 **MURTAGH'S**  
general practice

To all our medical colleagues, past and present, who have  
provided the vast reservoir of knowledge from which the  
content of this book was made possible

## NOTICE

Medicine is an ever-changing science. As new research and clinical experience broaden our knowledge, changes in treatment and drug therapy are required. The editors and the publisher of this work have checked with sources believed to be reliable in their efforts to provide information that is complete and generally in accord with the standards accepted at the time of publication. However, in view of the possibility of human error or changes in medical sciences, neither the editors, nor the publisher, nor any other party who has been involved in the preparation or publication of this work warrants that the information contained herein is in every respect accurate or complete. Readers are encouraged to confirm the information contained herein with other sources. For example, and in particular, readers are advised to check the product information sheet included in the package of each drug they plan to administer to be certain that the information contained in this book is accurate and that changes have not been made in the recommended dose or in the contraindications for administration. This recommendation is of particular importance in connection with new or infrequently used drugs.

## Professor John Murtagh AM

MBBS, MD, BSc, BEd, FRACGP, DipObstRCOG

Emeritus Professor in General Practice, School of Primary Health, Monash University, Melbourne

Professorial Fellow, Department of General Practice, University of Melbourne

Adjunct Clinical Professor, Graduate School of Medicine, University of Notre Dame, Fremantle, Western Australia

Guest Professor, Peking University Health Science Centre, Beijing

John Murtagh was a science master teaching chemistry, biology and physics in Victorian secondary schools when he was admitted to the first intake of the newly established Medical School at Monash University, graduating in 1966. Following a comprehensive postgraduate training program, which included surgical registrarship, he practised in partnership with his medical wife, Dr Jill Rosenblatt, for 10 years in the rural community of Neerim South, Victoria.

He was appointed Senior Lecturer (part-time) in the Department of Community Medicine at Monash University and eventually returned to Melbourne as a full-time Senior Lecturer. He was appointed to a professorial chair in Community Medicine at Box Hill Hospital in 1988 and subsequently as chairman of the extended department and Professor of General Practice in 1993 until retirement from this position in 2010. He now holds teaching positions as Emeritus Professor in General Practice at Monash University, Adjunct Clinical Professor, University of Notre Dame and Professorial Fellow, University of Melbourne. He combines these positions with part-time general practice, including a special interest in musculoskeletal medicine. He achieved the Doctor of Medicine degree in 1988 for his thesis 'The management of back pain in general practice'.

He was appointed Associate Medical Editor of *Australian Family Physician* in 1980 and Medical Editor in 1986, a position held until 1995. In 1995 he was awarded the Member of the Order of Australia for services to medicine, particularly in the areas of medical education, research and publishing.

One of his numerous publications, *Practice Tips*, was named as the British Medical Association's Best Primary Care Book Award in 2005. In the same year he was named as one of the most influential people in general practice by the publication *Australian Doctor*. John Murtagh was awarded the inaugural David de Kretser medal from Monash University for his exceptional contribution to the Faculty of Medicine, Nursing and Health Sciences over a significant period of time. Members of the Royal Australian College of General Practitioners may know that he was bestowed the honour of the namesake of the College library.

Today John Murtagh continues to enjoy active participation with the diverse spectrum of general practitioners—whether they are students or experienced practitioners, rural- or urban-based, local or international medical graduates, clinicians or researchers. His vast experience with all of these groups has provided him with tremendous insights into their needs, which is reflected in the culminated experience and wisdom of *John Murtagh's General Practice*.

## Dr Jill Rosenblatt

---

MBBS, FRACGP, DipObstRCOG, GradDipAppSci  
General Practitioner, Ashwood Medical Group  
Adjunct Senior Lecturer, School of Primary Health Care,  
Monash University, Melbourne

Jill Rosenblatt graduated in medicine from the University of Melbourne in 1968. Following terms as a resident medical officer she entered rural practice in Neerim South, Victoria, in partnership with her husband John Murtagh. She was responsible for inpatient hospital care in the Neerim District Bush

Nursing Hospital and in the West Gippsland Base Hospital. Her special interests were obstetrics, paediatrics and anaesthetics. Jill Rosenblatt also has a special interest in Indigenous culture and health since she lived at Koonibba Mission in South Australia, where her father was Superintendent.

After leaving rural life she came to Melbourne and joined the Ashwood Medical Group, where she continues to practice comprehensive general medicine and care of the elderly in particular. She was appointed Adjunct Senior Lecturer in the Department of General Practice at Monash University in 1980 and a teacher in the GP registrar program.

She gained a Diploma of Sports Medicine (RACGP) in 1985 and a Graduate Diploma of Applied Science in Nutritional and Environmental Medicine from Swinburne University of Technology in 2001.

Jill Rosenblatt brings a wealth of diverse experience to the compilation of this textbook. This is based on 45 years of experience in rural and metropolitan general practice. In addition she has served as clinical assistant to the Shepherd Foundation, the Menopause Clinics at Prince Henry's Hospital and Box Hill Hospital and the Department of Anaesthetics at Prince Henry's Hospital. Jill has served as an examiner for the RACGP for 39 years and for the Australian Medical Council for 16 years. She was awarded a life membership of the Royal Australian College of General Practitioners in 2010 and a Distinguished Service award of the College in 2014.

# Foreword

In 1960 a young schoolmaster, then teaching biology and chemistry in a secondary school in rural Victoria, decided to become a country doctor. He was part of the first intake of students into the Medical School of the newly established Monash University, and at the end of his six-year undergraduate medical course and subsequent intern and resident appointments his resolve to practise community medicine remained firm. After more than a decade in country practice with his life partner, Dr Jill Rosenblatt, during which he meticulously documented the cases he treated, in 1977 John Murtagh took up an academic position in the new Department of General Practice at Monash University. He subsequently moved through the ranks of Senior Lecturer, Associate Professor and Professor, now enjoying the title of Emeritus Professor.

Through his writing, pedagogy and research, John Murtagh became a national and international authority on the content and teaching of primary care medicine. It was during his tenure as Medical Editor of *Australian Family Physician* from 1986 to 1995 that the journal became the most widely read medical journal in Australia.

This text book provides a distillate of the vast experience gained by a once rural doctor, whose career has embraced teaching; whose abiding interest is in ensuring that disease, whether minor or life-threatening, is recognised quickly; and whose concern is that strategies to match each contingency are well understood.

The first edition of this book, published in 1994, achieved remarkable success on both the national and international scene. The second and third editions built on this initial success and the book has become known as the 'bible of general practice' in Australia. In addition to being widely used by practising doctors, it has become a popular and standard textbook in several medical schools and also in the teaching institutions for alternative health practitioners, such as chiropractic, naturopathy and osteopathy. In particular, medical undergraduates and graduates struggling to learn English have found the book relatively comprehensible. The fourth and fifth editions were updated and expanded, retaining the successful, user-friendly format including clinical photography and illustrations in colour. Dr Jill Rosenblatt joined John in authoring and editing the fifth and sixth editions.

This edition, launched 20 years after the first edition, represents a further milestone in Emeritus Professor John Murtagh's remarkable career. Having known

John and worked with him for almost three decades, I feel privileged to write this foreword to the sixth edition, adding to earlier forewords by the late Professor Schofield. During this 20-year period I have watched each edition blossom, only to be superseded by a bigger and better replacement. John Murtagh has become a legend nationally and internationally, and in a 2012 *Medical Observer* survey he was voted the most revered Australian doctor, ahead of Fred Hollows and Victor Chang.

This edition retains the time-honoured framework that has made it the seminal text for GPs and students of general practice worldwide. It is to general practice what 'Harrisons' is to internal medicine.

Although this edition retains the same format, it has a number of significant changes and additions. There is much more on chronic disease, in keeping with the increasing prevalence of chronic disease and the challenges it presents in treating an ageing community. Reflecting John's lifelong commitment to medical education, he has included more visual material, more practical tips for day-to-day clinical practice and importantly, more on therapeutics supported by references to *Therapeutic Guidelines*.

The expanded volume has necessitated a significant increase in references to original sources to substantiate the evidence base within this text. As expected in contemporary texts, there is also an abundance of online resources.

John Murtagh's works, including this text, have been translated into Italian by McGraw-Hill Libri Italia s.r.l., Portuguese by McGraw-Hill Nova Iorque and Spanish by McGraw-Hill Interamericana Mexico and also into Chinese, Greek, Polish and Russian. In 2009 *John Murtagh's General Practice* was chosen by the Chinese Ministry of Health as the textbook to aid the development of general practice in China. Its translation was completed later that year.

# Contents

The authors	v	Reviewers	xvi
Foreword	vii	Laboratory reference values	xix
Acknowledgments	x	Normal values: worth knowing by heart	xxi
Preface	xi	Abbreviations	xxii
Making the most of your book	xii		

## Part 1 The basis of general practice 1

Chapter 1	The nature, scope and content of general practice	2
Chapter 2	The family	7
Chapter 3	Consulting skills	14
Chapter 4	Communication skills	20
Chapter 5	Counselling skills	28
Chapter 6	Difficult, demanding and angry patients	39
Chapter 7	Health promotion and patient education	44
Chapter 8	The elderly patient	49
Chapter 9	Prevention in general practice	64
Chapter 10	Nutrition in health and illness	75
Chapter 11	Palliative care	83
Chapter 12	Pain and its management	93
Chapter 13	Research and evidence-based medicine	106
Chapter 14	Travel medicine	115
Chapter 15	Tropical medicine and the returned traveller	129
Chapter 16	Inspection as a clinical skill	141
Chapter 17	A safe diagnostic strategy	147
Chapter 18	Genetic conditions	156

## Part 2 Diagnostic perspective in general practice 175

Chapter 19	Depression	176
Chapter 20	Diabetes mellitus	185
Chapter 21	Drug and alcohol problems	202
Chapter 22	Anaemia	219
Chapter 23	Thyroid and other endocrine disorders	227
Chapter 24	Spinal dysfunction	239
Chapter 25	Urinary tract infection	242
Chapter 26	Malignant disease	251
Chapter 27	HIV/AIDS—could it be HIV?	259
Chapter 28	Baffling viral and protozoal infections	270
Chapter 29	Baffling bacterial infections	277
Chapter 30	Infections of the central nervous system	290
Chapter 31	Chronic kidney failure	296

Chapter 32	Connective tissue disease and the vasculitides	303
Chapter 33	Neurological dilemmas	313

## Part 3 Problem solving in general practice 331

Chapter 34	Abdominal pain	332
Chapter 35	Arthritis	355
Chapter 36	Anorectal disorders	379
Chapter 37	Thoracic back pain	387
Chapter 38	Low back pain	401
Chapter 39	Bruising and bleeding	422
Chapter 40	Chest pain	432
Chapter 41	Constipation	453
Chapter 42	Cough	464
Chapter 43	Deafness and hearing loss	478
Chapter 44	Diarrhoea	488
Chapter 45	The disturbed patient	506
Chapter 46	Dizziness/vertigo	525
Chapter 47	Dyspepsia (indigestion)	535
Chapter 48	Dysphagia	545
Chapter 49	Dyspnoea	549
Chapter 50	The painful ear	562
Chapter 51	The red and tender eye	575
Chapter 52	Pain in the face	591
Chapter 53	Fever and chills	601
Chapter 54	Faints, fits and funny turns	611
Chapter 55	Haematemesis and melaena	620
Chapter 56	Headache	623
Chapter 57	Hoarseness	641
Chapter 58	Jaundice	645
Chapter 59	Nasal disorders	662
Chapter 60	Nausea and vomiting	672
Chapter 61	Neck lumps	678
Chapter 62	Neck pain	683
Chapter 63	Shoulder pain	697
Chapter 64	Pain in the arm and hand	710
Chapter 65	Hip, buttock and groin pain	727
Chapter 66	Pain in the leg	740
Chapter 67	The painful knee	758
Chapter 68	Pain in the foot and ankle	779
Chapter 69	Walking difficulty and leg swelling	796
Chapter 70	Palpitations	803

Chapter 71	Sleep disorders	817
Chapter 72	Sore mouth and tongue	827
Chapter 73	Sore throat	838
Chapter 74	Tiredness/fatigue	847
Chapter 75	The unconscious patient	854
Chapter 76	Urinary disorders	863
Chapter 77	Visual failure	875
Chapter 78	Weight gain	888
Chapter 79	Weight loss	897

## Part 4 Chronic disorders: continuing management 905

Chapter 80	Allergic disorders including hay fever	906
Chapter 81	Anxiety disorders	914
Chapter 82	Asthma	923
Chapter 83	Chronic obstructive pulmonary disease	935
Chapter 84	Epilepsy	943
Chapter 85	Cardiovascular disease	951
Chapter 86	Hypertension	955
Chapter 87	Dyslipidaemia	972
Chapter 88	Chronic heart failure	977
Chapter 89	Osteoporosis	984

## Part 5 Child and adolescent health 989

Chapter 90	An approach to the child	990
Chapter 91	Specific problems of children	1000
Chapter 92	Surgical problems in children	1017
Chapter 93	Common childhood infectious diseases (including skin eruptions)	1028
Chapter 94	Behavioural and developmental issues and disorders in children	1041
Chapter 95	Child abuse	1054
Chapter 96	Emergencies in children	1062
Chapter 97	Adolescent health	1077

## Part 6 Women's health 1085

Chapter 98	Cervical cancer screening	1086
Chapter 99	Family planning	1094
Chapter 100	Breast pain (mastalgia)	1105
Chapter 101	Lumps in the breast	1110
Chapter 102	Abnormal uterine bleeding	1122
Chapter 103	Lower abdominal and pelvic pain in women	1130
Chapter 104	Premenstrual syndrome	1143
Chapter 105	The menopause	1147
Chapter 106	Vaginal discharge	1154
Chapter 107	Vulvar disorders	1162
Chapter 108	Basic antenatal care	1170
Chapter 109	Infections in pregnancy	1179

Chapter 110	High-risk pregnancy	1184
Chapter 111	Postnatal care	1200

## Part 7 Male health 1209

Chapter 112	Male health: an overview	1210
Chapter 113	Scrotal pain	1214
Chapter 114	Inguinoscrotal lumps	1219
Chapter 115	Disorders of the penis	1230
Chapter 116	Disorders of the prostate	1238

## Part 8 Sexual health 1249

Chapter 117	The subfertile couple	1250
Chapter 118	Sexual health	1258
Chapter 119	Sexually transmitted infections	1271
Chapter 120	Intimate partner violence and sexual assault	1283

## Part 9 Problems of the skin 1289

Chapter 121	A diagnostic and management approach to skin problems	1290
Chapter 122	Pruritus	1301
Chapter 123	Common skin problems	1311
Chapter 124	Acute skin eruptions	1335
Chapter 125	Skin ulcers	1348
Chapter 126	Common lumps and bumps	1358
Chapter 127	Pigmented skin lesions	1375
Chapter 128	Hair disorders	1385
Chapter 129	Nail disorders	1396

## Part 10 Accident and emergency medicine 1407

Chapter 130	Emergency care	1408
Chapter 131	The doctor's bag and other emergency equipment	1424
Chapter 132	Stroke and transient ischaemic attacks	1429
Chapter 133	Thrombosis and thromboembolism	1436
Chapter 134	Common skin wounds and foreign bodies	1442
Chapter 135	Common fractures and dislocations	1456
Chapter 136	Common sporting injuries	1479

## Part 11 Health of specific groups 1495

Chapter 137	The health of Indigenous peoples	1496
Chapter 138	Refugee health	1505
Chapter 139	Catchy metaphors, similes and colloquial expressions in medicine	1511

Appendix		1517
Index		1522

# Acknowledgments

---

The author would like to thank the Publication Division of the Royal Australian College of General Practitioners for supporting his past role as Medical Editor of *Australian Family Physician*, which provided an excellent opportunity to gather material for this book. Acknowledgment is also due to those medical organisations that have given permission to use selected information from their publications. They include the Preventive and Community Medicine committee of the RACGP (Guidelines for Preventive Activities in General Practice), Therapeutic Guidelines Limited (*Therapeutic Guidelines* series), the Hypertension Guideline Committee: Research Unit RACGP (South Australian Faculty) and the *Medical Observer*, publishers of *A Manual for Primary Health Care*, for permitting reproduction of Appendices I–IV.

Special thanks to the late Chris Sorrell for his art illustration, and to Nicki Cooper, Jenny Green and Caroline Menara for their skill and patience in typing the manuscript.

Many of the quotations at the beginning of chapters appear in either Robert Wilkins (ed), *The Doctor's Quotation Book*, Robert Hale Ltd, London, 1991, or Maurice B. Strauss (ed), *Familiar Medical Quotations*, Little, Brown & Co., New York, 1958.

Thanks also to Dr Bruce Mugford, Dr Lucie Stanford, Dr Mohammad Shafeeq Lone, Dr Brian Bedkobar, Dr Joseph Turner and Lesley Rowe for reviewing the manuscript, and to the publishing and production team at McGraw-Hill Education (Australia) for their patience and assistance in so many ways.

Finally, thanks to Dr Ndidi Victor Ikealumba for his expert review of *General Practice* sixth edition and his subsequent contribution.

# Preface

---

The discipline of general practice has become complex, expansive and challenging, but nevertheless remains manageable, fascinating and rewarding. *John Murtagh's General Practice* attempts to address the issue of the base of knowledge and skills required in modern general practice. Some of the basics of primary healthcare remain the same. In fact, there is an everlasting identity about many of the medical problems that affect human beings, be it a splinter under a nail, a sty of the eyelid, a terminal illness or simply stress-related anxiety. Many of the treatments and approaches to caring management are universal and timeless.

This text covers a mix of traditional and modern practice with an emphasis on the importance of early diagnosis, strategies for solving common presenting problems, continuing care, holistic management and 'tricks of the trade'. One feature of our discipline is the patient who presents with undifferentiated problems featuring an overlap of organic and psychosocial components. There is the constant challenge to make an early diagnosis and identify the ever-lurking, life-threatening illness. Hence the 'must not be missed' catch cry throughout the text. To reinforce this awareness, 'red flag pointers' to serious disease are included where appropriate. The general practice diagnostic model, which pervades all the chapters on problem solving, is based on the authors' experience, but readers can draw on their own experience to make the model work effectively for themselves.

This sixth edition expands on the challenging initiative of diagnostic triads (or tetrads), which act as a brief *aide-memoire* to assist in identifying a disorder from three (or four) key symptoms or signs. A particular challenge in the preparation of the text was to identify as much appropriate and credible evidence-based information as possible. This material, which still has its limitations, has been combined with considerable collective wisdom from experts, especially from the *Therapeutic Guidelines* series. To provide updated accuracy and credibility, the authors have had the relevant chapters peer reviewed by independent experts in the respective disciplines. These consultants are acknowledged in the reviewers section. The revised edition also has the advantage of co-authorship from experienced general practitioner Dr Jill Rosenblatt. A comprehensive book such as this one, which presents a basic overview of primary medicine, cannot possibly cover all the medical problems likely to be encountered. An attempt has been made, however, to focus on problems that are common, significant, preventable and treatable. Expanded material on genetic disorders, infectious diseases and tropical medicine provides a glimpse of relatively uncommon presenting problems in first-world practice.

*John Murtagh's General Practice* is written with the recent graduate, the international medical graduate and the medical student in mind. However, all primary-care practitioners will gain useful information from the book's content. A summarised form is available in Murtagh's Flash Cards App.

# Making the most of your book

## Diagnostic strategy models

Diagnostic strategy models for common presenting problems form the backbone of this book. *General Practice* is renowned for this unique and powerful learning feature, which was introduced in the first edition.

424 PART THREE • Problem solving in general practice

### The clinical approach

Differentiation of coagulation factor deficiencies and platelet disorders as the cause of a bleeding problem can usually be determined by a careful evaluation of the history and physical examination.

### History

Factors that suggest the presence of a systemic bleeding defect include:

- spontaneous haemorrhage
- severe or recurrent haemorrhagic episodes e.g. epistaxis
- bleeding from multiple sites
- bleeding out of proportion to the degree of trauma
- cutaneous bleeding
- gastrointestinal bleeding
- postpartum haemorrhage
- bleeding from tooth extraction/oral cavity
- menorrhagia
- muscle haematomas or haemarthrosis

If a bleeding diathesis is suspected it is essential to determine whether local pathology is contributing to the blood loss (e.g. postoperative bleeding, postpartum bleeding, gastrointestinal haemorrhage).

### Diagnostic tips

- Platelet abnormalities present as early bleeding following trauma.
- Coagulation factor deficiencies present with delayed bleeding after initial haemostasis is achieved by normal platelets.
- A normal response to previous coagulation stresses (e.g. dental extraction, circumcision or pregnancy) indicates an acquired problem.
- If acquired, look for evidence of MILD: Malignancy, Infection, Liver disease, Drugs.
- A diagnostic strategy is outlined in TABLE 39.2.

### Family history

A positive family history can be a positive pointer to the diagnosis:

- sex-linked recessive pattern: haemophilia A or B
- autosomal dominant pattern: vWD, dysfibrinogenemias
- autosomal recessive pattern: deficiency of coagulation factors V, VII and X

Enquire whether the patient has noticed blood in the urine or stools and whether menorrhagia is present in women. A checklist for a bleeding history is

Table 39.2 Purpura: diagnostic strategy model

Q. Probability diagnosis

A. Simple purpura (easy bruising syndrome)

- Senile purpura
- Corticosteroid-induced purpura
- Immune thrombocytopenic purpura
- Henoch-Schönlein purpura
- Liver disease, especially alcoholic cirrhosis
- Increased intravascular pressure, e.g. coughing, vomiting

Q. Serious disorders not to be missed

A. Malignant disease:

- leukaemia
- myeloma
- Aplastic anaemia
- Myelofibrosis

Severe infections:

- septicæmia
- meningococcal infection
- measles
- typhoid
- dengue/chikungunya

Disseminated intravascular coagulation

- Thrombotic thrombocytopenic purpura
- Fat embolism

Q. Pitfalls (often missed)

A. Haemophilia A, B vWD

- Posttransfusion purpura
- Trauma (e.g. domestic violence, child abuse)

Rarities:

- hereditary telangiectasia (Osler-Weber-Rendu syndrome)
- Ehlers-Danlos syndrome
- scurvy
- Fanconi syndrome

Q. The masqueraders

A. Drugs: examples (see 'Medication Record')

- sodium valproate
- various antibiotics
- quinine/quinidine
- thiazide diuretics
- NSAIDs/salicylates
- cytotoxics
- oral anticoagulants/heparin

Aspirin:

- aplastic anaemia

Q. Psychogenic factors

A. Factitious purpura

## Key facts and checkpoints

Key facts and checkpoints provide accurate statistics and local and global contexts.

### Key facts and checkpoints

- Cough is the commonest manifestation of lower respiratory tract infection.
- Cough is the cardinal feature of chronic bronchitis.
- Cough is a feature of asthma with sputum production, especially at night.
- Cough can have a psychogenic basis.
- Cough may persist for many weeks following an acute upper respiratory tract infection (URTI) as a result of persisting bronchial inflammation and increased airway responsiveness.<sup>1</sup>
- Postnasal drip is the commonest cause of a persistent or chronic cough, especially causing nocturnal cough due to secretions (mainly from chronic sinusitis) tracking down the larynx and trachea during sleep.
- The commonest causes of haemoptysis are URTI (24%), acute or chronic bronchitis (17%), bronchiectasis (13%), TB (10%). Unknown causes totalled 22% and cancer 4% (figures from a UK study).<sup>2</sup>

## Vertebral dysfunction with non-radicular pain

This outstanding common cause of low back pain is considered to be due mainly to dysfunction of the pain-sensitive facet joint. The precise pathophysiology is difficult to pinpoint.

## The staff of Asclepius

The staff of Asclepius icon highlights diseases for when you are specifically searching for information on a particular disease.

## Red and yellow flags

Red and yellow flags alert you to potential dangers. Red is the most urgent, but yellow also requires careful consideration.

### Yellow flag pointers

This term has been introduced to identify psychosocial and occupational factors that may increase the risk of chronicity in people presenting with acute back pain. Consider psychological issues if:

- abnormal illness behaviour
- compensation issues
- unsatisfactory restoration of activities
- failure to return to work
- unsatisfactory response to treatment
- treatment refused
- atypical physical signs

### Red flag pointers for low back pain

There are several so-called 'red flag' or precautionary pointers to a serious underlying cause of back pain (see TABLE 38.3). Such symptoms and signs should alert the practitioner to a serious health problem and thus guide selection of investigations, particularly plain films of the lumbar spine.

## Clinical framework

Clinical framework based on major steps of clinical features, investigations, diagnosis, management and treatment reflects the key activities in the daily tasks of general practitioners.

## Seven masquerades checklist

This unique feature of the book reminds you of potential and hidden dangers underlying patient presentations.

Infections of the central nervous system 293

**1 Brain abscess<sup>4,5</sup>**

A brain (cerebral) abscess is a focal area of infection in the cerebrum or cerebellum. It presents as a space-occupying intracerebral lesion. The infection can reach the brain by local spread or via the bloodstream, for example, endocarditis. There may be no clue to a focus of infection elsewhere but it can follow ear, sinus, dental, periodontal or other infection and also a skull fracture. The organisms are polymicrobial especially microaerophilic cocci and anaerobic bacteria in the non-immunosuppressed. In the immunosuppressed, *Toxoplasma*, *Nocardia* sp. and fungi.

**Clinical features**

Raised intracranial pressure

- Headache
- Nausea and vomiting
- Altered conscious state
- Papilloedema

**Other**

- Focal neurological signs such as hemiplegia, dysphasia, ataxia
- Seizures (30%)
- Fever (may be absent)
- Signs of sepsis elsewhere: e.g. teeth, endocarditis

**Investigations**

- MRI (if available) or CT scan
- FBE, ESR/CRP, blood culture
- Note: lumbar puncture is contraindicated.
- Consider endocarditis

**Management**

Management is urgent neurosurgical referral. Aspiration or biopsy is essential to guide antimicrobial treatment which may (empirically) include metronidazole IV and a cephalosporin e.g. ceftriaxone IV.

**2 Spinal subdural or epidural abscess**

These uncommon focal infections can be extremely difficult to diagnose so an index of suspicion is required to consider such an abscess. The usual organism is *Staphylococcus aureus*.

**Clinical features<sup>6</sup>**

- Back pain (increasing) ± radiculopathy
- Percussion tenderness over spine

- Evolving neurological deficit, e.g. gradual leg weakness and sensory loss ± fever (may be absent)

**Causes**

- Associated infection: furuncle, decubitus ulcer, adjacent osteomyelitis, discitis, other
- Back trauma with haematoma
- Post-subdural or epidural anaesthetic block
- One-third is spontaneous

**Investigations**

- Blood culture
- MRI scan to localise abscess and spinal cord pressure

**Management**

Urgent neurosurgical referral. Empirical therapy while awaiting culture results may include di/flucloxacillin IV + gentamicin IV, or vancomycin IV.

**Prion transmitted diseases<sup>7,8</sup>**

Prions are proteinaceous infected particles devoid of nucleic acid that can present with a wide spectrum of neurological presentations. The feature is transmissible spongiform encephalopathy (TSE) with Creutzfeldt-Jakob disease being the classic example. Other examples of TSE forms affecting humans are variant CJD, kuru (New Guinea) and fatal familial insomnia.

**3 Creutzfeldt-Jakob disease**

There are three distinct forms of CJD: sporadic (80–85%), familial (15%) and iatrogenic (1%). The annual incidence is one per million people. Usual transmission is from contaminated human tissue (e.g. corneal graft), cadaver pituitary human gonadotrophin or eating contaminated beef. There is no specific treatment for the disease.

**Clinical features**

- Progressive dementia (starts with personality change and memory loss—eventual loss of speech)
- Myoclonus/muscle spasms
- Fatigue and somnolence
- Variable neurological features (e.g. ataxia, chorea)

**DxT** fatigue + psychiatric symptoms + myoclonus → CJD

### Q. Seven masquerades checklist

- A. Depression  
Diabetes (ketoacidosis)  
Drugs (especially narcotics)  
Anaemia (sickle cell)  
Endocrine disorder (thyroid storm, Addison)  
Spinal dysfunction  
UTI (including urosepsis)
- Q. Is the patient trying to tell me something?
- A. May be very significant.  
Consider Münchhausen syndrome, sexual dysfunction and abnormal stress.

## Diagnostic triads

Key features that may discriminate between one disease and another are clearly presented.

**DxT** light-brown skin patches + skin tumours + axillary freckles → NF1

## Evidence-based research

Evidence-based research is recognised with a full chapter on research in general practice and evidence base, including more on qualitative models. In addition, substantial references are provided for every chapter.

### 13 Research and evidence-based medicine

*Not the possession of truth, but the effort of struggling to attain it brings joy to the researcher.*

Effective research is the trademark of the medical profession. When confronted with the great responsibility of understanding and treating human beings we need as much scientific evidence as possible to render our decision making valid, credible and justifiable.

Research can be defined as 'a systematic method in which the truth of evidence is based on observing and testing the soundness of conclusions according to consistent rules'<sup>1</sup> or, to put it more simply, 'research is organised curiosity'<sup>2</sup> the end point being new and improved knowledge.

In the medical context the term 'research' tends to conjure bench-type laboratory research. However, the discipline of general practice provides a fertile research area in which to evaluate the morbidity patterns and the nature of common problems in addition to the processes specific to primary health care.

There has been an excellent tradition of research conducted by GPs. Tim Murrell in his paper 'Nineteenth century masters of general practice'<sup>3</sup> describes the contributions of Edward Jenner, Caleb Parry, John Snow, Robert Koch and James MacKenzie, and notes that 'among the characteristics they shared was their capacity to observe and record natural phenomena, breaking new frontiers of discovery in medicine using an ecological paradigm'.

This tradition was carried into the 20th century by GPs such as William Pickles, the first president of the Royal College of General Practitioners, Keith Hodgkin and John Fry, all of whom meticulously recorded data that helped to establish patterns for the nature of primary health care. In Australia the challenge was taken up by such people as Clifford Jungfer, Alan Chancellor, Charles Bridges-Webb, Kevin Cullen and Trevor Beard in the 1960s,<sup>4</sup> and now the research activities of the new generation of GPs, academic-based or practice-based, have been taken to a higher level with the development of evidence-based medicine (EBM).

Based on the work of the Cochrane Collaboration and the initiatives of Chris Silagy and later Paul

Glassiou and Chris Del Mar in particular it has developed in the context of Australian general practice and now beyond that. The focus of EBM has been to improve health care and health economics. Its development has gone hand in hand with improved information technology. EBM is inextricably linked to research.

The aim of this chapter is to present a brief overview of research and EBM and, in particular, to encourage GPs, either singly or collectively, to undertake research—simple or sophisticated—and also to publish their work. The benefits of such are well outlined in John Howie's classic text *Research in General Practice*.<sup>5</sup>

#### Why do research?

The basic objective of research is to acquire new knowledge and justification for decision making in medical practice. Research provides a basis for the acquisition of many skills, particularly those of critical thinking and scientific methodology. The discipline of general practice is special to us with its core content of continuing, comprehensive, community-based primary care, family care, domiciliary care, whole-person care and preventive care. To achieve credibility and parity with our specialist colleagues we need to research this area with appropriate methodology and to define the discipline clearly. There is no area of medicine that involves such a diverse range and quantity of decisions each day as general practice, and therefore patient management needs as much evidence-based rigour as possible.

Our own patch, be it an isolated rural practice or an industrial suburban practice, has its own micro-epidemiological fascination. Thus, it provides a unique opportunity to find answers to questions and make observations about that particular community.

There are also personal reasons to undertake research. The process assists professional development, encouraging clear and critical thinking, improvement of knowledge and the satisfaction of developing new skills and opening horizons.

## Extensive coverage of paediatric and geriatric care, pregnancy and complementary therapies

Extensive coverage of paediatric and geriatric care, pregnancy and complementary therapies is integrated throughout, as well as devoted chapter content providing more comprehensive information in these areas.

Pain and its management 101

#### Aspirin

Aspirin is not in common use in children and should not be used <16 years since it has been associated with Reye syndrome.

For antiplatelet effects use low doses 2–5 mg/kg/day.

#### NSAIDs

NSAIDs have a proven safety and efficacy in children for mild to moderate pain and can be used in conjunction with paracetamol and opioids such as codeine and morphine. The advantage is their opioid-sparing effect. Contraindications include known hypersensitivity, severe asthma (especially if aspirin sensitive), bleeding diatheses, nasal polyposis and peptic ulcer disease.

Those commonly used for analgesia are:

- ibuprofen: 5–10 mg/kg (o) 6–8 hourly (max. 40 mg/kg/day)
- naproxen: 5–10 mg/kg (o) 12–24 hourly (max. 1 g/day)
- diclofenac: 1 mg/kg (o) 8 hourly (max. 150 mg/day)
- celecoxib 1.5–3 mg/kg (o) bd

The rectal dose is double the oral dose but only administered twice a day.

#### Opioid analgesics

##### Oral opioids

These have relatively low bioavailability but can be used for moderate to severe pain when weaning from parenteral opioids, for ongoing severe pain (e.g. burns) and where the IV route is unavailable.

##### Codeine

###### Usual dosage:

- 0.5–1 mg/kg (o), 4–6 hourly prn (max. 3 mg/kg/day)

More effective if used combined with paracetamol or ibuprofen (see caution about variations in polymorphisms).

##### Morphine

###### Immediate release:

- 0.2–0.4 mg/kg (o) 4 hourly prn

##### Fentanyl

Fentanyl citrate can be administered orally (transmucosal) as 'lollipops', transcutaneously as 'patches', or intranasally via a mucosal atomiser device (for painful procedures).

#### Parenteral opioids<sup>6</sup>

These are the most powerful parenteral analgesics for children in severe pain and can be administered in intermittent boluses (IM, IV or SC) or by continuous infusion (IV or SC). Infants under 12 months are more sensitive and need careful monitoring (e.g. pulse oximetry). This management is invariably in the hospital. Administration of parenteral opioids should not be undertaken without the availability of oxygen, resuscitation equipment and naloxone to reverse overdose.

#### Analgesics in the elderly

Older patients have the highest incidence of painful disorders and also surgical procedures. As a general rule, most elderly patients are more sensitive to opioid analgesics and to aspirin and other NSAIDs but there may be considerable individual differences in tolerance. Patients over 65 years should receive lower initial doses of opioid analgesics with subsequent doses being titrated according to the patient's needs.<sup>2</sup>

#### Some general rules and tips<sup>2</sup>

- Give analgesics at fixed times by the clock rather than 'prn' for ongoing pain.
- Regularly monitor your patient's analgesic requirements and modify according to needs and adverse effects.
- Start with a dose towards the lower end of the dose range and then titrate upwards depending on response.
- Avoid using compound analgesics and prescribe simple and opioid analgesics separately.
- Reserve the use of anti-emetics for the development of nausea and vomiting with opioids. Extrapyramidal reactions (dystonia and oculogyric crises) can be a problem with anti-emetics.
- Advise patients about the benefits of high-fibre foods if on analgesics. Prescribe a bulking agent or lactulose if necessary.

#### Prescribing NSAIDs

NSAIDs have analgesic, antipyretic and anti-inflammatory activity. They inhibit synthesis of prostaglandins by inhibiting cyclo-oxygenase (COX) present in COX-1 and COX-2. They are very effective against nociceptive pain.

The prescribing of aspirin and other NSAIDs is an area of increasing concern to all GPs, especially in the

12

## Practice tips

Practice tips consist of key points of use in the clinical setting.

### Practice tips

- Back pain that is related to posture, aggravated by movement and sitting, and relieved by lying down is due to vertebral dysfunction, especially a disc disruption.
- The pain from most disc lesions is generally relieved by rest.
- Plain X-rays are of limited use, especially in younger patients, and may appear normal in

## Clinical photos

Clinical photos provide authentic, visual examples of many conditions and serve as either a valuable introduction or confirmation of diagnosis.

FIGURE 15.4 Cutaneous leishmaniasis in a serviceman after returning from the Middle East

## Full colour illustrations

Full colour illustrations are provided, with more than 600 diagrams in the clean, simple style that has proved so popular.

FIGURE 38.5 The slump test: one of the stages

## Significantly enhanced index

The index has more sub-categories with bold page numbers indicating the main treatment of a topic, enabling you to quickly pinpoint the most relevant information. Page numbers in italics refer to figures and tables. Entries with 'see also' have cross-references to related, but more specific information on the topic.

### Index

Page numbers in **bold** indicate sections or extensive treatment of a topic.  
Page numbers in *italics* indicate figures or tables.  
Entries starting with numbers precede the alphabetical sequence, excepting numbers preceding the names of chemicals, which are ignored in filing. For example: 5-fluorouracil files as fluorouracil.

## Patient education resources

Indicates where you can find relevant information from *Murtagh's Patient Education* sixth edition to photocopy and hand out to patients.

### Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Backache
- Exercises for your lower back
- Sciatica
- Spondylosis

# Reviewers

The sixth edition underwent a rigorous peer review process to ensure that *General Practice* remains the gold standard reference for general practitioners around the world.

To that end, the author and the publishers extend their sincere gratitude to the following people who generously gave their time, knowledge and expertise.

## Content consultants

The authors are indebted to the many consultants who reviewed parts of the manuscript relevant to their areas of expertise and provided help and advice.

Dr Rob Baird	laboratory investigation
Dr Deborah Bateson	family planning
Dr Roy Beran	epilepsy; neurological dilemmas
Dr Peter Berger	a diagnostic and management approach to skin problems
Dr James Best	depression, anxiety, male health, child and adolescent health, communication skills
Professor Geoff Bishop	basic antenatal care
Dr John Boxall	palpitations
Dr Penny Burns	disaster medicine
Dr Jill Cargnello	hair disorders
Dr Paul Coughlin and Professor Hatem Salem	bruising and bleeding; thrombosis and thromboembolism
Mr Rod Dalziel	shoulder pain
Dr David Dunn and Dr Hung The Nguyen	the health of Indigenous peoples
Dr Robert Dunne	common skin wounds and foreign bodies
Professor Jon Emery	genetic disorders, malignant disease
Genetic Health Services, Victoria	genetic disorders
Dr Lindsay Grayson and Associate Professor Joseph Torresi	travel medicine, the returned traveller and tropical medicine
Dr Michael Gribble	anaemia
Mr John Griffiths	pain in the hip and buttock
Professor Michael Grigg	pain in the leg
Dr Gary Grossbard	the painful knee
Dr Peter Hardy-Smith	the red and tender eye; visual failure
Professor David Healy (deceased)	abnormal uterine bleeding
Assoc Professor Peter Holmes	cough; dyspnoea; asthma; COPD

Dr Ndid Victor Ikealumba and Dr Cheng I-Hao	refugee health, tropical medicine (Dr Ikealumba)
Professor Michael Kidd, Dr Ron McCoy and Dr Alex Welborn	human immunodeficiency virus infection
Professor Gab Kovacs	abnormal uterine bleeding; the subfertile couple
Professor Even Laerum	research in general practice
Dr Barry Lauritz (deceased)	common skin problems; pigmented skin lesions
Mr Peter Lawson (deceased) and Dr Sanjiva Wijesinha	disorders of the penis; prostatic disorders
Dr Peter Lowthian	arthritis
Mr Frank Lyons	common fractures and dislocations
Professor Barry McGrath	hypertension
Dr Joe McKendrick	malignant disease
Dr Clare Murtagh	cervical cancer screening, family planning, skin problems
Dr Luke Murtagh	pain and its management
Professor Robyn O’Hehir	allergic disorders, including hayfever
Dr Michael Oldmeadow	tiredness
Dr Frank Panetta	chest pain
Professor Roger Pepperell	high risk pregnancy, basic antenatal care, infections in pregnancy
Dr Geoff Quail	pain in the face, sore mouth and tongue
Mr Ronald Quirk	pain in the foot and ankle
Dr Ian Rogers	emergency care
Professor Avni Sali	abdominal pain, lumps in the breast, jaundice, constipation, dyspepsia, nutrition
Dr Hugo Standish	urinary tract infection, chronic kidney failure
Dr Richard Stark	neurological diagnostic triads
Professor Geoff Sussman	skin ulcers
Dr Paul Tallman	stroke and transient ischaemic attacks
Dr Alison Walsh	breastfeeding, post-natal breast disorders
Professor Greg Whelan	alcohol problems, drug problems
Dr Sanjiva Wijesinha	men’s health, scrotal pain, inguinoscrotal lumps
Dr Alan Yung	fever and chills, sore throat
Dr Ronnie Yuen	diabetes mellitus, thyroid and other endocrine disorders

A substantial number of people were involved in reviewing this book through surveys; their invaluable contribution is acknowledged below. We also take the opportunity to thank the other participants who preferred not to be named in this collective.

## Survey respondents

Ashraf Aboud	Clare Finnigan	Sophia Kennelly	Matthew Penn
Mehdi Alzaini	Anthony Fok	George Kostalas	Satish Prasad

# Laboratory reference values

These reference values and ranges are given in the system of international units (SI) and may vary from laboratory to laboratory.

An asterisk (\*) indicates that paediatric reference ranges differ from the adult range given.

Electrolytes/renal		Glucose	
Sodium	135–145 mmol/L	Glucose fasting	3–5.4 mmol/L
Potassium*	3.5–5.0 mmol/L	Glucose random	3–7.7 mmol/L
Chloride	95–110 mmol/L	HbA1c	4.7–6.1%
Bicarbonate	23–32 mmol/L		
Urea	3–8.0 mmol/L	Haematology	
Creatinine	♀ 50–110; ♂ 60–120 µmol/L	Hb*	♀ 115–165; ♂ 130–180 g/L
eGFR	>60 mL/min/1.72 m <sup>2</sup>	PCV*	♀ 37–47; ♂ 40–54%
Calcium*	2.10–2.60 mmol/L (total)	MCV*	80–100 fL
Phosphate	0.90–1.35 mmol/L	Reticulocytes	0.5–2.0%
Magnesium*	0.65–1.00 mmol/L	White cells	4.0–11.0 × 10 <sup>9</sup> /L
Uric acid*	♀ 0.12–0.40; ♂ 0.15–0.45 mmol/L	Platelets	150–400 × 10 <sup>9</sup> /L
		ESR	<20 mm; <35mm if >70 years
Liver function/pancreas		Band neutrophils*	(0.05 × 10 <sup>9</sup> /L)
Bilirubin*	<20 µmol/L (total) <3 µmol/L (direct)	Mature neutrophils*	(2.0–7.5 × 10 <sup>9</sup> /L)
AST*	<40 U/L	Lymphocytes*	(1.0–4.0 × 10 <sup>9</sup> /L)
GGT*	♀ <30; ♂ <50 U/L	Monocytes*	(0.2–0.8 × 10 <sup>9</sup> /L)
Alkaline phosphatase (ALP)*	25–100 U/L	Eosinophils*	(0.0–0.4 × 10 <sup>9</sup> /L)
Total protein	60–80 g/L	Folate	serum 7–45 nmol/L, red cell 360–1400 nmol/L
Albumin	38–50 g/L	s Vitamin B12	(150–700 pmol/L)
Amylase	30–110 U/L	Coagulation	
Lipase	<100 U/L	Bleeding time	2.0–8.5 min
		Fibrinogen	2.0–4.0 g/L

Prothrombin time	sec.
Prothrombin ratio INR	1.0–1.2
APTT	25–35 sec
D-dimer	<500 mg/mL

#### Others

s Creatine phospho kinase	<90 U/L
s Lead	<2 µmol/L
s C-reactive protein	<10 mg/L
Vitamin D	>75 nmol/L

#### Cardiac/lipids

Troponin I or T	<0.1 µg/L
CK total	♀ <200; ♂ <220 U/L
CK-MB	<25 U/L
Cholesterol*	<5.5 mmol/L
Triglycerides*	<1.7 mmol/L
HDL cholesterol	♀ 1–2.2; ♂ 0.9–2.0 mmol/L
LDL cholesterol	2–3.4 mmol/L

#### Thyroid tests

Free T <sub>4</sub>	10.0–25.0 pmol/L
Ultra-sensitive TSH*	0.4–5.0 mU/L
Free T <sub>3</sub>	3.3–8.2 pmol/L

#### Other endocrine tests

s Cortisol	8 am 130–700 nmol/L 4 pm 80–350 nmol/L
------------	---

FSH	1–9 IU/L (adult ♀) 10–30 IU/L (ovulation) 4–200 IU/L (postmenopausal)
Oestradiol menopausal	<200 pmol/L
Testosterone	♀ <3.5; ♂ 10–35 nmol/L

#### Tumour markers

PSA	0–1.0 mcg/L
CEA	<7.5 mcg/L
AFT	<10 mcg/mL
CA-125	<35 U/mL

#### Iron studies

Ferritin	♀ 15–200; ♂ 30–300 mcg/L
Iron	10–30 µmol/L
Iron-binding capacity	45–80 µmol/L
Transferrin	2–3.5 g/L
Transferrin saturation	♀ 15–45%; ♂ 15–55%

#### Blood gases/arterial

pH*	7.38–7.43
P <sub>a</sub> O <sub>2</sub> *	85–105 mmHg
P <sub>a</sub> CO <sub>2</sub> *	36–44 mmHg
Bicarbonate*	20–28 mmol/L
Base excess*	–3 to +3 mmol/L

# Normal values: worth knowing by heart

The following is a checklist that can be used as a template to memorise normal quantitative values for basic medical conditions and management.

Vital signs (average)	< 6 months	6 months – 3 years	3 – 12 years	Adult
Pulse	120–140	110	80 – 100	60 – 100
Respiratory rate	45	30	20	14
BP (mmHg)	90/60	90/60	100/70	≤ 130/85

Children's weight	1–10 years
Rule of thumb:	$Wt = (age + 4) \times 2 \text{ kg}$

## Fever—temperature (morning)<sup>(a)</sup>

(a) There is considerable diurnal variation in temperature so that it is higher in the evening (0.5–1°C). I would recommend the definition given by Yung et al. in *Infectious Diseases: a Clinical Approach*: 'Fever can be defined as an early morning oral temperature > 37.2°C or a temperature > 37.8°C at other times of the day'.

Oral > 37.2°C

Rectal > 37.7°C

## Diabetes mellitus—Diagnostic criteria: blood sugar

Random > 11.1 mmol/L

1 reading if symptomatic

2 readings if asymptomatic

Fasting > 7.0 mmol/L

or the 2 values from an oral GTT

## Hypokalaemia

Serum potassium < 3.5 mmol/L

## Jaundice

Serum bilirubin > 19 µmol/L

## Hyperkalaemia

Serum potassium > 5.0 mmol/L

## Hypertension

BP > 140/90 mmHg

## Alcohol excessive drinking

Males > 4 standard drinks/day

Females > 2 standard drinks/day

## Alcohol health guidelines

Males and females ≤ 2 standard drinks/day  
< 4 standard drinks/occasion

## Anaemia—haemoglobin

Males < 130 g/L

Females < 115 g/L

## Body mass index Wt (kg)/Ht (m<sup>2</sup>)

Normal 20–25

Overweight > 25

Obesity > 30

# Abbreviations

AAA	abdominal aortic aneurysm	APTT	activated partial thromboplastin time
AAFP	American Academy of Family Physicians	AR	autosomal recessive
ABA	Australian Breastfeeding Association	ARB	Angiotension II receptor blocker
ABC	airway, breathing, circulation	ARC	AIDS-related complex
ABCD	airway, breathing, circulation, dextrose	ARDS	adult respiratory distress syndrome
ABFP	American Board of Family Practice	ARR	absolute risk reduction
ABI	ankle brachial index	ART	anti retroviral therapy
ABO	A, B and O blood groups	ASD	atrial septal defect
AC	air conduction	ASIS	anterior superior iliac spine
AC	acromioclavicular	ASOT	antistreptolysin O titre
ACAH	autoimmune chronic active hepatitis	AST	aspartate aminotransferase
ACE	angiotensin-converting enzyme	ATFL	anterior talofibular ligament
ACL	anterior cruciate ligament	AV	atrioventricular
ACR	albumin creatine ratio	AVM	arteriovenous malformation
ACTH	adrenocorticotrophic hormone	AZT	azidothymidine
AD	aortic dissection		
AD	autosomal dominant	BC	bone conduction
ADHD	attention deficit hyperactivity disorder	BCC	basal cell carcinoma
ADT	adult diphtheria vaccine	BCG	bacille Calmette–Guérin
AF	atrial fibrillation	bDMARDs	biological disease modifying antirheumatic drugs
AFI	amniotic fluid index		
AFP	alpha-fetoprotein	BMD	bone mass density
AI	aortic incompetence	BMI	body mass index
AICD	automatic implantable cardiac defibrillator	BOO	bladder outlet obstruction
		BP	blood pressure
AIDS	acquired immunodeficiency syndrome	BPH	benign prostatic hyperplasia
AIIRA	angiotension II(2) reuptake antagonist	BPPV	benign paroxysmal positional vertigo
AKF	acute kidney failure	BSE	breast self-examination
ALE	average life expectancy		
ALL	acute lymphocytic leukaemia	Ca	carcinoma
ALP	alkaline phosphatase	CABG	coronary artery bypass grafting
ALT	alanine aminotransferase	CAD	coronary artery disease
ALTE	apparent life-threatening episode	CAP	community acquired pneumonia
AMI	acute myocardial infarction	CBE	clinical breast examination
AML	acute myeloid leukaemia	CBT	cognitive behaviour therapy
ANA	antinuclear antibody	CCB	calcium channel blocker
ANCI	antineutrophil cytoplasmic antibody	CCF	congestive cardiac failure
ANF	antinuclear factor	CCP	cyclic citrullinated peptide
a/n/v	anorexia/nausea/vomiting	CCT	controlled clinical trial
AP	anterior–posterior	CCU	coronary care unit
APF	Australian pharmaceutical formulary	CD <sub>4</sub>	T helper cell
APH	ante-partum haemorrhage	CD <sub>8</sub>	T suppressor cell

CDT	combined diphtheria/tetanus vaccine	CT	computerised tomography
CEA	carcinoembryonic antigen	CTD	connective tissue disorder
CFL	calcaneofibular ligament	CTG	cardiotocograph
CFS	chronic fatigue syndrome	CTS	carpal tunnel syndrome
cfu	colony forming unit	CVA	cerebrovascular accident
CHC	combined hormonal contraception	CVS	cardiovascular system
CHD	coronary heart disease	CXR	chest X-ray
CHF	chronic heart failure		
CI	confidence interval	DBP	diastolic blood pressure
CIN	cervical intraepithelial neoplasia	DC	direct current
CJD	Creutzfeldt–Jakob disease	DDAVP	desmopressin acetate
CK	creatinine kinase	DDH	developmental dysplasia of the hip
CK–MB	creatinine kinase–myocardial bound fraction	DDP	dipeptidyl peptidase
		DEXA	dual energy X-ray absorptiometry
CKD	chronic kidney disease	DHA	docosahexaenoic acid
CKF	chronic kidney failure	DI	diabetes insipidus
CMC	carpometacarpal	DIC	disseminated intravascular coagulation
CML	chronic myeloid leukaemia	DIDA	di-imino diacetic acid
CMV	cytomegalovirus	DIMS	disorders of initiating and maintaining sleep
CNS	central nervous system	DIP	distal interphalangeal
co	compound	dL	decilitre
COAD	chronic obstructive airways disease	DMARDs	disease modifying antirheumatic drugs
COC	combined oral contraceptive	DNA	deoxyribose-nucleic acid
COCP	combined oral contraceptive pill	DOM	direction of movement
COMT	catechol-O-methyl transferase	DRE	digital rectal examination
COPD	chronic obstructive pulmonary disease	DRABC	defibrillation, resuscitation, airway, breathing, circulation
COX	cyclooxygenase	drug	bd—twice daily
CPA	cardiopulmonary arrest	dosage	tid, tds—three times daily; qid—four times daily
CPAP	continuous positive airways pressure		
CPK	creatine phosphokinase	ds	double strand
CPPD	calcium pyrophosphate dihydrate	DS	double strength
CPR	cardiopulmonary resuscitation	DSM	diagnostic and statistical manual (of mental disorders)
CPS	complex partial seizures	DU	duodenal ulcer
CR	controlled release	DUB	dysfunctional uterine bleeding
CRD	computerised reference database system	DVT	deep venous thrombosis
CREST	calcinosis cutis; Raynaud's phenomenon; oesophageal involvement; sclerodactyly; telangiectasia	DxT	diagnostic triad
CRF	chronic renal failure		
CRFM	chloroquine-resistant falciparum malaria	EAR	expired air resuscitation
CRH	corticotrophin-releasing hormone	EBM	Epstein–Barr mononucleosis (glandular fever)
CR(K)F	chronic renal (kidney) failure	EBNA	Epstein–Barr nuclear antigen
CRP	C-reactive protein	EBV	Epstein–Barr virus
CSF	cerebrospinal fluid	ECC	external chest compression
CSFM	chloroquine-sensitive falciparum malaria	ECG	electrocardiogram
CSIs	COX-2 specific inhibitors		
CSU	catheter specimen of urine		

ECT	electroconvulsive therapy
ED	emergency department
EDD	expected due date
EEG	electroencephalogram
ELISA	enzyme linked immunosorbent assay
EMG	electromyogram
ENA	extractable nuclear antigen
EO	ethinyloestradiol
EPA	eicosapentaenoic acid
EPL	extensor pollicis longus
EPS	expressed prostatic secretions
ER	external rotation
ESRF	end-stage renal failure
ESR(K)F	end stage renal (kidney) failure
ERCP	endoscopic retrograde cholangiopancreatography
esp.	especially
ESR	erythrocyte sedimentation rate
ET	embryo transfer
ETT	endotracheal tube
<hr/>	
FAD	familial Alzheimer disease
FAP	familial adenomatous polyposis
FB	foreign body
FBE	full blood count
FDIU	fetal death in utero
FDL	flexor digitorum longus
FEV <sub>1</sub>	forced expiratory volume in 1 second
FHL	flexor hallucis longus
fL	femto-litre (10 <sup>-15</sup> )
FRC	functional residual capacity
FSH	follicle stimulating hormone
FTA-ABS	fluorescent treponemal antibody absorp- tion test
FTT	failure to thrive
FUO	fever of undetermined origin
FVC	forced vital capacity
FXS	fragile X syndrome
<hr/>	
g	gram
GA	general anaesthetic
GABHS	group A beta-haemolytic streptococcus
GBS	Guillain-Barré syndrome
GCA	giant cell arteritis
GESA	Gastroenterological Society of Australia
GFR	glomerular filtration rate
GGT	gamma-glutamyl transferase

GI	glycaemic index
GIFT	gamete intrafallopian transfer
GIT	gastrointestinal tract
GLP	glucagon-like peptide
GnRH	gonadotrophin-releasing hormone
GO	gastro-oesophageal
GORD	gastro-oesophageal reflux
GP	general practitioner
G-6-PD	glucose-6-phosphate
GSI	genuine stress incontinence
GU	gastric ulcer
GV	growth velocity
<hr/>	
HAV	hepatitis A virus
anti-HAV	hepatitis A antibody
Hb	haemoglobin
HbA	haemoglobin A
anti-HBc	hepatitis B core antibody
HBeAg	hepatitis Be antigen
anti-HBs	hepatitis B surface antibody
HBsAg	hepatitis B surface antigen
HBV	hepatitis B virus
HCG	human chorionic gonadotropin
HCV	hepatitis C virus
anti-HCV	hepatitis C virus antibody
HDL	high-density lipoprotein
HDV	hepatitis D (Delta) virus
HEV	hepatitis E virus
HFA	hydrofluoro alkane
HFM	hand, foot and mouth
HFV	hepatitis F virus
HGV	hepatitis G virus
HHC	hereditary haemochromatosis
HIDA	hydroxy iminodiacetic acid
HIV	human immunodeficiency virus
HLA-B <sub>27</sub>	human leucocyte antigen
HMGCoA	hydroxymethylglutaryl CoA
HNPCC	hereditary nonpolyposis colorectal cancer
HPV	human papilloma virus
HRT	hormone replacement therapy
HSIL	high grade squamous intraepithelial lesion
HSV	herpes simplex viral infection
H	hypertension
<hr/>	
IBS	irritable bowel syndrome
ICE	ice, compression, elevation

ICHPPC	International Classification of Health Problems in Primary Care	LDH/LH	lactic dehydrogenase
ICS	inhaled corticosteroid	LDL	low-density lipoprotein
ICS	intercondylar separation	LFTs	liver function tests
ICSI	intracytoplasmic sperm injection	LH	luteinising hormone
ICT	immunochromatographic test	LHRH	luteinising hormone releasing hormone
IDDM	insulin dependent diabetes mellitus	LIF	left iliac fossa
IDU	injecting drug user	LMN	lower motor neurone
IgE	immunoglobulin E	LNG	levonorgestrel
IgG	immunoglobulin G	LPC	liquor picis carbonis
IgM	immunoglobulin M	LRTI	lower respiratory tract infection
IGRA	interferon gamma release assay	LSD	lysergic acid
IHD	ischaemic heart disease	LSIL	low grade squamous intraepithelial lesion
IHS	International Headache Society	LUQ	left upper quadrant
IM, IMI	intramuscular injection	LUT	lower urinary tract
IMS	intermalleolar separation	LUTS	lower urinary tract symptoms
inc.	including	LV	left ventricular
INR	international normalised ratio	LVH	left ventricular hypertrophy
IOC	International Olympic Committee		
IOFB	intraocular foreign body	MAIS	<i>Mycobacterium avium intracellulare</i> or <i>M. sacrofulaceum</i>
IP	interphalangeal	mane	in morning
IPPV	intermittent positive pressure variation	MAOI	monoamine oxidase inhibitor
IR	internal rotation	MAST	medical anti-shock trousers
ITP	idiopathic (or immune) thrombocytopenia purpura	MB	myocardial base
IUCD	intrauterine contraceptive device	mcg	micrograms (also µg)
IUGR	intrauterine growth retardation	MCL	medial collateral ligament
IV	intravenous	MCP	metacarpal phalangeal
IVF	in-vitro fertilisation	MCU	microscopy and culture of urine
IVI	intravenous injection	MCV	mean corpuscular volume
IVP	intravenous pyelogram	MDI	metered dose inhaler
IVU	intravenous urogram	MDR	multi-drug resistant TB
		MG	myasthenia gravis
JCA	juvenile chronic arthritis	MHT	menopause hormone therapy
JVP	jugular venous pulse	MI	myocardial infarction
		MIC	mitral incompetence
KA	keratoacanthoma	MID	minor intervertebral derangement
KFT	kidney function test	MND	motor neurone disease
kg	kilogram	MRCP	magnetic resonance cholangiography
KOH	potassium hydroxide	MRI	magnetic resonance imaging
		MRSA	methicillin-resistant <i>staphylococcus aureus</i>
LA	local anaesthetic	MS	multiple sclerosis
LABA	long acting beta agonist	MSM	men who have sex with men
LBBB	left branch bundle block	MSST	maternal serum screening test
LBO	large bowel obstruction	MSU	midstream urine
LBP	low back pain	MTP	metatarsophalangeal
LCR	ligase chain reaction	MVA	motor vehicle accident

N normal  
 N saline normal saline  
 NAAT nucleic acid amplification technology  
 NAD no abnormality detected

# Part 1

## The basis of general practice

---

# The nature, scope and content of general practice

*Medical practice is not knitting and weaving and the labour of the hands, but it must be inspired with soul and be filled with understanding and equipped with the gift of keen observation; these together with accurate scientific knowledge are the indispensable requisites for proficient medical practice.*

Moses ben Maimon (1135–1204)

General practice is a traditional method of bringing primary health care to the community. It is a medical discipline in its own right, linking the vast amount of accumulated medical knowledge with the art of communication.

## Definitions

General practice can be defined as that medical discipline which provides 'community-based, continuing, comprehensive, preventive primary care', sometimes referred to as the CCCP model. It is regarded as synonymous with primary care and family practice.

The Royal Australian College of General Practitioners (RACGP) uses the following definitions of general practice and primary care:

General practice is that component of the health care system which provides initial, continuing, comprehensive and coordinated medical care for all individuals, families and communities and which integrates current biomedical, psychological and social understandings of health.

A general practitioner is a medical practitioner with recognised generalist training, experience and skills, who provides and co-ordinates comprehensive medical care for individuals, families and communities.

General/family practice is the point of first contact for the majority of people seeking health care. In the provision of primary care, much ill-defined illness is seen; the general/family practitioner often deals with problem complexes rather than with established diseases.

The RACGP has defined five domains of general practice:

- communication skills and the doctor–patient relationship
- applied professional knowledge and skills
- population health and the context of general practice

- professional and ethical role
- organisational and legal dimensions

Furthermore the RACGP has identified seven core characteristics of general practice:

- 1 whole person care
- 2 person centredness
- 3 continuity of care
- 4 comprehensiveness
- 5 diagnostic and therapeutic skills
- 6 a command of complexity and uncertainty
- 7 coordinated clinical teamwork

The American Academy of Family Physicians (AAFP) has expanded on the function of delivery of primary health care.<sup>1,2</sup>

Primary care is a form of delivery of medical care that encompasses the following functions:

- 1 It is 'first-contact' care, serving as a point-of-entry for patients into the health care system.
- 2 It includes continuity by virtue of caring for patients over a period of time, both in sickness and in health.
- 3 It is comprehensive care, drawing from all the traditional major disciplines for its functional content.
- 4 It serves a coordinative function for all the health care needs of the patient.
- 5 It assumes continuing responsibility for individual patient follow-up and community health problems.
- 6 It is a highly personalised type of care.

Pereira Gray<sup>3</sup> identifies six principles—primary care, family care, domiciliary care and continuing care, all designed to achieve preventive and personal care. 'We see the patient as a whole person and this involves breadth of knowledge about each person, not just depth of disease.'

General practice is not the summation of specialties practised at a superficial level and we must avoid the temptation to become 'specialoids'. In the

current climate, where medicine is often fragmented, there is a greater than ever need for the generalist. The patient requires a trusted focal point in the often bewildering health service jungle. Who is to do this better than the caring family doctor taking full responsibility for the welfare of the patient and intervening on his or her behalf? Specialists also need highly competent generalists to whom they can entrust ongoing care.

## Unique features of general practice

Anderson, Bridges-Webb and Chancellor<sup>4</sup> emphasise that 'the unique and important work of the general practitioner is to provide availability and continuity of care, competence in the realm of diagnosis, care of acute and chronic illness, prompt treatment of emergencies and a preventive approach to health care'.

The features that make general practice different from hospital- or specialist-based medical practices include:

- first contact
- diagnostic methodology
- early diagnosis of life-threatening and serious disease
- continuity and availability of care
- personalised care
- care of acute and chronic illness
- domiciliary care
- emergency care (prompt treatment at home or in the community)
- family care
- palliative care (at home)
- preventive care
- scope for health promotion and patient education
- holistic approach to management
- health care coordination

The GP has to be prepared for any problem that comes in the door (FIGURE 1.1).

Apart from these processes the GP has to manage very common problems including a whole variety of problems not normally taught in medical school or in postgraduate programs. Many of these problems are unusual yet common and can be regarded as the 'nitty gritty' or 'bread and butter' problems of primary health care.

In considering the level of care of symptoms, 25% of patients abandon self-care for a visit to the GP. Ninety per cent of these visits are managed entirely

within primary care. Levels of care are represented in FIGURE 1.1.<sup>5</sup>

FIGURE 1.1 Degrees of care of symptoms

## Holistic approach to management

The management of the whole person, or the holistic approach, is an important approach to patient care in general practice. Whole-person diagnosis is based on two components:

- 1 the disease-centred diagnosis
- 2 the patient-centred diagnosis

The disease-centred consultation is the traditional medical model based on the history, examination and special investigations, with the emphasis on making a diagnosis and treating the disease. The disease-centred diagnosis, which is typical of hospital-based medicine, is defined in terms of pathology and does not focus significantly on the feelings of the person suffering from the disease.

The patient-centred consultation not only takes into account the diagnosed disease and its management but also adds another dimension—that of the psychosocial hallmarks of the patient, including details about:

- the patient as a person
- emotional reactions to the illness
- the family
- the effect on relationships
- work and leisure
- lifestyle
- the environment

Taylor and colleagues, in their patient-centred model of health care, emphasise six interactive components of the patient-centred process:<sup>6</sup>

- 1 exploring both the disease and the illness experience
- 2 understanding the whole person
- 3 finding common grounds regarding management
- 4 incorporating prevention and health promotion
- 5 enhancing the doctor–patient relationship
- 6 being realistic regarding time and resources

Contemporary general practice focuses on patient-centred medicine, which, in alliance with evidence-based medicine, benefits both patient and doctor.

## Continuing care

The essence of general practice is continuity of care. The doctor–patient relationship is unique in general practice in the sense that it covers a span of time that is not restricted to a specific major illness. The continuing relationship involving many separate episodes of illness provides an opportunity for the doctor to develop considerable knowledge and understanding of the patient, the family and its stresses, and the patient's work and recreational environment.

In 2008 the World Health Organization (WHO) reaffirmed the global importance of primary health care with its landmark report *Primary Health Care Now More Than Ever*. WHO<sup>7</sup> highlighted the evidence that continuity of care through general practice contributed to the following better outcomes:

- lower all-cause morbidity
- better access to care
- fewer rehospitalisations
- fewer consultations with specialists
- less use of emergency services
- better detection of adverse effects of medication interventions

## Home visits

'You don't know your patient until you have seen them in their home.' Home visits are a goldmine of information about intra-family dynamics. They should cement the doctor–patient relationship if used appropriately. We are the only doctors who practise domiciliary care.

## Computers

Computers have simplified and streamlined the design and use of practice registers and patient-recall systems in addition to their use for accounting

purposes. Their potential for continuing care, patient education and doctor education is considerable.

## Common presenting symptoms

Common presenting symptoms in Australian practices are presented in **TABLE 1.1**,<sup>8</sup> where they are compared with those in the US.<sup>9</sup> The similarity is noticed but the different classification system does not permit an accurate comparison. In the third national survey of morbidity in general practice in Australia<sup>9</sup> the most common symptoms described by patients were cough (6.2 per 100 encounters), throat complaints (3.8 per 100), back complaints (3.6 per 100) and upper respiratory tract infection (URTI) (3.2 per 100). In addition, very common presentations included a check-up (13.7 per 100) and a request for prescription (8.2 per 100). McWhinney lists the 10 most common presenting symptoms from representative Canadian and British practices but they are divided between males and females.<sup>10</sup>

**Table 1.1** Most frequent presenting problems/symptoms (excluding pregnancy, hypertension, immunisation and routine check-up)

	Australia	United States
Cough	1	1
Throat complaint	2	2
Back pain	3	4
URTI	4	11
Rash	5	5
Abdominal pain	6	6
Depression	7	
Ear pain	8	3
Headache	9	10
Fever	10	7
Weakness/tiredness	11	
Diarrhoea	12	
Asthma	13	
Nasal congestion/sneeze	14	12
Chest pain	15	13
Knee complaint	16	8
Visual dysfunction		9

Source: Australian figures: Britt et al.<sup>8</sup>; United States figures (all specialties): De Lozier & Gagnon<sup>9</sup>

For males in the Canadian study these symptoms are (in order, starting from the most common) cough, sore throat, colds, abdominal/pelvic pain, rash, fever/chills, earache, back problems, skin inflammation and chest pain.

For females the five other symptoms that are included are menstrual disorders, depression, vaginal discharge, anxiety and headache.

In the British study the most common symptoms are virtually identical between males and females and include cough, rash, sore throat, abdominal pain, bowel symptoms, chest pain, back pain, spots, sores and ulcers, headache, muscular aches and nasal congestion.<sup>11</sup>

### Most frequent presenting symptoms in the author's practice

The most common presenting symptoms in the author's practice<sup>12</sup> were identified, with the emphasis being on pain syndromes:

- cough
- disturbance of bowel function
- pain in abdomen
- pain in back
- pain in chest
- pain in head
- pain in neck
- pain in ear
- pain in throat
- pain in joints/limbs
- rashes
- sleep problems
- tiredness/fatigue
- vaginal discomfort

These symptoms should accurately reflect Australian general practice since the rural practice would represent an appropriate cross-section of the community's morbidity, and the recording and classification of data from the one practitioner would be consistent.

### Symptoms and conditions related to litigation

Medical defence organisations have highlighted the following areas as being those most vulnerable for management mishaps:

- acute abdominal pain
- acute chest pain
- breast lumps
- children's problems, especially the sick febrile child <2 years, groin pain and lumps

- dyspnoea ± cough (? heart failure, cancer, TB)
- headache

### Common managed disorders

Excluding a general medical examination, hypertension and upper respiratory tract infection (URTI) were the two most common problems encountered in both the Australian and US<sup>13</sup> studies. The 23 most frequent individual disorders are listed in Table 1.2 and accounted for over 40% of all problems managed.<sup>8,14</sup>

**Table 1.2** Most frequently managed disorders/diagnoses (rank order) excluding prescriptions

	Australia	United States
General medical examination	1	1
Hypertension	2	3
URTI	3	2
Immunisation	4	*
Depression	5	6†
Acute bronchitis/bronchiolitis	6	13
Asthma	7	29
Back complaint	8	
Diabetes mellitus	9	8

Urinary tract infection	17	11
Female genital check-up, Pap test	18	(under 1)
Sinusitis	19	25
Occupational check-up	20	27
Oesophageal disease	21	27
Menopause complaint	22	27
Viral disease	23	–

\* not listed

† combined

Source: Australian figures: Britt et al.<sup>8</sup>; United States figures: Rosenblatt et al.<sup>13</sup>

The content of this textbook reflects what is fundamental to the nature and content of general practice—that which is common but is significant, relevant, preventable and treatable.

## Chronic disease management

A study of international target conditions<sup>15</sup> in chronic disease management has highlighted the importance of the following (as common themes):

- coronary heart disease
- chronic heart failure
- stroke
- hypertension
- diabetes mellitus type 2
- chronic obstructive pulmonary disease
- asthma
- epilepsy
- hypothyroidism
- chronic mental illness
- medication monitoring

*Whether in rich or poor countries, 'developed' or 'developing', the health of individuals is influenced by family life, and families are affected by the illnesses and misfortunes of their members.*

Ian McWhinney (1926–2012)

Working with families is the basis of family practice. Families living in relative harmony provide the basis for the good mental health of their members and also for social stability.

However, the traditional concept of the nuclear family, where the wife stays at home to care for the children, occurs in only about 15% of Australian families. Approximately 46% of Australian marriages end in separation. Families take many shapes and forms, among them single-parent households, de facto partnerships, same-sex couples and families formed by a partnership between two separated parents and their children. Psychosocial problems may occur in almost any family arrangement and family doctors need to know how to address such problems.

Family therapy is ideally undertaken by GPs, who are in a unique position as providers of continuing care and family care. It is important for them to work together with families in the counselling process and to avoid the common pitfalls of working in isolation and assuming personal responsibility for changing the family. We should understand that definitions of family vary greatly across cultures.

Bader<sup>1</sup> summarises working with families succinctly:

From the perspective of family therapy, working with families means avoiding the trap of being too directive, too responsible for the family's welfare, with the result that the family becomes overly dependent on the general practitioner for its health and development. From the perspective of family education, working with families means developing the skills of anticipating guidance, helping families to prepare, not only for the normal changes occurring as the family develops, but also for the impact of illness on the family system.

## Characteristics of healthy families

Successful families have certain characteristics, an understanding of which can give the family doctor a basis for assessing the health of the family and a goal to help set targets for change in disrupted families. Such characteristics are:

- *Healthy communication.* In this situation family members have freedom of expression for their feelings and emotions.
- *Personal autonomy.* This includes appropriate use of power sharing between spouses/partners.
- *Flexibility.* This leads to appropriate 'give and take' with adaptation to individual needs and changing circumstances.
- *Appreciation.* This involves encouragement and praise so that members develop a healthy sense of self-esteem.
- *Support networks.* Adequate support from within and without the family engenders security, resistance to stress and a healthy environment in general (see FIG. 2.1). The family doctor is part of this network.

FIGURE 2.1 Three generations of a supportive family network

- *Family time and involvement.* Studies have shown that the most satisfying hallmark of a happy family is 'doing things together'.
- *Spouse/partner bonding.* The importance of a sound marital relationship becomes obvious when family therapy is undertaken.
- *Growth.* There needs to be appropriate opportunities for growth of individual family members in an encouraging atmosphere.
- *Spiritual and religious values.* An attachment to spiritual beliefs and values is known to be associated with positive family health.

## Families in crisis

Doctors are closely involved with families who experience unexpected crises, which include illnesses, accidents, divorce, separation, unemployment, death of a family member and financial disasters.

## The effect of illness

Serious illness often precipitates crises in individual members of the family, crises that have not previously surfaced in the apparently balanced family system. It is recognised, for example, that bereavement over the unexpected loss of a child may lead to marital breakdown, separation or divorce.

In the long term, other family members may be affected more than the patient. This may apply particularly to children and manifest as school underachievement and behaviour disturbances.

During the crisis the obvious priority of the doctor is to the patient but the less obvious needs of the family should not be ignored.

## Guidelines for the doctor

- Include the family as much as possible, starting early in the acute phase of the illness. It may necessitate family conferences.
- Include the family on a continuing basis, especially if a long-term illness is anticipated. It is helpful to be alert for changes in attitudes, such as anger and resentment towards the sick member.
- Include the family in hospital discharge planning.
- If a serious change in family dynamics is observed, the use of experts may be needed.
- Offer a family conference at critical times.

## Significant presentations of family dysfunction

The following presentations may be indicators that all is not well in the family, and so the doctor needs to 'think family':

- marital or sexual difficulties
- multiple presentations of a family member—'the thick file syndrome'
- multiple presentations by multiple family members
- abnormal behaviour in a child
- the 'difficult patient'
- inappropriate behaviour in the antenatal and/or postpartum period
- drug or alcohol abuse in a family member
- evidence of physical or sexual abuse in one of the partners (male or female) or a child
- psychiatric disorders
- susceptibility to illness
- increased stress/anxiety
- complaints of chronic fatigue or insomnia

It is important that the family doctor remains alert to the diversity of presentations and takes the responsibility for identifying an underlying family-based problem.

## The patient and family dynamics

Family doctors see many patients who present with physical symptoms that have primarily an emotional or psychosocial basis with either little or no organic pathology. As many as 50–75% of patients utilising primary care clinics have a psychosocial precipitant as opposed to biomedical problems as the main cause of their visit.<sup>2</sup>

In order to understand the clinical manifestations of the sick role of patients, family doctors should first understand the individual's response to stress stimuli, which may come from external (family, work or sexual behaviour) or internal (personality trait or psychosocial) sources (see FIG. 2.2 and TABLE 2.1).

**Table 2.1** Areas of possible biopsychosocial dysfunction

Work	Family	Sex
Type of work	Present family	Sexual
Workload	(change of	dysfunction
Work	structure and	Disharmony
environment	function)	Deprivation
Goals	Extended family	Guilt
Work	(parents and	
satisfaction	relatives)	
	Growing	
	environment	
	(family tree)	

**FIGURE 2.2** Family dynamics and psychosomatic illness iceberg

## How to evaluate the family dynamics

- Carefully observe family members interacting.
- Invite the whole family to a counselling session (if possible).
- Visit the home: an impromptu home visit (with some pretext such as a concern about a blood test result) on the way home from work may be very revealing. This will be appropriate in some but not all family practice settings.
- Prepare a genogram (see [FIG. 18.1](#), [CHAPTER 18](#)): family dynamics and behaviour can be understood by drawing a family map or genogram (a diagrammatic representation of family structure and relationships).<sup>3,4</sup>

## The genogram

The genogram is a very valuable pedigree chart that usually covers three generations of a family tree.<sup>3</sup> Genograms are a useful strategy for involving family members who may have been reluctant to be involved in discussions on family matters.<sup>4</sup> An example, including the use of symbols, is shown in [FIGURE 18.1](#) (refer to [CHAPTER 18](#)).

## The family life cycle

Helpful in understanding the dynamics of the family is the concept of the family life cycle,<sup>5</sup> which identifies several clearly defined stages of development (see [TABLE 2.2](#)). Such an understanding can help the doctor form appropriate hypotheses about the problems

**Table 2.2** The family life cycle<sup>1</sup>

Stage	Tasks to be achieved
1 Leaving home	Establishing personal independence. Beginning the emotional separation from parents.
2 Getting married	Establishing an intimate relationship with spouse. Developing further the emotional separation from parents.
3 Learning to live together	Dividing the various marital roles in an equitable way. Establishing a new, more independent relationship with family.
4 Parenting the first child	Opening the family to include a new member. Dividing the parenting roles.
5 Living with the adolescent	Increasing the flexibility of the family boundaries to allow the adolescent(s) to move in and out of the family system.
6 Launching children: the empty-nest phase	Accepting the multitude of exits from and entries into the family system. Adjusting to the ending of parenting roles.
7 Retirement	Adjusting to the ending of the wage-earning roles. Developing new relationships with children, grandchildren and each other.
8 Old age	Dealing with lessening abilities and greater dependence on others. Dealing with losses of friends, family members and, eventually, each other.

patients are experiencing at a particular stage. Each stage brings its own tasks, happiness, crises and difficulties. This cycle is also well represented in [FIGURE 2.3](#), which indicates the approximate length of time on each of the stages.

## Family assessment

The assessment of families with problems can be formalised through a questionnaire that allows the collection of information in a systematic way in order to give an understanding of the functioning of the family in question.

## The questionnaire<sup>1</sup>

- 1 Family of origin
  - Could each of you tell us something about the families you grew up in?
  - Where do you come in the family?

**FIGURE 2.3** The family life cycle (approximate time in each stage).

Source: After McWhinney<sup>6</sup> and Duvall<sup>7</sup>

- Were you particularly close to anyone else in the family?
  - Were there any severe conflicts between family members?
  - Did anyone abuse you in any way?
  - Do you have much contact with any of your family now?
  - Have you tried to model (or avoid) any features for your own family?
- 2 History of the couple's relationship
- How did you two meet?
  - What attracted you to each other?
  - Why did you choose this person rather than someone else?
  - How did your families react to your choice?
  - How did the birth of your children affect your relationship?
  - When was your relationship at its best? Why?
- 3 Experience in counselling and enrichment
- Have any of you been to a marriage support program?
  - Have any of you been to any form of counselling?
  - Did you go alone or with another family member?
  - What did you like or dislike about the experience?
  - In what way was it helpful or unhelpful?
- 4 Expectations and goals
- Whose idea was it to come here?
  - What was the reaction of other family members?
  - Why did you come now?

- Was there any particular event that triggered the decision?
  - What does each of you hope to gain by coming for an assessment?
- 5 Family function<sup>1</sup>
- What is it like for each of you to live in this family? (If children are present, they should be asked first.)
  - Do you have any difficulty in talking to other members of the family? (Again, children first.)
  - Do you have any difficulty in expressing appreciation to each other? (Mention here that studies on healthy families show that both communication and appreciation rank in the top qualities.)
  - How do you show appreciation in this family?
  - How do you show affection in this family? (Again, children first.)
  - How satisfied are you with the present arrangement? Are there any changes you would like to see?
  - What ways have you used to resolve disagreements or change the way the family functions?

### Assessment based on the questionnaire

- Family members present in interview (names and ages)
- Missing members (names and ages)
- Presenting problems or reasons for family interview identified by whom? Any attempted solutions?

- Roles—structure, organisation (who is dominant and so on)
- Affect—predominant emotional tone and expressed emotions
- Communication—Who dominates? Who talks? Who listens to whom?
- Stage in the family life cycle
- Illness and sickness roles
- Coping mechanisms

## Family-based medical counselling

There are several brief counselling models to assist the family doctor in probing and counselling, using a simple infrastructure such as the BATHE model.

### The BATHE technique<sup>8</sup>

This really represents a diagnostic technique to identify sources of disharmony, which can act as a springboard for counselling.

The acronym BATHE stands for *background, affect, trouble, handling* and *empathy*, and can be summarised as follows.

#### Background

Enquire about possible areas of psychosocial problems to help elicit the context of the patient's visit.

- What is happening in your life?
- Is there anything different since before you got sick?
- How are things at home?

#### Affect

Affect is the 'feeling state' and includes anxiety, so it is wise to probe potentially sensitive areas.

- How do you feel about what is going on in your life?
- How do you feel about your home life?
- How do you feel about work/school?
- How do you feel about your (spouse/partner or daughter or...)?
- What is your mood like? Do you feel sad or happy?

#### Trouble

Enquire about how the patient's problems are troubling the patient.

- What about the situation troubles you most?
- What troubles or worries you most in your life?
- What worries you most at home?
- How stressed and upset are you about this problem?
- How do you think this problem affects you?

## Handling

- How are you handling this problem?
- Do you think that you have mishandled anything?
- Do you get support at home to help handle the problem?
- Where does your support come from?
- How do you feel that you are coping?

## Empathy

Indicate an understanding of the patient's distress and legitimise his or her feelings.

- That must be very difficult for you.
- That sounds really tough on you.

## Steps to bring about behaviour change

Fabb and Fleming have introduced the model of change, which is fundamental to initiating therapy. The five steps are:

- 1 *Dissatisfaction*. There must be dissatisfaction with the present pattern of behaviour.
- 2 *Alternative*. There must be an acceptable alternative behaviour pattern available.
- 3 *Emotional commitment*. There must be an emotional commitment to the new pattern of behaviour over the old.
- 4 *Practice with feedback*. There must be practice of the new behaviour, with feedback, to establish the new pattern as an available behaviour.
- 5 *Habituation with support*. There must be installation of the new behaviour in the normal work/living situation with support.

All of these must be present for change to occur. Steps 4 and 5 are often neglected, with the result that change does not occur or is less successful.

## Marital disharmony

Family doctors often have to provide marital counselling for one or both partners. The problems may be resolved quite simply or be so complex that marital breakdown is inevitable despite optimal opportunities for counselling.

Opportunities for prevention, including anticipatory guidance about marital problems, do exist and the wise practitioner will offer appropriate advice and counselling. Examples include an accident to a child attributable to neglect by a parent, or similar situation in which that parent may be the focus of blame, leading to resentment and tension. The practitioner could intervene from the outset to

alleviate possible feelings of guilt and anger in that marriage.

Some common causes of marital disharmony are:

- selfishness
- unrealistic expectations
- financial problems/meanness
- not listening to each other
- sickness (e.g. depression)
- drug or alcohol excess
- jealousy, especially in men
- fault finding
- 'playing games' with each other
- driving ambition
- immaturity
- poor communication

## Basic counselling of couples

The following text on basic counselling of couples,<sup>9</sup> which should be regarded as a patient education sheet, includes useful advice for couples:

The two big secrets of marital success are caring and responsibility.

## Some important facts

- Research has shown that we tend to choose partners who are similar to our parents and that we may take our childish and selfish attitudes into our marriage.
- The trouble spots listed above reflect this childishness; we often expect our partners to change and meet our needs.
- If we take proper care and responsibility, we can keep these problems to a minimum.
- Physical passion is not enough to hold a marriage together—'when it burns out, only ashes will be left'.
- While a good sexual relationship is great, most experts agree that what goes on *out* of bed counts for more.
- When we do something wrong, it is most important that we feel forgiven by our partner.

## Positive guidelines for success (summary)<sup>9</sup>

- 1 Know yourself.
- 2 Share interests and goals.
- 3 Continue courtship after marriage.
- 4 Make love, not war.

- 5 Cherish your mate.
- 6 Prepare yourself for parenthood.
- 7 Seek proper help when necessary.
- 8 Do unto your mate as you would have your mate do unto you.

The BE Attitudes (virtues to help achieve success)

<b>BE</b> honest	<b>BE</b> loyal
<b>BE</b> loving	<b>BE</b> desiring
<b>BE</b> patient	<b>BE</b> fun to live with
<b>BE</b> forgiving	<b>BE</b> one
<b>BE</b> generous	<b>BE</b> caring

## Making lists—a practical task

Make lists for each other to compare and discuss.

- List qualities (desirable and undesirable) of your parents.
- List qualities of each other.
- List examples of behaviour each would like the other to change.
- List things you would like the other to do for you.

Put aside special quiet times each week to share these things.

## Pitfalls<sup>1</sup>

The GP who is too closely attached to one or more members of the family can easily become trapped in the role of the 'rescuer' or 'saviour' of those members. The best defence against this trap is to respect the family's autonomy and work with the family to achieve the goals the family sets for itself, thus avoiding three major pitfalls for the GP in treating families:

- 1 assuming personal responsibility for changing the family
- 2 working alone, neglecting the assistance of the family
- 3 becoming a 'rescuer' or 'saviour'

## Other pitfalls

- Conducting therapy in the absence of a significant family member
- Breaching confidentiality of individuals within the family
- Failing to recognise the 'ganging-up effect'
- Taking sides
- Failing to use available resources
- Overrelating to your own experiences

## Possible solutions to avoid pitfalls<sup>1</sup>

- Let the patients do the work.
- Share the burden with a colleague or other resources.
- Ensure that the goals for therapy are realistic.
- Point out that all family members have to work together and that therapy works best when there is openness on all sides.
- Identify any tendency to look for scapegoats within the family.
- Look out for vulnerable family members—the ‘hidden patient.’
- Avoid trying to achieve quick solutions.
- Obtain clear-cut agreements on confidential matters and record this in the history.
- Keep an open mind and avoid forcing your own values on to the family.

*The essential unit of medical practice is the occasion when in the intimacy of the consulting room the person who is ill or believes himself (or herself) to be ill, seeks the advice of a doctor whom he (she) trusts. This is the consultation and all else in the practice of medicine derives from it.*

Sir James Spence 1960

The objectives of the consultation are to:

- determine the exact reason for the presentation
- achieve a good therapeutic outcome for the patient
- develop a strong doctor–patient relationship

### The skills of general practice

A successful outcome to the medical consultation depends on a whole array of skills required by the GP. Although interrelated, these skills, which can be collectively termed ‘consulting skills’, include clinical skills, diagnostic skills, management skills, communication skills, educative skills, therapeutic skills, manual skills and counselling skills.

Communication skills, which are fundamental to consulting skills, are the key to the effectiveness of the doctor as a professional, and expertise with these skills is fundamental to the doctor–patient relationship. Communication skills are essential in obtaining a good history and constitute one of the cornerstones of therapy (see CHAPTER 4).

A skilled interviewer will succeed in transmitting his or her findings to the patient so that they are clearly understood, are not unduly disturbing, and inspire trust and confidence in the physician.

### Models of the consultation

Several models that formalise the general practice consultation can be very useful for developing an understanding of the process of the consultation. Two classic models are those by Pendleton and colleagues,<sup>1</sup> and by Stott and Davis.<sup>2</sup> Pendleton and colleagues, in their landmark book *The Consultation: An Approach to Learning and Teaching*,<sup>1</sup> defined seven key tasks to the consultation, which serve as helpful guidelines:

- 1 To define the reason for the patient’s attendance, including:

- the nature and history of problems
  - their aetiology
  - the patient’s ideas, concerns and expectations
  - the effect of the problems
- 2 To consider other issues:
    - continuing problems
    - risk factors
  - 3 To choose, with the patient, an appropriate action for each problem
  - 4 To achieve a shared understanding of the problems with the patient
  - 5 To involve the patient in the management and encourage him or her to accept appropriate responsibility
  - 6 To use time and resources efficiently and appropriately:
    - in the consultation
    - in the long term
  - 7 To establish or maintain a relationship with the patient that helps to achieve the other tasks

The exceptional potential in each primary care consultation described by Stott and Davis,<sup>2</sup> which is presented in TABLE 3.1, also acts as an excellent aide-memoire to achieve maximal benefit from the consultation.

**Table 3.1** The potential in each primary care consultation

A	B
Management of presenting problems	Modification of health-seeking behaviour
C	D
Management of continuing problems	Opportunistic health promotion

Source: Stott & Davis<sup>2</sup>

## Phases of the consultation

The consultation can be considered in three phases, as follows:

- 1 Establishment of rapport
- 2 Diagnostic phase
  - the history
  - the physical and mental examination
  - investigations
- 3 Management phase
  - explanation and education
  - prescribing medication
  - procedural—therapeutic or extended diagnostic
  - referral
  - follow-up

### Practice tip

Remembering the patient's preferred name and their basic past history is powerful rapport.

**FIGURE 3.1** The consultation: establishment of good rapport is the foundation to successful consulting skills

## The history

The doctor has four basic tasks to perform during the history-taking phase of the consultation. These are to determine:

- 1 the patient's stated reason for attending
- 2 why the patient is attending today, or at this particular time in the course of this illness
- 3 a list of problems or supplementary symptoms
- 4 any other initially unspoken or hidden reason for attending (e.g. the fear of cancer)

The old medical cliché that 'a good history is the basis of the clinical examination' is as relevant as always. The art of history taking, which is based on good communication, is the most fundamental skill in general practice and requires a disciplined approach.

A very good approach is that used by Professor Rita Charon of Columbia University: 'I'm going to be your doctor, so I need to know a great deal about your body, health and life. Please tell me what you think I should know about yourself and your situation.'

Guidelines include:<sup>3</sup>

- Commence by eliciting the presenting complaint.
- Permit an uninterrupted history.
- Use appropriate language—keep the questions simple.
- Use specific questions to clarify the presenting complaint.
- Write notes or use the keyboard to record information but maintain as much eye contact as possible.
- Enquire about general symptoms, such as fatigue, weight changes, fever, headache, sleep and coping ability (see **TABLE 3.2**). These are important since they uncover 'red flags' for serious, life-threatening disorders.

**Table 3.2** Important general questions

Fatigue, tiredness or malaise  
Fever, sweating, shakes  
Weight change, especially loss  
Pain or discomfort anywhere  
Any unusual lumps or bumps  
Any unusual bleeding  
Skin problems—rash or itching

- Undertake a relevant systems review.
- A historical checklist includes past medical history, complete medication history, drug habits and sensitivities, family history, psychosocial history and preventive care history.
- Give feedback to the patient about your understanding of the problems and agenda, and correct any misconceptions.

## Good questions

In order to determine any underlying agenda or significant psychosocial problems, it is very helpful to use analytical questions. Such questions and inviting statements could include:

- Why have you come to see me today?
- Do you have any particular concern about your health?

- That really interests me—tell me more—it seems important.
- Where would you put your real feelings between 0 and 100%?
- What is it that's really upsetting or bothering you?
- What do you really think deep down is the cause of your problem?
- Are you basically satisfied with your life?
- Is there anything that I haven't asked you and that you should tell me about?
- Tell me about things at home.
- Tell me about things at work.
- Do you experience any bullying?
- Are you afraid that something bad is going to happen to you?
- Is your relationship with any particular loved one/person causing you stress? (This may lead to information about sensitive issues such as domestic violence or sexual problems.)
- Is there anything in your life that you would like to change?
- I'm concerned about what you are not telling me.

### Basic interviewing techniques

A number of basic interviewing techniques<sup>4</sup> encourage communication. It is important to use the least controlling interview techniques before embarking on direct questioning.

#### Questions

When the patient is asked a question, the doctor tends to take control of the interview, and so directs it along the lines of his or her own thinking or hypothesis generation. The problem is that if questions are used too early in the interview, the amount of desirable information is restricted and may disrupt the true priorities of the patient's concerns.

Open-ended questions and direct questions are very useful at appropriate times, while other questions are very restrictive. Examples, using pain as the 'problem', are:

- Open-ended question: 'Tell me about the pain.'
- Direct question: 'Where is the pain?'
- Closed question: 'Is the pain severe?'
- Leading question: 'The pain is severe?'
- Reflective question: 'You want to know the cause of the pain?'

### The open-ended question

The open-ended question is essential in initiating the interview. A question such as 'What kind of troubles have you been having?' says to the patient

'I'm interested in anything you may feel is important enough for you to tell me'.

The open-ended question gives the patient an opportunity to take temporary control of the consultation and to outline problems and concerns.

Ongoing interview strategies of listening and silence, facilitation and summarisation are outlined in **CHAPTER 4**, (section on Communication in the consultation).

### Information from other sources

Sometimes it is important to obtain information from other sources, especially friends or relatives. Off-handed comments from others may be loaded with 'cues' and one should be listening intently.

### Problem definition

Part of the diagnostic process is defining the patient's problem or problems. The more complex the presentation, the more necessary it is to have an orderly approach. It is clearly important to list the problems in a priority order. These problems may have been 'offered' by the patient, 'observed' by the doctor, 'derived' during the interview or 'known' from the past history. Problems can be conveniently considered as organic or physiological, and intrapersonal or social.<sup>5</sup>

### Touching the patient

Sometimes a natural response is to touch the distressed patient as a reassuring gesture. It is best to adopt a caring-and-support gesture, such as offering tissues to the weeping patient, but it may be quite acceptable for most patients to give a reassuring, momentary touch somewhere between the shoulder and wrist on the arm nearest to you. Touching should be a natural gesture that is comfortable for both the doctor and patient. Touch elsewhere should generally be avoided.

### The physical and mental examination

If a diagnostic hypothesis based on the history is being tested, the examination may be confined to one system or to one anatomical region. However, other regions, systems or a general examination may be undertaken for medicolegal or preventive reasons. Patients tend to feel vulnerable during the physical examination, so their sensitivity and modesty have to be respected. Generally, the examination is conducted in relative silence, with the doctor instructing the patient what to do.

Patients need to be warned of possible discomfort or pain that may accompany certain examinations, of the reason for the examination, and of its immediate

results, particularly if normal. Continued silence on the doctor's part is often interpreted by patients as being indicative of something serious or unusual being found. For the same reason the doctor's non-verbal behaviour is important.

## Medicolegal guidelines for examinations<sup>6,7</sup>

The following guidelines have been recommended by the NSW Medical Board for consultations and physical examinations:

- Carefully explain the nature and purpose of the physical examination before you start. Take particular care with explanations before rectal, vaginal, breast and genital examination.
- Indicate when an examination may be uncomfortable and ask the patient to advise if you are causing pain.
- If a patient is required to disrobe, explain to what extent undressing is required and why.
- A patient's modesty should be preserved when undressing and dressing before and after a physical examination. Privacy screens, sheets and gowns should be provided as a matter of course. Clinic staff should not interrupt physical examinations.
- If the patient requests the presence of a chaperone or a friend, this should be respected.
- Do not lock the door of the consultation room. The setting should allow the patient confidence to terminate the consultation at any time if he or she is uncomfortable.

## Investigations

It is often necessary to arrange for special tests to assist in the diagnostic process or to monitor the progress of certain illnesses or response to treatment. The informed consent of patients must be obtained. A collaborative decision for or against certain tests may be negotiated.

GPs have a responsibility (clinical and economic) to be very discerning and selective in the investigations that they choose. The questions that should be asked in decision making include:

- Is this investigation necessary?
- Will it change my management?

Richard Asher (1954) listed the questions a clinician should ask before requesting an investigation:<sup>8</sup>

- Why am I ordering this test?
- What am I going to look for in the result?

- If I find it, will it affect my diagnosis?
- How will this affect my management of the case?
- Will this ultimately benefit the patient?

In general, investigations should be performed only when the following criteria are satisfied:<sup>8</sup>

- The consequence of the result of the investigation could not be obtained by a cheaper, less intrusive method (e.g. taking a better history or using time).
- The risks of the investigation should relate to the value of the information likely to be gained.
- The result will directly assist in the diagnosis or have an effect on subsequent management.

### The three strikes and you're out rule

A very useful rule is to bail out of the diagnosis and refer to a colleague if you have failed to make a diagnosis after three consultations.

## Management phase of the consultation

The management phase of the consultation may immediately follow the information-gathering interview, or it may take place on review, after diagnostic tests or referral. It should be remembered that there are at least two people concerned in management: the doctor *and* the patient. Poor patient compliance with any proposed therapy can be a result of a poorly conducted management phase. It is necessary not only for the doctor to make statements concerning therapy and the reasons for the chosen therapy, but also for the information to be conveyed in a language appropriate to each patient's understanding.

Management includes immediate care, prevention and long-term care. Doctors generally tend to be authoritarian in their management proposals. Whole-person management, however, implies that the patient's views are listened to, explanations are offered where necessary by the doctor, and an educative approach is adopted to encourage the patient to actively participate in management and preventive behaviour, where possible.

The objectives of the management phase of the consultation are summarised in **TABLE 3.3**.

## The sequence of the management interview

The following, which represents an excellent teaching strategy, is a suggested *10-point plan* or sequence for conducting a management interview. These guidelines

**Table 3.3** Objectives of the management phase of the consultation

To make use of the doctor–patient relationship in therapy  
 To involve the patient as far as possible in the management of his or her own problem  
 To educate the patient about the illness  
 To promote rational prescribing  
 To achieve compliance in therapy  
 To emphasise preventive opportunities  
 To provide appropriate reassurance  
 To encourage continuity of ongoing care

will not always need to be applied in their entirety, and may need to be staged over a number of consultations. The use of this sequence should ensure identification of all the patient's problems by the doctor (including fears, feelings and expectations), adequate patient understanding of his or her problems, an acceptable and appropriate treatment plan being defined for each problem, preventive opportunities being addressed, and the patient being satisfied with the consultation and being clear about follow-up arrangements.

The sequence is as follows.

### 1 Tell the patient the diagnosis

If a diagnosis is not possible, describe the problem as it relates to the presenting symptoms.

