer swabs, viral media swab for possible herpes, 'snip' biopsy (where appropriate) for Donovanosis or malignancy, and urine for MCU. First-voided urine for NAAT (PCR) for *Gonococcus* and *Chlamydia* is an important investigation, especially for those who refuse swabs. Women can take their own tampon swabs for investigation. All sexually active females under 25 years should be screened opportunistically for *Chlamydia* (in particular) and gonorrhoea. Follow-up after therapy and contact

tracing, screening, treatment and notification are all necessary.

## Specific treatment<sup>8</sup>

Refer also to CHAPTER 119.

### Urethritis and cervicitis

amoxycillin 3 g (o) + probenecid 1 g (o)—single dose (use ceftriaxone in penicillin-resistant areas)

plus

azithromycin 1 g (o) as single dose

### Genital sores

Herpes simplex, syphilis and Donovanosis are much more common than chancroid and lymphogranuloma venereum. Serology for syphilis is essential. Advise to avoid sex and for males to use condoms until treatment is completed and lesions well healed.

### Syphilis

benzathine penicillin 1.8 g IM as single dose

### Donovanosis (granuloma inguinale)

azithromycin 0.5–1 g (o) once daily for 7 days<sup>17</sup>  
or

1 g (o) once weekly for 4 weeks  
(if not pregnant or breastfeeding); if so, give erythromycin or roxithromycin<sup>17</sup>

### Herpes simplex

See CHAPTER 119.

### Genital warts

See CHAPTER 119.

### Pelvic inflammatory disease

If sexually acquired, it is usually due to *Neisseria gonorrhoeae* or *Chlamydia trachomatis* (less likely). For treatment, see CHAPTER 103.

### Vaginal infections

Refer to CHAPTERS 106 and 119 for treatment. *Trichomonas vaginalis* is usually sexually transmitted, while *Candida albicans* and bacterial vaginosis are not.

## Communication tips<sup>23</sup>

- Don't assume English is a first language, particularly in remote areas.
- Don't assume a nod means understanding and/or agreement to treatment.

- Check hearing as chronic ear infections can impair it.
- Appreciate the different family network, particularly the tendency of grandmothers and aunts to care for children.
- Don't assume a broken appointment means the patient will not return for treatment. Often family and cultural duties take precedence.
- Be aware of cultural sensitivity.
- Don't touch a patient, particularly of the opposite sex, without seeking permission and explaining what you are doing.
- Be aware that patients may not be comfortable with direct questions about their family and health.
- Don't be too stern or authoritative during a consultation.
- Ensure receptionists and other staff understand the cultural sensitivities of Indigenous patients.
- Be accepting, respectful and non-judgmental.

## Practice tips

- Anaemia is common in Indigenous children—be on the lookout for it. Consider giving pyrantel embonate or mebendazole in a hookworm endemic area.
- Asthma is common—consider it in coughing children.
- In children with failure to thrive consider insufficient food, urinary tract infection, GIT infection or parasites and recurrent illness.
- Beware of diarrhoea in children—attend to fluid and electrolyte replacement.
- Think pelvic inflammatory disease in the woman of child-bearing age presenting with abdominal pain. Be watchful for penicillinase-producing *Neisseria gonorrhoeae* (although it remains uncommon in Indigenous communities).
- Consider the possibility of rheumatic fever or glomerulonephritis with *S. pyogenes* throat infection and treat with an optimal course of antibiotics (e.g. single injection of benzathine penicillin).
- In tropical areas consider diseases such as melioidosis, dengue and Ross River infection.
- Promote immunisation programs.
- Measles can be a very serious disease in Indigenous children and is highly contagious.
- In the fitting or aggressive patient, alcohol withdrawal is the commonest cause but the possibility of petrol sniffing should also be considered.

continued

## continued

- Kidney failure is more common in Indigenous people: look for it if proteinuria, diabetes, hypertension, general debility or recurrent infections.
- Serum creatinine measures are also useful. A level of <150 mmol/L is regarded as a safe limit for kidney function.
- Consider urine albumin–creatinine ratio (ACR) testing in adults to detect and monitor early kidney disease. As kidney disease has a rapidly progressive nature regular monitoring is important.<sup>19</sup> Kidney function must be monitored at least annually.
- Donovanosis (granuloma inguinale), which can be chronic and progressive, presents initially as raised beefy nodules or sores. Microscopy of scrapings or snip or pinch biopsy will confirm diagnosis.<sup>19</sup>
- If routine swabs for *Gonococcus* and *Chlamydia* infection are unobtainable for cultural reasons, use urine PCR testing.
- Medroxyprogesterone acetate (Depo-Provera) and Implanon are very useful contraceptive agents but always adhere to guidelines for informed consent.
- Because compliance with medication may be a problem with some patients, once-a-day therapy is recommended where possible.
- Point of Care laboratory equipment is very helpful for monitoring diabetic patients as it can be used in remote communities by trained health workers.

*A refugee is a person who owing to a well founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion is outside the country of his nationality and is unable or owing to such fear is unwilling to avail himself of the protection of that country.*

The United Nations Conference of Plenipotentiaries on the status of Refugees and Stateless Persons 1951<sup>1</sup>

The health of refugees is a special challenge for GPs, who are in an ideal opportunistic position to treat these disadvantaged people with their many mental and physical health problems.<sup>2</sup> About 13 000 refugees settle in Australia each year with the majority from Southern and South-East Asia, the Middle East and Saharan Africa. Refugees, especially refugee children, arrive with a variety of medical problems that may escape detection unless appropriate screening is undertaken. Many problems are asymptomatic, latent or occult and may be considered inconsequential by the affected person or guardian. Studies conducted in New South Wales in Australia<sup>3</sup> show that there is a high detection rate for diseases of personal and public health significance in a sample of such children from refugee specific clinics. Most of the children in the study had disorders that were asymptomatic. The study identified 25% with anaemia, 27% serology positive for schistosomiasis, and 16% with current or recent malaria, while 69% were hepatitis B non-immune, 25% were tuberculin skin test positive and 20% had low vitamin D levels.<sup>3</sup>

## Predeparture screening<sup>4</sup>

Refugees, like other migrants, have to meet predetermined health criteria to be granted a permanent visa. The basic medical requirements are:

- history and examination
- chest X-ray if  $\geq 11$  years of age
- HIV test if  $\geq 15$  years of age
- hepatitis B test if pregnant or an unaccompanied minor
- malaria-rapid antigen test
- tests for intestinal helminths (worms)
- MMR immunisation  $\leq 30$  years
- syphilis test if  $\geq 15$  years

Applicants are offered treatment for most disorders. However, active TB precludes the granting

of a visa. An additional 'fitness to fly' predeparture assessment is usually performed prior to travel. However, because of the high prevalence of both acute and chronic infective diseases and the inconsistencies of screening results, it is likely that many illnesses remain undiagnosed or untreated upon arrival in their new country.

## Communication issues

Good communication with the refugee and their families is fundamental to good outcomes. This involves appropriate rapport, understanding of and interest in their problems. A professional interpreter is the best tool available when dealing with a patient whose language is unfamiliar.<sup>4</sup> It is important to emphasise that confidentiality will be respected. Non-verbal communication is obviously an important strategy and includes empathetic nodding, listening and friendliness. It is most appropriate to be aware of the financial restraints of refugees, especially when a family needs treatment, and arrange for investigation, specialist referral and treatment in a public hospital setting. In the authors' experience refugees have a predilection for investigations and injections and these factors need to be tactfully weighed when explaining restrained management approaches (see FIGS 138.1 and 138.2).

## Medical assessment

All refugees should be offered a comprehensive health assessment, ideally within one month of arrival in Australia. Common presenting problems are summarised in TABLE 138.1.

## History

The usual approach should be followed but with an additional emphasis on the person's background and reasons for migration including any time in refugee camps, exposure to violence, torture, trauma and

**FIGURE 138.1** Initial health contact with a refugee family  
Photo courtesy of Dr Joshua Davis

**FIGURE 138.2** Typical African refugee family at home  
Photo by Newspix/Jay Town

**Table 138.1** Common presenting problems<sup>4</sup>

Psychological and behavioural disorders
Anaemia, especially iron deficiency
Oro-dental disease
Intestinal parasites
Malaria
<i>Helicobacter pylori</i> infection/peptic ulcer disease
Vitamin deficiencies, especially vitamin D
Disorders of special senses: skin, eyes, ears
Chronic disease

other forms of abuse including sexual trauma. The following checklist is recommended.<sup>5</sup>

- Presenting problem/s
- Family history including haemoglobinopathy or other genetic disorders
- Migration history
- Past history including tropical diseases
- Developmental history
- Immunisation
- Diet, with emphasis on vitamin intake
- Drug history, including drugs of addiction—especially IV use; smoking
- Mental health history
- Basic general life drives: appetite, weight, energy, sleep, mood, sex

**Examination**

- General: growth, weight, BMI, percentile charts
- Skin: note any rash, BCG scars, pallor, jaundice
- Hearing and vision
- Oro-dental
- Cardiovascular
- Respiratory
- Lymphopoietic: note any lymphadenopathy or hepatosplenomegaly
- Genitourinary: note any genital mutilation
- Urinalysis

**Screening (recommended investigations)<sup>5,6,7</sup>**

- FBE, ESR, CRP
- Electrolytes, KFTs, LFTs
- TB: chest X-ray, Mantoux tuberculin sensitivity test, interferon gamma release assay (IGRA)
- Malaria: thick and thin blood films, plasmodium rapid antigen test
- Blood-borne viruses: HIV, hepatitis B, hepatitis C
- STIs: syphilis, NAAT (PCR) for *Chlamydia* and *Gonococcus*
- Helminths: *Strongyloides* serology, microscopy of faeces
- Schistosomiasis serology

Consider: iron studies, serum vitamin D and B12, and serum electrophoresis for haemoglobinopathy screen.

**Specific common issues**

A summary of special issues for refugees is presented in **TABLE 138.2**.

**Table 138.2** Special issues for refugees

Social isolation and displacement
Tropical/third world diseases (e.g. helminths, malaria, schistosomiasis)
Infections (TB, hepatitis B and C, HIV)
Sexual and reproductive health
Female genital mutilation
Dental health
Nutritional deficiencies (e.g. rickets, vitamin B12)
Childhood growth and development
Immunisation status
Chronic medical problems
Specific genetic disorders

## Psychological issues<sup>7</sup>

Predictably these traumatised people experience a wide range of psychological sequelae, particularly loneliness/isolation, post-traumatic stress disorder with anxiety and depression. They experience the whole gamut of the usual life-stage conditions, financial concerns and gender-related issues that we encounter in everyday general practice. However, these problems are compounded possibly by cultural differences and poor language skills if they come from a non-English-speaking background. Effective communication and counselling skills are required to tease out, identify and manage any psychological disorders. Many refugees seem to manage very well with the transition, especially with the relief of being in a safe and supportive environment.