### 2 Establish the patient's knowledge of the diagnosis

This information provides a clear-cut baseline of information from which to launch the management phase of the consultation.

### 3 Establish the patient's attitude to the diagnosis and management

Unless this is done the doctor may already have begun to enter a conflicting relationship with the patient without knowing why and be unaware of underlying fears.

### 4 Educate the patient about diagnosis

- Correct any incorrect health beliefs recognised in point 2.
- Supplement the patient's existing knowledge to a level appropriate to the needs of the patient and the doctor.

Such illness education will be facilitated by the use of appropriate language, special charts and diagrams, models, investigation reports and other relevant aids (e.g. X-rays and ECGs).

## 5 Develop a management plan for the presenting problem

Develop precise instructions using three headings:

- *Immediate*: always included, even if no action is proposed
- *Long term*: for chronic, long-term or recurrent illnesses
- *Preventive*: sometimes specific measures apply—often patient education is the method required

The patient should be encouraged at this stage to participate in decision making regarding management and to make a commitment to the plans.

## 6 Explore other preventive opportunities

Common examples of preventive opportunities include immunisation, screening status (e.g. Pap test) and advice about smoking and alcohol problems and safe sex.

## 7 Reinforce the information

Emphasise information already given about the diagnosis and management by the use of other techniques, for example:

- Use the patient's own results (e.g. X-rays and ECGs).
- Encourage the patient to participate in the decision making and in accepting some degree of responsibility for his or her own management.

## 8 Provide take-away information

Examples of this important strategy include patient instruction leaflets and resource contacts.

## 9 Evaluate the consultation

When time permits, the doctor should encourage feedback regarding the patient's reaction to the way the consultation has been conducted, and establish whether the objectives of both have been met and the patient is satisfied with the outcome.

## 10 Arrange follow-up

Clear instructions for review need to be made, preferably by providing appointments or stating that no further review is needed. Follow-up not only shows patient response to management, but also enables the reinforcement and clarification of preventive measures and information given. It also allows involvement of others, particularly family members where appropriate.

## Closing the session

Good closure is an important strategy; ask 'Has this visit helped you and your problems—is there anything more I can do?'

## A patient management strategy

Brian McAvoy, writing in Fraser's excellent book *Clinical Method: A General Practice Approach*, presents a helpful aide-mémoire in the approach to patient management:<sup>8</sup>

- 1 reassurance and/or explanation
- 2 advice
- 3 prescription
- 4 referral
- 5 investigation
- 6 observation (follow-up)
- 7 prevention

## Prescriptions

It is worth emphasising that prescribing medicine is a relatively complex skill that requires considerable knowledge of the disease, patient's expectations, the drugs prescribed, their interactions and their adverse reactions. Part of this skill is making a decision not to prescribe medication when it is not absolutely necessary and then explaining the reasons and including non-pharmacological measures. This decision may be made in the context of a patient expecting a biochemical solution for his or her problem. As McAvoy points out, 'If in doubt whether or not to give a drug—don't'.<sup>8</sup>

## Referral

The decision to refer a patient is also another important skill. It is often difficult to find the right balance. Some practitioners refer excessively—others cling to their patients inappropriately. It is a mistake not to refer a patient with a serious chronic or life threatening disease. Apart from consultants and hospitals, referral should be considered to GP colleagues or partners with special interests or expertise, support groups and other members of the primary health care team, such as physiotherapists, dietitians, chiropodists and social workers. At all times the GP should act as the focal reference point and maintain control of patient management.

## The 'gatekeeper' role of the GP

A patient's GP is the obvious and ideal linchpin in the health care system to take responsibility for the patient's health concerns and management. The patient may become confused with the system, especially if his or her problems are many and

complex. The patient's GP has a vital role in acting as a 'gatekeeper' between primary and secondary care, and between paramedical services. The GP should always act in the patient's best interests and intervene, if necessary, to ensure that the patient is getting the best possible care.

## The healing art of the doctor

The counselling process in general practice is based on the therapeutic effect of the doctor. This well-recorded feature is reinforced if the doctor has a certain professional charisma, and is caring and competent. We cannot underestimate the dependency of our patients on this healing factor, especially where significant psychic factors are involved.

### Key points on patient management

- It is difficult, perhaps impossible, to reassure patients in the absence of an appropriate physical examination and certain investigations.
- Reassurance must always be appropriate and therefore based on a substantial foundation: inappropriate reassurance damages the credibility of both the doctor and his or her profession.
- The two key characteristics of the doctor in establishing the basis of a successful outcome for the doctor-patient relationship are caring and responsibility.
- Vital factors included in this relationship are good communication, genuine interest and trust.

*Most people have a furious itch to talk about themselves and are restrained only by the disinclination of others to listen. Reserve is an artificial quality that is developed in most of us as a result of innumerable rebuffs. The doctor is discreet. It is his business to listen and no details are too intimate for his ears.*

Hippocrates wrote:

In the art of medicine there are three factors—the disease, the patient and the doctor . . . It is not easy for the ordinary people to understand why they are ill or why they get better or worse, but if it is explained by someone else, it can seem quite a simple matter—if the doctor fails to make himself understood he may miss the truth of the illness.<sup>1</sup>

Francis Macnab, Doctor of Divinity and patient, wrote: ‘The style of the doctor, the communication of the doctor and the person of the doctor at the level of primary contact and primary care can be crucial in a person’s life.’<sup>2</sup>

Much of the art of general practice lies in the ability to communicate.

Research continues to focus the ‘blame’ for communication breakdown on the doctor, ignoring the role of the patient.<sup>3</sup>

## Communication

Communication can be defined as ‘the successful passing of a message from one person to another’.

There are five basic **elements** in the communication process:

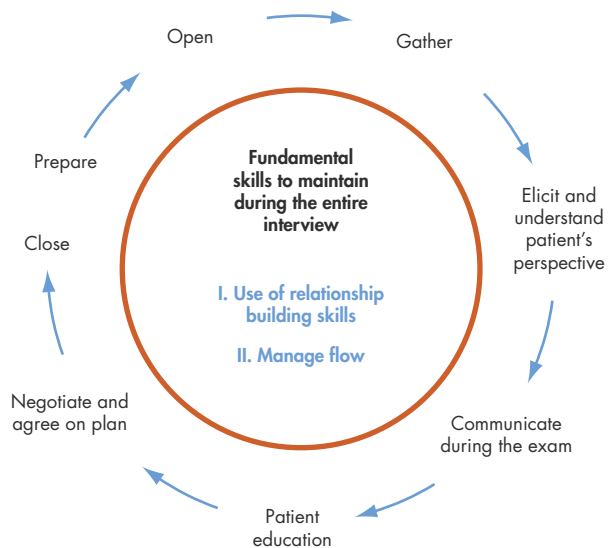

- the communicator
- the message
- the method of communicating
- the recipient
- the response

Important **principles** facilitating the communication process are:

- the rapport between the people involved
- the time factor, facilitated by devoting more time
- the message, which needs to be clear, correct, concise, unambiguous and in context
- the attitudes of both the communicator and the recipient

W Somerset Maugham (1874–1965), *Summing Up*

These elements and principles can be seen emerging in various phases through the consultation, as illustrated in **FIGURE 4.1**.

**FIGURE 4.1** The sequence of communication in the consultation

Source: Courtesy of the New York University Macy Initiative on Health Communication

## Communication in the consultation<sup>3,4</sup>

Communication in the consultation can be considered in the following sequence:

The doctor requires appropriate communication skills for complete diagnosis (physical, emotional and social) and competent management. It is important to be aware of the patient’s cultural background and educational level and allow for these factors. The majority of interaction between doctor and patient occurs in the traditional consultation.

## Prepare

The 'prepare' phase includes preparation done both well before the consultation and then just prior to the consultation. Well before consulting, the doctor should think about and prepare the physical environment. Comfort and privacy should be maximised, and distractions and interruptions minimised. The patient should be physically positioned to feel empowered (e.g. avoid talking across a desk or talking down to a patient on a bed).

As well as reviewing the environment, doctors should review themselves. They should do some self-reflection to consider what personal qualities, assumptions and values they have that may influence a consultation.

What kind of doctor and person are you? How do your age, gender, sexuality, social class, ethnicity and cultural background influence how you present yourself to and relate with others? Do you have certain attitudes (e.g. to complementary and alternative medicine), beliefs (e.g. on termination of pregnancy) and biases (e.g. intolerance of drug seekers) that others may or may not have? How do you dress? Do you have any eccentricities? How familiar or formal are you? What is your style? How do you think people perceive you?

Just prior to the consultation, a review of the patient's health record will improve the doctor's awareness of important facts about the patient. Opening the file is actually when the consultation starts. Here, crucial clues can be found, such as:

- what happened at the last consultation
- what are the important medical issues for this patient
- any recent test results or correspondence that have arrived
- even the names of partners, parents or children who may come into the room with the patient
- brief notes on personal characteristics, likes/dislikes (e.g. has needle phobia)

When a record is examined well, the reasons for the consultation can often be anticipated prior to the formal start of the consultation, giving the doctor a wonderful opportunity to improve communication.

Also prior to the consultation, increasingly in general practice we see patients as part of a team. The patient may previously have been seen by a practice nurse or a more junior doctor or medical student. This 'teamlet model of primary care'<sup>5,6</sup> has been shown to help elucidate patients' concerns, as have 'patient agenda forms', which patients fill out prior to

the consultation, prompting them to list what is on their agenda for the consultation.<sup>6,7</sup>

At first contact, we usually call a patient from the waiting room into the consulting room. Having your eyes and ears ready and focused here can give you invaluable information. What is the person wearing? What does his or her body language suggest? Who is accompanying the patient and how are they interacting with each other? Clues about their interests (e.g. a child's T-shirt reflecting a favourite TV character), their cultural and social backgrounds (e.g. dress and appearance) and even their medical issues at hand (e.g. a limp, a bandage or carrying an X-ray folder or hospital letter) abound in this 'pre-opener space'. Picking up on these clues early helps the doctor anticipate and reflect on issues before they emerge in the consultation, avoids communication breakdown, makes the patient feel that the doctor is interested in him or her and can make the doctor appear switched on and observant.

## Open

When we get to the 'opener' (e.g. 'What can I do for you today?' or 'How are you today?') and beyond, we should:<sup>8</sup>

- greet and address the patient by his or her preferred name (and anyone else entering the room)
- try to make the patient feel comfortable
- try to appear 'unhurried' and relaxed
- focus firmly on the patient
- use open-ended questions where possible
- make appropriate reassuring gestures

## Gather

It is in the early stages of the consultation that silence (on the doctor's part) can be golden. In what is termed *active listening*, we listen to more than the words—we are also alert to the messages buried in the words. We listen to the tone and rhythm and we look for the context of what we are hearing. We listen with understanding, in a relaxed, attentive silence. Note-taking, whether written or typed, should not become a barrier to appearing to listen; as it is done, it can be verbalised by the doctor, so the patient knows he or she is being heard. The computer should not be allowed to be the intrusive third person in the room.

Allowing the patient to talk (without interruption), and even leaving a slightly prolonged pause, often provides enough space for the patient's concerns to emerge. This is especially the case with psychosocial issues.<sup>9</sup>

This ability to elicit patient concerns is unfortunately not one that doctors have always done well. Stewart<sup>10</sup> summarises the evidence in this area:

50% of psychosocial and psychiatric problems are missed, physicians interrupt patients an average of 18 seconds into the patient's description of the presenting problem . . . 54% of patient problems and 45% of patient concerns are neither elicited by the physician nor disclosed by the patient . . . patients and physicians do not agree on the main presenting problem in 50% of visits and . . . patients are dissatisfied with the information provided to them by physicians.

This evidence is of course in relation to doctors as a whole and not just general practitioners, but it does illustrate how important and at times difficult effective communication in medical consultations can be.

Three techniques that have been demonstrated<sup>8,11</sup> to improve how we elicit patient concerns are:

- facilitation
- the open-to-closed cone
- summarisation

Facilitation refers to comments or behaviours by the doctor that encourage the patient to keep talking. This could include a head-nod, a 'hmm' at the right time, or 'Tell me more about that'. The open-to-closed cone is a gradual narrowing of focus from an indirect non-directive exploration to a more direct exploration. It is often difficult to resist the urge to 'dive in' and explore the initial concern raised and narrow the cone too quickly.<sup>6,12</sup>

After each problem or concern is elicited, the doctor should continue to explore to ensure there are not any more. What are the patient's concerns (e.g. headache, depressed mood) and needs (e.g. a prescription, a referral or a form to be filled out)?<sup>9</sup> The doctor does not take too much control of the conversation, does not direct the topic away from the patient's concerns and hence helps to demonstrate empathy as well as a real interest in the patient. Using a patient-centred approach leads to improved patient trust and satisfaction, more appropriate prescribing and more efficient practice.<sup>6</sup>

Summarisation is when the doctor provides the patient with an explicit verbal summary of the information gathered thus far in the consultation.<sup>11</sup> This helps to orientate the patient, acknowledging to him or her that the doctor has taken on board what they have said, and reflecting back to the patient the doctor's understanding of it.

If we initially 'limit ourselves to triage questions' and wait until 'all the cards are on the table',<sup>9</sup> it reduces the chance of patient concerns being missed. The value of a question like 'Is there anything else today?', and repeatedly making such an enquiry until we receive a 'no' in response, will help ensure we have obtained a complete understanding of the patient's agenda.<sup>9</sup>

Non-verbal communication

Non-verbal communication or body language is a vital feature of the communication process. Human communication takes place through the use of gestures, postures, position and distances (non-verbal communication or *body language*) more than by any other method. Non-verbal cues comprise the majority of the impact of any communicated message (see TABLE 4.1).<sup>13</sup>

Table 4.1 Impact of the message

Cue	%
Words alone	7
Tone of voice	38
Non-verbal communication	55

Recognition of non-verbal cues in our communication is important, especially in a doctor-patient relationship. The ability to identify non-verbal cues improves communication, rapport and understanding of the patient's fears and concerns. Recognising body language can allow doctors to modify their behaviour, thus promoting optimum communication.

Interpreting body language

The interpretation of body language, which differs between cultures, is a special study in its own right, but there are certain cues and gestures that can be readily understood. Examples illustrated include: the depressed patient (see FIG. 4.2); barrier-type signals, often used as a defensive mechanism to provide comfort or indicate a negative attitude (see FIG. 4.3); and a readiness gesture, indicating a desire to terminate the communication (see FIG. 4.4).

Having noted the non-verbal communication, the doctor must then deal with it. This may require confrontation—that is, diplomatically bringing these cues to the patient's attention and exploring the associated feeling further.

**FIGURE 4.2** Posture of a depressed person: head down, slumped, inanimate; position of desk and people correct

**FIGURE 4.3** Body language barrier signals: (A) arms folded, (B) legs crossed, (C) 'ankle lock' pose

**FIGURE 4.4** Body language: 'readiness to go' gestures

## The patient's perspective

*The treatment of disease must be completely impersonal; the treatment of a patient must be completely personal.*

Dr Francis Weld Peabody, Harvard, 1926

To be truly patient-centred, it is not enough merely to find out the patient's concerns and needs—we also need to explore his or her ideas, beliefs and expectations.<sup>8</sup> What is the patient's *perspective* on his

or her concerns and needs? What does the patient expect of you and from the consultation? What are the priorities?

To best meet this challenge, doctors should be vigilant for verbal and non-verbal cues that suggest frustrations, fears and anxieties.<sup>3</sup> A shuffle in a chair or a stiffening in posture may give a clue as to the emotional context a patient places on a particular issue. The issue is therefore not only whether we have listened, but whether we have understood.<sup>9</sup>

The patient's feelings and perspectives can also be further elicited by reflective statements. Examples of these include:

- you seem very sad today
- you seem upset about your husband
- it seems you're having trouble coping
- you seem to be telling me that . . .
- your main concern seems to me to be . . .

Discovering the patient's beliefs about illness will allow us to make statements to them that are congruent with those beliefs. This is especially important in mental health, where illness beliefs are often emotionally laden and unpredictable.

Understanding the patient's perspective also needs to be considered in a cultural context. Culture can have many dimensions, including ethnicity, age, gender, sexuality, community and religious beliefs. Being *culturally competent* by showing an interest in, respect for and sensitivity to that culture will help us achieve a shared understanding of where the patient is coming from and how he or she is seeing things.<sup>8</sup>

## Communicating during the physical examination or procedure

In the same way that we obtain consent for surgical procedures, we should also fully inform the patient of what we plan to do and obtain consent in any physical interaction with the patient. Physical examination can be very confrontational for some patients and this can be underestimated by the doctor. There may be factors of which the doctor is unaware that may make examination particularly difficult for the patient, such as unpleasant previous experiences, cultural, gender or sexual issues surrounding touch, or phobias about medical procedures or needles.

As well as preparing the patient, explaining during the examination or procedure what is happening and what we are observing and finding will help the patient feel valued and respected. We should also continue to keep an ear out for any further patient concerns being raised.<sup>3</sup>

## Patient education

If we are fully eliciting the patient's concerns and needs and are consulting using a patient-centred approach, a point is reached in the consultation where the information flow will need to go in the opposite direction—from doctor back to patient (in fact, in most consultations this flow often moves repeatedly back and forth). How we deliver this information is critical to patient communication.

When we are communicating information to a patient, it will be best understood and accepted when the information is congruent with the patient's beliefs. If these beliefs are helpful, we should recognise them and reinforce them. For instance, 'I agree with you; I think stress might be contributing to your pain here.'

Four techniques that will help maximise patient understanding are:

- signposting
- 'chunk and check'
- avoiding jargon
- using visual and physical techniques to communicate<sup>8</sup>

Signposting is a technique whereby the doctor explicitly states what he or she has done and/or is about to do (e.g. 'Andrew, I have finished examining you, now I would like to explain what I think the issues are' or 'Mrs Jones, I have two matters I would like to discuss: first . . .'). Signposting helps orientate the patient, which further helps him or her to relax and focus better on what you are saying.

Chunk and check is where the doctor provides a chunk of information to the patient and then immediately checks the patient's understanding of what has been said. Chunk and check works best when the chunks are small, as this information is often new to the patient and best digested in small grabs. It is frequently surprising to find how far away the patient's understanding is from what we intended to communicate, so this technique informs the doctor of any misunderstanding and hence provides an early opportunity to correct this.

Jargon is a barrier to communication in many professions (think accountants or IT technicians) and medicine is rife with jargon. However, jargon is not a dirty word. The way we are educated and the way doctors and other health professionals continue to communicate with each other is expedited by using jargon—it makes our communication more efficient by having a technical language to use.

On the other hand, when dealing with patients, using jargon not only impairs the patient's understanding, but can also be alienating and intimidating. What actually constitutes jargon is also often underestimated. While a doctor will usually realise that 'acute myocardial infarction' or 'cholecystectomy' are jargon, more subtle forms of jargon could include words such as 'complication', 'rare' or 'tumour'. A patient's understanding of such words may be very different from the doctor's, so checking this understanding will help protect against this. What is jargon will also vary from patient to patient. Factors such as age, education, language skills and cultural background can affect which forms of language and words are beyond the patient's understanding. The patient needs to have the cognitive and communicative capacity to understand the message.<sup>14</sup>

Visual and physical methods of conveying information given (or plans made) can include diagrams, models, patient hand-outs or information sheets.<sup>8</sup> Having ready access to electronic visual materials or websites on a desktop computer can also help. Videos on websites such as YouTube can be used to illustrate how the body functions, how a disease manifests, or a particular medical procedure, and directing patients to reputable and reliable information sources on the web or elsewhere (before they find unreliable information themselves) will help avoid misinformation and extend the communication beyond the consultation.

## Negotiate and agree on a plan

Looking beyond patient-centred communication, we can then think about planning: what do we intend to do, how we are going to decide this, who is going to do it? The preferred technique for this is *shared* or *collaborative decision making*.<sup>14,15</sup> The aim should be to have such collaboration at all stages of the consultation. But because patients can often feel intimidated, it is a challenge for the doctor to make the patient feel comfortable enough to do so.<sup>16</sup>

To enable this collaboration, the doctor and patient should treat each other's concerns with respect; this will lead to a shared responsibility for agenda setting.<sup>9</sup> Such collaboration, when done well, can lead to a coming-together of thinking that has been called a *shared mind*.<sup>14</sup> Strategies that will help achieve this include finding common ground, reaching consensus on a treatment plan and establishing a mutually acceptable follow-up plan.<sup>13</sup> 'This is what I would suggest, what do you think?' As a way of

thinking, a shared mind involves a doctor being mindful of the patient's values, thoughts and feelings (as well as those of his or her own), and seeing where the two connect.<sup>17</sup>

This mindfulness of each other's position can help the negotiation of what happens in the consultation and also avoid communication breakdowns. For instance, what shall we deal with today, and what should be delayed or rolled over to another consultation?<sup>9</sup> It can also help repair a communication breakdown. For example, if a patient is heading off at a tangent, if we are mindful of where he or she is coming from and what is important to that person, it will enable us to gently bring him or her back to the topic we feel is more pressing.

One technique that uses this principle is called an *empathic bridge*.<sup>9</sup> This is where we anchor the conversation in the patient's experience by reflecting or paraphrasing. From this anchor, we then manoeuvre the conversation back to where it needs to be (e.g. 'It sounds like your pumpkin soup recipe is something special. It is a pity you managed to cut your finger while making it today. Now let's have a look at that cut').

Another aspect of the doctor-patient relationship that enhances collaborative decision making, particularly in general practice, is *shared experiences*.<sup>18</sup> GP-patient relationships evolve over time, and a shared experience such as helping a patient through a difficult pregnancy, a major illness or even doing a home visit can enrich the relationship, deepen the connection and trust between doctor and patient, and lead to greater collaborative decision making.

## Close

How should we close a consultation? If we follow the principles of patient-centred communication and remember that we should keep our focus on the patient's concerns and needs, it soon becomes apparent.

First, is the patient aware of the imminent closure? Anxious and distressed patients may have no idea how long they have been ruminating about their concerns through the consultation, and be unaware that the waiting room full of people is actually starting to concern you. In such situations, letting them know in advance that closure is being planned (and why) will allow them to not feel pushed out of the room.

Secondly, making sure that there are no further disclosures of concerns or needs to come (yet again) will reduce the risk of what has been termed the

'doorknob presentation'—the raising of a patient concern that happens as the doctor puts his or her hand on the doorknob to leave the room (this has also been called the 'Oh, by the way doctor' syndrome in the USA, the 'à propos, docteur' in France, and 'tussen haakjes' in Denmark, which translates to 'between two brackets' or, as we may say, 'parenthetically').<sup>9</sup>

Thirdly, summarising the critical points of the consultation and planned actions and expectations will provide a final opportunity to identify gaps between what the doctor and patient are respectively thinking. We should also prepare a safety net by considering any possible unexpected outcomes to what is being planned (e.g. what a parent should watch out for and what to do if things worsen with the febrile infant patient).

Finally, we should thank and say farewell to the patient with an appropriate parting statement. Does this include a handshake? This may be determined by your style, the patient's style and cultural issues.

## Use of relationship-building skills

During the consultation and throughout a doctor-patient relationship over many consultations (and potentially, in general practice, over decades), effective communication is underpinned by using skills that develop the interpersonal relationship between doctor and patient.<sup>3,8</sup>

These skills include the doctor paying attention to non-verbal behaviour on display, as mentioned above, such as appropriate eye contact, posture, position and movement. Verbal cues such as the speed of speech, volume and tone can also be used. If using a computer or taking written notes, the doctor should do so in a fashion that does not interfere with dialogue or rapport. Also, given that patients are often highly emotionally invested in what we say, consulting in a manner that reflects confidence (without stepping over into arrogance) will help build trust.

Rapport, which originates from an old French word that literally means 'to carry back', can be engendered by fostering connections back and forth with the patient. Displaying empathy for the patient's situation or feelings, acknowledging his or her view or efforts, and dealing sensitively with embarrassing or disturbing topics such as pain or grief, will engender rapport. We can show we are willing to provide emotional support by overtly expressing our concern or understanding, or a willingness to help or offer partnership.<sup>8,16</sup> An offer such as 'I am really keen to help you with this situation' can go a long way.

Connections that build rapport can also happen away from medical issues, and are often more powerful. This is where the 'clues' that we were looking for at the beginning of the consultation can come into play. If a short interplay can happen between doctor and patient about something the patient is passionate about or interested in, which has nothing to do with the medical issues at hand, the patient will feel that he or she is respected as a person, not just as a medical presentation to be solved. Examples of such clues that could be picked up and explored by the doctor could be a favourite toy being held by a child, a book that a patient carries into the room, or the doctor noticing that the occupation of the patient is something he or she is interested in asking about. It comes down to patients feeling that the doctor is actually interested in them. When such connections are made, any tension in the consultation room can be seen to evaporate.

### Other rapport-building techniques

A person can develop a rapport with another by mimicking his or her body language, speech, posture, pace and other characteristics. Such techniques can be used to help the doctor communicate better with a patient and also to improve the patient's attitude by changing the patient's body language position.

#### Mirroring

Mirroring is a useful technique whereby the limb positions and body angles of the person you are talking to can be copied. A mirror image is formed of their position so that when they look at you they see themselves as in a mirror. It is not necessary to copy uncomfortable gestures or unusual limb positions, such as hands behind the head. A partial mirror is often sufficient.

#### Pacing

People exhibit a certain rhythm or pace that can be revealed through their breathing, talking, and movements of the head, hands or feet. If you can copy the pace of another person, it will establish a sense of oneness or rapport with them. Once this pace is established, you can change their pace by changing yours. This is called *leading*.

### Vocal copying

Vocal copying is another way to develop rapport with people. It involves copying intonation, pitch, volume, pace, rhythm, breathing and length of the sentence before pausing.

### Manage flow

At the end of the day, the doctor has a professional responsibility to appropriately meet the needs of the patient but also to keep control of a consultation so that it does not affect other consultations which follow. In most consultations, this is not difficult, but with a small proportion of patients, particularly those who have mental health and/or psychosocial issues to deal with, maintaining control and managing time can be challenging.<sup>19</sup>

A balance must be struck between maintaining control and not undermining the doctor-patient relationship.

The doctor having a 'wide-angle lens' on the consultation, so that he or she is mindful of where they are up to in the consultation and how much time has been taken up already, as well as the actual medical issues being discussed, will help anticipate a problem. Doing so subtly (e.g. not looking at a watch!) will help. It can be useful to have a wall clock situated behind the patient's chair or to be aware of where the consultation timer is on the computer screen. Being time aware can be particularly difficult for inexperienced doctors, who will be more focused on not making a mistake with the medical issues at hand. Naturally, even if the time is way over, it may be entirely appropriate to carry on if it is an important issue, such as with a suicidal or distressed patient.

If a consultation's flow is becoming problematic, the doctor should employ *appropriate use of power*.<sup>18</sup> This can be done with techniques such as setting rules in advance for patients where this is a problem (e.g. time limits for the consultation or limits on the number of concerns to be addressed). We can also use, if required, *blocking behaviours*, which can be verbal or non-verbal. These are behaviours that consciously block the flow of a consultation that is not being appropriately controlled. Examples include the doctor using body language that suggests he or she has something to say, or purposefully focusing on the (sometimes very short) space between a hyper-verbal patient's sentences to enable him or her to 'jump in' and take control of the consultation.

### Practice tips

- Using a patient-centred approach leads to improved patient trust and satisfaction, more appropriate prescribing and more efficient practice.

- Undertaking the strategies of facilitation, the open-to-closed cone and summarisation will help us effectively elicit patient concerns.
- Associated with listening, observe non-verbal language, which may in many instances be the most significant part of the communication process.
- Techniques that will help maximise patient understanding are signposting, 'chunk and check', avoiding jargon and using visual and physical techniques to communicate.
- Collaborative decision making helps the negotiation of what happens in the consultation and also avoids communication breakdowns.

### Key features of good communication

- A patient-centred approach
- Eliciting all of the patient's concerns
- Exploring the patient's ideas, beliefs and expectations
- Showing empathy and respect
- Summarising
- Avoiding jargon
- Collaborative decision making
- Good closure

*The doctor should have a kind disposition, great patience, self-possession, meticulous freedom from prejudice, an understanding of human nature resulting from an abundant knowledge of the world, adroitness in conversation and a special love of his calling.*

G Griesinger 1840

The *Macquarie Dictionary* says that counselling is 'giving advice': that it is 'opinion or instruction given in directing the judgment or conduct of another'. In the clinical context counselling can be defined as 'the therapeutic process of helping a patient to explore the nature of his or her problem in such a way that he or she determines his or her decisions about what to do, without direct advice or reassurance from the counsellor'.

The counselling process in general practice is based on the therapeutic effect of the doctor. There is an enormous and ever-increasing need for people in the community to have many of their emotional and social problems addressed by the health profession. Modern medicine has acquired a much more scientific face over recent years at the expense of its once respected humanistic one. Medicine is primarily a humanitarian pursuit, not an economic or scientific one, and uses science as a tool. Many feel that medicine is losing sight of this, at the considerable expense of its standing in the community.<sup>1</sup>

The public perceives that GPs can and do counsel people because more people go to their GP for counselling than to any other group of health workers, including psychologists, psychiatrists, social workers, marriage guidance counsellors and clergy.<sup>1</sup> People do not generally tell the doctor or even realise that counselling is exactly what led them to come to the doctor in the first place. The GP is, therefore, ideally placed in the community to make the most significant contribution to fill the community's needs in this area.

### The GP as an effective counsellor

GPs can be effective counsellors for the following reasons:<sup>2</sup>

- They have the opportunity to observe and understand patients and their environment.
- They are ideally placed to treat the whole patient.

- Their generalist skills and holistic approach permit GPs to have a broad grasp of a patient's problems and a multifaceted approach to treatment.
- They can provide treatment in comfortable and familiar surroundings, including the doctor's rooms and the patient's home.
- They are skilled at working as a member of a professional team and directing patients to more expert members of the team as necessary.
- They can readily organise 'contracts' with the patient.
- They often have an intimate knowledge of the family and the family dynamics.
- They fit comfortably into continuing patient care with appropriate follow-up treatment programs.

To be an effective counsellor the GP must prepare for this role, first by making a commitment to its importance, then by acquiring the knowledge and skills for basic counselling by reading, attending workshops and discussing cases with colleagues who are skilled in counselling.<sup>2</sup> Appropriate workshops are those based on the seminal model of therapy by Balint,<sup>3</sup> which aim to teach the patient new coping skills and so alleviate symptoms and improve the patient's functioning in social and occupational roles. Well-developed interviewing skills are essential, as is self-discipline to appreciate one's strengths and limitations.

### Features of counselling

Doctors can respond to patients' problems and distress by a spectrum of behaviours from doctor-centred, directive behavior (directed psychotherapy) or advice at one end, to patient-centred, non-directive behaviour at the other, where the patient does most of the talking (expressive psychotherapy).<sup>2</sup> In handling psychosocial problems, advice-giving is at one end of the spectrum and psychotherapy at the other.

Counselling, as an activity in general practice, can be represented by a moving point between these two extremes.<sup>1</sup>

Counselling can be seen as having the following features:<sup>1</sup>

- It is a clear-cut treatment option, like a course of antibiotics.
- It is a cooperative problem-solving process.
- It is an educational venture where patients learn new information and new activities.
- It is a developmental process for patients.
- It is a change process—often moving a patient from a ‘stuck state’.
- It is a goal-directed activity.
- It is a process of energising patients and lifting their morale.
- It is a sensitive response to problems within a caring relationship.

## A problem-solving approach

Defining the problem (what the matter really is) is the most important step in the process of patient care. The following outline is one approach to counselling that is applicable to a general practice context.<sup>1</sup>

- 1 Listen to the problem of first presentation: this involves listening not only to issues, events and experiences, but also to the patient’s feelings and distress. The emphasis here is more on the communication skills of facilitation, silence, clarification, reflection, paraphrasing, confrontation and summary, than on questioning. In many cases this phase of the counselling constitutes the major part of the therapy; for example, in grief or bereavement counselling, the doctor supports the patient through a natural but distressing process.
- 2 Define the problem, if possible in behavioural terms:  
Beneath the feeling is the experience, beneath the experience is the event, the event is related to a problem.<sup>4</sup>
- 3 Establish a contract for counselling, with an agreed number of visits initially (e.g. weekly half-hour or hour appointments for 4 to 6 weeks).
- 4 Define short-term and long-term goals for action.
- 5 Decide on one option—‘experimental action’.

- 6 Build an action program with the patient—negotiate ‘homework’ for the patient between visits.
- 7 Evaluate progress.
- 8 Continue action or select another option.
- 9 Evaluate progress.
- 10 Terminate or refer.

## Counselling models

### The PLISSIT model

The PLISSIT model, developed by Annon (1974)<sup>5</sup> as an aid in therapy for sexual problems, is a very useful model for problems presented as feelings where there is limited scope for intervention by the therapist.

The mnemonic PLISSIT stands for the following:

- P is for permission giving
- LI is for limited information
- SS is for specific suggestion
- IT is for intensive therapy

Annon emphasises that every primary care practitioner should be competent to offer ‘permission giving’ and ‘limited information’.

### The Colagiuri and Craig model

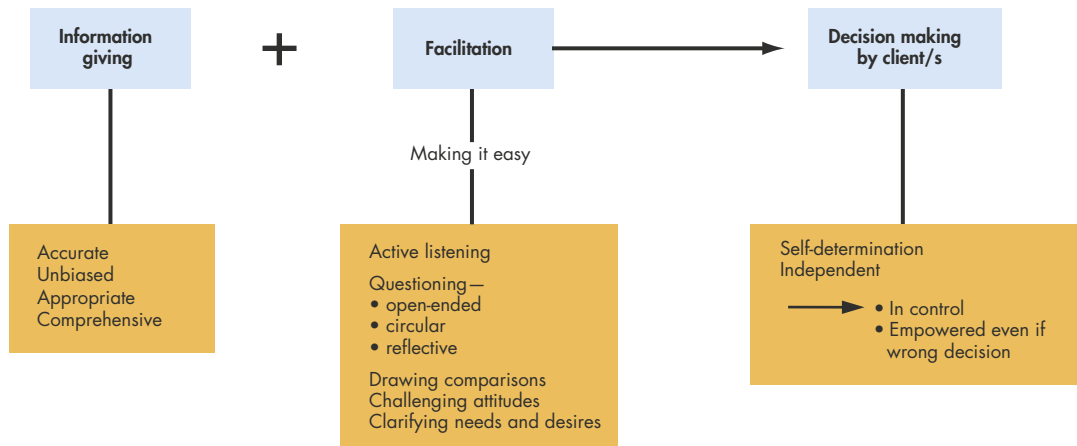

The medical counselling model was developed by Colagiuri and Craig (see FIG. 5.1)<sup>6</sup> as a useful tool for teaching contraceptive, abortion and sterilisation counselling. It can be applied in most situations as it empowers the patients to make their own decisions through facilitation as opposed to the directive and advisory learning model.

### The value of patient-centred counselling

There is evidence that the use of non-directive counselling techniques leads to more accurate diagnosis and therefore to more appropriate management and an improved outcome.<sup>7</sup>

Jerome Frank wrote in 1967: ‘The field of counselling and psychotherapy has for years presented the puzzling spectacle of unabating enthusiasm for forms of treatment where effectiveness could not be objectively demonstrated’.<sup>8</sup> Traux and Carkhuff<sup>9</sup> measured important aspects of the psychotherapeutic relationship and demonstrated what had long been recognised: the outcome was enhanced if practitioners had such qualities as accurate and sensitive awareness of the patient’s feelings, deep concern for the patient’s welfare (without attempting to dominate) and openness about their own reactions.

**FIGURE 5.1** Medical counselling model

Source: After Colagiuri and Craig<sup>6</sup>

5

The essential feature of the patient-centred approach is that the counsellor is more like a facilitator; that is, by the asking of well-directed questions it is hoped that patients can realise their own solutions for their problems.<sup>1</sup> This encourages patients to attain understanding and personal growth themselves rather than just put their personal affairs in the hands of someone else. This does not mean to say that the facilitator is passive in the process of assessing the relative merit of various solutions produced by the patient. The doctor-centred approach is most applicable for patients who are so confused or distraught that their ability to reflect usefully is temporarily or permanently inaccessible. Here, taking a more active and authoritarian role may be just what is required. It is therefore important to be flexible and move between the two ends of the spectrum as needed.

## Basics of counselling and psychotherapy

- Listening and empathy are the beginning of counselling.
- Good communication is the basis of counselling.
- The therapist must really care about the patient.
- Always be aware of the family context.
- It is important for therapists to handle and monitor their own feelings and emotions.
- Maintain eye contact.
- The therapist must tolerate and be comfortable with what the patient says.
- Confidentiality is essential.
- Counselling is easier if there is a good rapport with the patient, especially if a long-standing relationship exists.

- Counselling is difficult if a social relationship is present.
- Don't say to the patient 'I'm counselling you' or 'I'm giving you psychotherapy'—make it a natural communication process.
- The therapist must be versatile and adapt a counselling style to the clinical occasion.
- Characteristics of the effective counsellor have been demonstrated to be genuineness, non-possessive warmth for the patient, and accurate and empathetic understanding.

A fundamental feature of counselling is reflective listening to direct patients to think about and then resolve their problems.

Some useful interviewing skills used in counselling are summarised in **TABLE 5.1**.

## Counselling strategies<sup>4,7</sup>

- The therapy should be patient-centred.
- Use gentle, clever, probing questions.
- Facilitate the discussion to draw out relevant areas.
- It is important to be non-judgmental.
- Counsel through intuition and base it on common sense.
- Do not tell the patient what to do.
- Do not try to rush patients into achieving a happy ending.
- Provide guidance to allow the patient to gain insight.

**Table 5.1** Interview skills used in counselling

Use reflective statements.

Use silence.

Allow expressions of emotion.

Offer supportive comments.

Paraphrase and summarise.

Allow patients to correct your interpretations of their feelings.

Observe lack of congruence.

Try to understand what the patient is feeling:

- anger
- hostility
- fear
- manipulation
- seduction
- insecurity

Make intelligent guesses to prompt patient to continue.

Don't reassure too soon.

- Wherever possible, make therapy non-authoritarian and non-directional.
- Use appropriate 'gentle' confrontation to allow self-examination.
- Help patients to explore their own situation and express emotions, such as anxiety, guilt, fear, anger, hope, sadness, self-hate, hostility to others and hurt feelings.
- Explore possible feelings of insecurity and allow free expression of such feelings.
- Explore patients' belief systems and consider and respect their spiritual aspirations and conflicts.
- Ask key searching questions, such as:
  - 'What would be different in your life if you were well?'
  - 'Who are you mad at?'
  - 'If I understand you correctly you are telling me that . . .'
  - 'You seem to be telling me that . . .'
  - 'Correct me if I'm on the wrong track, but you are saying that . . .'
  - 'What do you think deep down is the cause of your problem?'
  - 'What does your illness do to you?'
  - 'Do you really worry about any things in particular?'
  - 'How do you think your problem should be treated?'
  - 'If you could change anything in your life, what would it be?'

Avoid:

- telling patients what they must do/offering solutions
- giving advice based on your own personal experiences and beliefs
- bringing up problems that the patient does not produce voluntarily

## What counselling is not

- Giving information
- Giving advice
- Being judgmental
- Imposing one's own values, behaviour and practices
- The same as interviewing
- Handing out patient education material

## Cautions<sup>1</sup>

- Individual doctors cannot be useful to all patients, so be selective.
- We cannot solve patients' problems for them.
- Patients' problems belong to them and not to their counsellors.
- Patients often have to change by only an inch in order to move a mile.
- If a counselling relationship is no longer productive, then terminate and refer.
- Most patients in primary care need information, support and a lift in morale, not long-term psychotherapy.

## Patients unlikely to benefit

The following groups of patients are not likely to benefit from counselling therapy<sup>1</sup> (i.e. relative contraindications):

- psychotic patients
- patients who have had an unrewarding experience with psychiatrists and other psychotherapists
- people who are antagonistic to the notion of a psychosocial diagnosis, subsequently found to be organic
- patients with little awareness or language to express emotional difficulty
- patients who do not believe doctors can treat psychosocial problems
- patients with a vested interest in remaining unwell who are therefore resistant to change (e.g. patients with work-related disabilities awaiting legal settlement)

- patients with chronic psychosomatic tendencies who are willing to do almost anything to maintain the relationship
- those in an intractable life situation who are unable or unwilling to change

## Types of psychotherapy<sup>2,10</sup>

- Interpersonal psychotherapy/counselling, ideal for primary care and the treatment of depression, is therapy for interpersonal problems.
- Mindfulness based on intervention therapy.
- Behaviour therapy (BT) is where the patient is directed to do something.
- Cognitive therapy (CT) is based on the identification of automatic thoughts that are invariably negative. Cognitions are thoughts, beliefs and perceptions.
- Cognitive behaviour therapy (CBT), which combines BT and CT.

## Cognitive behaviour therapy

CBT is a form of non-pharmacologic treatment emphasising self-help and aiming to change perceptions and behavior that may perpetuate symptoms and disability. It is basically a system of graded exposure (systematic desensitisation). It can be applied in any area of medical practice as a form of psychotherapy and is suitable in general practice for the treatment of depression, insomnia, eating disorders, delusions and hallucinations in psychotic disorders and anxiety in all forms, especially social anxiety disorder and phobias—in all of which CBT has proved to be better than a placebo.<sup>11</sup>

It is a relatively brief, active, directive and practical form of therapy. However, not all therapists or patients are suited to CBT.

The basic processes of CBT are to:

- define specific and concrete goals for functional activities and moods, e.g. pain control
- educate the patient
- teach basic skills for symptom control, relaxation and breathing control (especially for hyperventilation)
- identify, challenge and change maladaptive thoughts, feelings, perceptions and behaviour

Some basic principles and objectives of CBT are to:

- aim to bring about a desired change in patients' lives, i.e. aim to achieve desired goals
- assess, monitor and attempt to modify thoughts and behaviour

- reinforce positive behaviour and discourage negative behaviour
- educate about any misconceptions about a patient's illness
- encourage the patient to be an active participant (not a passive recipient)
- get patients to establish a problem list and hierarchy of problems
- aim for more realistic thinking and more adaptive responses

## Mindfulness

Mindfulness, which is based on meditation, is the process about raising awareness and a special way of paying attention to help the person cope with the daily events in their life.

The basic processes of mindfulness are to:

- train people to focus on the positive aspects of their lives and shut out distraction and negativity, i.e. attention training
- learn to concentrate in a restful way and cope with stress
- emphasise attentiveness to the present moment
- voluntarily reign in a wandering attention time and again

## Specific areas of counselling

Opportunities for basic counselling by the GP are ubiquitous in medical practice. Complex problems require referral but, even then, the GP still has an important role in continuing management.

Areas demanding counselling include:

- any crisis situation—breaking bad news
- bereavement or grief
- terminal illness/palliative care (CHAPTER 11)
- marital problems (CHAPTER 2)
- family problems (CHAPTER 2)
- sexual dysfunction (CHAPTER 118)
- chronic pain
- anxiety and stress (CHAPTER 81)
- depression (CHAPTER 19)
- intellectual handicap in a child
- infertility (CHAPTER 117)
- any disease or illness, especially severe illness
- sexual abuse/child abuse (CHAPTER 95)
- domestic violence (CHAPTER 120)
- insomnia and other sleep disturbances (CHAPTER 74)

## Crisis management

Crisis situations are not uncommon in general practice and people in crisis are usually highly aroused and

**FIGURE 5.2** Counselling skills: these skills include good eye contact, listening, empathy and appropriate communication skills

demanding. Examples include tragic deaths, such as children drowning or sudden infant death syndrome (SIDS), unexpected marital break-up and breaking bad news.

### Aims of crisis intervention

- Resolve the crisis and restore psychological equilibrium as quickly and constructively as possible.
- Encourage the person in crisis to regain control and take appropriate action.

### Principles of management

- Intervene early—actively and directly.
- Establish an empathetic alliance.
- Be accessible.
- Attend to family and social supports.
- Be prepared for the difficult phase of 24–48 hours.
- Do not carry the burden of crisis.
- Aim for brief, time-limited intervention (no more than six interviews over 6 weeks).
- When necessary, be prepared to provide short-term use of psychotropic drugs (e.g. a hypnotic), for two or three nights of good sleep.

### Ten rules to help those in distress

The following rules are given to those in crisis (personal explanation followed by a take-home hand-out):

- 1 *Give expression to your emotions.* You need to accept your reactions as normal and not be afraid to cry or call out. Try not to bottle up feelings.
- 2 *Talk things over with your friends.* Try not to overburden them but seek their advice and listen to them. Do not avoid talking about what has happened.

- 3 *Focus on things as they are now—at this moment.* Aim not to brood on the past and your misfortune. Concentrate on the future in a positive way.
- 4 *Consider your problems one at a time.* Try not to allow your mind to race wildly over a wide range of problems. You can cope with one problem at a time.
- 5 *Act firmly and promptly to solve a problem.* Once you have worked out a way to tackle a problem, go for it. Taking positive action is a step in allowing you to get on with life.
- 6 *Occupy yourself and your mind as much as possible.* Any social activity—sports, theatre, cards, discussion groups, club activity—is better than sitting around alone. Many people find benefit from a holiday visit to an understanding friend or relative. Religious people usually find their faith and prayer life a great source of strength at this time.
- 7 *Try not to nurse grudges or blame other people.* This is not easy but you need to avoid getting hostile. In particular, endeavour not to get angry with yourself and your family, especially your spouse.
- 8 *Set aside some time every day for physical relaxation.* Make a point of doing something physical, such as going for a walk, swimming or enjoying an easy exercise routine.
- 9 *Stick to your daily routine as much as possible.* At times of crisis a familiar pattern of regular meals and chores can bring a sense of order and security. Avoid taking your problems to bed and thus ensuring sleepless nights. Try to ‘switch off’ after 8 pm. Taking sleeping tablets for those few bad nights will help.
- 10 *Consult your family doctor when you need help.* Your doctor will clearly understand your problem because stress and crisis problems are probably the commonest he or she handles. Consult your doctor sooner rather than later.
  - Remember that there are many community resources to help you cope (e.g. your religious leader, social workers, community nurses, crisis centres and organisers within churches and other religious centres).
  - Take care: do drive carefully and avoid accidents, which are more common at this time.

### Bereavement

Bereavement or grief may be defined as deep or intense sorrow or distress following loss.<sup>12</sup> Raphael uses the term to connote ‘the emotional response to loss: the complex amalgam of painful affects including sadness, anger, helplessness, guilt, despair’.<sup>13</sup>

The GP will see grief in all its forms over a wide variety of losses. Although the nature of loss and patient reaction to it varies enormously, the principles of management are similar.

## Stages of normal bereavement

- 1 *Shock or disbelief.* Feelings include numbness and emptiness, searching, anxiety, fear and suicidal ideation, 'I don't believe it'. Concentration is difficult and spontaneous emotions, such as crying, screaming or laughing, tend to occur. There may be a sense of the deceased's presence, and hallucinations (visual and auditory) may occur.
- 2 *Grief and despair.* Feelings include anger, 'Why me?', guilt and self-blame, and yearning. Social withdrawal and memory impairment may occur. The feeling of intense grief usually lasts about 6 weeks and the overall stage of grief and despair for about 6 months, but it can resurface occasionally for a few years. The last few months involve feelings of sadness and helplessness.
- 3 *Adaptation and acceptance.* Features of the third stage include significant feelings of apathy and depression. This phase takes a year or more. Physical illness is common and includes problems such as insomnia, asthma, bowel dysfunction, headache and appetite disturbances.

## Pathological bereavement

Pathological bereavement can occur and may manifest as intense emotion, particularly anger, and multiple visits with somatic complaints; the patient often gets around to long dissertations about the deceased and the circumstances surrounding death. Extreme anger is likely when the sense of rejection is great, as with divorce or sudden death. Guilt can also be intense.<sup>12</sup>

Raphael's classification of the patterns of pathological grief and its various resolutions are presented in TABLE 5.2.<sup>13</sup>

### The GP as counsellor<sup>1</sup>

Important rules to bear in mind:

- The bereaved may be feeling very guilty.
- They may be angry towards their doctor or the medical profession in general.
- They need a clear explanation as to the exact cause and manner of death. Autopsy reports should be obtained and discussed.
- The bereaved tend to view an apparent lack of concern and support as disinterest or guilt.<sup>12</sup>
- Early intervention averts pathological grief.

**Table 5.2** Patterns and resolution of pathological grief

#### Morbid or pathological patterns

Absence, inhibition or delay of bereavement  
Distorted bereavement  
Chronic grief (intense anguish continues unabated)

#### Outcomes

- Normal resolution, satisfactory adjustment; reintegration in life, satisfying attachments
- General symptomatology (leading to increased care-eliciting behaviour)
- Depression, suicidal behaviour
- Other psychiatric disorders (anxiety state; phobia; mania; alcoholism; criminal activity, such as shoplifting)
- Altered relationship patterns
- Vulnerability to loss
- Anniversary phenomenon
- Death (more likely in the first 12 months)

The GP probably had a close relationship with the deceased and the family. The GP will have a special awareness of those at risk and the nature of the relationships within the family. The family is likely to maintain the relationship with the GP, expressing the physical and psychological effects of grief and consulting about intercurrent problems.<sup>12</sup>

Working through the stages of grief with patients will allow GPs to reach some acceptance of their own emotions, as well as ensure that patients feel supported and cared for, rather than distanced by embarrassment.

Help from religious sources is highly valued as it can meet both spiritual and personal needs. Other resources include funeral directors, hospice (and other) counsellors, and support groups, such as those for SIDS.<sup>12</sup>

At least 30 minutes should be allowed for consultations.

### Long-term counselling

Normal bereavement can persist for years. Ongoing counselling is indicated if it continues unabated or psychiatric referral sought if grief is extreme. Regular enquiries during routine consultations or meetings are important if the patient appears to be coping.

## Breaking bad news

Good communication skills are fundamental to giving bad news appropriately. When bad news is broken insensitively or inadequately the impact can be distressing for both giver and recipient, leaving lasting

scars for the latter. For the doctor it may represent professional failure, fear of people's reaction and feelings of guilt. Doctors should have a plan for this difficult process and learn how to cope with the recipient's reaction. Most of the circumstances described apply to unexpected death or anticipated death.

### Sharing bad news with a patient

This difficult task is based on sound communication skills and good dialogue. The meeting should be face to face, not over the phone or internet.

#### Basic guidelines

- Plan the consultation, check facts, set aside ample time.
- Meet in an appropriate room with privacy and no interruption.
- Ask the patient if they would like company (e.g. a relative or friend).
- Make good eye contact and be alert for non-verbal responses.
- Use simple, understandable language.
- Be honest and diplomatically to the point (don't cover up the issue).
- Allow time, silence, tears or anger.
- Avoid inappropriate methods (refer to 'avoid' in TABLE 5.4) and don't give precise predictions about life expectancy.

#### Management

Follow the 10 basic steps of the management interview (see CHAPTER 3) with the emphasis on the patient's understanding of the message and his/her feelings about it (see TABLE 5.3). Offer ongoing support and

**Table 5.3** Seven-step protocol for breaking bad news

- Assess the patient's interest in, and capacity for detailed information.
- Establish the patient's beliefs about the illness, and what he or she wants to know.
- Provide accurate information in small doses, checking regularly what has been understood.
- Monitor how the patient feels about the problem and what has been said.
- Repeat the messages as the illness progresses, especially after each new step of management and/or deterioration.
- Involve family members as much as the patient wants.
- Plan for continued involvement. An assurance of continuing contact between doctor and patient is important.

Source: After Buchanan<sup>14</sup>

arrangements for continuing involvement including allied health professionals.

### Coping with patient responses

- The responses cover a wide range—stunned silence, disbelief, acute distress, anger, extreme guilt.
- Be prepared for any of these responses.
- Appropriate training using simulated patients, video replays and skilled feedback improves communication skills.
- Give permission and encouragement for reactions, such as crying and screaming.
- Have a box of tissues available.
- A comforting hand on the shoulder or arm or holding a hand is an acceptable comfort zone.
- Offer a cup of tea or a cool drink if available.
- Ask the patients or relatives how they feel, what they would like to do and if they want you to contact anyone.
- Arrange follow-up.
- Give appropriate patient education material.
- Provide information about support services.

### Children

Remember that there are two 'patients'—child and family. The same 'bad news' principles apply. Talk in age-appropriate terms to the child with the aim of establishing their understanding of their illness and feelings.

### Unexpected death

Some basic initial rules:<sup>15</sup>

- If relatives have to be contacted it is preferable for the doctor (if at all possible) or a sympathetic police officer to make the contact personally, rather than a relatively matter-of-fact telephone call from the hospital or elsewhere.
- If a telephone message is necessary, it should be given by an experienced person.
- The relatives or close friends should not drive to the clinic alone.

The setting for the interview:

- Use a suitable quiet private room if possible.
- See the recipients of the news alone in the room.
- Advise that the meeting should be undisturbed.

### Guidelines for the doctor

- Be well prepared: check the facts and plan your approach.

- Always ask those involved if they have heard any news or know the reasons for the consultation.
- Always assess their understanding.
- Give information in an unhurried, honest, balanced, empathetic manner.<sup>16</sup>
- Look directly at the person you are talking to, be honest and direct, and keep information simple (avoid technical language).
- The sad news must be accompanied by positive support, understanding and encouragement.
- Give recipients time to react (offer time and moments of silence to allow the facts to sink in) and opportunities to ask questions.
- Avoid false reassurance.
- Remember that relatives appreciate the truth and genuine empathy.
- In the event of death, relatives should be given a clear explanation of the cause of death.

A list of guidelines for the interview is summarised in TABLE 5.4.<sup>15</sup>

**Table 5.4** Breaking bad news for unexpected death: recommended actions during the interview

#### Allow

##### Time

Opportunities to react

Silence

Touching

Free expression of emotions

Questions

Viewing of a dead or injured body

#### Avoid

Rushing

Bluntness

Withholding the truth

Platitudes

Protecting own inadequacies

Euphemisms

The notion 'nothing more can be done'

Using medical jargon

Meeting anger with anger

Leaving the patient or loved one without a follow-on contact

Source: After McLauchlan<sup>15</sup>

## The depressed patient

Studies have emphasised the importance and therapeutic efficacy of counselling in the management of the depressed patient.<sup>17</sup> The most practical approach

by the GP to the depressed patient is empathy, support and a logical explanation of their malaise. The author gives the following explanation to the patient.

Depression is a very real illness that affects the entire mind and body. It seriously dampens the five basic activities of humans, namely their energy for activity, sex drive, sleep, appetite and ability to cope with life. They cannot seem to lift themselves out of their misery or fight it themselves. Superficial advice to 'snap out of it' is unhelpful because the person has no control over it.

The cause is somewhat mysterious but it has been found that an important chemical is present in smaller amounts than usual in the nervous system. It is rather like a person low in iron becoming anaemic.

Depression can follow a severe loss such as the death of a loved one, a marital separation or financial loss. On the other hand it can develop for no apparent reason although it may follow an illness such as glandular fever or influenza, an operation or childbirth.

Emphasising the 'missing chemical' theory really helps patients and family come to terms with an illness that tends to have socially embarrassing connotations. It also helps compliance with therapy when antidepressant medication is prescribed.

Ongoing contact, support and availability are an important component of counselling with appropriate referral to someone with more expertise, should that be required. CBT is a most effective and important approach to the management of depressive illness.

## Chronic pain

Patients suffering from long-term pain are a special problem, especially those with back pain who seem to be on a merry-go-round of failed multiple treatments and complex psychosocial problems. These patients are frequently treated in pain clinics. As family doctors we often observe an apparently normal, pleasant person transformed into a person who seems neurotic, pain-driven and doctor-dependent. The problem is very frustrating to the practitioner, often provoking feelings of suspicion, uncertainty and discomfort.

De Vul and colleagues<sup>18</sup> list five subgroups of patients where perplexing pain presents as the major symptom:

- 1 pain as a symptom of depression
- 2 pain as a delusional symptom of psychosis
- 3 pain as a conversion symptom of hysterical neurosis
- 4 pain as a symptom of an unresolved bereavement reaction
- 5 pain as a symptom of a 'need to suffer'

Patients who somatise their symptoms present one of the most difficult challenges to our skills and usually require a multidisciplinary team approach.

Management involves:

- thorough medical assessment
- psychological assessment
- detailed explanations to the patient and family about treatment
- rational explanations about the cause of the pain
- management of associated problems (e.g. depression, sexual dysfunction)
- behavioural modification to encourage increased activity and a gradual return to normality

### A useful explanation

The author finds the following account a most useful method of explaining perplexing continuing back pain or neuralgia to patients (where there is no evidence of a persisting organic lesion).

Part of the problem is that psychological factors continue to aggravate and maintain the problem even though the reason for the pain in the first place may have disappeared. It is a similar problem to a person who has had a painful leg amputated. Even though it has been removed, the patient can still feel the leg and maybe even the pain. The patient has a 'phantom limb'. The nervous system, especially the brain, can play funny tricks on us in this way.

This means that even though the original disc injury has settled after several weeks, the body can still register the pain. This is more likely to occur in people who have become anxious and depressed about their problem. The pain continues. Someone once described it as a 'tension headache that has slipped down to the back'.

## Problem gambling

Problem or pathological gambling is persistent and recurrent maladaptive gambling behaviour despite its detrimental effect (disruption of personal, family or work life). It is undoubtedly a dependence disorder similar to alcohol and other drugs with a similar approach to management. Refer to DSM-5 criteria for pathological gambling. Prevalence: 0.5–1.5% adult population.

### Dangers

- Suicide risk (high)
- Major depression (up to 75%)
- Stress-related problems
- Domestic violence

### Key warning

- Gambling > \$200 week
- Chasing losses

### Other telltale signs

- Spending many hours gambling
- Placing larger, more frequent bets
- Lying about behaviour
- Being secretive
- Promising cutting back, but not doing it
- Impulsive activity
- Mood swings
- Gambling at the expense of other pleasant social activities
- Growing debts
- Excessive drinking

### First-line management

- Ask (as part of social history).
- Consider South Oaks Gambling screen to support provisional diagnosis.<sup>19</sup>
- Confront firmly if suspected.
- Consider using the Prochaska and Di Clemente model of change (CHAPTER 21).
- Provide education material.
- Look into the family (domestic violence?) and provide support.
- Advise the family not to provide 'rescue money'.
- There is no recommended pharmacological treatment.

### Counselling approach

Problem gambling is a treatable condition and GPs can provide a central role in management. As for smoking and alcohol dependence, a brief intervention and education consultation session about the impact of excessive behaviour can be most effective. CBT is a very effective treatment for gambling. It combines systematic discussion and carefully structured behavioural assignments to help patients modify problematic thinking patterns and behaviours. 'CBT directed towards correcting erroneous perceptions, irrational beliefs and misunderstanding of concepts of randomness and independence of chance events is a fundamental element of any therapeutic approach.'<sup>20</sup>

It is appropriate to use specialist gambling counsellors when one's intervention is not proving effective or where there is evidence of disturbing gambling problems. (Refer [www.gamblersanonymous.org](http://www.gamblersanonymous.org).)

## Summary: counselling skills strategies

- Provide guidance and facilitation to allow the patient to gain insight.
- Use appropriate 'gentle' confrontation to allow self-examination.
- Help patients to explore their own situation and express emotions such as anxiety, guilt, fear, anger, hostility and hurt feelings.
- Explore possible feelings of insecurity and allow free expression of such feelings.
- Ask key searching questions, such as:
  - What do you think deep down is the cause of your problem?
  - How do you think your problem should be treated?
- Provide 'okay' specific suggestions, such as:
  - I wonder if your basic problem is that you are a perfectionist?
  - Many people in your situation feel guilty about something that may even be trivial and need to feel forgiven.

Effective counselling comes from commitment, experience and a genuine caring compassionate feeling for patients and their ethos.

## Key rules to counselling

- The patient must leave feeling better.
- Provide *insight* into their illness and/or behaviour.
- Address any feelings of *guilt* (people must feel okay or forgiven about any perceived transgression).

If one feels out of one's depth, then immediate referral to an expert is important. CBT is a most appropriate therapy for most conditions.

# Difficult, demanding and angry patients

## 6

*There are patients in every practice who give the doctor and staff a feeling of 'heartsink' every time they consult.*

Thomas O'Dowd 1988<sup>1</sup>

Weston defines a 'difficult patient' as one with whom the physician has trouble forming an effective working relationship.<sup>2</sup> However, it is more appropriate to refer to difficult problems rather than difficult patients—it is the patients who have the problems while doctors have the difficulties.

The proportion of consultations that are taken up by *difficult patients* (also called *heartsink* or *hateful patients*) has been measured as being 15%.<sup>2</sup> While in the minority, by their nature they can often take up a disproportionate amount of the doctor's time, energy and emotional reserves. One difficult patient may disrupt an entire consulting session. The concept of the difficult patient was first popularised by the landmark paper by Groves in 1978<sup>3</sup>, and many difficult patient types have since been described. Four of the more common and better-known types<sup>4</sup> are as follows:

- 1 The dependent clinger  
Dependent clingers require constant reassurance, and have an unquenchable need for explanation, affection and attention. They may break social or professional barriers to meet this need, such as calling the doctor at home or continually making unplanned presentations at the surgery. The doctor can feel threatened by such patients, and if pushed away, dependent clingers can feel rejected, which may exacerbate their behaviour. They respond well to an empathic approach that needs to be delivered within clearly defined and enforced boundaries.
- 2 The entitled demander  
Entitled demanders attempt to control the doctor through intimidation and by inducing guilt or fear in the doctor. They project an air of superiority and entitlement, and may demand tests or consultation prioritisation, withhold payment and are often litigious. The doctor may understandably feel afraid and despairing in such situations, but this type of difficult patient is often driven by an underlying insecurity and is attempting to obtain control through bluster.

The appropriate use of power is clearly required for such patients, but it is important (and often difficult) to stay in control and interact in a respectful and non-confrontational manner. This may include pointing out calmly but clearly when boundaries are being crossed.

- 3 The manipulative help rejecter  
Manipulative help rejecters are patients who are on a self-destructive path but refuse to take important medical advice. They crave the relationship with the doctor and solving or improving the medical situation may threaten that relationship. Substance abuse is a common manifestation of how manipulative help rejecters present and manipulate the relationship, as are non-compliance and chronic pain issues. The doctor can feel frustrated and even demoralised, and it is important to reflect on our own feelings and expectations with such patients.
- 4 The self-destructive denier  
Rather than wanting to cling to the doctor (like the manipulative help rejecter), self-destructive deniers appear to want to damage themselves, their motivation driven by self-loathing. They may induce feelings of indifference or hatred in the doctor because of their destructive behaviour and apparent refusal to change their ways. An empathic approach is the most useful here, but this may be emotionally draining for the doctor.

An inevitably poor consultation will follow if we allow feelings of hostility to affect our communication with the difficult patient, especially the demanding, angry or 'compo' patient.

However, it is important not to misdiagnose organic disease and also to consider the possibilities of various psychological disorders, which may be masked. Hahn and Kroenke identified six diagnoses:<sup>3,5</sup>

- generalised anxiety disorders
- multi-somatoform disorder
- dysthymia

- panic disorder
- major depression
- drug dependency/alcohol abuse

It is therefore appropriate to maintain traditional standards by continually updating the database, integrating psychosocial aspects, carefully evaluating new symptoms, conducting an appropriate physical examination and being discriminating with investigations.

Management of the violent and dangerous patient is presented in **CHAPTER 45** on the disturbed patient.

## Management strategies

Our professional responsibility is to rise above interpersonal conflict and facilitate productive communication by establishing a caring and responsible relationship with such patients. An appropriate strategy is to follow Professor Aldrich's precepts for the 'difficult' patients who do not have an organic disorder or a psychiatric illness.<sup>6</sup>

- 1 Give up trying to cure them—they are using their symptoms to maintain their relationship with you: accept them as they are.
- 2 Accept their symptoms as expressions of their neurosis. Make a primary positive diagnosis—only test if you have to.
- 3 Structure a program for them, for example, 'Mrs Jones, I have decided that we should meet for 15 minutes every second Wednesday at 10 am.'
- 4 During the consultation, demonstrate your genuine interest in the person's life, garden, work and so on; show less interest, even boredom, for the litany of complaints.

Other management guidelines include the following.

- Use reassurance with caution—it is insufficient by itself and should be soundly based.
- Be honest and maintain trust.
- Allow the patient a fair share of your time—this is your part of the contract. At the same time indicate that there are limits to your time (set rules).
- Be polite yet assertive.
- Avoid using labels of convenience and placebo therapy.
- Be honest about your understanding (or lack of understanding) of the problems.
- Remember that the consultation is often the therapy, without a prescription.
- Do not undermine other doctors. Avoid collusion.
- Have limited objectives—zealous attempts to cure may be inappropriate.
- Do not abandon the patient, however frustrating the relationship. Accept this as a legitimate role.
- Remain available if alternative therapies are sought by the patient.
- Take extra care with the 'familiar' patient and sometimes the patient who brings gifts. Maintain your professional role.
- If you are uncomfortable with counselling, consider early referral to a counsellor while maintaining contact in the future.
- You may have to accept that there are some people no one can help.

## Complaints

Complaints from all groups of patients are common and disturbing. An ABCDE of dealing with them is presented in **TABLE 6.1**.

**Table 6.1** The ABCDE of dealing with complaints

- |          |   |
|----------|---|
| <b>A</b> | <b>A</b> cknowledge the complaint.                      |
| <b>B</b> | <b>S</b> et <b>B</b> oundaries for the patient.         |
| <b>C</b> | <b>S</b> how <b>C</b> ompassion and <b>C</b> aring.     |
| <b>D</b> | <b>D</b> etermine the reason for the behaviour.         |
| <b>E</b> | <b>E</b> scape or <b>E</b> xit, if there is an impasse. |

## A 'heartsink' survival kit

A pilot workshop of managing 'heartsink' patients described by Mathers and Gask<sup>7</sup> led to the formulation of a 'heartsink survival' model for the management of patients with somatic symptoms of emotional distress.

The first part of the three-part model, which is called 'feeling understood', includes a full history of symptoms, exploration of psychosocial cues and health beliefs, and a brief, focused, physical examination. In the second stage, termed 'broadening the agenda', the basic aim is to involve discussion of both emotional and physical aspects during the consultation. It includes reframing the patient's symptoms and complaints to provide insight into the link between physical, psychological and life events.

In the third stage, 'making the link', simple patient education methods are used to explain the causation of somatic symptoms, such as the way in which stress, anxiety or depression can exaggerate symptoms. It also includes projection or identification techniques using other sufferers as examples.

## The angry patient

Anger in patients and their relatives is a common reaction in the emotive area of sickness and healing. The anger, which may be concealed or overt, might be a communication of fear and insecurity. It is important to bear in mind that many apparently calm patients may be harbouring controlled anger. The practice of our healing art is highly emotive and can provoke feelings of frustration and anger in our patients, their friends and their relatives.

Anger is a normal and powerful emotion, common to every human being, yet with an enormous variety of expression. The many circumstances in medicine that provoke feelings of anger include:<sup>8</sup>

- disappointment at unmet expectations
- crisis situations, including grief
- any illness, especially an unexpected one
- the development of a fatal illness
- iatrogenic illness
- chronic illness, such as asthma
- financial transactions, such as high cost for services
- referral to colleagues, which is often perceived as failure
- poor service, such as long waits for an appointment
- problems with medical certificates
- poor response to treatment
- inappropriate doctor behaviour (e.g. brusqueness, sarcasm, moralistic comments, aloofness, superiority)

The patient's anger may manifest as a direct confrontation with the doctor or perhaps with the receptionist, with litigation or with public condemnation.

In an extreme example, a Melbourne doctor was shot and killed by an angry patient who had been denied a worker's compensation certificate for a claim considered unjustified.

When a patient expresses anger about the medical profession or our colleagues it may be directed at us personally and, conversely, if directed to us it may be displaced from someone else, such as a spouse, employer or other figure of authority.

## What is anger?

Anger is a person's emotional response to provocation or to a threat to his or her equilibrium. If inappropriate, it is almost always the manifestation of a deeper fear and of hidden insecurity. Angry, abusive behaviour may be a veiled expression of frustration, fear, self-rejection or even guilt.

On the other hand, its expression may be a defence against the threat of feeling too close to the doctor, who could have an overfamiliar, patronising or overly friendly attitude towards the patient. Some patients cannot handle this threatening feeling.

Basically, anger may be a communication of fear and insecurity. The patient could be saying, 'I am afraid there is something seriously wrong with me. Are you doing everything to help me?'

## Consulting strategies<sup>9</sup>

When one feels attacked unfairly, to react with anger is a natural human response. This response, however, must be avoided since it will damage the doctor-patient relationship and possibly aggravate the problem.

- The initial response should be to remain calm, keep still and establish eye contact.
- 'Step back' from the emotionally charged situation and try to analyse what is happening.
- Ask the patient to sit down and try to adopt a similar position (the mirroring strategy) without any aggressive pose.
- Address the patient (or relative) by the appropriate name, be it Mr or Mrs Jones or a first name.
- Appear comfortable and controlled.
- Be interested and concerned about the patient and the problem.
- Use clear, firm, non-emotive language.
- Listen intently.
- Allow patients to ventilate their feelings and help to relieve their burdens.
- Allow patients to 'be themselves'.
- Give appropriate reassurance (do not go overboard to appease the patient).
- Allow time (at least 20 minutes).
- For the threatening aggressive patient, sit closest to the door to allow escape should the patient turn violent.

## Analysing the responses

- Search for any 'hidden agenda'.
- Recognise the relationship between anger and fear.

## Recognising distress signals

It is important to recognise signs of deteriorating emotional distress:<sup>10</sup>

- body language (demonstrative agitated movements or closing in)
- speech (either becoming quiet or more rapid and louder)

- colour (either becoming flushed or pale)
- facial expression (as above, tense, tightening of muscles of eye and mouth, loss of eye contact)
- manner (impatient, threatening)

Skilful consulting strategies should then be employed. It is worthwhile having a contingency plan, such as memorising a telephone number to summon security help.

## Questions to uncover the true source of anger

The following represent some typical questions or responses that could be used during the interview.

### Rapport building

- 'I can appreciate how you feel.'
- 'It concerns me that you feel so strongly about this.'
- 'Tell me how I can make it easier for you.'

### Confrontation

- 'You seem very angry.'
- 'It's unlike you to be like this.'
- 'I get the feeling that you are upset with ...'
- 'What is it that's upsetting you?'
- 'What really makes you feel this way?'

### Facilitation, clarification

- 'I find it puzzling that you are angry with me.'
- 'So you feel that ...'
- 'You seem to be telling me ...'
- 'If I understand you correctly ...'
- 'Tell me more about this ...'
- 'I would like you to enlarge on this point—it seems important.'

### Searching

- 'Do you have any special concerns about your health?'
- 'Tell me about things at home.'
- 'How are things at work?'
- 'How are you sleeping?'
- 'Do you have any special dreams?'
- 'Do you relate to anyone who has a problem like yours?'
- 'If there's any one thing in your life that you would like to change, what would it be?'

Some important guidelines are summarised in

TABLE 6.2.

**Table 6.2** Guidelines for handling the angry patient

Do	Don't
Listen	Touch the patient
Be calm	Meet anger with anger
Be comfortable	Reject the patient
Show interest and concern	Be a 'wimp'
Be conciliatory	Evade the situation
Be genuine	Be overfamiliar
Allay any guilt	Talk too much
Be sincere	Be judgmental
Give time	Be patronising
Arrange follow-up	Be drawn into action
Act as a catalyst and guide	

## The drug-dependent doctor shopper<sup>11</sup>

Nicholas Carr's five-step approach:

- 1 Elicit request for drug early:  
'In what way did you think I could help?'  
'What sort of thing did you have in mind?'
- 2 Respectful refusal and brief minimal explanation:  
'I don't prescribe Valium (or requested drug).'
- 3 Avoid being drawn into the patient's agenda:  
'I understand this doesn't suit you, but I don't prescribe these drugs.'
- 4 Depersonalise:  
'It's nothing to do with you personally—this is the way I work.'
- 5 Offer alternative help:  
'I'm happy to talk about other ways of helping, but they don't involve a prescription.'

## Management

When confronted with an angry patient, the practitioner should be prepared to remain calm, interested and concerned. It is important to listen intently and allow time for the patient to ventilate his or her feelings.

A skilful consultation should provide both doctor and patient with insight into the cause of the anger and result in a contract in which both parties agree to work in a therapeutic relationship. The objective should be to come to amicable terms which, of course, may not be possible, depending on the nature of the patient's grievance.

If the problem cannot be resolved in the time available a further appointment should be made to continue the interview.

Sometimes it may be appropriate to advise the patient to seek another opinion. If the angry patient does have problems with relationships and seeks help, it would be appropriate to arrange counselling so that the patient acquires a more realistic self-image, thus leading to improved self-esteem and effectiveness in dealing with people. In addition, it should lead to the ability to withstand frustration and cope with the many vicissitudes of life—a most rewarding outcome for a consultation that began with confrontation.

## Health promotion<sup>1</sup>

*Health promotion* is the motivation and encouragement of individuals and the community to see good health as a desirable state that should be maintained by the adoption of healthy practices. It is also the process of helping people to increase control over and improve their health (WHO definition 2009).

For those who feel healthy, the message may have little meaning, but it is reinforced by contact with others who become ill, particularly within the family.

The Lalonde report<sup>1</sup> highlighted the notion that all causes of death and disease had four contributing elements:

- inadequacies of the existing health care system
- environmental hazards
- behavioural factors and unhealthy lifestyles
- human biological factors

## Health education

*Health education* is the provision of information about how to maintain or attain good health.

There are many methods, including the advertising of health practices, the provision of written information (e.g. about diet and exercise, immunisation, accident prevention and the symptoms of disease), and information about methods to avoid disease (e.g. sexually transmitted infection).

## Illness education

A lot of so-called 'health' education is, in reality, information about the cause of particular illnesses. Clearly, the medical practitioner is in a pre-eminent position to provide his or her patients with specific information about the cause of an illness at the time, either individually or to the family. This educative strategy has a preventive objective that is often the modification of help-seeking behaviour.

Every consultation is an opportunity to provide information about the condition under care and this can be reinforced in written, diagrammatic or printed form. Patients' own X-rays can be similarly used to illustrate the nature of the problem.

## Health promotion in general practice

GPs are ideally placed to undertake health promotion and prevention, mainly due to opportunity.

There are several reasons for this health promotion role:

- Population access: over 80% of the population visits a GP at least once a year.<sup>2</sup>
- On average, people visit a GP about five times each year.
- GPs have a knowledge of the patient's personal and family health history.
- The GP can act as leader or coordinator of preventive health services in his or her local area.
- The GP can participate in community education programs.
- GPs should undertake opportunistic health promotion—the ordinary consultation can be used not just to treat the presenting problem, but also to manage ongoing problems, coordinate care with other health professionals, check whether health services are being used appropriately and undertake preventive health activities.<sup>2</sup>

## Opportunistic health promotion

The classic model by Stott and Davis (see [TABLE 3.1](#) in [CHAPTER 3](#)) highlights the opportunities for health promotion in each consultation.<sup>3</sup> Since the consultation is patient-initiated, it is the doctor who needs to be the initiator of preventive health care. The potential in the consultation involves reactive and proactive behaviour by the doctor (see [FIG. 7.1](#)).<sup>4</sup>

**FIGURE 7.1** The potential in every general practice consultation

Source: Reproduced with permission from M Sales<sup>4</sup>

*Reactive professional behaviour* deals only with the presenting complaint. It may be performed with skill but if the practitioner is only trained to perform reactively then the opportunity for preventive and promotive health care will be lost.

*Proactive behaviour* is defined as professional behaviour that is necessary for the patient's well-being, but it is performed not merely as a response to the presenting problem and it is initiated by the doctor.<sup>4</sup> It includes health promotion, preventive care and screening and the early detection of disease, before it becomes symptomatic. Other aspects of proactive care are seen in **FIGURE 7.1**.

Proactive behaviour also includes:<sup>4</sup>

- continuing care of a previously treated problem (e.g. rechecking blood pressure, checking diabetic control, follow-up bereavement counselling)
- coordination of care by organising referral to appropriate agencies or specialists and maintaining adequate medical records
- the modification of abnormal or inappropriate help-seeking behaviour (e.g. the person who never attends is at risk from 'silent disease'; the too-frequent attender wastes resources and serious illness may be overlooked)

This mix of reactive and proactive behaviour is not appropriate in every consultation. It requires counselling skills and training in the delivery of quality general practice.

## Methods

- Being informed and updated by maintaining continuing medical education, especially in preventive roles.
- Using health promotional material for patient education:
  - handouts
  - waiting room posters
  - waiting room video systems
- Having an efficient medical record system.
- Operating a patient register and recall system.
- Encouraging regular health checks for at-risk groups.
- Providing regular advice on:
  - nutrition
  - exercise
  - stress management
  - weight control
- Providing personal health records to the parents of newborn babies.

## Health goals and targets

Health goals and targets as determined by the Health Targets and Implementation Committee<sup>5</sup> were set in three areas—population groups, major causes of illness and death, and risk factors (see TABLE 7.1).

**Table 7.1** Health promotion areas in which goals and targets have been set

### Population groups

The socioeconomically disadvantaged, Indigenous Australians, refugees, migrants, women, men, older people, children and adolescents

### Major causes of illness and death

Heart disease and stroke, cancers (including lung, breast, cervical and skin cancer), injury, communicable diseases, musculoskeletal disease, diabetes, disability, dental disease, mental illness, asthma

### Risk factors

Drugs (including tobacco smoking, alcohol misuse, pharmaceutical misuse or abuse, illicit drugs and substance abuse), nutrition, physical inactivity, high blood pressure, high blood cholesterol, occupational health hazards, unprotected sexual activity, environmental health hazards

Source: Health Targets and Implementation Committee<sup>5</sup>

The six priority health areas for Australians are:<sup>5</sup>

- asthma
- cancer control
- cardiovascular health
- diabetes mellitus
- injury prevention and control
- mental health

## Promoting healthy lifestyle in general practice

GPs can provide a simple framework to encourage patients to adopt a healthy lifestyle whether they have a particular disorder or not. The acronyms act as a good aide-mémoire for practitioners for opportunistic health promotion.

### The SNAP guide<sup>6</sup>

The SNAP guide was developed by the Royal Australian College of General Practitioners to address

important risk factors with patients with a view to encouraging change if appropriate. The guide comes as a comprehensive booklet and includes the 'Estimation of absolute 5-year risk of cardiovascular events' tables.

The SNAP guide can be summarised by the following risk factors.

**S** = Smoking

**N** = Nutrition

**A** = Alcohol

**P** = Physical activity

The guide emphasises that there are *health inequalities* in the community because the risk factors are far more prevalent in people from low-socioeconomic-status backgrounds and Indigenous Australians.

The guide focuses on the '5 As' as stages of change theory to promote change on lifestyle where appropriate (see TABLE 7.2).

**Table 7.2** The '5 As'

<b>1</b>	<b>Ask</b>	Identify patients with risk factors
<b>2</b>	<b>Assess</b>	Level of risk factor and its relevance to the individual in terms of health Readiness to change/motivation
<b>3</b>	<b>Advise</b>	Provide written information Provide a lifestyle prescription
<b>4</b>	<b>Assist</b>	Pharmacotherapies Support for self-monitoring
<b>5</b>	<b>Arrange</b>	Referral to special services Social support groups Phone information/counselling services Follow-up with the GP

This information can be accessed at <http://www.racgp.org.au/guidelines/snap>.

## The NEAT guide

The NEAT guide (see TABLE 7.3) is similar to the SNAP guide, but with a greater emphasis on counselling the patient about lifestyle and the importance of stress management.

## Psychosocial health promotion

There is a tendency for health goals and targets to focus mainly on physical illness and not emphasise mental health. However, this area represents an

**Table 7.3** The NEAT guide

<b>N</b>	<b>N</b> utrition: optimal diet
<b>E</b>	<b>E</b> xercise/physical activity
<b>A</b>	<b>A</b> voidance or moderation of potential harmful substances (CATS): <ul style="list-style-type: none"> <li>• caffeine</li> <li>• alcohol</li> <li>• tobacco</li> <li>• sugar, salt and social drugs</li> </ul>
<b>T</b>	<b>T</b> ranquillity and promotion of recreation, relaxation techniques, meditation

enormous opportunity for anticipatory guidance. It includes the important problems of stress and anxiety, chronic pain, depression, crisis and bereavement, sexual problems, adolescent problems, bullying, domestic abuse, child behavioural problems, psychotic disorders and several other psychosocial problems.

Time spent in counselling, giving advice and stressing ways of coping with potential problems such as suicide and deterioration in relationships is rewarding. GPs need to pay more attention to promoting health in this area, which at times can be quite complex.

## Patient education/hand-outs

Evidence has shown that intervention by GPs can have a significant effect on patients' attitudes to a change to a healthier lifestyle. If we are to have an impact on improving the health of the community, we must encourage our patients to take responsibility for their own health and thus change to a healthier lifestyle. They must be supported, however, by a caring doctor who follows the same guidelines and maintains a continuing interest. Examples include modifying diet, cessation of smoking, reduction of alcohol intake and undertaking exercise.

In an American survey of 360 patients, 90% reported wanting a pamphlet at some or all of their office visits. Overall, 67% reported reading or looking through and saving pamphlets received, 30% read or looked through them and then threw them away, and only 2% threw them away without review. Only 11% of males and 26% of females reported ever asking a doctor for pamphlets. More patients desired pamphlets than received them.<sup>7</sup>

Patient education materials have been shown to have a beneficial effect. Giving patients a hand-out about tetanus increased the rate of immunisation against tetanus among adults threefold.<sup>8</sup> An education booklet on back pain for patients reduced the number of consultations made by patients over the following year and 84% said that they found it useful.<sup>9</sup> Providing systematic patient education on cough significantly changed the behaviour of patients to follow practice guidelines and did not result in patients delaying consultation when they had a cough lasting longer than 3 weeks or one with 'serious' symptoms.<sup>10</sup>

There is no evidence that patient education has a harmful effect. Patient education about drug side effects has been shown not to have any detectable adverse effects.<sup>11</sup>

One form of patient education is giving hand-outs (either prepared or printed from a computer at the time of the consultation) to the patient as an adjunct to the verbal explanation which, it must be emphasised, is more important than the printed hand-out.

The patient education leaflets should be in non-technical language and focus on the key points of the illness or problem. The objectives are to improve the quality of care, reduce costs and encourage a greater input by patients in the management of their own illness. In modern society where informed consent and better education about health and disease is expected, this information is very helpful from a medicolegal viewpoint.

The author has produced a book called *Patient Education*, which has a one-page summary of each of 345 common medical conditions.<sup>12</sup> The concept is to photocopy the relevant problem or preventive advice and hand it to the patient or relative. Over the years the greatest demand (following a survey of requests for prints of the sheets) has been for the following (in order):

- exercises for your lower back (see FIG. 7.2)
- backache
- exercises for your neck
- your painful neck
- exercises for your knee
- breastfeeding and milk supply
- how to lower cholesterol
- breast self-examination
- testicular self-examination
- vaginal thrush
- menopause
- anxiety
- coping with stress
- depression
- bereavement

FIGURE 7.2 Patient education leaflet (diagrammatic part only): exercises for your lower back

## Summary

Recommended target areas for health promotion in general practice include:

- nutrition
- weight control
- substance abuse and control
  - smoking
  - alcohol
  - other drugs
- exercise practices
- appropriate sleep, rest and recreation
- safe sexual practices
- promotion of self-esteem and personal growth
- stress management

Important health promotion recommendations are to encourage patients to:<sup>13</sup>

- cease smoking
- reduce alcohol intake to safe levels (for healthy men and women, no more than two standard drinks per day and no more than four standard drinks on any single

occasion; young people under 15 years should avoid drinking and young people aged 15–17 years should delay drinking for as long as possible; when pregnant or breastfeeding, no alcohol is the safest option)

- limit caffeine intake to three drinks per day
- increase regular physical activity (at least 30 minutes per day for 3 days per week, sufficient to produce a sweat)
- reduce fasting plasma cholesterol to 4.0 mmol/L or less
- have a diastolic BP of less than 85 mmHg
- have a BMI of between 20 and 25 (see Chapter 9)
- reduce fat, refined sugar and salt intake in all food
- increase dietary fibre to 30 g/day
- build up a circle of friends who offer emotional support
- express their feelings rather than suppress them
- discuss their problems regularly with another person
- work continuously to improve their relationships with people
- not drive a car when angry, upset or after drinking
- follow cervical cancer screening guidelines
- avoid casual sex
- practise safe sex
- have an HIV antibody check before entering a relationship

*Last scene of all,  
That ends this strange eventful history,  
Is second childishness, and mere oblivion,  
Sans teeth, sans eyes, sans taste, sans everything*

William Shakespeare (1564–1616), *As You Like It*

The ageing (over 65 years) are the fastest growing section of the Australian population. The number of 'old-old' (over 85 years) is increasing at an even faster rate.<sup>1</sup> Life expectancy has risen to 84.3 years for women and 79.9 for men.<sup>2</sup>

The over-65s in 2001 made up 12.7% of the Australian population (13.4% in the US) and in 2013 made up 14.7% of the population. It is expected that this group will make up at least 20% of the population in 2031. A similar trend is expected in the US with 18% in 2040.<sup>2</sup>

The over-65s use twice the number of health services per head of population. They account for 25% of all hospital costs and 75% of all nursing home costs. They represent 29.6% of all general practice consultations.<sup>3</sup> Many are affected by multisystem disease. All are affected to a greater or lesser extent by the normal physiological changes of organ ageing.

Ageing is characterised by the following:<sup>1</sup>

- decrease in metabolic mass
- reduction in the functional capacity of organs

**FIGURE 8.1** Establishing rapport and support through the home visit to the elderly patient is an important security gesture

- reduced capacity to adapt to stress
- increased vulnerability to disease
- increased probability of death

Age-associated deterioration occurs with hearing, vision, glucose tolerance, systolic blood pressure, kidney function, pulmonary function, immune function, bone density, cognitive function, mastication and bladder function.

One of the main contributing factors is the problem of disuse. Encourage exercise, especially walking and water aerobics.

## Ageing and disease

Degenerative cardiovascular disease emerges with ageing according to the following approximate guidelines:

Age	
40	Obesity
50	Diabetes
55	Ischaemic heart disease
65	Myocardial infarction
70	Cardiac arrhythmias
75	Heart failure
80	Cerebrovascular accidents

## Deterioration in health and the 'masquerades'

Unexpected illness, including mental confusion (one of the major hallmarks of disease in the elderly), can be caused commonly by any of the so-called masquerades outlined in **CHAPTER 17**:

- depression
- drugs, including alcohol, anticholinergics
- diabetes mellitus

- anaemia
- thyroid disease
- urinary tract infection
- neurological dilemmas
  - Parkinson disease
  - cerebrovascular accident
- infections (e.g. bronchopneumonia)
- neoplasia
- giant cell arteritis/polymyalgia rheumatica

Common significant management disorders encountered in the elderly include:

- hypertension
- ischaemic heart disease and heart failure
- depression
- diabetes (type 2)
- dementia
- social and physical isolation
- osteoarthritis
- disorders of the prostate
- urinary incontinence
- locomotive (lower limb) disorders
  - neurological
  - peripheral neuropathy
  - ataxia
  - claudication due to vascular insufficiency
  - other peripheral vascular disease
  - claudication due to spinal canal stenosis
  - sciatica/nerve root paresis
  - osteoarthritis: hips, knees, feet
  - foot disorders (e.g. ingrown toenails)
  - leg ulceration

Important problems affecting the elderly are presented in **FIGURE 8.2**.

### The 'classic' triad<sup>4</sup>

Be mindful of the classic triad:

This can represent non-specific signs of acute illness, particularly infection. Aggressive antibiotic treatment is worth considering while awaiting the results of culture or clinical developments.

### Changes in sensory thresholds and homeostasis

A clinically significant feature in some elderly patients is the raising of the pain threshold and changes in

homeostatic mechanisms, such as temperature control. Consequently, these patients may have an abnormal response to diseases such as appendicitis, pyelonephritis, internal abscess, pneumonia and septicemia. There may be no complaints of pain and no significant fever but simply general malaise and abnormal behaviour, such as delirium, agitation and restlessness.

### Establishing rapport with the elderly patient

The elderly patient especially requires considerable support, understanding, caring and attention from a GP who can instil confidence and security in a patient who is likely to be lonely, insecure and fragile. This means taking time, showing a genuine interest and a modicum of humour, and always leaving detailed instructions.

One of the best ways to generate a good relationship is through home visits. The value of home visits can be considered under the precepts of the Royal Australian College of General Practitioners.<sup>5</sup>

- 1 Assessment, both initial and continuing: 'You don't know your patient until you've visited their home'.
- 2 Continuing care:
  - security to the patient
  - support for 'caring' family
  - effective monitoring/intervention role
  - effective liaison with patient/family
  - checking medication

Home visits can be considered in three categories:

- 1 an 'unexpected' visit (especially to a new patient)
- 2 a patient-initiated but routine request for a 'check-up and tablets'
- 3 the regular call—usually 2 to 4 weeks

These home visits are a 'security gesture' to the patient—evidence that they are supported in their desire to remain independent for as long as possible in their own home. They strengthen the patient–doctor relationship as a position of trust, which is of special importance to frail, elderly people feeling increasingly insecure and threatened.

If the patient is being supported by a spouse or relative, the doctor can provide continuous reassurance and support to all concerned as well as their continual assessment, both physical and mental. Finally, the home visit may become part of the terminal care of a dying patient, something that is very important to the elderly patient. Home visits can enhance the quality of life, both physical and mental, of an ageing person.

FIGURE 8.2 Significant problems affecting the elderly

## Loneliness in the elderly

Forbes points out that at least one in three elderly people feel lonely.<sup>6</sup> It is more likely to affect the 'old-old', widows and widowers, and those affected by disability. They may tend to stay indoors, troubled by depression, agoraphobia, social phobia, sensory impairment or incontinence of urine or faeces.

Possible signs of loneliness include:

- verbal outpouring
- drab clothing
- dependence on television
- body language with a 'defeated' demeanour
- prolongation of visit including holding on to one's hand

## Doctor behaviour that can irritate and confuse elderly patients

Ellard<sup>7</sup> has written a most interesting paper, based on a compendium of complaints by the elderly about their doctors, on behaviour that upsets the elderly:

- having a consulting room with slippery steps, poor lighting and inadequate handrails
- non-attention to simple courtesies by reception staff
- keeping them waiting
- having low soft chairs in the waiting room and surgery
- being overfamiliar, with addresses such as 'Pop' or first names for elderly females
- shouting at them on the assumption that they are deaf
- appearing rushed and keen to get the consultation over quickly
- forgetting their psychosocial problems and concentrating only on their physical problems (i.e. not treating the whole person)
- forgetting that they have several things wrong with them and using a different priority list from theirs
- being unaware that they may have seen other practitioners or may be taking additional medication
- failing to ask patients to give their understanding of what is wrong
- omitting to give printed patient education hand-outs about their problems and medications
- omitting to explain how the medication will work
- treating them as though they would have little comprehension of their health and treatment
- failing to respect their privacy, such as not knocking before entering the examination room
- failing to provide appropriate advice on various social services such as meals on wheels and other support groups
- failing to re-evaluate carefully their health and medication
- failing to take steps to reverse any deterioration in their health, including reluctance to refer

## Assessment of the elderly patient

The initial consultation should include a thorough clinical examination on the traditional lines of history, physical examination and selective laboratory investigation. At regular intervals during continuing care this careful assessment may need to be repeated.

### A golden rule

You don't know your patient until you've visited them at home.

## History

The medical history may be difficult to obtain and the help of a family member is recommended. The use of questionnaires, which can be completed at leisure at home with the help of family members, is most helpful as complementary to the medical interview.

Important specific areas to focus on are:

- previous medical history and hospitalisation
- immunisation status
- medications, prescription and OTC drugs
- alcohol intake, smoking
- problem list of complaints
- dependence on others
- members of household
- household problems
- comforts: heating, cooling, bedding, etc.
- ambulation/mobility/use of frame or stick
- meals: diet
- hygiene: bathing
- toileting: continence
- teeth: condition, ?dentures
- vision
- hearing (always ask about this)
- systems review, especially:
  - genitourinary function
  - gastrointestinal
  - cardiorespiratory
- locomotion, including feet
- nervous system, ?falls, giddiness, loss of balance, faints
- emotional and mental health
- evidence of depression
- history of bereavement
- history of abuse by carers, family members
- financial/insurance status

A thorough family history and psychosocial history is of prime importance. At all times concentrate on a general assessment of the patients' ability to communicate by evaluating mental status, comprehension, hearing, vision, mood and speech.

## Physical examination

The routine for the physical examination is similar to that of the younger adult but certain areas require more attention. The elderly patient expects to be examined adequately (especially having blood pressure measured) but requires appropriate dignity. It is recommended

that the practice nurse supervises dressing and undressing and prepares the patient for examination.

### Practice nurse

- Prepares for examination
- Helps with questionnaire
- Records weight and height
- Takes temperature, pulse and respiration
- Checks audiometry (if hearing problem)
- Checks ocular tension (if appropriate)
- Prepares cervical smear tray for female patient (if relevant)

### Doctor

The following areas should be examined:

- general appearance, including skin, hair and face (evaluate nutritional status)
- mental state examination (see FIG. 8.3)
- eyes: visual acuity
- ears: simple hearing test; auroscopic examination
- oral cavity, including teeth and gums
- neck especially thyroid
- lungs: consider peak flow meter
- pulse and blood pressure (repeat)
- heart; breasts
- abdomen; hernial orifices
- spine
- lower limbs: joints; circulation; feet including nails
- gait
- men: rectal examination; scrotum and testes
- women: cervical smear if appropriate

## 'Rules of 7' for assessment of the non-coping elderly patient

If your elderly patient presents with non-specific symptoms, unexpected deterioration in health and/or an inability to cope with the activities of daily living, consider the checklist precented in TABLE 8.1 in your assessment. Apart from confusion, other non-specific symptoms include drowsiness, poor concentration, apathy, fatigue/weakness/tiredness/lethargy, anorexia, nausea, weight loss, dyspnoea, immobility, 'stuck in bed or chair', stumbles or falls. It is also important to consider infections including pneumonia and the masquerades (see CHAPTER 17).

## The mini-mental state examination

Evidence of memory difficulty remains the best single indicator of dementia and should always be evaluated by formal memory testing. However, memory problems may be due to factors other than dementia, and demonstrating failure in other areas of cognitive functioning (language, spatial ability, reasoning) is

**Table 8.1** The 'rules of 7'

1	Mental state	?	Confusion/dementia Depression Bereavement, incl. pets Elderly abuse/bullying
2	Eyes	?	Visual acuity Cataracts/glaucoma
3	Ears	?	Deafness, e.g. wax Tinnitus
4	Mouth	?	Dentition Xerostomia Malnutrition
5	Medication	?	Polypharmacy Adverse reactions
6	Bladder and bowels	?	Incontinence Retention Urinary infection
7	Locomotion	?	Gait—antalgic; movement disorder, esp. Parkinson disease Arthritis—hips/knees Back/sciatica Feet—nails; neuropathy Circulation Leg ulcers

necessary to confirm the diagnosis of dementia.<sup>8</sup> A number of screening tests are available but the mini-mental state examination (MMSE), particularly the Folstein MMSE depicted in FIGURE 8.3, is commonly used and is the recommended test to use.

Another, somewhat simpler test is the 'Quick 10-step cognitive impairment test' (see TABLE 8.2).<sup>9,10</sup>

**Table 8.2** The quick 10-step cognitive impairment test

Scoring: questions 1 to 8: correct—0, incorrect—2; questions 9 and 10: correct—0, 1 error—2, >1 error—4

1	When were you born?
2	What year is it?
3	What month is it?
4	What is the date today?
Remember the following address: 25 Main Street, Newcastle	
5	What is your telephone number? (or if no telephone) What is your street address?
6	What time is it (to nearest hour)?
7	Who is the Prime Minister of Australia?
8	What year did World War II end?
9	Count backwards from 20 to 1.
10	Repeat the memory test I gave you.