According to one refugee children's group, children and adolescents may exhibit disorders such as:<sup>5</sup>

- behavioural problems
- aggression
- acting out
- running away
- poor concentration and school performance
- somatic complaints
- self-harming or suicidal ideation
- anxiety, phobias or depression

A recommended tool for assessing children's psychological well being is the *Strength and Difficulties Questionnaire*, available online at <[www.sdqscore.org](http://www.sdqscore.org)>.

## Vitamin D deficiency<sup>5</sup>

This is a prevalent problem, particularly in children, for a variety of reasons, including poor dietary intake, dark skin, relocation to higher latitudes and low levels in breast milk. Those undergoing rapid growth, particularly infants and adolescents, are at greatest risk of insufficiency. Most children will be asymptomatic but check for signs of rickets (see CHAPTER 9) and deficiency such as leg bowing, delayed walking, bone and muscle aches and weakness. Blood levels of 25-OH vitamin D <50 nmol/L require treatment—a particular problem for families in meeting the costs of treatment.

## Vitamin B12 deficiency<sup>8</sup>

It is important to recognise and treat vitamin B12 deficiency early to prevent permanent neurological changes. The problem can get overlooked in the complexity of multiple issues in refugees. It should be considered in the same context as any other vitamin and mineral deficiency such as vitamin D.

## Helicobacter pylori infection

Besides dietary deficiency the other major risk factor in developing countries is *Helicobacter pylori* infection with figures indicating that up to 90% of the population is infected<sup>5</sup> (see CHAPTER 47). This infection should be considered in any adult with symptoms suggestive of peptic ulcer disease or any child with chronic abdominal pain, other GIT symptoms and failure to thrive. Referral for upper GIT endoscopy with biopsy is recommended.

## Haemoglobinopathies<sup>5</sup>

Genetic disorders such as sickle-cell disease (Africa),  $\alpha$  and  $\beta$  thalassaemia and glucose-6-phosphate dehydrogenase (G6PD) (latter two Mediterranean, Africa and South-East Asia in particular) are over-represented in refugee populations (see CHAPTER 18). Affected people may be asymptomatic carriers or symptomatic, with symptoms including haemolysis precipitated by infection, cold, hypoxia, drugs and antioxidants. Look for skeletal abnormalities and hepatosplenomegaly on examination and screen with appropriate tests if clinically indicated.

## Hepatitis B

One issue is that routine hepatitis B vaccination does not occur in endemic areas of Asia and Africa from which the refugees originate. The rate of

infection there is at least eight times higher than the background infection rate of 0.9% in the general Australian population.<sup>5</sup> In particular those coming from refugee camps are highly susceptible to the spread of hepatitis B. Those with active infection may be asymptomatic and screening and subsequent management are important health issues for the refugees and the community. See [CHAPTER 58](#).

## Malaria

Malaria is a common infection in endemic regions where most African and South-East Asian refugees originate. Children under 5 years are at most risk and although predeparture testing should detect infected people, some may manifest the disease after arrival. The diagnosis is made on three separate thick and thin blood films but one single test supplemented with a rapid antigen test may be a practical way of detecting the disease (see [CHAPTER 15](#)). Treatment should be directed by an experienced consultant.

## Schistosomiasis

Schistosomiasis (see [CHAPTER 15](#)) is often encountered in African refugees; it is usually acquired in childhood from swimming in contaminated freshwater. Approximately 200 million people are infected worldwide. Many of those infected are asymptomatic while chronic infection may manifest as gastrointestinal symptoms (e.g. diarrhoea, nausea, abdominal pain), failure to thrive/weight loss, respiratory symptoms such as chronic cough, and urinary symptoms that include haematuria. Detecting eggs in the stool or urine may be difficult but serology has high sensitivity and specificity. Eosinophilia, which often correlates with duration, is a feature. If positive, a renal tract ultrasound is advisable and the patient should be referred to a renal physician. Treatment of the infection is with praziquantel.

## *Strongyloides* (human threadworm)

*Strongyloides* (see [CHAPTER 15](#)) is a common infestation in refugees with a prevalence of up to 11% in some groups.<sup>5</sup> It can survive asymptotically for decades but may present with recurrent abdominal pain and watery diarrhoea, failure to thrive/weight loss, and skin and respiratory symptoms (similar to schistosomiasis). Diagnosis is by identifying larvae in concentrated stool (see [FIG. 138.3](#)), which can be elusive, and by eosinophilia and serology, which

has good sensitivity and specificity. Treatment with ivermectin or albendazole can be complex and consultant help is advisable.

**FIGURE 138.3** *Strongyloides stercoralis* ova and parasite in stool

## Tuberculosis<sup>6</sup>

Tuberculosis (see [CHAPTER 29](#)) is a major health problem in the countries of origin of refugees. Most of those infected are asymptomatic and may go undiagnosed unless properly screened. It is important to detect those (particularly children) with latent infection and non-pulmonary disease. Investigations include a chest X-ray, tuberculin skin test (Mantoux) and an IGRA. It is recommended that all refugees should have a clinical assessment by a specialist chest clinic within 2 months of arrival. Special issues include:

- status of IGRA test, including ability to predict subsequent active TB
- HIV and TB
- multidrug-resistant TB

Both TB and HIV are reportable conditions in Australia and their management is specialised.

## Immunisation

Immunisation catch-up is a difficult area of management for all doctors treating refugees. Written records are the only reliable form of documentation but immunity from past immunisations cannot be taken for granted. It is advisable to follow formal catch-up guidelines, which are summarised in TABLE 138.3.

**Table 138.3** Catch-up immunisation schedule for newly arrived refugees<sup>6</sup>

Vaccine type	Age	Number of doses	Notes
MenCCV	>12 months	1	
DTP	<10 years	4	ADT later
	>10 years	3	
MMR	<10 years	2	
	≥10 years	2	
IPV (polio)	any	3	
Hepatitis B	<11 years	3	
	11–15 years	2	Adult form
	≥16 years	3	Adult form
Hib	2–11 months	2 or 3	Then booster
	12–14 months	1	Then booster
	15–59 months	1	
13vPCV (pneumococcus)	<7 months	3	
	7–11 months	2	
	12–59 months	1	
HPV (papilloma)	13–26 years	3	Females
BCG	Varies	1	Check criteria
Varicella	18 months–13 years	1	
	14 onwards	2	
Rotavirus	<6 months	2 or 3	

For specific details about minimum dosing interval availability and funding refer to the catch-up schedule (see Resources).

These guidelines are available in the latest edition of *The Australian Immunisation Handbook* (see Resources).

## Rehabilitation

A huge challenge facing refugees is the so called 'settlement issue' as they confront the complexities of adjusting to a totally new way of life with their various physical, psychological and social problems.

The settling process is a source of considerable stress as new arrivals, many with large families, are likely to move house several times in their first few years.

The general practitioner is ideally placed to act as an advocate for the rehabilitation of his or her patients and family. Of course, GPs from a similar background have an advantage, but special skills are required to understand the issues and to gain access to available rehabilitation and support services (see Resources). Resources are also provided by the RACGP.

## Key recommendations (Australasian Society for Infectious Diseases)<sup>6</sup>

- All refugees should be offered a comprehensive health assessment, ideally within one month of arrival in Australia.
- This should include:
  - screening for and treatment of the following conditions: tuberculosis, malaria, blood-borne viral infections, schistosomiasis, helminth infection and sexually transmitted infections
  - testing for and treatment of other infections (e.g. *Helicobacter pylori*) as indicated by clinical assessment
  - assessment of immunisation status, and catch-up immunisations where appropriate.
- The assessment can be undertaken by a GP or within a multidisciplinary refugee health centre.
- An appropriate interpreter should be used when required.
- The initial assessment should take place over at least two visits: the first for initial assessment and investigation, and the second for review of results and treatment/referral.
- Psychological, dental, nutritional, reproductive and developmental health issues should also be addressed at the post-arrival health assessment.

## Practice tips

- It is helpful to become familiar with the clinical features of the relevant tropical diseases.
- It is also advisable to learn about the significant cultural and religious customs of the ethnic groups that we are likely to encounter.
- Important diseases that 'must not be missed' include malaria, tuberculosis, schistosomiasis, HIV, typhoid fever, meningococcalitis and severe psychological illness such as psychosis and major depression, especially with suicide risk.

*continued*

*continued*

- Be aware of pseudo 'neutropenia' since some people, especially of African origin, have a different reference range for neutrophil counts.<sup>4</sup>
- Doctors should consider their own safety in dealing with people coming from a theatre of violence who may be subject to vicarious trauma (also known as secondary traumatic stress).<sup>4</sup>
- The use of professional interpreter services is a vital component of sound communication skills.
- Multidisciplinary health team care will help meet the needs of practitioners in addressing most problems, especially complex ones.
- Practitioners have a useful range of resources including refugee clinics in each state, chest clinics, torture and trauma services and immunisation advice.

# Catchy metaphors, similes and colloquial expressions in medicine

139

*Similes are like songs of love: they much describe; they nothing prove.*

Mat the w Prior (1664–1721)

It is interesting to reflect on learning habits and strategies of students. Experienced educators recognise that word associations with gimmicky connotations reinforce learning of various disorders in medicine.

<b>Adolescent knee</b>	Osgood–Schlatter disorder
<b>Age spots</b>	Lentigines
<b>Alabaster skin</b>	Hypopituitarism (pale hairless skin)
<b>Alice in Wonderland syndrome</b>	A state of unreality with a distorted view of oneself Associated with complex partial seizures and migraine Also experienced when falling asleep (esp. children)
<b>Athlete's foot</b>	Tinea pedis
<b>Barmaid's syndrome</b>	Chronic laryngitis
<b>Bath itch</b>	Polythemia vera
<b>Bird fancier's disease</b>	Psittacosis
<b>Black death</b>	Plague ( <i>Yersinia pestis</i> )—haemorrhage into skin → black areas
<b>Black dog</b>	Major depression
<b>Black fever/black sickness</b>	Visceral leishmaniasis—kala azar (darkening of skin on extremities)
<b>Black eschar (slough or scab) at bite site</b>	Typhus (esp. scrub typhus from tick bite)
<b>Black heel (talon noir)</b>	Petechiae due to trauma (sportspeople), melanoma
<b>Black lung</b>	Coal dust pneumoconiosis
<b>Black tongue</b>	Poor oral hygiene/debility, drugs (esp. antibiotics)
<b>Blackwater fever</b>	Chronic severe <i>Plasmodium falciparum</i> malaria