Evaluation: 0–8 not significant  
9–12 probably significant  
13–24 significant

Source: Adapted from Hodkinson<sup>9</sup> and Kingshill<sup>10</sup>

Mini mental state examination		
ASK the patient	INSTRUCTIONS for assessor	Score
Orientation		
What is the year, month, day and date? What is the season?	Ask specifically for omitted details, e.g. month, year. Score one point for each correct answer.	/5
Can you tell me where we are now?	Expect street no., road name, suburb, city, state. Ask in turn for each place (if necessary). Score one point for each correct answer.	/5
Registration		
'I am going to test your memory—I want you to repeat these three items after me, and hold them in your mind for when I ask you later.'	Name three unrelated objects (e.g. orange, camel, table) speaking clearly and slowly; repeat up to five times or until all three are learned, and ask to recall after each time. Only score after first attempt – 1 point for each correct answer.	/3
Attention and calculation		
'Beginning at 100, count backwards by 7' or, if patient is unable to perform this task, ask: 'Spell the word "WORLD" backwards'.	Stop after five answers—93, 86, 79, 72, 65; each correct answer scores one. Score equals number of letters before first mistake.	/5
Recall		
'What are the three words I asked you before?'	Score one point for each correct answer.	/3
Language		
'What is the name of this object?'	Show two objects. Point to a watch, and then a pen.	/2
'Please repeat this sentence "NO IFS, ANDS, OR BUTS".'		/1
Giving the patient a blank piece of paper, say: 'Take this paper in your right hand, fold it in half, and put it in your lap.'	Score one point for each step.	/3
Praxis (three tasks)		
1 'Read and obey this task.'	CLOSE YOUR EYES	Score only if patient closes eyes. /1
2 'Write a sentence'	Sentence must be sensible and contain a verb and subject.	/1
3 'Copy this design'	All 10 angles must be present with two intersecting (ignore tremor, scale and rotation).	/1
		/30
Scoring guide only: 21–24 (probable mild dementia); 10–20 (probable moderate impairment) <10 (severe impairment). A decline in score of greater than two points over 1 year may be significant. Note: These scores are used as a baseline to determine the criteria for prescribing anti-dementia drugs		Max score

FIGURE 8.3 A practical adaptation of the mini-mental state examination

## The clock-face drawing test

This relatively simple test provides a ready qualitative screening test to differentiate normal elderly from patients with cognitive impairment, particularly dementia.<sup>11</sup>

### Method

- Give the patient a blank, A4-sized piece of paper.
- Ask the patient to draw the face of a round clock and put the numbers in their correct positions on the face of the clock to represent the hours (see FIG. 8.4).
- Ask the patient to draw in the hands of the clock, indicating 10 minutes after 11 (or some other suitable time) (see FIG. 8.4).
- Repeat the instructions if the patient does not understand them.

FIGURE 8.4 The clock-face drawing test

### Scoring system

- A closed circle is drawn—3 points
- Numbers are in the correct position—2 points
- All correct numbers are included—2 points
- Clock hands are placed in the correct position—2 points

The maximum score is 9. A low score indicates the need for further evaluation and does not establish the criteria for dementia, being a pointer only.

## Laboratory investigations

The laboratory tests should be selected according to the evaluation of the patient and to costs versus potential benefits.

Recommended investigations for suspected dementia include:<sup>8,12</sup>

- kidney function
- hepatic function
- thyroid function
- full blood screen
- blood glucose
- serum electrolytes (especially if on diuretics)
- serum calcium and phosphate
- urinalysis
- serum vitamin B12 and folate
- serum vitamin D
- syphilis serology (consider HIV)
- chest X-ray
- neuroimaging: computed tomography (CT), especially non-contrast CT, or magnetic resonance imaging (MRI) (preferably)
- positron emission tomography (PET) scan or single photo emission computed tomography (SPECT) scan—for further information

## Behavioural changes in the elderly

As GPs, we are often called to assess abnormal behaviour in the elderly patient, with the question being asked, 'Is it dementia?' or 'Is it Alzheimer's, doctor?'.

There are many other causes of behavioural changes in people over the age of 65 years and dementia must be regarded as a diagnosis of exclusion. The clinical presentation of some of these conditions can be virtually identical to early dementia.

The clinical features of early dementia include:

- poor recent memory
- impaired acquisition of new information
- mild anomia (cannot remember names)
- personality change (e.g. withdrawn, irritable)
- minimal visuospatial impairment (e.g. tripping easily)
- inability to perform sequential tasks

The differential diagnosis for behavioural changes apart from dementia include several other common and important problems (which must be excluded) and can be considered under a mnemonic for dementia (see TABLE 8.3).<sup>12</sup>

All these conditions should be considered with the onset of deterioration in health of the elderly person. Even apparently minor problems—such as the onset of deafness (e.g. wax in ears), visual deterioration (e.g. cataracts), diuretic therapy, poor mastication and diet, urinary tract intercurrent infection, boredom and anxiety—can precipitate abnormal behaviour.

**Table 8.3** Mnemonic for DEMENTIA

<b>D</b>	<b>D</b> rugs and alcohol <b>D</b> epression
<b>E</b>	<b>E</b> ars <b>E</b> yes
<b>M</b>	<b>M</b> etabolic, e.g. hyponatraemia, diabetes mellitus, hypothyroidism
<b>E</b>	<b>E</b> motional problems (e.g. loneliness)
<b>N</b>	<b>N</b> utrition: diet (e.g. vitamin B group deficiency, teeth problems)
<b>T</b>	<b>T</b> umours, } of central nervous system <b>T</b> rauma }
<b>I</b>	<b>I</b> nfection
<b>A</b>	<b>A</b> rteriovascular disease → cerebral insufficiency

## Elder abuse

It is important to keep in mind the possibility of abuse of the elderly, especially where there is a family history of abuse of members. The issue is as important as child and spouse abuse. Over one million elderly people are estimated to be the victims of physical or psychological abuse each year in the US.<sup>4</sup> We should keep in mind the occasional possibility of Munchausen syndrome by proxy.

## Depression and dementia

The main differential diagnosis of dementia is depression, especially major depression, which is termed pseudodementia. The mode of onset is one way in which it may be possible to distinguish between depression and dementia. Dementia has a slow and surreptitious onset that is not clear-cut, while depression has a more definable and clear-cut onset that may be precipitated by a specific incident. Patients often have a past history of depression. Those with dementia have no insight; those with depression have insight, readily give up tasks, complain bitterly and become distressed by their inability to perform normal enjoyable tasks.

In response to cognitive testing, the typical response of the depressed patient is 'don't know', while making an attempt with a near-miss typifies the patient with dementia (see **TABLE 8.4**).

It is vital to detect depression in the elderly as they are prone to suicide: 'Nothing to look back on with pride and nothing to look forward to.' The middle-aged and elderly may not complain of depression, which can be masked. They may present with somatic symptoms or delusions.

**Table 8.4** Comparison of dementia and pseudodementia (commonly severe depression)

	Dementia	Pseudodementia
<b>Onset</b>	Insidious	Clear-cut, often acute
<b>Course over 24 hours</b>	Worse in evening or at night	Worse in morning
<b>Insight</b>	Nil	Present
<b>Orientation</b>	Poor	Reasonable
<b>Memory loss</b>	Recent > remote	Recent = remote
<b>Responses to mistakes</b>	Agitated	Gives up easily
<b>Response to cognitive testing (questions)</b>	Near-miss! Difficulty understanding	'Don't know' Slow and reluctant but understands words (if cooperative)

Note that depression occurs commonly in people with dementia, especially in the early stages.

## Dementia (chronic organic brain syndrome)

The incidence of dementia increases with age, affecting about 1 person in 10 over 65 years and 1 in 5 over 80 years. The important causes of dementia are:

- degenerative cerebral diseases, including
  - Alzheimer disease (about 60%)
  - dementia of frontal type (up to 10%)
  - dementia with Lewy bodies (up to 10%)
- vascular (15%)
- alcohol excess (5%)

*Note:* Mixed dementia should be considered.

Other causes of dementia:

- AIDS dementia
- cerebral tumours
- Creutzfeldt–Jakob disease
- Pick disease
- neurosyphilis
- amyloidosis

In Alzheimer disease, there is insidious onset with initial forgetfulness progressing to severe memory loss. In frontal dementias the earliest manifestations are personality change and alteration of behaviour, including social dysfunction. Dementia with Lewy bodies is characterised by any two of visual hallucinations, spontaneous motor Parkinsonism and fluctuations in the mental state. Vascular dementia usually starts suddenly and is accompanied by focal neurological signs with evidence of cerebrovascular disease.

The characteristic feature of dementia is impairment of memory. Abstract thinking, judgment,

verbal fluency and the ability to perform complex tasks also become impaired. Personality may change, impulse control may be lost and personal care deteriorate.

Risk factors for dementia include:

- family history
- late-onset depression
- hypothyroidism
- Down syndrome
- history of head injury
- HIV/AIDS
- generalised atherosclerosis
- Parkinson disease

Differential diagnosis of dementia includes:

- normal cognitive impairment of ageing
- delirium
- major depression
- drug abuse
- amnesic disorder
- various medical conditions (e.g. anaemia, thyroid/endocrine disorders)

The DSM-IV (TR) criteria for dementia are presented in TABLE 8.5 and clinical clues suggesting dementia in TABLE 8.6.

**Table 8.5** DSM-IV (TR) criteria for dementia of Alzheimer type (modified)

Diagnosis of dementia requires evidence of:

- |    |   |
|----|---|
| A1 | Clear evidence of decline in memory and learning  |
| A2 | At least one of the following cognitive disturbances: <ul style="list-style-type: none"> <li>• Language = aphasia</li> <li>• Motor actions = apraxia</li> <li>• Recognition = agnosia</li> <li>• Executive functioning (e.g. organising)</li> </ul> |
| B  | Disturbance significantly interferes with social and work functions   |
| C  | Gradual onset and continuing cognitive decline  |
| D  | Not due to known organic causes (e.g. drugs, cerebrovascular disorders)   |
| E  | Not due to delirium   |
| F  | Not due to another axis 1 disorder (e.g. major depression)  |

(a) Classified with or without behavioural disturbance

(b) Also with early onset <65 years or late onset >65 years

Source: *Diagnostic and Statistical Manual* (4th edn, revised). Washington, DC: American Psychiatric Association, 2000.

Note: DCM-IV considered more explicit than DSM-5

**Table 8.6** Clinical clues suggesting dementia

#### 1 Patient presentations

New psychological problems in old age

Ill-defined and muddled complaints

Uncharacteristic behaviour

Relapse of physical disorders

Recurrent episodes of confusion

#### 2 Problems noted by carers

'Not themselves'—change in personality (e.g. humourless)

Domestic accidents, especially with cooking and heating

Unsafe driving

False accusations

Emotional, irritable outbursts

Tendency to wander

Misplacing or losing items (e.g. keys, money, tablets, glasses)

Muddled on awakening at night

#### 3 Mental state observations

Vague, rambling or disorganised conversation

Difficulty dating or sequencing past events

Repeating stock phrases or comments

Playing down obvious, perhaps serious, problems

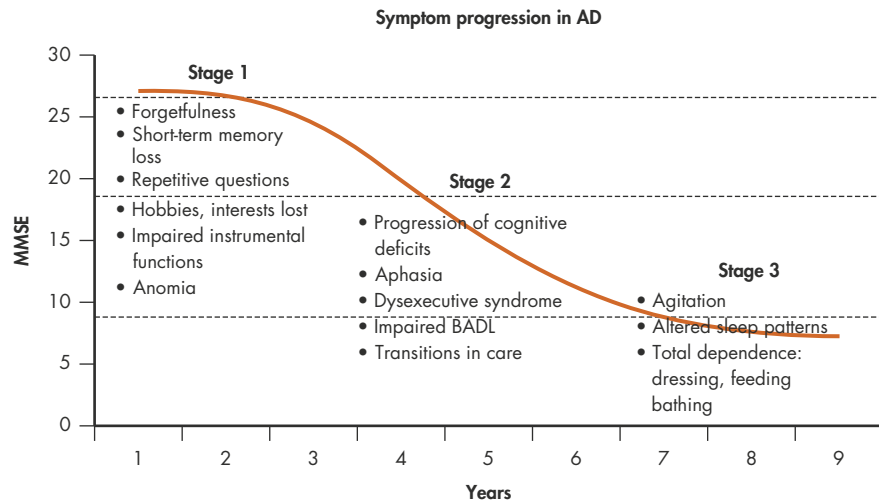

Deflecting or evading memory testing

Source: After McLean<sup>13</sup>

The many guises of dementia can be considered in terms of four major symptom groups:<sup>13</sup>

- 1 Deficit presentations—due to loss of cognitive abilities, including:
  - forgetfulness
  - confusion and restlessness
  - apathy (usually a late change)
  - self-neglect with no insight
  - poor powers of reasoning and understanding
- 2 Unsociable presentations—based on personality change, including:
  - uninhibited behaviour
  - risk taking and impulsive behaviour
  - suspicious manner
  - withdrawn behaviour
- 3 Dysphoric presentations—based on disturbed mood and personal distress, including:
  - depression (hopeless and helpless)
  - irritability with emotional outbursts
  - lack of cooperation
  - insecurity
- 4 Disruptive presentations—causing distress and disturbance to others, including:
  - aggressive, sometimes violent, behaviour
  - agitation with restlessness

The problem occasionally results in marked emotional and physical instability. It is sad and

BADL = basic activities of daily living.

Source: Modified from Feldman et al. *Clinical Diagnosis and Management of Alzheimer's Disease* (1st edn), 1998

**FIGURE 8.5** Symptom progression in Alzheimer disease

difficult for relatives to watch their loved ones develop aggressive and antisocial behaviour, such as poor table manners, poor personal cleanliness, rudeness and a lack of interest in others. Sometimes severe problems, such as violent behaviour, sexual promiscuity and incontinence, will eventuate.

There is always the likelihood of accidents with household items such as fire, gas, kitchen knives and hot water. Accidents at the toilet, in the bath and crossing roads may be a problem, especially if combined with failing sight and hearing. Such people should not drive motor vehicles.

Without proper supervision they are likely to eat poorly, neglect their bodies and develop medical problems, such as skin ulcers and infections. They can also suffer from malnutrition and incontinence of urine or faeces.

### Management of suspected dementia

Exclude reversible or arrestable causes of dementia:

- full medical history (including drug and alcohol intake)
- mental state examination
- physical examination
- investigations (see Laboratory investigations, above, and **CHAPTER 45**)
- psychometric assessment

### Management of dementia

There is currently no cure for dementia—the best that can be offered to the patient is tender, loving care.

Education, support and advice should be given to both patient and family. Multidisciplinary evaluation and assistance are needed. Regular home visits by caring, sympathetic people are important. Such people include relatives, friends, GPs, district nurses, home help, members of a dementia self-help group, religious ministers and meals on wheels. People with dementia tend to manage much better in the familiar surroundings of their own home and this assists in preventing behaviour disturbance.

Special attention should be paid to organising memory aids, such as lists, routines and medication, and to hygiene, diet and warmth. Adequate nutrition, including vitamin supplements if necessary, has been shown to help.

### Driving

Driving is a problem, especially as many are reluctant to give up their licence. Those with mild dementia are more likely to cause road accidents. In some states it is compulsory for doctors to report patients who are unfit to drive. If uncertainties arise or a patient is recalcitrant, refer to the local Road Traffic Authority. In Sweden it is recommended that those with moderate to severe dementia should not drive.

### Comorbidity/associated problems<sup>14</sup>

Depression can occur early in dementia and requires intervention. Demented patients are vulnerable to superimposed delirium, which is often due to:

- urinary tract infection
- other febrile illness

- prescribed medication
- drug withdrawal

Delirium should be suspected if a stable patient becomes acutely disturbed.

### Dementia and Parkinson disease

This is a very difficult yet common problem. One problem is that medication affects the mental processes. The choice of drugs is critical to care, so referral to an experienced team which can provide a good neuropsychiatric assessment is advisable. The best option appears to be the administration of:

- levodopa to maximum dose
- quetiapine at night

### Medication<sup>14</sup>

Demented patients often do not require any psychotropic medication. Antidepressant drugs can be prescribed for depression. The cholinesterase inhibitors donepezil, galantamine and rivastigmine appear to delay progression of dementia to a modest extent only.

### Available drugs for Alzheimer disease

#### Cholinesterase inhibitors

- donepezil 5 mg (o) nocte for 4 weeks, increase to 10 mg nocte as tolerated
- galantamine prolonged release 8 mg (o) daily for 4 weeks, increase to 16 mg daily
- rivastigmine 1.5 mg (o) bd for 2 weeks, increase gradually up to 6 mg bd  
or  
rivastigmine 4.6 mg transdermal daily for 4 weeks, then 9.2 mg daily

#### Aspartate (NMDA) antagonist

- memantine (Ebixa) 5 mg (o) mane for 1 week → 5 mg bd week two → 10 mg bd from week 4

Based on double-blind randomised trials of the two drugs donepezil and rivastigmine and using Cochrane data,<sup>14, 15</sup> the following points emerge:

- only modest improvement overall
- greatest improvement with higher doses
- higher doses less well tolerated
- long-term efficacy unknown
- clinical effectiveness in severe disease has not been demonstrated<sup>16</sup>

The newer agent memantine appears to have similar outcomes and can be used in combination.

Using evidence-based medicine criteria on numbers needed to treat (see CHAPTER 15), the

evidence shows that 13 patients must be treated with rivastigmine 6–12 mg/day for 6 months for one patient to display clinically meaningful improvement.<sup>16,17</sup>

To control psychotic symptoms or disturbed behaviour probably due to psychosis:<sup>14</sup>

olanzapine 2.5–10 mg (o) daily  
or  
risperidone 0.5–2 mg (o) daily

To control symptoms of anxiety and agitation use:

oxazepam 7.5 mg (o) one to three times daily

but benzodiazepines should be used only for short periods (maximum 2 weeks) as they tend to exacerbate cognitive impairment in dementia.

### Complementary therapy<sup>14</sup>

As yet there is insufficient evidence for the efficacy of complementary medicines such as *Ginkgo biloba*,<sup>18</sup> vitamin E<sup>19</sup> and other antioxidants in treating (alleviating symptoms in) dementia, despite some epidemiological evidence, especially in the case of vitamin E. However, we should encourage our patients in preventive healthy lifestyle strategies, such as optimal nutrition rich in essential vitamins and exercise. Deficiencies of folate, vitamin B12 and vitamin D should be treated.

### Dementia prevention strategies

This suggested program is based on the research work of Dr Michael Valenzuela.<sup>20</sup>

- Healthy blood pressure—‘a healthy heart means a healthy brain’—the strongest evidence for dementia prevention.
- The three keys:
  - A physical: walking 30–60 minutes 3–4 times a week, plus strength exercises, balance and stretching exercises—reportedly known to enhance brain cell growth, brain cell interconnections and angiogenesis
  - B mentally stimulating activities
  - C social activities in company that are both fun and rewarding.
- Alcohol control: avoid binge drinking and *always* promote a safe intake, i.e. 1–2 standard drinks with a meal for 3 days a week.
- Diet—Mediterranean in style, oily fish 2–3 times a week (consider Chia seed), 2 fruits and 5 vegetables daily.

## Causes of mild neurocognitive impairment

- Early dementia
- Benign senescent forgetfulness
- Depression
- Anxiety
- Acquired brain injury
- Physical illness

## Benign senescent forgetfulness<sup>21</sup>

This 'popular' term is also referred to as 'age-related memory loss' or 'mild cognitive impairment' of ageing. Features include:

- short-term forgetfulness
- inability to find the right word
- embarrassment about shortcomings
- feeling dithery
- inability to find items stored away
- forgetting to pay accounts

It is debatable whether these are truly benign cognitive impairment or early features of dementia.<sup>22</sup>

## Late life depression and suicide

The risk of suicide increases with age in males. The risk factors for late life suicide are:<sup>23</sup>

- male
- single
- recent bereavement
- social isolation
- recent relocation
- poor pain control
- feeling helpless/hopeless
- anhedonia
- indicating a wish to die
- recent alcohol abuse

The principles of treatment include supportive care, regular visits, CAT team, interpersonal psychotherapy, cognitive behavioural therapy and family support/interventions.

## Paraphrenia<sup>24</sup>

Paraphrenia, known as 'late onset' schizophrenia, is that condition where the symptoms and signs of paranoid psychosis appear for the first time in the elderly. In this apparent non-psychotic mental illness, the patient, who is usually an elderly female,

presents with paranoid delusions, such as a feeling of being watched or persecuted and even hallucinations. These are usually associated with visual and hearing problems. Treatment is with an anti-psychotic agent e.g. risperidone or olanzapine.

## Falls in the elderly

Falls in the elderly are a major problem as 30% of people over the age of 65 experience at least one fall per year, with 1 in 4 of these having significant injury. About 5% of falls result in fracture.<sup>25</sup> In 2002 (in Australia) there were approximately 1200 deaths in people over 75 years following falls.

The main causes are:

- neurological (e.g. cerebrovascular disease)
- sensory impairment (e.g. visual, vestibular)
- cardiovascular (e.g. postural hypotension, dysrhythmias)
- musculoskeletal (e.g. arthritis, foot disorders)
- fluid and electrolyte imbalance
- cognitive and psychological conditions (e.g. dementia, delirium)
- medication/drug related (e.g. sedatives, alcohol)
- physiological changes (e.g. gait disorders)
- environmental factors (e.g. slipping or tripping)
- combinations of the above
- vitamin D deficiency

The most significant clinical risk factors for falls have been shown to be visual impairment, impaired general function, postural hypotension, hearing impairment, low morale/depression, drug usage, especially sedatives, decreased lower limb strength including arthritis, and impaired balance and gait.

## Assessment

The history should embrace the above causes and risk factors. In particular, a description of the fall by a witness, the perceived dysfunction at the time of the fall and whether there was loss of consciousness is particularly important.

The physical examination should include cardiac function, neurological status, including the mini-mental function test, and the musculoskeletal system, including assessment of gait. The 'get up and go' test (see TABLE 8.7) is useful.

As special investigations (especially for those proving difficult to evaluate), consider full blood examination and erythrocyte sedimentation rate (ESR), blood sugar, urea and electrolytes, thyroid function tests, cardiac investigations (e.g. ambulatory electrocardiogram [ECG] monitoring, ambulatory

**Table 8.7** The 'get up and go' test: a brief test of postural competence

- 1 Get up from chair without use of arms.
- 2 Observe normal gait and 360° turn.
- 3 Carry out the Romberg test (slight push with eyes closed).
- 4 Observe tandem walking (heel toe, straight line).

blood pressure monitoring), vestibular function testing, and CT scans or MRI scans.<sup>26</sup>

## Management and prevention

Steps should be taken to correct any medical disorders and risk factors. It is appropriate to refer to a multidisciplinary team that includes occupational therapists and physiotherapists. Assessment of circumstances in the home is very helpful. This may lead to reducing environmental hazards and providing walking aids. Exercise training and medication reduction are also important strategies. (See [www.racgp.org.au/redbook](http://www.racgp.org.au/redbook), section 5.2: Falls and physical activity.)

## Prescribing and adverse drug reactions

Ageing is associated with increased rates of adverse drug reactions.<sup>1</sup> The rate of adverse drug reactions for a single medication rises from about 6% at age 20 years to about 20% at age 70 years.

For fewer than six medications taken concurrently, the rate of adverse drug reactions is about 6%. For more than six medications taken concurrently, the rate of adverse drug reactions jumps to 20%.<sup>1</sup> Approximately 15% of elderly patients admitted to hospital are suffering adverse drug reactions. Most adverse drug reactions are type A (dose related) rather than type B (idiosyncratic).<sup>27</sup>

## Factors predisposing to adverse drug reactions in the elderly<sup>1</sup>

Most adverse drug reactions in the elderly are entirely predictable. Most are merely an extension of the pharmacological action of the drug (e.g. all antihypertensives will reduce blood pressure and have the capacity to cause hypotension and falls in a person with impaired baroreceptor function or poor homeostasis in their vascular tree). Very few adverse reactions are idiosyncratic or unexpected.

The five mechanisms of adverse drug reactions in the elderly are:

- 1 *Drug–drug interaction.* For example, beta blockers given concomitantly with digoxin increases the risk of heart block and bradycardia. Alcohol used in combination with antidepressants increases the risk of sedation.
- 2 *Drug–disease interaction.* For example, in the presence of kidney impairment, tetracyclines carry an increased risk of kidney deterioration.
- 3 *Age-related changes leading to increases in drug plasma concentration.* Decreased kidney excretion can extend the half-life of medication, leading to accumulation and toxicity.
- 4 *Age-related changes leading to increased drug sensitivity.* For example, there is some suggestion that the pharmacological response to warfarin, narcotics and benzodiazepines is increased in the elderly. Conversely, the pharmacological response to insulin, theophylline and beta-adrenergic blocking agents is thought to be decreased.
- 5 *Patient error.* Multiple medications can lead to patient error. The incidence and prevalence of dementia also increases with age. Other problems include failing eyesight and reduced manual dexterity.

## Risk factors predisposing to medicine-related problems

Adverse drug effects in older people are influenced by multiple factors, with many exposed to more than one of these factors at a given time. Furthermore, their recovery from serious incidents such as a hip fracture is jeopardised, possibly ending in death.

Increasing the number of simultaneous medications increases the risk for all five mechanisms of adverse drug reactions.

In a study on adverse drug reaction in elderly patients the drugs most frequently causing admission to hospital were:<sup>28</sup>

- digoxin
- diuretics
- antihypertensives (including beta blockers)
- psychotropics and hypnotics
- analgesics and NSAIDs

The same study showed that drugs regularly prescribed without revision were:

- barbiturates
- benzodiazepines
- antidepressants
- antihypertensives
- beta blockers
- digoxin
- diuretics

Drug regimens should be kept as simple as possible to aid compliance and avoid or minimise drug interactions.

The elderly may need much lower doses of anxiolytics and hypnotics than younger patients to produce the same effect, thus rendering them more susceptible to adverse effects and toxicity. The elderly are especially liable to accumulate the longer-acting benzodiazepines.

In particular, any drug or combination of drugs with anticholinergic properties (e.g. tricyclic antidepressants, anti-Parkinsonian agents, antihistamines, phenothiazines and some cold remedies) can precipitate a central anticholinergic syndrome.<sup>13</sup>

The elderly are very prone to adverse effects to most of the more potent drugs, especially those for cardiac dysfunction and hypertension. Both ACE inhibitors and calcium-channel blockers have been shown to produce a greater fall in blood pressure in elderly compared with younger subjects, presumably related also to a reduced homeostatic response.<sup>27</sup>

### Practice tip

Beware of the 'triple whammy': ACE inhibitor + diuretic + NSAID.

8

## Starting medications<sup>14</sup>

The starting dose of a drug in the aged<sup>13</sup> should be at the lower end of recommended ranges. Dosage increments should be gradual and reviewed regularly.

That is, start low, go slow and monitor frequently. It is important to individualise doses for the elderly with the simplest dosage regimen.

## Minimising medication problems

- Write simple instructions on all prescriptions.
- Individualise doses for the elderly.
- Give patients a list of their medications.
- Ask them to bring the list and their medications at each visit.
- Update this list as necessary.
- Keep medication regimen as simple as possible.
- Consider a Dosette box or Webster pack for polypharmacy.
- At home visits use the opportunity to inspect medications.
- Observe for drug interactions and toxicity.
- Keep detailed records of all medications prescribed.

- Carefully review medication after discharge from hospital.

## Other tips for medication in the elderly

- Obtain relatives/carers' consent for medication, especially in the confused.

*When meditating over a disease, I never think of finding a remedy for it, but, instead, a means of preventing it.*

Louis Pasteur 1884

## Definitions<sup>1</sup>

*Prevention* may be defined as the means of promoting and maintaining health or averting illness.

It is concerned with removal or reduction of risks; early diagnosis; early treatment; limitation of complications, including those of iatrogenic origin; and maximum adaptation to disability.

The promotion of health concerns helping well people to learn healthy behaviours and to accept responsibility for their own well-being.

A preventive attitude implies that the doctor understands and can utilise the preventive potential in each primary care consultation by an 'opportunistic approach'. In addition to the traditional management of both presenting and continuing problems, the doctor takes the opportunity to modify the patient's health-seeking behaviour, to provide education about the illness, and to promote health by relating the patient's present condition to previous unhealthy behaviour.

A general reference for prevention is the RACGP red book—*Guidelines for Preventive Activities in General Practice* (8th edition). (See [www.racgp.org.au/your-practice/guidelines/redbook](http://www.racgp.org.au/your-practice/guidelines/redbook).)

## Primary prevention

*Primary prevention* includes action taken to avert the occurrence of disease. As a result there is no disease. Primary preventive strategies include:

- 1 education to bring about changes in lifestyle factors known to be associated with diseases (e.g. smoking cessation, healthy balanced diets, reduction in alcohol intake, exercise)
- 2 sterilisation of surgical instruments and other medical equipment
- 3 eradication, as with vector control of mosquitoes to prevent malaria
- 4 immunisation against infective diseases
- 5 sanitation, keeping our water supplies clean and disposing efficiently of sewage and industrial wastes
- 6 legislation to ensure that some of these primary preventive measures are carried out

## Secondary prevention

*Secondary prevention* includes actions taken to stop or delay the progression of disease.

The term is usually applied to measures for the detection of disease at its earliest stage, i.e. in the presymptomatic phase, so that treatment can be started before irreversible pathology is present. The early recognition of hypertension through routine testing (screening) of patients allows treatment during the presymptomatic phase of the illness process. Screening for cervical cancer allows the treatment of cervical dysplasia, a premalignant condition. Other examples include mammography and endoscopy for polyps of the large bowel.

## Tertiary prevention

*Tertiary prevention* includes the management of established disease so as to minimise disability.

The term is usually applied to the rehabilitation process necessary to restore the patient to the best level of adaptation possible when there has been damage of an irreversible nature. A patient who has suffered a stroke because of hypertension may be restored to a useful lifestyle with appropriate rehabilitation.

## Relationship between types of prevention

It can be seen that there is a clearer demarcation between primary and secondary prevention than between secondary and tertiary prevention, although the latter term is particularly useful in dealing with the elderly and the handicapped. Conceptually, curative medicine falls within the definitions of secondary and tertiary prevention while public health measures are mainly concerned with primary prevention. Prevention is really wider than medical practice but because of the success of public health practices in the past, more attention is now being focused on prevention by doctors (see FIG. 9.1).<sup>2</sup>

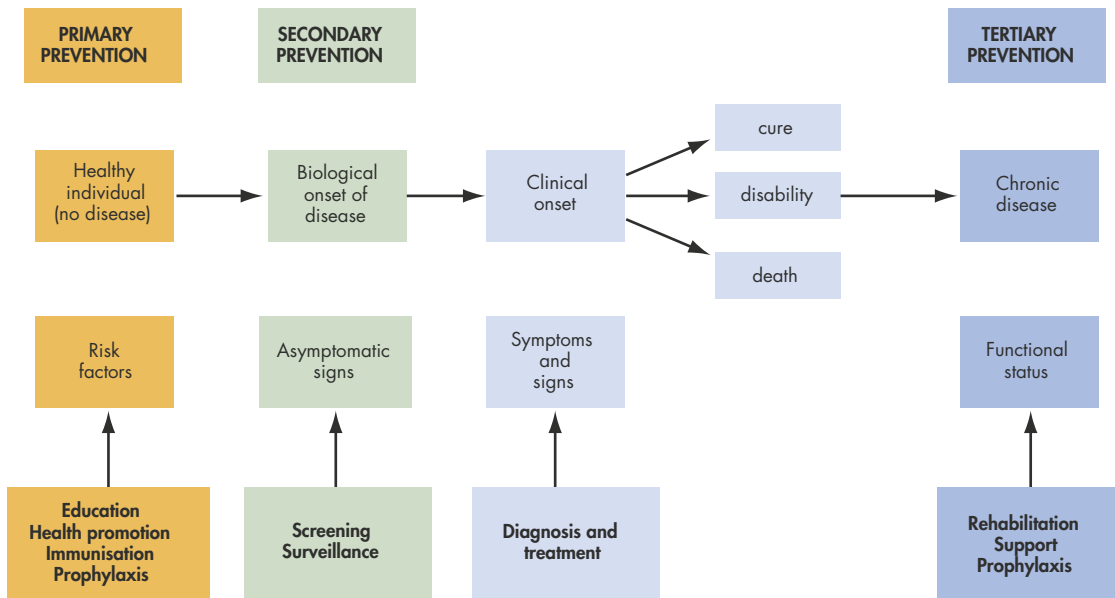

FIGURE 9.1 The phases of prevention in relation to the natural history of disease

As GPs our role in prevention is twofold.

- 1 First, we can recognise the preventable factors that are involved in an illness process and determine appropriate interventions.
- 2 Second, we can act to implement the preventive measure. In cases where the responsibility rests with the individual or the community, doctors can support prevention through education, applying political pressure or working with community agencies.

- addictions
- behavioural disorders
- occupational disorders
- premature vascular disease
- neoplasms
- handicap in the disabled
- certain 'other' diseases (e.g. diverticular disease)

Mortality is the only reliable index by which the outcome of preventive activities can be judged. Conditions can be ranked in importance as causes of premature death according to the 'person-years of life lost before 70 years' as follows:<sup>1</sup>

• Accidents, poisoning and violence	29%
• Neoplasms	19%
• Circulatory diseases	17%
• Perinatal conditions	10%
• Congenital conditions	7%

## The practice of preventive medicine

What is preventable?

The first step in the implementation of prevention is to define which specific diseases can be prevented and to what extent, given certain restraints such as human resources, technology and the cost to the community. All diseases have a potential preventability but it may be unrealistic to try to achieve this.

Diseases that can be prevented can be grouped according to their aetiology. They fall into the following broad categories:

- genetic disorders
- conditions occurring during pregnancy and the puerperium
- developmental disorders
- accidents
- infections

This gives quite a different perspective to prevention and explains why the efforts of public health authorities and practising doctors do not always coincide.

The interventions available to us in medical practice are as follows:

- 1 educational—health promotion, health education and illness education
- 2 screening
- 3 surveillance

- 4 interventional care—immunisation, behaviour modification and drug prophylaxis
- 5 rehabilitation

## Optimal opportunities for prevention

Primary prevention par excellence can be practised in general practice under the opportunities provided by the following clinical circumstances:

- antenatal care
- postnatal care
- advising people travelling overseas
- visits by infants with their parents
- times of crisis or potential crisis
- the premarital check-up

The Royal College of General Practitioners (UK) has identified the seven most important opportunities for prevention as:

- 1 family planning
- 2 antenatal care
- 3 immunisation
- 4 fostering the bonds between mother and child
- 5 discouragement of smoking
- 6 detection and management of raised blood pressure
- 7 helping the bereaved

## Mortality and morbidity considerations

An understanding of the mortality and morbidity patterns in the modern human being is essential to the planning of preventive programs. The great infectious diseases of the past, such as tuberculosis, syphilis, smallpox, influenza, diphtheria and streptococcal infections, have been largely contained but other diseases have become prominent as life expectancy increases. The great modern diseases are atherosclerosis (hardening of the arteries), malignant disease (cancer), HIV infection and iatrogenesis (doctor-induced illness). The two most common causes of death in Australia are cancer and cardiovascular disease, each accounting for approximately 29% of all deaths.<sup>3</sup>

By comparison, the ten leading causes of death in the world are (in order) ischaemic heart disease, stroke, lower respiratory tract infection, COPD, diarrhoeal disease, HIV/AIDS, cancer, diabetes mellitus, road injury and prematurity (WHO: Fact sheet 310; July 2013).

These diseases and the common causes of mortality (see TABLE 9.1) act as a focus for our energies in addressing preventive programs.

**Table 9.1** Common causes of deaths in Australia in 2012 (in rank order)

1	Ischaemic heart disease
2	Cerebrovascular disease
3	Dementia/Alzheimer disease
4	Tracheal, bronchial and lung cancer
5	Chronic lower respiratory disease
6	Diabetes mellitus
7	Colorectal cancer
8	Blood and lymph cancer
9	Diseases of the urinary system
10	Heart failure
11	Prostate cancer
12	Breast cancer
13	Influenza and pneumonia
14	Suicide, intentional self-harm

Source: Australian Bureau of Statistics, *Year Book Australia*, 2012

It is worth focusing on the changes in disease indices during the past generation in order to evaluate the effect of preventive and health promotion programs during this period (see TABLE 9.2).<sup>3</sup> The messages are to harness and promote with renewed vigour those strategies that are working, such as prevention of death from coronary artery disease and motor vehicle accidents, and to re-evaluate those important areas, such as Aboriginal mortality, HIV infection, cancer, suicide and asthma, which are bad news!

## A global strategy for good health

The World Health Organization (WHO) defines good health as 'a state of dynamic harmony between the body, mind and spirit of a person and the social and cultural influences which make up his or her environment'.

A considerable amount of epidemiological information has emerged to support what GPs have known for a long time—that a commonsense, healthy lifestyle not only promotes good health but also reduces the risk of the main causes of mortality and morbidity in this country, including cardiovascular disease and cancer.

The common theme for virtually all disease is to follow the nutrition and lifestyle guidelines presented in CHAPTER 10.

**Table 9.2** Major changes in public health in Australia, with trends in the two decades up to 2012

Improvements	Deterioration
Overall mortality	Cancer (overall)
Heart disease	Alcohol-related diseases
Stroke	Drug abuse
Smoking	Dementia
Road safety	Depression, mental health
Diseases controlled by immunisation	Health inequalities
Dental health	Obesity
Cancer	Diabetes
• cervix	Arthritis/musculoskeletal problems
• stomach	Fall injuries
• breast	Environmental pollution problems
• testis	
• colorectal	
Pregnancy complications	
Congenital abnormalities	
HIV/AIDS	

Source: G Egger, R Spark, I Donovan, *Health Promotion Strategies and Method*. Sydney: McGraw-Hill; 2013: 8<sup>4</sup>

## Behaviour modification

Lifestyle habits that have developed over many years can be very difficult to change even when the individual is well motivated to change. A variety of instructional, motivational and behavioural techniques can be used to initiate a lifestyle change program; GPs should be aware of these and use the resources of a multidisciplinary team to give support to motivated people who as a rule find behaviour modification difficult.

## Vascular disease

Risk factors for vascular disease (atherosclerosis) are:

- hypertension
- smoking
- high cholesterol
- diabetes
- obesity
- sedentary lifestyle
- stress
- alcohol excess
- poor diet
- family history

The guidelines for good health given in **CHAPTER 10**, if followed, will help prevent the development of cardiovascular and cerebrovascular disease.

It is worth noting that the death rate from coronary heart disease is about 70% higher for smokers than for non-smokers and for very heavy smokers the risk is almost 200% higher. It has been shown that the incidence of heart disease falls in those who have ceased smoking.

GPs can estimate the absolute 5-year risks of cardiovascular events in their patients by referring to the New Zealand Guidelines Group Cardiovascular Risk Charts ([www.nzgg.org.nz](http://www.nzgg.org.nz)).

The parameters used are:

- gender and age
- smoking status
- diabetes status
- blood pressure
- total cholesterol/HDL ratio

## Malignant disease

Primary prevention of cancer is an important objective and there is a need to focus on this vital factor as much as on secondary prevention. The interesting statistics on the 5-year survival rate for specific cancers are shown in **TABLE 9.3**.

That environmental factors are involved in the aetiology of colorectal cancer and other cancers is indicated by wide variations in incidence between different countries.

Suspicion falls on diet and there is epidemiological evidence implicating diets high in animal fats and low in insoluble fibre, fruits and vegetables, and also high alcohol consumption. It is noted that there are higher incidence rates in people migrating from low- to high-risk countries, such as Japanese to Hawaii<sup>5</sup> and Greeks and Italians to Australia.<sup>5</sup>

Studies in the US indicate that at least 35% of all cancer deaths are related to diet. Obese individuals have an increased risk of colon, breast and uterine cancers. High-fat diets are a risk factor for prostate, breast and colon cancers. Salt-cured, smoked and nitrate-cured foods increase the risk of upper GIT cancers. Foods rich in vitamin A and folate (dark green and deep yellow vegetables and fruits) and vitamin C and cruciferous vegetables (cabbage, Brussels sprouts, broccoli and cauliflower) are all

**Table 9.3** Cancer prognosis in Australia: 5-year survival (for cancer diagnosed 2003–2007)

Cancer	Male %	Female %
Melanoma—skin	88.8	93.9
Hodgkin lymphoma	85.1	87.8
Non-Hodgkin lymphoma	69.0	69.7
Kidney	70.6	70.2
Bowel	64.1	65.6
Stomach	25.6	26.0
Lung	11.9	15.6
Pancreas	4.8	5.3
Prostate	91.5	
Testis	97.4	
Breast		89.1
Cervix		72.3
All cancer	65.1	67.4

Source: Cancer Council of Australia ([www.cancer.org.au/about-cancer](http://www.cancer.org.au/about-cancer))

considered to have protective effects for various cancers.<sup>6,7</sup> Phytochemicals (plant chemicals) exist in these foods and in other vegetables and fruit that have a cancer-protective effect.<sup>8</sup>

Overall, diet, smoking, alcohol and occupational exposures (5%) appear to account for over 73% of all cancer mortality.<sup>7</sup>

Doll and Peto<sup>9</sup> considered that environmental factors were responsible for 80–90% of cancers and estimated that diet was a major factor in the cause of cancer in 40% of men and 60% of women.

## The role of immunity in cancer

The development of a number of cancers appears to be related to a depression of the individual's immune system, particularly in relation to cellular immunity, in a similar way (albeit on a different scale) to the effect of HIV infection. Studies have shown that the immune system is adversely influenced by:<sup>10</sup>

- stress, especially bereavement
- depression
- ageing
- drugs
- pollutants
- cigarette smoke
- inappropriate diet

- alcohol
- radiation

On the other hand, a protective effect on the immune system may be provided by:

- food antioxidants (see **TABLE 10.2** in **CHAPTER 10**)
- tranquillity
- meditation

In some instances malignancies appear to undergo unpredictable remissions with patients following an optimal diet, taking antioxidants, changing their lifestyle and practising meditation. However, an Australian study indicated that the enthusiasm for the value of antioxidants may be unjustified (see **CHAPTER 10**).

Diet certainly appears to be a most important factor in the primary prevention of disease. If immune deficient diseases can respond in such a way, imagine what a powerful primary preventive force such a lifestyle represents for all disease.

## Asthma and other respiratory diseases

The death rate and morbidity rate for asthma and other respiratory diseases is unacceptable and much of it can be prevented.<sup>11</sup> A report on the cost of asthma claimed that there is evidence that a significant proportion of diagnosed asthmatics are currently receiving treatment that does not provide the best possible control of the disease.<sup>11</sup>

Prevention means being better informed and treating such an 'irritable' disease as bronchial asthma aggressively. It means focusing on better assessment and monitoring (e.g. home use of the mini peak flow meter), better delivery of medication to the airways (e.g. use of spacers attached to inhalers and/or use of pumps and nebulisers) and appropriate management of the cause (inflammation of the bronchial tree) by the use of inhaled corticosteroids or sodium cromoglycate as the first-line treatment for significant asthma. An appropriate strategy is to follow the six-step asthma management plan (see **TABLE 9.4**) of the National Asthma Campaign.

The protective effect for asthma and COPD of vitamin C, fish oils, a low-salt diet and other natural antioxidants is highlighted by Sridhar.<sup>12</sup>

## Periodic health examination

Since 86% of the population visit a GP at some stage of the year,<sup>3</sup> and these people visit about five times each year (on average), GPs are in an ideal position to develop strategies for a periodic health examination.

**Table 9.4** The six-step asthma management plan

- 1 Establish the severity of the asthma.
- 2 Achieve best lung function.
- 3 Maintain best lung function—identify and avoid trigger factors.
- 4 Maintain best lung function—follow an optimal medication program.
- 5 Develop an action plan.
- 6 Educate and review regularly.

Source: National Asthma Campaign: Australia, 2008

An emphasis should be placed on the history in addition to the physical examination and related basic investigations.

As for any smooth-running quality professional program, it is important to be organised with prepared practice staff, checklists and record systems. The Royal Australian College of General Practitioners (RACGP) has developed a College Record System, which has several leaflets covering all approaches to the patient 'check-up'.<sup>13</sup>

The following guidelines for the periodic health examination are adapted from those recommended by the Preventive and Community Medicine Committee of the RACGP.<sup>13</sup> This represents appropriate screening at the front line of primary health care.

## Aims of screening

In practice, screening is not only to detect disease at its earliest stage, but also to find individuals at risk or those with established disease who are not receiving adequate care. There are three levels at which screening practice can be applied in general practice:

- 1 'well' individuals with risk factors that predispose to disease (e.g. obesity, uncomplicated essential hypertension, hyperlipidaemia)
- 2 asymptomatic individuals with signs of early disease or illness (e.g. developmental dysplasia of the hip, ectopic testis, glaucoma, bacteriuria of pregnancy, carcinoma in situ of cervix)
- 3 symptomatic individuals whose irreversible abnormalities are unreported but the effects can be controlled or assisted (e.g. visual defects, deafness, mental handicap).

## The history<sup>13</sup>

An appropriate history will allow the recognition of certain risk factors that may foreshadow future

disease. Though established patients will have a previously acquired database, their history should be reviewed and updated. It is recommended that the following items be included in history taking in the appropriate age groups.

*Family history.* In particular, cardiovascular disease, some cancers (breast, bowel, melanoma with dysplastic naevi), diabetes, asthma, genetic disorders and bowel disease will alert the doctor to specific risk factors (and psychological factors) for these patients.

*Suicide and accidents.* Consider the risk factors predisposing to suicide and accidents, which are the major preventable causes of death in children and young adults.

*Substance abuse.* Tobacco and alcohol are the major causes of preventable death in adults, although other drugs contribute to a lesser extent. Counselling by GPs, about smoking in particular, has been shown to be effective.

*Exercise and nutrition.* These factors have a role to play in preventing cardiovascular disease and to a lesser extent in blood pressure control, cancer, diabetes and constipation. They have an even greater role to play in improving general well-being and preventing morbidity.

*Occupational health hazards.* Consider these in working adults, as occupational health hazards can significantly contribute to morbidity and mortality (e.g. exposure to toxic substances, unsafe work practices). Specific examples include:

- coal miners—pneumoconiosis
- gold, copper and tin miners—silicosis
- asbestos workers and builders—asbestosis, mesothelioma
- veterinarians, farmers, abattoir workers—zoonoses
- aniline dye workers—bladder cancer
- health care providers—hepatitis B

*Physical functioning, home conditions and social supports.* Consider these in elderly people, as physical function and social supports are of crucial importance in determining whether they can care for themselves—intervention can prevent accidents and death.

*Sexuality/contraception.* Sexually transmitted infections are all preventable, as are unwanted pregnancies. Opportunities should be sought to ask young people, in particular, about their sexuality, and to counsel them. The question 'Do you have any concerns about sex?' is very useful in this context.

*Osteoporosis.* Osteoporosis affects nearly a third of all postmenopausal women, most of whom suffer

osteoporotic fractures. Fractures of the femoral neck have a particularly poor prognosis, with up to a third of these women dying within 6 months, and many more requiring continuing nursing home care. Bone loss accelerates at the time of the menopause, and can be reduced by hormone replacement therapy.

Women at risk of osteoporosis are short, slim, Caucasian; they drink coffee and alcohol, smoke, eat a high-protein and high-salt diet, and don't exercise.

*Masquerades in general practice.* It is worth considering the 'masquerades' (see CHAPTER 17, TABLES 17.4 AND 17.5), which may present as undifferentiated illness, as a means of following the important medical principle of early detection of disease: engendering a certain awareness.

Primary masquerades to consider are:

- depression
- diabetes mellitus
- drug problems
- anaemia
- thyroid disorders, especially hypothyroidism
- urinary tract infection
- vertebral (spinal) dysfunction

Hypothyroidism has been estimated to exist in up to 15% of women aged 60 and above, and searching for clues may elicit subtle symptoms and signs previously attributed to ageing.

*Relationships and psychosocial health.* Consider the mental health of patients, particularly the elderly, by enquiring about how they are coping with life, how they are coping financially, about their peace of mind and how things are at home. Focus on the quality of their close relationships (e.g. husband–wife, father–son, mother–daughter, employer–employee). Enquire about losses in their life, especially family bereavements.

## Screening for children<sup>13</sup>

Childhood health record books provide an excellent opportunity for communication between different health care givers; parents should be provided with the record books and encouraged to bring them to every visit. Various recommendations for screening are made under the following headings.

*Height/weight/head circumference.* Record height from age 3 and weight at regular intervals to age 5 years. Calculate the BMI. Record head circumference at birth and then up to 6 months. The adequacy of a child's growth cannot be assessed on one measurement and serial recordings on growth charts

are recommended. Head circumference recordings may provide further data about a child's growth.

*Hips.* Screen for congenital dislocation at birth, 6–8 weeks, 6–9 months and 12–24 months (see CHAPTER 65).

The flexed hips are abducted, checking for movement and a 'clunk' of the femoral head forwards (the test is most likely to be positive at 3–6 weeks and usually negative after 8 weeks). Shortening or limited abduction is also abnormal. Ultrasound examination is more sensitive than the clinical examination especially up to 3 to 4 months. Observe gait when starting to walk.

*Strabismus.* Strabismus should be sought in all infants and toddlers by occlusion testing (not very sensitive), examining light reflexes and questioning parents, which must be taken very seriously. Amblyopia can be prevented by early recognition and treatment of strabismus by occlusion and surgery. Early referral is essential.

*Visual acuity.* At birth and 2 months, eyes should be inspected and examined with an ophthalmoscope with a 3+ lens at a distance of 20–30 cm to detect cataracts and red reflexes. At 9 months gross vision should be determined by assessing ability to see common objects. Visual acuity should be formally assessed at school entry using Sheridan Gardiner charts.

*Hearing.* Hearing should be tested by distraction at 9 months or earlier; also by pure tone audiometry at 1000 and 4000 hertz when a child is 4 years (preschool entry) and 12 years.

*Note:* Formal audiological evaluation should be carried out at any time if there is clinical suspicion or parental concern. No simple screening test is very reliable for sensorineural or conductive deafness.

*Testes.* Screen at birth, and 6–8 weeks, 6–9 months and 3 years for absence or maldescent. Those who have been treated for maldescent have a higher risk of neoplastic development in adolescence.

*Oral health/dental assessment/fluoride.* Advise daily fluoride drops or tablets, if water supply is not fluoridated. Children's teeth should be checked regularly, particularly if a school dental service is not available. Advice should be given on sugar consumption, especially night-time bottles, and tooth cleaning with fluoride toothpaste to prevent plaque.

*Scoliosis.* Screening of females by the forward flexion test, which is carried out around 12 years of age, is of questionable value because of poor sensitivity and specificity.

*Congenital heart disease.* The heart should be auscultated at birth, in the first few days, at 6–8 weeks and on school entry.

**Femoral pulses.** Testing for absence of femoral pulses or delay between brachial/femoral pulses at birth and 8 weeks will exclude coarctation of the aorta. Refer the child immediately if concerned.

**Speech and language.** A child's speech should be intelligible to strangers by 3 years. It is related to hearing.

## General development

Apart from speech and language, check social and emotional development, toilet habits, behaviour and mood.

This includes 'parents' evaluation of developmental status' (PEDS) (see [www.pedstest.com](http://www.pedstest.com); [www.rch.org.au/ccch](http://www.rch.org.au/ccch)).

For general checklists, see [www.cdc.gov/actearly](http://www.cdc.gov/actearly). Be alert to the 'Red flags' of autism spectrum disorder (see CHAPTER 94).

## Screening in the elderly

Refer to CHAPTER 8.

## Screening for adults<sup>13</sup>

The following recommendations apply for adults.

**Weight.** Weight should be recorded at least every few years. Obesity is a major reversible health risk for adults, contributing to many diseases (e.g. heart disease, diabetes, arthritis). Body mass index (BMI) should ideally be between 20 and 25.

$$\text{BMI} = \text{weight (kg)} \div \text{height (m}^2\text{)}$$

Abdominal obesity is a major risk factor for adults. The waist:hip circumference ratio is regarded as a useful predictor of cardiac disease. Recommended waist:hip ratios are:

- males <0.9
- females <0.8

**Blood pressure.** Blood pressure should be recorded at least every 1–2 years on all people 16 years and over. There is no dispute that control of blood pressure results in reduced mortality from cerebrovascular accidents and, to a lesser extent, heart disease, kidney failure and retinopathy.

**Cholesterol.** All adults aged 45 and over should have a 5-yearly estimation of serum cholesterol. Total cholesterol is adequate for screening purposes. HDL levels give additional information. The National Heart Foundation recommends keeping cholesterol levels below 4.0 mmol/L. For most, dietary modification is sufficient to achieve these levels; some may require drug treatment.

**Fasting blood glucose.** Screen every 3 years for all patients >40 years of age.

**Cervical cancer.** Women aged 18–70 who have ever been sexually active should have a Pap test every 2 years, or HPV testing according to recommended national screening guidelines. Those over 70 who have never been screened should have two successive tests before screening is ceased. After consideration of the relative risks to the individual woman, she and her physician may choose to increase the interval between tests, but the interval should not be greater than 3 years.

Risk factors include:

- all women who are or ever have been sexually active
- early age at first sexual intercourse
- multiple sexual partners
- genital wart virus infection
- cigarette smoking
- use of combined oral contraception >5 years
- those with LSIL and HSIL on Pap tests

**Breast cancer.** Mammography should be performed at least every 2 years on women aged 50–70 years. It is not useful for screening prior to age 40 years due to difficulty in discriminating malignant lesions from dense tissue. Women aged 40 to 49 years may also choose to have a mammogram.<sup>13</sup> Mammography must not be used alone to exclude cancer if a lump is palpable. Such lesions require a complete appraisal since, even in the best hands, mammography still has a false-negative rate of at least 10%. Genetic testing should be considered in those at risk.

**Colorectal cancer (CRC).** A history should be taken, with specific enquiry as to family history of adenomas or colorectal cancer, past history of inflammatory bowel disease and rectal bleeding. Rectal examination should be performed as part of an examination. Faecal occult blood testing (FOBT) every 2 years is now recommended for screening for people over 50 years without symptoms and with average or slightly above average risk.

Should a positive history be elicited, then the following are recommended:

- past history of large bowel cancer or colonic adenomas—colonoscopy
- past or present history of ulcerative colitis—colonoscopy with biopsies
- familial polyposis, Gardner syndrome—sigmoidoscopy or colonoscopy

Prophylactic colectomy needs consideration in some individuals.

Apart from FOBT screening, the National Health and Medical Research Council (NHMRC) currently recommends 2-yearly colonoscopy for people from 25–30 years of age if there is a family history on the same side of the family of:

- three or more first or second degree relatives with CRC at any age
- two or more first or second degree relatives diagnosed as CRC <50 years of age
- a family member where genetic studies identify a high risk

Refer to the RACGP *Guidelines for Preventive Activities in General Practice*<sup>13</sup> for further information.

Genetic testing should be considered in those at risk.

**Prostate cancer.** Screening is controversial. The RACGP guidelines do not recommend routine screening with DRE, PSA or transabdominal ultrasound. Patients should make their own decision after being fully informed of the potential benefits, risks and uncertainties of testing. Doctors should also use their clinical judgment for their individual male patients.

**Skin cancer.** All patients should be informed regularly about the need for protection of the skin and eyes from ultraviolet (UV) radiation, using hats, clothing, sunglasses and sunscreens, and avoiding exposure during peak UV periods (10 am to 3 pm).

Skin cancer, which is increasing in incidence, is common in Australia, particularly in more northern areas. Squamous cell carcinoma, and melanoma in particular, may be lethal. Detection and treatment of early lesions prevents mortality and morbidity. Prevention of skin cancer by reduction of sun exposure should be taught to all patients.

**Oral hygiene/cancer.** Patients should be counselled about cessation of smoking and alcohol consumption, and dental hygiene should be taught. The oral cavity should be inspected annually in patients over the age of 40 years.

Although oral cancer has a relatively low incidence, premalignant lesions may be detected by inspection of the oral cavity. Its incidence is highest in elderly people with a history of heavy smoking or drinking. Poor dental hygiene may result in poor nutrition, particularly among the elderly.

*Cancer screening in summary*<sup>13</sup>

- Screen for breast, cervical and colorectal cancer.
- Routine population-based screening is at this stage of evidence not recommended for lung, melanoma, ovarian, prostate and testicular cancers.

## Immunisation

Basic diseases (diphtheria, tetanus, polio, whooping cough, measles, mumps, rubella) should be covered. Children and adolescents should be immunised according to the current NHMRC recommended standard vaccination schedule ([www.immunise.health.gov.au](http://www.immunise.health.gov.au)).

*Special considerations.* The NHMRC endorses hepatitis B vaccine for all infants and pre-adolescents (three doses). It also advises against injections into the buttock (challenged by many), preferring the anterolateral thigh for children under 12 months with the deltoid region being an alternative in older children and adults. The recommended needle is 23 gauge, 25 mm long. Do not postpone immunisation for minor illnesses such as mild URTI. Acellular pertussis vaccine, which reduces the risk of reactions, has become a standard component of triple antigen.

All adults should receive an adult diphtheria and tetanus (ADT) booster *each* 10 years.

All women of child-bearing years should have their rubella antibody status reviewed.

**Table 9.5** National Immunisation Program Schedule<sup>14</sup> (as from July 2013)

Age	Immunisation
Birth	Hepatitis B
2 months	DTP, Hib, hepatitis B, polio, pneumococcus, rotavirus
4 months	DTP, Hib, hepatitis B, polio, pneumococcus, rotavirus
6 months	DTP, polio, Hib, pneumococcus and hepatitis B (or at 12 months), rotavirus
12 months	Measles/mumps/rubella (MMR), Hib, meningococcus C and hepatitis B (or at 6 months)
18 months	Varicella, pneumococcus (ATSIP), measles, mumps, rubella (MMR)
4 years	DTP, polio, MMR (if not given at 18 months)
School programs 10–15 years (contact state authorities)	HPV, varicella, DTP (adult), hepatitis B

Hib = Haemophilus influenza type b

HPV = human papilloma virus

DTP (triple antigen) = diphtheria, tetanus, pertussis

ATSIP = Aboriginal and Torres Strait Islander People

## Adverse effects of vaccination

Common adverse effects are irritability, malaise, fever and a local reaction to the injection. There is a very small risk of anaphylaxis. It is advisable to wait 15–30 minutes for observation after vaccination. Paracetamol is recommended for fever and local pain; however, routine use at the time of or immediately after vaccination is not recommended.<sup>14</sup>

**Fever and illness.** Children with minor illness (providing the temperature is  $<38.0^{\circ}\text{C}$ ) may be vaccinated safely. Otherwise it should be delayed. A simple past febrile convulsion or pre-existing neurological disease is not a contraindication to pertussis vaccination. Absolute contraindications include encephalopathy within 7 days of a previous DTP or an immediate severe or anaphylactic reaction to DTP.

**Influenza.** Influenza immunisation is recommended on an annual basis for persons of all ages with chronic debilitating diseases, especially chronic cardiac, pulmonary, kidney and metabolic diseases, persons over 65 years of age, Indigenous Australian adults over 50 years of age and persons receiving immunosuppressant therapy. Health care personnel may wish to consider it for their own use.

**Pneumococcal disease.** This should be considered for the same risk groups as influenza vaccine. Those at higher risk of fatal pneumococcal infection (e.g. post-splenectomy or Hodgkin lymphoma), should receive a booster every 5 years. This is currently provided for all children.

**Hepatitis A.** Immunisation is recommended for:

- certain occupational groups at risk (e.g. health workers, child care workers, sewage workers)
- non-immune homosexual men

- those with chronic liver disease
- recipients of blood products
- travellers to hepatitis A endemic areas

**Hepatitis B.** Immunisation is recommended routinely for all children at birth, 2 months, 4 months and at either 6 or 12 months, and for individuals of all ages who, through work or lifestyle, may be exposed to hepatitis B and have been shown to be susceptible. Such groups would include health care personnel, personnel and residents of institutions, prisoners and prison staff, persons with frequent and/or close contact with high-risk groups, and persons at increased risk due to their sexual practices. Household contacts of any of the above groups should be considered for immunisation. Booster doses are not recommended for immunocompetent people but are recommended for immunosuppressed individuals. Universal vaccination represents a preventive step against hepatocellular cancer.

**Haemophilus influenza type b.** Hib immunisation is recommended for all children, especially those in child care. It is ideal to achieve immunity by the age of 18 months and preferably commencing at 2 months. Risk factors for Hib disease include day care attendance, presence of ill siblings under 6 years of age in the home and household crowding.

**Q fever.** People at reasonable risk from Q fever, particularly abattoir workers, should be given this vaccine, which is virtually 100% effective.

**Measles-mumps-rubella.** Both females and males should be immunised against measles, mumps and rubella at the age of 12 months and 4–5 years using the trivalent vaccine. All non-immune women who are postpartum or of child-bearing age should be immunised.

**Varicella vaccine.** This is available and one dose is given at 18 months. Those over 12 years have a course of two injections.

**Meningococcal vaccine.** Meningococcal disease is caused by *Neisseria meningitidis*, which has 13 serogroups of which A, B and C account for over 90% of isolated cases, with serogroup B responsible for most cases. A vaccine against serogroup B is available but not yet as part of the recommended schedule as evaluation studies are being assessed. The main vaccine that is available is a quadrivalent polysaccharide vaccine against serogroups A, C, Y and W135 for use in individuals over 2 years as a single injection. Universal prevention by immunisation remains unsatisfactory. It is most useful when a community outbreak due to proven serogroup C occurs.

**Rotavirus.** A course of three oral live attenuated rotavirus vaccines is given to children to cover a common

**FIGURE 9.2** Immunisation of an older child: important continuing preventive care

cause of childhood gastroenteritis. Inform parents of the risk of intussusception with the first dose.

*Human papilloma virus.* A course of three injections is given to Year 7 (or equivalent) schoolgirls (and boys in some states), although this is recommended for all females from 9–26 years.

*On the 20th of May 1747 on board the Salisbury at sea I took 12 patients in the scurvy with putrid gums, the spots and lassitude and weakness of their knees. They had a common diet—two were ordered a quart of cyder a day—two, elixir vitriol three times a day—two, 2 spoonfuls of vinegar three times a day—two were put on a course of sea water—two had 2 oranges and one lemon each day—two, nutmeg, garlic and other additives to barley water. The consequence was, that the most sudden and visible good effects were perceived from the use of the oranges and lemons with one being at the end of 6 days fit for duty.*

James Lind 1747, A (Summarised) *Account of Scurvy*

Good nutrition is fundamental to good health. It influences management in all branches of medicine. Modern people's health varies from the excesses of inappropriate nutrition, resulting in obesity and various degenerative disorders, to malnutrition and other deficiency states seen in those unfortunates deprived of nutrients.

The essential components of nutrition<sup>1</sup> can be classified as:

- macronutrients—proteins, fats and carbohydrates, which are interchangeable sources of energy and also water
- macrominerals—sodium, chloride, potassium, calcium, phosphate and magnesium
- micronutrients—water-soluble vitamins (e.g. C, B); fat-soluble vitamins (e.g. A, E, K); essential trace elements (e.g. copper, iodine, iron, zinc)

Nutritional factors may play a vital role in the causation of several of the major diseases, such as coronary artery disease, hypertension, diabetes and cancer.

Special diets are important in the management of many hereditary metabolic disorders, such as phenylketonuria and galactosaemia, and several other disorders such as coeliac disease.

## Protein<sup>2</sup>

Proteins are composed of carbon, hydrogen, oxygen, nitrogen, phosphorus, sulphur and iron. They make up the greater part of plant and animal tissue and provide the amino acids essential for the growth and repair of tissue. Protein in the body in muscle, connective tissue and enzymes is constantly being broken down, while dietary protein is hydrolysed to amino acids that are both essential and non-essential. A complete protein is one that contains all the nine indispensable amino acids, namely,

histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine.

Protein in animal products (fish, meat and milk) is of high quality and that in vegetable products is lower because of a limited supply of lysine (in cereals) and methionine and cysteine (in legumes).<sup>3</sup> Vegetarian diets are usually adequate in protein, especially if the combining vegetable groups complement each other in basic amino acid groups. Diets that exclude all animal products may be inadequate, especially in children. Infants and children require 2–2.2 g protein/kg/day.

- High protein content foods—lean beef and lamb, chicken, fish, eggs, milk, cheese, soy beans
- Medium protein content foods—bread, spaghetti, corn, potatoes (cooked), rice (cooked), cabbage, cauliflower

## Protein–energy malnutrition

This is a deficiency syndrome with a reduction in all macronutrients, energy (kilojoules) and many micronutrients due to an inadequate intake of protein and energy foodstuffs.

It is commonly found in infants and children in developing countries but can occur in persons of any age in any country.

Clinically, protein-energy malnutrition has three forms:

- 1 dry (thin, desiccated)—*marasmus*
- 2 wet (oedematous, swollen)—*kwashiorkor*
- 3 combined—*marasmic kwashiorkor*

## Marasmus

Clinical features:

- grossly underweight
- gross muscle wasting

- no fat
- hungry
- 'old man's' face
- no oedema
- normal hair

Caused by diet low in protein and calories.

### Kwashiorkor

Clinical features:

- oedema
- 'moon' face
- anorexic
- hair pale and thinned
- apathetic
- skin changes

Caused by a diet low in protein with some carbohydrate, leading to hypoalbuminaemia.

### Carbohydrates

Dietary carbohydrates include simple sugars, complex carbohydrates (starches) and indigestible carbohydrate (dietary fibre). Carbohydrates are the main source of dietary energy. The two most important crops feeding the world are rice and wheat, which are rich in starch. Starch and sucrose account for the majority of carbohydrates consumed in all diets. Carbohydrates that are available in food are:

- sugars—sucrose, lactose, maltose, glucose, fructose
- polyols—sorbitol, xylitol, maltitol, lactitol
- starch—amylose, amylopectin
- dextrose

As long as adequate energy and protein are provided in the diet, there is no specific requirement for dietary carbohydrate. A small amount—100 g/day—is necessary to prevent ketosis.<sup>3</sup>

### The glycaemic index (GI)

The GI, which applies to carbohydrate foods, is a numerical index based on a reference point of 100. It is a measure of the capacity to increase postprandial glucose levels compared to a glucose load. The standard food is glucose, which is given an arbitrary level of 100.

The higher the GI, then the higher the rise in blood glucose level and thus the greater the insulin response.

A list of the GI values of various foods is shown in **TABLE 10.1**.

### Fat

Dietary fat, which is composed mainly of fatty acids and dietary cholesterol, is the most concentrated source of food energy.<sup>2</sup>

Fatty acids are classified according to the number of unsaturated double bonds:

- nil—saturated (e.g. butyric and stearic acids)
- one—monounsaturated (e.g. oleic acid)
- more than one—polyunsaturated (e.g. linoleic acid, eicosapentanoic acid [EPA], docosahexanoic acid [DHA])

Polyunsaturated fatty acids (two or more unsaturated bonds) can be subdivided into:

- n-6 (e.g. linoleic acid, 2 unsaturated bonds; arachidonic acid, 4 unsaturated bonds)
- n-3—omega-3 fatty acids (e.g. alpha-linolenic acid, 3 unsaturated bonds; EPA, 5 unsaturated bonds; DHA, 6 unsaturated bonds)

The n-3 and n-6 polyunsaturated fatty acids with chain lengths of 18 or more are called essential fatty acids because they are required for vital body functions and animals, including humans, are unable to synthesise them.<sup>2</sup>

The proportions of saturated, monounsaturated and polyunsaturated fatty acids in the diet are important determinants of health and disease.<sup>2</sup> The current strategy is to reduce total fat intake and reduce saturated fats and increase unsaturated fats, especially n-3 polyunsaturated fats.

Fish oil contains omega-3 fatty acids, which are considered more potent than the omega-3 fatty acids found in plants. The value of omega-3 fatty acids in preventing cardiovascular mortality has been well proven. They have no effect on cholesterol levels but have a well-documented potent hypotriglyceridaemic effect.<sup>4</sup>

Cholesterol, which is a major constituent of cell membranes, is synthesised by the body and is not an essential nutrient. The plasma cholesterol level, and hence the amount of cholesterol in the diet, has been related to the development of atherosclerosis. However, other factors are related to the development and prevention of atherosclerosis. In the past decade, specific nutrients, especially plant sterols (phytosterols), soy protein and soluble fibre, have been shown to improve the plasma cholesterol profile, which has led to their appropriate inclusion in 'designer' foods targeting the health-conscious consumer market.<sup>4</sup>

**Table 10.1** Glycaemic index values<sup>3</sup>

Low GI (<60)	Moderate GI (60–85)	High GI (>85)
Apple/peach/pear/orange/banana (medium)	Noodles	Raisins
Pasta	Wholemeal/white bread (1 slice)	Dried dates
Baked beans	Sweet corn	Nutri-Grain/Weetbix/Rice Bubbles (50 g)
All Bran cereal	Chocolate (other)	Cornflakes
Porridge/Special K	Orange juice	Jasmine white rice
Yoghurt, ice-cream (low-fat)	White rice	Most Australian rice
Milk	Potato chips	Corn chips
Brown rice	Can of soft drink	Sweet biscuits
Peanuts	Rye bread	Sugar
Muesli and oats	Rockmelon/pineapple/apricot	Cordial/Gatorade/other sports drinks
Dark chocolate	Most biscuits and cakes	Glucose
Mixed grain bread		Potato (1 medium—120 g)
Sweet potato/peas		French fries
		White bread
		Baked or boiled potatoes/pumpkin
		Watermelon

## Nutritional assessment

The first step in nutritional assessment is to identify the high-risk patient.<sup>5</sup> Those at high risk of nutritional insufficiency include those with a history of obesity, eating disorders, chronic illness, psychological disorders, the elderly, the institutionalised, trauma victims and those with long periods of hospitalisation, including major surgery. Of particular interest is the rate of growth and development in infants and children and the body composition in children and adults.

When taking the history it is appropriate to include a 24-hour recall of foods eaten and ideally get the patient to complete a symptom questionnaire that can then be linked to a computerised nutritional evaluation program, such as Nutricheck.<sup>5</sup> Evaluate sunlight exposure.

A nutritionally focused physical examination should be performed on each patient at risk, with the emphasis on body weight, waist size, muscle wasting, fat stores and signs of micronutrient deficiencies.

Examples of the latter include zinc deficiency, which affects taste and smell and the skin. Deficiencies of vitamins B6 and B12 cause neurological disorders, such as peripheral neuropathy.<sup>2</sup> Alcoholism and malnutrition affect many systems, including the gastrointestinal system. The oral cavity, especially the gums, teeth and buccal mucosa, are affected by vitamin B complex and vitamin C deficiencies. Bones and joints are affected in scurvy, rickets, osteomalacia and osteoporosis. The important anthropometric measurements include height and weight, skin-fold thickness and waist:hip circumference ratio (refer to CHAPTER 78). Laboratory investigations depend on the clinical examination and should be selective.

## The general principles of optimal nutrition

In order to help people make healthy choices, the health foundations of several countries have developed recommendations for eating a healthy diet.

The heart-healthy eating pyramid of the Australian Nutrition Foundation (2012)<sup>2</sup> has a simplified system, namely:

- Eat most—vegetables, dried peas, beans and lentils, cereals, bread, fruit and nuts
- Eat moderately—lean meat, eggs, fish, chicken (without skin), milk, yoghurt, cheese
- Eat in small amounts—oil, margarine, reduced-fat spreads, butter, sugar

The RACGP in its red book<sup>6</sup> outlines dietary recommendations based on national guidelines. For adults this is summarised as follows.

Enjoy a wide variety of foods each day:

- five serves of vegetables and two serves of fruit
- three serves of cereals (including breads, rice, pasta and noodles)
- one or two serves of lean meat, fish, poultry and/or alternatives
- at least 2 g per day of alpha-linolenic acid by including foods such as canola-based or soy-bean-based oils and margarine spreads, seeds (especially linseeds), nuts (particularly walnuts), legumes (including soy beans), eggs and green leafy vegetables
- drink plenty of water

Take care to:

- limit saturated fat and moderate total fat intake, but consume about 500 mg per day of combined

docosahexaenoic acid and eicosapentaenoic acid through a combination of the following: two or three serves (150 g serve) of oily fish per week, fish oil capsules or liquid, food and drinks enriched with marine omega-3 polyunsaturated fatty acids

- limit salt intake to less than 6 g of salt a day (approximately 2300 mg of sodium a day), which is approximately 1½ teaspoons of salt
- limit alcohol intake
- consume only moderate amounts of sugars and foods containing added sugars
- prevent weight gain: be physically active and eat according to energy needs
- care for food: prepare and store it safely
- encourage and support breastfeeding.

## What is a serving?<sup>2</sup>

The following guides represent one serve:

Milk and milk products group:	1 cup (300 mL) of milk 200 g yoghurt 40 g cheese
Meat group:	60–100 g cooked lean meat, poultry or fish 2 eggs ⅔ cup of cooked legumes
Vegetable group:	1 cup raw leafy vegetables ½ cup other vegetables (cooked or raw) ¾ cup vegetable juice
Fruit group:	1 medium apple, banana, orange ½ cup of chopped, cooked or canned fruit ¾ cup fruit juice ¼ melon

*Note:* a serve is a measured unit while a portion is what is actually eaten, e.g. 1, 2 or 3 serves.

## The Lyon Heart Study<sup>7</sup>

This very impressive prospective, randomised, single-blinded, secondary prevention trial investigated the effects of a 'Mediterranean'-type diet containing a plant oil rich in omega-3 fatty acids on 605 subjects who had survived their first heart attack. The control group were given a low-cholesterol diet with a mix of unsaturated fats. The intervention group had a diet higher in oleic acid, omega-3 fatty acid, fibre and vitamin C (olive and canola oils were used in food preparation). In this group, the cardiovascular mortality was reduced by 73%. This

was far greater than the control group and also for groups taking lipid-lowering agents, and the benefit was independent of any reduction in cholesterol or triglycerides. One explanation is that the antioxidants and phytochemicals in the plant-based diet stabilise the endothelium of arteries.

Some consequent lessons for people with a high-lipid profile are:<sup>4,7</sup>

- Eat more fish—at least twice a week.
- Switch to skim-based dairy products—low-fat milk and yoghurts.
- Eat plenty of fruit, vegetables and grain food.
- Use monounsaturated (olive) oils and perhaps margarine instead of butter. However, use these cooking oils lightly.
- Use alternative toast spreads, e.g. hummus, baked beans, lentils, salmon.
- Limit intake of dietary cholesterol (less than 300 mg/day). Eat less animal-based food, dairy products, eggs (limit two a week), saturated fats, bakery food, fast food.

## Ornish nutritional program

Dean Ornish, a US cardiologist, was one of the first doctors to bring out a nutritional program to treat heart disease. The program involves drinking a lot of water, cutting down consumption of dairy produce and eating plenty of complex carbohydrates. Patients also exercise, undergo stress reduction and achieve ideal weight. The results showed that intensive changes in diet lead to regression of coronary heart disease.<sup>8</sup>

## Antioxidants

They may be much more important than doctors thought in warding off cancer, heart disease and the ravages of ageing. And no, you may not be getting enough of these crucial nutrients in your diet.

—Time magazine<sup>9</sup>

The antioxidant issue is still controversial and unclear. Empirical observation of healthy communities over the years indicates good health outcomes, especially with cardiovascular status, in people having an optimal diet containing high levels of vitamins and minerals (especially from fruit and vegetables).

Food antioxidants (see TABLE 10.2) appear to protect against free radicals, which can suppress immunity. Free radicals, which are usually a toxic form of oxygen containing an odd number of electrons, are produced by a variety of toxins.<sup>10</sup> Apart from the possible adverse effect to immunity from

free radicals, they may also damage body tissues, such as the liver in alcoholics, as well as increasing susceptibility to degenerative diseases.<sup>11</sup>

**Table 10.2** Food antioxidants

Vitamin A, especially beta-carotene  
 Vitamin C  
 Vitamin E  
 Ubidecarenone (co-enzyme Q10)  
 Selenium, zinc, manganese and copper (nutrient cofactors)

Source: After Sali<sup>10</sup>

However, Bury, in a review of the literature of antioxidant nutrients, concluded that 'high intake of antioxidant nutrients from food sources appears to offer some health advantage but claims for any therapeutic benefit of antioxidant supplements are premature and scientifically unjustified at present'.<sup>12</sup> On the other hand, studies have proved that antioxidants have a preventive role in macular degeneration (see CHAPTER 77). The jury appears to be still out on the true value of antioxidant supplements.

### Prime sources of antioxidants in food<sup>13</sup>

- Vitamin C—citrus fruits, berries, papaya, green leafy vegetables
- Vitamin E—seed-like cereal grains, nuts and oils (plants), eggs
- Beta-carotene—orange-coloured and dark-green leafy vegetables
- Selenium—grains, meats, Brazil nuts, fish
- Copper—cocoa, wheat bran, yeast
- Ubiquinone—meats, fish, peanuts
- Phytochemicals—soy, tea, green tea, herbs, apples, onions, cocoa

### Folate-containing foods<sup>9</sup>

- Green leafy vegetables—broccoli, spinach
- Wheat grain
- Wholegrain cereals
- Starchy beans—kidney and butter
- Peas, corn, cauliflower
- Nuts
- Avocado
- Liver
- Folic acid fortified foods (e.g. breakfast cereals)

## Vitamin deficiency disorders<sup>14</sup>

These are rare in our society but can occur sporadically and are not rare in children in some third world countries or in refugees from these countries. Deficiencies tend to be seen as a specific disorder or as a multivitamin effect.

- **Vitamin A (beta-carotene/retinol).** We hear about this deficiency causing night blindness and eye disease. It causes dryness with keratinisation of the conjunctivae and cornea. It causes growth retardation in children. Toxicity from overdosage of vitamin A is a serious problem.
- **Vitamin B complex**
  - **Vitamin B1 (thiamine)** deficiency causes beriberi and also Wernicke–Korsakoff syndrome (typically in alcoholics).
  - **Vitamin B2 (riboflavin)** deficiency causes growth retardation, dry scaly skin and angular cheilitis.
  - **Vitamin B3 (niacin, nicotinic acid)** deficiency causes pellagra.
  - **Vitamin B6 (pyridoxine)** deficiency may cause oral soreness, anaemia and CNS dysfunction.
  - **Vitamin B12 (cobalamin)** deficiency causes pernicious anaemia and memory dysfunction.
- **Vitamin C (ascorbic acid)** deficiency is responsible for scurvy. Clinical features: weakness, malaise, fatigue, bleeding swollen inflamed gums, atraumatic haemarthrosis, impaired wound healing, impaired bone growth. One sign is the hyperkeratotic hair follicle with surrounding hyperaemia. Diagnosis by decreased plasma ascorbic acid and X-rays of bones and joints.
- **Vitamin D (calciferols)** deficiency causes rickets in children and osteomalacia in adults. Clinical features (rickets): impaired growth, skeletal deformities (bow legs, pelvis, 'rachitic rosary'), inability to walk, bone pain (arms, legs, spine, pelvis), dental deformities, muscle weakness. In adults: muscle weakness, bone pain, bowing of long bones. Diagnosis: low plasma 25(OH) D<sub>3</sub> and phosphate; elevated PTH and alkaline phosphatase; X-rays of joints and long bones of leg.
- **Vitamin E (tocopherol)** deficiency causes no specific disease but may result in vague, undifferentiated symptoms and anaemia.
- **Vitamin K (phylloquinone)** deficiency is rare and can lead to an increased bleeding tendency.
- **Folic acid** deficiency is responsible for pernicious anaemia and neural tube defects in the fetus.

## Gout

Certain foods can aggravate gout. These include:

- tinned fish (e.g. sardines, anchovies)
- organ meats (e.g. liver, pancreas, brain, kidney)
- alcohol (the major one)
- fizzy, sugary soft drinks

Gout often occurs in males after they binge drink in their late 20s or 30s. Beer is particularly problematic. It is useful to recommend an increase in water consumption. Since gout and hyperuricaemia have a proven association with coronary artery disease, a healthy heart prevention diet is advisable.

## Dietary control of diabetes

Diabetes is an endemic problem in many communities, particularly in Indigenous communities. It is thought that for every two people diagnosed with diabetes, there may be one who is not diagnosed. Prevention of diabetes is very important and diet can play a significant role in this.

As many as 30% of people who suffer from diabetes are now taking insulin and oral hypoglycaemic medications. However, if sufferers can maintain an ideal weight and control symptoms through diet, the need for medications is reduced. Exercise is also very important.

Dietary principles for preventing and control of diabetes include:

- Follow the healthy eating guidelines.
- Keep to an ideal weight.
- Eat low-GI foods.
- Limit the consumption of fat and fatty products.
- Eat complex carbohydrates, such as starchy fibre foods, cereals and wholemeal bread.
- Avoid simple carbohydrates (e.g. sugar).
- Spread the consumption of carbohydrates throughout the day.

In summary, the diet for both type 1 and type 2 diabetes is based on achieving ideal weight and following a diet of high-fibre carbohydrates with a low GI and low fat.

## Obesity

Refer to **CHAPTER 78** for information on management of obesity.

## Anaemia and iron

Iron-deficiency anaemia is a common problem in our society, particularly in children from 6 months to 2 years who have been given a lot of cow's milk.

In such cases it is important to educate people about iron-rich foods and the quantities they need (see **CHAPTER 22**).

## Guidelines for safe consumption of alcohol (current NH & MRC recommendations)<sup>15</sup>

### Healthy males and females

- No more than two standard drinks per day
- No more than four standard drinks on any single occasion

### Young people

- People aged under 15 years should avoid alcohol altogether.
- People aged 15–17 years should delay drinking for as long as possible.

### Pregnancy and breastfeeding

- No alcohol is the safest option.

Refer to **CHAPTERS 21** and **108** for alcohol guidelines.

## Coeliac disease

Coeliac disease occurs as a result of sensitivity to gluten. It is quite common and often undiagnosed. In some cases, it can occur after a bout of gastroenteritis. It can be treated with a gluten-free diet.

- For breakfast, exclude wheat, barley, oats and rye.
- Any food containing gluten (e.g. flour and bread) should be avoided.
- Any food containing hidden ingredients (e.g. stock cubes) should be avoided.

## Foods associated with migraine

Common ones include:

- wine, particularly red wine
- cheese
- oranges
- tomatoes
- caffeine in some people

Other culprit foods might include amine-rich foods, such as bananas and avocados. It is helpful to ask patients to keep a diary to see if they can find links between what they eat and their migraine attacks. Some migraines are not linked to diet.

## Nutrition and chronic simple constipation

Important advice for treatment of constipation includes:

- Drink a lot of fluids, especially water and fruit juices.
- Eat foods with bulk and roughage (e.g. bran, fresh and dried fruits and wholemeal bread).

Foods that are high in roughage include (in order):

- bran
- carrots
- apples
- lettuce
- cabbage
- peas
- cauliflower
- bananas
- potatoes

Fruits are high in fibre and some are natural laxatives, such as:

- prunes
- figs
- rhubarb
- apricots
- pears

Studies show that most people do not eat enough fruit. According to a recent survey of Victorian schoolchildren, one-third did not have fruit during the day, one-third did have fruit and one-third only had it spasmodically.

## Recurrent urinary calculi

The dietary advice for recurrent urinary calculi (CHAPTER 34) includes:

- 1 Drink at least 2 L of water every day, or more if there is increased fluid loss: this is the most important step.
- 2 Minimise consumption of foods that contain oxalate or uric acid. Foods that contain oxalate include:
  - chocolate
  - coffee
  - cola and similar 'soft' drinks
  - rhubarb
  - tea

Foods that contain uric acid include:

- beer
- red wine

- red meat
- organ meats

- 3 Avoid milk in tea—calcium precipitates oxalate.
- 4 Avoid processed meats, organ meats (e.g. brain, kidney, liver and sweetbread), yeast spreads and other high-salt foods. Restrict salt intake.
- 5 Reduce animal protein consumption: restriction to one major meat meal a day (includes chicken and fish).
- 6 Add citrate-containing fruit juices to the diet, including grapefruit, apple and orange juice.
- 7 Eat a healthy diet of vegetables and fruit with a high fibre content.

## Iodine deficiency

The body needs small amounts of iodine to maintain normal function of the thyroid gland—crucial for normal growth and development. In iodine-deficient areas (in soil and water) there is a high rate of stillbirths, congenital hypothyroidism and cretinism. In adults, deficiency causes goitre and hypothyroidism. The usual intake of iodine in healthy persons is 100–200 mcg/day, mostly from iodised salt. An adequate intake is 150 mcg/day with higher requirements for pregnancy (220 mcg) and breastfeeding (290 mcg).<sup>16</sup> Measurement is by urinary iodine levels (WHO replete level standard  $\geq 100$  mcg/L and  $\geq 150$  mg/L in pregnancy<sup>16</sup>).

## Dietary guidelines for children and adolescents in Australia (NHMRC)<sup>15</sup>

**Encourage and support breastfeeding.**

**Children and adolescents need sufficient nutritious foods to grow and develop normally.**

- Growth should be checked regularly for young children.
- Physical activity is important for all children and adolescents.

**Enjoy a wide variety of nutritious foods.**

**Children and adolescents should be encouraged to:**

- eat plenty of vegetables, legumes and fruits
- eat plenty of cereals (including breads, rice, pasta and noodles), preferably wholegrain
- include lean meat, fish, poultry and/or alternatives
- include milks, yoghurts, cheese and/or alternatives

Reduced-fat milks are not suitable for young children under 2 years, because of their high energy needs,

but reduced-fat varieties should be encouraged for older children and adolescents.

- Choose water as a drink

Alcohol is not recommended for children.

**In addition, care should be taken to:**

- limit saturated fat and moderate total fat intake — low-fat diets are not suitable for infants
- choose foods low in salt
- consume only moderate amounts of sugars and foods containing added sugars

**Care for your child's food: prepare and store it safely.**

## Dietary guidelines for Australian adults (NHMRC)

(See [www.nhmrc.gov.au](http://www.nhmrc.gov.au))

**Enjoy a wide variety of nutritious foods.**

- Eat plenty of vegetables, legumes and fruits.
- Eat plenty of cereals (including breads, rice, pasta and noodles), preferably wholegrain.
- Include lean meat, fish, poultry and/or alternatives.
- Include milks, yoghurts, cheeses and/or alternatives. Reduced-fat varieties should be chosen, where possible.
- Drink plenty of water.

**Also, take care to:**

- limit saturated fat and moderate total fat intake
- choose foods low in salt
- limit your alcohol intake if you choose to drink
- consume only moderate amounts of sugars and foods containing added sugars.

**Prevent weight gain:**

- Be physically active and eat according to your energy needs.

**Care for your food: prepare and store it safely.**

## Summary of general dietary guidelines for good health

- Keep to an ideal weight.
- Eat a high-fibre diet.
- Eat more fruits and vegetables, least processed breads and cereals, preferably wholegrain.
- Eat fish at least twice a week (daily if possible).
- Choose a nutritious diet.
- Eat less saturated fat, refined sugar and salt.
- Use low-fat dairy products—milk and yoghurt.
- Avoid fast foods and deep-fried foods.

- Do not eat animal meat every day, and then only in small portions. Note that processed meats, such as sausages, have a very high fat content.
- Use monounsaturated (olive) oils and perhaps margarine instead of butter.
- Use olive oil for cooking rather than polyunsaturated oils.
- Always trim fat off meat.
- Limit alcohol intake to 2 standard drinks per day
- Drink more water.
- Limit salt intake; pepper is okay.
- Limit caffeine intake (0–3 drinks a day maximum).
- Check plasma cholesterol level and, if it is elevated, aim to reduce it with diet.

*Death should simply become a discreet but dignified exit of a peaceful person from a helpful society—without pain or suffering and ultimately without fear.*

Philippe Ariès 1977

*To enable a person to live in dignity, peace and comfort throughout their illnesses means responding to physical, psychological, emotional, social and spiritual needs.<sup>1</sup>*

E Fairbank, T Banks, *Palliative Care: The Nitty Gritty Handbook*

Palliative care is comprehensive, continuing, multi-disciplinary patient care that involves the patients and their carers, consultants, domiciliary nurses, social workers, clergy and other health professionals who are able to contribute to optimal team care.

The fundamental principles of palliative care are:<sup>2</sup>

- good communication
- management planning
- symptom control
- emotional, social and spiritual support
- medical counselling and education
- patient involvement in decision making
- support for carers

## The diseases

Palliative care applies not only to incurable malignant disease and HIV/AIDS but also to several other diseases, such as end-stage organ failure (heart failure, kidney failure, respiratory failure and hepatic failure) and degenerative neuromuscular diseases. Thirty per cent of the population will die from cancer.

## The special role of the family doctor

The GP is the ideal person to manage palliative care for a variety of reasons—availability, knowledge of the patient and family, and the relevant psychosocial influences. A key feature is the ability to provide the patient with independence and dignity by managing palliative care at home. Someone has to take the responsibility for leadership of the team and the most appropriate professional is a trusted family doctor.

Most patients and their families require answers to the following six questions.<sup>3</sup>

- What is wrong?
- What can medical science offer?
- Will I suffer?

- Will you look after me?
- How long will I live?
- Can I be looked after at home?

Caring honesty is the best policy when discussing the answers to these questions with the patient and family. Never lie to a patient and always avoid thoughtless candour.

## Support for patients and carers

Studies have indicated that the most common complaints of patients are boredom and fear of the unknown. This highlights the importance for the attending doctor of the following points.

- Give emotional support.
- Listen and be receptive to unexpressed 'messages'.
- Treat the sufferer normally, openly, enthusiastically and confidently.
- Show empathy and compassion.
- Employ good communication skills.
- Give honest answers without labouring the point or giving false hope.
- Provide opportunities for questions and clarification.
- Show an understanding of the patient's needs and culture.
- Adopt a whole-person approach: attend to physical, psychosocial and spiritual needs.
- Anticipate and be prepared for likely problems.

These next special points are worth emphasising.

- The patient needs a feeling of security.
- Provide reassurance that the patient will not suffer unnecessarily.
- Be prepared to take the initiative and call in others who could help (e.g. clergy, cancer support group, massage therapists).

- Patients must not be made to feel isolated or be victims of the so-called 'conspiracy of silence' in which families collude with doctors to withhold information from the patient.
- The worst feeling a dying patient can sense is one of rejection and discomfort on the part of the doctor.
- Always be prepared to refer to an oncologist or appropriate therapist for another opinion about further management. The family and patient appreciate the feeling that every possible avenue is being explored.

*Note:* Always establish what the patient knows and wants to know.

## The Gold Standards Framework (UK)

This framework, which provides an optimal model for palliative care by the primary care team, focuses on seven key tasks:

- 1 optimal quality of care
- 2 advanced planning (including out of hours)
- 3 teamwork
- 4 symptom control
- 5 patient support
- 6 carer support
- 7 staff support

The strategy has been shown to increase the number of patients dying in their preferred place with improved quality of care.<sup>4</sup>

## Symptom control

### Common symptoms

- boredom (the commonest symptom)
- loneliness/isolation
- fear/anxiety
- pain
  - physical
  - emotional
  - spiritual
  - social
- anorexia
- nausea and vomiting
- constipation

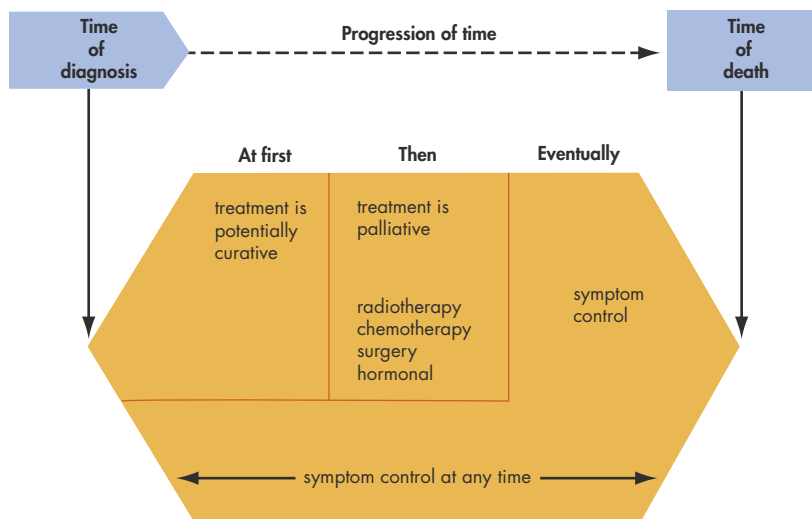

## The grief reaction

This follows five stages, as identified by Kübler-Ross:<sup>5</sup>

- 1 denial and isolation
- 2 anger
- 3 bargaining
- 4 depression
- 5 acceptance

This model provides a useful guideline in understanding the stages a patient and family will be experiencing.

The principles of symptom management are summarised in TABLE 11.1. The goals of treatment according to the different stages of cancer are presented in FIGURE 11.1.

**FIGURE 11.1** Stages of cancer management: the goals of treatment differ according to the different stages.

Source: After Buchanan et al.<sup>6</sup>

**Table 11.1** Principles of symptom management<sup>2</sup>

Determine the cause.  
 Treat simply.  
 Provide appropriate explanation of symptoms and treatment.  
 Provide regular review.  
 Give medication regularly around the clock, not ad hoc.  
 Plan 'breakthrough' pain-relieving doses.  
 Provide physical treatment as necessary (e.g. paracentesis, pleural tap, nerve block).  
 Provide complementary conservative therapy (e.g. massage, physiotherapy, occupational therapy, dietary advice, relaxation therapy).  
 Provide close supervision.

### Pain control in cancer

Pain is the commonest, most feared, but generally the most treatable symptom in advanced cancer. Achieving pain relief is one of the most important functions of palliative care and patients need reassurance that they can expect such relief. The principles of relief of cancer pain are:<sup>1</sup>

- 1 Treat the cancer.
- 2 Raise the pain threshold:
  - provide appropriate explanation
  - allow the patient to ventilate feelings and concepts
  - give good psychosocial support
  - use antidepressants or hypnotics.

**Table 11.2** Treatment options for cancer pain<sup>6,7</sup> (based on aetiology)

Aetiology	1st line treatment	2nd line treatment	Other treatment modalities to consider
Nociceptive pain: stimulation of sensory nerves	Aspirin	Opioids Corticosteroids Antidepressants NSAIDs	Radiotherapy Neurosurgery
Neuropathic pain: direct nerve involvement (e.g. brachialgia, sciatica)	Opioids Antidepressants (e.g. amitriptyline) Antiepileptics (e.g. carbamazepine, gabapentin)		Spinal morphine Local anaesthetic Ketamine
Dysaesthesia: superficial burning pain	Antidepressants	Opioids	Local anaesthetic TENS
Pressure pain: tumour-associated oedema (e.g. raised intracranial pressure)	Corticosteroids (e.g. dexamethasone)	Opioids	Radiotherapy Neurosurgery
Bony metastases and other tissue destruction	NSAIDs Aspirin Paracetamol (if NSAIDs contraindicated)	Opioids	Radiotherapy (the most effective) Bisphosphonates Hormones Orthopaedic surgery
Muscle spasm pain	Diazepam Clonazepam Baclofen	Opioids Dantrolene	
Viscus (hollow organ) obstruction (e.g. colic, tenesmus)	Antispasmodics (e.g. hyoscine)	Opioids Chlorpromazine Corticosteroids	Palliative surgery Radiotherapy
Metabolic effects: hypercalcaemia	Bisphosphonates (APD)		
Skin infiltration/ulceration	Aspirin Opioids	Corticosteroids	Treat infection Dressings Palliative surgery Radiotherapy

- 3 Add analgesics according to level of pain, for example, opioids (if necessary).
- 4 Use specific drugs for specific pain—not all pain responds to analgesics (refer TABLE 11.2).
- 5 Set realistic goals.
- 6 Organise supervision of pain control.

*Note:* The right drug, in the right dose, given at the right time relieves 80–90% of the pain.<sup>1</sup> Reports of the undertreatment of cancer pain persist.

## Use of analgesics<sup>7</sup>

The World Health Organization (WHO) analgesic ladder is an appropriate guide for the management of cancer pain (see FIG. 11.2).

These should be given by the clock and administered according to the three-step method.

### Step 1: Mild pain

Start with basic non-opioid analgesics:

aspirin 600–900 mg (o) 4 hourly (preferred)  
*or*  
 paracetamol 1 g (o) 4 hourly ± NSAID

### Step 2: Moderate pain

Use low dose or weak opioids (according to age and condition) or in combination with non-opioid analgesics (consider NSAIDs):

add morphine 5 to 10 mg (o) 4 hourly (2.5 mg in elderly)

FIGURE 11.2 World Health Organization pain relief ladder

increase in increments of 30–50% up to 15–20 mg

*or*

oxycodone 2.5 mg (in elderly) up to 10 mg (o)  
 4 hourly or CR

10 mg (o) 12 hourly

*or*

oxycodone 30 mg, rectally, 8 hourly

### Step 3: Severe pain

Maintain non-opioid analgesics. Larger doses of opioids should be used and morphine is the drug of choice:

morphine 10–15 mg (o) 4 hourly, increasing to 30 mg if necessary

*or*

morphine CR/SR tabs or caps (o) 12 hourly or once daily

- Give dosage according to individual needs (morphine CR/SR comes in 5, 10, 15, 20, 30, 50, 60, 90, 100, 120, 200 mg tablets or capsules).
- The proper dosage is that which is sufficient to alleviate pain.
- The usual starting dose is 20–30 mg bd.
- Give usual morphine 10 mg with first dose of morphine CR/SR and then as necessary for 'rescue dosing'.
- Gauge the probable dose of the long-acting morphine from the standard dosage.
- To convert to morphine CR/SR, calculate the daily oral dose of regular morphine and divide by 2 to get the 12 hourly dose.
- Do not crush or chew the tablets or capsules.