<b>Blue sclera</b>	Osteogenesis imperfecta
<b>Bones, stones, moans and abdominal groans</b>	Hyperparathyroidism
<b>Breakbone fever</b>	Dengue
<b>Breast mouse</b>	Fibroadenoma
<b>Brewer's droop</b>	Erectile dysfunction due to alcohol
<b>Buffalo hump</b>	Cushing syndrome
<b>Bulky calves</b>	Duchenne muscular dystrophy
<b>Bull neck infection</b>	Diphtheria
<b>Buried penis</b>	Synonymous with 'concealed penis' or 'inconspicuous penis'
<b>Butterfly rash (3)</b>	SLE (lupus), rosacea, mitral facies
<b>Can't pee, can't see, can't climb a tree</b>	Reiter's syndrome
<b>Cats (several)</b>	Cat scratch fever, cat's eye (retinoblastoma), toxoplasmosis, allergy, cat cry ('maladie du cri du chat')
<b>Chimneysweeper's wart</b>	SCC scrotal skin
<b>Cigarette-burn look to skin</b>	Staphylococcal impetigo
<b>Clay pipe lesion</b>	SCC lip
<b>Christmas tree rash pattern</b>	Pityriasis rosea
<b>Coca-Cola urine</b>	Post streptococcal glomerulonephritis
<b>Coffee grounds vomitus</b>	Gastric/duodenal bleeding
<b>Collar stud abscess</b>	TB abscess in neck
<b>Creeping (serpiginous) rash</b>	Cutaneous larvae migrans
<b>Crocodile tears syndrome</b>	Post Bell palsy (when eating)

<b>Cradle crap</b>	Toddler's diarrhoea
<b>Cupid's disease</b>	Increased libido in older people with neurosyphilis
<b>Deadly nightshade</b>	Belladonna
<b>Déjà vu (familiarity) + jamais vu (unreality)</b>	Complex partial seizure (temporal lobe epilepsy)
<b>Dinner fork deformity</b>	Colle fracture
<b>Dirty diaper (pants) gait</b>	Ataxic gait of cerebellar disease/dysfunction
<b>Doll's head sign</b>	People in coma/semi-coma with eyes focused on a fixed spot
<b>Donald Duck speech</b>	Pseudobulbar palsy of motor neurone disease
<b>Doughnut-shaped rash (at bite site)</b>	Lyme disease (tick bite)
<b>Dowager's hump</b>	Osteoporosis
<b>Duck bill deformity</b>	Zigzag (Z deformity) of thumb as in rheumatoid arthritis
<b>Duck waddling gait</b>	Osteitis pubis
<b>Elephant man</b>	Neurofibromatosis type 1 (Von Recklinghausen disease)
<b>Eyes</b>	
• almond shaped	Prader-Willi syndrome
• beefy = bloodshot eye	Subconjunctival haematoma
• glitter	Bright eyes of thyrotoxicosis (conjunctival oedema)
• lazy	Amblyopia
• pink (also a type of red eye)	Usually used to describe viral conjunctivitis
• red	Inflammation of conjunctivitis
<b>Facies/facial appearance</b>	
• bird-like	Scleroderma
• bulldog	Congenital syphilis
• chipmunk	Thalassaemia major
• elfin	William syndrome
• fish-like mouth	Turner syndrome
• fixed emotion facies + bronze corneal ring	Wilson disease (hepatolenticular degeneration)
• hatchet	Dystrophia myotonia
• Hippocratic/death mask	Peritonitis, cholera
• long face	Fragile X syndrome

• mask	Parkinson syndrome
• monkey	Hypopituitarism
• moon	Cushing syndrome
• old man face in child	Marasmus
• racoon	Basilar skull fracture
• toad	Hypothyroidism
<b>Faeces/stool</b>	
• China clay	Obstructive jaundice
• black stool	Melaena (blood) in faeces
• pea soup	Typhoid fever
• rabbit pellets	Irritable bowel syndrome
• red currant jelly	Intussusception
• rice water	Cholera
• silver stool	Carcinoma of ampulla of Vater
• toothpaste	Hirschsprung disease
<b>Farmer's lung</b>	Extrinsic allergic alveolitis due to mouldy hay
<b>Feet</b>	
• stinky or sneakers feet	Pitted keratolysis
• sweaty socks feet	Juvenile plantar dermatosis
• Trench (immersion) foot	Severe soft tissue injury due to prolonged
<b>Fever patterns</b>	
• quartan	Plasmodium malariae (every fourth day)
• quotidian (daily spikes)	Abscess, cytomegalovirus, pseudomonas infection
• stepladder	Typhoid
• undulant	Brucellosis, lymphoma (esp. Hodgkin lymphoma)
• tertian	Plasmodium vivax (every third day)
<b>Fiery serpent</b>	Guinea worm infestation
<b>Floater and flashes (of eyes)</b>	Ageing (vitreous detachment), retinal detachment, vitreous haemorrhage
<b>Funnybone</b>	Medial epicondyle of humerus
<b>Gardener's arm</b>	Sporotrichosis (a chronic fungal infection)
<b>Geographical tongue</b>	Benign migratory glossitis (unknown cause ? hypersensitivity reaction)

<b>Glue ears</b>	Sticky fluid of secretory otitis media
<b>Golfer's itch</b>	Summer leg rash
<b>Golfer's vasculitis</b>	Brachioradial pruritus
<b>Goose bumps/chicken skin/funky skin</b>	Piloerection
<b>Grey baby syndrome</b>	Adverse effect of chloramphenicol causing cardiovascular collapse
<b>Grunts and expletives</b>	Tourette syndrome
<b>Gum boil</b>	Small abscess on gum due to dental caries
<b>Happy puppet</b>	Angelman disease
<b>Hair</b>	
• kinky hair	Menkes syndrome (X linked)
• uncombable syndrome	Spun glass hair (AD)
<b>Hair of the dog</b>	An alcoholic drink to relieve a hangover
<b>Headaches</b>	
• alarm clock	Cluster headaches
• Asian food	Adverse effect of monosodium glutamate
• hot dog	Adverse effect of sodium nitrite
• ice-cream	Due to very cold food and drink—a form of vascular headache
• ice-pick	Sudden stabbing pains lasting few seconds—a vascular headache
• sex	Provoked by sexual activity especially with orgasm
• thunderclap—sudden	SAH, enlarging aneurysm or vascular malformation, meningitis
<b>Hi-Fi-Di disease</b>	Terminal kidney failure because of hiccoughs, fits, then dies
<b>Hirsutes</b>	Overgrowth of hair
<b>Horse kick pain</b>	Mittelschmerz
<b>Hydrophobia</b>	Extreme aversion to water with rabies since it causes painful pharyngeal spasms on drinking
<b>Icing sugar penile glans</b>	The white appearance of balanitis xerotica obliterans

<b>Itch</b>	
• winter	Asteatotic eczema
• golfer's	Summer leg rash
• jock	Tinea cruris
• bath	Polycythemia vera
<b>Inverted champagne bottle legs (aka rooster legs)</b>	Peroneal muscular dystrophy (Charcot-Marie-Tooth syndrome)
<b>Jacksonian march</b>	Jacksonian motor seizure (simple partial seizure)
<b>Jock itch</b>	Tinea cruris
<b>Kangaroo paw syndrome</b>	Repetitive strain injury of wrist in Australian workers
<b>King's evil</b>	Tuberculosis cervical lymphadenopathy
<b>Kinky hair syndrome</b>	Sparse steely hair of inherited copper deficiency (X-linked—in males)
<b>Lemon-tinged, sallow skin</b>	Chronic kidney failure, pernicious anaemia
<b>Lockjaw</b>	Tetanus—the effect of muscle spasm
<b>Locked-in syndrome</b>	Cerebrovascular accident causing patient to be mute and paralysed
<b>Malta fever</b>	Brucellosis
<b>Maple syrup odour</b>	Maple syrup urine disease
<b>Milky or white leg</b>	Phlegmasia alba dolens
<b>'My hat doesn't fit any more'</b>	Paget disease
<b>'My gloves don't fit any more'</b>	Acromegaly
<b>'My tongue seems too big for my mouth'</b>	Acromegaly, amyloid, hypothyroidism
<b>'I cannot whistle properly any more'</b>	Myaesthesia gravis, motor neurone disease
<b>Monkey glands</b>	A tongue-in-cheek reference to testicles following the controversial work of Serge Voronoff in Paris, who transplanted monkey testicles into the human scrotum
<b>Mousy body odour syndrome</b>	Phenylketonuria syndrome

**Musculoskeletal conditions**

• carpet-layer's knee/ housemaid's knee	Prepatellar bursitis
• clergyman's knee	Infrapatellar bursitis
• dancer's fracture	Fracture of base of fifth metatarsal bone
• gamekeeper's thumb/ skier's thumb	Ligamentous disruption of metacarpophalangeal joint
• golfer's elbow/ baseball pitcher's elbow/forehand tennis elbow	Medial epicondylitis
• jogger's knee	Patellofemoral joint pain syndrome
• jumper's knee	Patellar tendonopathy
• funny bone	Medial epicondyle of humerus
• march fracture	Stress fracture neck of 2nd metatarsal
• moviegoer's knee	Patellofemoral syndrome (aka chondromalacia patellae), where people attending the movies sit on the aisle so they extend their leg into the aisle for comfort
• nursemaid's arm	Pulled elbow in child
• policeman's heel	Plantar fasciitis
• runner's knee	Iliotibial band tendonitis
• shopping cart sign	Spinal canal stenosis
• soccer toe	Black or bruised toenails (subungual haematoma) due to trauma
• student's/plumber's elbow; beat elbow	Olecranon bursitis
• tennis elbow (backhand)	Lateral epicondylitis
• tennis leg/monkey muscle tear	Torn medial head gastrocnemius
• toddler's leg	Fractured tibia
• turf toe	Sprain of great toe due to hyperflexion injury
• washerwoman's sprain	De Quervain tenosynovitis
• weaver's or tailor's bottom	Ischial bursitis

**Muzzle face**

The distribution of peri-oral  
dermatitis

**Nettle rash**

Hives or urticaria

**Pearly papules**

Small benign developmental  
lumps on corona of glans of  
penis

**Peggy bloomers**

Women with facial rosacea,  
as described by Robert Burns

**Personality disorders**

• charming, alarming, disarming	Narcissitic
• hell raiser	Borderline antisocial
• mad dog	Impulsive antisocial
• prima donna	Narcissistic antisocial

**Philadelphia**

(a) Philadelphia  
chromosome—associated with  
chronic myeloid leukaemia,  
(b) the city of the Legion  
convention in 1976 where  
*Legionella pneumophila* CAP  
was first identified

**Pickwickian syndrome**

Respiratory failure due to  
gross obesity

**Pigeon toes**

In-toeing due to metatarsus  
varus, internal tibial torsion or  
medial femoral torsion

**Pill-rolling tremor**

Parkinson disease

**Pollyanna effect**

No matter the nature of  
treatment, the patient  
responds—traditionally used  
to describe the effect of  
antibiotics in otitis media

**Popeye syndrome**

Aka 'Drummer's forearm'—  
facioscapulohumeral muscular  
dystrophy: also appearance  
from a form of brachial plexus  
palsy

**Port-wine stain**

Capillary malformation

**Prickly heat**

Miliaria (heat rash)