### Guidelines

- Ensure that pain is likely to be opioid-sensitive.
- Give morphine orally (e.g. Ordine) (if possible) either by mixture (preferred) or tablets (e.g. Sevredol, Anamorph).
- Starting doses are usually in the range of 5–20 mg (average 10 mg).
- If analgesia is inadequate, the next dose should be increased by 50% until pain control is achieved.
- Give it regularly, usually 4 hourly, before the return of the pain (see FIG. 11.3).
- Many patients find a mixture easier to swallow than tablets (e.g. 10 mg/10 mL solution).

FIGURE 11.3 Appropriate schedule of analgesia to achieve optimal pain control<sup>8</sup>

- Constipation is a problem, so treat prophylactically with regular laxatives and carefully monitor bowel function.
- Consider oxycodone/naloxone (Targin) CR tablets for pain.
- Order a 'rescue dose' (usually 5–10 mg) for breakthrough pain or anticipated pain (e.g. going to toilet).
- Order antiemetics (e.g. haloperidol prn at first; usually can discontinue in 1–2 weeks as tolerance develops).
- Reassure the patient and family about the safety and efficacy of morphine (see TABLE 11.3). (Beware of opiophobia.)
- Using morphine as a mixture with other substances (e.g. Brompton's cocktail) has no particular advantage.
- Pethidine is not recommended (short half-life, toxic metabolites) and codeine and IM morphine should be avoided.
- Other opioids such as oxycodone and fentanyl are sometimes used instead of morphine (see CHAPTER 12).
- Fentanyl is a potent synthetic opioid which is available as a transdermal system. Effective and good for compliance. It is the least constipating opioid and can be used in kidney failure.
- Hydromorphone is a potent analgesic available as oral liquid, tablets and injection and is now widely used in palliative care. It facilitates oral dosing when a high opioid dose is required and because of its short half-life (2–3 h) may reduce the incidence of side effects in the frail and elderly but like oxycodone may need to be given 4 hourly if used alone.

Table 11.3 Common myths about morphine<sup>7</sup>

Morphine is a last resort

This is not so, and there is no maximum dose.

The patient will become addicted

This is rare and probably irrelevant in the context of palliative care.

The patient will need ever-increasing amounts

The drug does not lose its effect but is usually increased according to disease progression.

Morphine will cause respiratory depression

This is rarely a problem and may even help those with dyspnoea. An overdose can be reversed with an injection of naloxone.

Morphine will shorten life

The reverse may in fact apply. It is not being used for euthanasia but to control pain.

## Opioid rotation

This practice involves changing from one strong opioid to another in patients with dose-limiting side effects. Different opioids have differences in opioid receptor binding.

Morphine can be alternated with oxycodone, hydromorphone, methadone, fentanyl and others. Transdermal patches of fentanyl are an alternative to parenteral morphine.

### Conversion rules<sup>9</sup>

- Divide oral dose morphine by 3 for equivalent SC dose<sup>9</sup>  
e.g. 30 mg oral morphine = 10 mg SC
- 10 mg morphine SC = 150 mcg fentanyl SC or 2–3 mg hydromorphone SC

## Parenteral morphine

This is generally given subcutaneously (not IV or IM). Indications are:<sup>6</sup>

- 1 unable to swallow (e.g. severe oral mucositis; dysphagia; oesophageal obstruction)
- 2 bowel obstruction
- 3 severe nausea and vomiting
- 4 at high oral dose (i.e. above 100–200 mg dose) there appears to be no additional benefit from further dose increments

## Adjuvant treatment

Refer to TABLE 11.2. In all three steps of pain control consider the use of adjuvant ‘analgesics’; while not strictly speaking analgesics, they contribute to pain relief. Examples are corticosteroids, antidepressants, psychotropic agents and anticonvulsants.

## Pain control

Bone pain:

- aspirin, paracetamol, NSAIDs are helpful co-analgesics, consider denusomab

Neuropathic pain (direct involvement of nerves):

- antidepressants (e.g. amitriptyline)
- anticonvulsants (e.g. carbamazepine, gabapentin)
- ketamine, an anaesthetic agent, is valuable for difficult pain but requires expertise in administration

Neurological pressure:

- corticosteroids for spinal cord compression, oedema and raised intracranial pressure

e.g. dexamethasone 4–16 mg (o, sc or im)  
daily in morning  
or  
prednisolone 25–100 mg (o) daily

## Continuous subcutaneous infusion of morphine

When the oral and/or rectal routes are not possible or are ineffective, a subcutaneous infusion with a syringe driver (pump) can be used.

It is also useful for symptom control when there is a need for a combination of drugs (e.g. for pain, nausea and agitation). It may avoid bolus peak effects (sedation, nausea or vomiting) or trough effects (breakthrough pain) with intermittent parenteral morphine injections.

### Practical aspects

- Access to the subcutaneous space is via a 21 gauge butterfly needle, which is replaced regularly (1, 2, 3 or 4 days).
- Most regions are suitable. The more convenient are the abdomen, the anterior thigh, and the anterior upper arm (usually the anterior abdominal wall is used).
- The infusion can be managed at home.
- About one-half to two-thirds of the 24 hour oral morphine requirement is placed in the syringe.
- The syringe is placed into the pump driver, which is set for 24 hour delivery.
- Areas of oedema are not suitable.

## Spinal morphine

Epidural or intrathecal morphine is sometimes indicated for pain below the head and neck, where oral or parenteral opioids have been ineffective. It is necessary to insert an epidural or intrathecal catheter (anaesthetist or neurosurgeon).<sup>7</sup>

## Common symptom control

Common symptoms can be controlled as follows:<sup>1</sup>

### Anorexia

metoclopramide 10 mg tds  
or  
corticosteroids (e.g. dexamethasone 2–8 mg tds)  
high-energy drink supplements

### Constipation<sup>6,7,8</sup>

If opioids need to be maintained, the laxatives need to be peristaltic stimulants, not bulk-forming agents.

Treat as for any patient in the GP setting. Aim for firm faeces with bowels open about every third day.

e.g. lactulose 20 mL bd

or

Movicol, one to two sachets, in 125 mL water, 1, 2 or 3 times daily

Rectal suppositories, microenemas or enemas may be required (e.g. Microlax).

Shaw's (or PCU) cocktail is useful for severe constipation. With a small quantity of water melt one tablespoon of Senokot granules in a microwave oven. Add 20 mL Agarol and constitute to 100 mL with cold or warm milk or ice-cream.

*Tip:* Tilt the pelvis for defecation by sitting upright with books under feet for elevation.

## Noisy breathing and secretions<sup>7,10</sup>

Conservative: repositioning to one side, reduced parenteral fluids and nasogastric suction.

For conscious patient:

- hyoscine butylbromide (Buscopan) 20 mg SC, 4 hourly or 60–80 mg daily by SC infusion
- or
- glycopyrrolate 0.2 mg SC as a single dose followed by 0.6–1.2 mg/24 hrs by continuous SC infusion

For unconscious patient, as above, also consider:

- hyoscine hydrobromide 0.4 mg SC, 4 hourly or 0.8–2.4 mg/24 hrs by continuous SC infusion
- or
- atropine 0.4–0.6 mg SC 4–6 hourly (be cautious of delirium)

These agents dry secretions and stop the 'death rattle'.

## Dyspnoea

Identify the cause, such as a pleural effusion, and treat as appropriate. Pleural taps can be performed readily in the home (consider the PleurR catheter). Adjust the patient's posture. Corticosteroids can be given for lung metastases. Oxygen may be necessary to help respiratory distress in the terminal stages and bedside oxygen can be readily obtained. Morphine can be used for intractable dyspnoea e.g. 2.5–5 mg (o) 4 hourly, together with haloperidol or a phenothiazine for nausea. Use a short acting benzodiazepine e.g. lorazepam 0.25–5 mg sublingually if anxiety is a component.

## Terminal distress/restlessness<sup>7,10,11</sup>

(Exclude reversal causes, e.g. drugs, fear, faecal impaction, urinary retention.)

1st choice:

clonazepam

0.5 mg SC bolus or 0.25–0.5 mg (o) 12 hourly (drops SL) (3 drops = 0.3 mg) or tabs<sup>7</sup>

1–4 mg over 24 hours in SC syringe driver

or

midazolam 2.5–5 mg SC 1–3 hourly prn or

2.5–10 mg sublingual or intranasal

(or 15 mg/day by SC) infusion

If very severe:

add phenobarbitone as SC infusion or

(with care because of fitting) haloperidol

## Nausea and vomiting

If due to morphine:

haloperidol 1.5–5 mg daily<sup>1</sup>

(can be reduced after 10 days)

or

metoclopramide 10–20 mg (o) or SC 6 hrly

or

prochlorperazine (Stemetil)

5–10 mg (o) qid

or

25 mg rectally bd

Alternatives: promethazine, cyclizine

If due to poor gastric emptying, use a prokinetic agent: metoclopramide or cisapride or domperidone.

Consider ondansetron or tropisetron for nausea and vomiting induced by cytotoxic chemotherapy and radiotherapy (see CHAPTER 60).

## Wound dressings

To reduce pain, apply a mixture of 10 mg/mL topical morphine with 8 g/mL Intrasil hydrogel.

## Cerebral metastases

Common symptoms are headache and nausea. Consider corticosteroid therapy (e.g. dexamethasone 4–16 mg daily). Analgesics and antiemetics such as haloperidol are effective.

## Paraplegia

Paraplegia is especially prone to occur with carcinoma of the prostate, even when treated with LHRH analogues. The warning signs are the development of new back pain, paraesthesia in limbs or the recent development of urinary retention.<sup>1</sup> The objective is to prevent paraplegia developing. High-dose corticosteroids are given while arranging urgent hospital admission.

## Hiccoughs<sup>7,8</sup>

Try a starting dose of  
clonazepam 0.25–1 mg (o) bd  
or  
haloperidol 2.5 mg bd

Swallowing granulated sugar with or without vinegar does not appear to be effective. Other drugs reported to be beneficial include baclofen, midazolam, chlorpromazine, nifedipine and metoclopramide.

## Depression<sup>10</sup>

- mirtazapine 30 mg (o) daily, helpful for night-time sedation and appetite.
- consider methylphenidate (psychostimulant) 5 mg (o) bd since evidence indicates an improvement in symptoms<sup>12</sup>

## Weakness and weight loss

This problem may be assisted by a high-calorie and high-protein diet. Otherwise consider total parenteral nutrition. A list of high-energy drink supplements is provided in *Palliative Care: The Nitty Gritty Handbook*.<sup>1</sup>

## Delirium

Determine the cause, including adverse opioid effect. Investigations include FBE, MCU, CXR, pulse oximetry. Consider treatment with olanzapine and haloperidol (refer to CHAPTER 45).

## Hypercalcaemia

Consider hypercalcaemia in the presence of drowsiness, confusion, twitching and abdominal pain. It may be a paraneoplastic effect of myeloma and cancers (particularly lung and breast). It carries a poor prognosis—monitor serum calcium >3 mmol/L. Treat with rehydration, reduction of tissue mass and bisphosphonates.

## The AIDS patient

The same principles of management apply to the person suffering from the many manifestations of terminal AIDS, including pain. Many of these patients wish to die at home and there are excellent caring support groups to help. It is important to become acquainted with the service network. Because of opportunistic infections, there are many challenges facing the palliative care of such patients and some management guidelines are included in CHAPTER 27.

A very helpful guide to symptom control is presented in *Therapeutic Guidelines* by Ravenscroft et al. (pages 239–46).<sup>7</sup>

## Palliative care in children

### Principles of management

- Children should not be regarded as mini-adults.
- There is a different spectrum of illness apart from childhood cancer including congenital disorders such as cystic fibrosis, neurodegenerative disorders and cerebral palsy.
- The commonest malignancy is acute lymphatic leukaemia. Other important malignancies include: lymphomas, cerebral tumours, bone tumours and solid tumours.
- The focus of care is on the physical, mental and spiritual welfare of the child and the grieving family.
- Any pain must be accurately assessed.
- Morphine is the most commonly used opioid for pain although fentanyl and hydromorphone are now widely used.
- Nausea, vomiting and constipation require special attention.
- Avoid unpalatable medications and intramuscular injections.
- Adverse reactions to tranquillisers, corticosteroids, anti-emetics and aspirin are a special problem.
- Be prepared for home management, which is usually preferred by families.
- Pay attention to the impact on the vulnerable child, the parents and siblings. Consider support groups.

## Dying and grieving

The stages of the grieving process as described by Kübler-Ross may be experienced by both the patient and the family, albeit not exactly according to the five stages. The grieving process following the death of a loved one can vary enormously but many people are devastated.

The principles of care and counselling include:<sup>1</sup>

- Be available and be patient.
- Allow them to talk while you listen.
- Reassure them that their feelings are normal.
- Accept any show of anger passively.
- Avoid inappropriate reassurance.
- Encourage as much companionship as possible, if desired.

(See guidelines for crisis counselling given in CHAPTER 5.)

## Communicating with the dying patient

Good communication is essential between the doctor and patient in order to inform, explain, encourage and show empathy. However, it can be very difficult, especially with the cancer patient.

Good communication is dependent on honesty and integrity in the relationship. Telling the truth can be painful and requires sensitivity, but it builds trust that enables optimal sharing of other difficult concerns and decisions, such as abandoning curative treatment, explaining the dying process and perhaps addressing thoughts on euthanasia.

Improved communication will lead not only to better 'spiritual' care but also to better symptom control.<sup>1</sup> Give patients every opportunity to talk about their illness and future expectations, and be available and patient in offering help and support.

## Spiritual issues<sup>1</sup>

Spirituality is an important issue for all people, especially when faced with inevitable death. Many people are innately spiritual or religious and those with deep faith and a belief in 'paradise' appear to cope better with the dying process. Others begin to reflect seriously about spirituality and search for a meaning for life in this situation. Carers, including the attending doctor, should be sensitive to their needs and turmoil and reach out a helping hand, which may simply involve contacting a minister of religion.

Spiritual care builds on patients' existing resources to enable them to rise above the physical, emotional and social effects of their terminal illness.<sup>1</sup>

## Advanced care planning (ACP)

Attention to ACP is not only important but rewarding to all parties.

The principles are:

- recognising the need to prepare for approaching death is an important medical skill
- the family needs to know that the patient is dying
- ACP is best when the patient is cognisant and involved in the decision making
- the health care is primarily patient-centred
- ensure the appointment of Medical Enduring Powers of Attorney for your patient

- ACP is best prior to or on admission to the caring facility or 6 months before anticipated death—then continuing review
- case conference, ideally with the GP, within this 6 months
- facilitate end-of-life pathway policy prior to death—certainly within the final week
- need for agreement for clear goals of end-of-life care, including resuscitation issues

## The question of euthanasia

It should be an uncommon experience to be confronted with a request for the use of euthanasia,<sup>3</sup> especially as the media clichés of 'extreme suffering' and 'agonising death' are uncommonly encountered in the context of attentive whole-person continuing care. The non-use of life support systems, the use of 'round the clock' morphine, cessation of cytotoxic drugs, the use of ancillary drugs such as anti-depressants and anti-emetics, various nerve blocks and loving attention almost always help the patient cope without undue pain and suffering.<sup>3</sup>

### Practice tips

- Morphine is the gold standard for pain.<sup>13</sup>
- Consider prescribing antidepressants routinely for patients in pain.
- Remember the 'sit down rule' whereby the home visit is treated as a social visit—sitting down with the patient and family, having a 'cuppa' and sharing medical and social talk.<sup>3</sup>
- Early referral of terminal patients with difficult-to-control problems, especially pain, to a hospice or multidisciplinary team can enhance the quality of care. However, the patient's family doctor must still be the focus of the team.

*It is as much of the business of a physician to alleviate pain, and to smooth the avenues of death, when unavoidable, as to cure diseases.*

John Gregory (1725–73), *Lectures on the Duties and Qualifications of a Physician*

Pain is the capital symptom of humans—the great hallmark of disease—the signal par excellence to the patient and doctor that all is not well.

In modern medicine the successful management of chronic pain, in particular, still poses a great challenge. Its management or mismanagement is a yardstick of the excellence of that important bond—the doctor–patient relationship.

Pain is a multifactorial problem. The suffering patient must not only deal with the painful sensation itself but also cope with its possible serious significance.

- Does chest pain imply a pending heart attack?
- Does chronic ache or acute pain signify cancer?
- Does ‘whiplash’ imply neck pain to the grave?

Chronic pain is the most challenging problem. It must be emphasised that it always starts as an acute episode and that back pain accounts for the majority of cases of chronic pain encountered in general practice.

## Golden rules

- Acute pain = acute anxiety
- Chronic pain = chronic depression

## Definitions

*Pain* is defined as ‘an unpleasant sensory and motional experience associated with actual or potential tissue damage or described in terms of such damage’. The box below defines the variety of types of pain.

## Glossary of terms<sup>1</sup>

**Allodynia** Pain due to a stimulus that does not normally provoke pain.

Mechanical—light touch feels painful.

Temperature—hot/cold stimulus (normally not painful) is painful.

**Anaesthesia dolorosa** Pain in an area or region that is anaesthetic.

**Analgesia** Absence of pain in response to stimulation that would normally be painful.

**Causalgia** A syndrome of sustained burning pain, allodynia and hyperpathia after a traumatic nerve lesion, often combined with vasomotor and sudomotor dysfunction and later trophic changes (now known as complex regional pain syndrome II).

**Central pain** Pain associated with a lesion of the central nervous system.

**Dysaesthesia** An unpleasant abnormal sensation, whether spontaneous or evoked (e.g. formication—a feeling like ants crawling on the skin).

**Hyperaesthesia** Increased sensitivity to stimulation, excluding the special senses.

**Hyperalgesia** An increased response to a stimulus that is normally painful (i.e. painful stimulus feels

much more painful than expected, such as firm finger pressure).

**Hyperpathia** A painful syndrome, characterised by an increased reaction to a stimulus, especially a repetitive stimulus, as well as an increased threshold for sensory detection.

**Hypoaesthesia** Decreased sensitivity to stimulation, excluding the special senses.

**Hypoalgesia** Diminished pain in response to a normally painful stimulus.

**Incident pain** Pain that occurs on, or is exacerbated by, an activity (e.g. coughing, wound dressing, movement, weight-bearing).

**Neuralgia** Pain in the distribution of a nerve or nerves.

**Neuritis** Inflammation of a nerve or nerves.

**Neuropathic pain** Pain caused by a lesion or disease of the somatosensory nervous system.

**Neuropathy** A disturbance of function or pathological change in a nerve.

**Nociceptive pain** Pain arising from stimulation of superficial or deep tissue pain receptors (nociceptors) from tissue injury or inflammation. From Latin ‘nocere’, to injure.

*continued*

continued

**Paraesthesia** Abnormal sensation, whether spontaneous or evoked.

**Phantom pain** The sensation of the presence of a missing body part.

**Somatoform pain** Pain that has the qualities of pain arising from a physical (somatic) cause but not

attributable to any objectively demonstrable organic causation (i.e. the expression of psychological distress as physical symptoms).

**Visceral pain** A type of nociceptive pain that originates from activation of nociceptives of internal viscera (organs).

## Origins of pain<sup>1,2</sup>

In general terms, the origin of conscious pain can be subdivided into three broad types—nociceptive, neuropathic or psychogenic.

- 1 *Nociceptive pain* is pain arising from stimulation of superficial or deep tissue pain receptors (nociceptors) from tissue injury or inflammation. It requires an intact nervous system. *Nociception* is stimulation of peripheral nociceptors (i.e. nerve endings sensitive to a noxious stimulus).
- 2 *Neuropathic pain* is pain caused or initiated by a primary lesion or dysfunction (i.e. damage) in the peripheral or central nervous system. It can be subdivided into central pain, when the primary lesion is in the central nervous system, or peripheral pain. Neuropathic pain is a form of neurogenic pain in which there is actual nerve

cell or axonal damage due to inflammation, trauma or degenerative disease. It is typically a constant burning, episodic shooting or electric pain.

- 3 *Psychogenic pain* is pain arising in the absence of any discernible injury and where the predominant aetiology is psychological or psychiatric. However, it is a real and distressing entity to the patient.

It should be emphasised that these types may overlap and patients may have more than one type of pain.

The features of the main types of pain are summarised in [TABLE 12.1](#).

## Components of pain<sup>2</sup>

A conceptual approach to the components of pain is illustrated in [FIGURE 12.1](#).

**Table 12.1** Features of main types of pain<sup>2</sup>

Type of pain	Origin of pain	Symptoms and signs	Examples
<b>Nociceptive</b>			
1 Somatic	Skin mucosa Bones and joints Pleura and peritoneum	Localised stinging or burning Dull ache ± Pain on movement	Skin ulcers/abscess Aphthous ulcers Arthritis Minor fractures Pleurisy
2 Visceral	Solid or hollow organs	Deep, diffuse pain Poorly localised ± Colic ± Nausea and vomiting	Abdominal tumours Bowel obstruction Major surgery Ureteric/biliary colic
3 Muscle spasm	Skeletal muscle Smooth muscle	Pain worse on movement Severe colic Tenesmus	Acute low back pain (some) Ureteric/biliary colic Bowel obstruction Rectal dysfunction
<b>Neuropathic</b>			
1 Peripheral nerve	Nerve compression or peripheral nerve damage	Pain in nerve distribution ± Motor deficit ± Sensory deficit	Prolapse IV disc Limb amputation Peripheral neuropathies Post-herpetic neuralgia
2 Central pain	Cerebrovascular accident	Various pain syndromes (see text) ± Trophic changes	Stroke Spinal cord injury Multiple sclerosis

Developing an understanding of pain depends on the knowledge of relationships among nociception, pain, suffering and pain behaviour. The first three components cannot be measured or completely understood in individuals and only the pain behaviour can be observed and measured by parties other than the patient.

## Categories of pain

Pain can be subcategorised as:

- acute pain
- cancer/palliative pain
- chronic non-cancer pain

## Acute pain

Acute pain is pain of recent onset and short duration that usually has an obvious cause and a predictable duration. It is usually opioid sensitive. It is often due to nociception (e.g. postoperative pain).

Pain behaviour may be modified by socio-environmental factors (e.g. appropriate preparation for an operation results in lower postoperative analgesic requirements).

Early and appropriate interventions by GPs can have a major impact in improving the assessment and treatment of pain and helping to prevent the development of chronic pain, as in the chronic pain cycle. This applies particularly to acute musculoskeletal injury, such as acute neck and back pain and sporting injuries.

Problem areas in acute pain management include:

- acute back pain (CHAPTER 38)
- acute neck pain (CHAPTER 62)
- acute headache (CHAPTER 56)
- acute orofacial pain (CHAPTER 52)
- acute abdominal pain (CHAPTER 34)
- acute haemarthrosis (e.g. knee in haemophilia/sports injuries) (CHAPTER 67)
- acute chest pain (CHAPTER 40)
- sports injuries (CHAPTER 136)
- trauma
- burns
- neuropathic pain (e.g. herpes zoster)

## Chronic pain

Chronic pain may be defined as pain present for a period greater than 3 months or pain present for 4 weeks more than the expected time of recovery.

Chronic pain is the classic 'heartsink' problem of practitioners as it is far more difficult to manage and is often unresponsive to agents effective in acute pain relief, such as opioids. It is, in itself, a type of disease state.

The management of chronic pain may require a multidisciplinary pain clinic strategy in which biological (pathological), psychological and social contributions to pain behaviour can be evaluated and managed.

## Assessing and measuring pain

Pain is a subjective symptom and generates considerable emotion and frustration, and thus can be difficult to assess.

Four questions needed to assess any pain:

- What is the cause of the pain?
- What is the dominant mechanism—somatic, visceral or neuropathic?
- Is there a treatable cause and is the treatment of the cause optimal?
- Is there a significant incident factor?

## The history

The classic historical approach is still the most important approach. Patients can use the PQRST approach to describe their pain,<sup>2</sup> namely, P—palliative and provocative factors, Q—quality, R—radiation, S—severity and T—timing. Most practitioners use the SOCRATES approach to pain, namely:

- S Site
- O Onset and offset
- C Character
- R Radiation
- A Associated symptoms
- T Timing
- E Exacerbating and relieving factors
- S Severity

FIGURE 12.1 A conceptual approach to the components of pain: a biopsychosocial model

## Use of body charts

To assist with diagnosis and ongoing management of pain, it is helpful to get patients to chart the site and radiation of their pain on body charts—either total body charts or regional charts (e.g. the head). This is particularly helpful for spinal pain with referral patterns and fibromyalgia.

## Measurement of pain

Despite its subjective nature, it is good to record some type of repeatable measurement, especially for chronic pain requiring treatment outcomes. This involvement also helps the patient.

## Unidimensional scales

Visual analogue scales (VAS), which are used as a research tool and well validated, can be useful in recording both acute and chronic pain levels. An example of a simple VAS linear scale on which the

patient indicates the severity of their current pain is shown in **FIGURE 12.2**. A pictorial (faces) scale applicable to children is shown in **FIGURE 12.3**.

## Multidimensional scales

These scales, which are usually employed for chronic pain, take into account several aspects of pain perception in addition to assessing functional effects and levels of disability. Examples include the:

- McGill Pain Questionnaire
- Pain Disability Index
- Form 36 Health Survey (SF-36)
- Oswestry low-back pain questionnaire

## The holistic approach to pain management

Doctors should assess not only the somatic basis of the pain but also the patient's psyche, mood, coping ability, attitude and family.

**FIGURE 12.2** Assessing pain using a visual analogue scale and body chart: ideal for lumbosacral pain

FIGURE 12.3 Visual analogue scale: a faces pain rating scale ideal for children

The pain threshold can be lowered by factors such as fatigue, anger, depression, loneliness, home or work environment. On the other hand, the factors that raise the pain threshold include a happy or contented disposition, drive to return to work, empathy, companionship, sleep, rest, pleasant diversions and good home support.<sup>3</sup>

## Analgesic prescribing

The GP has an important responsibility not only to relieve patients' pain skilfully and completely (if possible) but to ensure that the appropriate drugs are prescribed without leading to dependence.

The three categories of pain—nociceptive pain, neuropathic pain and psychogenic pain—each require different therapeutic agents.<sup>4</sup> For nociceptive pain the traditional analgesics are used: paracetamol, aspirin, other NSAIDs and opioids. Neurogenic pain is treated with antidepressants, antiepileptics and membrane stabilisers. Agents used to treat muscle pain are muscle relaxants and baclofen.

Medications used to treat pain include:

- 'simple' analgesics (aspirin, paracetamol)
- NSAIDs, cyclo-oxygenase-2 (COX-2) specific inhibitors
- opioids (weak and strong)
- antidepressants (TCAs e.g. amitriptyline), SNRIs
- membrane stabilisers (anticonvulsants, antiarrhythmics)
- NMDA blockers (ketamine)
- $\alpha_2$  agonists (clonidine)

Chronic pain, such as chronic low back pain, represents a challenge but the challenge is to manage acute pain skilfully and prevent chronicity. O'Reilly<sup>4</sup> has provided some useful guidelines for the role of the GP in the management of chronic pain:

- Emphasise that cure is unlikely.
- Encourage the patient to accept responsibility for pain management.

- Provide ongoing support and interest.
- Promote activity rather than rest.
- Educate patients about their condition: review X-rays and discuss drugs, especially the long-term disadvantages of opioids and sedatives.
- Encourage time-contingent versus pain-contingent use of medication.
- Withdraw unsuitable drugs (e.g. opioids and sedatives).
- Consider use of undiagnosed depression or anxiety as amplifiers of pain perception and treat where necessary.
- Promote the use of relaxation, distraction and heat or ice packs rather than increased medication.
- Discuss strategy for management of flare-ups in advance.
- Refer for psychological support: mindfulness, acceptance-commitment therapy (ACT) and/or cognitive behaviour therapy recommended.

## Analgesics in common use<sup>2</sup>

### Paracetamol

Paracetamol has minimal anti-inflammatory activity but moderate analgesic (equipotent with aspirin) and antipyretic properties. It is metabolised by the liver and has an excretion half-life of approximately 4 hours. Adverse effects are uncommon but gastrointestinal discomfort such as dyspepsia and nausea can occur occasionally. It is well tolerated by patients with peptic ulcers and has no effect on platelet function. Use of 4 g or more per day over 12 months has been associated with chronic liver disease. It should be administered with caution in patients with kidney or hepatic dysfunction. Although less effective than NSAIDs for pain relief, its excellent safety in therapeutic doses makes it the first-line analgesic for mild to moderate pain.

Usual dosage:

1 g (o) 4 hourly (max. 4 g/day)

Formulations of paracetamol include:

- immediate release tablets and capsules
- oral solution and suspension
- chewable tablets
- soluble or effervescent tablets
- extended-action formulation—665 mg (may provide up to 8 hours pain relief)
- suppositories (125 mg, 250 mg, 500 mg forms)
- injectable formulation

## Aspirin

Aspirin has both analgesic and anti-inflammatory activity and is a very effective drug in adults for mild to moderate acute pain. It has an extremely short half-life and is metabolised to salicylic acid, which shares the above properties. The major problems with aspirin are gastrointestinal discomfort, ulceration and bleeding.

Usual dosage:

600 mg (o) 4 hourly (max. 4 g/day)

## Opioid analgesics

These agents are usually reserved for the treatment of severe pain. Commonly used agents are the weaker opioids—codeine, oxycodone, buprenorphine, tramadol—and the stronger ones—morphine, fentanyl, hydromorphone and methadone.

Adverse effects, which are common, dose dependent and quite variable, include nausea and vomiting, constipation, respiratory depression and dysphoria, oral hygiene problems and hyperalgesia. Ongoing assessment based on the 5As is recommended. These are: analgesic effect, activity, affect, abnormal behaviour, adverse effects.

## Codeine

Codeine, which is methylmorphine, is metabolised to morphine. Controlled trials have shown codeine 32 mg to be no more effective than aspirin 600 mg.<sup>5</sup> Disturbing side effects include nausea and constipation. Its use is best avoided because of its variable metabolism secondary to cytochrome CYP 2D6 polymorphism.

Usual dosage:

30–60 mg (o) 4 hourly (max. 180 mg/day)

## Oxycodone

Oxycodone is a synthetic opioid that is very effective orally. It is useful for moderate pain in bridging the gap between the simple analgesics and strong opioids.<sup>5</sup> The oral form has a duration of action of 4 hours.

Adverse side effects include nausea, constipation, confusion and itch. It is available as an injection and is equianalgesic to morphine.

Usual dosage:

10 mg (o) 4 hourly (max. 60 mg/day),  
controlled release, (various strengths) 12 hourly  
30 mg rectally (8–12 hourly [Prolozone])

Examples: Endone, Oxycontin, OxyNorm, Targin

## Dextropropoxyphene

This controversial drug is structurally related to methadone. Adverse effects include serious cardiac disorders, dysphoria, confusion, lightheadedness and constipation. It has been associated with relatively sudden death when taken in overdose, especially with alcohol.<sup>2</sup> Continuous use should be discouraged, particularly in elderly patients and those with cardiac disease.<sup>2</sup> Avoid prescribing it for new patients.

## Morphine

Morphine is the most effective and 'gold standard' opioid for the relief of moderate to severe pain and cancer pain (see CHAPTER 11). It is worth noting that injections are not more effective than oral administration in achieving pain relief. It should be titrated according to patients' needs. Dose reduction may need to be made in patients with impaired liver or kidney function and in elderly or debilitated patients.

*Note:* Dose requirements vary considerably and patient response should be monitored frequently. There may be no upper limit to dosage in cancer patients.

Usual dosage:<sup>2</sup>

10 mg (o) 4 times daily

SC injection 5–10 mg

IV injection 5–10 mg

equipotent dose: 30 mg (o) = 10 mg parenteral

## Methadone

Methadone is an effective oral analgesic with a long but variable half-life; it is given, preferably, once or at most twice a day. Relatively unsuitable for acute pain, it is valuable for chronic pain, although long-acting morphine preparations have displaced it. It should not be used in elderly patients or those with kidney dysfunction. Its place is in management of opioid dependency but it needs to be used with care because of the risk of respiratory depression and accumulation.

## Pethidine

Pethidine is a synthetic opioid with a short duration of action. A problematic adverse effect is accumulation of its toxic metabolite (norpethidine), which can cause myoclonic and general seizures.<sup>5</sup>

It has no place in the management of chronic pain, whether cancer or non-cancer, and possibly minimal use in acute pain.

### Fentanyl<sup>2</sup>

Fentanyl is a very potent synthetic opioid which can be administered IV, IM, SC, intranasal (children), transdermal or by the epidural route. Its efficacy is similar to morphine but it has fewer side effects and is the drug of choice in renal failure. The conversion factor is: 10 mg (SC) morphine = 150–200 mcg (SC) fentanyl.

Usual dosage:

preoperation/postoperation pain, 50–100 mcg IM or slow IV  
 patches (various strengths, deliver over 72 hours), initial dose 12–25 mcg/hour  
 It takes about 8–12 hours before effecting analgesia.  
 A 25 mcg patch is equivalent to 30–35 mg IV or 100 mg oral morphine daily.

### Hydromorphone

This is structurally similar to morphine but five times more potent. It is available for oral, parenteral and intraspinal use in moderate to severe pain. Like all opioids, the risk of drug dependence is high.

Usual dosage:

2–4 mg (o) every 4 hours  
 1–2 mg IM, SC or IV (slow) every 4–6 hours  
 4–8 mg daily of SR (sustained release) preparation

### Tramadol

Tramadol is an atypical analgesic with both opioid and non-opioid features. Its use is suitable for mild to moderate mixed nociceptive and neuropathic pain. Its advantages include analgesia with minimal sedation or respiratory depression and low abuse/dependence potential. Side effects include the serotonin effect, dizziness, vertigo, nausea, vomiting, constipation, headache, somnolence, tremor, confusion and hypersensitivity reactions. Seizures have been reported.<sup>6</sup>

Usual dosage:

(as 50 mg caps or SR tabs—100, 150 or 200 mg)  
 50–100 mg (o) 2–4 times daily or 100–200 mg (SR) twice daily  
 injection 100 mg/2 mL: 50–100 mg 4–6 hourly IM or slow IV

### Buprenorphine

This is a partial agonist opioid derived from the opium alkaloid thebaine. It is useful in pain management. Sublingual preparations (0.2 mg, 0.4 mg, 2 mg, 8 mg) are used for acute, chronic and cancer pain. It is also available as a transdermal patch (TD) e.g. Norspan and injection formulation. It is used in the treatment of opioid dependence.

The patches are available in 5, 10 and 20 mcg/24 hr patches (equivalent to 3, 6 and 12 mg morphine in a 24-hour period).

### Combined analgesics

Combined analgesics are freely available both as prescribed and over-the-counter (OTC) preparations for moderately severe pain. They usually consist of a simple analgesic such as paracetamol or aspirin combined with an opioid analgesic (usually codeine). The analgesics have an additive effect because they act at different receptor sites. The use of such preparations is generally not recommended but if both agents are needed it is advisable to prescribe them separately, thus enabling individual dose adjustments.<sup>2</sup>

### Methoxyflurane

This is a volatile anaesthetic agent that is administered as inhalational analgesia with the Pentrox Inhaler in emergency situations such as at the roadside. It can be used with oxygen or air. It provides pain relief after 8–10 breaths and it continues for several minutes. It should only be used if resuscitation facilities are available.

### Prescribing guidelines for opioids<sup>7</sup>

- As a rule, restrict to SR morphine.
- SR oxycodone is more 'likeable' for patient.
- TD buprenorphine is often a good starting agent.
- Tramadol is useful but has a potential serotonin adverse effect and ceiling effect.
- Fentanyl is potent and its use questionable.
- Do not initiate with hydromorphone or fentanyl.
- Hydromorphone is very complex—best for palliative care.
- Methadone has complex kinetics so avoid initiating unless well informed.
- At least 80% of total daily opioid should be given as an SR formulation.
- Use immediate release (IR) as a guide to consolidate SR doses.

- Avoid IR-only regimens—use co-analgesics to limit dose and side effects.
- Do not use hydromorphone or transdermal fentanyl as first-line opioids in opioid-naïve patients with chronic pain.
- Ensure that the pain syndrome is opioid sensitive.
- Good record keeping is mandatory.
- Beware of drug escalation.

## Pain in children

The management of pain in children requires considerable sensitivity and wisdom. There are many clinical myths about this issue, especially that children have a high pain tolerance and analgesia is relatively dangerous. The inappropriate pain management of circumcision is a classic example.

### Guiding principles<sup>8</sup>

- All children feel pain—as much as if not more than adults.
- Neonates do feel and remember pain—even the fetus feels pain.
- Children can localise and describe their pain.
- Pain in children can be masked and they often do not report pain.
- If a child complains of pain, they are serious and it is organic until proved otherwise.
- Consider other confusing factors (e.g. developmental delay).
- Consider children's fear of analgesic injections.
- Anxiety from anticipation of a procedure is a big issue—explanation, distraction and parental involvement help.
- Adverse effects of opioids, such as addiction, do not necessarily pose serious problems in children.<sup>2</sup>
- Analgesic medication should be dosed on a per-weight basis.
- Consider analgesic combinations with more severe pain (e.g. NSAID plus opioid).

### Assessment of pain

This is very important in children of all ages and should involve a careful history and examination. Self-reporting of pain is reliable in children over 4 years of age. Close observation of non-verbal cues and behaviour is important (e.g. severe pain may be indicated by quiet withdrawal and whimpering; tachycardia).

Scaling strategies can be used—the modified faces pain scale (see FIG. 12.3) is useful in younger children,

while older children and teenagers can use a visual analogue scale.

### Analgesia in children<sup>2,8</sup>

The three most commonly used analgesics in children are paracetamol, NSAIDs and opioids. TABLE 12.2 lists the hierarchy of analgesics to be used in children.

Table 12.2 The analgesic hierarchy<sup>7</sup>

Paracetamol
NSAID (ibuprofen, naproxen)
Combination oral therapy: <ul style="list-style-type: none"> <li>• paracetamol/codeine mixes</li> <li>• alternate: NSAID/paracetamol</li> </ul>
Parenteral opioid: <ul style="list-style-type: none"> <li>• bolus IM, IV; infusion; PCA</li> </ul>
Combination parenteral therapy: <ul style="list-style-type: none"> <li>• NSAID/opioid/ketamine</li> <li>• adjuvant clonidine</li> </ul>

### Paracetamol (acetaminophen)

This is generally safe and effective even in asthmatics in therapeutic doses. It is rapidly absorbed orally within 30 minutes and well absorbed rectally.

Usual dosage:

15 mg/kg (o) every 4 hours (max. 6 doses/day)

20 mg/kg rectally, every 6 hours

Rules:

maximum daily dose:<sup>6</sup>

90 mg/kg to max. 4 g (for 2 days only)

60 mg/kg/day if aged <6 months

a dose of 10 mg/kg is no more effective than placebo

- Don't exceed recommended daily doses.
- Don't use continuously >48 hours without review.
- Don't double up, e.g. use cold and flu tablets with paracetamol. Be cautious of drug combinations.
- Don't use in a trivial fever.

Cautions:

- Jaundice
- Repeated doses over several days when febrile and/or dehydrated

Hepatotoxicity is rare and does not usually occur in doses below 150 mg/kg/day but acute paracetamol overdose (single doses of >100 mg/kg) is a potentially life-threatening event.

## Aspirin

Aspirin is not in common use in children and should not be used <16 years since it has been associated with Reye syndrome.

For antiplatelet effects use low doses 2–5 mg/kg/day.

## NSAIDs

NSAIDs have a proven safety and efficacy in children for mild to moderate pain and can be used in conjunction with paracetamol and opioids such as codeine and morphine. The advantage is their opioid-sparing effect. Contraindications include known hypersensitivity, severe asthma (especially if aspirin sensitive), bleeding diatheses, nasal polyposis and peptic ulcer disease.

Those commonly used for analgesia are:

- ibuprofen: 5–10 mg/kg (o) 6–8 hourly (max. 40 mg/kg/day)
- naproxen: 5–10 mg/kg (o) 12–24 hourly (max. 1 g/day)
- diclofenac: 1 mg/kg (o) 8 hourly (max. 150 mg/day)
- celecoxib 1.5–3 mg/kg (o) bd

The rectal dose is double the oral dose but only administered twice a day.

## Opioid analgesics

### Oral opioids

These have relatively low bioavailability but can be used for moderate to severe pain when weaning from parenteral opioids, for ongoing severe pain (e.g. burns) and where the IV route is unavailable.

### Codeine

Usual dosage:

- 0.5–1 mg/kg (o), 4–6 hourly prn (max. 3 mg/kg/day)

More effective if used combined with paracetamol or ibuprofen (see caution about variations in polymorphisms).

### Morphine

Immediate release:

- 0.2–0.4 mg/kg (o) 4 hourly prn

### Fentanyl

Fentanyl citrate can be administered orally (transmucosal) as 'lollipops', transcutaneously as 'patches', or intranasally via a mucosal atomiser device (for painful procedures).

## Parenteral opioids<sup>8</sup>

These are the most powerful parenteral analgesics for children in severe pain and can be administered in intermittent boluses (IM, IV or SC) or by continuous infusion (IV or SC). Infants under 12 months are more sensitive and need careful monitoring (e.g. pulse oximetry). This management is invariably in the hospital. Administration of parenteral opioids should not be undertaken without the availability of oxygen, resuscitation equipment and naloxone to reverse overdose.

## Analgesics in the elderly

Older patients have the highest incidence of painful disorders and also surgical procedures. As a general rule, most elderly patients are more sensitive to opioid analgesics and to aspirin and other NSAIDs but there may be considerable individual differences in tolerance. Patients over 65 years should receive lower initial doses of opioid analgesics with subsequent doses being titrated according to the patient's needs.<sup>2</sup>

## Some general rules and tips<sup>2</sup>

- Give analgesics at fixed times by the clock rather than 'prn' for ongoing pain.
- Regularly monitor your patient's analgesic requirements and modify according to needs and adverse effects.
- Start with a dose towards the lower end of the dose range and then titrate upwards depending on response.
- Avoid using compound analgesics and prescribe simple and opioid analgesics separately.
- Reserve the use of anti-emetics for the development of nausea and vomiting with opioids. Extrapyramidal reactions (dystonia and oculogyric crises) can be a problem with anti-emetics.
- Advise patients about the benefits of high-fibre foods if on analgesics. Prescribe a bulking agent or lactulose if necessary.

## Prescribing NSAIDs

NSAIDs have analgesic, antipyretic and anti-inflammatory activity. They inhibit synthesis of prostaglandins by inhibiting cyclo-oxygenase (COX) present in COX-1 and COX-2. They are very effective against nociceptive pain.

The prescribing of aspirin and other NSAIDs is an area of increasing concern to all GPs, especially in the

elderly with their increasing propensity to the pain of arthritic conditions and demands for relief. About 15% of the patients on a GP's list in the UK will present with a locomotor problem.<sup>9</sup> A common response to the symptoms of rheumatic complaints is to prescribe NSAIDs; in the US 55% of all visits by patients with arthritis will lead to a prescription for a NSAID.<sup>10</sup>

Unfortunately, the use of NSAIDs involves a high incidence of side effects, ranging from the trivial to the lethal, with many deaths from bleeding ulcers, especially in the elderly. The NSAIDs 'epidemic' prevails because the agents continue to be perceived as the best available for the relief of arthritic symptoms. Of particular concern, however, is the widespread use of NSAIDs for common problems such as back pain when the main cause is dysfunctional or mechanical without evidence of inflammation. Surprisingly, many of these patients appear to achieve a good response to NSAIDs.

The choice of NSAIDs can be controversial. Some are claimed to have more adverse effects than others but there is little evidence of substantial differences.<sup>4,11</sup> There is no doubt that particular NSAIDs are of great value in specific rheumatic conditions. Both indomethacin and phenylbutazone are more effective for the spondyloarthropathies and gout.<sup>11</sup> It is worthwhile being mindful of their half-lives. NSAIDs with short half-lives include aspirin, diclofenac, tiaprofenic acid, ketoprofen, ibuprofen and indomethacin. NSAIDs with long half-lives include diflunisal, naproxen, sulindac, piroxicam and tenoxicam, and these are useful in the treatment of chronic pain such as bony metastases in cancer.

TABLE 12.3 shows the classification of NSAIDs.

**Table 12.3** Classification of NSAIDs<sup>2</sup>

Action	Example
Non-selective inhibitors of COX-1 and COX-2, mainly in CNS	Paracetamol
Non-selective inhibitors of COX-1 and COX-2, acting in both CNS and periphery	Aspirin Ketorolac Other NSAIDs
Selective NSAIDs	
Specific inhibitors of COX-2	Celecoxib Etoricoxib Meloxicam Parcoxib
Preferential inhibitors of COX-2 over COX-1	Meloxicam

Note: COX = cyclo-oxygenase

**Table 12.4** Persons at higher risk from NSAID-induced side effects (after Ryan)<sup>11</sup>

#### Definite

Age >65 years  
Prior ulcer disease or complication  
High-dose, multiple NSAIDs  
Concomitant corticosteroid therapy  
Duration of therapy (>3 months)  
*Helicobacter pylori*

#### Possible

Conditions necessitating NSAID treatment (e.g. RA)  
Female sex  
Ischaemic heart disease/hypertension  
Kidney impairment  
Smoking  
Alcohol excess

Studies have identified certain patients who appear to have significant risk factors for the likely development of NSAID lesions (gastropathy). NSAID ulceration and its complications (see TABLE 12.4) are more prevalent in the elderly, particularly in females.

It is likely that NSAIDs have been prescribed too readily in Australia, particularly in general practice.<sup>11</sup> In a review,<sup>12</sup> a reduction of NSAID prescribing was recommended, particularly for conditions where inflammation is not a major feature (e.g. osteoarthritis and 'mechanical' back pain). Consumption has declined, probably in part because of media publicity. Haslock emphasises that those who both stop and start NSAIDs must recognise some clinical responsibilities.<sup>13</sup>

Those who start the drug have obligations to:

- ensure there is an appropriate indication for it
- provide education about the drug to the patient—its purpose, side effects and dosage regimen
- monitor its continuing need, effectiveness and safety
- give the patient permission to telephone about any concerns
- be prepared to deal with side effects
- eradicate known *H. pylori* infection

Those who stop medication have an equal obligation to:

- ascertain whether there is still a need for its therapeutic action
- take the necessary steps, if the need exists, to provide an alternative

There is evidence that peptic ulcers that develop in patients taking NSAIDs heal faster if the NSAID is dropped.<sup>14</sup>

There is no evidence that using an enteric-coated NSAID preparation or using the rectal route for administration reduces gastric damage as it is mediated almost entirely systemically after the NSAID has been absorbed.<sup>11</sup> Furthermore, trials have indicated that the efficacy of using H<sub>2</sub>-receptor antagonists for preventing NSAID gastrointestinal complications is low to absent.

An anti-inflammatory dose of fish oil should be considered as part of long-term treatment to minimise NSAID use.

A major advance has been the realisation that there are two forms of cyclo-oxygenase: cyclo-oxygenase 1 (COX-1) and cyclo-oxygenase 2 (COX-2). These both act as rate-limiting enzymes in prostaglandins and thromboxane synthesis. The respective roles of these two isoforms are depicted in **FIGURE 12.4**.

The coxibs are a group of NSAIDs synthesised to inhibit COX-2 specifically. They are on a par as an analgesic with the COX-1 inhibitors. Their gastrointestinal adverse reactions are less, but they have all the other adverse effects and drug interactions of COX inhibitors. The cardiovascular problems, including increased blood pressure, thrombosis (fatal myocardial infarction and stroke), and impairment of kidney function experienced with rofecoxib indicate the potential problems of these agents. If prescribed for patients at risk of thrombosis aspirin should be added.<sup>15</sup>

Parecoxib is a COX-2 agent that is very effective for postoperative pain as an IM or IV injection. Newer agents include etoricoxib (Arcoxia).

All NSAIDs (i.e. selective and non-selective COX-2 inhibitors) produce their prime anti-inflammatory effect by blocking COX-2 function.

Topical NSAID gel formulations have doubtful effectiveness and although absorbed in small amounts can still cause gastrointestinal haemorrhage.<sup>2</sup>

## NSAIDs and the elderly

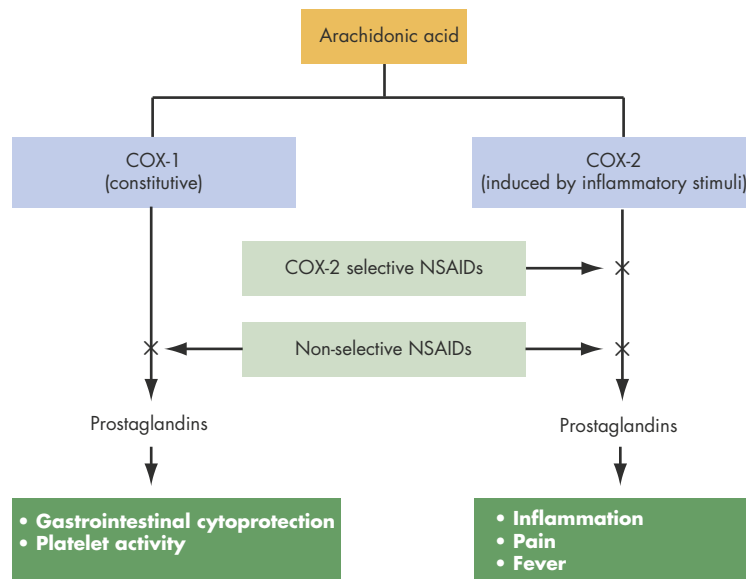

NSAIDs with short half-lives (e.g. ibuprofen and diclofenac) may be safer in the elderly and all NSAIDs should be used in reduced dosage. Patients should be monitored for fluid retention and hypertensive control and kidney function.<sup>2</sup>

## Prescribing recommendations

- Recommend intermittent use of NSAIDs based on appropriate patient education. Intermittent courses for 14 days can work well in chronic conditions, remembering that it takes about 10 days for NSAIDs to achieve maximal effectiveness. Ibuprofen is usually first choice.
- Consider protective combinations (e.g. diclofenac + misoprostol).

## Neuropathic pain<sup>16</sup>

Neuropathic pain can be defined as pain associated with injury, disease or surgical section of the

**FIGURE 12.4** Synthesis of prostaglandins from arachidonic acid may be mediated by one of two forms of cyclo-oxygenase

peripheral or central nervous system. It is a common (affects about 1% of the population) although under-identified condition.<sup>17</sup>

Considerations regarding neuropathic pain include:

- essentially due to nerve damage
- frequently involves both peripheral (mainly) and central sensitisation
- has a multiplicity of clinical pain features
- many responsible mechanisms (e.g. neuroma, demyelination, loss of normal sensory input, enhanced sympathetic activity)

### Clinical features<sup>1</sup>

- Burning, shooting, electric or stabbing pain
- Paroxysmal or spontaneous pain
- Pain in the absence of ongoing tissue damage
- Pain in an area of sensory loss (dolorosa)
- Allodynia (e.g. pain on light touch)
- Hyperpathia
- ± Hyperalgesia
- ± Dysaesthesia (e.g. 'ants crawling on skin')
- ± Delay in onset of pain after nerve injury
- Radiating electric shock-like pains in nerve distribution (e.g. Tinel's sign—tapping of neuroma or nerve)
- Often refractory to simple analgesics and NSAIDs
- Poor response to opioids
- ± Autonomic nervous system instability (e.g. pallor or cyanosis, excessive warmth or cold, sweating changes)

Examples of neuropathic pain states include:

- post-herpetic neuralgia
- trigeminal neuralgia ('tic douloureux')
- atypical facial pain
- phantom limb pain
- complex regional pain syndrome I (reflex sympathetic dystrophy)
- complex regional pain syndrome II (causalgia)
- other neuralgias
- diabetic/alcoholic peripheral neuropathy
- spinal cord injury pain
- late brachial/lumbar sacral plexus tumour infiltration
- post-stroke pain
- arachnoiditis

### Treatment<sup>16</sup>

For initial pain relief, use aspirin or paracetamol or a NSAID. However, it is usual to depend on the use of analgesic adjuvants, either orally (mainly

tricyclic antidepressants [TCAs] and anti-epileptics) or parenterally, such as lignocaine or ketamine. Adjuvants should be started in low doses and increased as necessary to the maximum tolerated level.

#### Antidepressants (first line)

TCAs:

amitriptyline 10–25 mg (o) nocte increasing every 7 days to 75–100 mg max.

Consider another TCA (e.g. nortriptyline or doxepin)<sup>2</sup>

SNRIs

duloxetine (consider for peripheral diabetic neuropathy)

30 mg (o) daily (to max. 60 mg)

and/or

#### Anti-epileptic agents

carbamazepine 50–100 mg (o) bd initially increasing to 400 mg bd max.

or

gabapentin 100–300 mg (o) daily (nocte) initially, increasing as tolerated to three times daily (max. 2400 mg)

#### Note re gabapentin

- It is renally excreted, therefore caution in elderly and renally impaired.
- Try a test dose of 100 mg (o) at night in the elderly.
- Side effects include drowsiness, dizziness and generalised fatigue.

or

sodium valproate 200–600 mg (o) bd

or

pregabalin 75 mg (o) daily initially, up to 300 mg bd<sup>17</sup>

Ketamine infusions have been used for the central desensitisation of chronic neuropathic pain but evidence of benefit is limited.

### Some guiding rules<sup>2</sup>

- TCAs may be better for constant burning pain.
- Anti-epileptics may be better for sharp shooting pain.
- Carbamazepine is the drug of choice for trigeminal neuralgia.
- Doses of TCAs are much smaller than those for treating depression.

### Evidence base

- Level 1 evidence shows that about 70% of patients have a significant response to carbamazepine.<sup>18,19</sup>

- The newer anti-epileptic gabapentin has proven efficacy for diabetic neuropathy<sup>20</sup> and post-herpetic neuralgia.<sup>21</sup>

### Painful diabetic neuropathy<sup>22</sup>

It is important to realise that painful diabetic neuropathy tends to occur in mild or even unrecognised cases of diabetes and sometimes may be a presenting symptom. Pain in the feet and legs is found in 11.6% of people with type 1 diabetes and in 31.2% of people with type 2 diabetes.

The classic complaint is burning in the feet with possible associated aching, cramping and tingling sensations. The symptoms are often worse during the night. Non-diabetic causes of painful neuropathy can include deficiency states associated with alcoholism and vitamin B12 deficiency, uraemia and ischaemic neuropathy associated with peripheral vascular disease. First-line treatment is TCAs and then duloxetine or gabapentin.

### Somatoform pain disorder

In somatoform pain, which is sometimes referred to as psychogenic pain, the patient complains of severe and distressing pain that has the qualities of pain arising from a physical (somatic) cause, but which cannot be attributed to objectively demonstrable organic pathology.<sup>2</sup> Pain occurs in association with emotional conflict or psychosocial problems deep enough to point to their possible causation.

Differential diagnoses include occult organic pain, depression, substance abuse, malingering and rare disorders such as sickle cell anaemia and porphyria. Management is difficult and is based on caring support devoid of promoting the 'sick role'. Psychological treatments are directed towards helping the patient to cope and 'live with the pain'. The possibility of comorbid depression should be addressed and if it is possible an appropriate trial of antidepressants can be tried. Referral for CBT or similar psychotherapies or to a pain clinic are options.

#### Practice tips

- Stop opioids if not effective/not improving function and wean by 10% of daily dose per week (this may take months).
- Physiotherapy has an important role in the management of pain.

*Not the possession of truth, but the effort of struggling to attain it brings joy to the researcher.*

Goffhold Lassing (1729–81)

Effective research is the trademark of the medical profession. When confronted with the great responsibility of understanding and treating human beings we need as much scientific evidence as possible to render our decision making valid, credible and justifiable.

Research can be defined as ‘a systematic method in which the truth of evidence is based on observing and testing the soundness of conclusions according to consistent rules’<sup>1</sup> or, to put it more simply, ‘research is organised curiosity’,<sup>2</sup> the end point being new and improved knowledge.

In the medical context the term ‘research’ tends to conjecture bench-type laboratory research. However, the discipline of general practice provides a fertile research area in which to evaluate the morbidity patterns and the nature of common problems in addition to the processes specific to primary health care.

There has been an excellent tradition of research conducted by GPs. Tim Murrell in his paper ‘Nineteenth century masters of general practice’<sup>3</sup> describes the contributions of Edward Jenner, Caleb Parry, John Snow, Robert Koch and James MacKenzie, and notes that ‘among the characteristics they shared was their capacity to observe and record natural phenomena, breaking new frontiers of discovery in medicine using an ecological paradigm’.

This tradition was carried into the 20th century by GPs such as William Pickles, the first president of the Royal College of General Practitioners, Keith Hodgkin and John Fry, all of whom meticulously recorded data that helped to establish patterns for the nature of primary health care. In Australia the challenge was taken up by such people as Clifford Jungfer, Alan Chancellor, Charles Bridges-Webb, Kevin Cullen and Trevor Beard in the 1960s,<sup>4</sup> and now the research activities of the new generation of GPs, academic-based or practice-based, have been taken to a higher level with the development of evidence-based medicine (EBM).

Based on the work of the Cochrane Collaboration and the initiatives of Chris Silagy and later Paul

Glasziou and Chris Del Mar in particular it has developed in the context of Australian general practice and now beyond that. The focus of EBM has been to improve health care and health economics. Its development has gone hand in hand with improved information technology. EBM is inextricably linked to research.

The aim of this chapter is to present a brief overview of research and EBM and, in particular, to encourage GPs, either singly or collectively, to undertake research—simple or sophisticated—and also to publish their work. The benefits of such are well outlined in John Howie’s classic text *Research in General Practice*.<sup>5</sup>

## Why do research?

The basic objective of research is to acquire new knowledge and justification for decision making in medical practice. Research provides a basis for the acquisition of many skills, particularly those of critical thinking and scientific methodology. The discipline of general practice is special to us with its core content of continuing, comprehensive, community-based primary care, family care, domiciliary care, whole-person care and preventive care. To achieve credibility and parity with our specialist colleagues we need to research this area with appropriate methodology and to define the discipline clearly. There is no area of medicine that involves such a diverse range and quantity of decisions each day as general practice, and therefore patient management needs as much evidence-based rigour as possible.

Our own patch, be it an isolated rural practice or an industrial suburban practice, has its own micro-epidemiological fascination. Thus, it provides a unique opportunity to find answers to questions and make observations about that particular community.

There are also personal reasons to undertake research. The process assists professional development, encouraging clear and critical thinking, improvement of knowledge and the satisfaction of developing new skills and opening horizons.

The author undertook many small studies on common, everyday problems during 10 years in country practice to determine the most effective treatments for which no or minimal evidence in the literature could be found. Many of these recommendations—for problems such as tennis elbow, cold sores, aphthous ulcers, ingrown toenails, hiccoughs, back pain, nightmares, temporomandibular dysfunction and warts—appear in this text. Although the numbers were relatively small, it was a useful study to compare treatments for about 10 or 20 cases to test hypotheses and allow trends to emerge. The results from a large controlled trial would, of course, take precedence over these recommendations if they differed. However, the exercise, albeit limited, added immense interest to one's practice, which at times can be tedious without such scholarly challenges.

An important reason to undertake research is to conform with quality assurance processes that are now being expected of practitioners. The significant processes evaluating our accountability for quality control include audits of our own records, studies of critical incidents and morbidity studies.

## Who should do research?

Any GP searching for answers to questions and who has the opportunities should undertake research. Research is largely opportunistic; for some it may be an impulsive reaction to a fascinating observation, for others a carefully conceived plan.

It can be undertaken in solo practice where the ability for personalised supervision of outcomes in patients is unique but where double-blind controlled trials are often impossible.

Research can be collaborative, and in fact this is an excellent way to get started. This can occur in a group practice.

Practitioners with computer skills and information technology at their fingertips are ideally placed to undertake research. Many GPs who have started 'small' have progressed to great heights of research activity, especially using their computer skills. In the process of posing questions and eventually finding the answers they frequently refer to the experience as 'good fun'.

The Royal Australian College of General Practitioners (RACGP) promotes and supports general practice research (visit [www.racgp.org.au/researchfoundation/grants](http://www.racgp.org.au/researchfoundation/grants) or email [research@racgp.org.au](mailto:research@racgp.org.au)).

## Asking questions

We often ask questions during the course of managing patients and such questions can form the basis of a research project, however simple.

Typical questions might be:

- Is all night-time cough in children due to asthma?
- Is suicide or attempted suicide in adolescent males precipitated by sexual problems?
- Is cancer precipitated by stress or unhappiness?
- Is recurrent migraine caused by cervical dysfunction?
- Is there any significant difference in response to various antibiotics to treat otitis media in children presenting in general practice?
- Does the distribution of leaflets by the receptionist in the waiting room lead to increased immunisation rates or Pap tests?
- Are my patients satisfied with the services they receive?
- Does the provision of patient information leaflets for the management of hypertension (or diabetes) lead to better compliance?

## Research on what?

General practice has its own unique characteristics including illness content, processes, epidemiology, health services, quality assurance and doctor–patient relationships. The special contact with patients provides opportunities to evaluate their perspectives on health service delivery, psychosocial issues and communication skills. The old saying 'dig where you are' is relevant to all of us. GPs invariably develop their own special interests and this is a logical area in which to conduct research. Conducting a morbidity and prescribing survey in a practice is a simple and fascinating study. If the results are added to a wider study, invaluable information about the nature of general practice is obtained.<sup>5,6,7</sup>

The development of the International Classification of Health Problems in Primary Care and the International Classification of Process in Primary Care, by the World Organization of National Colleges and Assemblies of General Practice and the WHO, have greatly assisted the process of morbidity studies. This information is now presented in the publication *International Classification of Primary Care* (ICPC).<sup>8</sup>

Research in general practice obviously covers many clinical areas studied by other groups but we may ask different types of questions, study different populations and use different methodologies, especially qualitative methods.

It would be logical to conduct research on those common problems requiring continuing care by the GP. These include:

- alcohol problems
- anxiety and depression
- arthritis
- chronic back pain and neck pain
- cancer
- cardiovascular disorders
- diabetes mellitus
- epilepsy
- hypertension
- migraine and other headache
- women's health

Special opportunities, such as the observation that certain diseases or conditions are linked with specific circumstances, present frequently in primary care. An example is the observation that a group of farmers who presented to their rural practitioner over a period of time with lymphosarcoma were all exposed to a specific herbicide to control blackberry growth on their farms. This led to further, statewide investigations of this association, which indicated a significant link between the agent and the disease.

## Understanding terminology

### Validity and reliability

- An ideal method of collecting research material is one that is valid.
- A valid method is one that measures what it claims to measure.
- A reliable method is one that produces repeatable results.

*Validity* refers to the 'true' answer, which must be relevant, complete and accurate. Three significant questions that evaluate validity are:<sup>1</sup>

- Is the study useful or is the result inconclusive?
- Do you accept the results of this study as applied to the source population?
- Do the results apply to the population in which you would be interested?

*Internal validity* refers to the adequacy of the study methods in reference to the study population, while *external validity* refers to the generalisability of the results to the general population.

*Reliability* refers to the stability of question-and-answer response and is most successfully measured by testing and then retesting (repeatedly). The most

frequently used method of testing for repeatability is to repeat application of the test.

## Sensitivity, specificity and predictive values

Sensitivity and specificity, which are integral to validity, are important considerations in decision making in medicine, particularly in choosing appropriate investigations for disease diagnoses. The method of calculation of sensitivity, specificity and predictive values is summarised in [FIGURE 13.1](#).

The *sensitivity* of a test depends on the proportion of people with the characteristic (disease) in whom the test is positive (i.e. percentage positive with disease). For example, if the sensitivity for a sign is 90% then the sign will be detected in 90% of the people but not in 10%. The ultimate sensitive test is one that detects all true positive cases.

The *specificity* of a test depends on the proportion of people without the characteristic (disease) in whom the test is negative (i.e. percentage negative of healthy people). The ultimate specific test is one that detects all the truly negative (disease-free) cases. A *gold standard* test is one that is as close to 100% specificity and 100% sensitivity as possible.

### Aide-mémoire tip

SPIN—Specific tests where a positive helps rule IN disease

SNOUT—Sensitive tests where a negative helps rule OUT disease

A clinical example of sensitivity and specificity is presented in [TABLE 13.1](#).

**Table 13.1** The predictability of signs and symptoms for carpal tunnel syndrome<sup>9</sup>

	Sensitivity (%)	Specificity (%)
Paraesthesia	97	4
Waking at night	91	14
Anaesthesia	57	61
Phalen's test	58	54
Tinel's test	42	63
Two point discrimination test	6	98

Predictive values that are useful indices of validity can be expressed as positive and negative values. Consider the example of a patient presenting with

	Test positive	Test negative		
Condition present	A True positive	C False negative	A + C	Sensitivity $\frac{A}{A + C} \%$
Condition absent	B False positive	D True negative	B + D	Specificity $\frac{D}{B + D} \%$
	Positive predictive value $\frac{A}{A + B} \%$	Negative predictive value $\frac{D}{C + D} \%$		

**Sensitivity:**

**Specificity:**

**Positive predictive value:**

**Negative predictive value:**

How often a test shows pathology when it is present

How often a test is normal when no pathology present

Indicates the likelihood of the patient having disease when the test is positive

Indicates the likelihood of the patient not having disease when the test is negative

**FIGURE 13.1** Definitions of sensitivity, specificity and predictive values

haematuria. In general practice the positive predictive value for carcinoma as the cause would be less than 5% but is about 50% in the inpatient hospital setting.

## Incidence and prevalence

It is easy to confuse the meanings of these two terms:

- *Incidence* refers to the number of new cases of a disease (or factor of interest) occurring in a defined population within a specified period of time.
- *Prevalence* refers to the total number of individuals who have the disease (or factor of interest) at a particular time in a population. The number is divided by the number of people in the population at that time.
  - Example: the prevalence of multiple sclerosis in temperate climates is 1 in 1000–2000 compared with 1 in 10 000 in the tropics. The incidence of multiple sclerosis in the Australian state of Victoria (population 4 400 000) is 8 per 100 000 per year.

## Bias

This is any effect occurring during the investigation that tends to produce results that depart systematically from the true values. Varieties of

bias include *measurement bias* (e.g. fault with a sphygmomanometer recording blood pressure), *confounding bias* (e.g. influence of alcohol on a study investigating the association between stress and hypertension) and *selection bias* (e.g. using hospital outpatients in a community-based study).

## Confounding

This is a situation in which a measure of the effect of exposure on risk is distorted by the association of exposure with other (known or unknown) factors that influence the outcome.<sup>1</sup> A confounder is a factor that distorts the apparent magnitude of the effect of a study on risk.

## Chance

One must question the probability that the results favouring the experimental intervention could have occurred by chance; therefore, we resort to statistical help in the form of a probability statement or significance level.

## How is the research undertaken?

'Getting started' can be quite difficult for the beginner. However, assistance that should be accessed is available from several sources including

individual GPs with research experience, university departments of general practice and the RACGP research committee. It is appropriate to seek out a suitable supervisor for the study. A chronological method follows.

- 1 *The idea.* Start with an idea or question, which needs to be interesting, relevant, significant and answerable.<sup>10</sup> It may be appropriate to develop a hypothesis at this stage.
- 2 *Float the idea.* Next, discuss the idea with colleagues or an appropriate accessible authority.
- 3 *Do a literature search.* Review the literature, for example, a Medline search or checking with a central research 'bank'. Undertake a critical review.
- 4 *Prepare a plan.* This can be a short written plan outlining the methodology for the study.
- 5 *Evaluate the plan.* Then, contact a supervisor or appropriate authority to evaluate the study plan, which may be referred to a reference group or research committee.
- 6 *Methodology: develop a protocol.*
  - Prepare background; outline objectives and develop a hypothesis.
  - Select target population using clear criteria and appropriate numbers.
  - Design the research:
    - qualitative or quantitative?
    - questionnaire/s
  - Assess internal validity.
  - Consider statistical implications early:
    - number of patients
    - method for data analysis
  - Recruit subjects and assistants.
  - Assess the timeframe.
  - Assess the ethical considerations → ethics approval committee.
- 7 *Consider a preliminary pilot study and project timetable.*
- 8 *Seek funding.* Solicit advice for appropriate funding bodies.
- 9 *Conduct the study.*
- 10 *Undertake data/statistical analysis.*
- 11 *Undertake interpretation and conclusions.*
- 12 *Prepare for publication.*

## Research design

### Hypothesis development

The reasoning process of the researcher is based on the null hypothesis—that is, an experimental group does not differ from a control 'normal' group in outcome.

The question to consider is: 'What is the probability that results from the experimental intervention would have occurred by chance?'. The answer is based on a probability statement: 'The probability that the positive results occurred by chance is less than 5% ( $P < 0.05$ )'.<sup>11</sup>

### Selecting a representative sample of appropriate size

Two basic components of subject selection are sample size and sample representativeness. The latter should be selected in a well-controlled manner.

A common question is: 'What is the ideal size of the sample?'. There is no fixed answer but it must be adequate to produce statistically meaningful results.

Recruitment of patients is a particular skill and often hard work, but it is easier if the researcher has a large pool of patients with whom he or she enjoys a good relationship. A useful rule is to aim to approach  $3n$  patients if you wish to work with a sample size of  $n$ .

Some guidelines for choosing the sample size are:<sup>11</sup>

- the more the individuals in the population differ, the larger the required sample
- the more planned comparisons, the larger the size
- larger sample sizes allow detection of smaller differences

### Types of research<sup>1</sup>

The two broad categories of research in general practice are qualitative research, which is based on observation and talking with people, and quantitative research, which is based on measurement and analysis of data collection.

Research can also be classified as primary research, which includes both qualitative and quantitative methods, and secondary research, which involves systematic reviews and meta-analysis.

### Qualitative research<sup>12</sup>

This research is basically concerned with evaluating human behaviour from the subject's perspective. It is based on close observation and is expressed in a descriptive way. It addresses questions that begin 'Why?', 'How?', 'In what way does?'.

### Common qualitative approaches

- Phenomenology
- Ethnography
- Grounded theory

- Biography (life story, narrative enquiry)
- Case study

The methods used are:

- interviews (open-ended, semi-structured)
- focus groups
- participation observation
- document analysis

Qualitative research is an excellent method for generating hypotheses and can lead to quantitative research.

### Phenomenology

The central focus of philosophy/method is the lived experience of the world of everyday life. It describes events, situations, experiences and concepts. It provides:

- detailed descriptions of an experience or event as it is lived
- deeper understandings and sensitivities
- improved thoughtful provision of care

Examples:

- effects of Viagra (and other agents) on marital/sexual relationships
- experience of carers in Alzheimer disease
- effects of workplace bullying on absenteeism

### Ethnography (ethnos = a nation)

This examines cultures, peoples and societies including subgroups, e.g. adolescents. It is the basis of anthropology. The investigator usually identifies one or more key witnesses (informants) and interviews them to clarify observations.

### Grounded theory

This is the development of new theory through the collection and analysis of data. It seeks to identify the core social processes within a given context in order to build theory that is grounded in the reality of those being studied.

### Quantitative research

Quantitative research is research based on the collection of data in numerical quantities and asks a specific narrow question, such as 'What is the chance that . . .?' or 'What proportion of . . .?'. It is concerned with hypothesis testing, reliability and validity and is the cornerstone of epidemiology. It can be classified broadly as observational, which includes case control, cross-sectional and cohort studies, and experimental, which includes the classic controlled trial.<sup>12</sup>

- *Case control (or retrospective) study* is an observational study in which people with a disease (cases) are compared with those without it (control group).
  - Examples: Patients with mesothelioma were investigated for exposure to asbestos or other agents; the mothers of children born with birth defects were investigated for an association with drug intake during pregnancy.
- *Cross-sectional or prevalence study* follows a correlation approach using existing databases. It is a survey of the frequency of disease, risk factors or other characteristics in a defined population at one particular time.
  - Example: The prevalence of diabetes mellitus (diagnosed and undiagnosed) was investigated in an Aboriginal community living in a particular area of metropolitan Sydney.
- *Cohort (or prospective) study* is also referred to as 'follow-up'. The study follows a group (cohort) of individuals with a specified characteristic or disease over a period of time. Comparisons may be made with a control group.
  - Example: 120 patients with chronic sciatica were followed over 10 years to determine the outcome of their pain and neurological deficit. These were compared with a matched group who had undergone laminectomy.
- *Clinical controlled trial* is an experimental study that tests for hypothesised outcomes. An intervention is conducted on a randomly selected group of people and compared with a matched control group not subject to the specific intervention. The objective is to establish a causal relationship between the intervention and the hypothesised outcome. The ideal scientific trial is a **double-blind trial** where neither staff nor the participating patient are aware the participant is in the intervention or control group. This is the typical study when assessing the outcome of a drug trial as compared with placebo.

### Meta-analysis

Meta-analysis is the process that systematically assesses compatible randomised controlled trials by merging the data (from usually smaller and inconclusive trials) to draw a 'firmer' conclusion from larger numbers of subjects.

## Evidence-based medicine

Evidence-based medicine (EBM) is a process of basing clinical practice on validated information. According to one of its modern architects, David Sackett, it is 'the explicit, judicious and conscientious use of current best available evidence in making decisions about the care of individual patients'.<sup>13</sup> According to Silagy and Haines, 'EBM is the integration of the best available scientific evidence with your clinical expertise and knowledge, your intuition, your wisdom'.<sup>14</sup>

The process of using EBM should be very comfortable for GPs because scientific methodology and evidence is second nature to us and has been the basis of our clinical decision making prior to and subsequent to graduation.

The proposed five steps of EBM are similar to basic research methodology:<sup>14</sup>

- 1 Construct a clinical question or define the problem.
- 2 Search for the evidence.
- 3 Appraise the quality and relevance of the evidence.
- 4 Apply it to the care of an individual patient.
- 5 Evaluate how effective it is.

The statistical methodologies used in EBM cover the traditional research methods but there is an emphasis on the methods of risk reduction, absolute and relative risk reduction and numbers needed to treat. These definitions are included in the glossary of terms later in this chapter.

GPs have a responsibility to their patients to be well versed with the best evidence when making decisions about management (see **TABLE 13.2**), whether it be for a minor surgical procedure, selection of drugs, selection of an investigation or referral to the most appropriate consultant. If the best evidence reveals that a certain practice we are using is of no value or there may be more efficacious methods to our favoured method, then we should be prepared to change. On the other hand, if we find that a certain method works for us and there is no current evidence that it is the most appropriate one or the evidence is equivocal, then there is no compelling reason to change.

GPs need a healthy scepticism about what is best evidence and claims for treatment in addition to the skill of critical appraisal of research/evidence. We tend to be impressed by the perception that evidence is a numbers game. However, the great work of James Lind (see the introduction to **CHAPTER 10**) shows that facts do not necessarily involve large numbers.

**Table 13.2** Levels of evidence

- |   |   |
|---|---|
| 1 | Evidence obtained from a systematic review of all relevant randomised trials.   |
| 2 | Evidence obtained from at least one properly designed randomised controlled trial.  |
| 3 | Evidence from well-controlled trials that are not randomised, or well-designed cohort or case-control studies, or multiple time series (with and without the intervention). |
| 4 | Opinions of respected authorities; based on clinical experience; descriptive studies; or reports of expert committees.  |

Source: Modified from the NHMRC.

For EBM to be accepted by GPs the information needs to be readily accessible, user friendly, significant, relevant and, perhaps, believable.

The strength of EBM is that it can provide the answers to very important everyday decisions, especially in screening and preventive medicine, where guidelines have fluctuated over the decades. The most recent RACGP guidelines for preventive activities in general practice<sup>15</sup> highlight the value of current evidence (see [www.racgp.org.au/your-practice/guidelines](http://www.racgp.org.au/your-practice/guidelines) for presentation).

GPs are currently faced with important decisions about the effectiveness of complementary therapies, which are very tempting to embrace or trial when searching for ways to manage difficult problems, such as chronic fatigue syndrome, fibromyalgia, chronic asthma, chronic pain syndromes and other chronic diseases. We are hopeful that EBM can provide the answers to best practice in addition to evaluating individual therapies.

To counterbalance the strengths (potential or real) of EBM there are concerns that it will be seized by bureaucrats to develop 'cook book' guidelines, Holy Writ or economic rationalisation. Others are concerned about the perceived lack of flexibility. A very interesting critical review, especially affecting psychiatry, was presented by John Ellard in his paper 'What exactly is evidence-based medicine?'.<sup>16</sup> He questioned the validity of the evidence underpinning EBM and the biases of both the proponents of 'science' and 'art' with the caution of Louis Pasteur: 'The greatest derangement of the mind is to believe in something because one wishes it to be so'.<sup>17</sup>

## Glossary of terms<sup>18,19</sup>

Apart from the terms and definitions used in preceding pages it is important to highlight the following terms used in EBM/research.

**Absolute risk reduction (ARR)** The absolute difference in event rates between two intervention or treatment groups. It gives an indication of the baseline risk and treatment effect. An *ARR* of 0 means no difference and thus the treatment has no effect.

Example: The *ARR* for prophylactic ciprofloxacin in the case cited is  $10 - 2 = 8$  per 100 (0.08) or 8%.

### Accessing the evidence

By computer/CD-ROM:

- The Cochrane library includes:
  - The Database of Systemic Reviews
  - Database of Abstracts of Reviews of Effectiveness
- [www.thecochranelibrary.com](http://www.thecochranelibrary.com) or [www.cochrane.org](http://www.cochrane.org)
- Bandolier: [www.medicine.ox.ac.uk/bandolier/](http://www.medicine.ox.ac.uk/bandolier/) A UK journal on EBM with excellent summaries on NNT for a host of common interventions

**Analysis of variance** This allows comparisons between the means of two samples of similar populations with a normal distribution. The contribution to variance for each variable can be determined and tested for statistical significance.

**Clinical significance** The benefit to people receiving an intervention compared to the control group being great enough to warrant the intervention. It is based on measure of effect.

**Confidence interval** The statistically derived range of values around a trial result in which the probability is that the true result will be within the range.

A 95% (standard) confidence interval for a sample indicates that there is a 95% chance that the interval includes the true population proportion whose care complies with the evidence. It is a measure of the certainty that the figures are correct.

**Control event rate (CER)** The percentage of subjects in the control group that experienced the event of interest.

**Experimental event rate (EER)** The percentage of subjects in the intervention group that experienced the event of interest.

**Kappa** Cohen's kappa measures the agreement between the evaluations of two raters when both are rating the same object. A value of 1 indicates perfect agreement. A value of 0 indicates that agreement is no better than chance. It is an appropriate statistic for tables that have the same categories in the columns as in the rows (e.g. when measuring agreement between two raters).

**Number needed to treat (NNT)** The number of people who must be treated over a given period of time with the experimental therapy (specific intervention) to achieve one good outcome or prevent one adverse outcome. This incorporates the duration of treatment. It is a measure of the absolute relative risk. Obviously the lower the *NNT*, the better the treatment. It is calculated as  $100/ARR$  (%); that is, the reciprocal of the *ARR*.

In the above example the number needed to treat would be 12 to 13 for 60 days.

*Note:* The *NNT* will be different for different patient populations depending on their baseline risk for developing the outcome of interest.

**Odds ratio** The probability of the occurrence of an event to its non-occurrence.

### Publications

- Clinical evidence: BMJ Publishing Group, refer to [www.clinicalevidence.org](http://www.clinicalevidence.org)
- Evidence-based medicine. BMJ Publishing Group

**Probability (P) value** The probability that an observed difference occurred by chance. The standard convention is that there is only a 5% (1 in 20) probability that the difference would fall outside this range by chance alone (i.e. a *P* value of 0.05 or 5%).

**Relative risk (RR)** The ratio of the risk of the outcome (e.g. disease or death) in the treatment/exposure group compared with the control/unexposed group. *RR* informs us how many times more likely an event will occur in the treatment group compared with the control group.

**Calculation:**  $RR = EER/CER$

$RR = 1$  means no difference, so treatment has no effect

$RR > 1$  means the treatment increases the risk of disease/death

$RR < 1$  means the treatment decreases the risk

Example: If the risk of death from people exposed to inhalation of anthrax spores is reduced from 10 in 100 cases to 2 in 100 cases with 60 days of prophylactic ciprofloxacin, the *RR* of death in this group is 0.20 or 20%.

**Relative risk reduction (RRR)** The proportional reduction of adverse events between the treatment/experimental and the control groups in a trial (i.e. *RRR* is the ratio of the absolute risk reduction to the risk of the outcome in the control group). An alternative way to calculate the *RRR* is to subtract the *RR* from 1 (i.e.  $RRR = 1 - RR$ ). In the example it is:  $1 - 0.2 = 0.80$  or 80% or:

$$RRR = \frac{ARR}{10} = \frac{8}{10} = 0.80 \text{ or } 80\%$$

*continued*

continued

RRR is probably the most commonly reported measure of treatment effects but the ARR gives a more realistic picture.

**Risk (R)** The probability that an event (death or disease) will occur.

**Statistical significance** The likelihood of a difference between two groups being real. It is the possibility that the difference occurred by chance alone. It is based on confidence intervals and *P* values. A 0.5

confidence level suggests that 19 times out of 20 the finding of the difference between the two groups is valid.

**Type I error** A type I error occurs when a study concludes that there is a difference between two groups when there is no difference.

**Type II error** A type II error occurs when a study concludes that no difference exists between groups when there is a true difference.

## Critical appraisal of published research

The objective of critically appraising a paper is to determine whether the methods and results of the research have significant validity to produce useful information. The appraisal starts with a careful review of the abstract, which ideally should be presented in a structured format.

- 1 What were the objectives of the study?
- 2 Were the ethical aspects properly followed?
- 3 What was the study design?
- 4 Were there any potential problems associated with the design?
- 5 Were all the patients who entered the study properly accounted for at its conclusion?
- 6 What were the important results?
- 7 How would you interpret and explain these results?

## Emporiatrics—the science of travel medicine

With over 600 million international trips being taken annually, the health problems faced by travellers are considerable and variable depending on the countries visited and the lifestyle adopted by the traveller.<sup>1</sup> There is evidence that many travellers are receiving inaccurate predeparture travel advice. Travellers to North America, Europe and Australasia are usually at no greater risk of getting an infectious disease than they would be at home, but those visiting the less developed tropical and subtropical countries of Africa, Central and South America and South-East Asia are at significant risk of contracting infectious diseases. The immunocompromised are those at greatest risk.

Problems range in complexity from the most frequent and usually benign problems, such as traveller's diarrhoea, to more exotic and potentially fatal infections such as malaria, Japanese encephalitis and HIV. It must also be remembered that in some countries with volatile political changes there is the possibility of injury, incarceration or being left stranded. Travel means transport and thus the potential for accidents and crippled body and bank balance. Insurance for such contingencies is as important as preventive health measures.

## Principles of pre-travel health care

- Advise the patient to plan early—at least 8 weeks beforehand.
- Advise a dental check.
- Allow adequate time for consultation (e.g. 30–45 minutes).
- Individualise advice.
- Provide current information.
- Provide written as well as verbal advice.
- Provide a letter concerning existing medical illness and treatment.
- Encourage personal responsibility.

## Key facts and checkpoints

- The main diseases facing the international traveller are traveller's diarrhoea (relatively mild) and malaria, especially the potentially lethal *Plasmodium falciparum* malaria.
- Most cases of traveller's diarrhoea are caused by enterotoxigenic *Escherichia coli* and *Campylobacter* species.
- Enteroinvasive *E. coli* (a different serotype) produces a dysentery-like illness similar to *Shigella*.
- Traveller's diarrhoea is contracted mainly from contaminated water and ice used for beverages, washing food or utensils, or cleaning teeth.
- Poliomyelitis is endemic in at least 20 countries and thus immunisation for polio is still important.
- One bite from an infected mosquito during a single overnight stop in a malaria area can result in a possible lethal infection.
- Infections transmitted by mosquitoes include malaria, yellow fever, Rift Valley fever, Japanese B encephalitis, chikungunya and dengue fever. Avoiding their bites is excellent prevention.
- Every year approximately 1000 Australians catch malaria while travelling overseas.
- Malaria is a dusk-till-dawn risk only, but bites from daytime mosquitoes can cause dengue.
- *P. falciparum* malaria is steadily increasing, as is resistance to newer antimalarials.
- It is important for GPs to consult a travel medicine database to obtain specific information about 'at risk' countries.
- Avoid tattooing, ear-piercing, acupuncture or any skin puncturing while overseas.
- The commonest causes of death in travellers overseas are trauma (26%), particularly traffic accidents, and homicide (16.9%).

## Gastrointestinal infections

The commonest problem facing travellers is traveller's diarrhoea but other important diseases

caused by poor sanitation include hepatitis A, and worm infestations such as hookworm and schistosomiasis.

Contamination of food and water is a major problem, especially in third world countries.

Reputable soft drinks, such as Coca-Cola, should be recommended for drinking. Indian-style tea, in which the milk is boiled with tea, is usually safe, but tea with added milk is not. The food handlers can be infected and the water used to wash food may be contaminated.

## § Traveller's diarrhoea

Traveller's diarrhoea is a special problem in Mexico, Nepal, India, Pakistan, South-East Asia, Latin America, the Middle East and Central Africa and its many colourful labels include 'Bali Belly', 'Gippy Tummy', 'Rangoon Runs', 'Tokyo Trots' and 'Montezuma's Revenge'. It occurs about 6–12 hours after taking infected food or water.

The illness is usually mild and lasts only 2 or 3 days. It is unusual for it to last longer than 5 days. Symptoms include abdominal cramps, frequent diarrhoea with loose, watery bowel motions and possible vomiting. Very severe diarrhoea, especially if associated with the passing of blood or mucus, may be a feature of *Shigella* sp or *Campylobacter* sp infections and amoebiasis.

Most traveller's diarrhoea is caused by enterotoxigenic *E. coli* (ETEC), *Campylobacter* sp, *Shigella* sp and *Salmonella* sp. Travellers are infected because they are exposed to slightly different types or strains of *E. coli* from the ones they are used to at home.<sup>2</sup>

The possible causes of diarrhoeal illness are listed in TABLE 14.1.

### Treatment

Refer to FIGURE 14.1.<sup>2,3</sup>

The key factor in treatment is rehydration.

### Mild diarrhoea

- Maintain fluid intake—Gastrolyte.
- Antimotility agents (judicious use: if no blood in stools)—avoid in children.  
loperamide (Imodium) 2 caps statim then 1 after each unformed stool (max. 8 caps/day)  
or  
diphenoxylate with atropine (Lomotil) 2 tablets statim then 1–2 (o) 8 hourly  
Imodium is the preferred agent.

Table 14.1 Causes of diarrhoea in travellers

	Causative organism	Type of illness
<b>Bacteria</b>	<i>Escherichia coli</i>	Traveller's diarrhoea
	<i>Shigella</i> species	Dysentery
	<i>Salmonella</i> species	Typhoid fever, food poisoning
	<i>Campylobacter jejuni</i>	Traveller's diarrhoea, dysentery
	<i>Vibrio cholerae</i>	Cholera
	<i>Vibrio parahaemolyticus</i>	Traveller's diarrhoea
	<i>Yersinia enterocolitica</i>	Traveller's diarrhoea
	<i>Aeromonas hydrophila</i>	Traveller's diarrhoea
	<i>Staphylococcus aureus</i> (toxin)	Food poisoning
	<i>Clostridium perfringens</i>	Food poisoning
<b>Viruses</b>	<i>Bacillus cereus</i>	Food poisoning
	Rotavirus	Children's diarrhoea
<b>Protozoa parasites</b>	Norwalk virus	Traveller's diarrhoea
	Cryptosporidium	Amoebiasis
	<i>Entamoeba histolytica</i>	Giardiasis
	<i>Giardia lamblia</i>	Strongyloidiasis
	<i>Strongyloides stercoralis</i>	
	Schistosomiasis	
	Cyclosporiasis	
	Cryptosporidiosis	
	Isoporiasis	
	Chemicals	Capsicum (chilli)

### Moderate diarrhoea<sup>3</sup>

- Attend to hydration.
- Patient can self-administer antibiotic—e.g. single dose norfloxacin or azithromycin (especially in India, Nepal and Thailand).
- Loperamide in adults.

### Severe diarrhoea (patient toxic and febrile)

- ? Admit to hospital.
- Attend to hydration—use an oral hydrate solution (e.g. Gastrolyte).
- Loperamide in adults.
- Antibiotic: norfloxacin, ciprofloxacin or azithromycin (usually 3 days).

*Note:* There is increasing resistance to doxycycline and cotrimoxazole, especially in South-East Asia.

### Persistent diarrhoea

Any travellers with persistent diarrhoea after visiting less-developed countries, especially India and China,

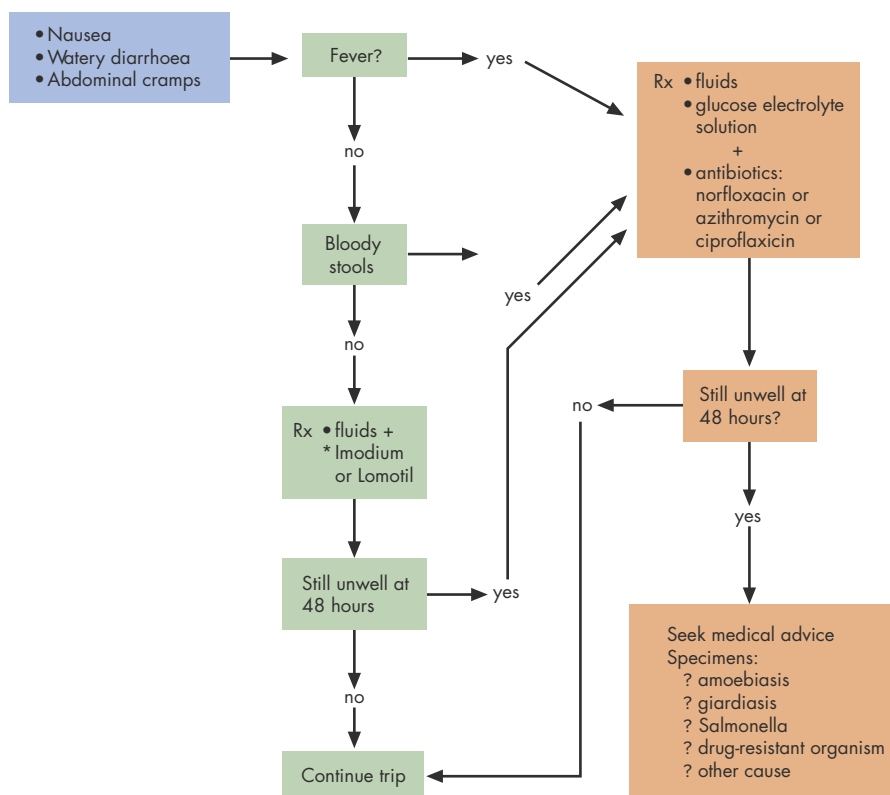

FIGURE 14.1 Algorithm for adult travellers with acute diarrhoea

Source: After Locke<sup>2</sup>

may have a protozoal infection such as amoebiasis or giardiasis. If the patient has a fever and mucus or blood in the stools, suspect amoebiasis. Giardiasis is characterised by abdominal cramps, flatulence, and bubbly, foul-smelling diarrhoea persisting beyond 2 to 4 days. Take three specimens of faeces for analysis. In some cases serology may be helpful (e.g. amoebiasis).

### Treatment

- Giardiasis: tinidazole or metronidazole
- Amoebiasis: metronidazole or tinidazole

Patient can self-administer these drugs and carry them if visiting areas at risk, but they can have a severe adverse reaction with alcohol.

### Preventive advice

The following advice will help prevent diseases caused by contaminated food and water. These 'rules' need only be followed in areas of risk such as Africa, South America, India and other parts of Asia.

- Purify all water by boiling for 10 minutes. Adding purifying tablets is not so reliable, but if the water cannot be boiled some protection is provided by adding Puratabs (chlorine) or iodine (2% tincture of iodine), which is more effective than chlorine—use 4 drops iodine to 1 litre of water and let it stand for 30 minutes.
- Do not use ice. Drink only boiled water (supplied in some hotels) or well-known bottled beverages (mineral water, 7-Up, Coca-Cola, beer).
- Avoid fresh salads or raw vegetables (including watercress). Salads or uncooked vegetables are often washed in contaminated water. Bananas and fruit with skins are safe once you have peeled and thrown away the skin but care should be taken with fruit that may possibly be injected with water.
- Be wary of dairy products such as milk, cream, ice-cream and cheese.

- Avoid eating raw shellfish and cold cooked meats.
- Avoid food, including citrus fruits, from street vendors.
- Drink hot liquids wherever possible.
- Use disposable moist towels for hand washing.
- Vaccines against ETEC are in development.

### Golden rule for preventing diarrhoea

If you can't peel it, boil it or cook it—don't eat it.

## § Malaria

### General aspects

- Travellers to all tropical countries are at some risk of this protozoal infection.
- Malaria is endemic in 102 countries;<sup>4</sup> 2.3 billion people are at risk, with 500 million affected every year.
- The risk is very low in the major cities of Central and Southern America and South-East Asia but can be high in some African cities.
- In humans malaria is caused by four species of plasmodium:
  - *Plasmodium vivax* and *P. ovale*—tertian malaria
  - *P. falciparum*—malignant tertian malaria
  - *P. malariae*—quartian malaria
  - *P. knowlesi*—presents like vivax and falciparum
- Malaria is either benign (vivax, ovale) or malignant (falciparum).
- Resistance to many drugs is increasing:
  - The lethal *P. falciparum* is developing resistance to chloroquine and the antifolate malarials (Fansidar and Maloprim).<sup>4</sup>
  - Resistance is now reported to mefloquine and artemether.
  - Resistance is common in South-East Asia, Papua New Guinea (PNG), northern South America and parts of Africa.
- Chloroquine is used infrequently as it is only effective in limited areas of the world but not PNG.
- The long-awaited vaccine will make all the complex drug management much simpler. However, it still appears to be many years away despite considerable research.
- Patients who have had splenectomies are at grave risk from *P. falciparum* malaria (PFM).

- People die from malaria because of delayed diagnosis, delayed therapy, inappropriate therapy and parasite–host factors.
- It is recommended that pregnant women and young children do not travel to malarious areas (if possible).
- Practitioners should follow updated recommended guidelines (e.g. WHO therapeutic guidelines (antibiotic)).

**DxT** fever + chills + headache → malaria

### Malaria risk assessment

The risk of catching malaria is increased by:

- being in a malaria area, especially during and after the wet season
- a prolonged stay in a malaria area, especially rural areas, small towns and city fringes
- sleeping in unscreened rooms without mosquito nets over the bed
- wearing dark clothing with short-sleeved shirts and shorts
- taking inappropriate drug prophylaxis
- an incomplete course of prophylaxis

### Malaria prevention

Travellers should be advised that malaria may be prevented by following two simple rules:

- 1 avoid mosquito bites
- 2 take antimalarial medicines regularly

In order to avoid mosquito bites, travellers are advised to:

- keep away from rural areas after dusk
- sleep in air-conditioned or properly screened rooms
- use insecticide sprays to kill any mosquitoes in the room or use mosquito coils at night
- smear an insect repellent on exposed parts of the body; an effective repellent is diethyl-m-toluamide (Muskol, Repellem, Rid)
- use mosquito nets (tuck under mattress; check for tears)
- impregnate nets with permethrin (Ambush) or deltamethrin
- wear sufficient light-coloured clothing, long sleeves and long trousers to protect whole body and arms and legs when in the open after sunset
- avoid using perfumes, cologne and after-shave lotion (also attract insects)

## Important considerations in malaria prophylaxis

- 1 Minimise exposure to mosquitoes and avoid bites.
- 2 Know areas of risk:
  - tropical South America (southern Mexico to northern half South America)
  - tropical Africa (sub-Saharan to northern South Africa)
  - Nile region, including remote rural Egypt
  - Southern Asia, especially tropical areas
- 3 Know areas of widespread chloroquine resistance:
  - Asia, tropical South America (rare north of Panama Canal), sub-Saharan, East Africa
- 4 Consider several factors:
  - intensity of transmission
  - season and length of stay
  - itinerary
    - urban—hotel
    - urban—non-hotel
    - rural—housing
    - rural—backpacking
  - resistance patterns
  - host factors
    - age
    - pregnancy

- associated illness
- compliance

- 5 Know the antimalarial drugs (see TABLE 14.2).
- 6 Balance risk benefit of drug prophylaxis: drug side effects versus risk of PFM.
- 7 Visiting areas of PFM does not automatically require the use of potentially harmful drugs.<sup>1</sup>
- 8 Those at special risk are pregnant women, young children and the immunocompromised. Advise against travel.
- 9 No drugs give complete protection.

## Drug prophylaxis

Refer to WHO guidelines ([www.who.int/ith/en](http://www.who.int/ith/en)).

## Guidelines

- Accommodation in large, air-conditioned hotels in most cities of South-East Asia (dusk–dawn) for <2 weeks: no prophylaxis required.
- For low-risk travel (urban: dusk–dawn) in areas of high resistance for <2 weeks: chloroquine adequate; use a treatment course of Malarone if necessary (see TABLE 14.3).
- For short- and long-term travel to rural areas of high resistance (e.g. South-East Asia including Thailand, Kenya, Tanzania, Ecuador, Venezuela, Brazil): doxycycline daily alone or mefloquine (once a week). Atovaquone and proguanil (Malarone) is also very useful for short-term travel.