**Prune belly**

Congenital absence of a layer  
of abdominal muscles

**Prune juice discharge**

Ectopic pregnancy

**Ptomaine poisoning**

Food poisoning due to  
nitrogenous putrifying waste

**Pulseless disease**

Takayasu arteritis

**Pump bumps**

Tender bursa over bony  
prominence near attachment  
of Achilles tendon

<b>Q fever</b>	'Query' fever—a zoonosis due to <i>Coxiella burnetii</i>
<b>Rabbit fever</b>	Tularaemia, a zoonotic infection of wild rodents (esp. rabbits)
<b>Rachitic rosary (chest)</b>	A ring of costochondral 'beads' seen in rickets
<b>Raggedy Ann syndrome</b>	Chronic fatigue syndrome
<b>Red cherry spot (at macula)</b>	Central retinal artery occlusion
<b>Red man syndrome</b>	Injection of IV vancomycin infusion
<b>Restless legs</b>	Ekbom syndrome (urge to move legs at rest, esp. at night)
<b>Risus sardonius</b>	Tetanus
<b>Rodent ulcer</b>	Basal cell carcinoma
<b>Roman breast plate</b>	Scleroderma
<b>Rose spots</b>	Pink spots with typhoid
<b>Saddle nose</b>	Congenital syphilis
<b>Saint Vitus dance</b>	Sydenham chorea (chorea minor, rheumatic chorea)—purposeless body movements subsiding without neurological complications (St Vitus is patron saint of dancers and children)
<b>Sausage abdomen mass</b>	Intussusception
<b>Sausage digits</b>	Swollen arthritic fingers of seronegative spondyloarthropathies (e.g. psoriasis)
<b>Scalded skin syndrome</b>	Peeling infected skin due to <i>Staphylococcus aureus</i>
<b>Shin splints = tibial stress syndrome</b>	Pain and localised tenderness over distal posteromedial border of tibia in active athletes
<b>Sick building syndrome</b>	Symptoms of nasal, eye and other mucous membrane irritation, dry skin and headache associated with air conditioning in 'sealed' buildings
<b>Sister Mary Joseph's nodule</b>	A secondary malignant tumour in the umbilicus suggestive of intra-abdominal malignancy