**Table 14.2** Common drugs used for malarial prophylaxis<sup>4,5,6</sup>

	Adult dosage	Children's dose	Comments
<b>Chloroquine</b> (Chlorquin)	300 mg base (2 tabs) same day each week 1 week before, during, 4 weeks after exposure	5 mg base/kg up to maximum adult dose	Only antimalarial approved for pregnancy Aggravates psoriasis Beware of retinopathy
<b>Doxycycline*</b>	100 mg each day, 2 days before, during, 4 weeks after	>8 years only 2 mg/kg/day up to 100 mg	Photosensitivity reactions
<b>Mefloquine</b> (Lariam)*	250 mg (1 tab) same day each week, 1 week before, during, 4 weeks after	Not recommended <45 kg; >45 kg as for adults	Side effects: dizziness, 'fuzzy' head, blurred vision, neuropsychiatric Beware of beta blockers
<b>Atovaquone+proguanil</b> (Malarone)*	250 mg / 100 mg (1 tab) with food same day each week 2 days before, during, 7 days later	Junior tablets 62.5 mg/25 mg 11–20 kg: 1 tablet/day 21–30 kg: 2 tablets/day 31–40 kg: 3 tablets/day >40 kg: 1 adult tab/day	Avoid in pregnant women or women breastfeeding infants <11 kg Avoid in severe kidney impairment Side effects: GIT upset, headache, dizziness, myalgia—others

\* chloroquine-resistant areas

**Table 14.3** Drugs used for uncomplicated chloroquine-resistant malaria (presumptive breakthrough where professional medical care unavailable, i.e. emergency self-treatment)<sup>5,6</sup>

	Adult dose	Children's dose
Artemether/ lumefantrine (Riamet)	4 tablets at 0, 8, 24, 36, 48, 60 hours	Only if >12 years, >35 kg
Atovaquone/ proguanil (Malarone) (if not used for prophylaxis)	4 tablets daily for 3 days	11–20 kg: 1 tablet 21–30 kg: 2 tablets 31–40 kg: 3 tablets

### Summary of malaria recommendations<sup>5,6</sup>

- 1 PFM area:  
mefloquine 250 mg/week  
or  
doxycycline 100 mg/day  
or  
atovaquone + proguanil
- 2 Multidrug-resistant area:  
Malarone for prophylaxis  
+  
standby treatment: Malarone or artemether + lumefantrine (Riamet)

## Specific infectious diseases and immunisation

Protection from many types of infection is available through immunisation. All travellers should be immunised against tetanus, polio and diphtheria and measles. Protection against tetanus requires an initial course of three injections followed by a booster every 10 years.

Vaccinations are required for special circumstances. Yellow fever vaccination is a legal requirement for any travellers returning from a yellow fever endemic area. Cholera is not usually required.

Some travellers may be exposed to tuberculosis, hepatitis, plague, rabies, typhoid, typhus and meningococcal infection. Immunisation against these is available and recommended for those at risk. Smallpox has now been eradicated from the world and therefore smallpox vaccination is no longer required for any traveller.

Japanese B encephalitis presents as a special problem to the traveller.

TABLE 14.4 outlines a summary of recommendations to consider.<sup>7,8</sup>

## Compulsory immunisations

The two vaccinations that may be required before visiting 'at risk' areas are yellow fever and meningococcus.

### Yellow fever

Yellow fever is a serious viral infection spread by *Aedes* mosquitoes and, like malaria, is a tropical disease. Yellow fever vaccination, which is the only WHO-required vaccine, is essential for travel to or through equatorial Africa and northern parts of South America, and for re-entry to Australia from those countries.

**DxT** fever + bradycardia + jaundice  
→ yellow fever

One injection only is required and the immunisation is valid for 10 years. Children aged less than 9 months should not be given this vaccine. It should not be given within 3 weeks of cholera vaccine.

*Note:* It is important to check specific country requirements in the WHO book on vaccination requirements.<sup>9</sup>

According to the WHO a certificate against yellow fever is the only certificate that should be required for international travel. The requirements of some countries are in excess of international health regulations. However, vaccination against yellow fever is strongly recommended to all travellers who intend to visit places other than the major cities in the countries where the disease occurs in humans.

### Meningococcal infection

Meningitis due to this organism is a contagious lethal disease. It is common in Nepal, Mongolia, Vietnam and parts of Africa and Asia, especially in the dry season. Travellers trekking through the Kathmandu valley of Nepal and those attending the Haj pilgrimage to Saudi Arabia are at special risk and should have the vaccine. However, some countries require immunisation for entry.

## Voluntary immunisation

Precautions against the following diseases are recommended for those travellers who may be at special risk.<sup>5</sup>

## § Hepatitis A, B

Hepatitis A is a common problem in rural areas of developing countries. There is a declining level of antibodies to hepatitis A in developed countries and adults are at special risk so one or two doses of hepatitis A vaccine should be given. A blood test for hepatitis A antibodies can be carried out to determine a person's immunity.

### Prevention

The rules of avoiding contaminated food and water apply (as for traveller's diarrhoea). Hepatitis A vaccine is given as a course of two injections.

Hepatitis B is endemic in South-East Asia, South America and other developing countries. Vaccination is recommended, especially for people working in such countries, particularly those in the health care area or those who may expect to have sexual or drug contact. If patients have a 'negative' HBV core IgG titre, then vaccination would be worthwhile (three doses: 0, 1 and 6 months). Hepatitis E has a high mortality rate in pregnant women.

The usual approach for non-immunised people is to give the combined hepatitis A and B vaccine (Twinrix) as a course of three injections.

## § Typhoid

Typhoid immunisation is not required for entry into any country but is recommended for travel to third world countries where the standards of sanitation are low. It should be considered for travellers to smaller cities, and village and rural areas in Africa, Asia, Central and South America and Southern Europe.

The parenteral (subcutaneous) vaccine can be used but the single dose typhi Vi vaccine or the oral vaccine, which have fewer side effects, are generally preferred. The oral vaccine, which is given as a series of three or four capsules, appears to afford protection for about 5 years but is contraindicated in the immunocompromised.

## § Cholera

Cholera vaccination is not officially recommended by the WHO because it has only limited effectiveness. It is advisable for health care workers or others at risk entering an endemic area. Cholera is given as an oral vaccine (Dukoral) over 1 week prior to exposure. It is not recommended in children under 5 years or pregnant women.

**Table 14.4** Summary of preventive measures and vaccinations<sup>7</sup>

All travellers, all destinations  
Tetanus toxoid and diphtheria booster  
if >10 years since last dose  
if >5 years for third world travel  
give CDT <5 years ADT >5 years

Routine vaccination for all Australians  
Tetanus, diphtheria, pertussis  
Hepatitis B  
*Haemophilus influenzae*  
Measles, mumps, rubella  
Influenza  
Pneumococcal disease  
Poliomyelitis  
Rotavirus  
Varicella

Selected vaccinations based on risk  
Cholera  
Hepatitis A  
Japanese encephalitis  
Meningococcal disease\*  
Rabies  
Tick-borne encephalitis  
Tuberculosis (BCG if mantoux -ve)  
Typhoid fever  
Yellow fever\*

Other

Preventive measures against gastrointestinal infections, mosquito bites, malaria (where applicable), sexually transmitted infections

\* legal requirement in some countries

## § Japanese B encephalitis

This mosquito-borne flavivirus infection presents a real dilemma to the traveller and doctor because it is a very severe infection (mortality rate 20–40%) with high infectivity and high prevalence in endemic countries.

The disease is prevalent during the wet season in the region bounded in the west by Nepal and Siberian Russia and in the east by Japan and Singapore, especially in Nepal, Burma, Korea, Vietnam, Thailand, China, eastern Russia and the lowlands of India. Rice paddies and pig farms are areas of risk. The usual preventive measures against mosquito bites are important.

**DxT** febrile illness + vomiting + stupor  
→ Japanese B encephalitis

## § Rabies

Rabies vaccination is recommended for some international aid workers or travellers going to rabies-endemic areas for periods of more than 1 month or even for short periods of working with affected animals in those areas. The vaccination can be effective after the bite of a rabid animal, so routine vaccination is not recommended for the traveller. Affected animals include dogs, cats, monkeys, camels and feral (wild) animals. A traveller who sustains a bite or scratch or even is licked by an animal in countries at risk should wash the site immediately with soap or a detergent, and then seek medical help. The prebite vaccination does not remove the need for postexposure vaccination.

**DxT** painful bite + paraesthesia + hydrophobia (pain with drinking) → rabies

## § Plague

Plague is still prevalent in rodents in countries such as Vietnam, Brazil, Peru, Ecuador and Kenya. Although not compulsory, vaccination is recommended for those engaged in field operations in plague areas and rural health workers who may be exposed to infected patients. Two doses are given to adults (three to children <12 years) and a booster every 6 months.

## Special problems

### Prevention of sexually transmitted infections

Casual sexual contacts place the traveller at risk of contracting a serious, perhaps fatal, sexually transmitted infection (STI). The common STIs, especially prevalent in South-East Asia and Africa, are non-specific urethritis (NSU), gonorrhoea (especially penicillin-resistant strains), hepatitis B and syphilis. HIV infection is a rapidly increasing problem, with heterosexual transmission common in Africa and in South-East Asia. Unusual STIs such as lymphogranuloma venereum, chancroid and donovanosis are more common in tropical developing countries. A practical rule is to assume that all 'at risk' travellers are both ignorant and irresponsible and advise accordingly.

### Rules for prevention

- Never permit blood, semen or vaginal fluids from a sexual partner to enter your body, unless you are absolutely certain they are not STI carriers.
- Abstain or take your partner (condoms and diaphragms do not give absolute protection).

## Exposure to STIs

If a patient has had unprotected intercourse and is at definite risk of acquiring an STI, such as penicillin-resistant gonorrhoea or NSU, the following may be appropriate:<sup>1</sup>

- ceftriaxone 250 mg IM (as a single dose)
- doxycycline 100 mg (o) for 10 days or azithromycin 1 g (o) statim

## Drugs

Possession of and trafficking in drugs is very hazardous and many people are held in foreign prisons for various drug offences. The penalty for carrying drugs can be death.

Countries that currently may enforce the death penalty are Burma, China, Indonesia, Malaysia, Singapore, Thailand and Turkey. Travellers should be warned about taking cannabis while in a foreign country, as it can cause profound personality changes in the user.

*Drug addicts should under no circumstances travel.* Young travellers should be wary about accepting lifts or hitchhiking in countries 'at risk'.

## Pregnancy and travel

Most international airlines do not allow passengers to travel after the 36th week of pregnancy and may require a doctor's certificate after 28 weeks. Air travel is contraindicated in the last month of pregnancy and until the 7th day after delivery. The past obstetric history should be taken into account. The same health risks apply except that most antimalarial tablets and vaccinations are not recommended. Live vaccinations (measles, rubella, influenza) are generally contraindicated<sup>9</sup> but the WHO considers it safe to have polio vaccine. Administration of killed or inactivated vaccines, toxoids and polysaccharides is permitted during pregnancy. Yellow fever vaccine is considered safe after the 6th month. As a general rule pregnancy and travel to third world countries do not mix and pregnant women should be advised not to travel to these countries.

Tetanus immunisation is important as protection is passed on to the child during early infancy.

Immunoglobulin can be safely given as prevention against hepatitis.

The antimalarial drugs chloroquine, quinine and proguanil may be given to pregnant women but all others mentioned in TABLE 14.2 are contraindicated.

## Children and travel

Although children, including infants, are good travellers and adapt well, their resistance, especially to heat and infections, is lower. A child can suffer from acute dehydration very rapidly.<sup>9</sup> Air travel is not recommended for infants of less than 7 days or premature infants.

The change in atmospheric pressure on landing can cause distressing ear pain, so taking a bottle during descent is recommended.

In tropical areas it is important to keep children well hydrated and they should wear loose cotton clothing. A good guide to the health of children is the amount and colour of their urine. If it is scanty and concentrated they are not getting sufficient fluid.

Most vaccines (diphtheria, tetanus, poliomyelitis, BCG) can safely be given in the first few weeks of life. Measles is common overseas and it is worthwhile considering it even under 12 months. Yellow fever vaccine should not be given under 12 months. Hence the importance of protection against mosquito bites. Malaria prophylaxis is important. Chloroquine, proguanil and quinine may be given safely to infants. However, as a rule young children should be discouraged from travel.

## Air travel

Air travel is safe and comfortable, but jet lag and air sickness are problems that face many travellers.

### Jet lag

This is the uncomfortable aftermath of a long flight in which the person feels exhausted and disoriented, and has poor concentration, insomnia and anxiety. The problem on arrival is poor concentration and judgment during the daytime.

Other symptoms that may occur include anorexia, weakness, headache, blurred vision and dizziness.

Jet lag is a feature of flying long distances east-west or west-east through several time zones, causing the person's routine daily rhythm of activity and sleep to get out of phase. The worst cases appear to be in those travelling eastbound from England to Australia. It can occur with travel in any direction, but the north-south flights are not so bothersome.

## Factors influencing jet lag

*Personal factors.* These include age, state of health, tolerance to change, preparation for the long trip and, very importantly, the emotional and mental state.

*General factors.* Noise, vibration, air humidity and sitting still for long periods can influence jet lag.

*Specific factors.* Duration of the flight, time of departure, and changes in climate and culture at the destination affect the severity of jet lag. The problem is aggravated by:

- stress of the pretrip planning
- last-minute rushing and anxiety
- lack of sleep during the trip
- overeating and excessive alcohol during the flight
- smoking

## How to minimise the problem (advice to patients)

### Before the flight

- Allow plenty of time for planning.
- Plan a stopover if possible.
- If possible, arrange the itinerary so that you are flying into the night.
- Ensure a good sleep the night before flying.
- Ensure a relaxed trip to the airport.
- Take along earplugs if noise (75–100 decibels) is bothersome.

### During the flight

- *Fluids.* Avoid alcohol and coffee. Drink plenty of non-alcoholic drinks such as orange juice and mineral water.
- *Food.* Eat only when hungry and even skip a meal or two. Eat the lighter, more digestible parts of your meals and avoid fatty foods and rich carbohydrate foods.
- *Dress.* Women should wear loose clothes (e.g. long skirts, comfortable jeans, light jumpers) and avoid restrictive clothing. Wear comfortable (not tight) shoes and take them off during the flight.
- *Sleep.* Try to sleep on longer sections of the flight (give the movies a miss). Close the blinds, wear special eye masks and ask for a pillow. Sedatives such as temazepam (Euhypnos or Normison) or antihistamines can help sleep.
- *Activity.* Try to take regular walks around the aircraft and exercise at airport stops. Keep feet up when resting, and exercise by flexing the

major muscles of the legs. Avoid resting the calves of legs against the seat for long periods. Rest without napping during daylight sectors.

- *Special body care.* Continually wet the face and eyes.

A wetting agent such as hypromellose 0.5% eye drops can help those with a tendency to sore eyes.

### At the destination

Take a nap for 1–2 hours if possible.

Wander around until you are tired and go to bed at the usual time. It is good to have a full day's convalescence and avoid big decision making soon after arrival. Allow about 3 days for adjustment after the London to Australia flight.

### Role of melatonin<sup>10</sup>

The importance of melatonin, a hormone secreted by the pineal gland, is somewhat controversial. However, a major review of trials by the Cochrane Library pointed to its efficacy for alleviating jet lag. Oral medication in a 5 mg dose close to the desired or usual bedtime decreased jet lag. One possible explanation is that it has a low-grade hypnotic effect.

### Who is fit to fly?

Patients with these problems should avoid flying<sup>9,11</sup> or be assessed for fitness:

- upper airways congested by infection, including influenza, e.g. within 6 weeks of severe acute respiratory illness
- acute gastroenteritis
- severe respiratory disease (COPD, chronic bronchitis, pneumothorax)
- recent thoracic surgery
- cystic fibrosis
- pulmonary tuberculosis (people should not fly until rendered non-infective)
- past history of respiratory problems while flying (dyspnoea, chest pain, confusion)
- unstable heart failure
- severe anaemia (below 7.5 g/dL)
- pregnancy beyond 200 days (28 weeks) (up to 36 weeks if necessary)
- previous violent or unpredictable behaviour
- within 7 days of a myocardial infarction
- within 3 days of a cerebrovascular accident
- within 5–10 days of major surgery
- brain tumour or recent skull fracture
- recent eye surgery
- severe or poorly controlled hypertension
- poorly controlled epilepsy

Special precautions are required by travellers with the following problems:

- *Colostomy.* Patients should wear a large colostomy bag and take extra bags.
- *Varicose veins.* Such patients should wear supportive stockings and exercise frequently.
- *Plaster casts.* Those with broken limbs in plaster should be careful of swelling.
- *Pacemakers.* Those with pacemakers may have a problem with X-rays at some overseas airports. Mention it to security officials before passing through security equipment.
- *Epilepsy.* Medication should be increased on the day of travel.
- *Diabetics.* Diabetics should discuss their therapy and control with their doctor. They should carry sweets.

### Prevention of DVT

There is a risk of DVT in any person flying on long international flights. Risk factors include: increasing age, clotting tendency, i.e. thrombophilia, past history of DVT, family history of DVT, smoking, obesity, varicose veins, dehydration, significant illness, recent major surgery and oestrogen therapy (see CHAPTER 133).

Prevention is by:

- keeping hydrated—drink ample fluids but avoid alcohol and caffeine drinks
- in-flight exercises, such as foot pumps, ankle circles, knee lifts
- compression stockings (class 18–20)
- medication for those at risk, e.g. thrombophilia, Clexane 80 mg SC 12 to 24 hourly (if no contraindication) use one dose for travel to South-East Asia and two doses for travel to Europe

### Travel sickness

Almost everyone is sick when sailing on rough seas. However, some people, especially children, suffer sickness from the effect of motion on a boat, in a car or in a plane. The larger the boat, plane or car, the less the likelihood of sickness; travel by train rarely causes sickness. Nearly all children grow out of the tendency to have travel sickness, but many adults remain 'bad' sailors.

The problem is caused by sensitivity of the semicircular canals of the inner ear. They are affected by the movement and vibration of travel. Some people have sensitive inner ear canals and are prone to

sickness, especially on certain types of journeys (e.g. winding roads through hills) and in certain vehicles.

The main symptoms of travel sickness are nausea, vomiting, dizziness, weakness and lethargy. Early signs are pallor and drowsiness, and sudden silence from an active, talkative child.

## How to minimise the problem

- 1 Keep calm and relaxed before and during travel. With children avoid excitement and apprehension about the travelling. Encourage activities such as looking at distant objects; discourage activities such as reading and games that require close visual concentration.
- 2 Lie down, if possible, because this rests the inner ear canals and reduces the urge to vomit. If travelling by car, stop regularly for breaks. Passengers should use the front seat if possible.
- 3 Do not have a large meal a few hours before the journey or during it; avoid milk and fried or greasy foods. Do not travel with an empty stomach: have a light simple meal about an hour before and do not drink too much. Glucose drinks such as lemonade are suitable, as are glucose sweets and biscuits while travelling.

## Medication for travel sickness

Many medicines are available for travel sickness. They include hyoscine, various antihistamines and other phenothiazine derivatives, all of which can cause drowsiness; although a problem for drivers, this sedative effect may be helpful for children or for those travelling long distances by plane.

Phenothiazine derivatives that provide appropriate anti-labyrinthine activity include prochlorperazine (Stemetil), promethazine hydrochloride (Phenergan) and promethazine theoclate (Avomine).

Combination antihistamine and hyoscine preparations for travel sickness include Travacalm and Benacine (see TABLE 14.5).

Hyoscine comes in tablet form, either alone or in combination and in the now popular adhesive patches.

## Recommended medications

### Car travel: adult passengers and children

- dimenhydrinate (Dramamine)  
or  
promethazine theoclate (Avomine)  
or

hyoscine (Kwells)

These preventive oral preparations should ideally be taken 30–60 minutes before the trip and can be repeated 4–6 hourly during the trip (maximum 4 tablets in 24 hours).

- hyoscine dermal discs (Scop)

If available, one of these adhesive patches should be applied to dry, unbroken, hairless skin behind the ear, 5–6 hours before travel and left on for 3 days. Wash the hands thoroughly after applying and removing the disc—be careful of accidental finger-to-eye contact.

## Sea travel

Sea travel generally poses no special problems apart from motion sickness and the possibility of injuries in the aged. The larger the ship, the less likely the problem. Those prone to sea sickness are advised to take anti-emetics 60 minutes before sailing and for the first 2 days at sea until they obtain their 'sea legs'. However, the use of hyoscine transdermal delivery systems is recommended for convenience.

Experienced seamen's 'tricks':

- always keep looking to the horizon
- plug one ear with cotton wool or Blu-Tack
- drink ginger drinks, e.g. 'dry ginger', ginger beer

## Severe sea sickness

The standard treatment is promethazine (Phenergan) 25 mg IM injection. If injections are not possible, prochlorperazine (Stemetil) suppositories can be used.

## The aged

Generally the elderly travel well but should take safeguards to avoid falls. The Chief Surgeon on P & O's flagship recommends that elderly people should bring the following:

- a letter from their doctor stating diagnosis and medication
- a spare set of spectacles
- a spare set of dentures
- a walking stick (if appropriate)

## Altitude sickness<sup>12</sup>

High altitudes pose special problems for people who live at low altitude, especially if they have heart and lung disease. The severity depends on altitude, the speed of ascent, the temperature and level of activity. The high altitudes of Africa (Kilimanjaro, Kenya), India, Nepal (Himalayas), the Rockies of Canada and

**Table 14.5** Medication to consider for motion sickness

Drug (genre)	Brand names and formulations	Dosage	
		Adults	Children
Antihistamines			
Pheniramine	Avil 10 mg, 50 mg Syrup 3 mg/mL	25–50 mg tds	infants 10 mg bd <10 years: 10 mg tds >10 years: 10–20 mg tds
Promethazine theoclate	Avomine 25 mg	25 mg statim or nocte for long journeys	<5 years: ¼ tab 5–10 years: ½ tab >10 years: 1 tab
Promethazine hydrochloride	Phenergan 10 mg, 25 mg Syrup 1 mg/mL	25 mg bd	1–5 years: 5 mg bd 5–12 years: 10 mg bd
Related phenothiazines			
Prochlorperazine	Stemetil suppositories 5 mg, 25 mg	5–15 mg tds	0.2 mg/kg bd or tds <10 kg: avoid
Hyoscine			
Hyoscine hydrobromide	Kwells 0.3 mg tab Travacalm HO	1–2 tab statim then 1 tab 4–6 hour prn (max. 4 doses/24 hours)	2–7 years: ¼ tab >7 years: ½ tab (max. 4 doses/24 hours)
	1.5 mg transdermal (Scop*)	1 patch per 72 hours	avoid <10 years
Combinations			
Hyoscine (0.2 mg) + dimenhydrinate (50 mg) + caffeine (20 mg)	Travacalm Original	1–2 tabs statim (max. 4 doses/24 hours)	<2 years: avoid 2–3 years: ¼ tab 4–7 years: ¼–½ tab 8–13 years: ½–1 tab (max. 4 doses/24 hours)

*General rules:* All tablets should be taken 30–60 minutes before departure and repeated 4–6 hourly as necessary (aim for maximum of 4 doses per 24 hours). Antihistamines should be used less frequently and some may be used once a day. Take care with drowsiness, pregnancy, the elderly and prostatic problems. Common adverse effects are drowsiness, irritability, dry mouth, dizziness and blurred vision, which are compounded by alcohol, antidepressants and tranquillisers. Hyoscine overdosage (from skin discs) can include confusion, memory loss, giddiness and hallucinations.

\*Scop is available in some other countries, and from time to time in Australia.

the US, and the Andes of South America provide such problems. It is usually safe to trek under 2500 m altitude but rapid ascent beyond this commonly precipitates altitude sickness. Serious altitude sickness occurs at 3500–5800 m.

## Forms

- 1 Acute mountain sickness (mild to severe)
- 2 High-altitude pulmonary oedema
- 3 High-altitude cerebral oedema

## Clinical features

- Usually within 8–24 hours of exposure
- Frontal headache (worse in morning and when supine)
- Malaise, fatigue, anorexia, nausea, insomnia

*More severe:* fluid retention (peripheral or facial oedema), dyspnoea, vomiting, dry cough, dizziness

*Serious:* marked dyspnoea, neurological symptoms and signs

## Prevention

- Careful acclimatisation with gradual ascent<sup>11</sup>
- Spend 2–3 days at intermediate altitudes
- Ascent rate less than 300 m per day above 3000 m (that is, try not to sleep at an altitude 300 m higher than that of the previous day)
- Ample fluid intake (more water than usual)
- Avoid alcohol
- Acetazolamide (Diamox) 250 mg 8 hourly the day before ascent; continue 3–6 days (deaths from mountain sickness have still occurred while on this drug)

## Treatment

- Immediate (urgent and rapid) descent to below 2000 m
- Oxygen
- Dexamethasone (e.g. 4 mg, 6 hourly)

## Travellers' medical kit

If a person intends to travel for a long time the following represents a comprehensive medical kit. It should not be regarded as an alternative to seeking appropriate medical help if it is available. Typical examples of general items are included in brackets.

## Materials

- Alcohol swabs
- Band-aids and Elastoplast dressing strip
- Bandages (2 cotton gauze, 2 crepe × 10 cm)
- Pocket torch
- Steristrips or 'butterfly strips' (to patch small cuts)
- Sterile gauze and cotton wool
- Thermometer
- Scissors and tweezers
- Safety pins
- Water purification tablets or iodine solution

## Topical items

- Antifungal cream
- Chlorhexidine/cetrimide antiseptic cream (Savlon)
- Condoms
- Corticosteroid cream (e.g. hydrocortisone)
- Insect repellent containing diethyl-m-toluamide (DEET, Muskol, Repellem or Rid)
- Insecticide spray
- Mosquito net repellent solution: permethrin (Ambush—ICI)
- Nasal spray or drops
- Stingose spray (for bites and stings)
- Strepsils
- UV antisenburn cream (factor 15 +)

## Medication checklist

The medications below marked with \* usually require a prescription.

- Antibiotics\*
  - amoxycillin + clavulanate forte
  - norfloxacin 400 mg (6 tablets for 3 days)
  - azithromycin (for children)
- Antacid tablets—for heartburn or indigestion
- Antimalarials\*—where appropriate (including malaria emergency self-treatment)
- Diamox tablets\* for acute mountain sickness
- Fasigyn\* 2 g or Flagyl\* 2.4 g—for amoebiasis or giardiasis
- Laxative (Senokot)
- Imodium\* or Lomotil\*—for diarrhoea
- Motion sickness tablets (Avomine, Kwells or Phenergan)
- Paracetamol tablets—for fever or pain
- Sleeping tablets\* (temazepam, promethazine)
- Rehydration mixture (Gastrolyte)
- Throat lozenges
- EpiPen—if history of anaphylaxis

## General tips for the traveller

### Checklist for at risk countries

- If you can't peel it, boil it or cook it, don't eat it.
- Boil or purify water, avoid dairy products, ice-cream, shellfish, food left in open, salads, raw fruit and vegetables, ice and recooked or reheated food.
- Never walk around barefoot at night in snake areas (and use a torch).
- Always shake your shoes before putting them on.
- Never wear nylon items in hot tropical areas.
- Never bathe, wade or drink in rivers, lakes or harbours unless you know they are bilharzia free.
- Keep yourself well covered after dark and use a mosquito net.
- Use insect repellent on skin frequently.
- Use an insecticide spray in your bedroom.
- Seek medical help if bitten by an excited dog, after washing bite.

### Other tips

- Organise a dental check before departure.
- Arrange stopovers on a long flight (if possible).
- Take along a spare pair of spectacles and adequate medication.
- Arrange health and travel insurance.
- Check out your nearest embassy/consulate when visiting remote areas or politically unstable countries.
- Take a letter from your doctor with your medical record.
- Consider a traveller's medical kit.
- Never carry a parcel or luggage through Customs to oblige a stranger or recent acquaintance.
- Abstain from sex with a stranger.
- Have a credit card that allows a quick cash advance or an airline ticket purchase (for many countries a policy of 'if you get sick, then get out' is necessary).
- Most death and injury among travellers is caused by motor accidents. Avoid overcrowded long-distance buses in African and South Asian countries (and elsewhere)—trains are safer.

<[www.traveldoctor.com.au](http://www.traveldoctor.com.au)>  
Centers for Disease Control and Prevention <[www.cdc.gov/travel](http://www.cdc.gov/travel)>

*Our lot is a perilous age . . . but where shall we fly to escape from pestilences that come and pestilences that do not come, from ships that bring us yellow fever, from cattle diseases that can only be exterminated by exterminating the cattle, from infectious patients whose pulses must be felt with a pair of tongs and their chests explored with tarred stethoscopes.*

Jacob Bigelow 1860

Doctors in western countries—including Australia, with its own tropical diseases in the far north—are more likely to encounter tropical diseases in the traveller returning from countries where these disorders are endemic. Many of these diseases are likely to be encountered in newly arrived refugees (see **CHAPTER 138**). The diseases include bacterial infections such as tuberculosis (a huge problem), plague, melioidosis, leprosy, typhoid/cholera, zoonoses. Other infections to be considered are parasitic, *Rickettsia* and myriad viral infections including haemorrhagic fevers, various types of encephalitis, yellow fever, polio, hepatitis, lyssavirus such as rabies and bat bite infections, dengue and influenzas.

It is worth reviewing the various protozoal and helminthic parasitic infections that need to be considered in the sick returned traveller.<sup>1</sup> The helminths (worms) include cestodes (tapeworms), trematodes (flukes) and nematodes (roundworms).

- **Protozoal infections:** African trypanosomiasis (sleeping sickness), American trypanosomiasis (Chagas disease), amoebiasis, babesiosis, coccidiosis and microsporidiosis, cryptosporidiosis, giardiasis, leishmaniasis—cutaneous and visceral (kala-azar), malaria, toxoplasmosis, trichomonas
- **Cestodes (tapeworms):** Cysticercosis (*Taenia solium*, *T. saginata*), echinococcus (hydatid disease)
- **Trematodes (flukes):** Schistosomiasis (bilharziasis), clonorchiasis, paragonimiasis
- **Nematodes (roundworms):** Ascariasis, enterobiasis (pinworm), *Dracunculus medinensis* (Guinea worm), filariasis, hookworm, larva migrans (cutaneous and visceral), strongyloidiasis, trichinosis (*Trichinella spiralis*), trichuriasis (whipworm)

## Problems in the returned tropical traveller

- Most will present within 2 weeks except HIV seroconversion infection.
- Common infections encountered are dengue fever, giardiasis, hepatitis A and B, gonorrhoea or *Chlamydia trachomatis*, malaria and helminthic infestations.
- An important non-infection problem requiring vigilance is deep venous thrombosis (DVT) and thromboembolism.
- The asymptomatic traveller may present for advice about exposure (without illness) or about an illness acquired such as rabies, malaria, schistosomiasis and STIs.

## Gastrointestinal symptoms

### Mild diarrhoea

- Stool microscopy and culture
- Look for and treat associated helminthic infestation (e.g. roundworms, hookworms)

### Moderate or prolonged (>3 weeks) diarrhoea

Usually due to *Giardia lamblia*, *Entamoeba histolytica*, *Campylobacter jejuni*, *Salmonella*, *Yersinia enterocolitica* or *Cryptosporidium*.<sup>2</sup>

- Stool examination (three fresh specimens):
  - microscopy
  - wet preparation
  - culture
- Faecal Multiplex PCR (if available)
- Treat pathogen (see guidelines under diarrhoea in **CHAPTER 14** and **44**)

Non-pathogens such as *Escherichia coli* and *Endolimax nana* are often reported but do not treat specifically.

*Note:* Consider exotic causes such as schistosomiasis, strongyloidiasis and ciguatera in unusual chronic post-travel 'gastroenteritis'.

### Persistent abdominal discomfort

This common syndrome includes bloating, intestinal hurry and borborygmi, and often follows an episode of diarrhoea. Usually no pathogens are found on stool examination. However, giardiasis can be difficult to detect and an empirical course of tinidazole (2 g statim) is worthwhile. Any persistent problem then is a type of postinfective bowel dysfunction or irritable bowel. Reassurance is important.

### Rash/other skin lesions

- Maculopapular: consider dengue, HIV, typhus, syphilis, arbovirus infections, leptospirosis, Q fever
- Petechiae: viral haemorrhagic fevers, leptospirosis, dengue
- Rose spots: typhoid
- Eschar: typhus (tick and scrub), anthrax
- Chancre: African trypanosomiasis, syphilis

### Fever

- Causes range from mild viral infections to potentially fatal cerebral malaria (see Table 15.1) and meningococcal septicaemia.
- An Australian study of fever in returned travellers<sup>3</sup> revealed the most common diagnosis was malaria (27%) followed by respiratory tract infection (24%), gastroenteritis (14%), dengue fever (8%) and bacterial pneumonia (6%). The commonness of malaria was supported by results from the GeoSentinel Surveillance Network.<sup>4</sup>
- The common serious causes are malaria, typhoid, hepatitis (especially A and B), dengue fever and amoebiasis.
- Most deaths from malaria have occurred after at least 3 or 4 days of symptoms that may be mild. Death can occur within 24 hours. Factors responsible for death from malaria include delayed presentation, missed or delayed diagnosis (most cases), no chemoprophylaxis and old age.
- Refer immediately to a specialist unit if the patient is unwell.
- Be vigilant for meningitis and encephalitis.
- Be vigilant for amoebiasis—can present with a toxic megacolon, especially if antimotility drugs are given.
- If well but febrile, *first-line screening tests*:
  - full blood examination and ESR
  - thick and thin films

**Table 15.1** Fever and malaise in the returned traveller: diagnostic strategy model

*Note:* All fever in a returned traveller is malaria until proved otherwise!

Q.	Probability diagnosis
A.	Viral respiratory illness (e.g. influenza) Malaria Hepatitis (may be subclinical) Gastroenteritis/diarrhoeal illness Dengue
Q.	Serious disorders not to be missed
A.	Malaria Tuberculosis Typhoid Encephalitis Meningococcal meningitis Meliodosis Amoebiasis (liver abscess) HIV seroconversion illness
Q.	Pitfalls (often missed)
A.	Ascending cholangitis Infective endocarditis Cytomegalovirus Epstein-Barr virus Dengue fever Lyme disease Bronchopneumonia Ross River fever  <i>Rarities</i> Chikungunya Legionnaire disease Schistosomiasis African trypanosomiasis Typhus Yellow fever Rift Valley fever Spotted fever Lassa fever Hanta virus Ebola and other haemorrhagic fevers
<i>Note:</i> Three causes of a dry cough (in absence of chest signs) are malaria, typhoid, amoebic liver abscess.	
Q.	Seven masquerades checklist
A.	Drugs (reaction to antimalarials) Urinary infection Investigations (if no obvious cause) Full blood examination (? eosinophils) Thick and thin blood films Blood culture Liver function tests Urine—micro and culture Stool—micro and culture ESR/CRP New malaria tests e.g. rapid diagnostic test Acute phase serology (hold pending convalescent serology)

- liver function tests
- urine for micro and culture

- Refer immediately if malaria is proven or if fever persists after a further 24 hours.

## § Malaria

See FIGURE 15.1.

- Incubation period: *P. falciparum* 7–14 days; others 12–40 days
- Most present within 2 months of return
- Can present up to 2 or more years
- Can masquerade as several other illnesses

### Clinical features

See CHAPTER 14.

- High fever, chills, rigor, sweating, headache
- Usually abrupt onset
- Can have atypical presentations (e.g. diarrhoea, abdominal pain, cough)

### Other features

- Beware of modified infection.
- Must treat immediately. Delay may mean death.
- Typical relapsing patterns often absent.
- Thick smear allows detection of parasites (some laboratories are poorly skilled with thick films).
- Thin smear helps diagnose malaria type.
- If index of suspicion is high, repeat the smear ('No evidence of malaria' = 3 negative daily thick films). Newer tests (e.g. polymerase chain reaction [PCR] tests and immune chromatographic test [ICT] card tests for PFM) show promise. Cerebral malaria and blackwater fever are severe and dramatic. The Para check V test (a desktop test) is accurate and needs to be positive before prescribing artemether in some areas.

### Treatment<sup>5,6</sup>

- Admit to hospital with infectious disease expertise. Rule out G6PD deficiency
- Supportive measures, including fluid replacement
- *P. vivax*, *P. ovale*, *P. malariae*<sup>5</sup>  
artemether + lumefantrine 20 mg + 120 mg (Riamet)  
4 tablets with food at 0, 8, 24, 36, 48, 60 hours (i.e. 24 tablets) in 60 hours  
+  
primaquine dose by weight to achieve a total dose of 6 mg/kg. For most people this equals 30 mg (o) daily for 14–21 days

#### Typical features

headache  
malaise  
fever/chills  
prostration  
sweating  
myalgia

#### Other possible features

cerebral problems  
• delirium  
• convulsions  
• coma  
anaemia  
jaundice  
vomiting

FIGURE 15.1 Clinical features of malaria

- *P. falciparum*<sup>5</sup> uncomplicated:  
Riamet (as above)  
or  
quinine sulphate 600 mg (o) 8 hourly, 7 days  
+  
doxycycline 100 mg (o) 12 hourly, 7 days  
or  
clindamycin 300 mg (o) tds, 7 days (children, pregnancy)  
complicated (severe):  
artesunate 2.4 mg/kg IV statim, 12 hours, 24 hours, then once daily until oral therapy (Riamet) is possible  
or  
quinine dihydrochloride 20 mg/kg up to 1.4 g IV (over 4 hours) then after 4-hour gap 7 mg/kg IV 8 hourly until improved (ECG/cardiac monitoring)  
then  
quinine (o) 7 days  
Note: Check for hypoglycaemia. Beware if antimalarial use in previous 48 hours.

## § Typhoid fever

Incubation period 10–14 days

### Clinical features

- Insidious onset
- Headache prominent
- Dry cough
- Fever gradually increases in 'stepladder' manner over 4 days or so
- Abdominal pain and constipation (early)
- Diarrhoea (pea soup) and rash—rose spots (late)
- ± splenomegaly

**DxT** 'stepladder' fever + abdominal pain + relative bradycardia → typhoid (early)

### Diagnosis

- On suspicion—blood and stool culture
- Serology not very helpful

### Treatment

- Azithromycin 1 g (o) for 7 days  
or
- Ciprofloxacin 500 mg (o) bd for 7–10 days

### § Cholera

Incubation period few hours–5 days

### Clinical features

#### Variable

- Subclinical
- Mild, uncomplicated episode of diarrhoea
- Fulminant lethal form with severe water and electrolyte depletion, intense thirst, oliguria, weakness, sunken eyes and eventually collapse

**DxT** fever + vomiting + abrupt onset 'rice water' diarrhoea → cholera

### Diagnosis

Stool microscopy and culture (*Vibrio cholerae*)

### Treatment

- In hospital with strict barrier nursing
- IV fluid and electrolytes
- Doxycycline

## VIRAL HAEMORRHAGIC FEVERS

These include: yellow fever, Lassa fever etc., dengue fever and chikungunya.

### § Yellow fever

Milder cases may present with flu-like symptoms and relative bradycardia (Faget's sign) and albuminuria. Severe cases experience these symptoms with abrupt fever then prostration, jaundice and abnormal bleeding from the gums and possibly haematemesis. Diagnosis is by ELISA testing.

**DxT** fever + bradycardia + jaundice + bleeding → yellow fever

### § Lassa fever, Ebola virus, Marburg virus, Hanta virus

These rare but deadly tropical diseases usually commence with a flu-like illness, gastrointestinal symptoms with thrombocytopenia, anaemia and, if severe, findings consistent with disseminated intravascular coagulation leading to bleeding and possibly shock and frank haemorrhage. Hanta virus tends to cause respiratory symptoms, including cough, progressing to respiratory difficulty. Seek urgent expert help.

### Ebola

- Incubation period: 2–16 days
- Transmission: direct body contact (body fluids esp. blood, vomit from affected or dead person), infected animals, contaminated objects (needles, medical equipment)
- Early symptoms: constitutional (fever, malaise, headache), upper respiratory (flu-like, cough etc.), abdominal (pain, nausea, vomiting, diarrhoea)
- May progress to severe symptoms as above then multiorgan failure
- Diagnosis: PCR, histopathology
- Treatment is supportive esp. IV fluids

### § Dengue fever<sup>7</sup>

Also known as 'breakbone' fever, it is widespread in the south-east Pacific and endemic in Queensland. A returned traveller with myalgia and fever <39° C is more likely to have dengue than malaria.

### Clinical features

- Mosquito-borne (*Aedes aegyptii*) viral infection
- Incubation period 5–6 days
- Abrupt onset fever, malaise, headache, nausea, pain behind eyes, severe backache, prostration

- Sore throat
- Severe aching of muscles and joints
- Fever subsides for about 2 days, then returns
- Maculopapular rubelliform rash on limbs → trunk (hand pressure for 30 seconds causes blanching)
- Petechial rash common (even in absence of thrombocytopenia)
- Generalised erythema with 'islands of sparing' ± Diarrhoea
- The rare haemorrhagic form is very severe; may present with shock, which is usually fatal
- Later severe fatigue and depression (prone to suicide)

*Note:* A large-scale survey of dengue patients showed the symptoms as fever 100%, myalgia 79%, rash 74%, headache 68%, nausea 37%.

**DxT** fever + severe aching + rash → dengue fever

### Diagnosis

- Dengue-specific IgM serology—best on day 5
- PCR
- FBE: leukopenia; thrombocytopenia in haemorrhagic form

### Treatment

- Symptomatic with rest, fluids and analgesics (paracetamol). Avoid antibiotics and corticosteroids

### Prevention

- Avoid mosquito bites—no vaccine available

## Chikungunya

This is an alpha-viral mosquito-borne infection with a similar clinical picture to dengue fever; it can cause haemorrhagic fever. It is encountered in tropical South-East Asia, Indian Ocean islands and parts of Africa.

### Diagnosis

- Positive serology

## Encephalitis

Encephalitis presents with fever, nausea and vomiting then progressing to stupor, coma and convulsions. Mosquito-borne cases include Japanese B encephalitis and West Nile fever.

Consider mosquito-borne encephalitis and meningococcal meningitis in a patient presenting with headache, fever and malaise before neurological symptoms such as delirium, convulsions and coma develop.

## Melioidosis

This serious disease with a high mortality is caused by the Gram-negative bacillus *Burkholderia pseudomallei*, a soil saprophyte that infects humans mainly by penetrating through skin wounds, especially abrasions. It is mostly acquired while wading in rice paddies. It is mainly a disease of third world countries and occurs between 20° North and 20° South of the equator, mainly in South-East Asia and including northern Australia. It may manifest as a focal infection or as septicaemia with abscesses in the lung, kidney, skin, liver or spleen. It is called the 'Vietnamese time bomb' because it can present years after the initial infection, as seen in Vietnamese war veterans.

### Clinical features

- Fever, headache, cough, pleuritic pain and generalised myalgia

**DxT** fever + pneumonia + myalgia → melioidosis

### Diagnosis

- Blood culture, swabs from focal lesions, haemagglutination test

### Treatment (adults)<sup>8</sup>

- Ceftazidime 2 g IV, 6 hourly  
or
- Meropenem 1 g IV, 6 hourly  
or
- Imipenem 1 g IV, 6 hourly
- All for at least 14 days, followed by oral cotrimoxazole ± doxycycline bd + folic acid for 3 months

### Prevention

- Traumatized people with open wounds (especially diabetics) in endemic areas (tropical South-East Asia) should be carefully nursed.

## Plague

Plague (Black Death), which is caused by the Gram-negative bacterium *Yersinia pestis*, is endemic in parts

of Asia, Africa and the Americas. It is transmitted by the flea: 'the flea bites the infected rat and then bites the human'.

### Clinical features

There are basically two forms:

- 1 bubonic plague—painful suppurating inguinal or axillary lymphadenitis (buboes) (see FIG. 15.2)
- 2 pneumonic plague—flu-like symptoms with haemoptysis, septicaemia and a fatal haemorrhagic illness ( $\pm$  buboes)

There is a rapid onset of high fever and prostration with black patches of skin due to subcutaneous haemorrhage.

FIGURE 15.2 Young Vietnamese woman with a left inguinal bubo

Photo courtesy Dr RA Cooke

### Diagnosis

- Serology and smear/culture of buboes

### Treatment

- Streptomycin and doxycycline

### § Rabies

Rabies is a rhabdovirus acquired by bites from an infected mammal, for example a dog, cat, monkey, fox or bat.

### Clinical features

Prodromal symptoms can include malaise, headache, abnormal behaviour including agitation and fever. It progresses to either paralytic 'dumb rabies' or encephalitic 'furious rabies', which involves excessive salivation and excruciating spasms of the pharyngeal muscles on drinking water (in particular). The patient is terrified of drinking water despite a great thirst (hydrophobia).

**DxT** painful/itchy bite + agitation + hydrophobia → rabies

### Diagnosis

- Viral testing

### Treatment

- Post-bite prophylaxis (endemic area)

Wash the wound immediately then clean it. Administer rabies vaccine (if unimmunised) and rabies immune immunoglobulin ASAP (within 48 hours).

### § Ciguatera

This is a type of food poisoning caused by eating tropical fish, especially large coral trout and large cod, caught in tropical waters (e.g. the Caribbean and tropical Pacific). The problem is caused by a type of poison that concentrates in the fish after they feed on certain micro-organisms around reefs. Ciguatera poisoning presents within hours as a bout of 'gastroenteritis' (vomiting, diarrhoea and stomach pains) and then symptoms affecting the nervous system, such as muscle aching and weakness, paraesthesia and burning sensations of the skin, particularly of the fingers and lips. There is no cure for the problem but it can be treated with IV fluids and possibly mannitol infusion or gammaglobulin. It is unwise to eat large predatory reef fish, especially their offal (mainly the liver).

### § Hansen's disease (leprosy)

Hansen's disease (Gerhard Hansen, 1869) is caused by the acid-fast bacillus *Mycobacterium leprae*. It is a disorder of tropical and warm temperate regions, especially South-East Asia. It is considered to be transmitted by nasal secretions with an incubation period of 2–6 years. It affects the skin and nerves, especially of the extremities.

### Clinical features

(WHO 1999)

Diagnosis is one or more of:

- Skin lesions—usually anaesthetic; hypopigmented or reddish maculopapules or annular lesions (see FIG. 15.3)
- Thickened peripheral nerves with loss of sensation, e.g. ulnar (elbow), median (wrist), common peroneal (knee) and greater auricular (neck); also peripheral neuropathy or motor nerve impairment

**FIGURE 15.3** Advanced lepromatous leprosy. This patient has multiple nodules on his ear and the greater auricular nerve is markedly thickened.

Courtesy Dr RA Cooke

- Demonstration of acid-fast bacilli in a skin smear or on biopsy
- It can be localised (tuberculoid) or generalised (lepromatous)

### Diagnosis

- Diagnosis is by biopsy, the lepromin test, cultivation of the organisms or by PCR tests

### Treatment

- Referral to specialists or a specialist centre is advisable for shared care.
- WHO treatment recommendations are multiple drug therapy, e.g. rifampicin, clofazimine and dapsone, but therapy is constantly being evaluated (see [www.who.int/lep](http://www.who.int/lep)).

### § Scrub typhus

Scrub typhus is found in South-East Asia, northern Australia and the western Pacific. It is caused by *Rickettsia tsutsugamushi*, which is transmitted by mites.

### Clinical features

- Abrupt onset febrile illness with headache and myalgia
- A black eschar at the site of the bite with regional and generalised lymphadenopathy
- Short-lived macular rash
- Can develop severe complications (e.g. pneumonitis, encephalitis)

### Diagnosis

- Serological assays

### Treatment

- Doxycycline 100 mg bd for 7–10 days

### § Queensland tick typhus

Queensland tick typhus, which is caused by *Rickettsia australis*, is directly related to a tick bite. The symptoms are almost identical to scrub typhus, although less severe, and the treatment is identical.

### Tropical parasitic infections<sup>1</sup>

Travellers to tropical or subtropical areas are at risk of more unusual infections. Most of these infections are contracted through contaminated food and water, insect bites and walking barefoot on contaminated soil. The risk of such infections is highest in rural areas of countries other than Europe, North America and Australasia. Parasitic infections other than malaria include the following.

### § African trypanosomiasis (sleeping sickness)

#### Clinical features

##### Stage 1 (haemolympathic)

- Incubation period about 3 weeks
- Fever, headache and a skin chancre or nodule
- Lymphadenopathy, hepatosplenomegaly

##### Stage 2 (meningoencephalitic)

- weeks or months later
- cerebral symptoms including hypersomnolence

### Diagnosis

- Demonstrating trypomastigotes in peripheral blood smear or chancre aspirate

### Treatment

- Suramin IV
- Infectious disease consultation essential

### Prevention

- Avoid bites of the tsetse fly. If visiting areas of East, Central and West Africa, especially the safari game parks, travellers should use insect repellent and wear protective light-coloured clothing, including long sleeves and trousers.

### § Leishmaniasis

#### Visceral leishmaniasis (kala-azar)

This is transmitted by bites of sand flies and by blood transfusions and IV drug use.

### Clinical features

- The haemopoietic system is targeted and presenting features include fever, wasting, hepatosplenomegaly and lymphadenopathy
- Among other signs is hyperpigmentation of the skin, hence the Hindu name kala-azar ('black fever')
- Most cases are subclinical

### Diagnosis

- Serology and tissue biopsy

### Cutaneous leishmaniasis

This may be encountered in travellers and servicemen and servicewomen returning from the Middle East, especially the Persian Gulf, and also travellers returning from Central and South America. The protozoa is transmitted by a sandfly and has an average incubation period of 9 weeks.

### Clinical features

The key clinical finding is an erythematous papule (see FIG. 15.4).

FIGURE 15.4 Cutaneous leishmaniasis in a serviceman after returning from the Middle East

### Diagnosis

- Performing a punch biopsy and culturing tissue in a special medium

### Treatment

- Treatment for extensive lesions is with high-dosage ketoconazole for 1 month.
- Smaller lesions should be treated topically with 15% paromomycin and 12% methyl benzethonium chloride ointment applied bd for 10 days.<sup>9</sup>
- A special vaccine is available in some Middle Eastern countries (e.g. Israel).

### § Schistosomiasis (bilharzia)

The infestation is caused by parasite organisms (schistosomes) whose eggs are passed in human excreta, which contaminates watercourses (notably stagnant water) and irrigation channels in Egypt, other parts of Africa, South America, some parts of South-East Asia and China. Freshwater snails are the carriers (vectors).

### Clinical features

- The first clinical sign is a local skin reaction at the site of penetration of the parasite (it then invades liver, bowel and bladder). This site is known as 'swimmer's itch'.
- Within a week or so there is a generalised allergic response, usually with fever, malaise, myalgia and urticaria.
- A gastroenteritis-like syndrome can occur (nausea, vomiting, diarrhoea) and respiratory symptoms, particularly cough.
- Clinical findings, such as in trypanosomiasis, include lymphadenopathy and hepatosplenomegaly.

### Diagnosis

- Serology
- Detecting eggs in the stools, the urine or in a rectal biopsy

### Treatment

- Praziquantel (may need retreatment)

### Prevention

- Travellers should be warned against drinking from, or swimming and wading in, dams, watercourses or irrigation channels, especially in Egypt and other parts of Africa.

### § Amoebiasis

Amoebiasis (*Entamoeba histolytica*) can be diagnosed in a sick traveller returning from an endemic area with severe diarrhoea characterised by blood and mucus. Complications include fulminating colitis, amoebomas (a mass of fibrotic granulation tissue) in the bowel and liver abscess. Acute amoebic dysentery is treated with oral tinidazole or metronidazole.

### Amoebic liver abscess

#### Clinical features

- High swinging fever
- Profound malaise and anorexia

- Tender hepatomegaly
- Effusion or consolidation of base of right chest

There is often no history of dysentery, and jaundice is unusual.

### Diagnosis

- Serological tests for amoeba and by imaging (CT scan)

### Treatment

- Metronidazole and by percutaneous CT-guided aspiration

### § Giardiasis

*Giardia lamblia* infection is usually acquired from contaminated drinking water.

### Clinical features

- Often asymptomatic
- Symptoms include abdominal cramps, bloating, flatulence and bubbly, foul-smelling diarrhoea, which may be watery, explosive and profuse.

### Diagnosis

- Three specimens of faeces for analysis (cysts and trophozoites): ELISA/PCR

### Treatment

- Scrupulous hygiene: metronidazole or tinidazole

### § Cutaneous myiasis

Myiasis, which refers to the infestation of body tissues by the larvae (maggots) of flies, often presents as itchy 'boils'. Primary myiasis invariably occurs in travellers to tropical areas such as Africa (Tumbu fly) and Central and South America (bot fly), whereby the fly can introduce the larvae into the skin, or it can be due to secondary invasion of pre-existing wounds. All cutaneous bot fly lesions look like an unusual boil but with a small circular hole. Close inspection of lesions may reveal part or all of the larva. The simplest treatment is lateral pressure and tweezer extraction or place paraffin jelly (Vaseline) or thick ointment over the lesion to induce emergence by restricting oxygen, then apply a topical antibiotic.

## WORMS (HELMINTHS)

Worms that inhabit the human intestine can be classified into nematodes (roundworms), cestodes (tapeworms) and trematodes (flukes).

The roundworms, which include pinworm (*Enterobius vermicularis*), whipworm (*Trichuris*

*trichiura*), human roundworm (*Ascaris lumbricoides*), human threadworm (*Strongyloides stercoralis*), hookworm (*Ankylostomiasis*), filariasis and larva migrans are the most prevalent worldwide and are usually asymptomatic in infected people.

### § Pinworm

Also known as 'threadworm', this is a ubiquitous parasite infesting mainly children of all social classes. They are tiny white worms about 1 cm long that multiply profusely and are spread readily between individuals by close contact (see FIG. 15.5). Virtually all children have been infected by the time they reach high school but at any one time approximately 50% of the 5–10 years age group will harbour pinworms.

### Clinical features (usually asymptomatic)

- Pruritus ani (in about 30% of cases)
- Diarrhoea (occasionally)

### Diagnosis

- Inspect anus in child about 1 hour after going to sleep (see FIG. 15.5)
- Collect eggs with adhesive tape on perianal skin early morning—send to laboratory

FIGURE 15.5 Pinworms: female worms appearing soon after a sleep to lay eggs

### Treatment

#### Management (troublesome cases)

- Scrupulous hygiene by family
- Hands should be washed thoroughly after toileting and before handling food

- Clip fingernails short (eggs lodge under nails)
- Patient should wear pyjamas (not nightgowns) and shower each morning
- Bed linen, nightwear and underwear changed and washed in very hot water daily for several days
- Vacuum room of affected person daily
- Have a veterinarian check any pets, especially dogs

### Medication

- Any one of pyrantel, albendazole or mebendazole—as single dose orally  
pyrantel 10 mg/kg up to 750 mg  
or  
mebendazine 100 mg (child <10 kg: 50 mg)  
or  
albendazole 400 mg (child <10 kg: 200 mg)
- Repeat in 2–3 weeks—both patient and household contacts

### § Human roundworm

Adult worms are about 20–40 cm long and are usually acquired from contaminated food and water overseas. Many cases are asymptomatic but come to notice when they emerge from the anus, mouth or nostril (causing anxiety in the family!). Some will present with abdominal discomfort, failure to thrive, intestinal obstruction, cough, anaemia or biliary disease. They may be seen in radiological contrast examinations.

### Diagnosis

- By finding eggs in the faeces. The worm is very sensitive to any of the three agents used for pinworm. May give positive faecal occult blood test.

### Treatment

- A first-line option is pyrantel 20 mg/kg up to 750 mg orally, as a single dose—to be repeated after 7 days if a heavy infestation.

### § Whipworm

These used to be common in Indigenous communities, possibly causing failure to thrive, anaemia, abdominal pain and diarrhoea and rectal prolapse with heavy chronic infestation. The worms are about 1–2 cm long.

### Diagnosis

- Faecal microscopy

### Treatment

- Single large doses of mebendazole or albendazole

### § Hookworm

These are found in humid tropical regions but are now uncommon in northern Australia. About 1–1.5 cm long, the parasites are acquired by walking barefoot (or wearing thongs or sandals) on earth contaminated by faeces. The larvae penetrate the skin, travel through the lungs and settle in the small intestine.

### Clinical features

The first sign is local irritation or ‘creeping eruption’ at the point of entry, known as ‘ground itch’, which is often unnoticed. This subsides within 2 days or so followed 1–2 weeks later by respiratory symptoms, which may be associated with bronchitis and bronchopneumonia. They can cause iron/protein deficiency anaemia in chronic infestation. Hookworm infection is the commonest cause of iron deficiency anaemia in the world.

### Diagnosis

- As with other helminths, diagnosis is by finding eggs on microscopy of faeces

### Treatment

- A single dose of mebendazole 100 mg bd for 3 days or 400 mg single dose pyrantel

### Prevention

- Travellers should be warned to wear shoes and socks in endemic areas to prevent the entry of the larvae into the skin of the feet.

### § Human threadworm (*Strongyloides*)

These are tiny parasites (2 mm or so) and have a worldwide distribution. Infestation can cause symptoms such as recurrent abdominal pain and swelling and diarrhoea, skin and respiratory symptoms, with blood eosinophilia. *Strongyloides* can live and reproduce in the body for many years. The problem is aggravated by corticosteroid therapy and may present with a severe infection, such as septicaemia. High-risk people include migrants and refugees from tropical developing countries, returned soldiers, former prisoners of war from South-East Asia and workers or residents in northern Aboriginal communities.

**DxT** abdominal pain (low grade) + recurrent diarrhoea + blood eosinophilia → *strongyloides*

## Diagnosis

- Detecting faecal larvae or duodenal biopsy
- ELISA: highly specific, sensitive

## Treatment

- Ivermectin 200 mcg/kg (o) two doses 2 weeks apart (not in children < 5 years) or albendazole 200 mg bd for 3 days

Adverse effects are common. Beware of these drugs in pregnancy and children.

## § Cutaneous larva migrans

Cutaneous larva migrans (creeping eruption) (see FIG 15.6) should be suspected in any pruritic, erythematous lesion with a serpiginous eruption on the skin, especially the hands, legs and feet of a person from a subtropical or tropical area. It is caused by the larvae of dog or cat hookworms penetrating and migrating throughout human skin, the larva always being just ahead of the lesion it causes. The diagnosis is based on the classic clinical appearance and by eosinophilia. Biopsy is usually not indicated. The problem is usually self-limiting.

FIGURE 15.6 Cutaneous larva migrans on the leg: close-up of a serpiginous burrow

## Diagnosis

- Clinical (characteristic appearance), eosinophilia (biopsy usually not indicated)

## Treatment

- Ivermectin (single dose)  
or

Albendazole

Antihistamines for pruritus

Note: This is usually a self-limiting problem.

## Prevention

- As for hookworm. Moist sandy soil contaminated with dog or cat faeces is a common source.

## § Filariasis

This nematode infection has two main forms which are spread by mosquitoes and biting black flies respectively.

- 1 Lymphatic filariasis causes acute adenolymphangitis and chronic lymphoedema with obstruction of lymph flow. The latter can manifest as a hydrocele, scrotal oedema or elephantiasis especially of the extremities, genitals and breasts. Diagnosis is by blood film and serology.
- 2 Onchocerciasis (river blindness) starts as a nodule at the bite site followed by chronic skin disease and eye lesions such as uveitis and optic atrophy. It is the second leading cause of blindness worldwide. Diagnosis is by PCR testing, treatment by ivermectin.

## § Hydatid disease

Hydatid disease is acquired by ingesting eggs of the dog parasite *Echinococcus granulosus*, which is found in sheep farming areas here and in several countries in Asia. The parasites can migrate anywhere but usually form hydatid cysts in the liver and lungs.

## Clinical features

There may be no symptoms although the patient may complain of abdominal discomfort or cystic lesions on the skin and other sites. Rupture of a cyst (usually hepatic) can cause severe anaphylaxis with possible death.

## Diagnosis

- Serological tests and ultrasound

## Treatment

- Usually surgical removal of a cyst and albendazole

## § Dracunculus medinensis (Guinea worm)

This is the longest nematode. It is transmitted by tiny crustaceans in water.

### Clinical features

- Local symptoms include pain and intense itching at the skin ulcer or blister as the worm emerges into the skin

### Treatment

- Slow extraction of pre-emerging worms as they exit the skin
- Metronidazole  $\pm$  corticosteroids

*More mistakes, many more, are made by not looking than by not knowing.*

Sir William Jenner (1815–98)

GPs have an ideal opportunity to practise the art of careful observation and to notice all the signs and features characteristic of a patient from the time seen in the waiting room until the physical examination. We should be ‘like Sherlock Holmes’ in our analysis of the patient and accept the challenge of being astute diagnosticians and proud members of a noble profession.

It is important to stand back (so to speak) and look at the patient’s general appearance and demeanour. We should be assessing their mood and affect as much as their physical appearance. The first assessment to make is ‘Does the patient look sick?’.

## First impressions

The first impression of the patient is always striking in some way and we should discipline ourselves to be as analytical as possible.

A rapid inspection from a trained observer may be all that is necessary to allow the observer to pinpoint specific disorders, such as anaemia, hyperthyroidism, jaundice, acromegaly and alcohol abuse. Such ‘spot’ diagnosis is not justifiable unless the original signs are supported by further examination, which must be comprehensive.

The following observations should therefore be made:

- facial characteristics
- abnormalities of the head and neck
- examination of the mouth
- character and distribution of hair
- examination of the skin (in general)
- height and weight
- posture and gait
- genitalia
- examination of extremities (hands, feet, nails, etc.)

## Physiognomy

Physiognomy, from the Greek *physiognomonía*, meaning the judging of one’s nature, is the art of judging character from the features of the face. It flourished

during the Middle Ages. According to Addison<sup>1</sup>, ‘everyone is in some degree a master of that art which is physiognomy; and naturally forms to themselves the character of a stranger from the features of the face’. In reality, all doctors use a physiognomical approach to diagnose many medical conditions, although we may not be as expert at the art as we should be.

The face is a person’s most immediate means of communicating with others; it is a shield and banner, a mask and a mirror. It reveals mental faculties and emotional turmoil. It is the first perspective gained of patients as they walk into the consulting room.

## The face as a mirror of disease

A fascinating aspect of the art of clinical medicine is the clinical interpretation of the patient’s facies. Not only are specific skin lesions common on the face but the face may also mirror endocrine disorders and organ failure such as respiratory, cardiac, kidney and liver failure.

Jaundice may be masked by the natural colour of the cheeks but the yellow conjunctivae will be distinctive. A marked plethoric complexion may be seen in chronic alcoholics (alcohol may produce a pseudo-Cushing syndrome), in Cushing disease or in polycythaemia. Thickening of the subcutaneous tissues may be seen in chronic alcoholism, acromegaly and myxoedema, and the puffiness of the eyelids in the latter condition may simulate the true subcutaneous oedema of kidney disease.

An individual’s personality and mood rarely fail to leave an impression on the facial characteristics. This is partly due to the alteration in facial lines and wrinkles, which may become modified in anger, irritability, anxiety and stress. More profound changes occur with mental disease. Various CNS diseases, such as Parkinson disease and myopathies, can affect facial expression (e.g. the immobile face of the patient with Parkinson disease).

The appearance of the eyes can also be very significant and may reflect underlying systemic disease (see FIG. 16.1).

FIGURE 16.1 Kayser–Fleischer ring around the cornea in a patient with Wilson disease

## Diagnostic facies

### Acromegalic

The enlarged characteristic face is due to a large supra-orbital ridge that causes frontal bossing, a broad nose and a prominent broad and square lower jaw. Other features include an enlarged tongue and soft tissue swelling of the nose, lips and ears (CHAPTER 23).

### Adenoidal

Due to mouth breathing in children: a narrow nose/nares, a high-arched palate (the 'Gothic' palate), prominent incisor teeth, undershot jaw with a perpetually open mouth and 'stupid' expression.

### Alcoholic (due to chronic use)

It is important to recognise the characteristic changes as early as possible—a plethoric face, thickened 'greasy' skin, telangiectasia, suffused conjunctivae and rosacea. Other features may include rhinophyma, parotid swelling and characteristic changes to the lips and corners of the mouth.

### Bird-like (systemic sclerosis: CREST syndrome)

The bird-like features—beaking of the nose, limitation of mouth opening, puckering or furrowing of the lips and a fixed facial expression—are due to binding down of facial skin. Other features include telangiectasia on the face and hands.

### Chipmunk (thalassaemia major)

There is bossing of the skull, hypertrophy of the maxillae (which tends to expose the upper teeth), prominent malar eminences and depression of the

bridge of the nose. The major haemoglobinopathies cause hyperplasia of the skull and facial bones because of an increase in the bone marrow cavity.

### Choleric

The patient with cholera has a pale face with cold clammy skin, sunken eyes, hollow cheeks and a forlorn, apathetic look (similar to the Hippocratic facies).

### Cushingoid

The face has a typical 'moon shape', plethora, hirsutism (more obvious in women), acne (CHAPTER 23).

### Facial nerve palsy

Features include unilateral drooping of the corner of the mouth and flattening of the nasolabial fold (CHAPTER 33).

- Upper motor neurone (UMN) type: the forehead movement is spared
- Lower motor neurone (LMN) type (e.g. Bell palsy, Ramsay–Hunt syndrome): lack of forehead muscle tone

### Hippocratic

This describes the deathly, mask-like features of advanced peritonitis—sunken eyes; 'gaunt' face; 'collapsed' temples; dry, crusty lips; and clammy forehead.

### Marfanoid (Marfan syndrome)

The typical tall stature, arachnodactyly and chest deformities, combined with the facial features of a subluxation of the lens of the eye and high-arched palate, help to pinpoint the diagnosis (CHAPTER 18).

### Mitral (mitral valve disease, especially mitral stenosis)

This is typically shown in flushed or rosy cheeks with a bluish tinge due to dilatation of the malar capillaries. It is associated with pulmonary hypertension.

### Mongoloid (Down syndrome)

The facial features include a flat profile, with crowded features, a round head, dysplastic lowset ears, protruding tongue, mongoloid slant of the eyes with epicanthic folds, mouth hanging open and peripheral silver iris spots (Brushfield's spots) (CHAPTER 18).

### Myopathic (myopathy/myasthenia gravis)

Facial characteristics include an expressionless, 'tired'-looking face with bilateral ptosis.

**FIGURE 16.2** Thyrotoxicosis illustrating a typical thyroid stare

### Myotonic (dystrophia myotonia)

Typical features include frontal baldness, expressionless triangular facies, partial ptosis, cataracts and temporal muscle atrophy.

### Myxoedemic (hypothyroidism)

The face usually has an apathetic look and is 'puffy' with possible periorbital oedema. There is broadening of the lower part of the face. The skin (not the sclera) may appear yellow (due to hypercarotenaemia) and is generally dry and coarse. Other features may include thin, coarse, listless hair and loss or thinning of the outer third of the eyebrows. The tongue is usually enlarged and the patient speaks with a 'thickened', croaking, slow speech (CHAPTER 23).

### Obese

The distinguishing feature from the 'moon face' of Cushing disease is the general roundness and uniform fatness of the face.

### Paget (Paget disease)

The main feature is skull enlargement, notably of the frontal and parietal areas (the head circumference is usually greater than 55 cm, which is abnormal)—the 'hat doesn't fit any more' hallmark. Other features include increased bony warmth and deafness (CHAPTER 69).

### Parkinsonian

Characteristic is the mask-like facies with lack of facial expression and fixed unblinking stare. There is immobility of the facial muscles (CHAPTER 33).

### Peutz–Jegher's

Pigmented macules (1–5 mm in diameter) occur on lips, buccal mucosa and fingers.

### Smoker's

A face older than the years with premature gross wrinkling of the skin, stained teeth, deep raspy voice, 'loose' cough, smell of tobacco.

### Thyrotoxic (hyperthyroidism)

The prominent eyes (sclera may not be covered by the lower eyelid) and conjunctivitis are features of the thyrotoxic patient (CHAPTER 23). The thyroid stare (a frightened expression) may also be present (see FIG. 16.2).

### Turner syndrome

The facial characteristics include ptosis—'fishlike' mouth, small chin (micrognathia), low-set ears and deafness. Cardiac lesions include coarctation of the aorta and pulmonary stenosis. Webbing of the neck is the classic sign (CHAPTER 18).

### Uraemic

A sallow 'muddy' complexion with uraemic fetor—an ammoniacal halitosis.

### Specific characteristics

Various facial signs may be present. The causes of these signs are listed below.

#### Butterfly 'rash'

- SLE  
Erythema, scaling with a discrete red advancing edge on the cheeks and bridge of the nose; the sharp border, lack of pustules and adherent scale make it differ from rosacea
- Rosacea  
Papules, pustules and telangiectasia on an erythematous background on cheeks, forehead and chin
- Erysipelas  
Painful, erythematous, indurated skin infection with a well-defined raised edge
- Seborrhoeic dermatitis  
Red and scaly rash involving eyebrows, eyelids, nasolabial folds
- Photosensitivity eruptions  
Erythematous on areas that are exposed to the sun

### Chloasma/melasma

Increased browning pigmentation, usually confined to symmetrical areas of the cheeks (FIG. 16.3). Common in pregnancy and caused by drugs:

- combined oral contraceptive pill
- hydroxychloroquine (Plaquenil)
- diphenylhydrazine

**FIGURE 16.3** Melasma (chloasma) in the typical distribution soon after the birth of the second child. Sometimes called the mask of pregnancy.

### Malar flush

- Mitral stenosis
- Pulmonary stenosis
- Rosacea
- SLE
- Mesenteric adenitis

### Spider naevi

- Pregnancy
- Liver disease
- Vitamin B deficiency in normal people

### Enlarged tongue

- Acromegaly
- Hypothyroidism
- Amyloidosis
- Down syndrome

### Cataracts

- Senility
- Corticosteroid therapy
- Diabetes
- Hypoparathyroidism
- Dystrophia myotonia
- Trauma
- Ocular disease (e.g. glaucoma)

### Telangiectasia

- Systemic sclerosis
- CREST syndrome
- Liver disease (e.g. alcoholism)

### Cyanosis

Cyanosis is a bluish discolouration of the skin and mucous membranes due to deoxygenated haemoglobin concentrated in the superficial blood vessels. The arterial oxygen saturation is 80–85% before it is clinically apparent. It is classified as central or peripheral.

#### Central

Cyanosis is present in parts of the body with good circulation, such as the lips and tongue. The areas feel warm. The main causes are pulmonary disease, pulmonary oedema, cyanotic congenital heart disease (right to left shunt), respiratory depression, polycythaemia (see FIG. 16.4).

#### Peripheral

Cyanosis is in the extremities, such as the outer surface of the lips, nose and ears. The areas feel cold. The main causes are peripheral vascular disease, cardiac failure, 'shock', exposure to cold, left ventricular failure and all causes of central cyanosis.

### Clubbing of fingers

#### Features

- Loss of usual angle between base of nail and nail fold
- Curvature in two planes
- Increased sponginess in base of nail
- Increased convexity of nail
- Mainly caused by respiratory disease

#### Causes

- 1 Lung disease:
  - carcinoma
  - bronchiectasis

**FIGURE 16.4** Adolescent patient with central cyanotic heart disease and associated clubbing of the fingers

- cystic fibrosis
- abscess/empyema
- pulmonary fibrosis
- 2 Heart disease:
  - infective endocarditis
  - cyanotic congenital heart disease (see FIG. 16.4)
- 3 Liver disease:
  - cirrhosis
- 4 Gastrointestinal disease:
  - ulcerative colitis
  - Crohn disease
  - coeliac disease
- 5 Congenital

### Increased pigmentation

Increased pigmentation is not common but if obvious in areas exposed to the sun, look for 'hidden' areas, such as the inner aspect of the forearms. Causes include those listed below.

### Increased melanocyte-stimulating hormone (MSH)

- Addison disease (see CHAPTER 23)
- Cushing syndrome
- Ectopic ACTH syndrome

### Metabolic

- Hyperthyroidism
- Haemochromatosis (see FIG. 16.5)
- Cirrhosis of the liver
- Porphyria
- Chronic kidney failure
- Malnutrition/malabsorption
- Pregnancy

**FIGURE 16.5** Patient showing pigmentation of primary haemochromatosis and associated arthritis of fingers

## Drugs

- Amiodarone
- Antibiotics (busulphan, bleomycin, minocycline)
- Antimalarials (chloroquine/hydroxychloroquine)
- Arsenic, gold, silver
- Chemotherapy
- Dapsone
- Oral contraceptive pill (OCP)
- Phenothiazines
- Photochemotherapy (PUVA)
- Psoralens
- Thiazides

## Tumours

- Lymphomas
- *Acanthosis nigricans*
- Metastatic melanoma

## References

*For most diagnoses all that is needed is an ounce of knowledge, an ounce of intelligence, and a pound of thoroughness.*

Anon (1951), *Lancet*

The discipline of general practice is probably the most difficult, complex and challenging of all the healing arts. Our field of endeavour is at the very front line of medicine and as practitioners we shoulder the responsibility of the early diagnosis of very serious, perhaps life-threatening, illness in addition to the recognition of anxiety traits in our patients.

The teaching of our craft is also an exciting challenge and presupposes that we have a profound comprehension of our discipline.

Our area is characterised by a wide kaleidoscope of presenting problems, often foreign to the classic textbook presentation and sometimes embellished by a 'shopping list' of seemingly unconnected problems or vague symptoms—the so-called undifferentiated illness syndrome.<sup>1</sup> Common undifferentiated symptoms include tiredness or fatigue, sleeping problems, anxiety and stress, dizziness, headache, indigestion, anorexia and nausea, sexual dysfunction, weight loss, loss of interest, flatulence, abdominal discomfort and chest discomfort.<sup>2</sup> It is important, especially in a busy practice, to adopt a fail-safe strategy to analyse such presenting problems. Such an approach is even more important in a world of increasing medical litigation and specialisation.

To help bring order to the jungle of general practice problems, the author has developed a simple model to facilitate diagnosis and reduce the margin of error.

## The concept of diagnostic triads

A most useful guide to learning or memorising diagnoses, especially of elusive and uncommon conditions, is to remember three key points to the condition. The cognitive process of learning these so-called 'triads' and even 'tetrads' provides a useful template for the diagnostic methodology required in general practice. Some simple examples are shown below.

Examples such as these are interspersed throughout the text, especially in this chapter, and are prefixed by the symbol DxT.

### Examples of diagnostic triads

**DxT** angina + dyspnoea + blackouts  
→ aortic stenosis

**DxT** menstrual dysfunction + obesity + hirsutism → polycystic ovarian syndrome

**DxT** malaise + night sweats + pruritus  
→ Hodgkin lymphoma

**DxT** abdominal pain + diarrhoea + fever  
→ Crohn disease

**DxT** vertigo + vomiting + tinnitus → Ménière syndrome

**DxT** dizziness + hearing loss + tinnitus  
→ acoustic neuroma

**DxT** fatigue + muscle weakness + cramps  
→ hypokalaemia

## The basic model

The use of the diagnostic model requires a disciplined approach to the problem with the medical practitioner quickly answering five self-posed questions. The questions are shown in **TABLE 17.1**.

This approach, which is based on considerable experience, requires the learning of a predetermined plan which, naturally, would vary in different parts of the world but would have a certain universal application in the so-called developed world.

**Table 17.1** The diagnostic model for a presenting problem

- 1 What is the probability diagnosis?
- 2 What serious disorders must not be missed?
- 3 What conditions are often missed (the pitfalls)?
- 4 Could this patient have one of the 'masquerades' in medical practice?
- 5 Is this patient trying to tell me something else?

Each of the above five questions will be expanded.

An excellent acronym on this theme, 'PROMPT', was devised by a reader, Dr Kelly Teagle:

- P Probability
- R Red flag
- O Often missed
- M Masquerades
- P Patient wants to
- T Tell me something

Another contribution is by Flinders University medical student, Judah:

Things are not always cut and dried:

- C Connective tissue disorders
  - U UTIs, particularly in very old and very young
  - T Thyroid disease
- and
- D Depression
  - R remember to Rule out serious and Rare causes
  - I Iatrogenic causes
  - E Emotional needs
  - D Diabetes

## 1 The probability diagnosis

The probability diagnosis is based on the doctor's perspective and experience with regard to prevalence, incidence and the natural history of disease. GPs acquire first-hand epidemiological knowledge about the patterns of illness apparent in individuals and in the community, which enables them to view illness from a perspective that is not available to doctors in any other disciplines. Thus, during the medical interview, the doctor not only is gathering information, allocating priorities and making hypotheses, but also is developing a probability diagnosis based on acquired epidemiological knowledge.

## 2 What serious disorders must not be missed?

While epidemiological knowledge is a great asset to the GP, it can be a disadvantage in that he or she is so familiar with what is common that the all-important rare cause of a presenting symptom may be overlooked. On the other hand, the doctor in the specialist clinic, where a different spectrum of disease is encountered, is more likely to focus on the rare at the expense of the common cause. However, it is vital, especially working in the modern framework of a litigation-conscious society, not to miss serious, life-threatening disorders.

To achieve early recognition of serious illness, the GP needs to develop a 'high index of suspicion'. This

is generally regarded as largely intuitive, but this is probably not the case, and it would be more accurate to say that it comes with experience.

The serious disorders that should always be considered 'until proven otherwise' include malignant disease, acquired immunodeficiency syndrome (AIDS), coronary disease and life-threatening infections such as meningitis, meningococcal infection (see FIG. 17.1), *Haemophilus influenza* b infections, septicaemia and infective endocarditis (see TABLE 17.2).

Myocardial infarction or ischaemia is extremely important to consider because it is so potentially lethal and at times can be overlooked by the busy practitioner. It does not always manifest as the classic presentation of crushing central pain but can present as pain of varying severity and quality in a wide variety of sites. These sites include the jaw, neck, arm, epigastrium and interscapular region. Coronary

FIGURE 17.1 Meningococcal infection: complications of infarction (DIC) including gangrene from meningococcaemia

**Table 17.2** Serious 'not to be missed' conditions

Neoplasia, especially malignancy
HIV infection/AIDS
Asthma/anaphylaxis
Severe infections, especially:
• meningococcal infection (see Fig. 17.1)
• epiglottitis
• infective endocarditis
• pneumonia/influenza/SARS
• clostridia infections e.g. tetanus, botulism, gas gangrene
Coronary disease
• myocardial infarction
• unstable angina
• arrhythmias
Imminent or potential suicide
Intracerebral lesions (e.g. subarachnoid haemorrhage)
Ectopic pregnancy

**Diagnostic triads for life-threatening conditions (examples)**

- 
- DxT** fever + rigors + hypotension → septicaemia
  - DxT** fever + vomiting + headache → meningitis
  - DxT** fatigue + dizziness ± syncope → cardiac arrhythmia
  - DxT** fever + drooling + stridor (child) → epiglottitis
  - DxT** headache + vomiting + altered consciousness → subarachnoid haemorrhage (SAH)
  - DxT** abdominal pain + amenorrhoea + abnormal vaginal bleeding → ectopic pregnancy
  - DxT** fatigue + dyspnoea on exertion + dizziness → cardiomyopathy

artery disease may manifest as life-threatening arrhythmias that may present as palpitations and/or dizziness. A high index of suspicion is necessary to diagnose arrhythmias.

**Consider M<sup>2</sup>I<sup>2</sup>**

A traditional way of classifying serious diseases is the pathology aide-mémoire:

- Malignancy
- Metabolic

- Infarction
- Infection

**Danger: think VIC**

V = Vascular

I = Infection (severe)

C = Cancer

**Red flags**

Red flags (alarm bells) are symptoms or signs that alert us to the likelihood of significant harm. Such underlying disease *must not be missed* and demands careful investigation. Examples include weight loss, vomiting, altered cognition, fever >38°C, dizziness, and/or syncope at the toilet and pallor. Red flags will be outlined under presenting symptoms throughout the text.

**3 What conditions are often missed?**

This question refers to the common 'pitfalls' so often encountered in general practice. This area is definitely related to the experience factor and includes rather simple, non-life-threatening problems that can be so easily overlooked unless doctors are prepared to include them in their diagnostic framework.

Classic examples include smoking or dental caries as a cause of abdominal pain, allergies to a whole variety of unsuspected everyday contacts, foreign bodies, occupational or environmental hazards as a cause of headache, respiratory discomfort or malaise, and faecal impaction as a cause of diarrhoea. We have all experienced the 'red face syndrome' from a urinary tract infection, whether it is the cause of fever in a child, lumbar pain in a pregnant woman or malaise in an older person. The dermatomal pain pattern caused by herpes zoster prior to the eruption of the rash (or if only a few sparse vesicles erupt) is a real trap.

A typical pitfall is Addison disease, where some patients can wait up to 15 years before being diagnosed. The absence of subdued classic pigmentation (see FIG. 17.2) can mask the early diagnosis.

Haemochromatosis can be a surprise diagnosis, often discovered by serendipity following a screening blood test for unexplained fatigue. Coeliac disease is a classic master of disguise in both children and adults. Research by dermatologists<sup>4</sup> has highlighted that it can present in a number of ways that can affect the skin and hair. Apart from typical gastrointestinal symptoms, such as chronic diarrhoea, steatorrhoea, weight loss, anorexia and abdominal distension, the following atypical symptoms have been described:

- nutritional presentations, including folate, zinc or iron (in particular) deficiency

- grouped blisters around the knees, elbows and buttocks (dermatitis herpetiformis)
- hair loss and mouth ulcers

**FIGURE 17.2** Woman with Addison disease showing facial pigmentation

Menopausal symptoms can also be overlooked as we focus on a particular symptom. Some important pitfalls are given in **TABLE 17.3**.

#### Diagnostic triads for some 'pitfalls'

**DxT** fatigue + weight loss + diarrhoea  
→ coeliac disease

**DxT** anorexia/nausea + faecal leaking + abdominal bloating → faecal impaction

**DxT** abdominal cramps + flatulence + profuse diarrhoea → giardiasis

**DxT** lethargy + tiredness + arthralgia  
→ haemochromatosis

**DxT** lethargy + abdominal pains + irritability (in child) → lead poisoning

**DxT** aching bones + waddling gait + deafness → Paget disease

**DxT** malaise + cough + fever (± erythema nodosum) → sarcoidosis

**DxT** (male child) snorting, blinking + oral noises (e.g. grunts) ± loud expletives  
→ Tourette syndrome

**Table 17.3** Classic pitfalls

Abscess (hidden)
Addison disease
Allergies
Candida infection
Chronic fatigue syndrome
Coeliac disease
Domestic abuse, including child abuse
Drugs (see Table 17.4)
Endometriosis
Faecal impaction
Foreign bodies
Giardiasis
Haemochromatosis
Herpes zoster
Lead poisoning
Malnutrition (unsuspected)
Menopause syndrome
Migraine (atypical variants)
Paget disease
Pregnancy (early)
Sarcoidosis
Seizure disorders
Tourette syndrome
Urinary infection

## 4 The masquerades

It is important to utilise a type of fail-safe mechanism to avoid missing the diagnosis of these disorders. Some practitioners refer to consultations that make their 'head spin' in confusion and bewilderment, with patients presenting with a 'shopping list' of problems. It is in these patients that a checklist is useful. Consider the apparently neurotic patient who presents with

headache, lethargy, tiredness, constipation, anorexia, indigestion, shortness of breath on exertion, pruritus, flatulence, sore tongue and backache. In such a patient we must consider a diagnosis that links all these symptoms, especially if the physical examination is inconclusive; this includes iron deficiency anaemia, depression, diabetes mellitus, hypothyroidism (see FIG. 17.3) and drug abuse.

A century ago it was important to consider diseases such as syphilis and tuberculosis as the great common masquerades, but these infections have been replaced by iatrogenesis, malignant disease, alcoholism, endocrine disorders and the various manifestations of atherosclerosis, particularly coronary insufficiency and cerebrovascular insufficiency.

**FIGURE 17.3** Hypothyroidism in a 60-year-old woman, a classic masquerade, with a slow subtle onset of facial changes

If the patient has pain anywhere it is possible that it could originate from the spine, so the possibility

of spinal pain (radicular or referred) should be considered as the cause for various pain syndromes, such as headache, arm pain, leg pain, chest pain, pelvic pain and even abdominal pain. The author's experience is that spondylogenic pain is one of the most underdiagnosed problems in general practice.

A checklist that has been divided into two groups of seven disorders is presented in TABLES 17.4 and 17.5. The first list, 'the seven primary masquerades', represents the more common disorders encountered in general practice; the second list includes less common masquerades—although some, such as Epstein-Barr mononucleosis, can be very common masquerades in general practice.

**Table 17.4** The seven primary masquerades

- 1 Depression
- 2 Diabetes mellitus
- 3 Drugs
  - iatrogenic
  - self-abuse
    - alcohol
    - narcotics
    - nicotine
    - others
- 4 Anaemia
- 5 Thyroid and other endocrine disorders
  - hyperthyroidism
  - hypothyroidism
  - Addison disease
- 6 Spinal dysfunction
- 7 Urinary tract infection (UTI)

Neoplasia, especially malignancy of the so-called 'silent areas', can be an elusive diagnostic problem. Typical examples are carcinoma of the nasopharynx and sinuses, ovary, caecum, kidney and lymphoietic tissue. Sarcoidosis is another disease that can be a real masquerade (see CHAPTER 49).

Systemic lupus erythematosus (SLE) has been described as 'the great pretender'.<sup>5</sup> The two most common symptoms are joint pain and fatigue but it is a multisystem disease that may present with involvement of any of these organ systems and may not initially be recognised as such.

As a practical diagnostic ploy, the author has both lists strategically placed on the surgery wall immediately behind the patient. The lists are rapidly perused for inspiration should the diagnosis for a particular patient prove elusive.

**Table 17.5** The seven other masquerades

- 1 Chronic kidney failure
- 2 Malignant disease
  - lymphomas
  - lung
  - caecum/colon
  - kidney
  - multiple myeloma
  - ovary
  - pancreas
  - metastasis
- 3 HIV infection/AIDS
- 4 Baffling bacterial infections
  - syphilis
  - tuberculosis
  - infective endocarditis
  - the zoonoses
  - *Chlamydia* infections
  - atypical pneumonias (e.g. Legionnaire disease)
  - others
- 5 Baffling viral (and protozoal) infections
  - Epstein–Barr mononucleosis
  - TORCH organisms (e.g. cytomegalovirus)
  - hepatitis A, B, C, D, E
  - mosquito-borne infections
    - malaria
    - Ross River fever
    - dengue fever
    - others
- 6 Neurological dilemmas
  - Parkinson disease
  - Guillain–Barré syndrome
  - seizure disorders
  - multiple sclerosis
  - myasthenia gravis
  - space-occupying lesion of skull
  - migraine and its variants
  - others
- 7 Connective tissue disorders and the vasculitides
  - Connective tissue disorders
    - systemic lupus erythematosus (SLE)
    - systemic sclerosis
    - dermatomyositis
    - overlap syndrome
  - Vasculitides
    - polyarteritis nodosa
    - giant cell arteritis/polymyalgia rheumatica
    - granulomatous disorders

## 5 Is the patient trying to tell me something?

The doctor has to consider, especially in the case of undifferentiated illness, whether the patient has a 'hidden agenda' for the presentation.<sup>6</sup> Of course, the

patient may be depressed (overt or masked) or may have a true anxiety state. However, a presenting symptom such as tiredness may represent a 'ticket of entry' to the consulting room. It may represent a plea for help in a stressed or anxious patient. We should be sensitive to patients' needs and feelings, and, as listening, caring, empathetic practitioners, provide the right opportunity for the patient to communicate freely.

Deep sexual anxieties and problems, poor self-esteem, and fear of malignancy or some other medical catastrophe are just some of the reasons patients present to doctors.

The patient with a self-induced bruising (see FIG. 17.4) was a health professional who was deeply attracted to an inpatient haematologist (Munchausen syndrome).

The author has another checklist (see TABLE 17.6) to help identify the psychosocial reasons for a patient's malaise.

### Diagnostic triads for some 'masquerades'

**DxT** malaise + fever + cough (± erythema nodosa) → TB or sarcoidosis

**DxT** fever + sore throat + cervical lymphadenopathy → EB mononucleosis

**DxT** fatigue + a/n/v + sallow skin → chronic kidney failure

**DxT** polyuria + polydipsia + skin/orifice infections → diabetes mellitus

**DxT** FUO + cardiac murmur + embolic phenomena → infective endocarditis

**DxT** fatigue + polyarthritides + fever or skin lesions → SLE

**DxT** loin pain + haematuria + palpable loin mass → kidney carcinoma

**DxT** malaise + weight loss + cough → lung carcinoma

**DxT** fever + myalgia/headache + non-productive cough → atypical pneumonia

**DxT** malaise + night sweats + painless lymphadenopathy → non-Hodgkin lymphoma

**DxT** arthralgia + Raynaud phenomenon + GORD (± skin changes) → systemic sclerosis

**DxT** fatigue + headache + jaw claudication → temporal arteritis

**DxT** weakness + back pain + weight loss → multiple myeloma

**DxT** lethargy + physical/mental slowing + constipation → hypothyroidism

Note: Diagnostic triads for neurological dilemmas are included in CHAPTER 33.

**FIGURE 17.4** Artefactual purpura showing an unusually symmetrical distribution in sites that can be reached by the patient (a 'ticket of entry')

In the author's experience of counselling patients and families, the number of problems caused by interpersonal conflict is quite amazing and makes it worthwhile to specifically explore the quality of close relationships, such as those of husband–wife, mother–daughter and father–son.

Another common yet overlooked stressor is bullying,<sup>7</sup> whether it is in the workplace, school, university, home, internet or elsewhere. It is a significant public health issue. The current fashion for tough, dynamic, 'macho' management styles has created a culture in which bullying can thrive. As GPs we should be more aware of the possibility

**Table 17.6** Underlying fears or image problems that cause stress and anxiety

- 1 Interpersonal conflict in the family
- 2 Identification with sick or deceased friends
- 3 Fear of malignancy
- 4 STIs, especially AIDS
- 5 Impending 'coronary' or 'stroke'
- 6 Sexual problem
- 7 Drug-related problem
- 8 Crippling arthritis
- 9 Financial woes
- 10 Other abnormal stresses

that workplace bullying may be contributing to the stresses with which many patients present. A simple, direct, routine question such as 'How are things at work?' can create an opportunity to raise the issue.

Identification and transference of illness, symptoms and death, in particular, are important areas of anxiety to consider. Patients often identify their problems with relatives, friends or public personalities who have malignant disease. Other somatoform disorders and the factitious disorders, including the fascinating Munchausen syndrome, may be obvious or extremely complex and difficult to recognise. These subtle psychosocial issues are usually termed 'yellow flags'.

### Yellow flags<sup>3</sup>

Yellow flags are signs or behaviours that flag or indicate a psychosocial barrier to recovery. They have been described originally within the framework of chronic pain and disability, especially chronic back pain, and require a shift in our focus of care. Conditions to consider are anxiety, depression, adjustment disorder and personality disorder. Typical yellow flags are presented in **TABLE 17.7**

**Table 17.7** Yellow flags: examples

- Abnormal illness behaviour
- Devious behaviour
- Cancelling appointments
- Treatment non-compliance/refusal
- Somatisation
- Absenteeism from work
- Poor work performance
- Personal neglect
- Relationship breakdown
- Law and order incidents

A survey by researchers at Melbourne's Centre for Behavioural Research<sup>7</sup> revealed that the three most feared diseases are cancer (81%), heart disease (32%) and HIV/AIDS (21%).

The bottom line is that patients are often desperately searching for security and we have an important role to play in helping them.

## Some examples of application of the model

### Hiccough

- 1 Q. Probability diagnosis
  - A. Food and alcohol excess
  - Psychogenic/functional
  - Postoperative
    - gastric distension
    - phrenic nerve irritation
- 2 Q. Serious disorders not to be missed
  - A. Neoplasia
    - CNS
    - neck
    - oesophagus
    - lung
  - Subphrenic abscess
  - Myocardial infarction/pericarditis
  - CNS disorders (e.g. CVA infection)
  - Chronic kidney failure
- 3 Q. Pitfalls
  - A. Alcohol excess
  - Smoking
  - Aerophagy
  - Gastrointestinal disorders
    - oesophagitis
    - peptic ulcer
    - hiatus hernia
    - cholecystitis
    - hepatomegaly
  - Rarities*
  - Sudden temperature change
  - Neck cysts and vascular abnormalities
- 4 Q. Seven masquerades checklist
 

A. Depression	–
Diabetes	–
Drugs	✓
Anaemia	–
Thyroid disorder	–
Spinal dysfunction	Possible
UTI	–
- 5 Q. Is the patient trying to tell me something?
  - A. Emotional causes always to be considered.

## Halitosis

(see CHAPTER 72)<sup>9</sup>

- 1 Q. Probability diagnosis
  - A. Dietary habits—odour-causing foods e.g. garlic
  - Poor oral hygiene
  - Oro-dental disease e.g. gingivitis, dental abscess
  - Dry mouth (e.g. on waking)
  - Smoking/alcohol
- 2 Q. Serious disorders not to be missed
  - A. Malignancy: lung, oropharynx, larynx, stomach, nose, leukaemia
  - Pulmonary tuberculosis
  - Quinsy
  - Oral candidiasis
  - Lung abscess
  - Blood dyscrasias/leukaemia
  - Uraemia
  - Hepatic failure
- 3 Q. Pitfalls
  - A. Nasal and sinus infection
  - Systemic infection
  - Appendicitis
  - Bronchiectasis
  - Hiatus hernia
  - Starvation
  - Rarities*
  - Pharyngeal and oesophageal diverticula
  - Sjögren syndrome
  - Scurvy
- 4 Q. Seven masquerades checklist
  - A. Depression
  - Diabetes: acidosis (acetone)
  - Drugs
  - Anaemia
  - Thyroid disorder
  - Spinal dysfunction
  - UTI
- 5 Q. Is the patient trying to tell me something?
  - A. Possible manifestation of psychogenic disorder
  - Halitophobia

## Practice tips

- Follow the 'baseball rule' for a delayed or puzzling diagnosis: 'Three strikes and you're out'.
- Infarction—think fast!
- Intervention time rules:
  - acute coronary events: 60–90 minutes
  - stroke: 3–4 hours
  - femoral artery: 4 hours
  - torsion of testis: 4–6 hours

## Patient education resources

*People love to oversimplify genetics, saying we have a ‘gene for cancer’ or a ‘gene for diabetes’. But the fact is, genes determine only so much. Identical twins are identical genomes, yet one may develop juvenile diabetes and the other typically doesn’t. Understanding the role of genes should help pinpoint environmental factors . . . The genome is a history book showing the entire 6 billion-member human species traces back 7000 generations to a tiny founding population of some 60 000 people. Our species has only a modest amount of genetic variation—the DNA of any two humans is 99.9% identical.*

The family doctor has an important role to play in the exciting and rapidly expanding world of medical genetics. The role includes routine diagnosis, early detection, and community and ethical guidance. Virtually all of the three billion nucleotides of the human genome have been sequenced and the knowledge of their organisation into the known 30 000–35 000 functional units or genes continues to become more sophisticated.<sup>2</sup>

The genome project has commenced mapping out ‘single nucleotide polymorphisms’ (SNPs) as signposts throughout the genome to assist in locating disease-associated genes and studying variations between individuals.<sup>3</sup> Any two unrelated individuals differ by one base per every thousand or so—these as SNPs—and it is believed that SNPs contribute to the risk of common disease rather than directly cause disease. If we carry the wrong set of SNPs, we can be predisposed to various diseases.

Genetic testing is now available for many common hereditary disorders, such as the *HFE* genes for haemochromatosis, presymptomatic DNA tests are available for the hereditary neurological disorders, such as Huntington disease, and predictive DNA testing is available for some forms of hereditary cancer, such as breast and colon cancer, and in the future for cardiovascular disease and diabetes.<sup>4</sup> Also in the future, pharmacogenetics, which predicts genetically determined responses to pharmaceuticals, will greatly assist rational prescribing, and gene therapy is a futuristic treatment modality.<sup>5</sup>

An important recent development in gene expression has been advances in DNA technology, with the detection of fetal DNA in maternal plasma,

Eric Land er, Human Geno me Project , 2000<sup>1</sup>

thus allowing an excellent screening test for Down syndrome.<sup>6</sup>

### Epigenetics

Epigenetics, meaning ‘on top of’ traditional genetic inheritance, is a study of changes in genetic expression or cellular phenotype caused by mechanisms other than changes in the DNA sequence. These factors, which include environment, lifestyle, nutrition and psychosocial influences, can influence the outcomes of chronic illness such as cancer, diabetes, autoimmune disorders and ageing. The incurred changes are heritable. This is an expanding development.

A summary of the prevalence of genetic disease is presented in **TABLE 18.1**.

Table 18.1 Prevalence of genetic disease (after Kingston) <sup>7</sup>	
Type of genetic disease	Estimated prevalence per 1000 population
Single gene	
Autosomal dominant	2–10
Autosomal recessive	2
X-linked recessive	1–2
Chromosomal abnormalities	6–7
Common disorders with appreciable genetic component	7–10
Congenital malformations	20
Total	38–51

## Key facts and checkpoints

- All people carry a small number of recessive genes, which are carried asymptotically.
- The background risk that any couple will bear a child with a birth defect is about 4%. This risk is doubled for a first-cousin (consanguineous) couple.<sup>8</sup>
- Although the majority of cancers are not inherited, some people carry inherited genetic mutations for certain cancers, notably breast and ovarian (linked), colorectal and others on a lesser scale, such as prostate cancer and melanoma.
- GPs should look out for a family history of cancer, including the number of people with cancer on both sides of the family, the type of cancer and the age and onset of primary cancers.
- A GP caring for 1000 patients would expect to have 15–17 patients with a hereditary cancer predisposition.
- As genetic testing becomes more accessible it is prudent to be aware of the psychological consequences to patients of predictive or presymptomatic testing. Specialised genetic counselling is advisable.
- Carrier screening is now widely used for thalassaemia, Tay–Sachs disorder and cystic fibrosis.
- Prenatal screening and testing for genetic disorders is also a reality, especially for Down syndrome, fetal abnormalities and the haemoglobinopathies. Once again, careful selection, screening and counselling is important.
- Genetic services and familial cancer clinics provide an excellent service for referral, especially for genetic counselling expertise and advice about appropriate services and genetic testing.
- Pharmacogenetics and gene therapy are the future hope for targeted treatments based on a person's genetic profile.

## The spectrum of genetic disorders

The list of inherited disorders continues to grow as evidence supports intuition that certain conditions are hereditary. It is important for the family doctor to be aware of this potential. We are familiar with the more common classic disorders, such as cystic fibrosis, thalassaemia, Down syndrome and haemochromatosis, but it is incumbent on us to be conversant with the genetic basis of diseases such as cancer, particularly breast, ovarian and bowel cancer, in addition to the childhood chromosomal/microdeletion syndromes and various inborn errors of metabolism.

## The genogram

The genogram is a valuable pedigree chart that usually covers at least three generations of a family tree. It is a simple and disciplined means of gathering data about an individual couple or family to determine inheritance patterns. The data have to be gathered with tact and care. A useful strategy is to encourage patients to develop their own family genogram using charts as templates (resource: Centre for Genetic Education, NSW Health, [www.genetics.edu.au](http://www.genetics.edu.au)).

An example including the use of symbols is shown in **FIGURE 18.1**.

## SPECIFIC IMPORTANT GENETIC DISORDERS

### § Haemochromatosis

Hereditary haemochromatosis (HHC), which is a disorder of iron overload, is the most common serious single gene genetic disorder in our population.

It is a common condition in which the total body iron concentration is increased to 20–60 g (normal 4 g). The excess iron is deposited in and can damage several organs:

- liver—cirrhosis (10% develop cancer)
- pancreas—‘bronze’ diabetes
- skin—bronze or leaden grey colour
- heart—restrictive cardiomyopathy
- pituitary—hypogonadism, impotence
- joints—arthralgia (especially hands), chondrocalcinosis

It is usually hereditary (autosomal recessive = AR) or may be secondary to chronic haemolysis and multiple transfusions.

*Note:* Hereditary haemochromatosis is the genetic condition; hemosiderosis is the secondary condition.

### Genetic profile<sup>8</sup>

Being an autosomal recessive disorder, the patient must inherit two altered (mutated) copies of the gene (see **FIG. 18.2** for a thalassaemia example). It is a problem mainly affecting Caucasians, usually from middle age onwards. About 1 in 10 people are silent carriers of one mutated gene, while 1 in 200 are homozygous and are at risk of developing haemochromatosis. These people can have it to a variable extent (the penetrance factor), and some are asymptomatic while others have a serious problem. It is rare for symptoms to manifest before the third decade.<sup>9</sup>

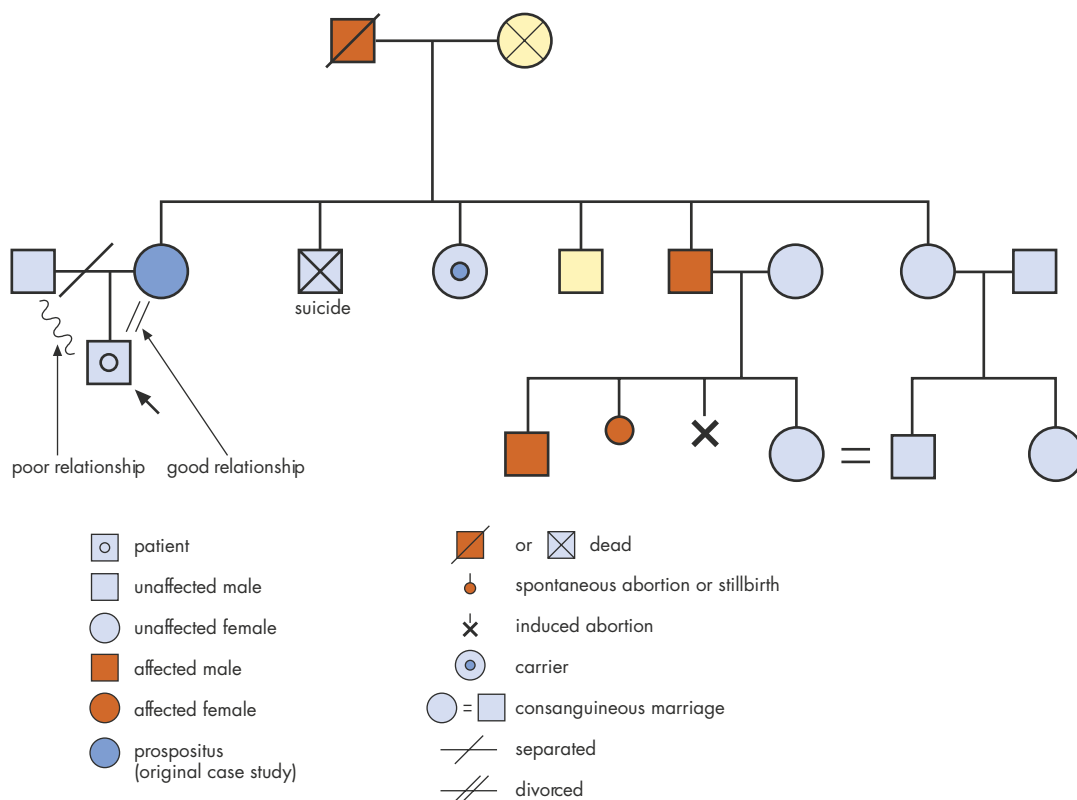

FIGURE 18.1 Genogram: illustration of a family tree for an inherited disorder

The two common identified specific mutations in the *HFE* gene are C282Y and H63D (another is S65C):

- homozygous C282Y—high risk for HHC
- homozygous H63D—unlikely to develop clinical HHC
- heterozygous C282Y and H63D—milder form of HHC

The key diagnostic sensitive markers are serum transferrin saturation and the serum ferritin level. The serum iron level is not a good indicator. An elevated ferritin level is not diagnostic of HHC but is the best serum marker of iron overload.

### Clinical features

- May have extreme lethargy, signs of chronic liver disease, polyuria and polydipsia, arthralgia, erectile dysfunction, loss of libido and joint signs

Signs: look for hepatomegaly, very tanned skin, cardiac arrhythmias, joint swelling, testicular atrophy.

### Diagnosis

- Increased serum transferrin saturation >45%
- Increased serum ferritin level (see levels CHAPTER 22)

- CT or MRI—increased iron deposition in liver
- Liver biopsy (if liver function test enzymes are abnormal or ferritin >1000 mcg/L or hepatomegaly). MRI may take over from biopsy to evaluate liver status.
- Genetic studies: *HFE* gene—a C282Y and/or H63D mutation
- Screen first-degree relatives (serum ferritin levels and serum transferrin saturation in older relatives and genetic testing in younger ones). No need to screen before adulthood.

*Note:* Full blood count (FBE) and erythrocyte sedimentation rate are normal.

### Management

- Refer for specialist care
- Weekly venesection 500 mL (250 mg iron) until serum iron stores are normal (may take at least 2 years), then every 3–4 months to keep serum ferritin level <100 mcg/L (usually 40–80 mcg/L), serum transferrin saturation <50%, and iron levels normal
- Desferrioxamine can be used but not as effective as venesection

**FIGURE 18.2** Typical genogram of inheritance of an autosomal recessive disorder: thalassaemia

- Normal diet
- Avoid or limit alcohol
- Life expectancy is normal if treated before cirrhosis or diabetes develops

## § Thalassaemia

The thalassaemias, the most common human single-gene disorders in the world, are a group of hereditary disorders characterised by a defect in the synthesis of one or more of the globin chains ( $\alpha$  or  $\beta$ )—there are two of each ( $\alpha_2$ ,  $\beta_2$ ). This causes defective haemoglobin synthesis leading to hypochromic microcytic anaemia.  $\alpha$ -thalassaemia is usually seen in people of Asian origin while  $\beta$ -thalassaemia is seen in certain ethnic groups from the Mediterranean, the Middle East, South-East Asia and the Indian

subcontinent. However, in our multicultural communities one cannot assume a person's origins. It is recommended that all women of child-bearing age be screened for thalassaemia.

### Genetic profile<sup>8</sup>

$\alpha$ -thalassaemia is usually due to the deletion of one or more of the four genes for  $\alpha$ -globin, the severity depending on the number of genes deleted: deletion of all four genes— $\alpha$ -thalassaemia (hydrops fetalis); of three genes—haemoglobin H disease, which results in lifelong anaemia of mild-to-moderate degree; of one or two genes—a symptomless carrier.

In  $\beta$ -thalassaemia, the  $\beta$ -chains are produced in decreased quantity rather than having large deletions. People who have two mutations (one in each  $\beta$ -globin gene) have  $\beta$ -thalassaemia major.

- $\beta$ -thalassaemia minor—a single mutation (heterozygous)—the carrier or trait state
- $\beta$ -thalassaemia major—two mutations (homozygous)—the person who has the disorder

Inheritance is illustrated in **FIGURE 18.2**. If both parents are carriers, there is a 1 in 4 chance that their child will have the disorder.

### Clinical features

Carriers are clinically asymptomatic and do not need treatment apart from counselling. Patients with thalassaemia major present with symptoms of severe anaemia (haemolytic anaemia). Without treatment, children with thalassaemia major are lethargic and inactive, show a failure to thrive or to grow normally, and delayed puberty, hepatosplenomegaly and jaundice. Signs usually appear after 6 months and death from cardiac failure used to be common but with regular blood transfusions and iron-chelating treatment people can now live in good health.

**DxT** pallor + jaundice + hepatosplenomegaly  
→ thalassaemia major

### Diagnosis<sup>9</sup>

- FBE: in most carriers the mean corpuscular haemoglobin/mean corpuscular volume is low but can be normal. There is usually mild hypochromic microcytic anaemia but this is severe with the homozygous type.
- Haemoglobin electrophoresis: measures relative amounts of normal adult haemoglobin (HbA) and other variants (e.g. HbA<sub>2</sub>, HbF). This will detect most carriers.
- Serum ferritin level: helps distinguish from iron deficiency, which has a similar blood film.
- DNA analysis: for mutation detection (mainly used to detect or confirm carriers).

### Treatment for thalassaemia major

Treatment is based on a regular blood transfusion schedule for anaemia. Avoid iron supplements. Folate supplementation and a low-iron diet are advisable. Excess iron is removed by iron chelation (e.g. desferrioxamine). Allogenic bone marrow transplantation has been used with success.<sup>10</sup> Splenectomy may be appropriate.

### Cystic fibrosis<sup>9</sup>

Cystic fibrosis is the result of a defect in an ion channel protein, the cystic fibrosis transmembrane receptor,

which is found in the membranes of cells lining the exocrine ducts. The defect affects the normal transport of chloride ions, leading to a decreased sodium and water transfer, thus causing viscid secretions that affect the lungs, pancreas and gut.

### Genetic profile<sup>7</sup>

- The most common AR paediatric illness
- About 1 in 2500 Caucasians affected
- About 1 in 20–25 are carriers
- A mutation ( $\delta$ -F508) of chromosome 7 is the most common of some 500 possible mutations of the gene. This deletes a single phenylalanine residue from a 1480-aminoacid chain.

### Clinical features

- General: malaise, failure to thrive, exercise intolerance
- Chronic respiratory problems: cough, recurrent pneumonia, bronchiectasis, sinus tenderness, nasal polyps
- Gastrointestinal: malabsorption, pale loose bulky stools, jaundice (pancreatic effect), meconium ileus (10% of newborn babies)
- Infertility in males (atrophy of vas deferens)
- Pancreatic insufficiency
- Early mortality but improving survival rates (mean age now 31 years)

**DxT** failure to thrive + chronic cough + loose bowel actions → cystic fibrosis

### Diagnosis

- Screening for immunoreactive trypsin in newborns detects 75%
- Sweat test for elevated chloride and sodium levels
- DNA testing for carriers identifies only the most common mutations (70–75%)

### Treatment

- Early diagnosis and multidisciplinary team care are important
- Physiotherapy for drainage of airway secretions
- Hypertonic saline solution (by nebuliser) preceded by a bronchodilator
- Treatment of infections: therapeutic and prophylactic antibiotics
- Oral pancreatic enzyme replacement
- Dietary manipulation
- Lung and liver transplantation are considerations

There is currently no cure for cystic fibrosis; treatment is based on correcting the nutritional deficiencies and minimising chest infections.

## § Neurofibromatosis

There are two types of this autosomal dominant (AD) disorder:

- NF1—peripheral neurofibromatosis (von Recklinghausen disorder)
- NF2—central type, bilateral acoustic neuromas (schwannomas) (rare)

The gene for NF1 is carried on chromosome 17 and NF2 on chromosome 22. Diagnostic genetic testing is not routinely available. Diagnosis is by clinical examination.

**DxT** light-brown skin patches + skin tumours + axillary freckles → NF1

### Clinical features of NF1<sup>8</sup>

- Six or more café-au-lait spots (increasing with age)
- Freckling in the axillary or inguinal regions
- Flesh-coloured cutaneous tumours (appear at puberty)
- Hypertension
- Eye features (iris hamartomas)
- Learning difficulty
- Musculoskeletal problems (e.g. scoliosis, fibrous dysplasia, pseudoarthrosis)
- Optic nerve gliomas

### General rule

- One-third asymptomatic, only have skin stigmata
- One-third minor problems, mainly cosmetic
- One-third significant problems (e.g. neurological tumours)

### Management

- No special treatment available
- Surgical excisions of neurofibromas as appropriate
- Refer to a special clinic, including neurofibroma clinic
- Careful surveillance—report new symptoms
- Yearly examination for children and adults, including blood pressure, neurological, skeletal and ophthalmological examination

## § Duchenne muscular dystrophy (DMD)

DMD is a progressive proximal muscle weakness disorder with replacement of muscle by connective tissue. Becker muscular dystrophy is a less severe variant.

## Genetic profile

DMD is an X-linked recessive condition. It is caused by a mutation in the gene coding for dystrophin, a protein found inside the muscle cell membrane.

### Clinical features<sup>8</sup>

- Usually diagnosed from 2–5 years
- Weakness in hip and shoulder girdles
- Walking problems: delayed onset or starting in boys aged 3–7
- Waddling gait, falls, difficulty standing and climbing stairs
- Pseudohypertrophy of muscles, especially calves
- Most in wheelchair by age 10–12
- ± Intellectual retardation
- Most die of respiratory problems by age 25
- Gowers sign: patient uses ‘trick’ method by using hands to climb up his or her legs when rising to an erect position from the floor

**DxT** male child + gait disorder + bulky calves → DMD

### Diagnosis

- Elevated serum creatinine kinase level
- Electromyography
- Direct dystrophin gene testing
- Muscle biopsy

### Treatment

- Counselling, especially genetic counselling, education, screening (especially mother)
- No specific treatment available; support; corticosteroids delay progression

## § Dystrophin myotonia

Genetic profile: AD disorder.

### Clinical features

- Typically presents 20–30 years as myotonia (tonic muscle spasm)
- Muscle weakness esp. hands, legs, face, neck
- Slow relaxation of hand grip
- ‘Hatchet face’—long haggard look with atrophy of facial muscles
- Frontal baldness in men
- Cataracts
- Mental impairment
- Cardiac disturbances e.g. cardiomyopathy
- Endocrine abnormalities e.g. diabetes

Investigation: electromyography.

## § Familial periodic paralysis

See CHAPTER 33.

### INHERITED ADULT ONSET NEUROLOGICAL DISORDERS<sup>11</sup>

These disorders have the following common features.

- They are serious and usually eventually fatal.
- Onset is in adulthood.
- They are currently incurable.
- They affect successive generations.
- Most are inherited from a parent in an autosomal dominant fashion.
- Specific genetic testing is usually available.

Examples of inherited adult onset neurological conditions are:

- Huntington disease
- Creutzfeldt–Jakob disease and other prion diseases
- familial Alzheimer disease
- familial epilepsy
- familial motor neurone disease
- Friedreich ataxia
- hereditary peripheral neuropathies (Charcot–Marie–Tooth disease)
- mitochondrial disorders
- hereditary spastic paraparesis
- muscular dystrophies
- myotonic dystrophy
- spinal muscular atrophy
- spinocerebellar ataxias

A minority of these conditions are due primarily to a dominantly inherited genetic alteration (mutation), e.g. Huntington disease, and are usually more accessible to genetic testing. Some gene alterations (polymorphism) may be associated with a higher risk of developing certain neurological conditions. Testing for polymorphisms is more complex. If concerned about a hereditary basis, GPs should refer their patients with these disorders to a neurologist or a neurogenetics clinic.

## § Huntington disease<sup>9</sup>

### Genetic profile

- Inherited as an AD disorder.
- The responsible mutant gene has been located on the short arm of chromosome 4.
- One genetic mutation accounts for the vast majority of cases, which means that there is an accurate diagnostic test.
- Both sexes are equally affected.

**DxT** chorea + abnormal behaviour + dementia + family history → Huntington disease

### Clinical features

- Insidious onset and progression of chorea
- Onset most often between 35 and 55 years
- Mental changes—change in behaviour (can be as early as childhood or in very late life), intellectual deterioration leading to dementia
- Family history present in the majority
- Motor symptoms: flicking movements of arms, lilted gait, facial grimacing, ataxia, dystonia
- Usually a fatal outcome 15–20 years from onset

### Treatment

- There is no cure or specific treatment
- Supportive treatment with agents such as haloperidol

### Genetic testing and counselling

This is available, sensitive and important because offspring have a 1 in 2 risk and the onset may be late—after childbearing years. It is appropriate to refer to expert centres for those seeking it. Of interest is that only 20% have undergone testing since it became available, indicating that those at risk generally prefer the uncertainty of not knowing the reality.

## § Familial Alzheimer disease (FAD)

Early onset familial Alzheimer disease (EoFAD), which accounts for less than 1% of all Alzheimer disease, is defined as the presence of two or more affected people with onset age <65 years in more than one generation of a family, with postmortem pathologically proven Alzheimer disease in at least one person. Mutations in any one of three different forms (alleles) of the susceptible APOE gene are known to cause FAD.<sup>9,12</sup>

## § Parkinson disease

Most cases are sporadic, and the majority of cases with a family history do not have a clear inheritance pattern and could be the result of several factors including a genetic predisposition or simply a chance aggregation. Consider referral to a neurogenetics clinic for families with unusual features, such as familial aggregation and/or early onset Parkinson disease.

## § Motor neurone disease (MND) (amyotrophic lateral sclerosis)

Five to 10% of motor neurone disease is inherited, with an autosomal dominant inheritance pattern. Inherited MND shows familial aggregation and an earlier age of onset than average (40s or younger); otherwise clinical features are essentially the same as the sporadic form (see CHAPTER 33). If more than one family member presents with MND consider referral to a neurogenetic clinic.

## The epilepsies

The epilepsies comprise a group of disorders with differing genetic components and the inheritance or genetic contribution relates to each specific disorder. Further studies on this subject are in progress. If there are two or more individuals in a family with epilepsy, referral for advice about the nature and inheritance about their form of epilepsy may be appropriate.

## Psychiatric conditions

Serious psychotic and mood disorders can run in families, especially schizophrenia and bipolar disorder, which have a clear genetic component that appears to be complex and poorly understood (see TABLE 18.2). To date no genes causing schizophrenia have been identified, but large regions on some chromosomes have been associated with schizophrenia. Individuals with a first-degree relative with bipolar disorder or purely depressive (unipolar) have an increased risk of a mood disorder, but the genetics are not understood. Tourette syndrome is another psychological disorder that has a hereditary basis through an autosomal dominant gene with variable expression (penetrance).

**Table 18.2** Genetic risks (approximate) in schizophrenia and bipolar disorder

Affected relative	Schizophrenia (% risk)	Bipolar (% risk)
Nil (general population)	1	2–3
Parent	13	15
Both parents	45	50
Sibling	9	13
Monozygotic twin	40	70
Dizygotic twin	10	20

Source: Harper P. *Practical Genetic Counselling*. Oxford: Butterworth Heinemann, 1988

## HEREDITARY HAEMOGLOBINOPATHIES, HAEMOLYTIC DISORDERS, BLEEDING AND CLOTTING DISORDERS<sup>9,13</sup>

The commonest haemoglobinopathies are the thalassaemias (see earlier in this chapter), which are caused by a deficiency in the quality of globin chains, whereas other haemoglobinopathies are caused by structural variations in the globin chain. These conditions include HbS (sickle cell), HbC, HbD, HbE, HbO and HbLepore.

Other inherited conditions that can cause haemolytic anaemia are those with a red cell membrane defect and include hereditary spherocytosis, hereditary elliptocytosis and hereditary stomatocytosis.

## Sickle cell disorders

The most important abnormality in the haemoglobin (Hb) chain is sickle cell haemoglobin (HbS), which results from a single base mutation of adenine to thymine leading to a substitution of valine for glutamine at position 6 on the  $\beta$ -globin chain. The defective Hb causes the red cells to become deformed in shape—'sickled'. The sickled cells tend to flow poorly and clog the microcirculation, resulting in hypoxia, which compounds the sickling. Such attacks, which result in tissue infarction, are called 'crises'. Sickling is precipitated by infection, hypoxia, dehydration, cold and acidosis, and may complicate operations. The autosomal recessive disorder occurs mainly in Africans (25% carry the gene), but it is also found in India, South-East Asia, the Middle East and southern Europe.

- Heterozygous state for HbS = sickle cell trait
- Homozygous state = sickle cell anaemia/disease

## § Sickle cell anaemia

This varies from being mild or asymptomatic to a severe haemolytic anaemia and recurrent painful crises. It may present in children with anaemia and mild jaundice. Children may develop digits of varying lengths from the hand-and-foot syndrome due to infarcts of small bones.

Features of infarctive sickle crises include:

- bone pain (usually limb bones)
- abdominal pain
- chest—pleuritic pain
- kidney—haematuria
- spleen—painful infarcts
- precipitated by cold, hypoxia, dehydration or infection

Hb electrophoresis is needed to confirm the diagnosis.

Long-term problems include chronic leg ulcers, susceptibility to infection, aseptic necrosis of bone (especially head of femur), blindness and chronic kidney disease. The prognosis is variable. Children in Africa often die within the first year of life. Infection is the commonest cause of death.

### Sickle cell trait

People with this usually have no symptoms unless they are exposed to prolonged hypoxia, such as anaesthesia and flying in non-pressurised aircraft. The disorder is protective against malaria.

### § Hereditary spherocytosis

This is the commonest cause of inherited haemolytic anaemia in northern Europeans. It is an autosomal dominant disorder of variable severity, although in 25% of patients neither parent is affected, suggesting spontaneous mutation in some instances. Jaundice may present at birth or be delayed or occur not at all. Splenomegaly is a feature and splenectomy is considered to be the treatment of choice in severe cases. Maintenance of folic acid levels is important.

### Bleeding disorders

In inherited bleeding deficiency disorders, there are deficiencies of vital factors (see CHAPTER 39). The common significant disorders are:

- haemophilia A (factor VIII deficiency)—X-linked recessive
- haemophilia B (factor IX deficiency)—X-linked recessive
- von Willebrand disease (deficiency of factor VIII:C + defective platelet factor)—autosomal dominant

Others to consider are:

- hereditary haemorrhagic telangiectasia (Osler–Weber–Rendu disease)
- inherited thrombocytopenia

### Thrombophilia

This should be considered in patients with a past and/or family history of DVT or other thrombotic episodes (see CHAPTER 133). There are several causes, including important inherited factors, which are:

- factor V Leiden gene mutation (activated protein C resistance)
- prothrombin gene mutation

- protein C deficiency
- protein S deficiency
- antithrombin deficiency

It is important to be aware of these factors, especially in people with a past history of unexplained thrombotic episodes. Prescribing the oral contraceptive pill (OCP) is an issue but preliminary screening for thrombophilias is not recommended. In factor V Leiden, the most common factor in this group, there is a 35-fold increased risk of thrombosis for those taking the OCP.

### CHROMOSOMAL/MICRODELETION SYNDROMES (CHILDHOOD EXPRESSION)<sup>9</sup>

The following disorders, whose clinical features manifest in children, present with developmental and intellectual disability.

### § Down syndrome<sup>14</sup>

Down syndrome (trisomy 21) is based on typical facial features (flat facies, slanting eyes, prominent epicanthic folds, small ears), hypotonia, intellectual disability and a single palmar crease.

**DxT** typical facies + hypotonia + single palmar crease → Down syndrome

### Facts

- 95% have extra chromosome of maternal origin (trisomy 21)
- Remainder due to either unbalances, translocations or mosaicism
- Prenatal screening tests include early ultrasound (nuchal lucency) and maternal serum screening in first trimester (serum maternal and fetal DNA). Karyotyping of chorionic villus sampling on amniocytes for pregnancies at risk is available.
- Prevalence 1 in 650 live births

### Associated disorders

- Seizures (usually later onset)
- Impaired hearing
- Leukaemia
- Hypothyroidism
- Congenital anomalies (e.g. heart, duodenal atresia, Hirschsprung, TOF)
- Alzheimer-like dementia (fourth–fifth decade)
- Atlantoaxial instability
- Coeliac disease
- Diabetes

## Management

- Assess child's capabilities
- Refer to agencies for assessment (e.g. hearing, vision, developmental disability unit)
- Advise on sexuality, especially for females (i.e. menstrual management, contraception) as fertility must be presumed
- Genetic counselling for parents

## § Edward syndrome<sup>9</sup>

Trisomy 18

### Clinical features

These include:

- incidence 1 in 2000 live births (approx.)
- microcephaly
- facial abnormalities e.g. cleft lip/palate
- malformations of major organs
- malformations of hands and feet—clenched hand posture
- neural tube defect

Prognosis is poor—about one-third die in first month, <10% live beyond 12 months.

Prenatal diagnosis is available.

## § Patau syndrome<sup>9</sup>

Trisomy 13

### Clinical features

These include:

- incidence 1 in 7000 (approx.)
- microcephaly
- brain and heart malformation
- cleft lip/palate
- polydactyly
- neural tube defect

Prognosis is poor—50% die within first month.

## § Fragile X syndrome (FXS)<sup>14</sup>

FXS presents as a classic physical phenotype with large prominent ears, long narrow face, macroorchidism and intellectual disability. It is the most common inherited cause known of developmental disability and should always be considered. The cause is the result of an increase in the size of a trinucleotide repeat in the *FMR-1* gene on the X chromosome (the number of sequences determines carrier or full mutant status). Any individual with significant development delay should be tested for FXS.

**DxT** characteristic facies + intellectual disability + large testes → FXS

## Facts

- M:F ratio 2:1
- Prevalence 1 in 1000–4000
- Variable spectrum of characteristic features, making detection difficult in some cases
- Up to 1 in 300 females may be carriers
- Family history of intellectual disability
- Affects all ethnic groups
- Females may appear normal but may be affected

## Diagnosis

- Cytogenetic testing (karyotyping)
- DNA test (specific for full mutation as well as carriers)

## Associated disorders

- Intellectual disability (IQ < 70)
- Autism or autistic-like behaviour
- Attention deficit in 10% (with or without hyperactivity)
- Seizures (20%)
- Connective tissue abnormalities
- Learning disability and speech delay
- Coordination difficulty

## Management

- Careful genetic appraisal and counselling
- Assessment of child's capabilities
- Multidisciplinary assessment, including developmental disability unit
- Referral for integration of speech and language therapy, special education, behaviour management
- Pharmacological treatment of any epilepsy, or attention or mood behaviour disorders
- Medications may determine whether the child remains in the community or not

## § Prader–Willi syndrome

This uncommon disorder (1 in 10 000 to 15 000) has classic features, especially a bizarre appetite and eating habits, of which the GP should be aware. It is probable that there are many undiagnosed cases in the community. The most common cause is a deletion of the short arm of chromosome 15.

**DxT** neonatal hypotonia + failure to thrive + obesity (later) → Prader–Willi syndrome

## Clinical features

- Hypotonic infants with weak suction and failure to thrive, then voracious appetite causing morbid obesity

- Usually manifests at 3 years
- Intellectual disability
- Narrow forehead and turned-down mouth
- Small hands and feet
- Hypogonadism

### Management

- Early diagnosis and referral
- Multidisciplinary approach
- Expert dietetic control

With proper care and support, longevity into the eighth decade is a reality.<sup>14</sup>

### § Williams syndrome

Williams syndrome (idiopathic hypercalcaemia or elfin face syndrome) is due to a microdeletion on chromosome 7, a deletion in the elastin gene.

Children have a distinctive elfin facial appearance, mild pre- and postnatal growth retardation, mild microcephaly and mild-to-moderate developmental delay. In the first 2 years of life, feeding problems, vomiting, irritability, hyperacusis, constipation and failure to thrive may lead to presentation, but children are rarely diagnosed at this stage.

**DxT** 'elfin' face + intellectual disability + aortic stenosis → Williams syndrome

### § Marfan syndrome<sup>9</sup>

This is a systemic connective tissue disorder characterised by abnormalities of the skeletal, cardiovascular and ocular systems. It has variable expressions and is a potentially lethal disorder. If untreated, death in the 30s and 40s is common.

**DxT** tall stature + dislocated lens and myopia + aortic root dilatation → Marfan syndrome

### Genetic profile

- Mutations in the fibrillin gene on chromosome 15
- Autosomal dominant
- Prevalence about 5 per 100 000
- No specific laboratory test to date

### Clinical features

- Disproportionally tall and thin
- Long digits—arachnodactyly

- Kyphoscoliosis
- Joint laxity (e.g. genu recurvatum)
- Myopia and ectopic ocular lens
- High arched palate
- Aortic dilatation and dissection
- Mitral valve prolapse

### Management

- Needs surveillance of eyes, heart and thoracic aorta
- Echocardiography, possibly aortic root dilatation
- Long-term  $\beta$ -blockade therapy reduces rate of dilatation
- Consider prophylactic cardiovascular surgery
- Genetic counselling for the family

### § Tuberous sclerosis (epiloia)

This is an autosomal dominant disorder due to mutations in one of two genes located on chromosomes 9 and 16. A feature is tube-like growths that affect multiple systems including the brain.

**DxT** facial rash + intellectual disability + seizures → tuberous sclerosis

The above triad of features is classic but not applicable to all cases.

### § Noonan syndrome

This is an AD disorder with mutation of chromosome 11. It has been described as a male Turner syndrome but affects both sexes.

**DxT** facies + short stature + pulmonary stenosis → Noonan syndrome

### Clinical features<sup>14</sup>

- Characteristic facies—down-slanting palpebral fissures, widespread eyes, low-set ears  $\pm$  ptosis
- Short stature
- Pulmonary valve stenosis
- Webbed neck
- Failure to thrive, usually mild
- Abnormalities of cardiac conduction and rhythm
- $\pm$  Intellectual disability

### Treatment

- Refer to genetic service
- Evaluation of cardiac status
- Consider vision, hearing, clotting status, possible epilepsy

## § Angelman syndrome

Genetic profile

- Abnormal chromosome 15

### Clinical features (a wide spectrum)

- Hand flapping
- ‘Puppet’-like ataxia
- Frequent laughter/smiling
- Microcephaly by age 2 years
- Developmental delay
- Speech impairment
- Seizures
- Cannot live independently

Diagnosis based on clinical features and genetic studies.

Treatment with minocycline is promising.

## § Progeria

Sporadic mutation of LMA gene that codes for a protein leads to early cell death.

Accelerated ageing—manifests in early childhood causing premature death (median age 12 years) from vascular disease. No known treatment.

## SEX CHROMOSOME ABNORMALITIES

## § Klinefelter syndrome<sup>9</sup>

This is due to an extra X chromosome, resulting in a male phenotype and occurring in 1 in 800 live births.

**DxT** lanky men + small testes + infertility → Klinefelter syndrome

### Genetic profile

- XXY genotype
- The extra X chromosome is usually of maternal origin
- About 30 or more variants of the disorder

### Clinical features

Marked variation but usually:

- tall men with long limbs
- small firm testes  $\leq 2$  cm
- infertility (azoospermia)

There may be:

- sparse facial hair
- learning difficulties
- intellectual disability
- gynaecomastia
- increased risk of breast cancer and diabetes

### Treatment

- Transdermal testosterone

## § Turner syndrome (gonadal dysgenesis)

This is due to only one X chromosome, occurring in 1 in 4000 live female newborns; 99% of conceptions are miscarried.<sup>15</sup>

**DxT** short stature + webbed neck + facies → Turner syndrome

### Genetic profile

- 45 chromosomes of XO karyotype (typical Turner's karyotype in 50% of cases)
- Many are mosaics (e.g. 45X/46XX chromosomes)
- Phenotypes vary

### Clinical features of typical XO karyotype

- Short stature—average adult height 143 cm
- Primary amenorrhoea in XO patient; infertility
- Webbing of neck
- Typical facies: micrognathia, low hairline
- Lymphoedema of extremities
- Cardiac defects (e.g. coarctation of aorta)

Mental deficiency is rare.

### Treatment

- Hormone-based (e.g. growth hormone, hormone replacement therapy)

## Intersex states

These are uncommon chromosomal disorders of sexual development (DSD) in which the appearance of the external genitalia is either ambiguous or at variance with the individual's chromosomal sex. The inappropriate term ‘hermaphrodite’ should be avoided.

The conditions include:

- mixed gonadal dysgenesis
- ovotesticular disorder DSD
- 46, XX DSD (androgenised females)
- 46, XY DSD (underandrogenised males)

The latter may be caused by inadequate production of androgen or inadequate response to androgen, which includes the ‘androgen insensitivity syndrome’. This syndrome, made prominent through athletes with a male genotype but female phenotype, results from a mutation of the gene encoding the androgen receptor.

## § Congenital adrenal hyperplasia

See CHAPTER 23.

### FETAL ALCOHOL SYNDROME<sup>16</sup>

This important syndrome is caused by the teratogenic effects of alcohol (not a chromosomal abnormality) and is estimated to involve 2 in 1000 live births. The phenotype varies with the dosage and gestational timing of the alcohol exposure.<sup>16</sup> Caution needed not to overdiagnose.

**DxT** abnormal facies + growth retardation + microcephaly → fetal alcohol syndrome

### Clinical features

See FIGURE 18.3.

- Markedly underweight until puberty
- Learning difficulties
- Microcephaly
- Characteristic facies (needs 2 of \*)
  - shortened palpebral fissures\*
  - long, smooth featureless philtrum\*
  - thin upper lip\*
  - upturned nose
- Hyperactivity
- Congenital heart disease often seen

FIGURE 18.3 Fetal alcohol syndrome: facial features

Source: Shutterstock.com

- Skeletal abnormalities

Diagnosis based on alcohol history in pregnancy.

### Management

- By preventive strategies with community education about the harmful effects of drinking, especially in early pregnancy

### OTHER TYPES OF HEREDITARY DISORDERS

The many examples include familial hypercholesterolaemia (AD) and the AR disorders for which genetic testing is available, namely Gaucher disease, Tay–Sachs disease, glycogen storage disease, phenylketonuria, galactosaemia, homocystinuria, the porphyrias and glucose-6-phosphate dehydrogenase (G-6-PD) deficiency.

## § Glucose-6-phosphate dehydrogenase deficiency

G-6-PD deficiency is a common disorder affecting over 400 million people worldwide. It is the most common red-cell enzyme defect that causes episodic haemolytic anaemia because of the decreased ability of red blood cells to cope with oxidative stresses. It is an X-linked recessive inherited disorder with a high prevalence among people of African, Mediterranean or Asian ancestry. In some countries such as Malaysia there is a national screening program. Consider the disorder in male black people (see CHAPTER 138).

The important clinical features are:

- asymptomatic in many
- neonatal jaundice—infants at risk should be observed after delivery (at least 5 days)
- episodic acute haemolytic anaemia—triggered by antioxidants and infections, and drugs, especially antimalarials, sulphonamides, nitrofurantoin, quinolones, traditional medicines, vitamins C and K, high dose aspirin, fava (broad) beans and naphthalene (e.g. moth balls)

There is no specific treatment. Known precipitants should be avoided. Avoid penicillin and probenecid.

Diagnosis is by G-6-PD assay and a blood film during an attack.

## § Gaucher disease

Gaucher disease, which is due to a deficiency of the lysosomal enzyme glucocerebrosidase, leads to anaemia and thrombocytopenia as a result primarily

of hypersplenism. There is chronic bone pain and 'crises' of bone pain. Consider it in children with fatigue, bone pain, delayed growth, epistaxis, easy bruising and hepatosplenomegaly. Replacement enzyme therapy is available.

### § Galactosaemia<sup>9</sup>

Galactosaemia is an inborn error of metabolism in which the body is unable to metabolise galactose to glucose. There are three clinical syndromes caused by differing enzyme deficiencies, one of which is galactose-1-phosphate uridyl transferase, which causes the classic syndrome. It is an autosomal recessive disorder with an incidence of about 1 in 60 000 births. As lactose is the major source of galactose, the infant becomes anorexic and jaundiced within a few days or weeks of taking breast milk or lactose-containing formula. It can be rapidly fatal. Management is with a galactose (mainly lactose)-free formula such as soy with added calcium and vitamins.

### § Phenylketonuria (PKU)<sup>9</sup>

This autosomal recessive disorder of the catabolism of the amino acid, phenylalanine, is caused by a deficiency of phenylalanine hydroxylase activity, leading to an elevation of plasma phenylalanine, which if untreated can cause intellectual disability (often very severe) and other neurological symptoms, such as seizures. Neonatal screening for high blood phenylalanine levels (the Guthrie test) is performed routinely.

Treatment aims to limit phenylalanine intake so that essential amino acid needs are met but not exceeded. Diet therapy must commence as soon as possible. Females who have been treated for PKU need pre-pregnancy counselling and dietary management during pregnancy to prevent damage to the fetus by high phenylalanine levels.

### § The porphyrias

The three most common porphyrias are acute intermittent porphyria, porphyria cutanea tarda (the commonest) and erythropoietic protoporphyria, which are caused by deficiencies of the third, fifth and eighth enzymes, respectively, of the haem biosynthesis pathway. Their clinical features are quite different.

#### Acute intermittent porphyria

This autosomal dominant disorder is the most serious of the porphyrias although it remains clinically silent in the majority of patients who carry the trait. It is due to a deficiency of porphobilinogen (PBG) deaminase.

### Clinical features

- Recurrent unexplained abdominal pain crises
- Usually young women (teens or 20s)
- Recurrent psychiatric illnesses, abnormal behaviour
- Acute peripheral or nervous system dysfunction (e.g. peripheral neuropathy, hypotonia)
- PBG in urine during attack
- Hyponatraemia
- Attacks precipitated by various drugs (e.g. anti-epileptics, alcohol, sulphonamides, barbiturates)

**DxT** severe abdominal pain + abnormal illness behaviour + 'red' urine → acute intermittent porphyria

### Diagnosis

- Urine PBGs (high) and serum sodium (very low) during 'attack'
- Erythrocyte PBG deaminase testing to screen relatives

### Treatment

- Avoid 'unsafe' drugs
- High-carbohydrate diet, glucose for attack

### § Glycogen storage disease (liver glycogenoses)

This is a group of inherited disorders caused by a deficiency of one or more enzymes involved in glycogen breakdown, leading to the deposition of abnormal amounts of glycogen in tissues, especially the liver. The best-known type is 1A (von Gierke disorder), an autosomal recessive disorder due to deficiency of glucose-6-phosphatase (G-6-P). It is seen in several ethnic groups. It typically causes growth retardation, hepatomegaly, renomegaly, hypoglycaemia (can be severe), lactic acidosis and hyperlipidaemia. Children have characteristic morphological features—short, doll-like facies with fat cheeks, thin extremities and large abdomen (hepatomegaly).

Diagnosis is by abnormal plasma lactate and lipid levels, liver biopsy and recently by gene analysis for the G-6-P gene.

Treatment is aimed to prevent hypoglycaemia and lactic acidosis via frequent carbohydrate feedings, such as uncooked cornstarch and overnight nasogastric glucose infusion. The prognosis is poor.

## § Tay–Sachs disease

About 1 in 25 Ashkenazi Jews is a carrier of Tay–Sachs disease (gangliosidosis), an AR disorder caused by a total deficiency of hexosaminidase A resulting in an accumulation of gangliosides in the brain.

The infantile form is fatal by age 3 or 4 with early progressive loss of motor skills, dementia, blindness, macrocephaly and cherry-red retinal spots. The juvenile onset form presents with dementia and ataxia, with death at age 10–15. The adult form has progression of neurological symptoms following clumsiness in childhood and motor weakness in adolescence. Carrier testing is available and prenatal diagnosis is available.

## SINGLE GENE CARDIAC DISORDERS

Includes:

- cardiomyopathies
- arrhythmia syndromes e.g. long QT syndrome
- sudden cardiac death families

## § Congenital long QT syndrome

This is an autosomal dominant condition with predisposition to ventricular arrhythmias, syncopal/fainting spells and sudden death, particularly during exercise. Confirm or exclude by ECG when suspected—interval 0.5–0.7 seconds. Management includes sports restrictions,  $\beta$ -blockers and pacemaker or AICD.

## § Hypertrophic cardiomyopathy

This is an AD disorder with several genetic mutations. It is the most common cause of sudden cardiac death among athletes.

### Clinical features

- Fatigue
- Exertional dyspnoea and chest pain
- Palpitations
- Dizziness/syncope

Diagnosis by ECG (LV hypertrophy) and doppler echocardiography.

Insertion of AICD may prevent sudden death.

## § Familial hyperlipoproteinaemia<sup>17</sup>

There are several types of genetic disorder of lipid metabolism including the better-known familial hypercholesterolaemia and familial combined hyperlipidaemia. The former is identified by elevated

cholesterol, corneal arcus juvenalis, tendon xanthomas in the patient or their first- and second-degree relatives and also by a DNA mutation. Homozygous patients present with atherosclerotic disease in childhood and early death from myocardial infarction. Heterozygotes may develop the disorder in their 30s or 40s.

This is common, being 1 in 500 Caucasians, 1 in 70 in Lebanese and Afrikaners. Eighty per cent are undiagnosed and missing out on preventive treatments. GPs have an important role in screening people with premature ischaemic heart disease to look for phenotype characteristics of the condition.

## FAMILIAL CANCER<sup>18</sup>

The majority of cancer is not inherited; rather it is acquired because of genetic mutations in several genes of a cell in a specific tissue during an individual's lifetime. Twenty to twenty-five individuals in a population of 1000 have a family history of bowel or breast cancer.<sup>9</sup>

However, some people carry inherited genetic mutations from conception that predispose them to developing certain cancers, particularly colorectal, breast and ovarian cancer, at a relatively young age. Up to 5% of some cancers are considered familial and the genetic basis of some of these is now understood. Most are AD with 50% of offspring being affected.

The three most significant familial cancer inherited susceptibility syndromes are:

- hereditary breast–ovarian cancer syndrome (*BRCA*<sub>1</sub> and *BRCA*<sub>2</sub> genes)
- hereditary non-polyposis colorectal cancer (HNPCC)
- familial adenomatous polyposis (FAP)

## Features of breast–ovarian cancer syndrome<sup>8,9</sup>

- Mutations in either of the two genes—*BRCA*<sub>1</sub> and *BRCA*<sub>2</sub>—result in a strong predisposition for both breast and ovarian cancer
- Mutations present in about 1 in 800 of the general population (male and female), who are carriers
- Dominant inheritance
- The risk of developing breast cancer is 10-fold and 40–80% of cases occur before the age of 70 years<sup>17</sup>
- The prognosis in these women is the same as for sporadic cases
- Early age of onset of breast cancer
- Male breast cancer (6% in males with *BRCA*<sub>2</sub> gene mutation)

- Coexistence of ovarian and breast cancer in the same family
- Carriers of mutations *may* be at an increased risk of prostate cancer, pancreatic cancer and colorectal cancer, although this is controversial for the latter two

### Risk indicators for familial breast-ovarian cancer

- Two first-degree or second-degree relatives on one side of the family with cancer
- Individuals with age of onset of cancer <50 years
- Individuals with bilateral or multifocal breast cancer
- Individuals with ovarian cancer
- Breast cancer in a male relative
- Jewish ancestry

### Colorectal cancer<sup>18</sup>

Both sexes have a risk of approximately 5% of developing bowel cancer in their lifetime. In some this risk is increased due to an inherited predisposition.

The two key disorders are HNPCC and FAP.

### Lynch syndrome (hereditary non-polyposis colorectal cancer)

- Caused by a defect in one of the genes responsible for DNA mismatch repair
- Affects 1 in 1000 individuals
- Autosomal dominant
- Early age of onset
- Increased risk of certain extracolonic cancers, including endometrial, stomach, ovary and kidney tract cancers

### Familial adenomatous polyposis

- Less common than HNPCC; affects about 1 in 10 000
- Caused by a mutation in the *APC* gene
- Usually hundreds or thousands of polyps
- Eventually almost 100% of cases develop colon cancer without prophylactic colectomy
- Median age of diagnosis 40 years
- Small increased risk of other cancers (e.g. thyroid, cerebral)

### Individuals at risk

For Lynch syndrome (HNPCC):

- Three or more close relatives with bowel cancer

- Two or more close relatives with bowel cancer and:
  - more than one bowel cancer in same relative
  - onset of bowel cancer before 50 years
  - a relative with endometrial cancer or ovarian cancer
 (Refer: [www.ncbi.nlm.nih.gov/pubmed/14970275](http://www.ncbi.nlm.nih.gov/pubmed/14970275).)

For FAP:

- A relative with bowel cancer with polyposis
- Individuals with multiple polyposis

### Other cancers where family history is significant

- Melanoma: an inherited mutation in certain genes (e.g. *BRAF* gene) is considered to be involved in up to 5% of melanomas.
- Prostate: family history is a risk factor; some genes are susceptible.
- Several other cancers can develop as a mutation e.g. stomach, pancreas, kidney, thyroid, uterus (Cancer Council Australia, family cancer clinics helpline: 13 11 20).

### The role of the GP in familial cancer<sup>18</sup>

The GP has an important role in identifying potential high-risk patients and families and in addressing their concerns.

- Take a family history and involve at least three generations.
- Map a family tree: include any diagnosed breast, ovarian or colorectal cancers in any relative and *any* type of cancer in first-degree or second-degree relatives on either side of the family.
- Record the age of onset and site of cancer in first-degree relatives.
- Confirm reports of cancer from medical records.
- Assess risk (high, low or intermediate) using guidelines from your country's national cancer guidelines e.g. the NHMRC guidelines in Australia.
- Reassure low-risk patients but provide general preventive and screening guidelines.
- Refer all patients at potentially high risk to a familial cancer clinic.

Services at these clinics involve:

- risk assessment
- genetic testing
- counselling, including pre- and post-testing
- surveillance advice

Management is based on early detection and potential prophylactic methods, for example:

- for breast cancer—regular imaging and clinical examination
- for ovarian cancer—transvaginal ultrasound and serum CA-125 detection
- for FAP and HNPCC—annual colonoscopy, faecal occult blood test

Patients at high risk will ask about prophylactic colectomy, mastectomy and oophorectomy, for which there are reasonable indications, but it is necessary to refer to a cancer geneticist for expert evaluation before such decisions are made.

## Predictive genetic testing

The Human Genetics Society of Australia strongly advises against predictive or presymptomatic genetic testing of children for disease where there is no pre-emptive treatment in childhood. It should only be carried out in children if an effective treatment or preventive strategy is available. It raises issues of confidentiality, informed consent and harmful effects on self-esteem.<sup>9</sup>

Routine genetic testing is only advisable for high-risk individuals, such as those with a family history.

The ethical issues for adults are also considerable and for the individual the decision is difficult and requires considerable counselling via a clinical genetics service. This applies particularly to those at risk of Huntington disease and other adult-onset neurodegenerative conditions for which no preventive treatment exists.

## Prenatal screening and diagnosis of genetic disorders<sup>19</sup>

Approximately 2% of births are associated with congenital abnormalities, of which 1 in 7 are chromosomal, the most common of which is Down syndrome (trisomy 21). Antenatal screening tests that can now be performed for several conditions are mainly:

- screening tests for Down syndrome and other trisomies
- screening tests for thalassaemias/haemoglobinopathies
- second-trimester ultrasound scans for fetal abnormalities, such as neural tube defects (NTD) and abdominal wall defects (AWD)

## Screening for Down syndrome

This has a live birth incidence of 1.4 per 1000 in Australia.<sup>17</sup> The risk of conceiving a child with Down syndrome increases proportionally with age (see FIG. 18.4). For a woman aged 21, it is 1 in 1000, while for a woman aged 35, it is 1 in 275 and for a woman aged 45, it is 1 in 20.

The tests available to test for Down syndrome can be divided into two types:<sup>5</sup>

- 1 screening tests (maternal serum screening/MSST; free fetal DNA at 10–12 weeks gestation; nuchal transparency ultrasound)
- 2 diagnostic tests (chorionic villus sampling, amniocentesis)

The most reliable method is obtaining fetal tissue by these last means but there is a significant risk of miscarriage (1 in 100 for chorionic villus sampling and 1 in 200 for amniocentesis).

## Consanguinity

Consanguinity is the situation where a couple shares one or more common ancestors. Consanguineous relationships occur in most societies and in some cultures are associated with particular advantages and religious traditions.<sup>8</sup>

The concern about the issue has been questioned by a study in the *Journal of Genetic Counselling*, which suggested 'aside from a thorough history, there is no need to offer genetic testing on the basis of consanguinity alone'. In a comment on this study which indicated that 'cousins run few risks in mating', the author pointed out that people like Charles Darwin, Queen Victoria and Albert Einstein married first cousins and Darwin's children, in particular, were brilliant. In parts of Saudi Arabia 39% of all marriages are between first cousins.<sup>20</sup> On the other hand, there are substantiated records of problems with inherited disorders. Twenty-four US states ban the marriage of first cousins and the Catholic Church, with 2000 years of experience, has opposed cousin marriages for over 1000 years.

First cousins share a pair of grandparents and are statistically at an increased risk for autosomal recessive conditions. The baseline risk that any couple will have a baby with a birth defect is 3–4%.<sup>8</sup> In addition, empirical data show that for first cousin marriage there is an additional 4% risk of having a child with a birth defect—this includes malformations such as intellectual impairment and many rare

FIGURE 18.4 Risk of Down syndrome by maternal age

autosomal recessive disorders. So the combined risk is 8% irrespective of a positive family history, which is an important consideration in counselling these people.<sup>8</sup>

For siblings the risk of increase in birth defects is 30% and 19% for second cousins.

### Rare but helpful diagnostic tips

- Dark black urine on exposure = alkaptonuria

**DxT** arthritis + pigmentation of ear cartilage + black urine with alkalisation  
→ alkaptonuria

- Red urine on exposure = porphyria
- Blue diapers = tryptophan malabsorption syndrome
- Maple syrup odour (urine and perspiration) = maple syrup urine disease (AR) (an amino acid metabolic disorder)

**DxT** odour + hypertonicity + seizures (infancy) → maple syrup urine disease

- Mousy body odour = phenylketonuria
- 'Fish-like' mouth with micrognathia = Turner syndrome
- 'Chipmunk' facies = thalassaemia major
- 'Doll-like' facies = glycogen storage disease (G-6-P deficiency)
- Elfin face = Williams syndrome
- Butterfly-like facial rash in children = tuberous sclerosis
- Weak suction + delayed sitting and crawling = Prader-Willi syndrome
- 'Happy puppet' features = Angelman syndrome
- Characteristic eyes: wide-spaced, down-slanting openings, ptosis = Noonan syndrome
- Long fingers and limbs = Marfan syndrome
- High-pitched meowing cry, low-set ears, mental retardation = 'cat-cry' syndrome (maladie du cri du chat)
- Blue sclera = osteogenesis imperfecta

## Part 2

# Diagnostic perspective in general practice

---

# 19 Depression

*I am ignorant and impotent and yet, somehow or other, here I am, unhappy, no doubt, profoundly dissatisfied . . . In spite of everything I survive.*

Aldous Huxley (1894–1963)

Untreated, depression can result in disability and death.<sup>1</sup> It is present in at least 17% of patients who present to GPs<sup>2</sup> and has a 12-month prevalence of 5% and a lifetime risk of 15%.<sup>3</sup> It is often unrecognised,<sup>1</sup> yet moderate to severe depression is as disabling as congestive heart failure.<sup>1</sup> Further, depression is the *leading* cause of disability for all conditions among both sexes, both in Australia and worldwide.<sup>4,5</sup> The lifetime risk of suicide in patients diagnosed with depression is 6% and treatment halves this risk.<sup>1</sup>

Despite being treatable, 60% of sufferers have not used any form of health service in the previous months.<sup>4</sup> Lack of awareness, stigma and shame on behalf of the patient contribute to this. Of those receiving treatment, three-quarters will be managed in general practice.<sup>5,6</sup> As Whitford<sup>4</sup> notes:

It is clear that the main focus of activity aimed at reducing the burden of common mental health disorders in Australia is in primary care. Specialist mental health services play a supporting, but not central, role.

Depression is a chronic relapsing organic brain disease. Its mean onset is at 27 years of age. However, 40% of sufferers present by 20 years of age.<sup>7</sup> The average duration of episodes is 3–4 months and 40% of patients will relapse within a 12-month period.<sup>7</sup>

The cause of depression is multifactorial, having biological, psychological and social factors. Mood disorders in general have a strong familial tendency, and the risk of developing a depressive disorder can be thought of in terms of a 'stress-vulnerability model'. That is, an individual may have a genetically determined vulnerability and if enough stress is endured a mood disorder may result. Those who are more genetically vulnerable require less stress, but if enough stress is applied, any individual can develop a mood disorder.

When stress is present, the more vulnerable individual will develop increased glucocorticoid activity. This leads to increased neuronal mitochondrial activity, which can result in 'mitochondrial dropout' and neuronal death.

Stress will also lead to a decrease in the protective brain-derived neurotrophin factor (BDNF), which can result in neuronal death—also referred to as 'glial dropout'. Serotonin, noradrenalin and to a lesser extent dopamine lead to RNA replication of BDNF, and the complicated and poorly understood biochemical cascade that occurs 'beyond the receptor' is the reason for the slow response to antidepressants.

The result of this neuronal trauma leads to decreased activity in the prefrontal cortex and increased activity in the limbic system, particularly the amygdala and hippocampus. This traumatic effect on the brain of prolonged stress can actually be seen microscopically with decreased neuronal numbers on electron microscope images, and macroscopically on MRI scans, with sufferers showing a one-third loss of volume of the hippocampus. A good take-away message to give patients here is that stress and depression are more than just unpleasant—they are bad for your brain.

## Classifications

- The DSM-5 classification divides depressive disorders into major depressive disorder (MDD), disruptive mood dysregulation disorder, persistent depressive disorder (PDD) and premenstrual dysphoric disorder. Other 'specified' and 'unspecified' disorder categories allow for diagnosis of those patients who fall short of the various diagnostic criteria.
- MDD includes those disorders with one or more major depressive episodes. Excluding criteria include any previous mania or hypomania, and the episode not being attributable to a psychotic disorder, or a substance or medical condition.
  - MDD is subclassified with coded course and severity specifiers. These include mild, moderate and severe, with psychotic features, in partial remission and in full remission.

- Non-coded specifiers can also be used, including ‘with anxious distress’, ‘with mixed features’, ‘with melancholic features’, ‘with atypical features’, ‘with mood-congruent psychotic features’, ‘with catatonia’, ‘with peripartum onset’ and ‘with seasonal pattern’.
- Persistent depressive disorder (PDD) refers to long-standing (2 years or more) depression of mild severity.
- Adjustment disorder with depressed mood is a less severe form of depression without sufficient criteria for major depression. It is very common and occurs in response to identifiable stressors (‘reactive depression’, e.g. loss of employment). Its duration is usually no longer than 6 months.

The two key criteria for major depressive disorder (MDD) in the DSM-5 are a pervasive depressed mood and marked loss of interest or pleasure (otherwise referred to as anhedonia) persisting for at least 2 weeks. Other criteria (listed below) include sleep issues, fatigue, lack of energy, poor concentration and feelings of worthlessness.

In a general practice setting, having a checklist of these symptoms to work through with a patient can be a useful part of the assessment of the depressed patient. However, the DSM criteria can be too rigid for general practice, with many patients whom GPs recognise as having psychological issues not meeting DSM-5 criteria.<sup>3</sup> As Ian Hickie puts it, ‘Primary care psychiatry is not specialist psychiatry in general practice.’<sup>8</sup>

## Questions to assess level of depression

- What do you think is the matter with you?
- Do you think that your feelings are possibly caused by nerves, anxiety or depression?
- Can you think of any reason why you feel this way?
- Do you feel down in the dumps?
- Do you feel that you are coping well?
- Do you have any good times?
- Has anything changed in your life?
- How do you sleep? Do you wake early?
- What time of the day do you feel at your worst?
- Where would you put yourself between 0% and 100% (a visual analogue scale is useful here)?
- Have you felt hopeless?
- Do you brood about the past?
- What is your energy like?
- What is your appetite like?
- Are you as interested in sex as before?
- Do you feel guilty about anything?

- Do you feel that life is worthwhile?
- Has the thought of ending your life occurred to you?
- Do you cry when no one is around (especially useful for children)?

Two particularly good questions are:

- In the past month, have you been bothered by the fact that you feel down, depressed or hopeless?
- In the past month, have you often been bothered by the fact that you have little interest or pleasure in doing things?

## DSM-5 diagnostic criteria for major depressive disorder

At least five of the following symptoms nearly every day for 2 weeks (criterion 1 or 2 essential):

- 1 depressed mood (subjective or objective)
- 2 loss of interest or pleasure
- 3 change in weight (5% change over 1 month) or appetite
- 4 insomnia or hypersomnia
- 5 psychomotor agitation or retardation
- 6 loss of energy or fatigue
- 7 worthlessness or guilt
- 8 impaired concentration or indecisiveness
- 9 recurrent thoughts of death or suicide ideation or any suicide attempt

Source: *Diagnostic and Statistical Manual* (5th edition). Washington, DC: American Psychiatric Association, 2013.

## Depression scales

Depression scales are useful both to detect potential mood disorders (i.e. screening) and to monitor an individual patient over time. Scales commonly used include K10 (a distress score) and DASS 21 or 42 (for depression and anxiety symptoms).

## Somatisation

Another issue with depression in the primary care setting is recognising somatising patients who present without obvious psychological symptoms. Non-specific symptoms such as insomnia, prolonged fatigue, headache, nausea and musculoskeletal pain are common presentations in people with depression.<sup>9</sup> Studies suggest GPs find it challenging to identify these patients, and that using self-reporting patient-screening tools can help with identification.<sup>3</sup>

### Key facts and checkpoints

- Depression is common, serious and treatable.
- Depression is a chronic relapsing organic brain disease.
- The cause of depression is multifactorial, and can be thought of in terms of a 'stress-vulnerability model'.
- Somatising patients without obvious psychopathology are common and difficult to recognise and manage.

### Depression in the elderly

The rate of antidepressant prescribing for Australians over 80 years of age is higher than for any other age group.<sup>10</sup> Despite this, depression in the elderly is underdiagnosed.<sup>11</sup> Depression can have bizarre features in the elderly and may be misdiagnosed as dementia or psychosis. Agitated depression is the most frequent type of depression in the aged. Features may include histrionic behaviour, delusions and disordered thinking.

Depression is often missed in the elderly because it is atypical and less expressive, and patients tend to be ashamed and reluctant to admit it.

A useful clue can be a change in sleep pattern. Medical illness is also an important precipitant of depression in the elderly.

Older patients may have more side effects from medications (especially nausea, dizziness, falls and hyponatraemia).<sup>11</sup> They also tend to have only a modest response to antidepressants, and, if medication is used, a low initial dose and slow increase is recommended.<sup>1</sup> Psychological therapies can be useful, but tend to be underused.<sup>11</sup>

### Depression in children and adolescents

Sadness is common in children, but depression, although not as common, does occur and is characterised by feelings of helplessness, worthlessness and despair. Parents and doctors both tend to be unaware of depression in children.<sup>12</sup>

Major depression in children and adolescents may be diagnosed using the same criteria as for adults, namely loss of interest in usual activities and the presence of a sad or irritable mood, persisting for 2 weeks or more. In children, irritability may be more prominent than sadness.<sup>13</sup> The other constellation of depressive symptoms, including somatic complaints, may be present. Examples include difficulty in getting to sleep, not enjoying meals, poor concentration and low self-esteem. Poor motor skills and family instability are an association. Depression can present

as antisocial behaviour or as a separation anxiety (e.g. school refusal). Although suicidal thoughts are common, suicide is rare before adolescence.

Depressed adolescents are a difficult challenge for the general practitioner. Effective engagement and establishing rapport in a 'youth-friendly' environment is critical. Tips for fostering engagement with young people<sup>14</sup> include:

- explaining confidentiality
- speaking to the young person directly, as well as to parents and carers (where appropriate)
- treating the young person as responsible and capable of contributing to decision making
- taking a curious, non-intrusive and respectful stance
- being open and honest as much as possible
- clarifying what the young person wants from you
- establishing agreed goals or explaining clearly why you cannot help
- being honestly interested in what the young person has to say
- being yourself—don't fake it
- using metaphor and humour (where appropriate) to build rapport
- using language that is clear and easily understood and avoiding jargon; overuse of slang is probably worse than not using it at all
- warning the young person if you are going to ask questions about topics that may be difficult (e.g. sexual matters)
- avoiding getting into a controlling, authoritarian position
- remembering that engagement may wax and wane

See **CHAPTER 97** for treatment of depression in adolescents.

### Perinatal depression

This term refers to depression occurring either in the antenatal period or in the 12 months after delivery. It affects 9% of women during pregnancy and 16% after the birth<sup>15</sup> and affects the well-being of the woman, the baby and significant others. Anxiety is likely to be as or more common.<sup>15</sup> Women at risk of perinatal depression include those with previous mental health problems, those who do not have support, those who have been through difficult times (e.g. family problems, abuse or loss), or who feel isolated either by distance or culture or both.

Because it is so prevalent, routine screening is recommended by the beyondblue guidelines. This involves implementing the use of the Edinburgh

Postnatal Depression Scale (EPNDS), a validated screening tool, at least once, preferably twice, both antenatally and postnatally. Asking permission and explaining the process before implementing the screening is helpful. Women at higher risk will require more intense screening and monitoring.

Some good questions<sup>15</sup> to ask a woman you are concerned about include:

- Have you ever had a period of 2 weeks or more when you felt particularly low or down?
- Do you sometimes worry so much that it affects your day-to-day life?
- Have you ever needed treatment for a mental health condition?
- Has anyone in your family experienced severe mental health problems?
- When you were growing up, did you feel cared for and protected?
- If you currently have a partner, do you feel safe in this relationship?
- Do you or others think that you or your partner have a problem with drugs or alcohol?
- Have you had any major stressors, changes or losses in the past 12 months?
- When you were growing up, was your mother emotionally supportive of you?
- If you found yourself struggling, what emotional support would you have available? Who could help provide that?

If perinatal depression is identified, the GP should take into account the individual woman's context, her family and cultural setting, and use a family-centred approach. Because of the intense emotions involved in having a baby, establishing a strong therapeutic relationship, using an open collaborative approach and active listening techniques, will help to develop trust, confidence, mutual respect and empowerment. Psycho-education should be provided and appropriate follow-up and continuity of care, with (if appropriate) a co-ordinated team approach.

If a woman or a baby is at risk, urgent referral is recommended. Pharmacological therapies can be used in pregnancy, but the benefits need to be balanced against the risks to both mother and fetus. Psychosis in perinatal depression is fortunately rare but does occur, and requires urgent psychiatric assessment. Refer to **CHAPTER 111**.

## Management of depression

Important considerations from the outset are:

- Is the patient a suicide risk?

- Does the patient require inpatient assessment?
- Is referral to a specialist psychiatrist indicated?

## Suicide assessment

If the symptoms are major and the patient appears in poor health or is a suicide risk, referral is appropriate.

The importance of putting these safety issues at the beginning of the management process is reflected in the SET A PACE<sup>7</sup> model of treatment, proposed by Mahli et al.

To clarify the risk of suicide and appropriate response, ask about:<sup>14</sup>

- suicidal thoughts
- plan
- lethality
- means
- past history
- suicide of family member or peer

## Low risk (fleeting thoughts of self-harm or suicide but no current plan or means):

- Discuss availability of support and treatment options.
- Arrange follow-up consultation (timing of this will be based on clinical judgment).
- Identify relevant community resources and provide contact details.

## Medium risk (suicidal thoughts and intent but no current plan or immediate means):

- Discuss availability of support and treatment options.
- Organise reassessment within 1 week.
- Have contingency plan in place for rapid reassessment if distress or symptoms escalate.
- Develop a safety plan (a prioritised written list of coping strategies and sources of support to use when experiencing suicidal thinking).

## High risk (continual/specific suicidal thoughts, intent, plan and means):

- Ensure that the person is in an appropriately safe and secure environment.
- Organise reassessment within 24 hours and monitoring for this period.
- Follow-up outcome of assessment.

After safety is established (and this will need to be continually reassessed at each consultation), the two other aspects that need to be developed early in the process (and also continue on through the long-term

management of the patient) are **educating** the patient about his or her condition and individual situation, and establishing a **therapeutic relationship**.

Assessment includes:

- **characterising** the symptom profile
- **calibrating** the severity and chronicity—rating scales can be employed here
- **corroborating** (if possible and appropriate) medical and psychiatric comorbidities and context. Significant psychiatric, physical and social comorbidities of depression are common. These include 49% suffering an anxiety disorder, 40% reporting child sexual abuse, 57% child physical abuse, 42% having been at some stage afraid of their partner and 72% reporting a chronic physical condition.<sup>16</sup> Putting the patient's condition into his or her individual psychosocial and medical context will improve the assessment
- **considering** coping styles, and the social, financial and occupational consequences of the patient's condition and situation

This assessment is often spread over multiple consultations.

## Treatment

The basic treatments are outlined by the acronym **PACE** (which purposefully places priority on the psychological treatments—see FIG. 19.1). These are:

- **Psychological**, including basic psychological treatments, such as advice on lifestyle changes, problem solving, guided self-help, structured supervised exercise and supportive counselling.<sup>1,6</sup> All patients with depression should be offered these types of support.<sup>1,14</sup> More sophisticated techniques, such as cognitive behaviour therapy (CBT) or interpersonal therapy (IPT) may be used for

selected patients<sup>7</sup> and should be undertaken only by appropriately trained doctors or therapists.<sup>6</sup> Another option that some patients may prefer is computer-based cognitive behaviour therapy (CBT) programs.<sup>11</sup> CBT involves teaching patients new ways of positive thinking, which have to be relevant and achievable for the patient (see CHAPTER 5). Patients need to be able to recognise their own negative cognitions, including their anxieties and worries.

- **Antidepressants:** antidepressant medication is useful in moderate to severe depression (TABLE 19.1), or when depression has an anxiety disorder codiagnosis.<sup>11</sup> Antidepressant therapy should be avoided if bipolar disorder is suspected, and screening should be actively conducted for symptoms of past or previous mania.<sup>11</sup>
  - In terms of which drug to use, there is no single drug that is preferred. However, selective serotonin reuptake inhibitors (SSRIs) are considered to have the most favourable balance of benefit to harm in moderate to severe depression.<sup>11</sup> Sexual dysfunction and gastrointestinal side effects are common.<sup>7</sup> Other suitable first-line agents are reboxetine (common side effects include hypersomnia, fatigue and nausea) and mirtazepine (which can cause weight gain and drowsiness).<sup>7</sup> SSRIs have a relatively flat dose response curve, but dose increase within the recommended range is reasonable if there is a partial response at a lower dose and no troublesome side effects.
  - Combining different antidepressants or augmentation with lithium or antipsychotics should be done with psychiatrist supervision.<sup>7</sup>
  - Serotonin and noradrenaline reuptake inhibitors (SNRIs) appear to be more effective

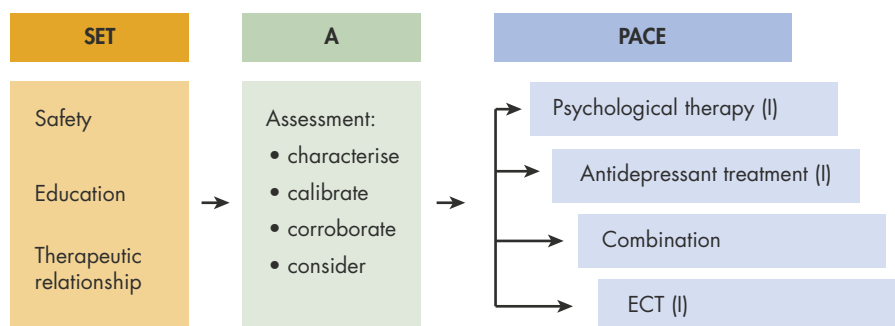

FIGURE 19.1 The SET A PACE model of treatment of depression

Source: Adapted from G Mahli et al.<sup>7</sup>

in treating severe depression symptoms (and may be a suitable first-line option here) but otherwise adverse effects may limit them to second-line treatment.<sup>7</sup> Tricyclic antidepressants (TCAs) and monoamine oxidase inhibitors (MAOIs) are considered second-line because of their side effect profiles.<sup>13</sup>

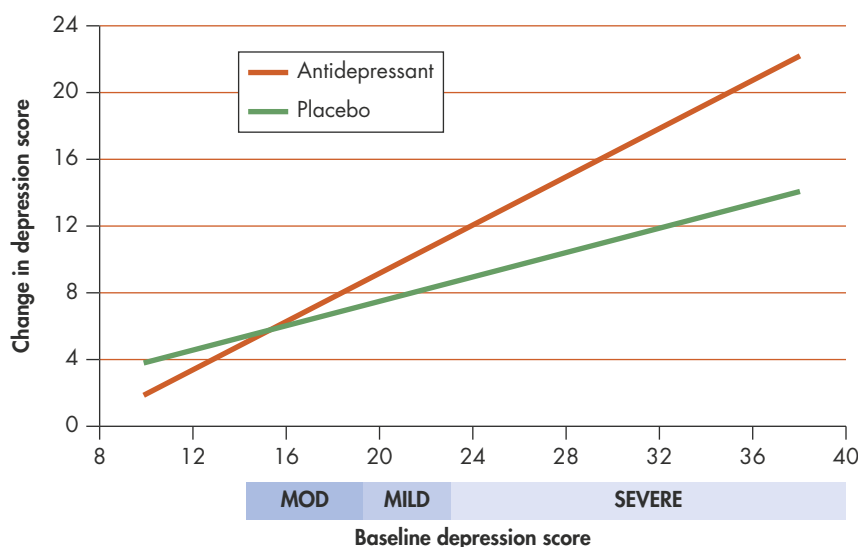

The benefit of medication in moderate depression is equivalent to psychological therapies such as CBT/IPT and both of them are around 20% more likely to achieve remission than placebo.<sup>1</sup> In severe depression, medication is more effective than psychological therapies (see FIG. 19.2), though the latter in addition may help reduce relapse rates once remission is achieved by medication.<sup>1,6</sup>

The aim of treatment of depression is to achieve and maintain remission (see FIG. 19.3).<sup>1</sup> Remission is defined as having minimal or no symptoms of depression,<sup>7</sup> and a good way of asking patients about this is to ask 'Do you think you are back to your normal self?'

When using antidepressants, if a response is not evident in the first 2 weeks or there is an inadequate response in 6 weeks, then it is unlikely that this medication will work for this patient, and a treatment change is recommended.<sup>7</sup> A washout period will be required before a second medication is tried. Patients need close monitoring early on in the course of treatment, and weekly monitoring may be helpful.<sup>11</sup> If remission is not achieved in 3 months, then consider a second opinion and continue active treatment.<sup>7</sup>

**Table 19.1** First-line pharmacological treatment options for depression<sup>13</sup>

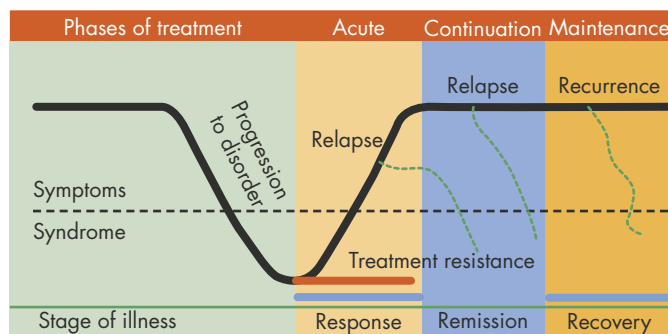

Drug	Usual initial dose	Maximum dose
<b>SSRIs</b>		
citalopram	20 mg (10 mg >65 years)	40 mg (20 mg >65 years)
escitalopram	10 mg	20 mg
fluoxetine	20 mg	80 mg
fluvoxamine	50 mg (at night), then 100 mg after 5–7 days	300 mg
paroxetine	20 mg	60 mg
sertraline	50 mg, then 100 mg after 5–7 days	200 mg
<b>SNRIs</b>		
desvenlafaxine (controlled-release)	50 mg	200 mg
duloxetine	60 mg	120 mg
venlafaxine (controlled-release)	75 mg	375 mg
<b>Other</b>		
mirtazepine	15–30 mg (at night)	60 mg

**FIGURE 19.3** Terminology used in depression and treatment

(Response is defined as a significant reduction in symptoms and signs, and remission is the state of minimal or no symptoms/signs, but lacking full functional recovery.)

Source: Adapted from Kupfer et al. Long term treatment of depression. *J Clin Psychiatry*, 1991; 52: 28–34

19

- A combination of antidepressants and psychological therapy can be considered if there is an inadequate response to either therapy alone. Combining medication with psychological therapy is more effective than either therapy alone in moderate or severe depression.<sup>7</sup>
- **ECT (electroconvulsive therapy)** is a relatively safe and effective therapy for severe or resistant depression. There is some risk of transient short-term cognitive impairment and long-term memory impairment, and this therapy is reserved for severe depression when pharmacotherapy has failed;<sup>7</sup> it is administered under the supervision of a psychiatrist.

Possible indications include:

- psychotic depression (e.g. delusions, hallucinations)
- melancholic depression unresponsive to antidepressants
- severe postnatal depression and psychosis
- substantial suicide risk
- ineffective antidepressant medication and/or previous response to ECT
- severe psychomotor depression: refusal to eat or drink, depressive stupor, severe personal neglect

Immediate referral for hospital admission is necessary in most of these circumstances. The course, which is highly variable and individually tailored, is about 8–12 sessions given at 1–3 sessions a week. The most

common initial ECT method is unilateral therapy.<sup>1</sup>

Transcranial magnetic stimulation, where no anaesthetic is required, is a procedure being explored as a less invasive alternative to ECT.

### Useful management guidelines

- **Mild depression:** psychological therapy
- **Moderate depression:** psychological therapy and/or antidepressants
- **Severe depression:** antidepressants, and consider addition of psychological therapy to maintain remission. Consider psychiatric review, ECT.

### When to refer

- Uncertainty about diagnosis
- Inpatient care obviously necessary
- Severe depression
- Inability to cope at home
- Psychotically depressed (with delusions or hallucinations)
- Substantial suicide risk
- Failure of response to routine antidepressant therapy
- Associated psychiatric or physical disorders
- Depression in the elderly can be a difficult problem—where diagnosis including dementia is doubtful
- Children with apparent major depression

## Choice of treatment

The choice of treatment should be determined together by doctor and patient, and the best outcomes are likely when a good therapeutic alliance is formed<sup>6</sup> and patient preferences are taken into account.<sup>11</sup> To quote the RANZCP guidelines: 'Of greatest benefit is the therapeutic relationship, which enables agreement on treatment selection and continuation.'<sup>1</sup> A strong determining factor on patient preference may be the patient's own previous experience of treatments, or his or her perceptions of treatment results in other people they know or potential adverse effects of the proposed treatment.<sup>11</sup>

Whatever treatment is chosen by the doctor and patient working together, the choice is less important than persisting with treatment. As the beyondblue guidelines state, it is 'not so much what you do but that you keep doing it'.<sup>6</sup> This is why consistent follow-up and monitoring is so beneficial.

## Complementary and alternative therapies

Complementary and alternative therapies are widely used for depression. It is estimated that only 50% of Australians who are depressed receive an evidence-based professional intervention.<sup>17</sup> A large driver for this is the public's belief in complementary and alternative therapies. One study<sup>18</sup> showed 57% regarded vitamins, minerals, tonics or herbal medicines as likely to be helpful for treating depression, compared with 29% who regarded antidepressants as likely to be helpful.

Despite this, none of these therapies is supported by evidence, though some warrant further evaluation.<sup>19</sup> Because of their common usage (nearly half of Australians have used a complementary medicine in the previous 12 months),<sup>19</sup> actively enquiring about use of any complementary and alternative therapies in patients with depression is advised.

One of the more commonly used and extensively researched alternative therapies is St John's wort (*Hypericum perforatum*), which has had mixed results in the research on its effectiveness. One review of the literature suggests it is effective in mild to moderate depression,<sup>20</sup> though two others suggest it is not.<sup>21,22</sup>

Regardless of its effectiveness (or not), it has a lot of medication interactions. These include HIV medicines, warfarin, digoxin, anticonvulsants, oral contraceptives and triptans. Because of this, care

needs to be taken with using St John's wort, including when switching between different preparations that may contain different amounts of active compound.

## Serotonin syndrome

- While rare, serotonin syndrome is a serious adverse reaction to the use of SSRIs and other serotonergic medications, including St John's wort.
- Symptoms must coincide with the introduction or dose increase of a serotonergic agent. Drugs to be considered here include antidepressants, opioids (especially tramadol), stimulant drugs, illicit drugs, anti-emetics, lithium and selegiline.
- Other causes, such as infection, substance abuse or withdrawal, must be excluded.
- At least three of the symptoms or signs attributed to the syndrome must be present, e.g.:
  - mental status/behaviour changes (e.g. agitation, confusion, hypomania, seizures)
  - altered muscle tone (e.g. tremor, shivering, myoclonus, hyper-reflexia)
  - autonomic instability (e.g. hypertension or hypotension, tachycardia, fever, diarrhoea)

The offending agents should be withdrawn immediately and supportive therapy initiated; refer to an emergency department.

## Continuing treatment

If antidepressant medication is used and remission achieved, it is recommended that it be continued for a minimum of 12 months for an initial episode, and for 2–3 years in subsequent episodes or in those at high risk of relapse.<sup>1,11</sup> Risk factors for relapse include:<sup>7,11</sup>

- residual depressive symptoms
- 2 or more prior episodes in the past 5 years
- 3 or more prior episodes
- history of severe or prolonged depression (especially with psychosis or attempted suicide)
- comorbid medical problems
- life stressors

When remission is achieved, and the treatment is in the maintenance phase, ongoing monitoring of treatment effectiveness, tolerability and adherence is recommended.<sup>7</sup> Encouragement to persist with the treatment will improve compliance.<sup>1</sup> When ceasing medication, withdrawal reactions are common, so a gradual withdrawal by halving the dose each week may help reduce these.<sup>1</sup>

*Those labouring with this Disease, piss a great deal more than they drink. Authors who affirm the drink to be little or nothing changed are very far from the truth, because the urine very much differed both from the drink taken in and also in being wonderfully sweet as if it were imbued with honey or sugar.*

Thomas Willis (1621–75), *The Pissin g Evil*

*Diabetes* comes from a Greek word meaning ‘to pass or flow through’ (i.e. excessive urination) and *mellitus* means ‘sweet’. It is a disease caused by a relative or absolute deficiency of insulin.

There are two main types of diabetes (see TABLE 20.1).

- Type 1 is also known as juvenile onset diabetes or insulin dependent diabetes mellitus (IDDM).
- Type 2 is also known as maturity onset diabetes or non-insulin dependent diabetes mellitus (NIDDM).

Type 1 has an autoimmune causation which is also responsible for a late-onset form known as late onset autoimmune diabetes in adults (LADA).

## Diabetes: a real masquerade

The onset of type 2 diabetes can be subtle and by stealth. Studies have demonstrated that it takes, on average, 7–9 years before a patient is diagnosed.<sup>1</sup> At any one given time 50% of patients with type 2 diabetes are undiagnosed. The Australian Diabetes, Obesity and Lifestyle Study (AUSDIAB) in 2000 showed that one in four adult Australians have abnormal glucose metabolism.<sup>2</sup> In general figures the prevalence of diagnosed and undiagnosed diabetes is 4% each and a further 16% have impaired fasting glucose or impaired glucose tolerance.<sup>3</sup> Very importantly, about 35% of newly diagnosed diabetic patients are already harbouring complications of diabetes.<sup>1</sup> The challenge for GPs is to be on constant lookout for these patients, especially those at risk. Type 2 diabetes is becoming more prevalent in industrial countries—partly due to the ageing population and partly because our lifestyle encourages us to ‘eat more and walk less’.<sup>3</sup> Furthermore, 60% of our population are overweight or obese.

**Table 20.1** Clinical differentiation between type 1 and type 2 diabetes

	Type 1	Type 2
<b>Relative frequency (approx.)</b>	10–15%	85–90%
<b>Peak age incidence</b>	10–30 years	>40 years
<b>Age of onset</b>	Usually young <20	Usually middle-aged >40
<b>Onset</b>	Rapid	Insidious/slow
<b>Presentation</b>	Polyuria, polydipsia weight loss	Milder symptoms, often asymptomatic
<b>Weight at onset</b>	Low (thin)	High (obese)
<b>Ketoacidosis</b>	Yes	Rare
<b>Familial</b>	Weak	Strong
<b>Insulin status</b>	Deficient	Resistant
<b>Complications</b>	Yes	Yes

*Note:* These are generalisations and the clinical features may vary (e.g. type 2 diabetic patients may be thin and have a rapid onset; type 1 patients may exhibit a weak genetic link).

## Key facts and checkpoints

- In Australians older than 25 years the prevalence of diabetes is 7.5%, with another 10.6% having impaired glucose tolerance.<sup>2</sup>
- About 30% of these people will develop clinical diabetes within 10 years.<sup>3</sup>
- Many type 2 diabetics are asymptomatic.
- Diabetes can exist for years before detection and complications may be evident.
- Type 2 diabetes is not a mild disease. About one-third of those surviving 15 years will require insulin injections to control symptoms or complications.<sup>4</sup>
- Blood glucose may be temporarily elevated during acute illness, after trauma or surgery.

**FIGURE 20.1** Skin signs of diabetes: (a) Recurrent staphylococcus folliculitis (b) *Candida albicans* erosio interdigitalis (c) *Candida albicans* balanitis

Complications occur in type 2 diabetes as well as in type 1.

- There are several causes of secondary diabetes that are very uncommon (see TABLE 20.2).

- Asymptomatic people of high risk of undiagnosed diabetes should be screened by blood glucose measurement.

**Table 20.2** Causes of secondary diabetes

Endocrine disorders

Cushing syndrome

Acromegaly

Phaeochromocytoma

Polycystic ovarian syndrome

Pancreatic disorders

Haemochromatosis

Chronic pancreatitis

Drug-induced diabetes (transient)

Thiazide diuretics

Oestrogen therapy (high dose—not with low-dose HRT)

Corticosteroids

Other transient causes

Gestational diabetes

Medical or surgical stress

### Clinical features

The classic symptoms of uncontrolled diabetes are:

- polyuria
- polydipsia
- loss of weight (type 1)
- tiredness and fatigue
- propensity for infections, especially of the skin and genitals (vaginal thrush)

The young type 1 diabetic person typically presents with a brief 2–10 week history of the classic triad of symptoms:

**DxT** thirst + polyuria + weight loss  
→ type 1 diabetes

Other possible symptoms are:

- vulvovaginitis
  - pruritus vulvae
  - balanitis
- } due to *Candida albicans*

- nocturnal enuresis (type 1)
- blurred vision/visual changes

Symptoms of complications (may be presenting feature) include:

- staphylococcal skin infections
- polyneuropathy: tingling or numbness in feet, pain (can be severe if present)
- impotence
- arterial disease: myocardial ischaemia, peripheral vascular disease

## History

The history of a suspected or known diabetic patient should cover the following features including assessment of cardiovascular risks and end-organ damage.

- Specific symptoms:
  - polyuria
  - polydipsia
  - loss of weight
  - polyphagia
  - tiredness/malaise/fatigue
  - nocturia
- Related general symptom review:
  - cardiovascular (e.g. chest pain, dyspnoea)
  - urinary function
  - sexual function
  - neurological (e.g. tingling in feet/hands)
  - vision (e.g. blurred)
  - infection tendency (e.g. skin, urine, genital)
  - genital itching
- General:
  - family history
  - medication
  - smoking and alcohol
  - obstetric history (where applicable)
  - physical activity
  - nutrition/eating habits

## Examination

The physical examination should ideally follow the protocol for annual review.

Initial screening for suspected diabetes should include:

- general inspection including skin
- BMI (weight/height)
- waist circumference
- visual acuity
- blood pressure—lying and standing

- test for peripheral neuropathy: tendon reflexes, sensation (e.g. cotton wool, 10 g monofilament, Neurotips)
- urinalysis: glucose, albumin, ketones, nitrites

## Investigations

- Initial: fasting or random blood sugar, follow-up oral glucose tolerance test (OGTT) if indicated
- Other tests according to clinical assessment (e.g. glycated haemoglobin (HbA1c), lipids, kidney function, ECG)

## Risk factors

- Age >40 years
- Family history
- Overweight/obesity
- Sedentary lifestyle
- Positive obstetric history
- Women with polycystic ovarian syndrome (PCOS)
- Hypertension/ischaemic heart disease
- Medication causing hyperglycaemia
- Ethnic/cultural groups: Aboriginal and Torres Strait Islanders (ATSI), Pacific Islanders, people from Indian subcontinent, Chinese, Afro-Caribbeans

## Screening (type 2)<sup>5</sup>

- People with impaired fasting glucose/impaired glucose tolerance
- Age >40 years
- Age >30 years with: family history (first-degree relative with type 2), obesity (BMI >30), hypertension
- Age >20 years from high prevalence ethnic groups (e.g. ATSI, Pacific Islanders)
- Previous gestational diabetes; history of large babies
- People on long-term steroids
- People on atypical antipsychotics
- Polycystic ovarian syndrome, especially if overweight
- Cardiovascular disease and other risk factors

The optimal frequency is every 3 years from age 40 years using AuSDRISK ([www.diabetesaustralia.com.au/Understanding-Diabetes/Are-You-at-Risk/](http://www.diabetesaustralia.com.au/Understanding-Diabetes/Are-You-at-Risk/)) and annually in very high-risk groups, including ATSI.<sup>6</sup>

## Diagnosis

Diabetes is diagnosed as follows:<sup>3,5</sup>

- 1 If symptomatic (at least two of polydipsia, polyuria, frequent skin infections or frequent genital thrush):
  - fasting venous blood glucose (VBG)  $\geq 7.0$  mmol/L on two separate occasions

- or
  - random VBG (at least 2 hours after last eating)  $\geq 11.1$  mmol/L on two separate occasions
  - or
  - HbA1c  $> 6.5\%$
- 2 If asymptomatic:
- at least two separate elevated values, either fasting, 2 or more hours post-prandial, or the two values from an oral glucose tolerance test (OGTT)

*Note:* If random or fasting VBG lies in an uncertain range (5.5–11.0 mmol/L) in either a symptomatic patient or a patient with risk factors (over 50 years, overweight, blood relative with type 2 diabetes or high blood pressure), perform an OGTT. The cut-off point for further testing has now been reduced to 5.5 mmol/L.<sup>5,7</sup>

The 2 hour blood sugar on an OGTT is still the gold standard for the diagnosis of uncertain diabetes, i.e.  $> 11.1$  mmol/L.

The OGTT should be reserved for true borderline cases and for gestational diabetes. A screening (oral glucose challenge) test at 26–30 (usually 28) weeks gestation is sometimes used during pregnancy.

### § Prediabetes

This is the condition where the VPG is elevated above the normal range (i.e. 6.1–6.9) but does not satisfy the type 2 diagnostic criteria. It includes two states:

- impaired fasting glucose (IFG)
- impaired glucose tolerance (IGT)

Urinalysis is unreliable in diagnosis since glycosuria occurs at different plasma glucose values in patients with different kidney thresholds.

For a summary of diagnosis of diabetic states refer to [FIGURE 20.2](#).

## Diabetes in children

A study by Sinah and colleagues detected impaired glucose tolerance in 25% of 55 obese children (4 to 10 years of age) and 21% of 112 obese adolescents (11 to 18 years of age).<sup>9</sup> Type 2 diabetes was identified in 4% of obese adolescents. However, over 30% of newly diagnosed diabetes in children and adolescents is upon presentation with diabetic ketoacidosis. Children with type 1 diabetes usually exhibit the classic features of polyuria, polydipsia, weight loss and lethargy. Be aware of unusual presentations such as urinary disorders including enuresis or daytime wetting accidents when a misdiagnosis of urinary infection or some other condition is sometimes forthcoming. The diagnosis can be made by an elevated random or fasting blood sugar. Oral glucose tolerance tests are inappropriate in the very young. Upon diagnosis it is appropriate to refer the child or adolescent to a multidisciplinary diabetes team.

## Gestational diabetes

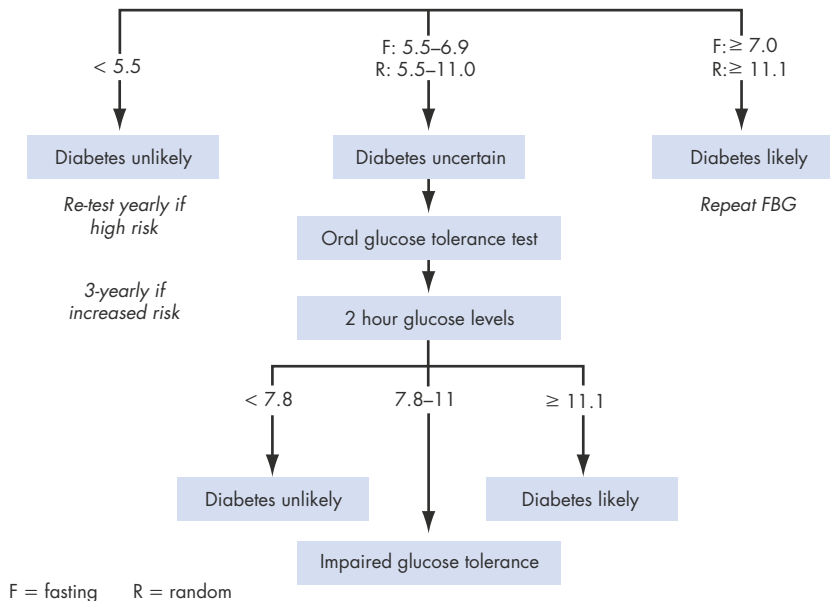

Gestational diabetes is the onset or initial recognition of abnormal glucose tolerance during pregnancy. Pregnancy is diabetogenic for those with a genetic predisposition. All pregnant women should be screened at 28 weeks with an oral glucose challenge test or OGTT. If the blood glucose level is  $> 7.8$  mmol/L or if diabetes is otherwise suspected a diagnostic oral glucose tolerance test is indicated. The WHO definition of gestational diabetes is fasting blood sugar of  $\geq 7$  mmol/L or a 2-hour level of  $\geq 7.8$  mmol/L—refer to [CHAPTER 108](#).

## Diabetes in the elderly

The incidence of diabetes rises with age. The elderly have increased mortality and morbidity from the

**Table 20.3** Interpreting diagnostic tests for diabetes<sup>8</sup>

Test		Normal	Intermediate hyperglycaemia	Diabetes
Venous blood glucose concentration	fasting	up to 6 mmol/L	6.1–6.9 mmol/L	$\geq 7$ mmol/L
	random	up to 6 mmol/L		$\geq 11.1$ mmol/L
Oral glucose tolerance test	2-hour venous blood glucose concentration	up to 7.7 mmol/L	7.8–11 mmol/L	$\geq 11.1$ mmol/L
HbA1c				$\geq 48$ mmol/mol (6.5%)

**FIGURE 20.2** Blood glucose levels—venous plasma (mmol/L)

Source: Reproduced with permission from *Diabetes Management in General Practice. Guidelines for Type 2 Diabetes*. Melbourne: Diabetes Australia & RACGP.<sup>5</sup>

disease and require careful monitoring, especially with adverse drug effects aggravated by polypharmacy and comorbidities. Special issues include diet, foot care and postural hypotension.

## Complications of diabetes

Complications may occur in patients with both type 1 and type 2 diabetes, even with early diagnosis and treatment (see FIG. 20.3).

Type 1 diabetics still have a significantly reduced life expectancy. The main causes of death are diabetic nephropathy and vascular disease (myocardial infarction and stroke).

Diabetes causes both macrovascular and microvascular complications but microvascular disease is specific to diabetes. Special attention should be paid to the 'deadly quartet' associated with type 2 diabetes.<sup>7,10</sup>

Macrovascular complications include:

- ischaemic/coronary heart disease
- cerebrovascular disease
- peripheral vascular disease

An analysis of patients with type 2 diabetes in the HOPE study<sup>11,12</sup> showed a benefit of ramipril to reduce the risk of:

- death (24%)
- myocardial infarction (22%)

- stroke (33%)
- cardiovascular death (37%)
- overt nephropathy (24%)

Consider organs/problems affected by diabetes under the mnemonic 'KNIVES':

- Kidney
- Nerves
- Infection
- Vessels
- Eyes
- Skin

## Microvascular disease

The small vessels most affected from a clinical viewpoint are the retina, nerve sheath and kidney glomerulus. In younger patients it takes about 10 to 20 years after diagnosis for the problems of diabetic retinopathy, neuropathy and nephropathy to manifest.

## Nephropathy

Prevention of diabetic nephropathy is an essential goal of treatment. Early detection of the yardstick, which is microalbuminuria, is important as the process can be reversed with optimal control. The dipstick method is unreliable. Screening is done simply by an overnight collection (10–12 hours) of all urine, including the first morning sample. It is sent

FIGURE 20.3 The complications of diabetes

to the laboratory to determine the albumin excretion rate. Microalbuminuria is 20–200 mcg/minute (two out of three positive collections). A simpler method is the albumin/creatinine ratio (see CHAPTER 31).

ACE inhibitors should be used for evidence of hypertension.

## § Retinopathy and maculopathy

Retinopathy develops as a consequence of microvascular disease of the retina. Its prevalence is related to the duration of illness but up to 20% of people with type 2 diabetes have diabetic retinopathy at the time of diagnosis. The European multicentre study<sup>13,14</sup> showed that diabetes is the single most common cause of blindness in European adults in the 16–64 years age groups. It is recommended that patients should undergo fundoscopy each year by an expert. Assessment is by direct ophthalmoscopy (with dilated pupils), retinal photography and fluorescein angiography (depending on the state of the patient's fundi). Early diagnosis of serious retinopathy is vital since the early use of laser photocoagulation may delay and prevent visual loss.

## § Neuropathy

The following types of neuropathy may occur:

- radiculopathy (diabetic lumbosacral radiculoplexopathy)
- sensory polyneuropathy
- isolated mononeuropathy and multiple mononeuropathy
  - isolated peripheral nerve lesions (e.g. median nerve)
  - cranial nerve palsies (e.g. III, VI)
  - amyotrophy
- autonomic neuropathy, which may lead to:
  - erectile dysfunction
  - postural hypotension and syncope
  - impaired gastric emptying (gastroparesis)
  - diarrhoea
  - delayed or incomplete bladder emptying
  - loss of cardiac pain → 'silent' ischaemia
  - hypoglycaemic 'unawareness'
  - sudden arrest, especially under anaesthetic

## Infections

Poorly controlled diabetics are prone to infections, especially:

- skin: mucocutaneous candidiasis (e.g. balanitis, vulvovaginitis), staphylococcal infections (e.g. folliculitis)

- urinary tract: cystitis (women), pyelonephritis and perinephric abscess
- lungs: pneumonia (staphylococcal, streptococcal pneumonia), others; tuberculosis

## Diabetic metabolic complications

- Hypoglycaemia
- Diabetic ketoacidosis
- Hyperosmolar hyperglycaemia
- Lactic acidosis

## Other complications

- Cataracts
- Refractive errors of eye
- Sleep apnoea
- Depression
- Musculoskeletal: neuropathic joint damage (Charcot type arthropathy), tendon rupture
- Foot ulcers (related to neuropathy)

## Prevention of diabetes

Several large studies have demonstrated that it is possible to prevent or delay the onset of diabetes in those at risk.<sup>13,14</sup> It involves intensive lifestyle intervention in individuals who are overweight with impaired glucose tolerance or raised fasting blood glucose. One strategy is to follow the SNAP guidelines (Smoking, Nutrition, Alcohol, Physical activity). The essentials are healthy eating, weight loss and physical activity. This represents an important approach that GPs can recommend to their patients at risk.