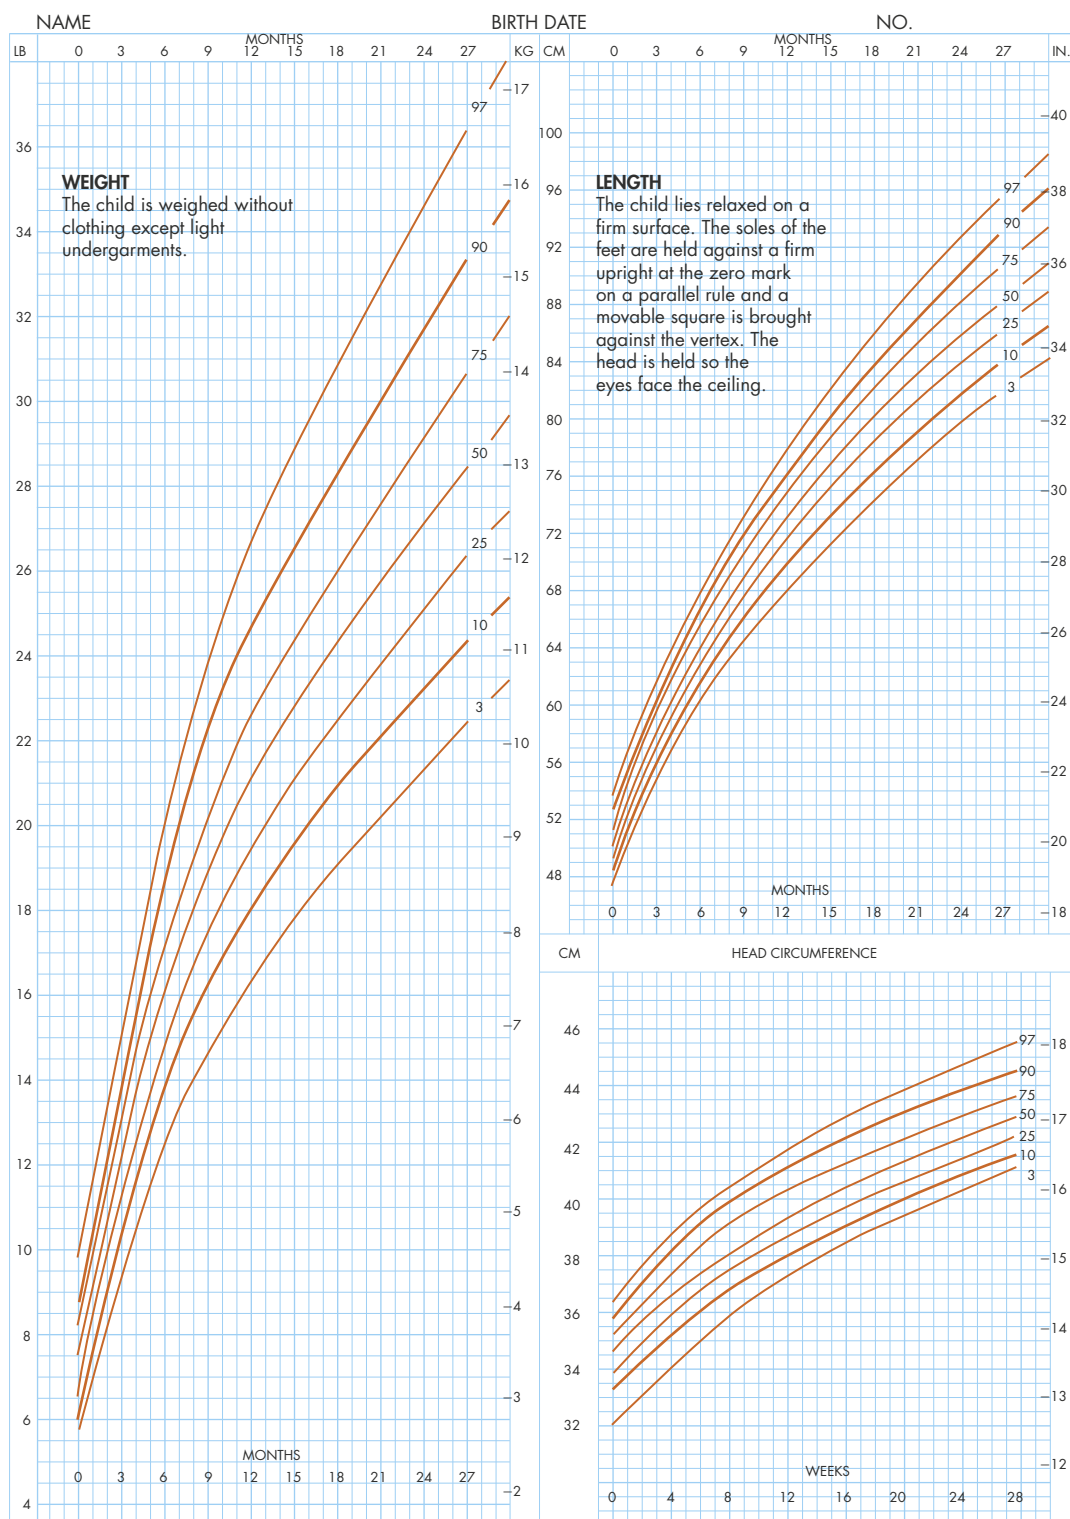

<b>Sitz bath</b>	A bath of warm, medicated water deep enough to cover hips
<b>Slapped face or cheek</b>	Erythema infectiosum
<b>Sleeping sickness</b>	The somnolent state associated with African trypanosomiasis
<b>Snail track ulcer</b>	Found in the oral mucous membrane in secondary syphilis
<b>Snarling smile (especially with exercise)</b>	Myasthenia gravis
<b>Spider fingers</b>	Marfan syndrome
<b>Splinter haemorrhage</b>	Infective endocarditis
<b>Stiff man/person syndrome</b>	Stiff trunk and abdomen of an autoimmune neuromuscular disorder
<b>Stork bite/salmon patch</b>	Naevus flammeus (dilated capillaries on face, eyelids, neck)
<b>Strawberry naevus</b>	Cavernous haemangioma
<b>Sulphur granules</b>	Actinomycoses
<b>Summer leg = golfer's vasculitis</b>	An erythematous pruritic rash on the legs after prolonged exercise such as in golf and hiking—invariably in summer months
<b>Sun downing</b>	Mild to moderate delirium at night in elderly institutionalised patients
<b>Sun spots</b>	Solar keratoses
<b>Surfer's ear</b>	Exostoses of ear
<b>Swan neck</b>	Deformity of rheumatoid arthritis (in fingers)
<b>Swimmer's ear</b>	Otitis externa
<b>Swimmer's itch</b>	Schistosomiasis
<b>The Thinker (Rodin)</b>	Myasthenia gravis
<b>Tongue</b>	
• black or hairy	Dark elongated filiform papillae
• geographic tongue (erythema migrans)	Changing patterns of erythema and hyperkeratosis on surface of tongue (probably hypersensitivity reaction)
• pipe smoker's tongue or palate	Nicotine staining on tongue and palate

<b>Tremor</b>		<b>Warfarin</b>	
• pill-rolling	Parkinson disease	An acronym for Wisconsin Alumni Research Foundation + arin (from coumarin)	
• wing beating (flapping)—asterixis	Hepatic failure	<b>Watermelon stomach</b>	
<b>Too many toes syndrome</b>		Gastric antral vascular ectasia	
	Rupture of tibialis posterior muscle	<b>Wet paint syndrome</b>	
<b>Two lovely black eyes (spontaneous)—also 'panda eyes'</b>		A compulsion to try things despite the chance of harm	
	Amyloidosis	<b>Winchester goose</b>	
<b>Urine</b>		Inguinal lymphadenopathy of STIs (classically syphilis)	
• black (black on standing)	Alkaptonuria	<b>Winter itch</b>	
• maple syrup	Maple syrup disease	Asteatotic eczema on dry lower legs of elderly	
• red (on standing in sunlight)	Porphyria	<b>Witch's milk</b>	
• sweet pee	Diabetes mellitus	Milk from the enlarged breasts of babies (see <b>CHAPTER 81</b> )	
<b>Vietnamese time bomb</b>		<b>Writer's cramp, typist's cramp, pianist's cramp, golfer's cramp</b>	
	Melioidosis	Focal dystonias (sustained involuntary contractions of the hand and possibly forearm) initiated by these activities

INFANT BOYS

## Appendix III Percentile charts: girls

# Appendix IV Percentile charts: boys

## Appendix V The Australian Nutrition Foundation: weight for height chart

# Index

Page numbers in **bold** indicate sections or extensive treatment of a topic.

Page numbers in *italics* indicate figures or tables.

Entries starting with numbers precede the alphabetical sequence, excepting numbers preceding the names of chemicals, which are ignored in filing. For example: 5-fluorouracil files as fluorouracil.