## Management of diabetes mellitus

The main objectives for the GP in the optimal management of the diabetic patient, in order to prevent the development of cardiovascular disease and other complications, are:<sup>5</sup>

- 1 to achieve strict glycaemic control as measured by (most importantly) glycated haemoglobin (HbA1c) and by blood glucose
- 2 to achieve blood pressure control ( $\leq 130/80$  mmHg, supine)
- 3 to achieve control of blood cholesterol level

*Note:* Refer to the estimations of cardiovascular risk (see FIGS. 85.1 and 85.2 in CHAPTER 85).

## Management principles

- Provide detailed and comprehensive patient education, support and reassurance.

- Achieve control of presenting symptoms.
- Achieve blood pressure control ( $\leq 130/80$  mmHg supine).
- Develop a diabetic care plan.
- Emphasise the importance of the diet: good nutrition, adequate complex carbohydrates, protein, restricted fats and sugars.
- Promptly diagnose and treat urinary tract infection.
- Treat and prevent life-threatening complications of ketoacidosis or hyperosmolar coma.
- Treat and prevent hypoglycaemia in those taking insulin and oral hypoglycaemic agents.
- Organise self-testing techniques, preferably blood glucose monitoring.
- Detect and treat complications of diabetes—neuropathy, nephropathy, retinopathy, vascular disease.

## 20

## Metabolic syndrome<sup>8</sup>

Beware of the deadly metabolic syndrome (syndrome X or insulin resistance syndrome).

- Upper truncal obesity (waist circumference)  $>102$  cm♂:  $>88$  cm♀ (European population) *plus* any 2 or more of the following
- $\uparrow$  triglycerides  $>1.7$  mmol/L
- $\downarrow$  HDL cholesterol  $<1.0$  ♂:  $<1.3$  mmol/L ♀
- fasting glucose  $\geq 5.5$  mmol
- BP  $\geq 130/85$

This syndrome is associated with increased risk for the development of type 2 diabetes and atherosclerotic vascular disease. Aggressive treatment is required.

## Monitoring techniques

- Blood glucose estimation (fasting and post-prandial)
- Urine glucose (of limited usefulness)
- Urine ketones (for type 1 diabetes)
- Glycated haemoglobin (HbA<sub>1c</sub>) (essential to know glycaemic control)
- Microalbuminuria (regarded as an early and reversible sign of nephropathy)
- Blood pressure
- Serum lipid levels
- Kidney function (serum urea/creatinine eGFR)
- ECG

Control guidelines are summarised in **FIGURE 20.4** and **TABLE 20.4**.

The reference ranges vary in different laboratories.

**FIGURE 20.4** Control guidelines for diabetic management

**Table 20.4** Suggested guidelines for glycaemic control (blood glucose mmol/L)<sup>5,6,15</sup>

	Ideal	Suboptimal or unacceptable
Before meals (fasting)	$<5.5$	$>7.7$
After meals (2 hours post-prandial)	$<7$	$>11$
HbA <sub>1c</sub> %*	$<7$	$>11$

\*HbA<sub>1c</sub> is an index of the mean plasma glucose levels over the preceding 2–3 months (assume a reference range of 4.5–8%).

## Goals of management<sup>5,6</sup>

All people with diabetes should be encouraged to maintain the following goals for optimum management of their diabetes:

- Blood glucose (fasting) ideal 4–6 mmol/L NHMRC 6–8 mmol/L
- Blood glucose (postprandial) 8–10 mmol/L
- HbA<sub>1c</sub>  $\leq 7\%$  (53 mmol/mol)
- Total cholesterol  $<4.0$  mmol/L
- LDL cholesterol  $<2.0$  mmol/L
- HDL cholesterol  $\geq 1.0$  mmol/L
- non-HDL-C  $<2.5$  mmol/L
- triglycerides  $<2.0$  mmol/L
- Blood pressure  $<130/80$  mmHg without proteinuria  $\leq 125/75$  mmHg with proteinuria (1 g/day)

• BMI	18–25 where practicable
• Urinary albumin excretion	<20 mcg/min timed overnight collection <20 mg/L spot collection
• Albumin creatinine ratio	<2.5 mg/mmol—men <3.5 mg/mmol—women
• Cigarette consumption	zero
• Alcohol intake	≤2 standard drinks, 20 g/day (men and women)
• Exercise	at least 30 minutes walking (or equivalent) 5 or more days/week (total 150 minutes/week)

## Blood glucose monitoring at home

This can be done using visual strips or a glucose meter (glucometer). Patients should be advised about the most appropriate glucometer to obtain.

### How often and when?

- Type 1 diabetes:
  - four times a day (before meals and before bedtime) at first and for problems
  - twice a day (at least once)
  - may settle for 1–2 times a week (if good control)
- Type 2 diabetes:
  - twice a day (fasting and 2–3 hours post-prandial)
  - if good control—once a week or every 2 weeks

*Note:*

- Capillary blood glucose is approximately 7% higher than venous blood.
- Glucometer error is usually  $\pm 5\%$ .

## Glycated haemoglobin

Glycated haemoglobin is abnormally high in diabetics with persistent hyperglycaemia and is reflective of their metabolic control. The major form of glycohaemoglobin is haemoglobin A<sub>1c</sub>, which normally comprises 4–6% of the total haemoglobin.<sup>4</sup> Glycohaemoglobins have a long half-life and their measure reflects the mean plasma glucose levels over the past 2–3 months and hence provides a good method of assessing overall diabetic control. It should be checked every 3–6 months.

## § Type 1 diabetes

The three main objectives of the treatment of type 1 diabetes are:

- maintain good health, free from the problems of hyperglycaemia and hypoglycaemia
- achieve proper growth and maturation for children and protect the fetus and mother in a mother with type 1 diabetes
- prevent, arrest or delay long-term macrovascular and microvascular complications

### Insulin regimens for type 1 diabetes<sup>5,8</sup>

The most commonly used insulin injection preparations are the 'artificial' human insulins. Insulins are classified according to their time course of action:

- rapid-acting and short duration (ultra-short)—insulin lispro, insulin aspart
- short-acting—neutral (regular, soluble)
- intermediate-acting—isophane (NPH) or lente
- long-acting—ultralente, insulin detemir, insulin glargine
- pre-mixed short/intermediate—biphasic (neutral + isophane)

Also: continuous subcutaneous insulin infusion.

### Starting insulin<sup>8</sup>

Shared care with an endocrinologist is recommended.

It is important to use the simplest regimen for the patient and to provide optimal education about its administration and monitoring. Full replacement of insulin is achieved by using 2, 3 or 4 injections per day. See TABLE 20.5 for available insulins.

- 1 *The pre-mixed 2 injection (biphasic) system*  
Give twice daily, 30 minutes before breakfast and before evening meal (e.g. Mixtard 30/70, Humulin 30/70—the most common)
  - Typical starting dose: 0.3 IU/kg/day—for a 70 kg person use 10 units bd
- 2 *3 injections per day*
  - Short-acting insulin before breakfast and lunch
  - Intermediate- or long-acting insulin before evening meal
- 3 *4 injections (basal-bolus) system*
  - Short-acting insulin before breakfast, lunch and dinner (bolus)
  - Intermediate-acting or long-acting insulin at bedtime (basal)

**FIGURE 20.5** Illustration of time course of insulin injections regimens

Insulin requirements often vary significantly even in the same individual under different lifestyle conditions. The new rapid-acting analogues can be taken with meals.

## Methods of giving insulin injections

### When

Get the patient to develop a set routine, such as eating meals on time and giving the injection about 30 minutes before the meal.

### Where

Into subcutaneous tissue—the best place is the abdomen. The leg is also acceptable. It is advisable to keep to one area such as the abdomen and avoid injections into the arms, near joints and the groin. The injection should be given at a different place each time, keeping a distance of 3 cm or more from the previous injection. This reduces the risk of the development of lipodystrophy. The means of delivery is the insulin syringe or the insulin delivery pen.

### How

Pinch a large area of skin on the abdomen between the thumb and fingers and insert the needle straight in. After withdrawing the needle, press down firmly (do not rub or massage) over the injection site for 30 seconds.

### Guidelines for the patient<sup>5</sup>

- Take your insulin every day, even if you feel ill.
- Do not change your dose unless instructed by your doctor or you are competent to do so yourself.

**Table 20.5** Available insulins<sup>5,8</sup>

Type	Brand name
Ultra-short-acting (peak 1 hour, duration 3.5–4.5 hours)	
Insulin lispro	Humalog*
Insulin aspart	NovoRapid**
Insulin glulisine	Apidra*
Short-acting (peak 2–5 hours, duration 6–8 hours)	
Neutral (regular)	Actrapid**
	Humulin R*
	Hypurin Neutral*
Intermediate-acting (duration 12–24 hours)	
Isophane (NPH)	Humulin NPH*
	Protaphane**
	Hypurin Isophane
Long-acting (analogues)	
Insulin glargine (duration 24–36 hours)	Lantus
Insulin detemir (duration up to 24 hours)	Levemir
Premixed (short- and intermediate or long-acting)	
Lispro 25%/Protamine 75%	Humalog Mix 25*
Lispro 50%/Protamine 50%	Humalog Mix 50*
Insulin aspart 30%/Protamine 70%	NovoMix 30**
Neutral 30%/Isophane 70%	Humulin 30/70*
	Mixtard 30/70**
Neutral 50%/Isophane 50%	Mixtard 50/50**

\*Available in cartridges for use in pen injectors

\*\*Available in cartridges for use in pen injectors or in disposable insulin pens

## Problems

Injection sites should be inspected regularly because lipohypertrophy or lipodystrophy can occur.

## Sick days

Have a prearranged action plan.

Never omit the insulin dose even if the illness is accompanied by nausea, vomiting or marked anorexia. More top-up insulin is usually required (rapid/fast acting).

Maintain glucose. Keep regular blood glucose checks (a concern if >15 mmol/L).

Seek support and help.

## Sport

Encourage sporting activities. Careful planning (use expert help) and monitoring of blood sugar is required. Insulin doses may need to be adjusted before activities.

Additional carbohydrate may be needed.

## Glycaemic targets for adults with type 1 diabetes

- HbA1c — 53 mmol/mol
- Blood glucose — fasting preprandial 4–7 mmol/L  
— postprandial 5–10 mmol/L

## § Type 2 diabetes<sup>8,15</sup>

First-line treatment (especially if obese):

- diet therapy
- exercise program

Most symptoms improve within 1 to 4 weeks on diet and exercise.<sup>3</sup> Prescribe and ask about exercise at every visit. Aim for an average of 20–30 minutes a day. Suggest variations such as social type exercises. The secret to success is patient compliance through good education and supervision. The role of a diabetic education service, especially with a dietitian, can be invaluable. If unsatisfactory control persists after 3–6 months, consider adding an oral hypoglycaemic agent (see TABLE 20.6). These agents include insulin

**Table 20.6** Commonly prescribed oral hypoglycaemic agents<sup>8</sup> (with examples)

Drug	Duration of action (hours)	Daily dose range	Notes including main generic adverse effects
<b>Biguanides</b>			
Metformin	12	0.5–3 g	Usually reserved for obese but now first line Side effects: • GIT disturbances (e.g. diarrhoea, a/n/v) • avoid in cardiac, kidney and hepatic disease • lactic acidosis, a rare but serious complication
<b>Sulfonylureas</b>			
Gliclazide	18–24	40–320 mg	Hypoglycaemia most common side effect Others: weight gain (common), rash and GIT (rare) Shorter acting sulfonylurea is preferred in elderly
Glipizide	16–24	2.5–40 mg	Longer acting potent ones cause troublesome hypoglycaemia in elderly
Glibenclamide	18–24	2.5–20 mg	
Glimepiride	>24	1–4 mg	
<b>α-glucosidase inhibitors</b>			
Acarbose	3	150–600 mg	Flatulence, skin rashes, diarrhoea, liver effects
<b>Thiazolidinediones</b>			
(glitazones)			Caution with heart failure
Pioglitazone	24	15–45 mg	Oedema, weight gain, heart failure
Rosiglitazone	24	4–8 mg	Hepatic effects, fracture risks
<b>DPP-4 agonists (gliptins)</b>			
Sitagliptin	>24	25–100 mg	Rhinorrhoea, headache hypersensitivity e.g. urticaria
Vildagliptin	>24	50–100 mg	Dizziness, fatigue
<b>SGLT<sub>2</sub> inhibitors</b>			
canagliflozin	24	100–300 mg	A type of diuretic, beware kidney failure
dapagliflozin	24	5–10 mg	• genitourinary infections • dehydration, dizziness, hypoglycaemia

secretagogues, such as sulfonylureas and glitinides, which increase insulin production, and insulin sensitisers, such as metformin and the glitazones, which reduce insulin resistance. If glycaemic targets are not achieved on monotherapy, usual practice is to combine a secretagogue and a sensitiser.

Consider metformin as the first-line agent for all patients with type 2 diabetes, irrespective of their weight, unless contraindicated. The usual starting dose is 500 mg once or twice daily. It has proven benefits over the sulphonylureas, especially in those that are overweight. Other benefits include no significant weight gain, no hypoglycaemia and an improved lipid profile. If monotherapy does not provide adequate glycaemic control, a combination of metformin with a sulfonylurea or other agent (see FIG. 20.6) is recommended.<sup>16</sup>

When the first oral hypoglycaemics fail (secondary failure) one of the new agents can be added (e.g. a gliptin, acarbose, one of the glitazones). The glitazones can be used as monotherapy but are used more often in combination with metformin, sulfonylureas or insulin but not rosiglitazone.<sup>15</sup> The newest treatment options in type 2 diabetes include:<sup>16</sup>

- dipeptidyl peptidase-IV (DDP-IV) inhibitors known as gliptins, such as sitagliptin
- sodium glucose cotransporter 2 (SGLT2) inhibitors taken orally e.g. dapagliflozin, canagliflozin
- glucagon-like peptide-1 receptor (GLP-1) agonist (e.g. exenatide, liraglutide) given by SC injection

The classic symptoms of hyperglycaemia may be present but more commonly patients experience general disability. Approximately 30% of type 2 patients eventually require insulin even after years of successful oral therapy. An algorithm for the management of type 2 diabetes is presented in FIGURE 20.6.

It is important not to delay the introduction of insulin. However, insulin will not substitute for healthy eating and activity.

### Starting insulin in type 2 diabetes<sup>13,17</sup>

More than 30% of patients will eventually require insulin, often after 10–15 years of successful oral therapy.<sup>8</sup> Before commencing insulin one should be assured that the patient's lifestyle activities are being adequately addressed and that oral medication (at recommended maximum dose) is appropriate. There is no clear-cut rule about when to start insulin for patients with HbA<sub>1c</sub> >7%, but this can be as early as when drug therapy does not provide adequate

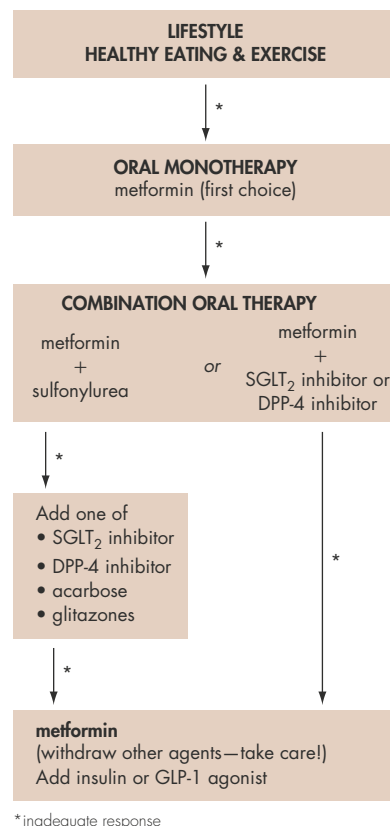

FIGURE 20.6 Step-up approach to management of type 2 diabetes<sup>8</sup>

control. A golden rule is 'don't delay initiating basal insulin' and then 'start low and go slow'.<sup>17</sup>

When commencing patients on insulin, reassure them that the injections are not as uncomfortable as finger pricks and that they will feel much improved with more energy. Short-term intensive treatment (approximately 2 weeks) can induce long-term improvement in glycaemic control to the extent of being off insulin for months to years.

It is appropriate to refer to your diabetic team for shared care at this point—when starting insulin.

### Suggested stepwise approach<sup>13,15</sup>

#### Step 1

- Continue oral agents: metformin + sulfonylurea ± glitazone or acarbose or DPP-4 inhibitor (limited to 3).
- Add 10 units isophane insulin at bedtime.

#### Step 2

- Titrate insulin therapy according to fasting blood glucose (6 mmol/L).

- Increase insulin in about 4–5 U increments every 3–4 days (or more gradually).
- Cease glitazone, acarbose, gliptin or SGLT<sub>2</sub> inhibitor (if used).

### Step 3

If larger doses of insulin are required (NPH or mixed regimen), gradually withdraw sulfonylurea, continue metformin and review.

*Note:* The combination of a glitazone and insulin has been shown to improve control of diabetes sometimes to the extent of being able to reduce insulin dosage. In patients with type 2 diabetes needing relatively high doses of insulin, the addition of a glitazone is worth considering.

## The importance of diet and nutrition

Nutrition management is based on controlling weight, having a healthy eating plan and supplementing it with exercise. It is recommended to eat a wide variety from all food groups:

- protein 10–20%, fat 20–40%, carbohydrate 35–60%
- reduce fat, especially saturated fats, sugar and alcohol

Type 1 patients often require three meals and sometimes regular snacks each day. Type 2 patients usually require less food intake and restriction of total food intake.

## Principles of dietary management

- Keep to a regular nutritious diet.
- Achieve ideal body weight.
- Reduce calories (kilojoules):
  - added sugar
  - dietary fat
- Follow the glycaemic index values (see [www.glycaemicindex.com](http://www.glycaemicindex.com)).
- Increase proportions of vegetables, fresh fruit and cereal foods.
- Special diabetic foods are not necessary.
- Qualitative diets, rather than quantitative diets (such as ‘exchanges’ or ‘portions’), are now used.

## The importance of exercise<sup>5,15</sup>

Exercise is fundamental to good management. Exercise is any physical activity that keeps you fit. Good examples are brisk walking (e.g. 2 km per day), jogging, tennis, skiing and aerobics. Aim for at least 30 minutes three times a week, but daily exercise is ideal. Go slow when you start and increase your pace gradually.

## Psychosocial considerations

The psychological and social factors involving the patient are very influential on outcome. Considerable support and counselling is necessary to help both patient and family cope with the ‘distress’ of the diagnosis and the discipline required for optimal control of their blood glucose. Reasons for poor dietary compliance and insulin administration must be determined and mobilisation of a supportive multidisciplinary network (where practical) is most helpful. The GP should be the pivot of the team. Joining a self-support group can be very helpful.

## Foot care

Foot problems are one of the commonest complications that need special attention; prevention is the appropriate approach. Pressure sores can develop on the soles of the feet from corns, calluses, ill-fitting footwear, and stones and nails. Minor injuries such as cuts can become a major problem through poor healing. Infection of the wound is a major problem. The patient’s footwear must be checked.

## Control of hypertension

Studies have highlighted the importance of blood pressure control to reduce macrovascular and microvascular complications in diabetes patients.<sup>18</sup> Their blood vessels (both macro and micro) are more susceptible to hypertensive, namely >130/85 mmHg, damage. Non-pharmacological measures should be tried first.

Preferred pharmacological agents are ACE inhibitors or ARBs and calcium-channel blockers.<sup>6,15</sup>

Current recommendations are for tight control of blood pressure to below a threshold of 130/80 mmHg in patients with uncomplicated diabetes.<sup>15</sup>

### Getting to target blood pressure (<130/80 mmHg)\*

- Step 1: Diet, exercise, weight control
- Step 2: ACEI or ARB
- Step 3: ACEI/ARB and diuretic
- Step 4: Beta blocker
- ARB = angiotensin reuptake blocker

\* <125/75 mmHg if proteinuria >1 g/day present

## Control of dyslipidaemia<sup>5,15</sup>

Mixed hyperlipidaemia is a common finding in patients with diabetes. Dyslipidaemia (especially hypercholesterolaemia) is an independent risk factor for the macrovascular complications of diabetes and proper control is important. Non-pharmacological measures should be tried first. The preferred agents are HMG-CoA reductase inhibitors and resins for hypercholesterolaemia and fibrates and resins for mixed hyperlipidaemia.

Targets should be:

- total cholesterol—<4 mmol/L
- triglycerides—<1.5 mmol/L
- HDL cholesterol—≥1 mmol/L
- LDL cholesterol—<2.0 mmol/L

## Management in summary<sup>18</sup>

The ABC of diabetic care is summarised in TABLE 20.7. The key to ongoing control of diabetes is to maintain the HbA<sub>1c</sub> below 7%. In patient review, the National Health and Medical Research Council (NHMRC) guidelines emphasise lifestyle review as step one.<sup>15</sup> Emphasise the importance of self-monitoring. A useful lifestyle evaluation mnemonic is NEAT:

- Nutrition—eat less, reach ideal weight, healthy low fat/complex carbohydrate diet
- Exercise—including 'walk more', interesting physical activities
- Avoidance of toxins—alcohol, tobacco, salt, sugar, illicit drugs
- Tranquillity—rest, recreation and stress reduction

Antihypertensives and statins have an important role in management. A meta-analysis of the use of low-dose acetyl salicylic acid (75–150 mg/day) showed cardiovascular risk reduction in people with diabetes.<sup>19</sup> It is appropriate that a 'type 2 tablet' has been advocated for most people with diabetes.<sup>20</sup> The suggested pill mix is *metformin, an ACE inhibitor, a statin and aspirin*.

**Table 20.7** The ABC of diabetes care<sup>3</sup>

Risk factor	Target
HbA <sub>1c</sub>	<7%
BP	<130/80*
Cholesterol	<4 mmol/L**
Salicylates	Aspirin 75–150 mg/day
Smoking	Quit

\* <125/75 if proteinuria exists

\*\* corresponding to LDL cholesterol <2.0 mmol/L

## METABOLIC COMPLICATIONS OF DIABETES

### \$ Hypoglycaemia

Hypoglycaemia<sup>5,8</sup> occurs when blood glucose levels fall to less than 3.0 mmol/L. It is more common with treated type 1 diabetes but can occur in type 2 diabetes patients on oral hypoglycaemic drugs, notably sulphonylureas (biguanides hardly ever cause hypoglycaemia). It is appropriate to ask often about symptoms of hypoglycaemia: 'recurrent hypoglycaemia begets hypoglycaemic unawareness'.

### Clinical variations

- 1 Classic warning symptoms: sweating, tremor, palpitations, hunger, peri-oral paraesthesia. Usually treated with refined carbohydrate (e.g. glucose; sugar in the mouth).
- 2 Rapid loss of consciousness, usually without warning—hypoglycaemic unawareness is less common.
- 3 Coma: stuporose, comatose or 'strange' behaviour.

For mild cases give something sweet by mouth, followed by a snack.

Treatment of hypoglycaemia requires one dose of carbohydrate.

Dose: (one of)

- 2 barley sugars
- 6 jelly beans
- glass of lemonade
- teaspoon of honey

Take one dose, and don't repeat unless still unwell 10 minutes later. Follow with a complex carbohydrate meal.

### Treatment (severe cases or patient unconscious)

#### Treatment of choice

20–30 mL 50% glucose IV until fully conscious (instil rectally using the nozzle of the syringe if IV access difficult)

or

(alternative) 1 mL glucagon IM or SC

Admit to hospital if concerned (rarely necessary). Ascertain cause of the hypoglycaemia and instruct the patient how to avoid a similar situation in the future.

### \$ Diabetic ketoacidosis<sup>5</sup>

This life-threatening emergency requires intensive management. It usually occurs during an illness (e.g. gastroenteritis) when insulin is omitted.

## Clinical features

- Develops over a few days, but may occur in a few hours in 'brittle' diabetics
- Preceding polyuria, polydipsia, drowsiness
- Vomiting and abdominal pain
- Hyperventilation—severe acidosis (acidotic breathing)
- Ketonuria

## Management

- Arrange urgent hospital admission.
- Give 10 units rapid-acting insulin IM (not SC).
- Commence IV infusion of normal saline.

*Tip:* The comatose patient requires water, sodium (3L N saline), potassium (KCl) and insulin.

## § Hyperosmolar hyperglycaemia<sup>5</sup>

Patients with this problem may present with an altered conscious state varying from stupor to coma and with marked dehydration. The onset may be insidious over a period of weeks, with fatigue, polyuria and polydipsia. The key features are marked hyperglycaemia and dehydration without ketoacidosis. It occurs typically in uncontrolled type 2 diabetes, especially in elderly patients. Sometimes they have previously undiagnosed diabetes. There may be evidence of an underlying disorder such as pneumonia or a urinary infection. The essential findings are extreme hyperglycaemia and high plasma osmolality. The condition has a high mortality—even higher than ketoacidosis.

## Treatment

- IV fluids, e.g. normal to ½ normal saline, given slowly
- Insulin—relatively lower doses than acidosis

## § Lactic acidosis<sup>5,8</sup>

Patients with lactic acidosis present with marked hyperventilation 'air hunger' and confusion. It has a high mortality rate and must be considered in the very ill diabetic patient taking metformin, especially if kidney function is impaired. The risk of lactic acidosis is low if the therapeutic dose of metformin is not exceeded. The investigations reveal blood acidosis (low pH), low bicarbonate, high serum lactate, absent serum ketones and a large anion gap. Treatment is based on removal of the cause, rehydration and alkalinisation with IV sodium bicarbonate.

## Other issues in diabetic patients

### Erectile dysfunction<sup>8</sup>

The prevalence of erectile dysfunction in men over 40 years may be as high as 50%. It may be caused by macrovascular disease, pelvic autonomic neuropathy or psychological causes. Those with organic-based ED may benefit from appropriate counselling and (if not taking nitrates) one of the phosphodiesterase inhibitors, starting with a low dose. The risk of cardiovascular disease needs to be evaluated.

### Female sexual dysfunction

Autonomic dysfunction may result in reduced vaginal lubrication with arousal in women, but not the degree of sexual dysfunction that affects men. Appropriate education, reassurance and the use of lubricants should be helpful.

### Postural hypotension<sup>8</sup>

Autonomic neuropathy-related postural hypotension may be compounded by medication, including antihypertensives and anti-angina agents. Persistent problems may be helped by graduated compression stockings to decrease venous pooling. If it continues to be a severe problem, the use of oral fludrocortisone may be helpful.

### Gastroparesis

Symptoms of gastroparesis (due to autonomic neuropathy) with decreased gastric emptying include a sensation of fullness, dysphagia, reflux or recurrent nausea and vomiting, especially after meals. Treatment options include medication with domperidone, cisapride or erythromycin. A recent development is injections of botulinum toxin type A into the pylorus via gastroscopy to facilitate gastric emptying.

### Diabetes and driving<sup>5</sup>

Diabetes may impair driving through medication causing hypoglycaemia or its complications including visual impairment. In 2003 revised medical standards, *Assessing Fitness to Drive*, were released for drivers of private and commercial vehicles. Patients are expected to provide details to the driver licensing authority and to their vehicle insurance company. There are specific legal obligations of medical practitioners and drivers. In general terms people controlled by diet alone have no restrictions for driving whereas those on insulin may obtain a conditional licence subject to annual or 2-yearly review. Further details can be found at <[www.austroads.com.au/drivers-vehicles/assessing-fitness-to-drive](http://www.austroads.com.au/drivers-vehicles/assessing-fitness-to-drive)>.

## Contraception

The combined oral contraceptive pill is generally regarded as the most appropriate option for birth control in women not interested in permanent sterilisation. It is important in history taking to keep polycystic ovarian syndrome in mind.

## The future<sup>5,16</sup>

- Use of immunosuppressants and immunomodulators for type 1 diabetes
- Increased availability glucagon-like peptide and amylin-like peptides for type 2 diabetes
- Continuous implantable venous glucose monitoring
- Combination 'type 2 tablet'
- Inhaled insulin
- Transplantation:
  - combined kidney/pancreas
  - islet cells

## Treatment errors and pitfalls<sup>15</sup>

- Avoid prescribing oral hypoglycaemic agents prematurely. Allow a reasonable trial of diet and exercise for type 2 patients, especially if they are overweight.
- Review the need for continued oral therapy after 3 months of treatment.
- Glucose tolerance tests should be avoided if the diagnosis can be made on the basis of symptoms and fasting or random blood sugar (a glucose load carries a risk of hyperosmolar coma).
- Keep an eye on the development of ketones in type 1 patients by checking urinary ketones and, if present, watch carefully because diabetic ketoacidosis is a life-threatening emergency.

## When to refer<sup>8</sup>

- Type 1 diabetic patients for specialist evaluation and then 1- to 2-yearly review
- Type 2 diabetic patients:
  - all young patients
  - those requiring education
  - those requiring insulin
  - those with complications
- For ophthalmological screening: at least every 2 years to inspect retina
- Diabetics with treatable complications, including:
  - retinopathy
  - nephropathy
  - neuropathy: test annually

## Shared care

The management of the diabetic patient provides an ideal opportunity for shared care between a cooperative team comprising the patient, the GP and the specialist diabetic team. The objective is to encourage patients to attend their own doctor for primary care and be less reliant on hospital outpatient services or the diabetic clinics. A well-coordinated arrangement with good communication strategies provides optimal opportunities for the ongoing education of the patient, the GP and the specialist diabetic team.

## Practice tips

- For every diagnosed diabetic there is an undiagnosed diabetic, so vigilance for diagnosing diabetes is important.
- Follow-up programs should keep to a prepared format. A format that can be used is presented in TABLES 20.8 and 20.9.
- Hyperglycaemia is a common cause of tiredness. If elderly type 2 diabetic patients are very tired, think of hyperglycaemia and consider giving insulin to improve their symptoms.
- The management of the diabetic patient is a team effort involving family members, a nurse education centre, podiatrists, domiciliary nursing service, GP and consultant.
- If a diabetic patient (particularly type 1) is very drowsy and looks sick, consider first the diagnosis of ketoacidosis.
- Foot care is vital: always examine the feet when the patient comes in for review.
- Treat associated hypertension with ACE inhibitors or a calcium-channel blocker (also good in combination).
- Use a team approach and encourage joining special support groups (e.g. Diabetes Australia).
- 'Never let the sun go down on pus in a diabetic foot'—admit to hospital.<sup>16</sup>
- If a foot ulcer hasn't healed in 6 weeks, exclude osteomyelitis. Order an MRI and investigate the vasculature.
- Prevention/detection of coronary heart disease should be an integral part of all consultations.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Diabetes
- Diabetes: blood glucose monitoring at home
- Diabetes: foot care for diabetics

- Diabetes: healthy diet for diabetes
- Diabetes: Insulin injections
- Diabetes: type 1
- Diabetes: type 2

**Table 20.8** Diabetes control: 3-monthly review

Discourage smoking and alcohol.  
 Review symptoms.  
 Review nutrition.  
 Check weight (BMI), BP, urine.  
 Review self-monitoring.  
 Review exercise and physical activity.  
 Review HbA1c (test at least every 6 months).  
 Review lipid levels (test at least every 12 months).

**Table 20.9** Diabetes control: an annual review program<sup>5</sup>

1 History  
 Smoking and alcohol use  
 Symptoms of hypoglycaemia, hyperglycaemia  
 Check symptoms relating to eyes, circulation, feet\*  
 Immunisation

---

2 Examinations  
 Weight, height, BMI  
 Blood pressure—standing and lying  
 Examine heart\*  
 Carotid and peripheral pulses\*  
 Eyes:  
 • visual acuity (Snellen chart)  
 • ? cataracts  
 • optic fundi (or ophthalmologist referral)\*  
 • ? diabetic retinal photography  
 Tendon reflexes and sensation for peripheral neuropathy\*  
 Skin (general)  
 Foot examination including footwear\*  
 Check injection sites  
 Urine examination: albumin, ketones, glucose, nitrites

---

3 Review biochemical levels

\* These items comprise a program for detection of long-term complications. They should be conducted annually, commencing 5 years after diagnosis.

Thomas Guthrie (1803–73)

Drug-related problems are true masquerades in family practice. This includes prescribed drugs, over-the-counter drugs and social or illegal street drugs. It is important therefore that all prescribing doctors maintain a high index of suspicion that any clinical problem may be associated with their treatment of the patient.

## Adverse drug reactions

An adverse drug effect is defined as ‘any unwanted effect of treatment from the medical use of drugs that occurs at a usual therapeutic dose’. Almost every drug can cause an adverse reaction, which must be elicited in the history. Any substance that produces beneficial therapeutic effects may also produce unwanted, adverse or toxic effects. The severity of the reaction may range from a mild skin rash or nausea to sudden death from anaphylaxis. A study has shown that the incidence of adverse reactions increases from about 3% in patients 10–20 years of age to about 20% in patients 80–89 years of age.<sup>1</sup>

Reactions can be classified in several ways—side effects, overdosage, intolerance, hypersensitivity and idiosyncrasy. However, a useful classification of unwanted effects is divided into type A and type B.

*Type A reactions* are the most common and involve *augmented pharmacology*; that is, they are caused by unwanted, albeit predictable, effects of the drug. Examples include:

- constipation due to verapamil
- blurred vision and urinary outflow problems due to tricyclic antidepressants
- hyperuricaemia due to thiazide diuretics

Type A reactions are dose-dependent.

*Type B reactions* are by definition *bizarre*. The reactions are unpredictable from known properties of

the drug. Examples include hepatotoxicity and blood dyscrasias.

## Golden rules for prevention of adverse effects

Before prescribing any drug the prescriber should consider the following rules:

- 1 Is the drug really necessary?
- 2 What will happen if it is not used?
- 3 What good do I hope to achieve?
- 4 What harm may result from this treatment?

## Common adverse effects

There is an extensive list of clinical problems caused by drugs as side effects or interactions that are highlighted throughout this book. Common side effects include:

- CNS—malaise, drowsiness, fatigue/tiredness, headache, dizziness
- CVS—palpitations, peripheral oedema, hypotension
- GIT—nausea, vomiting, dyspepsia, change in bowel habit (diarrhoea, constipation)
- skin—rash, pruritus, flushing
- psychiatric/emotional—insomnia, irritability, anxiety, depression, agitation

## Drugs that commonly produce adverse effects

- Antidepressants (number 1 cause): tricyclics, MAOIs, SSRIs
- Antimicrobials: penicillin/cephalosporins, sulphonamides, tetracyclines, streptomycin, ketoconazole

- Anticonvulsants: carbamazepine, phenobarbitone, phenytoin, sodium valproate
- Anti-inflammatories and analgesics: aspirin/salicylates, opioids (e.g. codeine, morphine), NSAIDs, gold salts, DMARDs, bDMARDs
- Antihypertensive agents: several
- Cardiac agents: digoxin, quinidine, amiodarone, other antiarrhythmics
- Diuretics: thiazides, frusemide
- Tranquillisers: phenothiazines, benzodiazepines, barbiturates, chlorthalidoxepoxide
- Other drugs: cytotoxics, hormones, allopurinol, warfarin

## Tobacco use

'Smoking is good for you', according to an old Arab proverb. 'The dogs will not bite you because you smell so bad; thieves will not rob you at night because you cough in your sleep and you will not suffer the indignities of old age because you will die when you are relatively young.'

Tobacco smoking is the largest single, preventable cause of death and disease in Australia. It has been estimated to have caused approximately 15 000 deaths in 2004–05, over six times the number of deaths from road accidents.<sup>2</sup> Diseases attributed to smoking are summarised in **FIGURE 21.1**. Signs of major dependence are smoking within 30 minutes of waking and  $\geq 20$  cigarettes a day.

## Advice to patients (quitting)

Several studies have highlighted the value of opportunistic intervention by the family doctor. It is important not only to encourage people to quit but also to organise a quitting program and follow-up. In Australia 80% of smokers (representing about 30% of the adult population) have indicated that they wish to stop smoking. Point out that it is not easy and requires strong will power. As Mark Twain said, 'Quitting is easy—I've done it a thousand times.'

- Educate patients about the risks to their health and the many advantages of giving up smoking, and emphasise the improvement in *health, longevity, money savings, looks and sexuality*.
- Point out the following advantages to quitting:
  - food tastes better
  - sense of smell improves
  - exercise tolerance is better
  - sexual pleasure is improved
  - bad breath improves
  - risk of lung cancer drops: after 10–15 years of quitting it is as low as someone who has never smoked
  - early COPD can be reversed
  - decreases URTIs and bronchitis
  - chance of premature skin wrinkling and stained teeth is less
  - removes effects of passive smoking on family and friends
  - removes problem of effects on pregnancy
- The extent of nicotine dependence can be assessed using a questionnaire (based on the Fagerstrom Test) and scoring system.<sup>3</sup> As a baseline ask about the number of cigarettes smoked per day, how soon after waking to smoking the first cigarette of the day and any difficulties with coping with antismoking venues (e.g. cinemas, plane travel).

## Intervention: the 5A framework

- Ask about and document tobacco use at every opportunity.
- Assess motivation and confidence to quit: 'Are you interested in quitting?'
- Advise all smokers to quit (in a diplomatic way).
- Assist the smoker to stop with counselling and pharmacotherapy.
- Arrange follow-up to maintain quit advice or non-smoking.

- Ask them to keep a smoker's diary.
- If they say no to quitting, give them motivational literature and ask them to reconsider.
- If they say yes, make a contract (example below).

## A contract to quit

*'I ..... agree to stop smoking on .....  
I understand that stopping smoking is the single best  
thing I can do for my health and that my doctor has  
strongly encouraged me to quit.'*

..... (Patient's signature)  
..... (Doctor's signature)

- These motivated patients will require educational and behavioural strategies to help them cope with quitting. Ongoing support by their GP is very important.
- Organise joining a support group.
- Contact your local Quitline (or similar service) for information about and support for quitting.

FIGURE 21.1 Possible serious adverse effects of nicotine smoking

- Arrange follow-up (very important), at least monthly, especially during first 3 months.
- Going 'cold turkey' (stopping completely) is preferable but before making the final break it can be made easier by changing to a lighter brand, inhaling less, stubbing out earlier and reducing the number. Changing to cigars or pipes is best avoided.

### Withdrawal effects<sup>3</sup>

The initial symptoms are restlessness, cravings, hunger, irritability, poor concentration, headache and frustration (refer TABLE 21.1). After about 10 days most of these effects subside but it takes about three

months for a smoker to feel relatively comfortable with not smoking any more. Nicotine replacement therapy certainly helps patients cope.

Table 21.1 Nicotine withdrawal symptoms (DSM-5)

- 1 Irritability, frustration or anger
- 2 Anxiety
- 3 Difficulty concentrating
- 4 Increased appetite
- 5 Restlessness
- 6 Depressed mood
- 7 Insomnia

## Treatment

### Pharmacological<sup>3</sup>

*Nicotine replacement therapy (NRT)*, which should be used in conjunction with an educational support program, has been proved to be effective and is available as chewing gum, inhaler, oral spray, lozenges, sublingual tablets or transdermal patches (the preferred method). Ideally the nicotine should not be used longer than 3 months. Eight weeks of patch therapy is as effective as longer courses.

NRT should be directed at smokers who are motivated to quit. There is little evidence that drug treatment will benefit individuals with low levels of nicotine dependence who smoke fewer than 10 cigarettes a day.<sup>4</sup>

All forms of NRT are effective: a pooled analysis of all NRT trials showed an absolute increase in cessation at 1 year of 7% compared to placebo.<sup>4</sup>

NRT should start at the quit date, not while still smoking.

### Nicotine gum<sup>3</sup>

This is available as 2 mg and 4 mg.

- Low dependence (less than 10 cigarettes per day, not needing to smoke within 30 minutes of waking): use non-pharmacological methods rather than replacement
- Moderate dependence (10–20 cigarettes per day, smoking within 30 minutes of waking): 2 mg, chew 8–12 pieces daily
- High dependence (>20 per day, waking at night to smoke or first thing after waking): 4 mg initially, 6–10 pieces chewed daily changing to 2 mg after 4–8 weeks

Useful points:

- Chew each piece slowly for about 30 minutes.
- Ensure all the nicotine is utilised.
- Chew at least 6 pieces per day, replacing at regular intervals (not more than 1 piece per hour).
- Use for 3 months, weaning off before the end of this period.

### Transdermal nicotine<sup>3</sup>

This is available as 16-hour or 24-hour nicotine patches in three different strengths. The patients should stop smoking immediately on use.

Recommendations:

- low to moderate dependence (10–20 cigarettes/day): 14 mg/24 hour or 10 mg/16 hour patch, daily; aim to cease within 12 weeks

- high dependence (>20/day): 21 mg/24 hour or 15 mg/16 hour patch; change to 14 mg or 10 mg patch after 4–6 weeks; aim to cease within 12 weeks

Apply to non-hairy, clean, dry section of skin on upper outer arm or upper chest and leave in place for 24 hours. Rotate sites with a 7-day gap for reuse of a specific site.

### Nicotine inhaler

Uses cartridges in a mouthpiece resembling smoking.

- 6–12/day for 12 weeks then taper

### Nicotine lozenges and sublingual tablets

These are available in 2 mg and 4 mg strengths, the strength used according to the level of dependence.

### Combination therapy

Controlled trials have shown enhanced outcomes when nicotine patches are combined with gum or inhaler. Consider it for highly addicted smokers.

There is no current conclusive evidence to support combining NRT with the other oral agents<sup>3</sup> (listed below).

### Other agents for smoking cessation<sup>5</sup>

#### Bupropion (Zyban)

This oral agent has a similar effectiveness to NRT.

Adverse effects include insomnia and dry mouth (both common), with serious effects, such as allergic reactions and increased seizure risk.<sup>6</sup> It is contraindicated in persons with a history of epilepsy.

Recommended dose: 150 mg (o) daily for 3 days then bd for 8 weeks.

#### Varenicline tartrate (Champix)<sup>3,5</sup>

- Commence with 0.5 mg (o) daily for 3 days titrating slowing to 1 mg bd by day 7 until the end of the 12-week course

It is an effective agent but there are several side effects, especially nausea.<sup>6</sup>

#### Nortriptyline

- Titrate to 75 mg (o) daily, starting 14 days before quit date then continue for 12 weeks

*Note:* Regular follow-up for all methods is essential for outcome.

## § Alcohol problems

Excessive drinking of alcohol is one of the most common and socially destructive problems in the world. One survey found that 5% of Australian men and 1%

of women were alcohol-dependent. It also showed that 86% of men and 79% of women drink alcohol, with 8.3% of the population drinking alcohol every day.<sup>6</sup>

- Alcohol is estimated to have a harmful effect on about 1 in 10 people.
- At least 20–40% of acute general and psychiatric hospital admissions have an alcohol-related illness.
- About 20%-plus of fatal traffic accidents involve alcohol.
- The author's study<sup>8</sup> identified alcohol dependence in 9.7% of the population studied and a further group of problem drinkers that included the 'explosive' or binge drinker (see FIG. 21.2). Problem drinkers represent about 15–20% of the population.

## Excessive and harmful drinking

National Health and Medical Research Council (NHMRC) revised guidelines addressing harmful drinking are presented in TABLE 21.2.<sup>3,7</sup>

High-risk and harmful drinking occurs at >6 standard drinks (SDs) a day (average) for men and >4 SDs for women.

The main causes of alcohol-related deaths are road trauma, cancer and alcoholic liver disease.<sup>7</sup>

## Clinical pointers to alcohol abuse

Facial features of the patient can be a helpful pointer, albeit of the more advanced drinker. These include:

- plethoric facies
- puffy 'greasy' facies

FIGURE 21.2 Prevalence of alcohol drinking patterns in the adult population (figures expressed as a percentage)

**Table 21.2** Recommended guidelines to reduce health risks from drinking alcohol, NHMRC 2009<sup>7</sup>

**Guideline 1** Reducing the risk of alcohol-related harm over a lifetime

For healthy men and women, drinking no more than 2 standard drinks on any day reduces the lifetime risk of harm from alcohol-related disease or injury.

**Guideline 2** Reducing the risk of injury on a single occasion of drinking

For healthy men and women, no more than 4 standard drinks on a single occasion reduces the risk of harm arising from the occasion.

**Guideline 3** For children and young people under 18 years of age not drinking alcohol is the safest option

- Parents and carers should be advised that children <15 years are at the greatest risk of harm from drinking and that for this age group, not drinking alcohol is especially important.
- For young people 15–17 years, the safest option is to delay the initiation of drinking for as long as possible.

**Guideline 4** Maternal alcohol consumption can harm the developing fetus or breastfeeding baby

- For women who are pregnant or planning a pregnancy not drinking is the safest option.
- For women who are breastfeeding not drinking is the safest option.

- telangiectasia
- rosacea + rhinophyma
- suffused ('bloodshot') conjunctivae
- prominent lower lip with chelitis of corners of mouth
- smell of stale alcohol or very 'minty' sweet breath (masking effect)

## Taking a drinking history

This requires tact and skill and it must be noted that many problem drinkers considerably understate the level of their intake.

## Useful strategies<sup>8</sup>

- Ask questions as part of a matter-of-fact enquiry into health risk factors, such as smoking and diet.
- Place the onus of denial on the patient by asking questions such as 'When did you last drink alcohol?' rather than 'Do you ever drink alcohol?'
- Record your patient's intake quantitatively in terms of standard drinks or grams of alcohol.
- Confirm the history by enquiring about the time spent drinking per day and expenditure on alcohol.

## Useful questionnaires

There are several questionnaires that can be most helpful, assuming the patient is fully cooperative. Two or more positive replies for the CAGE questionnaire<sup>9</sup> are suggestive of a problem drinker.

- 1 Have you ever felt you should CUT down on your drinking?
- 2 Have people ANNOYED you by criticising your drinking?
- 3 Have you ever felt bad or GUILTY about your drinking?
- 4 Have you ever had a drink first thing in the morning to steady your nerves or get rid of a hangover? (an EYE-OPENER)

Another very practical questionnaire is AUDIT (the Alcohol Use Disorders Identification Test) developed by the World Health Organization <[http://whqlibdoc.who.int/hq/1989/WHO\\_MNH\\_DAT\\_89.4.pdf](http://whqlibdoc.who.int/hq/1989/WHO_MNH_DAT_89.4.pdf)> to facilitate the early detection of problem drinkers in primary care.

## Laboratory investigations

The following blood tests may be helpful in the identification of excessive chronic alcohol intake:

- blood alcohol
- serum GGT: elevated in chronic drinkers (returns to normal with cessation of intake)
- MCV: >96 fL

Other changes:

- abnormal liver function tests (other than GGT)
- carbohydrate deficient transferrin (quite specific—dependent on an enzyme induced by alcohol)
- HDLs elevated
- LDLs lowered
- serum uric acid elevated

## Measuring alcohol intake

One standard drink contains 10 g of alcohol, which is the amount in one middy (or pot) of standard beer (285 mL), two middies of low-alcohol beer or five middies of super-light beer. These are equal in alcohol content to one small glass of table wine (122 mL), one glass of sherry or port (60 mL) or one nip of spirits (30 mL) (see FIG. 21.3).

- 1 stubbie or can of full-strength beer = 1.4 standard drinks
- 1 light beer = 0.9 standard drinks
- 1 × 750 mL bottle of beer = 2.6 standard drinks
- 1 × 750 mL bottle of wine = 7 standard drinks

## Alcohol dependence

Alcohol dependence is a syndrome in which an individual demonstrates clinically significant impairment or distress as manifested by three or more of the following, occurring at any time in the same 12-month period:

- 1 tolerance
- 2 withdrawal
- 3 drinking in larger amounts or for a longer period than intended
- 4 unsuccessful attempts to cut down or control drinking
- 5 a great deal of time spent in activities necessary to obtain, use or recover from the effects of alcohol
- 6 important social, occupational or recreational activities reduced or given up because of drinking
- 7 continued drinking despite knowledge of having persistent or recurrent problems caused by or exacerbated by drinking

## Approach to management

The challenge to the family doctor is early recognition of the problem. There are specific target areas which should be considered carefully by the GP. Several studies have shown that early intervention and brief counselling by the doctor are effective in leading to rehabilitation.<sup>10</sup> Some of the results are very revealing.

- Patients expect their family doctor to advise on safe drinking levels.
- They will listen and act on our advice.<sup>11</sup>
- Treatment is more effective if offered before dependence or chronic disease has developed.<sup>11</sup>

Of prime concern to the GP is the assessment of whether the patient is interested in changing his or her excessive drinking behaviour. The proposed model of change by Prochaska and Di Clemente helps identify the stage reached by the patient (see FIG. 21.4).<sup>12</sup>

FIGURE 21.3 Standard drinks

**FIGURE 21.4** Prochaska's and Di Clemente's<sup>12</sup> proposed model of change to facilitate the identification of behavioural stages and the provision of counselling for treating dependence on alcohol, tobacco and other drugs

21

Precontemplators are satisfied users who are either unconcerned about their drinking or have no desire to change. However, if there is any evidence of ambivalence or concern about drinking then the opportunity exists for motivational interviewing techniques.

Patients are not likely to offer concern about their drinking problem spontaneously but are often receptive to the initiative coming from their doctor.

The family doctor is ideally placed to identify and treat the problem of alcohol because the individual who abuses alcohol will tend to surface at some point in the provision of primary health care.

### A brief practical management plan<sup>13</sup>

Giving patients feedback about their level of alcohol consumption, presenting objective evidence of harm and setting realistic goals for reducing alcohol intake induces many to change their drinking behaviour.

A six-step management plan, which has been employed in a general-practice early intervention program, is as follows:

- 1 Feed back the results of your assessment and specifically the degree of risk associated with their daily alcohol intake and bout drinking. Emphasise any damage that has already occurred.
- 2 Listen carefully to their reaction. They will need to ventilate their feelings and may respond defensively.

- 3 Outline the benefits of reducing drinking: (e.g. save money, better health, weight loss).
- 4 Set goals for alcohol consumption that you both agree are feasible. In most cases this will involve reduction to below certain 'safe limits'.
  - For men: aim for fewer than 12 SDs per week.
  - For women: aim for fewer than 8 SDs per week. It is best for pregnant women not to drink.
  - For patients with illness who are physically dependent on alcohol, long-term abstinence is advisable.
- 5 Set strategies to keep below the upper safe limits e.g.:
  - quench thirst with non-alcoholic drinks before having an alcoholic one
  - switch to low-alcohol beer
  - take care which parties you go to: avoid constant parties and other high-risk situations
  - explore new interests—fishing, cinema, social club, sporting activity
- 6 Evaluate progress by having patients monitor their drinking by using a diary; check that any abnormal blood test results are returning to normal. Make a definite appointment for follow-up and give appropriate literature such as *Alcohol: Harmful Use of Alcohol*. Obtain consent for a telephone follow-up. A useful minimum intervention plan is presented in **TABLE 21.3**.

**Table 21.3** Minimum intervention technique plan (5–10 minutes)

- 1 Advise reduction to safe levels
- 2 Outline the benefits
- 3 Provide a self-help pamphlet
- 4 Organise a diary or other feedback system
- 5 Obtain consent for a telephone follow-up
- 6 Offer additional help (e.g. referral to an alcohol and drug unit or to a support group)

### Follow-up (long consultation 1 week later)

Review the patient's drinking diary. Explore any problems, summarise, listen and provide support and encouragement. If appointment is not kept, contact the patient.

### Specialist services

According to progress and the patient's wishes and consent, specialist treatment units, group therapy and attendance at meetings of Al-Anon or AA

are potential sources of help to keep the alcohol-dependent person abstinent and coping.

### 'Anti-craving' drugs

The following show a modest effect on assisting abstinence:

- acamprosate 666 mg (o) tds
- naltrexone 50 mg (o) daily (under close supervision)

## Withdrawal symptoms

Symptoms of a 'hangover' include headache, nausea, irritability, malaise and a mild tremor. Withdrawal from alcohol in a chronic problem drinker includes:

- agitation
- prominent tremor
- sweating
- insomnia
- seizures
- delirium tremens (DTs)

The aim of treatment for acute withdrawal symptoms is to prevent development of DTs. Maintain fluid, electrolytes and nutrition. Add vitamin B complex, including thiamine, because the patient is invariably thiamine deficient.

If medication is required:

- diazepam 20 mg (o) every 2 hours (up to 100 mg (o) daily) titrated against clinical response (taper off after 2 days) in the hospitalised or well-supervised patient
- thiamine 100 mg IM or IV daily for three days, then 300 mg (o) daily for several weeks
- vitamin B group supplement (o) or IM daily
- for psychotic features add haloperidol 1.5–5 mg (o) bd or 5 mg IM as single dose if necessary

### § Delirium tremens

DTs is a serious life-threatening withdrawal state. It has a high mortality rate if inadequately treated and hospitalisation is always necessary.

### Clinical features

- May be precipitated by intercurrent infection or trauma
- 1–5 days after withdrawal (usually 3–4 days)
- Disorientation, agitation
- Clouding of consciousness
- Marked tremor
- Visual hallucinations (e.g. spiders, pink elephants)
- Sweating, tachycardia, pyrexia
- Signs of dehydration

### Treatment<sup>14</sup>

- Hospitalisation
- Correct fluid and electrolyte imbalance with IV therapy
- Treat any systemic infection
- Thiamine (vitamin B1 300 mg IM or IV daily for 3–5 days, then thiamine 300 mg (o) daily
- Diazepam 5 mg by slow IV injection (over several minutes) every half hour until symptoms subside or diazepam 20 mg (o) every 2 hours (up to max. 100 mg daily) until symptoms subside This dose is usually required for 2–3 days, then should be gradually reduced till finished. If psychotic features (e.g. hallucinations and delusions) add haloperidol 1.5–5 mg (o) bd, titrated to clinical response

*Note:* Chlorpromazine is not recommended because of its potential to lower seizure threshold. Diazepam and haloperidol may worsen the symptoms of hepatic toxicity.

### § Alcohol overdose<sup>14</sup>

Overdose is potentially fatal. The average lethal blood alcohol concentration is about 0.45–0.5%. Death from a lower concentration may occur with other sedative drugs. Alcohol withdrawal may begin at 0.1%. Treatment of overdose is supportive and symptomatic. No stimulants should be given. Overdose may cause hypoglycaemia and metabolic acidosis.

### § Hangover

A type of acute drug toxicity causing headache, nausea and fatigue.

### Prevention

- Drink alcohol on a full stomach.
- Select alcoholic drinks that suit you: avoid champagne.
- Avoid fast drinking—keep it slow.
- Restrict the quantity of alcohol.
- Dilute your drinks.
- Avoid or restrict smoking while drinking.
- Drink three large glasses of water before retiring.

### Treatment

- Drink ample fluids especially water because of relative dehydration effect of alcohol.
- Take two paracetamol tablets for headache.
- Drink orange juice or tomato juice, with added sugar.
- A drink of honey in lemon juice helps.
- Tea is a suitable beverage.
- Have a substantial meal but avoid fatty food.

## Illicit drugs

Several psychotropic substances are used for their effects on mood and other mental functions. Many of the severe problems are due to withdrawal of the drug. Symptomatic behaviour common to illicit drugs includes:

- rapid disappearance of clothing and personal belongings from home
- signs of unusual activity around hang-outs and other buildings
- loitering in hallways or in areas frequented by addicts
- spending unusual amounts of time in locked bathrooms
- inability to hold a job or stay in school
- rejection of old friends
- using the jargon of addicts

The drugs include crack, which is a cocaine base where the hydrochloride has mostly been removed, usually in a microwave oven. Crack can be inhaled or smoked (see FIGS 21.5 and 21.6). Ice is the crude form of methamphetamine, a derivative of amphetamine FIG 21.6. Speed is dexamphetamine.

## Party drugs

Ecstasy is another 'designer' drug which is an amphetamine derivative—methylenedioxymethamphetamine (MDMA). It has high abuse potential, some hallucinogenic properties and a tendency to neurotoxicity, as proved on PET brain scans. It is popular in rave parties. Deaths have occurred, reportedly in association with relative dehydration or excessive hydration. Treatment for

FIGURE 21.5 'Meth mouth' in a young man actively smoking methamphetamine

overdosage involves correction of fluid and electrolyte disturbances. An increasingly popular drug is fantasy (gamma-hydroxybutyrate), which has sedative and anaesthetic effects similar to alcohol. A popular party drug, it is implicated as a 'date rape' drug. There is no specific antidote.<sup>13</sup> Another party drug is ketamine, which is a short-acting anaesthetic with hallucinogenic properties. It can produce nausea and vomiting if used with alcohol. Like fantasy, treatment of overdosage is symptomatic.

## The drug list

Illicit drugs taken by injecting drug users in Victoria, Australia in 2005 were:

- heroin 89%
- cannabis 87%
- speed 75%
- ice 29%
- cocaine 15%
- base 13%

Source: Illicit drug reporting system

A summary of the effects of illicit or hard street drugs is presented in TABLE 21.4.

A list of street drugs and their slang names is presented in TABLE 21.5.

## § Narcotic dependence

This section will focus on heroin dependence.

## Typical profile of a heroin-dependent person<sup>15</sup>

- Male or female: 16–30 years
- Family history: often severely disrupted, such as parental problems, early death, separation,

FIGURE 21.6 Methamphetamine ice with pipe

**Table 21.4** Illicit substance abuse: a summary of hallmarks

Drug	Physical symptoms	Look for	Dangers
<b>Amphetamines including methamphetamines</b> (3 forms) <ul style="list-style-type: none"> <li>• speed—powder</li> <li>• base—oily paste</li> <li>• ice—crystalline</li> </ul>	Aggressive or agitated behaviour, giggling, silliness, euphoria, rapid speech, fever, confused thinking, anorexia, insomnia, extreme fatigue, dry mouth, shakiness, anxiety	Jars of pills of varying colours, chain smoking; white powder and crystals can also be snorted or injected	Hypertension, death from overdose, hallucinations, paranoia, may cause temporary psychosis, stroke, cardiac arrest
<b>Barbiturates</b>	Drowsiness, stupor, dullness, slurred speech, drunk appearance, vomiting	Pills of various colours	Death from overdose or as a result of withdrawal, addictions, convulsions
<b>Cannabis/marijuana</b>	Initial euphoria, floating feeling, sleepiness, lethargy, wandering mind, enlarged pupils, lack of coordination, craving for sweets, changes of appetite, memory difficulty	Strong odour of burnt leaves, small seeds in pocket lining, cigarette paper, discoloured fingers	Inducement to take stronger narcotics, recent medical findings reveal that prolonged usage causes cognitive defects, precipitates or exacerbates schizophrenia
<b>Ecstasy (methylenedioxymethamphetamine)</b>	Anxiety, panic, sweating, 'loving' feelings, jaw clenching, teeth grinding, bizarre overactive behaviour, hallucinations, increased heart rate, BP and body temperature, feelings of confidence, happiness and love	Small tablets of various colours, shapes, sizes and designs, also comes in powder and capsules	Convulsions, risk of death from heart attack, cerebral haemorrhage, hyperthermia, fluid imbalance with hyponatraemia, acute kidney failure, DIC, liver toxicity, hangover, depression
<b>Fantasy (gamma-hydroxybutyrate)</b>	Relaxation and drowsiness, dizziness, relaxed inhibition/euphoria, increased sexual arousal, impaired mobility and speech	Colourless, odourless liquid Also powder and capsules	Tremors and shaking, amnesia, coma, convulsions, death from high doses
<b>Glue sniffing</b>	Aggression and violence, drunk appearance, slurred speech, dreamy or blank expression	Tubes of glue, glue smears, large paper or plastic bags or handkerchiefs	Lung/brain/liver damage, death through suffocation or choking
<b>LSD (lysergic acid diethylamide)</b>	Severe hallucinations, feelings of detachment, incoherent speech, cold hands and feet, vomiting, laughing and crying	Cube sugar with discolouration in centre, strong body odour, small tube of liquid	Suicidal tendencies, unpredictable behaviour, chronic exposure causes brain damage, LSD causes chromosomal breakdown
<b>Narcotics</b> (a) opioids (e.g. heroin)	Stupor/drowsiness, marks on body, watery eyes, loss of appetite, running nose, constricted pupils, loss of sex drive	Needle or hypodermic syringe, cotton, tourniquet—string, rope, belt, burnt bottle, caps or spoons, bloodstain on shirt sleeve, glass in envelopes	Death from overdose, mental deterioration, destruction of brain and liver, hepatitis, embolisms
(b) cocaine	Similar effects to amphetamines—muscle pains, irritability, paranoia, hyperactivity, jerky movements, euphoria, dilated pupils	Powder: in microwave ovens; inhaled, snorted or injected	Hallucinations, death from overdose—sudden death from arrhythmias, seizures, mental disorders, severe respiratory problems

**Table 21.5** A street drug dictionary

Amphetamines or uppers	
Benzedrine	Roses, beanies, peaches
Dexedrine	Dexies, speed, hearts, pep pills, fast, go-ee, uppers, sulphate
Methedrine	Meth, crystals, white light, ice, whiz
Drinamyl	Purple hearts, goof balls
Amphetamine derivatives	
Ecstasy	E, eggs, eckies, XTC, 'the love drug', Mitsubishis, MDMA, vitamin E, X, Adam, death
Crank	Crystal M, crank
Hallucinogens	
LSD	Acid, blue cheer, strawberry fields, barrels, sunshine, pentagons, purple haze, peace pills, blue light, trips
Cannabis (Indian hemp)	
1 Hashish (the resin)	Hash, resin
2 Marijuana (from leaves)	Pot, tea, grass, hay, weed, locoweed, Mary Jane, rope, bong, jive, Acapulco gold
Cigarettes	Reefers, sticks, muggles, joints, spliffies, head, smoko, ganga
Smoking pot	Blow a stick, blast a joint, blow, get high, get stoned
Narcotics	
Morphine	Morph, Miss Emma
Heroin	H, Big H, Big Harry, GOM (God's own medicine), crap, junk, horse dynamite (high-grade heroin), lemonade (low-grade heroin). Injection of dissolved powder: mainlining, blast, smack. Inhalation of powder: sniffing
Cocaine	Coke, snow, lady of the streets, nose candy, ICE, snort, C, flake, rock, blow, vitamin C, crack, shabu, baby
H & C	Speed balls
Oxycontin	Hillbilly heroin
Miscellaneous	
Fantasy	GBH (grievous bodily harm), liquid G, liquid E, liquid ecstasy, liquid X, fantasy
Barbiturates	Devils, barbies, goof balls
Benzodiazepines	Rowies, moggies
Ketamine	'K', vitamin K, special K, K hole
Solvents	Chroming

divorce, alcohol or drug abuse, sexual abuse, mental illness, lack of affection

- Personal history: low threshold for toleration, unpleasant emotions, poor academic record, failure to fulfil aims, poor self-esteem
- First experiments with drugs are out of curiosity, and then regular use follows with loss of job, alienation from family, finally moving into a 'drug scene' type of lifestyle

## Methods of intake

- 1 Oral ingestion
- 2 Inhalation (see FIG. 21.5)
  - intranasal
  - smoking

### 3 Parenteral

- subcutaneous
- intramuscular
- intravenous (see FIG. 21.7)

## Withdrawal effects<sup>14,15</sup>

These develop within 12 hours of ceasing regular usage. Maximum withdrawal symptoms usually occur between 36 and 72 hours and tend to subside after 10 days.

- Anxiety and panic
- Irritability
- Chills and shivering
- Excessive sweating
- 'Gooseflesh' (cold turkey)

**FIGURE 21.7** Intravenous heroin injection signs: linear tracks and scarring from repeated venepunctures along the course of a vein. Less common sites are the lower leg, dorsum of foot, neck and dorsal vein of penis.

Photo courtesy John Jagoda

- Loss of appetite, nausea (possibly vomiting)
- Lacrimation/rhinorrhoea
- Tiredness/insomnia
- Muscle aches and cramps
- Abdominal colic
- Diarrhoea

A secondary abstinence syndrome is identified<sup>15</sup> at 2–3 months and includes irritability, depression and insomnia.

## Complications of narcotic dependence

### Medical

- Acute heroin reaction: respiratory depression—may include fatal cardiopulmonary collapse. Since the early 2000s opioid deaths have fallen from peak levels of the 1990s, when there was a glut of heroin.
- Injection site: scarring, pigmentation, thrombosis, abscesses, ulceration (especially with barbiturates)
- Distal septic complications: septicaemia, infective endocarditis, lung abscess, osteomyelitis, ophthalmitis
- Viral infections: hepatitis B, hepatitis C (refer to **CHAPTER 58**), HIV infection (refer to **CHAPTER 27**)
- Neurological complications: transverse myelitis, nerve trauma
- Physical disability: malnutrition

### Social

- Alienation from family, loss of employment, loss of assets, criminal activity (theft, burglary, prostitution, drug trafficking)

## Management

Management is complex because it includes the medical management not only of physical dependence and withdrawal but also of the individual complex social and emotional factors. The issues of impaired liver function, hepatitis B and C and HIV prevention also have to be addressed. Sociological tests for these illnesses should be considered.

Patients should be referred to a treatment clinic and then a shared-care approach can be used. The treatments include cold turkey (abrupt cessation) with pharmacological support, acupuncture, high doses of vitamin C, methadone substitution and drug-free community education programs.

Maintenance programs that include counselling techniques are widely used for heroin dependence. Acute toxicity requires injections of naloxone.

## Opioid withdrawal<sup>14</sup>

Buprenorphine withdrawal (short term) is used to prevent the emergence of a withdrawal syndrome in contradistinction from buprenorphine maintenance, where there is an extended treatment period.

### Initial dose

- buprenorphine 4–8 mg (o) as a single daily dose, increasing to 12 mg (max) on day 3, then reduce gradually over the next 3–5 days

*Note:* If autonomic signs, use clonidine 5–15 mg/kg/day (o) in 3 divided doses for 7–10 days then taper off. If anxiety and agitation, use diazepam 5–20 mg (o) qid (with care). Clonidine can be used as first-line treatment because of relative safety. These drugs are preferred to methadone for the management of opioid withdrawal. Diazepam can be used to treat problematic anxiety and agitation, but avoid benzodiazepines unless supervision is available.

## Maintenance programs for long-term opioid dependence<sup>14</sup>

There are currently three alternative programs—methadone, buprenorphine and naltrexone—which are substitutes for heroin and other opioids.

### Methadone

Seek specialist advice before starting treatment. The dose needs to be determined individually according to past use and initial response to methadone.

- Methadone 20 mg (o) daily initially. Stabilise dose over 3 weeks. Beware of doses >40 mg, especially in unwell patients. Maintenance 50–80 mg (o) daily.

### Buprenorphine

- Buprenorphine 2–8 mg sublingual, once daily initially, increase to 8–24 mg daily or alternative days once stabilised. It is less dependent and prone to overdose than methadone but can precipitate withdrawal if used too soon.

### Naltrexone

Care is required in giving naltrexone to a person physically dependent on opioids. A naloxone challenge test is used.<sup>14</sup> If no evidence of withdrawal give:

- Naltrexone 25 mg (o) initially increasing to 50 mg daily on day 2 if tolerated. Careful supervision with appropriate counselling is required.

The natural history of opioid dependence indicates that many patients do grow through their period of dependence and, irrespective of treatments provided, a high percentage become rehabilitated by their mid-30s.

### § Stimulant substance abuse

The stimulants include amphetamines and their analogues, ephedrine, cocaine and certain appetite suppressants.

### Stimulant-induced syndrome<sup>14</sup>

- Aggressive behaviour
- Paranoid behaviour
- Irritability
- Transient toxic psychosis
- Delirium
- Schizophrenic-like syndrome

### Treatment

- Withdrawal of drugs
- Cognitive behaviour therapy
- No firm evidence on effectiveness of drugs

### Stimulant-withdrawal syndrome<sup>14</sup>

This syndrome should be suspected in people whose occupation involves shift work, interstate transport driving or multiple jobs presenting with the following symptoms:

- drowsiness
- hypersomnia, then insomnia
- irritability
- aggressive behaviour
- dysphoria
- urge to resume drugs

### Treatment

- Psychological support and encouragement
- Desipramine (or similar tricyclic antidepressant) 75 mg (o) nocte (increasing as necessary)
- Bromocriptine 1.25 mg (o) bd has also been used for cocaine withdrawal

### § Hallucinogen abuse

Hallucinogens in use include lysergic acid (LSD), phencyclidine (angel dust), diethylamide and many synthetics. Symptoms include psychotic behaviour, including severe hallucinations. Withdrawal from these drugs is not usually a problem but 'flashbacks' can occur. Treatment, especially where there is fear or anxiety, is diazepam 10–20 mg (o) statim.

### Treatment (medication to counter symptoms)<sup>14</sup>

- haloperidol 2.5–10 mg (o) daily  
or
- diazepam 10–20 mg (o) repeated every 2 hours prn (to max 120 mg daily)

### § Cannabis (marijuana) use

Cannabis is a drug that comes from the plant *Cannabis sativa*, the Indian hemp plant. It is a stimulant and a hallucinogen. It contains the chemical tetrahydrocannabinol, which makes people get 'high'. It is commonly called marijuana, grass, pot, dope, hash or hashish. Other slang terms are Acapulco gold, ganga, herb, J, jay, hay, joint, reefer, weed, locoweed, smoke, tea, stick, Mary Jane, Panama red and spliffy (see TABLE 21.5). Marijuana comes from the leaves, while hashish is the concentrated form of the resinous substances from the head of the female plant and can be very strong (it comes as a resin or oil). The drug is usually smoked as a leaf (marijuana) or a powder (hashish), or hashish oil is added to a cigarette and then smoked. The effects of taking cannabis depend on how much is taken, how it is taken, how often, whether it is used with other drugs and on the particular person.<sup>16</sup> The effects vary from person to person. The effects of a small-to-moderate amount include:

- feeling of well-being and relaxation
- decreased inhibitions
- woozy, floating feeling
- lethargy and sleepiness
- talkativeness and laughing a lot
- red nose, gritty eyes and dry mouth

- unusual perception of sounds and colour
- nausea and dizziness
- loss of concentration
- looking 'spaced out' or drunk
- lack of coordination
- delusions and hallucinations (more likely with larger doses)
- a form called skunk or mad weed causes paranoia

The effects of smoking marijuana take up to 20 minutes to appear and usually last 2 to 3 hours and then drowsiness follows.<sup>16</sup> The effect on psychomotor function is similar to alcohol and this can impair driving skills. The main problem is habitual use with the development of dependence; dependence (addiction) is worse than originally believed.

### Long-term use and addiction

The influence of pot has a severe effect on the personality and drive of the users. They lose their energy, initiative and enterprise. They become bored, inert, apathetic and careless. A serious effect of smoking pot is the inability to concentrate and loss of memory. Some serious problems include:

- deterioration of academic or job performance
- anxiety and paranoia
- respiratory disease (more potent than tobacco for lung disease): causes COPD, laryngitis and rhinitis
- often prelude to taking illicit drugs
- becoming psychotic (resembling schizophrenia): the drug appears to unmask an underlying psychosis<sup>16</sup>
- impaired ability to drive a car and operate machinery

### Withdrawal

Sudden withdrawal produces insomnia, night sweats, nausea, depression, myalgia, irritability and maybe anger and aggression. However, the effects are often mild with recovery within a few days in many, but heavy users have a severe withdrawal.

### Management

No specific treatment is available.

The best treatment is prevention. People should either not use it or limit it to experimentation. If it is used, people should be prepared to sleep it off and not drive.

## § Anabolic steroid misuse

The apparent positive effects of anabolic steroids include gains in muscular strength (in conjunction with diet and exercise) and quicker healing of muscle injuries. However, the adverse effects, which are dependent on the dose and duration, are numerous.

Adverse effects in women are:

- masculinisation—male-pattern beard growth
- suppression of ovarian function
- changes in mood and libido
- hair loss

In adult men, adverse effects are:

- feminisation: enlarged breasts, high-pitched voice
- acne
- testicular atrophy and azoospermia
- libido changes
- hair loss

Severe effects with prolonged use include:

- liver function abnormalities, including hepatoma
- tumours of kidneys, prostate
- heart disease

In prepubescent children there can be premature epiphyseal closure with short stature.

## Drugs in sport<sup>17</sup>

It is important for GPs to have a basic understanding of drugs that are banned and those that are permissible for elite sporting use. The guidelines formulated by the International Olympic Committee (IOC) Medical Commission and the World Anti-Doping Agency are generally adopted by most major sporting organisations.<sup>10</sup> TABLES 21.6 and 21.7 provide useful guidelines. The IOC's list of prohibited drugs is regularly revised. Banned drug groups include stimulants, narcotics, cannabinoids (e.g. marijuana), anti-oestrogen agents (e.g. tamoxifen), glucocorticosteroids (e.g. prednisolone), anabolic agents, diuretics and various hormones. Banned methods include blood doping (the administration of blood, red blood cells and related blood products), enhancement of oxygen transfer (e.g. erythropoietin, efaproxiral), gene doping and pharmaceutical, chemical and physical manipulation (substances or methods that alter the integrity and validity of the urine testing).

Restricted drugs include alcohol, marijuana, local anaesthetics, corticosteroids and beta blockers. Practitioners can check the guidelines and provide written notification to the relevant authority.

**Table 21.6** Prohibited list: World Anti-Doping Guide (valid 1 January 2014)<sup>17</sup>

Classes	Examples
Prohibited substances at all times	
S1 Anabolic agents	Methandienone, nandrolone, stanozolol, testosterone, oxandrolone, DHEA, tetrahydrogestrinone, clenbuterol, zeronol, androstenediol
S2 Peptide hormones, growth factors and related substances	Growth hormone, corticotrophin, chorionic gonadotrophin and LH (in males), erythropoietin (EPO), darbepoietin (dEPO), SERMS, insulin <i>Note:</i> masking agents such as probenecid, epitestosterone, diuretics and plasma expanders are banned.
S3 Beta-2 agonists	All beta-2 agonists, including both optical isomers (except inhaled salbutamol and salmeterol according to recommended guidelines)
S4 Hormone antagonists and modulators	Aromatase inhibitors e.g. anastrozole, letrozole; SERMS e.g. raloxifene, tamoxifen; other anti-oestrogenic substances e.g. clomiphene; myostatin inhibitors; metabolic modulators—insulins
S5 Diuretics and other masking agents	Acetazolamide, frusemide, hydrochlorothiazide, triamterene, indapamide, spironolactone (and related substances)
Prohibited substances in competition	
S6 Stimulants	Amiphenazole, amphetamines, cocaine, ephedrine, mesocarb, terbutaline,* adrenaline, salmeterol,* salbutamol,* selegiline, pseudoephedrine, phenylpropanolamine, modafinil
S7 Narcotics**	Diamorphine (heroin), methadone, morphine, pethidine, pentazocine, buprenorphine, hydromorphone, oxycodone, oxymorphone, fentanyl
S8 Cannabinoids	Natural (e.g. cannabis, hashish, marijuana) or synthetic THC and cannabimimetics (e.g. 'spice')
S9 Glucocorticosteroids	All glucocorticosteroids are prohibited when administered by oral, IV, IM or rectal routes
Substances prohibited in particular sports	
P1 Alcohol	Prohibited in competition only—aeronautic, archery, automobile, karate, motorcycling, power boating (doping threshold 0.10 g/L)
P2 Beta blockers	Prohibited in competition only e.g. atenolol, carvedilol, metoprolol, propranol, timolol (Check list and sports e.g. archery, shooting, golf, skiing)
Prohibited methods	
M1 Enhancement of oxygen transfer	
M2 Chemical and physical manipulation	
M3 Gene doping	

\* Permitted by inhaler but only with therapeutic use exemption (TUE).

\*\* Caffeine, codeine, dextromethorphan, dextropropoxyphene, dihydrocodeine, tramadol, diphenoxylate and pholcodeine are permitted.

See [www.wada-ama.org](http://www.wada-ama.org) (World Anti-Doping Agency) or <https://checksubstances.asada.gov.au/> for updated information.

**Table 21.7** Guidelines for treatment of specific conditions: International Olympic Committee Medical Code 2008

Asthma	
Allowed	Salbutamol inhaler, salmeterol inhaler, terbutaline inhaler, formoterol inhaler
Banned	Sympathomimetic products (e.g. ephedrine, pseudoephedrine, isoprenaline, systemic beta-2 agonists), oral corticosteroids
Cough	
Allowed	All antibiotics, steam and menthol inhalations, cough mixtures containing antihistamines, pholcodine, dextromethorphan, dihydrocodeine
Banned	Sympathomimetic products (e.g. ephedrine, phenylpropanolamine)
Diarrhoea	
Allowed	Diphenoxylate, loperamide, products containing electrolytes (e.g. Gastrolyte)
Banned	Products containing opioids (e.g. morphine)
Hayfever	
Allowed	Antihistamines, nasal sprays containing a corticosteroid or antihistamine, sodium cromoglycate preparations
Banned	Products containing ephedrine, pseudoephedrine
Pain	
Allowed	Aspirin, codeine, dihydrocodeine, ibuprofen, paracetamol, tramadol, all NSAIDs, dextropropoxyphene
Banned	Products containing opioids (e.g. morphine) or caffeine
Vomiting	
Allowed	Domperidone, metoclopramide

Other drug groups permitted by WADA:

- antidepressants
- antihypertensives (excluding beta blockers)
- caffeine
- eye medications
- oral contraceptives
- skin creams and ointments
- sleeping tablets

Check websites including <www.olympic.org>.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Alcohol: harmful use of alcohol
- Amphetamines
- Cocaine
- Ecstasy
- Heroin
- Smoking: Quitting
- Cannabis (marijuana)

*There's never none of these demure boys come to any proof; for their drink doth so over cool their blood, and making many fish-meals, that they fall into a kind of male green-sickness.*

William Shakespeare (1564–1616), *King Henry IV*

Anaemia is a label, not a specific diagnosis. Anaemia is defined as a reduction in red blood cell numbers or a haemoglobin (Hb) level below the normal reference level for the age and sex of that individual.

The WHO defines anaemia as haemoglobin <130 g/L for men, <120 g/L for women and <110 g/L in pregnant women and school-aged children.

## § Anaemia: a masquerade

Anaemia is regarded as a masquerade because the problem can develop surreptitiously and the patient may present with many seemingly undifferentiated symptoms before the anaemia is detected. Once identified, a cause must be found.

### Key facts and checkpoints

- In Australia, most people with anaemia will have iron deficiency ranging from up to 5% for children to 20% for menstruating females.<sup>1</sup>
- The remainder will mainly have anaemia of chronic disorders.
- The incidence of haemoglobinopathy traits, especially thalassaemia, is increasing in multicultural Western societies.
- If a patient presents with precipitation or aggravation of myocardial ischaemia, heart failure or intermittent claudication, consider the possibility of anaemia.
- The serum ferritin level, which is low in cases of iron-deficiency anaemia, is probably the best test to monitor iron-deficiency anaemia as its level reflects the amount of stored iron.
- Normal reference values for peripheral blood are presented in TABLE 22.1.

**Table 22.1** Normal reference values for peripheral blood: adults

	Male	Female
<b>Haemoglobin (g/L)</b>	130–180	115–165
Red cells ( $\times 10^{12}/L$ )	4.5–6	4–5.5
PCV (haematocrit)	40–53	35–47
MCV (fL)	80–100	
<b>Platelets (<math>\times 10^9/L</math>)</b>	150–400	
<b>White cell count (<math>\times 10^9/L</math>)</b>	4–11	
Neutrophils	2.5–7.5	
Lymphocytes	1.5–4	
Monocytes	0.2–1	
Eosinophils	<0.5	
<b>Reticulocytes (%)</b>	0.5–2	
<b>ESR (mm/hour)</b>	<20 mm	
	<35 mm if >70 years

### Clinical features

Patients with anaemia may be asymptomatic. When symptoms develop they are usually nonspecific. Symptoms can include:

- tiredness/fatigue
- muscle weakness
- headache and tinnitus
- lack of concentration
- faintness/dizziness
- dyspnoea on exertion
- palpitations
- angina on effort
- intermittent claudication
- pica—usually brittle and crunchy food, e.g. ice (iron-deficiency anaemia)

**DxT** fatigue + palpitations + exertional dyspnoea → anaemia

## Signs

*Non-specific signs* include pallor, tachycardia, systolic flow murmur and angular cheilosis.

If severe, signs can include ankle oedema and cardiac failure.

*Specific signs* include jaundice—haemolytic anaemia, and koilonychia (spoon-shaped nails)—iron-deficiency anaemia.

## History

The history may indicate the nature of the problem:

- iron deficiency: inadequate diet, pregnancy, GIT loss, menorrhagia, NSAID and anticoagulant ingestion
- folate deficiency: inadequate diet especially with pregnancy and alcoholism, small bowel disease
- vitamin B12 deficiency: previous gastric surgery, ileal disease or surgery, pernicious anaemia, selective diets (e.g. vegetarian, fad)
- haemolysis: abrupt onset anaemia with mild jaundice
- possibly lead toxicity, especially in children

## Classification of anaemia

The various types of anaemia are classified in terms of the red cell size—the mean corpuscular volume (MCV):

- microcytic—MCV  $\leq 80$  fL
- macrocytic—MCV  $>100$  fL
- normocytic—MCV 80–100 fL

*Note:* Upper limit of MCV varies from 95–100 fL depending on age and laboratory.

TABLE 22.2 outlines a classification of some of the more common causes of anaemia encountered in general practice. There can be an interchange of disorders between the above groups, for example, the anaemia of chronic disorders (chronic infection, inflammation and malignancy) can occasionally be microcytic as well as normocytic; the anaemia of hypothyroidism can be macrocytic in addition to the more likely normocytic; the anaemia of bone marrow disorder or infiltration can also be occasionally macrocytic.

### MICROCYTIC ANAEMIA—MCV $\leq 80$ FL

The main causes of microcytic anaemia are iron deficiency and haemoglobinopathy, particularly thalassaemia. Consider lead poisoning.

## Iron-deficiency anaemia<sup>3</sup>

Iron deficiency is the most common cause of anaemia worldwide. It is the biggest cause of microcytic anaemia, with the main differential diagnosis of microcytic anaemia being a haemoglobinopathy such as thalassaemia.

An understanding of the interpretation of iron studies is important in management.

## Clinical features

- Microcytic anaemia
- Serum ferritin level low (NR: F 15–200 mcg/L: M 30–300 mcg/L)
- Serum iron level low
- Increased transferrin level
- Reduced transferrin saturation
- Response to iron therapy

## Non-haematological effects of chronic iron deficiency

- Angular cheilosis/stomatitis
- Glossitis
- Oesophageal webs
- Atrophic gastritis
- Brittle nails and koilonychia

## Causes<sup>1</sup>

### Blood loss

- Menorrhagia
- Gastrointestinal bleeding (e.g. carcinoma, haemorrhoids, peptic ulcer, hiatus hernia, GORD, NSAID therapy)
- Frequent blood donations
- Malignancy
- Hookworm (common in tropics)

### Increased physiological requirements

- Prematurity, infant growth
- Adolescent growth
- Pregnancy

### Malabsorption

- Coeliac disease
- Postgastrectomy

### Dietary

- Inadequate intake
- Special diets (e.g. fad, vegetarianism)
- Pica—eating unnatural food e.g. dirt, ashes

**Table 22.2** Selected causes and investigations of anaemia

Causes/classification	Primary diagnostic features	Secondary investigations
<b>Microcytic (MCV &lt;80 fL)</b>		
Iron deficiency	s.Fe ↓; s.ferr ↓; transferrin ↑	Therapeutic trial of iron; GIT evaluation for blood loss
Haemoglobinopathy (e.g. thalassaemia)	s.Fe N or ↑; s.ferr N or ↑	Haemoglobin investigation, e.g. electrophoresis
Sideroblastic anaemia (hereditary)	s.Fe N or ↑; s.ferr N or ↑	Bone marrow examination
<b>Occasionally microcytic</b>		
Anaemia of chronic disease (sometimes microcytic)	s.Fe ↓; s.ferr N or ↑; transferrin ↓	Specific for underlying disorder
<b>Macrocytic (MCV &gt;100 fL)</b>		
<b>(a) With megaloblastic changes</b>		
Vitamin B12 deficiency	s.B12 ↓; rc.Fol N or ↑	IF antibody assay; Schilling test
Folate deficiency	s.B12 N; rc.Fol ↓	Usually none
Cytotoxic drugs	Appropriate setting; s.B12 N; rc.Fol N	None
<b>(b) Without megaloblastic changes</b>		
Liver disease/alcoholism	Appropriate setting; uniform macrocytosis; s.B12 N; rc.Fol N	Liver function tests
Myelodysplastic disorders (including sideroblastic anaemia)	Specific peripheral blood findings; s.B12 N; rc.Fol N	Bone marrow examination
<b>Normocytic (MCV 80–100 fL)</b>		
Acute blood loss/occult	Isolated anaemia; Retic ↑	Dictated by clinical findings
Anaemia of chronic disease <sup>1</sup>	Appropriate setting; Retic ↓	s.Fe ↓ and s.ferr N or ↑
Haemolysis	Specific red cell changes; Retic ↑	s.Bil and s.LDH ↑; s.hapt ↓ specific tests for cause
Chronic kidney disease	Isolated anaemia; Retic ↓	Kidney function
Endocrine disorders (e.g. hypothyroidism)	Appropriate setting; isolated anaemia; Retic ↓	Specific endocrine investigation

Abbreviations: MCV = mean corpuscular volume; s.Fe = serum iron; s.ferr = serum ferritin; s.B12 = serum vitamin B12; rc.Fol = red cell folate; IF = intrinsic factor; Retic = reticulocyte count; s.Bil = serum bilirubin; s.LDH = serum lactate dehydrogenase; s.hapt = serum haptoglobin; N = normal; ↓ = reduced; ↑ = elevated; GIT = gastrointestinal

Source: Adapted from 'Anaemia', *MIMS Disease Index*,<sup>1</sup> with permission of MIMS Australia, a division of MediMedia Australia Pty Limited<sup>1</sup>

## Investigations

Investigations are based on the history and physical examination, including the rectal examination. If GIT bleeding is suspected the faecal occult blood test is not considered very valuable but appropriate investigations include gastroscopy and colonoscopy, small bowel biopsy and small bowel enema.

## Haematological investigations: typical findings

- Microcytic, hypochromic red cells
- Anisocytosis (variation in size), poikilocytosis (shape)—pencil-shaped rods

- Low serum iron level
- Raised iron-binding capacity
- Serum ferritin level low (the most useful index)
- Soluble transferrin receptor factor—this factor is increased in iron deficiency, but not in chronic disease. It is very helpful therefore in differentiating iron deficiency from other forms. It is an indirect marker of what is happening in the bone marrow.<sup>4</sup>

The state of the iron stores is assessed by considering the serum iron, the serum ferritin and the serum transferrin levels in combination. Typically,

**Table 22.3** The interpretation of iron studies<sup>2</sup>

Condition	Serum Fe	TIBC	% Transferrin saturation	Ferritin
Iron deficiency	↓	N or ↑	↓	↓ ↓
β-thalassaemia	N or ↑	N	N or ↑	N or ↑
Anaemia of chronic disease	↓	N or ↓	↓	N or ↑
Sideroblastic anaemia	N or ↑	N	N or ↑	↑
Haemochromatosis	↑	↓	↑ ↑	↑ ↑

N = normal

in iron deficiency, the serum iron and ferritin levels are low and the transferrin high, but the serum iron level is also low in all infections—severe, mild and even subclinical—as well as in inflammatory states, malignancy and other chronic conditions. Serum ferritin estimations are spuriously raised in liver disease of all types, chronic inflammatory conditions and malignancy; transferrin is normally raised in pregnancy. Since each of these estimations can be altered in conditions other than iron deficiency, all three quantities have to be considered together to establish the iron status (see TABLE 22.3).<sup>2</sup>

### Treatment<sup>4</sup>

- Correct the identified cause.
- Diet—iron-rich foods, vitamin C rich foods (see TABLE 22.4). Iron is present in meat and legumes as  $\text{Fe}^{+++}$  and therefore requires gastric acid for conversion to  $\text{Fe}^{++}$ .
- Iron preparations:
  - oral iron (ferrous sulphate 1–2 tablets daily between meals for 6 months) e.g. Ferro-Gradumet with orange juice or ascorbic acid until Hb is normal
  - parenteral iron preferably by IV infusion is probably best reserved for special circumstances (there is a risk of an allergic reaction). Avoid blood transfusions if possible.

### Response

- Anaemia responds after about 2 weeks and is usually corrected after 2 months (if underlying cause addressed).<sup>1</sup>
- Oral iron is continued for 3 to 6 months to replenish stores.
- Monitor progress with regular serum ferritin levels.
- A serum ferritin level >50 mcg/L generally indicates adequate stores.

**Table 22.4** Optimal adult diet for iron deficiency

Adults should limit milk intake to 500 mL a day while on iron tablets.

Avoid excess caffeine, fad diets and excess processed bread.

Eat ample iron-rich foods (especially protein).

#### Protein foods

Meats—beef (especially), veal, pork, liver, poultry

Fish and shellfish (e.g. oysters, sardines, tuna)

Seeds (e.g. sesame, pumpkin)

Eggs, especially egg yolk

#### Fruits

Dried fruit (e.g. prunes, figs, raisins, currants, peaches)

Juices (e.g. prune, blackberry)

Most fresh fruit

#### Vegetables

Greens (e.g. spinach, silver beet, lettuce)

Dried peas and beans (e.g. kidney beans)

Pumpkin, sweet potatoes

#### Grains

Iron-fortified breads and dry cereals

Oatmeal cereal

For better iron absorption, add foods rich in vitamin C (e.g. citrus fruits, cantaloupe, Brussels sprouts, broccoli, cauliflower).

### Failure of iron therapy

Consider:

- poor compliance
- continuing blood loss
- malabsorption (e.g. severe coeliac disease)
- incorrect diagnosis (e.g. thalassaemia minor, chronic disease)
- bone marrow infiltration

### Thalassaemia

This inherited condition is seen mainly (although not exclusively) in people from the Mediterranean basin, the Middle East, north and central India and South-East Asia, including south China. The heterozygous

form is usually asymptomatic; patients show little if any anaemia and require no treatment. The condition is relatively common in people from these areas. The homozygous form is a very severe congenital anaemia needing lifelong transfusional support but is comparatively rare, even among the populations prone to thalassaemia (refer to [CHAPTER 18](#)).<sup>2</sup>

The key to the diagnosis of heterozygous thalassaemia minor is significant microcytosis quite out of proportion to the normal Hb or slight anaemia, and confirmed by finding a raised HbA<sub>2</sub> on Hb electrophoresis. DNA screening analysis is now available. The importance of recognising the condition lies in distinguishing it from iron-deficiency anaemia, for iron does not help people with thalassaemia and is theoretically contraindicated. Even more importantly, it lies in recognising the risk that, if both parents have thalassaemia minor, they run a one in four chance of having a baby with thalassaemia major in every pregnancy, with devastating consequences for both the affected child and the whole family.

Treatment of thalassaemia major is transfusion to a high normal Hb with packed cells plus desferrioxamine.

## § Haemoglobin E

This Hb variant is common throughout South-East Asia.<sup>4</sup> It has virtually no clinical effects in either the homozygous or heterozygous forms, but these people have microcytosis, which must be distinguished from iron deficiency; moreover, if the *HbE* gene is combined with the thalassaemia gene, the child may have a lifelong anaemia almost as severe as thalassaemia major. Both genes are well established in the South-East Asian populations in Australia as well as in their own countries.

## MACROCYTIC ANAEMIA—MCV >100 FL

### § Alcohol and liver disease

Each individually, or in combination, leads to macrocytosis with or without anaemia. The importance of this finding lies in its often being the first indication of alcohol abuse, which can so frequently go unnoticed unless there is a firm index of suspicion. Chronic liver disease due to other causes may also be late in producing specific clinical symptoms.

### § Drug toxicity

Cytotoxic drugs, anticonvulsants in particular, and various others (see [TABLE 22.5](#)) may cause macrocytosis. This is of little clinical significance

**Table 22.5** Drugs causing macrocytosis<sup>2,5</sup>

Alcohol	
Cytotoxics/ immunosuppressants	Azathioprine Methotrexate 5-fluorouracil
Antibiotics	Cotrimoxazole Pyrimethamine (incl. Fansidar and Maloprim) Zidovudine
Anticonvulsants	Phenytoin Primidone Phenobarbitone

and does not need correction unless associated with anaemia or other cytopaenia.

## § Myelodysplastic syndromes

These conditions have been recognised under a variety of names, such as 'refractory anaemia' and 'preleukaemia', for a long time, but only relatively recently have they been grouped together. They are quite common in the elderly but may be seen in any age group (refer [TABLE 22.2](#)).

These conditions frequently present as a macrocytic anaemia with normal serum vitamin B12 and red cell folate, and are unresponsive to these or any other haematinics. They are usually associated with progressive intractable neutropaenia or thrombocytopenia or both, and progress slowly but relentlessly to be eventually fatal, terminating with infection, haemorrhage or, less often, acute leukaemia.

## § Vitamin B12 deficiency (pernicious anaemia)

Although well recognised, this is a much less common cause of macrocytosis than the foregoing conditions. It is usually caused by lack of intrinsic factor due to autoimmune atrophic changes and by gastrectomy. Anaemia does not develop for about 3 years after total gastrectomy. Vitamin B12 deficiency may also be seen together with other deficiencies in some cases of malabsorption and Crohn disease.

Vitamin B12 (cobalamin) is found in the normal diet but only in foods of animal origin and consequently very strict vegetarians may eventually develop deficiency. Causes of food vitamin B12 deficiency are:<sup>4</sup>

- atrophic gastritis
- *H. pylori* infection
- H<sub>2</sub> receptor blockers
- PPI drugs
- other drugs, e.g. OCP, metformin

- chronic alcoholism
- HIV
- strict vegan diet

The clinical features are anaemia (macrocytic), weight loss and neurological symptoms, especially a polyneuropathy. It can precipitate subacute combined degeneration of the cord. The serum vitamin B12 is below the normal level (normal range 150–700 pmol/L).

B12 >220 pmol/L = deficiency unlikely  
<148 pmol/L = deficiency

Intrinsic factor antibody level is diagnostic.

### Treatment (replacement therapy)<sup>1,6</sup>

- Vitamin B<sub>12</sub> (1000 mcg i.e. 1 mg) IM injection; body stores (3–5 mg) are replenished after 10–15 injections given every 2 to 3 days
- Maintenance with 1000 mcg injections every third month
- Can use crystalline oral B12
- Co-therapy with oral folate 5 mg/day (initially) is indicated.<sup>6,7</sup>
- Transfusion is best avoided. May need additional iron.

### § Folic acid deficiency

Diagnostic test: serum folate (normal range 7–45 nmol/L) and red cell folate—best test (normal >630 nmol/L)

The main cause is poor intake associated with old age, poverty and malnutrition, usually associated with alcoholism. It may be seen in malabsorption and regular medication with anti-epileptic drugs such as phenytoin.<sup>6</sup> It is rarely, but very importantly, associated with pregnancy, when the demands of the developing fetus together with the needs of the mother outstrip the dietary intake—the so-called ‘pernicious anaemia of pregnancy’ which, if not recognised and treated immediately, can still be a fatal condition. Unlike vitamin B12, folic acid is not stored in the body to any significant degree and requirements have to be satisfied by the daily dietary intake, which invariably meets the requirement of 5–10 mcg/day. Folic acid is present in most fruit and vegetables, especially citrus fruits, nuts and green leafy vegetables (see CHAPTER 10).

### Treatment (replacement therapy)

Oral folate 5 mg/day to replenish body stores (5–10 mg). This takes about 4 weeks but continue for 4 months. Vitamin B12 is usually given unless levels normal.

## NORMOCYTIC ANAEMIA<sup>2</sup> (ANAEMIAS WITHOUT CHANGE IN THE MCV)

### § Acute haemorrhage

This is the most common cause of normocytic anaemia and is usually due to haematemesis and/or melaena.

### § Chronic disease

#### Chronic inflammation

Intercellular iron transport within the marrow is suppressed in inflammation so that, despite normal iron stores, the developing red cells are deprived of iron and erythropoiesis is depressed. If the inflammation is short-lived, the fall in Hb is not noticeable but, if it continues, an anaemia may develop that responds only when the inflammation subsides.

### Malignancy

Anaemia may develop for the same reasons that apply to chronic inflammation.

### § Kidney failure

This is often associated with anaemia due to failure of erythropoietin secretion and is unresponsive to treatment, other than by alleviating the insufficiency or until erythropoietin is administered.

### § Haemolysis

Suspect haemolytic anaemia if there is a reticulocytosis, mild macrocytosis, reduced haptoglobin, increased bilirubin and urobilinogen. Haemolytic anaemias are relatively infrequent. The more common of the congenital ones are hereditary spherocytosis, sickle cell anaemia and deficiencies of the red cell enzymes, pyruvate kinase and G-6-PD, although most cases of G-6-PD deficiency haemolyse only when the patient takes oxidant drugs such as sulphonamides or eats broad beans—‘favism’.

Acquired haemolytic anaemias include those of the newborn due to maternal haemolytic blood group antibodies passing back through the placenta to the fetus, and adult anaemias due to drug toxicity or to acquired auto-antibodies. About half of the latter are idiopathic and half associated with non-Hodgkin lymphomas, and the anaemia may be the presenting sign of lymphoma. Some of these antibodies are active only at cool temperatures—cold agglutinin disease; others act at body temperature and are the more potent cause of autoimmune haemolytic anaemia.

## § Bone marrow replacement

This may be due to foreign tissue, such as carcinomatous metastases or fibrous tissue as in myelofibrosis; it may also be due to overgrowth by one or other normal elements of the bone marrow, as in chronic myeloid leukaemia, chronic lymphocytic leukaemia and lymphoma, as well as by acute leukaemic tissue. A leuco-erythroblastic picture, in which immature red and white cells appear in the peripheral blood, is often seen when the marrow is replaced by foreign tissue.

## Anaemia in children

### Haemoglobin reference range

Infant	term (cord blood)	135–195 g/L
	3–6 months	95–135 g/L
Child	1 year	105–135 g/L
	3–6 years	105–140 g/L
	10–12 years	115–145 g/L

Important causes of anaemia in childhood include iron-deficiency anaemia (quite common), thalassaemia major, sickle-cell anaemia and drug-induced haemolysis. Consider one of the haemoglobinopathies in children of Mediterranean, South-East Asian, Arabic or African-American descent, especially with a family history, normal ferritin level or anaemia resistant to iron therapy. Investigate with Hb electrophoresis.

Drugs that can cause haemolysis (the film will have reticulocytosis, spherocytosis and fragmented red cells) include some antibiotics (e.g. sulfamethoxazole, antimalarials and some anti-inflammatories).

Think of anaemia in adolescents, especially females with a rapid growth spurt at the menarche and a relatively poor diet.

### Iron deficiency in children<sup>8</sup>

- Iron deficiency is present in up to 10–30% of children in high-risk groups.
- It is often subclinical and anaemia develops in relatively few.
- It can lead to reduced cognitive and psychomotor performance (even without anaemia).
- High-risk groups include those infants <6 months who are premature and/or with low birthweight; toddlers 6–36 months with a diet high in cow's milk and low in iron-containing foods; those exclusively breastfed after 6 months; those with delayed introduction of solids; those

with general poor food intake; and those with lack of vitamin C in their diet. Bottle-feeding encourages a high milk intake and reduces the appetite for solid food.

- Possible clinical features include irritability, lethargy, minor behavioural changes, poor growth, dyspnoea and pallor.

### Prevention

- Give iron and multivitamin supplements to very premature and low birthweight (<1000 g) infants.
- Introduce iron-containing solids early—at 4 to 5 months, e.g. cereals, vegetables, egg and meat.
- Encourage breastfeeding and avoid cow's milk in the first 12 months.<sup>6</sup>
- Avoid excessive cow's milk up to 24 months.
- Use iron-fortified formulas and cereals.

### Important sources of iron

Infant milk formulas, meat, especially red meat (also fish and chicken), green vegetables and legumes, dried fruit, juices, fortified cereals, egg yolk.

### Treatment

Treatment is mainly with ferrous gluconate (1 mL/kg of 300 mg/5 mL mixture). Continue for 3 months after Hb has normalised.

### Practice tips

- Iron-deficiency anaemia is blood-loss anaemia until proved otherwise.
- It is possible to be tired from iron deficiency without anaemia.
- Blood-loss anaemia is usually due to menorrhagia or gastrointestinal loss until proved otherwise.
- Investigations for suspected anaemia should include FBE, ESR and iron studies. Others to consider are Hb electrophoresis, vitamin B12 and folate levels and kidney function tests.
- Hypothyroidism can cause a normocytic or a macrocytic anaemia.
- A therapeutic trial of iron (without investigations) is indefensible.
- Intramuscular injections of iron can tattoo so use with care: an IM iron dose is not 'stronger' than an oral iron dose.

*It would indeed be rash for a mere pathologist to venture forth on the uncharted sea of the endocrines, strewn as it is with the wrecks of shattered hypotheses, where even the most wary mariner may easily lose his way as he seeks to steer his bark amid the glandular temptations whose siren voices have proved the downfall of many who have gone before.*

William Boyd (1885–1969)

Thyroid disorders can be a diagnostic trap in family practice and early diagnosis is a real challenge. A family practice of 2500 patients can expect one new case of thyroid disorder each year and 10 ‘cases’ in the practice.<sup>1</sup> The diagnosis of an overactive or underactive thyroid can be difficult as the early clinical deviations from normality can be subtle.

The clinical diagnosis of classical Graves disease is usually obvious with the features of exophthalmos, hyperkinesis and a large goitre but if the eye and neck signs are absent it can be misdiagnosed as an anxiety state. Elderly patients may present with only cardiovascular signs, such as atrial fibrillation and tachycardia, or with unexplained weight loss.

The hypothyroid patient can be very difficult to diagnose in the early stages, especially if the patient is being seen frequently. Hypothyroidism often has a gradual onset with general symptoms such as constipation and lethargy.

If suspected, serum thyroid stimulating hormone (TSH) or thyrotropin should be requested.

Other common endocrine disorders include diabetes mellitus, hyperprolactinaemia, calcium metabolic disorder, PCOS, sexual dysfunction and subclinical hypogonadism. They may be difficult to diagnose in the early stages of development. The pituitary is the master gland and its regulating hormones are depicted in [FIGURE 23.1](#).<sup>2,3</sup>

## Tests for thyroid disorders<sup>2,3</sup>

### Thyroid function tests

Advances in technology have allowed the biochemical assessment of thyroid function to change dramatically in recent years with the introduction of the serum free thyroxine (T<sub>4</sub>) and the monoclonal TSH assays. With the highly sensitive TSH assays it is now possible to distinguish suppressed TSH levels (as in hyperthyroidism) from low and normal levels of TSH.

**FIGURE 23.1** Pituitary hormones

However, the new assays are not foolproof and require interpretation in the context of the clinical picture. The serum TSH level is the most sensitive index of thyroid function and is the preferred test for suspected thyroid dysfunction. If necessary repeat TSH in 3–6 months.

Serum tri-iodothyronine (T<sub>3</sub>) measurement and serum free thyroxine (T<sub>4</sub>) can be useful in suspected T<sub>3</sub> toxicosis where serum T<sub>4</sub> level may be normal, and for monitoring patients with treated thyroid dysfunction.

The relative values are summarised in [TABLE 23.1](#).

### Thyroid autoantibodies

Raised autoantibodies (antimicrosomal or antithyroid peroxidase) are suggestive of Hashimoto thyroiditis (autoimmune thyroiditis). Antithyroglobulin, antithyroid peroxidase and TSH receptor antibodies are elevated in Graves disease, the TSH receptor antibody being very specific for Graves disease.

### Fine needle aspiration

This is the single most cost-effective investigation in the diagnosis of thyroid nodules. It is the best way to assess a nodule for malignancy. Care needs to be taken in the interpretation of the cytology results in conjunction with an experienced cytologist/pathologist.

**Table 23.1** Summary of thyroid function tests<sup>2</sup>

	TSH	free T <sup>4</sup>	free T <sup>3</sup>	Antithyroid antibodies
<b>Normal range</b>	0.4–4.5 mU/L	10–22 pmol/L	3.3–8.0 pmol/L	
<b>Hypothyroidism</b>				
Primary	↑*	↓*	N or ↓ (not useful)	N or ↑
Secondary (pituitary dysfunction)	N or ↓	↓	N or ↓ (not useful)	N
<b>Hyperthyroidism</b>	↓*	↑*	↑*	N or ↑
<b>Sick euthyroid</b>	N or	N or ↓	N or ↓	N

Notes: Results similar to hyperthyroidism can occur with acute psychiatric illness.

Normal ranges vary between laboratories.

\* Main tests

## Thyroid isotope scan

The scan may help in the differential diagnosis of thyroid nodules and in hyperthyroidism. A functioning nodule is said to be less likely to be malignant than a non-functioning nodule (cyst, colloid nodule, haemorrhage are non-functioning; carcinoma is usually non-functioning).

## Thyroid ultrasound

A thyroid ultrasound is usually more sensitive in the detection of thyroid nodules. A multinodular goitre may be diagnosed on ultrasound while the clinical impression may be that of a solitary nodule (the other nodules not being palpable clinically). A multinodular goitre is said to be less likely to be malignant than a solitary thyroid nodule. An ultrasound allows for follow-up of thyroid nodule(s) to note if there are any changes in size over a period of time and to then discuss appropriate intervention with the patient. It can also differentiate a solid from a cystic mass.

## CT scan

CT scan of the thyroid may be used particularly to determine if there is significant compression in the neck from a large multinodular goitre with retrosternal extension. Again follow-up CT scans may allow one to determine the progression or otherwise of such a goitre.

## § Hypothyroidism (myxoedema)

Hypothyroidism, which is relatively common, is more prevalent in elderly women (up to 5%).<sup>4</sup> The term *myxoedema* refers to the accumulation of mucopolysaccharide in subcutaneous tissues. The early changes are subtle and can be misdiagnosed, especially if only a single symptom is dominant.

Patients at risk include those with:

- previous Graves disease
- autoimmune disorders (e.g. rheumatoid arthritis, type 1 diabetes)
- Down syndrome
- Turner syndrome
- drug treatment: lithium, amiodarone, interferon
- previous thyroid or neck surgery
- previous radioactive iodine treatment of the thyroid

## Clinical features

The main features are:

- constipation
- cold intolerance
- tiredness/lethargy/somnolence
- physical slowing
- mental slowing
- depression
- huskiness of voice
- puffiness of face and eyes
- pallor
- loss of hair
- weight gain

**DxT** tiredness + husky voice + cold intolerance → myxoedema

## Physical examination

See **FIGURE 23.2**. The main signs are:

- sinus bradycardia
- delayed reflexes (normal muscular contraction, slow relaxation)

FIGURE 23.2 Clinical features of hypothyroidism

- coarse, dry and brittle hair
- thinning of outer third of eyebrows
- dry, cool skin
- skin pallor or yellowing
- obesity
- goitre

Other diverse presentations of thyroid disorders are given in TABLE 23.2.

### § Hashimoto thyroiditis (autoimmune thyroiditis)

Hashimoto thyroiditis, which is an autoimmune thyroiditis, is the commonest cause of bilateral non-thyrotoxic goitre in Australia. Features are:

- bilateral goitre
- classically described as firm and rubbery

**Table 23.2** Various diverse presentations of thyroid disorders<sup>2,4</sup>

	Hypothyroidism	Hyperthyroidism
<b>General</b>	Lethargy, tiredness Dry skin Husky voice	Weakness Sweaty skin, especially hands
<b>Psychiatric</b>	Depression Dementia Psychosis (myxoedema madness)	Anxiety/irritability Hyperkinesia Psychosis
<b>Musculoskeletal</b>	Myofibrositis Myalgia Joint effusions	Muscle weakness Proximal myopathy
<b>Skin</b>	Dry, cool skin Vitiligo	Warm, thin, soft, moist skin Vitiligo Pretibial myxoedema
<b>Cardiovascular</b>	Ischaemia Cardiomegaly Pericardial effusion Bradycardia Hyperlipidaemia	Tachycardia Atrial fibrillation Heart failure Systolic hypertension
<b>Endocrine</b>	Galactorrhoea Goitre Infertility	Goitre Gynaecomastia
<b>Gynaecological</b>	Menstrual irregularity Menorrhagia (mainly) Oligomenorrhoea	Oligomenorrhoea
<b>Neurological</b>	Neuropathy Nerve entrapment (e.g. carpal tunnel) Ataxia	Periodic paralysis Tremor
<b>Haematological</b>	Anaemia	—
<b>Emergency</b>	Myxoedema coma Postanaesthetic hypoventilation	Thyroid crisis
<b>Other</b>	Reduced libido Weight gain Cold intolerance Constipation	Reduced libido Eye signs Fever (uncommon) Onycholysis Premature grey hair Weight loss

- patients may be hypothyroid or euthyroid with a possible early period of thyrotoxicosis

Diagnosis is confirmed by a strongly positive antithyroid microsomal antibody titre and/or fine needle aspiration cytology.<sup>3</sup>

Hashimoto thyroiditis may present as postpartum hypothyroidism. The hypothyroidism may resolve in 6–12 months or may be permanent.<sup>3</sup>

### Laboratory diagnosis of hypothyroidism

Thyroid function tests (see TABLE 23.1):

- T<sub>4</sub>—subnormal
- TSH—elevated (>10 is clear gland failure)

If T<sub>4</sub> is low and TSH is low or normal, consider pituitary dysfunction (secondary hypothyroidism) or sick euthyroid syndrome. A raised TSH and T<sub>4</sub> in normal range denotes ‘subclinical’ hypothyroidism and treatment is appropriate albeit controversial.<sup>2,5</sup>

Interpretation of TFTs can be difficult but requires matching to the clinical ‘picture’ and consultant advice.

### Other tests

- Serum cholesterol level elevated
- Anaemia: usually normocytic; may be macrocytic
- ECG: sinus bradycardia, low voltage, flat T waves

### Management<sup>6,7</sup>

Confirm the diagnosis, provide appropriate patient education, and refer the patient where appropriate.

Exclude coexisting hypoadrenalism and ischaemic heart disease before T<sub>4</sub> replacement.

*Note:* Treatment as primary hypothyroidism when hypopituitarism is the cause may precipitate adrenal crisis.

### Thyroid medication

- Thyroxine 100–150 mcg daily (once daily)

*Note:* Start with low doses (25–50 mcg daily) in elderly and those with ischaemic heart disease and 50–100 mcg in others. Avoid overdosage.

- Aim to achieve TSH levels of 0.5–2 mU/L.
- Monitor TSH levels monthly at first. As euthyroidism is achieved, monitoring may be less frequent (e.g. 2–3 months). When stable on optimum dose of T<sub>4</sub>, monitor every 2–3 years. Treatment is usually lifelong.

### Special treatment considerations

- *Ischaemic heart disease.* Rapid thyroxine replacement can precipitate myocardial infarction, especially in the elderly.
- *Pregnancy and postpartum.* Continue thyroxine during pregnancy; watch for hypothyroidism (an increased dose of T<sub>4</sub> is often required).
- *Elective surgery.* If euthyroid, can stop thyroxine for one week. If subthyroid, defer surgery until euthyroid.
- *Myxoedema coma.* Urgent hospitalisation under specialist care is required. Intensive treatment is required, which may involve parenteral T<sub>4</sub> or T<sub>3</sub>.

### Neonatal hypothyroidism

Misdiagnosing this serious condition leads to failure to thrive, retarded growth and poor school performance. If untreated it leads to permanent intellectual damage (cretinism). The clinical features of the newborn include coarse features, dry skin, supra-orbital oedema, jaundice, harsh cry, slow feeding and umbilical hernia. It is detected by routine neonatal heel prick blood testing. Thyroxine replacement should be started as soon as possible, at least before 2 weeks of age to avert intellectual retardation.

### When to refer<sup>4</sup>—hypothyroidism

- Doubt about diagnosis, diagnostic tests or optimum replacement dosage

- Apparent secondary hypothyroidism, severe illness and associated ischaemic heart disease
- Concurrent autoimmune disease
- Hypothyroidism with goitre, postpartum thyroid dysfunction and in the neonate
- Myxoedema coma

### § Hyperthyroidism (thyrotoxicosis)

Hyperthyroidism is also relatively common and may affect up to 2% of women, who are affected four to five times more often than men (see FIG. 23.3). Graves disease is the most common cause followed closely by nodular thyroid disease.

### Causes<sup>3,6</sup>

- Graves disease (typical symptoms with a diffuse goitre and eye signs)
- Autonomous functioning nodules
- Subacute thyroiditis (de Quervain thyroiditis)—viral origin

FIGURE 23.3 Thyrotoxicosis patient with exophthalmos and goitre

Photo courtesy Duncan Topliss

- Excessive intake of thyroid hormones—thyrotoxicosis factitia
- Iodine excess
- Amiodarone (beware of this drug)

### Key facts and checkpoints

- The classic symptoms may be lacking in elderly patients who may have only cardiovascular manifestations (e.g. unexplained heart failure or cardiac arrhythmias).
- Care has to be taken not to dismiss hyperthyroidism as severe anxiety.

### Clinical features

- Heat intolerance
- Sweating of hands
- Muscle weakness
- Weight loss despite normal or increased appetite
- Emotional lability, especially anxiety, irritability
- Palpitations
- Frequent loose bowel motions

**DxT** anxiety + weight loss + weakness → thyrotoxicosis

### Physical examination

See **FIGURE 23.4**. Signs are (usually):

- agitated, restless patient
- warm and sweaty hands
- fine tremor (place paper on hands)
- goitre
- proximal myopathy
- hyperactive reflexes
- bounding peripheral pulse
- ± atrial fibrillation

### Eye signs

- Lid retraction (small area of sclera seen above iris)
- Lid lag
- Exophthalmos
- Ophthalmoplegia in severe cases

### Investigations

- $T_4$  (and  $T_3$ ) elevated
- TSH level suppressed
- Radioisotope scan
- Antithyroid peroxidase

The isotope scan enables a diagnosis of Graves disease to be made when the scan shows uniform

increased uptake. Increased irregular uptake would suggest a toxic multinodular goitre, while there is poor or no uptake with de Quervain thyroiditis and thyrotoxicosis factitia.

### Management

- Establish the precise cause before initiating treatment.
- Educate patients and emphasise the possibility of development of recurrent hyperthyroidism or hypothyroidism and the need for lifelong monitoring.
- Monitor for cardiovascular complications and osteoporosis.

### Treatment<sup>7,8,9</sup>

- Radioactive iodine therapy ( $^{131}\text{I}$ )
- Thionamide antithyroid drugs (initial doses)
  - carbimazole 10–45 mg (o) daily in divided doses
- or
- propylthiouracil 200–600 mg (o) daily in divided doses
- Adjunctive drugs
  - beta blockers (for symptoms in acute florid phase, e.g. propranolol 10–40 mg, 6 to 8 hourly); diltiazem or atenolol are alternatives
  - lithium carbonate (rarely used when there is intolerance to thionamides)
  - Lugol's iodine: mainly used prior to surgery
- Surgery
  - subtotal thyroidectomy
- or
- total thyroidectomy

### Treatment (Graves disease)

There is no ideal treatment, and selection of antithyroid drugs, radioiodine or surgery depends on many factors, including age, size of goitre, social and economic factors and complications of treatment.

### Guidelines<sup>6,7</sup>

- Younger patients with small goitres and mild case—18-month course antithyroid drugs
- Older patients with small goitres—as above or radioiodine (preferably when euthyroid)
- Large goitres or moderate-to-severe cases—antithyroid drugs until euthyroid, then surgery or  $^{131}\text{I}$
- In Australia (as in the US)  $^{131}\text{I}$  is being increasingly used

FIGURE 23.4 Clinical features of hyperthyroidism

### Treatment (autonomous functioning nodules)

Control hyperthyroidism with antithyroid drugs, then surgery or  $^{131}\text{I}$ . Long-term remissions on antithyroid drugs in a toxic nodular goitre are rare.

### Treatment (subacute thyroiditis)<sup>7</sup>

Hyperthyroidism is usually transient and follows a surge of thyroxine after a viral-type illness. Symptoms include pain and/or tenderness over the goitre (especially on swallowing) and fever. In the acute phase treatment is based on rest, analgesics

(aspirin 600 mg (o) 4–6 hourly) and soft foods. Rarely, when pain is severe, corticosteroids may be used. Antithyroid drugs are not indicated but beta-blockers can be used to control symptoms.

### § Thyroid crisis (thyroid storm)<sup>7</sup>

Clinical features are marked anxiety, weight loss, weakness, proximal muscle weakness, hyperpyrexia, tachycardia (>150 per minute), heart failure and arrhythmias. It is usually precipitated by surgery or an infection in an undiagnosed patient.

It requires urgent intensive hospital management with antithyroid drugs; IV saline infusion, IV corticosteroids, anti-heart failure and antiarrhythmia therapy.

## When to refer<sup>10</sup>—hyperthyroidism

- Doubt about the diagnosis
- Severe hyperthyroidism, especially if there is coexisting thyrocardiac disease
- Pregnant patients with hyperthyroidism
- Progression of exophthalmos
- Ideally all cases

## § Thyroid nodules

A thyroid nodule is defined as a discrete lesion on palpation and/or ultrasonography that is distinct from the rest of the thyroid gland.

### Causes

- Dominant nodule in a multinodular goitre (most likely)
- Colloid cyst
- True solitary nodule: adenoma, carcinoma (papillary or follicular)

### Investigations

- Ultrasound imaging
- Fine-needle aspiration cytology
- Thyroid function tests

## § Thyroid carcinoma

The main presentations are a painless nodule, a hard nodule in an enlarged gland or lymphadenopathy. Papillary carcinoma is the most common malignancy. Although rare compared with non-malignant lesions (such as colloid nodules, cysts, haemorrhage and benign adenomas), it is important not to miss carcinoma because of the very high cure rate with treatment. This often involves total thyroidectomy, ablative <sup>131</sup>I treatment, thyroxine replacement and follow-up with serum thyroglobulin measurements, <sup>131</sup>I/thallium scanning and neck ultrasound. Fine-needle aspiration is the investigation of choice.

## PITUITARY DISORDERS

## § Pituitary tumours<sup>10</sup>

These are invariably benign adenomas. They can present with hormone deficiencies, features of hypersecretory syndromes (e.g. prolactin, GH, ACTH) or by local tumour mass symptoms (e.g. headache, visual field loss).

## § Hyperprolactinaemia<sup>11</sup>

The main causes (of many) are a pituitary adenoma (micro- or macro), pituitary stalk damage, drugs—such as antipsychotics, various antidepressants, metoclopramide, cimetidine, oestrogens, opiates, marijuana—and physiological causes such as pregnancy and breastfeeding.

### Clinical features

- Symptoms common to males and females: reduced libido, subfertility, galactorrhoea (mainly females)
- Females: Amenorrhoea/oligomenorrhoea
- Males: erectile dysfunction, reduced facial hair

### Diagnosis

- Serum prolactin and macroprolactin assays
- MRI: consider if headache, etc.

Refer for management, which may include a dopamine agonist such as cabergoline or bromocriptine.

## § Acromegaly

Symptoms suggestive of acromegaly include:

- excessive growth of hands (increased glove size)
- excessive growth of tissues (e.g. nose, lips, face)
- excessive growth of feet (increased shoe size)
- increased size of jaw and tongue; kyphosis
- general: weakness, sweating, headaches
- sexual changes, including amenorrhoea and loss of libido
- disruptive snoring (sleep apnoea)
- deepening voice

**DxT** nasal problems + fitting problems (e.g. rings, shoes) + sweating → acromegaly

### Diagnosis<sup>7,10</sup>

- Plasma growth hormone excess
- Elevated insulin-like growth factor 1 (IGF-1) (somatomedin)—the key test
- X-ray skull and hands
- MRI scanning pituitary
- Consider associated impaired glucose tolerance/diabetes

Obtain old photographs (if possible).

Treatment: pituitary microsurgery.

## § Diabetes insipidus and SIADH

Impaired secretion of vasopressin (antidiuretic hormone) from the posterior pituitary leads to polyuria, nocturia and compensatory polydipsia resulting in the passage of 3–20 L of dilute urine per day. There are several causes of diabetes insipidus (DI), the commonest being postoperative (hypothalamic-pituitary), which is usually transient only. Other causes of cranial DI include tumours, infections and infiltrations. In nephrogenic DI the kidney tubules are insensitive to vasopressin. Differential diagnosis includes compulsive (psychogenic) water drinking. The syndrome of secretion of inappropriate antidiuretic hormone (SIADH) is caused by cancer (e.g. lung, lymphomas, kidney, pancreas), pulmonary disorders, various intracranial lesions and drugs such as carbamazepine and many antipsychotic agents. Management of SIADH is essentially fluid restriction.

The treatment of DI is desmopressin, usually given twice daily intranasally.

**DxT** weakness + polyuria + polydipsia  
→ diabetes insipidus

## § Hypopituitarism<sup>7</sup>

This rare disorder should be considered with:

- a history of postpartum haemorrhage
- symptoms of hypothyroidism
- symptoms of adrenal insufficiency
- symptoms suggestive of a pituitary tumour
- thin, wrinkled skin: 'monkey face'
- pale 'alabaster' skin/hairlessness

**DxT** (female): amenorrhoea + loss of axillary and pubic hair + breast atrophy → hypopituitarism

**DxT** (male): ↓ libido + impotence + loss of body hair → hypopituitarism

Investigate with serum pituitary hormones, imaging and triple stimulation test.

## ADRENAL DISORDERS

It is worth keeping in mind the uncommon disorders of the adrenal cortex, which can also be difficult to diagnose in the early stages, namely:

- chronic adrenal insufficiency (Addison disease)—deficiency of cortisol and aldosterone

- Cushing syndrome—cortisol excess
- primary hyperaldosteronism (refer CHAPTER 86)

## § Addison disease<sup>7</sup>

Autoimmune destruction of the adrenals is the most common cause.

### Clinical features

- Lethargy/excessive fatigue/weakness
- Anorexia and nausea
- Diarrhoea/abdominal pain
- Weight loss
- Dizziness/funny turns, syncope: hypoglycaemia (rare); postural hypotension (common)
- Hyperpigmentation, especially mucous membranes of mouth and hard palate, skin creases of hands

If Addison disease remains undiagnosed, wasting leading to death may occur. Severe dehydration can be a feature. Delayed diagnosis is a huge problem.

**DxT** fatigue + a/n/v + abdominal pain  
(± skin discolouration) → Addison disease

### Diagnosis

- Elevated serum potassium, low serum sodium
- Low plasma cortisol level (fails to respond to synthetic adrenocorticotrophic hormone [ACTH])
- The short synacthen stimulation test is the definitive test
- Consider adrenal autoantibodies and imaging ? calcification of adrenals

Treatment: corticosteroid replacement—hydrocortisone/fludrocortisone acetate.

## Addisonian crisis

An Addisonian crisis develops because of an inability to increase cortisol in response to stress, which may include intercurrent infection, surgery or trauma.

### Clinical features

- Nausea and vomiting
- Acute abdominal pain
- Severe hypotension progressing to shock
- Weakness, drowsiness progressing to coma

### Urgent management

- Establish IV line with IV fluids
- Hydrocortisone sodium succinate 200 mg IV and 100–200 mg 4–6 hourly
- Arrange urgent hospital admission

## § Cushing syndrome<sup>7</sup>

The five main causes are:

- iatrogenic—chronic corticosteroid administration
- pituitary ACTH excess (Cushing disease)
- bilateral adrenal hyperplasia
- adrenal tumour (adenoma, adenocarcinoma)
- ectopic ACTH or (rarely) corticotrophin-releasing hormone (CRH) from nonendocrine tumours (e.g. oat cell carcinoma of lung)

The clinical features (see FIG. 23.5) are caused by the effects of excess cortisol and/or adrenal androgens.

### Clinical features

- Proximal muscle wasting and weakness
- Central obesity, buffalo hump on neck
- Cushing facies: plethora, moon face, acne
- Weakness
- Hirsutism
- Abdominal striae
- Thin skin, easy bruising
- Hypertension
- Hyperglycaemia (30%)
- Menstrual changes (e.g. amenorrhoea)
- Osteoporosis
- Psychiatric changes, especially depression
- Backache

**FIGURE 23.5** 62-year-old woman with Cushing syndrome, showing centripetal obesity, hirsutism and virilisation (wearing a wig), 'moon' face, thin extremities and plethora appearance

Photo courtesy David Dammerly

### Diagnosis (apart from iatrogenic cause)

- Cortisol excess (plasma or 24-hour urinary cortisol)
- Dexamethasone suppression test
- Inferior petrosal sinus sampling
- Serum ACTH
- Radiological localisation: MRI for ACTH-producing pituitary tumours; CT scanning for adrenal tumours

## § Primary hyperaldosteronism<sup>7</sup>

Most commonly due to an adrenal adenoma.

### Conn syndrome

Usually asymptomatic but any symptoms are features of hypokalaemia:

- weakness
- cramps

- paraesthesia
- polyuria and polydipsia

### Investigations

- aldosterone (serum and urine) ↑
- plasma renin ↓
- Na ↑, K ↓, alkalosis

Refer for treatment including possible surgery to excise adenoma.

## § Pheochromocytoma<sup>10</sup>

A dangerous tumour of the adrenal medulla. Clinical features are paroxysms or spells of:

- hypertension
- headache (throbbing)
- sweating
- palpitations
- pallor/skin blanching

- rising sensation of tightness in upper chest and throat (angina can occur)

### Investigations

- Series of three 24-hour free catecholamines  
↑ VMA
- Abdominal CT or MRI scan

### Treatment

- Excise tumour, cover with alpha and beta blockers

## § Congenital adrenal hyperplasia (adrenogenital syndrome)<sup>7</sup>

An AR condition with 21-hydroxylase deficiency being the most common of several forms. There is inadequate synthesis of cortisol and aldosterone with increased androgenisation. Major problem is adrenal failure ± salt-losing state (SLS). In females, ambiguity of external genitalia and hirsutism before puberty usually occurs. Males may have normal urogenital development but SLS is a concern. Infants of either sex may present with failure to thrive or vomiting and dehydration (SLS). Lifelong glucocorticoid treatment is required. Wearing an alert bracelet or necklace is strongly recommended for these patients.<sup>7</sup> <www.medicalert.com.au>

## § Adrenal tumours<sup>10</sup>

Most of those detected by abdominal imaging are benign and termed 'incidentalomas' but serious tumours include adrenal carcinoma, pheochromocytoma, neuroblastoma, glucocorticoid or a mineral corticoid secreting tumour.

Rule: tumours >4 cm require thorough assessment as malignant tumours are large.

## CALCIUM DISORDERS

### § Hypercalcaemia<sup>10</sup>

Suspect hypercalcaemia if there is weakness, tiredness, malaise, anorexia, nausea or vomiting, abdominal pain, constipation, thirst, polyuria, drowsiness, dizziness, personality changes, muscle aches and pains, visual disturbances. Measure urea and electrolytes (especially calcium), creatinine, albumin.

Primary hyperparathyroidism, familial hypercalciuric hypercalcaemia and neoplasia, especially lung and breast (with metastases to bone), account for

over 90% of cases. Other causes include Paget disease, sarcoidosis and milk-alkali syndrome. Investigations include ESR, serum parathyroid hormone (N: 1.0–7 pmol/L), serum ACE levels, serum alkaline phosphatase, chest X-ray, Sestamibi scan and bone scan.

**DxT** weakness + constipation + polyuria → hypercalcaemia

**DxT** cramps + confusion + tetany → hypocalcaemia

## § Primary hyperparathyroidism<sup>10</sup>

Hyperparathyroidism is caused by an excessive secretion of parathyroid hormone and is usually due to a parathyroid adenoma. The classic clinical features of hyperparathyroidism are due to the effects of hypercalcaemia. Rarely, a parathyroid crisis in a misdiagnosed patient may result in death from severe hypercalcaemia.

Classic mnemonic: bones, moans, stones, abdominal groans

### Diagnosis

- Exclusion of other causes of hypercalcaemia
- Serum parathyroid hormone (elevated)
- TC-99m Sestamibi scan to detect tumour

## § Hypocalcaemia<sup>7</sup>

This usually presents with tetany or more generalised neuromuscular hyperexcitability and neuropsychiatric manifestations. The sensory equivalents are paraesthesia in the hands, feet and around the mouth (distinguish from tetany seen in the respiratory alkalosis of hyperventilation). There may be seizures and cramps. The diagnosis is by measurement of serum total calcium concentration in relation to serum albumin (s. calcium <2.10 mmol/L).

Two important signs are:

- Trousseau sign: occlusion of the brachial artery with BP cuff precipitates carpopedal spasm (wrist flexion and fingers drawn together)
- Chvostek sign: tapping over parotid (facial nerve) causes twitching in facial muscles

Treatment involves careful adjustments in dosage of calcitriol and calcium to correct hypocalcaemia and avoid hypercalcaemia and hypercalciuria (the latter may lead to kidney impairment).

## § Hypoparathyroidism

Hypoparathyroidism is the most common cause of hypocalcaemia. Causes include postoperative thyroidectomy and parathyroidectomy, congenital deficiency (DiGeorge syndrome) and idiopathic (autoimmune) hypoparathyroidism. The main features are neuromuscular hyperexcitability, tetany and neuropsychiatric manifestations.

*The spine is an ordered series of bones running down your back. You sit on one end of it, sometimes too hard with ill effect, and your head sits on the other. Poor spine—what a load.*

Anon , 19TH century

Spinal or vertebral dysfunction can be regarded as a masquerade mainly because the importance of the spine as a source of various pain syndromes has not been emphasised in medical training. Practitioners whose training and treatment are focused almost totally on the spine may swing to the other extreme and some may attribute almost every clinical syndrome to dysfunction of spinal segments. The true picture lies somewhere in between.

The diagnosis is straightforward when the patient is able to give a history of a precipitating event such as lifting, twisting the neck or having a motor vehicle accident, and can then localise the pain to the midline of the neck or back. The diagnostic problem arises when the pain is located distally to its source, whether it is radicular (due to pressure on a nerve root) or referred pain. The problem applies particularly to pain in anterior structures of the body.

If a patient has pain anywhere it is possible that it could be spondylogenic and practitioners should always keep this in mind.

The various syndromes caused by spinal dysfunction will be presented in more detail under neck pain, thoracic back pain and lumbar back pain.

## § Cervical spinal dysfunction<sup>1</sup>

The cervical spine is the origin of many confusing clinical problems and syndromes.

### Clinical problems of cervical spinal origin

Pain originating from disorders of the cervical spine is usually, although not always, experienced in the neck. The patient may experience headache, or pain around the ear, face, arm, shoulder, upper anterior or posterior chest.<sup>2</sup>

Possible symptoms:

- neck pain
- neck stiffness
- headache
- 'migraine'-like headache

- facial pain
- arm pain (referred or radicular)
- myelopathy (sensory and motor changes in arms and legs)
- ipsilateral sensory changes of scalp
- ear pain (peri-auricular)
- scapular pain
- anterior chest pain
- torticollis
- dizziness/vertigo
- visual dysfunction

FIGURE 24.1 indicates typical directions of referred pain from the cervical spine. Pain in the arm (brachialgia) is common and tends to cover the shoulder and upper arm as indicated.

If the cervical spine is overlooked as a source of pain (such as in the head, shoulder, arm, upper chest—anterior and posterior—and around the ear or face) the cause of the symptoms will remain masked and mismanagement will follow.

FIGURE 24.1 Possible directions of referred pain from the cervical spine

Dysfunction of the cervical spine can cause many unusual symptoms such as headache and vertigo, a fact that is often not recognised. Despite teaching to the contrary from some, the cervical spine is a common cause of headache, especially dysfunction of the facet joints at the C1–2 and C2–3 levels. The afferent pathways from these levels share a common pathway in the brain stem as the trigeminal nerve, hence the tendency for pain to be referred to the head and the face (see CHAPTER 52).

Manipulation of the cervical spine can be a dramatically effective technique, but it should be used with care and never used in the presence of organic disease and vertebrobasilar insufficiency. It should, therefore, be given only by skilled therapists. Two groups at special risk from quadriplegia are those with rheumatoid arthritis of the neck and Down syndrome, because of the instability of the odontoid process.

However, good results can be achieved by gentler techniques, such as mobilisation and muscle energy therapy (refer CHAPTER 62).

§ Thoracic spinal dysfunction

The most common and difficult masquerades related to spinal dysfunction occur with disorders of the thoracic spine (and also the low cervical spine), which can cause vague aches and pains in the chest, including the anterior chest. This applies particularly to unilateral pain.

Pain in the thoracic spine with referral to various parts of the chest wall and upper abdomen is common in all ages and can closely mimic the symptoms of visceral disease, such as angina pectoris and biliary colic (TABLE 24.1). If a non-cardiac cause of chest pain is excluded, then the possibility of referral from the thoracic spine should be considered in the differential diagnosis.<sup>3</sup> People of all ages can experience thoracic problems and it is surprisingly common in young people, including children.

Pain of thoracic spinal origin may be referred anywhere to the chest wall, but the commonest sites are the scapular region, the paravertebral region 2–5 cm from midline and, anteriorly, over the costochondral region (see FIG. 24.2).

Thoracic pain of lower cervical origin<sup>4</sup>

The clinical association between injury to the lower cervical region and upper thoracic pain is well known, especially with ‘whiplash’ injuries. It should be noted that the C4 dermatome is in close proximity to the T2 dermatome.

Table 24.1 Conditions mimicked by thoracic spinal dysfunction (usually unilateral pain)

Cardiovascular
Acute coronary syndromes
Angina
Pericarditis
Dissecting aneurysm
Chest/respiratory
Pleurisy
Pneumothorax
Carcinoma lung esp. mesothelioma
Pulmonary infarction
Tuberculosis
Fractured rib, esp. cough fracture
Renal
Renal colic
Urinary infection/pyelonephritis
Gastrointestinal
Biliary colic
Appendicitis
Diverticulitis
Others
Herpes zoster
Epidemic pleurodynia (Bornholm disease)
Precordial catch (stitch in side)
Costochondritis
Hernia (symptomatic)
Muscular tears

The T2 dermatome appears to represent the cutaneous areas of the lower cervical segments, as the posterior primary rami of C5, C6, C7, C8 and T1 innervate musculature and have no significant cutaneous innervation.

The pain from the lower cervical spine can also refer pain to the anterior chest, and mimic coronary ischaemic pain. The associated autonomic nervous system disturbance can cause considerable confusion in making the diagnosis.

The medical profession tends to have a blind spot about various pain syndromes in the chest, especially the anterior chest and upper abdomen, caused by the common problem of dysfunction of the thoracic spine. Doctors who gain this insight are amazed at how often they diagnose the cause that previously did not enter their ‘programmed’ medical minds.

Physical therapy to the spine can be dramatically effective when used appropriately. An example of this therapy is shown in FIGURE 24.3 (see also FIG. 37.8 in CHAPTER 37) and for the lumbar spine refer to FIGURES 38.15 and 38.16 in CHAPTER 38. Unfortunately, many

**FIGURE 24.2** Examples of referral patterns for the thoracic spine

of us associate it with quackery. It is devastating for patients to create doubts in their minds about having a 'heart problem' or an 'anxiety neurosis' when the problem is spinal and it can be remedied simply (see **CHAPTER 38**).

### § Lumbar-sacral spinal dysfunction

The association between lumbar dysfunction and pain syndromes is generally easier to correlate. The pain is usually located in the low back and referred to the buttocks or the backs of the lower limbs. Pain manifestations of radiculopathy (sciatica) may follow dermatome patterns (see **FIG. 66.1** in **CHAPTER 66**). Problems arise with referred pain to the pelvic area, groin and anterior aspects of the leg. Such patients may be diagnosed as suffering from inguinal or obturator hernial and nerve entrapment syndromes.

Typical examples of referral and radicular pain patterns from various segments of the spine are presented in **FIGURE 24.4**.

**FIGURE 24.3** Spinal manipulation of mid-thoracic spine in patient with no 'red flags' or serious disease

C = cervical; T = thoracic; L = lumbar; S = sacral

**FIGURE 24.4** Examples of referred and radicular pain patterns from the spine (one side shown for each segment)

*Experience has taught them, as mine has me, that one must listen to reason and agree with Hippocrates, Galen, Avicenna and many others, ancient and modern, that there is no surer way to determine the temperaments and constitutions of people of either sex than to look at the urine.*

Davach de la Riviere (18TH century), *The Mirror of Urines*

Urinary tract infection (UTI) is a common problem affecting all ages and accounts for approximately 1% of all attendances in general practice. It is very common in sexually active women but uncommon in men and children.

Organisms causing UTI in the community are usually sensitive to most of the commonly used antibiotics. The important decision to make is whether to proceed with further investigation of the urinary tract. The morbidity of urinary infections in both children and adults is well known but it is vital to recognise the potential for progressive kidney damage, ending in chronic kidney failure. The main task in the prevention of chronic pyelonephritis is the early identification of patients with additional factors, such as reflux or obstruction, which could lead to progressive kidney damage.

### § UTI as a masquerade

UTI can be regarded as a masquerade when it presents with a constitutional problem or general symptoms, without symptoms suggestive of a urinary infection such as frequency, dysuria and loin pain. This applies particularly to infants and young children and the elderly but is not uncommon in adult women and in pregnancy. Acute UTI may occasionally present as acute abdominal pain.

In infants and children, presenting non-specific symptoms include:

- fever
- lethargy and irritability
- poor feeding
- failure to thrive
- vomiting
- abdominal pain
- diarrhoea

In the elderly:

- confusion
- behaviour disturbance
- fever of undetermined origin

### Key facts and checkpoints

- Screening of asymptomatic women has shown that about 5% have bacterial UTI.<sup>1</sup>
- About 1% of neonates and 1–2% of schoolgirls have asymptomatic bacteriuria.<sup>2</sup>
- About one-third of women have been estimated to have symptoms suggestive of cystitis at some stage of their life.
- The vast majority of these women have anatomically normal kidney tracts, are at no significant risk from the UTI and respond quickly to simple therapy. The prevalence of underlying abnormalities is estimated at around 4%.<sup>3</sup>
- UTIs are largely caused by organisms from the bowel that colonise the perineum and reach the bladder via the urethra. In many young women infections are precipitated by sexual intercourse. Ascending infection accounts for 93% of UTIs.
- Haematogenous infection can occur sometimes, especially with the immunocompromised patient.
- All males and females less than 5 years old presenting with a UTI require investigation for an underlying abnormality of the urinary tract.
- In the presence of a normal urinary tract there is no evidence that UTI leads to progressive kidney damage.
- Always consider any family history of urinary tract abnormalities.
- Infants less than six months old with a UTI have a significant risk of bacteraemia.
- Consider the NSAID tiaprofenic acid as a cause of non-infective cystitis.

### Risk factors

- Female sex
- Sexual intercourse
- Sexually transmitted infection
- Diabetes mellitus

- Diaphragm contraception
- Pregnancy
- Immunosuppression
- Menopause
- Urinary tract obstruction/malformation/stricture
- Instrumentation
- Bladder polyps, carcinoma, diverticula, stones
- Diverticulitis with colo-vesical fistula (? pneumaturia)

## Classification and clinical syndromes

### Sterile pyuria

This is defined as the presence of pus cells but a sterile urine culture.<sup>2</sup> The common causes of sterile pyuria are:

- contamination of poorly collected urine specimens
- urinary infections being treated by antibiotics, i.e. inadequately treated infections
- analgesic nephropathy
- staghorn calculi
- other kidney disorders (e.g. polycystic kidney)
- bladder tumours
- tuberculosis
- chemical cystitis (e.g. cytotoxic therapy)
- appendicitis

### Asymptomatic bacteriuria<sup>4</sup>

This is defined as the presence of a significant growth of bacteria in the urine (concentration  $>10^8$  colony-forming units/L), which has not produced symptoms requiring consultation.<sup>1</sup>

Screening for and treatment of asymptomatic bacteriuria is not recommended except for:

- pregnant women because of the risk of pyelonephritis and pregnancy complications (see CHAPTER 109)
- patients before urological procedures (e.g. TURP)

### Symptomatic bacteriuria

This is defined as the presence of frequency, dysuria and loin pain alone or in combination, together with a significant growth of organisms on urine culture.<sup>2</sup>

The clinical differentiation between cystitis or lower UTI and kidney or upper UTI cannot be made accurately on the basis of symptoms, except in those patients with well-defined loin pain and/or tenderness.

### Acute cystitis (dysuria-frequency syndrome)<sup>1</sup>

- Inflammation of the bladder and/or urethra is associated with dysuria (pain or scalding with micturition) and/or urinary frequency.
- In severe cases, haematuria may be present, and the urine may have an offensive smell.
- Constitutional symptoms are minimal or absent.
- Other causes of dysuria and frequency include urethritis, prostatitis and vulvovaginitis, all of which can normally be distinguished clinically.

### Acute pyelonephritis<sup>1</sup>

- Acute bacterial infection of the kidney produces loin pain and constitutional upset, with fever, rigors, nausea and sometimes vomiting.
- The symptoms of acute cystitis are often also present.
- The differential diagnosis includes causes of the acute abdomen, such as appendicitis, cholecystitis and acute tubal or ovarian diseases. The presence of pyuria and absence of rebound tenderness are helpful in distinction.

The clinical manifestations of UTI are summarised in FIGURE 25.1.

### Uncomplicated urinary tract infection

This is cystitis occurring in the uninstrumented non-pregnant female without structural or neurological abnormalities.

### Complicated urinary tract infection<sup>4</sup>

This is associated with anatomical or functional abnormalities (e.g. diabetes, urinary calculi) that increase the risk of serious complications or treatment failure.

### Urethral syndrome

The urethral syndrome (sometimes termed abacterial cystitis) is that where the patient presents with dysuria and frequency but does not show a positive urine culture.<sup>3</sup>

- 30–40% of adult women with urinary symptoms have this syndrome.<sup>3</sup>
- Many actually have bacterial cystitis but a negative culture.
- The organisms may be anaerobic or fastidious in their culture requirements.
- The organisms may include *Ureaplasma*, *Chlamydia* and viruses.

- The urine may have antiseptic contamination or residual antibiotic.
- The infection may be undergoing spontaneous resolution at the time of the culture.

### Interstitial cystitis<sup>3</sup>

This is an uncommon but important cause of the urethral syndrome.

- The classic symptoms are frequency day and night and a dull suprapubic ache relieved briefly by bladder emptying.
- The feature is small haemorrhages on distension of the bladder.

- Treatment is hydrodistension  $\pm$  a course of tricyclics, for example amitriptyline.

### Laboratory diagnosis

The laboratory diagnosis of UTI depends on careful collection, examination and culture of urine.

### Collection of urine<sup>1</sup>

It is best to collect the first urine passed in the morning, when it is highly concentrated and any bacteria have been incubated in the bladder overnight. Preferably the urine should be taken to the laboratory

#### Symptoms

##### Generalised

- fever
- chills
- sweating
- rigors
- headache
- nausea
- vomiting
- diarrhoea

indicate  
kidney  
infection

#### Upper tract

- pulse
- respiration
- blood pressure

loin tenderness  
? mass

suprapubic tenderness

#### Consider

vaginal examination  
rectal examination (males)

FIGURE 25.1 Clinical manifestations of urinary tract infection

immediately, but it can be stored for up to 24 hours at 4°C to prevent bacterial multiplication.

- **Clean catch midstream specimen of urine (MSU).** This is best collected from a full bladder, to allow at least 100 mL of urine to be passed before collection of the MSU. It is important that the urine flow is continuous, and the container is moved in and out of the stream collecting at least 20 mL.
  - In women, a tampon should first be inserted and the vulva washed with clean water (to avoid contamination with vaginal and vulval organisms). Sit on the toilet and swing one knee to the side as far as possible. The labia are then held apart with the fingers of one hand to prevent contact with the urinary stream while the specimen is collected after passing a small amount of urine into the toilet.
  - In males, the foreskin (if present) is retracted and the glans washed with clean water.
  - In children a midstream clean catch (MCC) is useful (although prone to contamination) especially in the hands of experienced collectors. The parent holds the child over a sterile bowl placed under cleansed genitalia.
- **Catheter specimen of urine (CSU).** In women who have difficulty with collecting an uncontaminated MSU (as is commonly the case in the elderly, the infirm and the grossly obese), a short open-ended catheter can be inserted and a specimen collected after 200 mL has flushed the catheter.
- **Suprapubic aspirate of urine (SPA).** This is an extremely reliable way to detect bacteriuria in neonates and in patients where UTI is suspected but cannot be confirmed because of low colony counts or contamination in an MSU. Under local anaesthetic, a needle (lumbar puncture needle in adults) is inserted into the very full bladder about 1–2 cm above the pubic symphysis, and 20 mL is collected by a syringe. Any organisms in an SPA specimen indicate UTI (see FIG. 25.2).

## Urine specimen collection in children

All children with a first UTI require investigation. It is diagnosed by significant growth on MSU, CSU, MCC or SPA.

- Bag specimen: cannot diagnose UTI
- MSU—usually by 3–4 years when cooperative
- MCC—practical and reliable
- SPA—reliable and the best option
- CSU—for failed SPA or those unable to void on request

FIGURE 25.2 Suprapubic aspiration of urine in a child

## Dipstick testing

Dipstick findings of urinary leucocytes or nitrite are suggestive of UTI and may be an indication for empirical treatment if asymptomatic. The reagents in dipstick testing are generally sensitive but have to be interpreted with care. Leucocyte esterase dipsticks are useful in detecting pyuria and give a good guide to infection with a specificity of 94–98% (2–6% false positive) and 74–96% sensitivity (4–26% false negatives).<sup>5</sup> Positive nitrite dipsticks give a useful guide to the presence of bacteria. Unexplained haematuria detected by dipstick analysis needs investigation.

## Microscopic examination

The urine is examined under a microscope to detect pyuria (more than 10 pus cells—WBCs—per high-powered field) but should be examined in a counting chamber to calculate the number of WBCs/mL of urine. In the counting chamber pyuria is >8000 WBC/mL in phase-contrast microscopy. Pyuria is a very sensitive sign of UTI.

Vaginal squames and debris indicate contamination.

## Culture of the urine

The nature and number of organisms present in the urine are the most useful indicators of UTI.<sup>1</sup>

- Most common are enteric organisms. *Escherichia coli* (especially) and *Staphylococcus saprophyticus* are responsible for over 90% of UTIs, with other Gram-negative organisms (*Klebsiella* sp. and *Proteus* sp.), *enterococci* sp. and Gram-positive cocci (*Streptococcus faecalis* and other staphylococci) also responsible.

- Infections due to organisms other than *E. coli* (e.g. *Pseudomonas* sp.) are suggestive of an underlying kidney tract abnormality.
- If  $>10^5$  colony forming units (cfu) per mL of bacteria are present in an MSU, it is highly likely that the patient has a UTI.
- On the other hand, it is most important to realise that up to 30% of women with acute bacterial cystitis have less than  $10^5$  cfu/mL in the MSU. For this reason, it is reasonable to treat women with dysuria and frequency even if they have  $<10^5$  cfu/mL of organisms in an MSU.

### Summary: MCU (microscopy and culture urine)

Significant levels for UTI:

- Microscopy: WBC  $>10$  per mL ( $10 \times 10^6$ /L)
- Culture: counts  $>10^5$  cfu/mL ( $10^8$ /L)

### Other investigations

- FBE, ESR/CRP, blood culture (if febrile and unwell), consider U&E, PSA (men)

### § Acute uncomplicated cystitis

Advice to women (especially if recurrent attacks):

- Keep yourself rested.
- Drink a lot of fluid: 2–3 cups of water at first and then 1 cup every 30 minutes.
- Try to empty your bladder completely each time.
- Gently wash or wipe your bottom from front to back with soft, moist tissues after opening your bowels (for prevention in recurrent attacks).
- Use analgesics such as paracetamol for pain.
- Make the urine alkaline by taking sodium citrotartrate (4 g orally 6 hourly)—not if taking nitrofurantoin.

### UTI: basic management

- Urine dipstick
- Microculture (clean catch)
- First-line antibiotics—trimethoprim or cephalexin
- Alkaliniser for severe dysuria
- High fluid intake
- Check sensitivity—leave or change ABs
- Repeat MCU within 48 hours after AB course

Consider further investigation (see TABLE 25.1)

**Table 25.1** Investigation of urinary tract infections

Investigations are indicated in:

All children

All males

All women with:

- acute pyelonephritis
- recurrent infections:  $>2$  per year
- confirmed sterile pyuria
- other features of kidney disease, e.g. haematuria

Basic investigations include:

MCU—microscopy and culture (post-treatment)

Kidney function tests: plasma urea and creatinine, eGFR

Intravenous urogram (IVU) and/or ultrasound

Special considerations:

In children: micturating cystogram

In adult males: consider prostatic infection studies if IVU normal

In severe pyelonephritis: ultrasound or IVU (urgent) to exclude obstruction

In pregnant women: ultrasound to exclude obstruction

### Treatment (non-pregnant women)<sup>3</sup>

Multiple dose therapy is preferred to single dose therapy.

Use for 5 days in women (trimethoprim—3 days).

Use for 10 days in women with known urinary tract abnormality:

- trimethoprim 300 mg (o) daily for 3 days (first choice)  
or
- cephalexin 500 mg (o) daily for 5 days  
or
- amoxycillin/+ clavulanate 500/125 mg (o) 12 hourly for 5 days  
or
- nitrofurantoin 50 mg (o) 6 hourly for 5 days  
or
- norfloxacin 400 mg (o) 12 hourly for 3 days (if resistance to above agents proven and if susceptible)

Caution about tendonopathy, including rupture.

Follow-up: MCU 1–2 weeks later.

Note:

- Avoid using important quinolones—norfloxacin or ciprofloxacin—as first-line agents.

- Cotrimoxazole is not first line because it has no advantage over trimethoprim and has more side effects.
- Treatment failures are usually due to a resistant organism or an underlying abnormality of the urinary tract.

### Pregnant women<sup>4</sup>

UTI in pregnant women requires careful surveillance. Asymptomatic bacteriuria should always be excluded during early pregnancy because it tends to be blown into a full infection.

Treatment of acute cystitis (empirical):

- cephalexin 500 mg (o) 12 hourly for 5 days  
*or*
- nitrofurantoin 100 mg (o) 12 hourly for 5 days  
*or*
- amoxycillin + clavulanate 500/125 mg (o) 12 hourly for 5 days

Repeat MCU at least 48 hours after completion. Asymptomatic bacteriuria should be treated with a week-long course. Refer to **CHAPTER 109**.

### Adult males<sup>4</sup>

Consider the cause (see risk factors above).

Investigations: MCU, U&E, ultrasound.

Treatment (empirical, while awaiting investigation):

- trimethoprim 300 mg (o) daily for 14 days  
*or*
- cephalexin 500 mg (o) 12 hourly for 14 days  
*or*
- amoxycillin + clavulanate 500/125 mg (o) 12 hourly for 14 days

*Note:* all males with a UTI should be investigated to exclude an underlying abnormality, e.g. prostatitis, obstruction.

### § Acute pyelonephritis

Mild cases can be treated with oral therapy alone using double the dosage of drugs recommended for uncomplicated cystitis, except for trimethoprim when the same dosage is recommended. Treatment should be continued for 10 days. Ciprofloxacin (500 mg (o) 12 hourly) or norfloxacin (400 mg (o) 12 hourly) is used for 10 days if resistance to these drugs is proven.

For severe infection with suspected septicæmia, admit to hospital and treat initially with parenteral antibiotics for 2 to 5 days after taking urine for microscopy and culture and blood for culture.

- amoxycillin 2 g IV 6 hourly<sup>4</sup>  
*plus*
- gentamicin 4–6 mg/kg/day, single daily IV dose  
Follow with oral therapy for a total of 14 days.

Drug levels of gentamicin require monitoring. Gentamicin can be replaced with IV cefotaxime or ceftriaxone.

All patients should be investigated for an underlying urinary tract abnormality.

### § Recurrent or chronic urinary tract infections

Recurrent infections occur as a relapse of a previously treated infection or because of re-infection, often with differing organisms. Persistent (chronic) UTIs indicate that the organism is resistant to the antimicrobial agents employed or that there is an underlying abnormality such as a kidney stone or a chronically infected prostate in the male patient. Such infections may be treated with prolonged courses of an appropriate antibiotic or removal of the focus of infection.<sup>6</sup>

In men and children, an anatomical abnormality is usual, while recurrent cystitis in women often occurs despite a normal tract. In men, instruction on perineal hygiene, more frequent bladder emptying and post-intercourse voiding may assist in the prevention of re-infection.

### Treatment<sup>4</sup>

A 10- to 14-day course of:

- amoxycillin/potassium clavulanate (500/125 mg) (o) 12 hourly  
*or*
- trimethoprim 300 mg (o) once daily  
*or*
- cephalexin 500 mg (o) 12 hourly  
*or*
- norfloxacin 400 mg (o) 12 hourly (if proven resistance to above agents)

### Prevention including antibiotic prophylaxis<sup>4</sup>

In some female patients with recurrent UTI a single dose of a suitable agent within 2 hours after intercourse is adequate but, in more severe cases, courses may be taken for 3–6 months or on occasions longer. Adult doses given:

- trimethoprim 150 mg (o) nocte  
*or*
- cephalexin 250 mg (o) nocte

or

- norfloxacin 200–400 mg (o) nocte (if proven resistance to others)

### Cranberries

A recent Cochrane review on the use of cranberries (*Vaccinium macrocarpon*) for the prevention of UTI concluded that there was evidence to recommend cranberry juice or tablets for the prevention of recurrent symptomatic UTIs in women, but poor evidence for its use in the treatment of UTI, in the management of asymptomatic bacteriuria, or in the prevention of UTIs in children.<sup>7,8</sup>

An appropriate regimen is 150 mL cranberry juice or one tablet (1:30 parts concentrated juice) twice daily.

### Urinary tract infection in children

By the age of 10 years, about 3% of boys<sup>9</sup> and 10% of girls will have had at least one episode of a urinary tract infection.

UTI in infants and very young children is often kidney in nature and may be associated with generalised symptoms such as fever, vomiting, diarrhoea and failure to thrive. Offensive urine may be noted. Causes of 'smelly' urine in children are urinary infection and/or dehydration especially with gastroenteritis. Symptoms of dysuria and frequency appear only after the age of 2 years when the child is able to indicate the source of the discomfort. In a girl or boy (rare presentation) with symptoms of dysuria and frequency an underlying abnormality is likely to be present with a reported incidence of vesicoureteric reflux (VUR) as high as 40% and scarred kidneys (reflux nephropathy) in 27%.<sup>3</sup>

Thus the early detection of children with VUR and control of recurrent kidney infection could prevent the development of scars, hypertension and chronic kidney failure. Radiological investigation of children with UTIs shows normal kidneys in approximately 66% and reflux in approximately 33%.

It is best to perform the ultrasound first and within the first 3 days for a febrile UTI. A urine specimen is essential before antibiotics are given.

### Guidelines for investigation<sup>10</sup>

- <1 year—ultrasound; consider micturating cystourethrogram (MCUG) if LIS abnormal
  - if both negative, no further investigation

- if abnormal, follow up referral/investigation
- >1 year—ultrasound

The dimercaptosuccinic acid scintigraph scan is the gold standard for diagnosis of kidney scarring and measurement of differential kidney function. It is usually reserved for children with dilating VUR.

### Treatment (mild infection in children)<sup>4,5</sup>

Empirical treatment in children 12 months or more while awaiting culture results.

Treatment should be taken orally for 5 days:

- trimethoprim 4 mg/kg (max. 150 mg) bd (suspension is 50 mg/5 mL)
- or
- cephalexin 12.5 mg/kg (max. 500 mg) bd
- or
- cotrimoxazole 4/20 mg/kg, (max. 160/800 mg) bd
- or
- amoxycillin/potassium clavulanate 12.5/3.1 mg/kg (max. 500/125 mg) orally bd

Norfloxacin and ciprofloxacin should be avoided routinely in children unless required on MCU.

Check MCU in 3 weeks.

### Severe infections in children<sup>4</sup>

For empirical treatment in those ≥12 months who appear septic or are vomiting, and infants <12 months, give gentamicin IV + amoxy/ampicillin IV. Subsequent treatment should be guided by culture results and clinical results with early change to oral therapy.

Duration of therapy: usually 10–14 days.

### Vulvovaginitis in children

Although vulvovaginitis can affect women of any age, it is more prevalent in girls between 2 and 8 years. It can be confused with a UTI where there is dysuria, which is a common symptom from this type of dermatitis (see CHAPTER 107).

### Urinary infections in the elderly

The typical settings in which UTIs occur in the elderly are in the frail, those who are immobilised, and those with faecal incontinence and inadequate bladder emptying. The presenting symptoms may be atypical, especially with upper UTI where fever of undetermined origin and behaviour disturbances may be a feature. In men, obstructive uropathy from prostatism should be excluded by ultrasound.

Uncomplicated infections should be treated the same way as for other age groups but no anti-microbial treatment is recommended for asymptomatic bacteriuria.

### § Genitourinary tuberculosis

The genitourinary tract is involved in 3–5% of cases of tuberculosis.<sup>11</sup> The genital and urinary tracts are often involved together as a result of miliary spread.

The commonest presenting complaints are dysuria and frequency, which can be severe. Other symptoms include strangury when the bladder is severely affected, loin pain and haematuria. Routine urine culture shows sterile pyuria.

Diagnosis is made on specific urine culture for myco-bacterium, or biopsy of bladder lesions or the typical X-ray appearance of distorted calyces and medullary calcification. Treatment is with antituberculosis drugs.

### § Candiduria<sup>4</sup>

The presence of *Candida albicans* in the urine is common. Antifungal therapy is not recommended if associated with indwelling catheters but is recommended if associated with upper UTIs and/or systemic candidiasis.

Use fluconazole 200 mg (o) daily for 7 days.

### § Prostatitis

Consider bacterial prostatitis in men with few urinary symptoms (frequency, urgency and dysuria), flu-like illness, fever, low backache and perineal pain. The prostate is exquisitely tender on rectal examination. For mild to moderate infection, give the same oral antibiotics as for cystitis: amoxycillin + clavulanate 500/125 mg (o) bd for 4–6 weeks. If severe, use amoxy/ampicillin 2 g IV 6 hourly plus gentamicin (see CHAPTER 116).

### Common treatment errors<sup>1</sup>

- Not treating women with dysuria and frequency merely because there are  $<10^5$  cfu/mL in an MCU
- Overtreating women with acute cystitis and normal urinary tracts; single-dose therapy is effective in 70–80% of cases, and overtreatment often leads to vaginal candidiasis or antibiotic-induced diarrhoea
- Using single-dose therapy in patients with known anatomical abnormalities

- Failing to consider chronic prostatic infection in men with recurrent UTI and a normal IVU

### When to refer

- It is wise to refer all patients with urinary tract abnormalities to a nephrologist or urologist for advice on specific management.
- Refer also if the simple methods outlined above do not control recurrent UTI.
- Refer males with urinary infections that are not clearly localised to the prostate.
- Refer patients with impaired kidney function.

### Practice tips

- Most symptomatic UTIs are acute cystitis occurring in sexually active women with anatomically normal urinary tracts.
- A clinical diagnosis based on experience, plus a positive nitrite dipstick test and the finding of pyuria by office microscopy, will generally enable immediate curative treatment.
- A 3-day course of trimethoprim 300 mg daily is a suitable first choice for acute uncomplicated cystitis in women.
- Avoid overinvestigation of patients in whom there is a low likelihood of demonstrating structural abnormalities.
- The ultrasound examination may not detect calculi, small tumours, clubbed calyces and papillary necrosis.
- In males the prostate is the most common source of recurrent UTI.
- UTI is commonly associated with microscopic haematuria (occasionally macroscopic haematuria).
- Persisting haematuria should be investigated.
- Due to the rising level of *E. coli* resistance, amoxycillin is no longer recommended unless susceptibility of the organism is proven.<sup>3</sup>

*Cancers of the tongue and mouth begin with a small hard lump, and sometimes with a little sore; both of which are attended with pricking pains, and they spread in the same manner with cancerous sores in other parts. It is so great an evil, that the slightest suspicion of it occasions very great uneasiness.*

William Heberden (1710–1801)

The terms *malignancy*, *cancer* and *neoplasia* are usually used interchangeably. The differences between a malignant tumour and a benign tumour are summarised in TABLE 26.1.

**Table 26.1** Different characteristics of benign and malignant tumours

Benign	Malignant
Well-differentiated	Undifferentiated
Non-invasive	Invasive
Slow growth	Rapid growth
Not anaplastic	Anaplastic
Not metastatic	Metastatic

Malignant disease accounts for 1 in 8 deaths of people under 35 years in Australia and 3 in every 10 (29%) of deaths in those over 45 years.<sup>1</sup> Cancer is the only major cause of death in Australia that is increasing in both sexes. At current rates about 1 in 3 males and 1 in 4 females will develop a cancer, excluding non-melanoma skin cancers, by the age of 75.<sup>1</sup>

The six most common causes of death from cancer in Australia and the US are cancer of the lung, bowel, breast, prostate, lymphoma and pancreas.

Neoplasia, especially malignancy of the silent areas, can present as undifferentiated illness and be a real masquerade. The so-called 'silent' malignancies that pose a special problem include cancer of the ovary, pancreas, kidney, caecum and ascending colon, liver (hepatoma), melanoma and haematological tissue.

This chapter focuses on the general features of several of these malignancies in order to promote early diagnosis and urgent referral at the primary care level. Specific common cancers are discussed in other chapters.

Acute emergency problems that can develop with various malignancies include spinal cord compression,

malignant effusions, disseminated intravascular coagulation and hypercalcaemia.

## Cancer in children<sup>2,3</sup>

Although uncommon in children under 15 years, cancer is the second most common cause of death in this age group. The most common cancers (in order) are leukaemias, especially acute lymphocytic leukaemia (34%); brain tumours, especially astrocytoma (20%); lymphomas, especially non-Hodgkin (13%); neuroblastoma; Wilms tumour; soft tissue tumours, especially rhabdomyosarcoma; and bone tumours.

Survival has improved dramatically in recent decades, indicating the value of early diagnosis and referral for expert treatment.

Studies have highlighted the importance of GPs responding to concerns of parents even if they could find no abnormality after examination. Parents of children eventually diagnosed with cancer and who were in dispute with their GP were alerted by signs and symptoms which were often vague, non-specific and common, or unusual or 'scary'. They felt that their child 'wasn't right'.<sup>2</sup>

## Clinical manifestations

The clinical manifestations of malignancy are usually due to:

- pressure effects of the growth
- infiltration or metastases in various organs (e.g. liver, brain, lungs, bone, blood vessels)
- systemic symptoms, including paraneoplastic effects

## Systemic symptoms

These can be divided into general non-specific effects and paraneoplastic syndromes, which are the remote effects caused by the tumour.

## Undifferentiated general symptoms

- Tiredness/fatigue/weakness
- Anorexia and nausea
- Weight loss
- Fever
- Thirst (hypercalcaemia)
- Drowsiness (hyponatraemia)

## Paraneoplastic effects

The paraneoplastic effects or syndromes are very important clinically because they may provide an early clue to the presence of a specific type of cancer, in addition to the possible lethal effect of the metabolic or toxic effect (e.g. hyponatraemia). These effects include:

- ectopic hormone production
- skin abnormalities
- metabolic effects: fever/sweats, weight loss/cachexia
- haematological disorders: anaemia, erythrocytosis/polycythemia, coagulation disorder, others
- neuropathies and CNS abnormalities
- collagen vascular disorders
- nephrotic syndrome

A summary of various paraneoplastic syndromes is presented in [TABLE 26.2](#).

**Table 26.2** Paraneoplastic syndromes and associated tumours: more common examples

Hormone excess syndrome	Tumour
Cushing	Lung, kidney, adrenal, thymoma, pancreas
ACTH	Lung, kidney, thymoma, thyroid
Gonadotrophins	Lung, hepatoma, choriocarcinoma
Other syndromes	Tumour
Hypercalcaemia	Lung, breast, kidney, multiple myeloma, prostate, pancreas, adrenal, hepatoma
Fever	Kidney, hepatoma, lymphoma, pancreas, thymoma
Neurologic	Lung, breast, thymoma, Hodgkin, prostate
Coagulopathy	Lung, breast, hepatoma, prostate, pancreas
Thrombophlebitis	Kidney, pancreas, prostate
Polycythaemia	Kidney, hepatoma
Dermatomyositis	Lung, breast, pancreas

## Clinical approach

A history of constitutional symptoms that are often quite undifferentiated (often bizarre) may provide the clue to the possibility of an underlying malignancy. An occupational history may be relevant to the clinical problem (see [TABLE 26.3](#)).

**Table 26.3** Occupational causes of cancer

Agent	Occupation	Cancer
Arsenic	Chemical industry	Lung, skin, liver
Asbestos	Insulation worker	Mesothelioma
Benzene	Glue worker, varnisher	Leukaemia
Radiation	Mining	Various
Soot, coal tar	Chimney sweep	Skin
Ultraviolet light	Farmer, sailor, outdoor worker	Skin
Vinyl chloride	PVC manufacturing	Liver (angiosarcoma)

## Familial cancer

Although the great majority of cancer is not inherited, some individuals carry inherited genetic mutations from conception that predispose them to developing certain cancers, particularly colorectal, breast and ovarian cancers. Refer to [CHAPTER 18](#).

## Tumour markers<sup>4</sup>

A tumour marker is an abnormal characteristic that is specific for a particular type of malignancy (e.g. the Philadelphia chromosome for chronic myeloid leukaemia). Other examples include human chorionic gonadotrophin (HCG) (elevated in trophoblastic tumours and germ cell neoplasms of the testes and ovaries) and the oncofetal antigens—carcinoembryonic antigen (CEA) and alpha-fetoprotein (AFP).

CEA and AFP are not specific markers but are elevated in certain tumours and are very useful in monitoring tumour activity.

Tumour markers have a limited role in diagnosis of malignant disease because several have low sensitivity and specificity. The most valuable are those associated with testis cancer—AFP and beta-HCG. Markers may be an adjunct to diagnosis of certain malignancies, including the rather inaccurate

CEA for bowel cancer and CA-125 for ovarian cancer. These markers are summarised in **TABLE 26.4**.

**Table 26.4** Common tumour markers

Tumour marker	Condition
AFP	Testicular cancer (non-seminomatous)
	Hepatocellular carcinoma
	GI/T cancers with and without liver metastases
CA-125	Ovarian cancer (non-mucinous), breast
CA-15-3	Breast
CA-19-9	Pancreas, colon, ovary
CEA	Colorectal cancer
	Pancreatic, breast, lung, small intestine, stomach, ovaries
PSA*	Prostate cancer
hCG	Choriocarcinoma
	Hydatidiform mole
	Trophoblastic diseases
α-microglobulin	Multiple myeloma, some lymphomas

\* PSA = prostate-specific antigen

## § Lung cancer

Apart from non-melanoma skin cancer, lung cancer is the most common cancer in Australia in terms of both incidence and death, accounting for at least 20% of cancer deaths.<sup>1</sup> In the US it accounts for 28% of cancer deaths in men and 24% of deaths in women. Only 10–25% are asymptomatic at the time of diagnosis but lung cancer can cause an extraordinary variety of clinical symptoms and signs with a reputation for several paraneoplastic syndromes. Refer to **CHAPTER 42** and **CHAPTER 49**.

The paraneoplastic syndromes include hypercalcaemia, Cushing syndrome, carcinoid syndrome, dermatomyositis, visual loss progressing to blindness from retinal degeneration, cerebellar degeneration and encephalitis.

The presentation of cough and chest pain renders it less of an 'occult' malignancy than several other types.

**DxT** malaise + weight loss + cough → lung cancer

## Kidney tumours

The most important tumours of the kidney are adenocarcinoma (80% of all kidney tumours)<sup>3</sup> and nephroblastoma (Wilms tumour).

## § Kidney cell cancer

Kidney cell cancer (adenocarcinoma, hypernephroma) has a great diversity of presenting symptoms, including:

- general symptoms of neoplasia e.g. malaise, FUO
- haematuria (60%)
- loin pain (40%)
- loin mass (palpable kidney)
- signs of anaemia
- left supraclavicular lymphadenopathy
- varicocele (left side)
- hypertension
- symptoms of metastases (to liver, lungs, brain, bones): respiratory symptoms, neurological symptoms and signs, bone pain, pathological fracture (vertebral collapse)
- urinalysis—67% positive for blood

Diagnosis is confirmed by imaging e.g. CT MRI.

Refer for radical nephrectomy.

The classic triad of symptoms, although in a small percentage of patients, is as follows.

**DxT** haematuria + loin pain + palpable kidney mass → kidney cell cancer

## § Wilms tumour (nephroblastoma)

Wilms tumour is responsible for 10% of all childhood malignancies. Clinical features include:<sup>3</sup>

- peak incidence 2–3 years
- general symptoms of neoplasia
- palpable mass 80%
- abdominal pain 30%
- haematuria 25%

Diagnosis is confirmed by urine cytology, ultrasound or CT/MRI scan.

Early diagnosis with nephrectomy and chemotherapy leads to a very favourable prognosis (90% 5-year survival).

**DxT** haematuria + abdominal mass + malaise → Wilms tumour

## § Neuroblastoma<sup>5</sup>

Probably the most common cancer in infancy (usually <2–3 years). 90% present under 5 years. It is a tumour of the adrenal medulla (50%) and sympathetic nervous system, especially retroperitoneal neural tissue in abdomen (30%) but also in chest and neck.

First symptoms often vague:

- fatigue, anorexia, nausea, fever
- abdominal pain, abdominal swelling
- anaemia and weight loss

May present with metastases e.g. bone pain.

Diagnosis: CT scan, skeletal survey; biopsy required.

Treatment is based on surgical resection then chemotherapy ± localised radiotherapy. Good response to therapy especially if <18 months.

## § Ovarian cancer<sup>6</sup>

Ovarian cancer has the highest mortality rate of all the gynaecological cancers because the majority of patients present in the late stage of the disease. It is responsible for 5% of deaths in females. It is usually asymptomatic prior to the development of metastases. Epithelial tumours are the most common of malignant ovarian tumours. They are uncommon under 40 years of age and the average age of diagnosis is 50 years.

The most common presentation is abdominal swelling (mass and/or ascites), abdominal bloating or discomfort. Non-specific symptoms, which may be present for a long time before diagnosis, include abnormal uterine bleeding, urinary frequency, weight loss, abdominal discomfort, reduced capacity for food, diarrhoea, anorexia, nausea and vomiting (refer to CHAPTER 103).

Diagnosis is supported by pelvic ultrasound and serum CA-125 tumour marker. A new test is the OvPlex™ serum test, which measures five serum markers.

**DxT** abdominal discomfort + anorexia + abdominal bloating/distension → ovarian cancer

## § Carcinoma of caecum and ascending colon<sup>4</sup>

Malignancy in this area is more likely to present with symptoms of anaemia without the patient noting obvious blood in the faeces or alteration of bowel habit. Refer to CHAPTER 41.

**DxT** blood in stools + abdominal discomfort + change in bowel habit → colon cancer

## § Pancreatic cancer

This is another cancer with vague symptoms, metastasising early and late presentation. It is mainly ductal adenocarcinoma, which, if in the head of the pancreas, presents with painless jaundice and if in the body and/or tail presents with epigastric pain radiating to the back, relieved by sitting forward (refer to CHAPTER 58).

**DxT** jaundice + anorexia + abdominal discomfort/pain → pancreatic cancer

## The leukaemias<sup>7</sup>

The leukaemias are caused by an acquired malignant transformation in the stem cell in the haemopoietic system. Acute leukaemia has a rapidly fatal course if untreated, while chronic leukaemia has a variable chronic course with an inevitable fatal outcome. See FIGURE 26.1. The main features of each type are as follows.

The usual age range for acute lymphatic leukaemia (ALL) is 2–10 years with a second peak at about

FIGURE 26.1 Clinical features of a child with leukaemia<sup>6</sup>

40 years. The median age of presentation of acute myeloid leukaemia (AML) is 55–60 years.

## § Acute leukaemia

### Symptoms

- General constitutional (e.g. malaise)
- Symptoms of anaemia
- Susceptibility to infection (e.g. sore throat, mouth ulceration, chest infection)
- Easy bruising and bleeding (e.g. epistaxis, gingival bleeding)
- Bone pain (notably in children with ALL) and joint pain
- Symptoms due to infiltration of tissues with blast cells (e.g. gingival hypertrophy in AML)

**DxT** malaise + pallor + bone pain → ALL  
**DxT** malaise + pallor + oral problems → AML

### Signs

- Pallor of anaemia
- Petechiae, bruising
- Gum hypertrophy/gingivitis/stomatitis
- Signs of infection
- Variable enlargement of liver, spleen and lymph nodes
- Bone tenderness, especially sternum

### Diagnosis

- FBE and film: normochromic/normocytic anaemia; pancytopenia with circulatory blast cells; platelets: usually reduced
- Bone marrow examination
- PCR studies
- Cytogenetics

Treatment: chemotherapy, immunotherapy, stem cell therapy.

*Note:* As a rule, relapse of acute leukaemia means imminent death unless bone marrow transplantation is successful. The mean 5-year survival rate for childhood ALL is about 75–80%, for adult ALL 30%; for AML it varies with age with poorer survival, about 20%, over 55 years of age.

## § Chronic myeloid leukaemia (CML)

### Clinical features

- A disorder of middle age, typically 40–60 years
- Insidious onset

- Constitutional symptoms: malaise, weight loss, fever, night sweats
- Symptoms of anaemia
- Splenomegaly (very large); abdominal discomfort
- Priapism
- Gout
- Markedly elevated white cell count (granulocytes)
- Marked left shift in myeloid series
- Presence of Philadelphia chromosome

**DxT** fatigue + fever/night sweats + abdominal fullness (splenomegaly) → CML

## § Chronic lymphocytic leukaemia (CLL)

### Clinical features

- A disorder of late middle age and elderly
- Insidious onset
- Constitutional symptoms: malaise, weight loss, fever, night sweats
- Lymphadenopathy (large rubbery nodes)—neck, axilla, groin (80%)
- Moderately enlarged spleen and liver (about 50%)
- Mild anaemia
- Lymphocytosis  $>15 \times 10^9/L$
- 'Mature' appearance of lymphocytes
- Consider cytogenetics

*Note:* Most cases require no specific therapy but observation.

**DxT** fatigue + weight loss + fever/night sweats + lymphadenopathy → CLL

## THE LYMPHOMAS<sup>4</sup>

Lymphomas, which are malignant tumours of lymphoid tissue, are classified as Hodgkin lymphoma and non-Hodgkin lymphoma on the basis of histological appearance of the involved lymph tissue.

## § Hodgkin lymphoma

### Clinical features

- Painless (rubbery) lymphadenopathy, especially cervical nodes
- Constitutional symptoms (e.g. malaise, weakness, weight loss)
- Fever and drenching night sweats—undulant (Pel–Ebstein) fever

- Pruritus
- Alcohol-induced pain in any enlarged lymph nodes
- Possible enlarged spleen and liver

Diagnosis is by lymph node biopsy with histological confirmation. Other tests: FBE, CXR, CT/MRI (to stage), bone marrow biopsy, functional isotopic scanning. Staging is by using Ann Arbor nomenclature (IA to IVB). Treatment includes chemotherapy, immunotherapy and radiotherapy.

**DxT** malaise + fever/night sweats + pruritus  
→ Hodgkin lymphoma

## § Non-Hodgkin lymphomas

Non-Hodgkin lymphomas are a heterogeneous group of cancers of lymphocytes derived from the malignant clones of B or T cells.

### Clinical features

- Painless lymphadenopathy—localised or widespread
- Constitutional symptoms possible, especially sweating
- Pruritus is uncommon
- Extra nodal sites of disease (e.g. CNS, bone, skin, GIT)
- Possible enlarged liver and spleen
- Possible nodular infiltration of skin (e.g. mycosis fungoides)

Diagnosis is by lymph node biopsy.  
CXR and CT abdomen to stage.

**DxT** malaise + fever/night sweats + lymphadenopathy → non-Hodgkin lymphoma

## § Multiple myeloma

Multiple myeloma is a clonal malignancy of the differentiated  $\beta$  lymphocyte—the plasma cell. It is regarded as a disease of the elderly, the mean age of presentation being 65 years.<sup>8</sup> It is asymptomatic in 20% of patients. The classic presenting triad in an older person is anaemia, back pain and elevated ESR which helps to differentiate it from monoclonal gammopathy of uncertain significance (MGUS).

Other investigations include serum protein electrophoresis and immunofixation, Sestamibi scan.

### Clinical features

- Bone pain (e.g. backache)—in more than 80% of patients
- Bone tenderness e.g. femur, ribs, spine
- Weakness, tiredness
- Weight loss
- Recurrent infections e.g. chest infection
- Symptoms of anaemia
- Bleeding tendency
- Replacement of bone marrow by malignant plasma cells
- Kidney failure
- Associated with amyloidosis

**DxT** weakness + unexplained back pain + susceptibility to infection → multiple myeloma

### Diagnosis

Diagnostic criteria comprise the presence of:<sup>6</sup>

- paraprotein in serum (on electrophoresis)
- Bence–Jones protein in urine
- bony lytic lesions on skeletal survey

Treatment is with chemotherapy including thalidomide or lenalidomide: 5-year median survival.

## § MGUS

Monoclonal gammopathy of undetermined significance (MGUS) involves the production of paraprotein (M protein) by non-cancerous cells in the absence of other clinical manifestations of multiple myeloma. It is associated with various disorders. MGUS is usually asymptomatic but peripheral neuropathy can occur. No chemotherapy treatment is recommended.

## § Carcinoid syndrome

Hormone secretion by carcinoid cells causes the characteristic carcinoid syndrome long before local growth or metastatic spread of the tumour is apparent (80% metastasise). Most carcinoid tumours are asymptomatic.

### Clinical features

- Classic triad: skin flushing (especially face), diarrhoea (with abdominal cramps), valvular heart disease
- Other possible features: wheezing, telangiectasia, hypotension, cyanosis
- Sites of tumours: appendix/ileum, stomach, bronchi

## Diagnosis

- 24 hour urine 5-hydroxyindoleacetic acid
- plasma chromogranin A/hepatic ultrasound

## Polycythaemia vera

This is a malignant proliferation of RBCs and also WBCs and platelets.

## Clinical features

- Older person
- Fatigue
- Headache, dizziness, tinnitus
- Pruritus after hot bath, shower
- Epistaxis
- Facial plethora
- Splenomegaly
- Thrombosis

## Investigations

- FBE and haematocrit
- Bone marrow biopsy
- Genetic mutations—JAK2 mutation

## Potentially curable malignant tumours

Several tumours are curable by chemotherapy even in the advanced stage. Such tumours are as follows.

## Haematological tumours

- Some lymphomas
- Hodgkin lymphoma
- Acute lymphatic leukaemia
- Acute myeloid leukaemia

## Solid tumours

- Choriocarcinoma
- Testicular teratoma
- Neuroblastoma
- Wilms tumour (nephroblastoma)
- Burkitt tumour
- Embryonal rhabdomyosarcoma

## Tumours curable by adjuvant chemotherapy

- Breast cancer (especially up to stage 2)
- Osteogenic cancer
- Soft tissue cancer
- Colorectal cancer

## Survival rates

Common cancers and their 5-year survival rates over a 15-year period (1982–2007) have been published by

the Cancer Council Victoria (see TABLE 9.3, CHAPTER 9, and TABLE 26.5, below). These show improving trends for many cancers. The lowest survival rate was for mesothelioma at 4%.

**Table 26.5** Common cancers and their 5-year survival rates<sup>9</sup> (a collation of surveys)

Cancer	%
Testicular	98
Melanoma	91
Thyroid	92
Hodgkin lymphoma	86
Breast	89
Uterus	84
Prostate	89
Bladder	51
Non-Hodgkin lymphoma	69
Colon	63
Ovary	41
Stomach	25
Lung	12
Liver	10
Pancreas	5

## Metastatic tumours

It is very helpful for the practitioner to have a working knowledge of possible primary sources of tumour when metastatic lesions are detected in various organs.

Common sites of metastatic presentation are the lymph nodes, liver, lung, mediastinum and bone. Other sites include the brain, bone marrow, peritoneum, retroperitoneum, skin and the spinal cord.

These important sites (listed below) are followed by likely primary sources with the most likely listed first.

- *Bone.* Breast, prostate, lung, Hodgkin lymphoma, kidney, thyroid, melanoma
- *Brain.* Breast, lung, colon, lymphoma, kidney, melanoma, prostate
- *Liver.* Colon, pancreas, liver, stomach, breast, lung, melanoma
- *Lung and mediastinum.* Breast, lung, colon, kidney, testes, cervix/uterus, Hodgkin lymphoma, melanoma

- **Lymph nodes:**
  - *High cervical.* Hodgkin lymphoma, lymphoma, squamous cell carcinoma, oropharynx, nasopharynx
  - *Low cervical.* Lung, stomach, lymphoma, Hodgkin lymphoma, oropharynx, larynx, skin, tongue
  - *Axillary.* Breast, lung, lymphoma
  - *Inguinal.* Lymphoma, ovary, uterus, vulva, prostate, skin
- **Retroperitoneum.** Lymphoma, Hodgkin lymphoma, ovary, uterus, testes, prostate
- **Skin.** Lung, colon, melanoma, Kaposi sarcoma

It is important to keep in mind those malignancies that are potentially curable and refer as soon as possible.

## Cancer with an unknown primary

Cancer without a clear primary source is present in about 5% of all cases. If the diagnosis cannot be made on the history, physical examination and baseline tests, then the key to excluding treatable primaries is adequate immunohistological staining on a tissue biopsy. It is worth referring for investigation as these could be treatable primaries. Adenocarcinoma is common in 40% resulting from lung and pancreatic cancer. Poorly differentiated neoplasms include lymphoma, melanoma and sarcoma. The mean survival time in patients with an unknown primary is 6 months.<sup>10</sup>

## Prevention

Preventive measures for malignant disease are addressed in more detail in **CHAPTER 9**. The significant decrease in deaths from cancer of the stomach in this country in recent years is probably reflected in our improved diet with more fresh fruit and vegetables. Important preventive measures include an appropriate healthy diet, no smoking, sun protection, HPV vaccination and perhaps safe sex measures. Of concern is the rapid increase in the incidence of prostate cancer, chronic myeloid leukaemia, myeloma and non-Hodgkin lymphoma and adenocarcinoma of the oesophagus.

### Triads to consider

**DxT** anorexia + weight loss + jaundice (± epigastric pain) → pancreatic cancer

**DxT** fatigue + dysphagia + weight loss → oesophageal cancer

**DxT** anorexia + dyspepsia + weight loss → stomach cancer

**DxT** headache + a/n/v + ataxia → medulloblastoma (children)

**DxT** fever + malaise (extreme) + a/n/v (± anaemia) → neuroblastoma

**DxT** mental dysfunction + vomiting + (waking) headache → cerebral tumour (late)

**DxT** indrawn eye + small pupil + ptosis (± anhydrosis) → Horner syndrome (? lung cancer)

W Somerset Maugham (1874–1965), *Of Human Bondage*

## § HIV: a modern masquerade

HIV, the cause of the well-known AIDS, can rightly be included as one of the clinical masquerades of modern medicine. Public health measures in the Western world have limited the spread of the infection. By contrast, the incidence in Africa and Asia continues to rise at an alarming rate. The World Health Organization estimated that in 2010,<sup>1</sup> 34 million adults and children were living with HIV, including 23 million in sub-Saharan Africa and 25 000 in Australia, with 2.7 million newly infected and increasing, while 1.8 million people with HIV died. In 2012, the average age of people newly diagnosed with HIV infection was 37 years and about 86% were male; most infections are in men who have sex with men (MSM). The conversion rate of HIV to AIDS has been 33% but it is improving with antiretroviral therapy (ART), which has dramatically changed people's lives. HIV is now a chronic disease management problem. The introduction of combination treatment with the protease inhibitors in November 1995 changed the previously understood natural history of the disease.

The benefit of early diagnosis has become even more impressive since the discovery that HIV is not a latent infection throughout most of its course. Soon after initial infection, an explosive replication of HIV occurs, which is brought under control by the immune system in 6 to 8 weeks as the host-versus-virus interaction reaches an active and dynamic equilibrium. This dynamic situation continues throughout a person's lifetime, with as many as 10 billion new viroids produced and up to 2 billion CD<sub>4</sub> lymphocytes destroyed and replaced daily. Clinical immunodeficiency develops when the body's ability to replace CD<sub>4</sub> cells is finally exhausted, resulting in further uncontrolled viral replication. Viral load assays based on molecular techniques have revolutionised our understanding of the natural history of HIV disease. These advances make it imperative to make the diagnosis early in the course

of the disease in order to start combination treatment to lessen the viral load.

The management of HIV infection is a specialised field but the GP is central in prevention, diagnosis, counselling, monitoring and shared management of HIV disease. The GP must be alert to the benefits of early diagnosis as summarised in [TABLE 27.1](#).

**Table 27.1** The benefits of early HIV diagnosis

To individual patients
Prolongation of the asymptomatic period
Delayed disease progression
Prevention of opportunistic infections
Optimal maintenance of health through patient education and counselling
Cures are only likely with early intervention
To the cohort of HIV-positive individuals
Monitoring of advances in treatment
Increased participation in research and clinical trials
Development of new services to meet changing patient needs
To the community
Documentation of changes in epidemiology
Reduced high-risk activities
Contact tracing
Control of HIV transmission
To the doctors
Time to influence the course of disease
Time to counsel the patient

## Key facts and checkpoints

- HIV is a retrovirus with two known strains that cause a similar spectrum of syndromes: HIV-1 and HIV-2 (mainly confined to West Africa). It infects T-helper cells bearing the CD<sub>4</sub> receptor.
- Always consider HIV in those at risk: enquire about history of STIs, injection of illicit drugs, past blood transfusions, sexual activities and partners.
- About 50% of patients develop an acute infective illness similar to glandular fever within weeks of acquiring the virus (the HIV seroconversion illness).<sup>1</sup> The main features are fever, lymphadenopathy, lethargy and possibly sore throat, and a generalised rash.
- If these patients have a negative infectious mononucleosis test, perform an HIV antibody test, which may have to be repeated in 4 weeks or so if negative.
- Patients invariably recover to enter a long period of good health for 5 years or more.<sup>2</sup>
- The so-called 'set point' is where the plasma viral load drops to a steady level for many years.
- *Pneumocystis jiroveci* (ex *carinii*) pneumonia (PJP) is the commonest presentation of AIDS.
- Approximately 15–40% of HIV-positive children are infected from HIV-infected mothers.<sup>3</sup>
- Infants born to these mothers may develop the disease within a few months, with 30% affected by the age of 18 months.
- The time for the onset of AIDS in HIV-affected adults varies from 2 months to 20 years or longer; the median time is around 10 years.
- In family practice the most common presentation of HIV-related illness is seen in the skin/oral mucosa, for example, candidiasis and herpes.<sup>4</sup>
- TB is a common, serious but treatable complication of HIV.
- HIV antibody testing is a two-stage process: the antigen–antibody test for screening followed by another method (e.g. Western blot) if positive.
- New rapid HIV tests or point of care HIV tests will overcome barriers, including delays to diagnosis.
- The seroconversion period from acquiring HIV infection to a positive antibody test varies between individuals: this period is known as the 'window period'.
- All HIV-infected patients require regular monitoring for immune function and viral load. The viral load test monitors viral activity.
- The level of immune depletion is best measured by the CD<sub>4</sub> positive T-lymphocyte (helper T-cell) count—the CD<sub>4</sub> cell count. The cut-off points for good health (asymptomatic) and severe disease

appear to be 500 cells/ $\mu$ L and 200 cells/ $\mu$ L respectively.<sup>2</sup>

- Most patients with AIDS will need lifelong<sup>1</sup> daily medication with a combination of antiretroviral drugs.

## Occurrence and transmission

HIV can be isolated from blood, tissues, semen, saliva, breast milk, cervical and vaginal secretions and tears of infected persons. HIV is transmitted in semen, blood and vaginal fluids, transplanted organs and breast milk through:

- unprotected sexual intercourse (anal or vaginal) and in rare cases oral sex with an infected person
- infected blood entering the body (through blood transfusion or by IV drug users sharing needles/syringes)
- needle-stick injury
- artificial insemination, organ transplantation
- infected mothers (to babies during pregnancy, at birth or in breast milk)

Infection with HIV can occur via the vagina, rectum or open cuts and sores, including any on the lips or in the mouth. Social (non-sexual) contact and insect vectors have not been implicated in transmission.

## Stages<sup>5</sup>

The clinical stages of HIV disease are summarised in TABLE 27.2.<sup>6</sup>

## Acute (seroconversion) illness

At least 50% of patients have an acute illness associated with seroconversion. The illness usually occurs within 6 weeks of infection and is characterised by fever, night sweats, malaise, severe lethargy, anorexia, nausea, myalgia, arthralgia, headache, photophobia, sore throat, diarrhoea, lymphadenopathy, generalised maculoerythematous rash and thrombocytopenia. The main symptoms are headache, photophobia and malaise/fatigue. Neurological manifestations, including meningoencephalitis and peripheral neuritis can occur. Acute HIV infection should be considered in the differential diagnosis of illnesses resembling glandular fever. This illness, which resembles infectious mononucleosis, is self-limiting and usually resolves within 1 to 3 weeks. However, chronic lethargy, depression and irritability may persist after the acute illness. Non-specific viraemic sequelae such as mucosal ulceration, desquamation, exacerbation of seborrhoea and recurrences of herpes simplex may occur (see FIG. 27.1).

**Table 27.2** Clinical stages of HIV disease<sup>6</sup>

Clinical stage	Common clinical features	CD <sub>4</sub> count
<b>Seroconversion illness</b> (self-limited 1–3 weeks)	Fever, headache (may have aseptic meningitis), sore throat, maculopapular rash, lymphadenopathy, splenomegaly Atypical lymphocytes on FBE cells	Transient decrease, commonly followed by a return to near-normal levels
<b>Asymptomatic</b>	Headaches Persistent generalised lymphadenopathy	Usually >500 cells/ $\mu$ L Gradual decrease of 50–80 cells/ $\mu$ L
<b>Symptomatic—early</b>	Oral and vaginal candidiasis, oral hairy leukoplakia, seborrhoeic dermatitis, psoriasis, recurrent varicella zoster infection, cervical dysplasia, unexplained fever, sweats, weight loss, diarrhoea, tuberculosis	Usually 150–500 cells/ $\mu$ L
<b>Symptomatic—late</b>	PJP, Kaposi sarcoma, oesophageal candidiasis, cerebral toxoplasmosis, lymphoma, HIV-1 associated dementia complex, cryptococcal meningitis	Usually <150 cells/ $\mu$ L
<b>Advanced</b>	CMV retinitis, cerebral lymphoma, <i>Mycobacterium avium</i> complex (MAC) infection	Usually <50 cells/ $\mu$ L

Reproduced with permission<sup>6</sup>

Acute illness may be accompanied by neutropenia, lymphopenia, thrombocytopenia, and mildly elevated ESR and serum transaminases. During recovery lymphocytosis may occur with appearance of atypical mononuclear cells and an inversion of the CD<sub>4</sub><sup>+</sup>:CD<sub>8</sub><sup>+</sup> ratio due to elevation of CD<sub>8</sub><sup>+</sup> cells. It is seronegative for EBV.

Differential diagnoses are given in **TABLE 27.3**.

**Table 27.3** Differential diagnoses of primary HIV infection

Epstein–Barr mononucleosis

Syphilis: secondary

TORCH organisms:

- toxoplasmosis
- rubella
- CMV (especially)
- herpes simplex

Disseminated gonococcal infection

Hepatitis A, B, C, D or E

Influenza

Other virus infections

### Subsequent stage

After the acute illness, HIV disease passes into an asymptomatic stage of variable time, up to several years.

Later constitutional symptoms develop along with minor opportunistic infections such as oral candidiasis, herpes simplex and herpes zoster. This early symptomatic stage is referred to as AIDS-related complex and is regarded as a prodromal to AIDS.

### AIDS-defining conditions

The original US Centers for Disease Control (CDC) classification has been modified with time to provide a more simplified scheme for defining AIDS. The HIV/AIDS case surveillance system simply specifies a list of clinical conditions associated with the late stages of HIV infection as being ‘AIDS-defining’.<sup>7</sup>

The AIDS-defining conditions are:

- candidiasis of bronchi, trachea or lungs
- candidiasis, oesophageal
- cervical cancer, invasive
- coccidioidomycosis, disseminated or extrapulmonary
- cryptococcosis, extrapulmonary
- cryptosporidiosis, chronic intestinal (>1 month’s duration)
- cytomegalovirus (CMV) disease (other than liver, spleen, or nodes)
- CMV retinitis (with loss of vision)
- encephalopathy, HIV-related

**DxT** fever + severe malaise + lymphadenopathy → acute HIV

- herpes simplex virus (HSV): chronic ulcer(s) (>1 month's duration); or bronchitis, pneumonitis or oesophagitis
- histoplasmosis, disseminated or extrapulmonary
- isosporiasis, chronic intestinal (>1 month's duration)
- Kaposi sarcoma
- lymphoma, Burkitt (or equivalent term)
- lymphoma, immunoblastic (or equivalent term)
- lymphoma, primary, of brain
- *Mycobacterium avium* complex of *M. kansasii*, disseminated or extrapulmonary
- *Mycobacterium tuberculosis*, any site (pulmonary or extrapulmonary)
- *Mycobacterium*, other species or unidentified species, disseminated or extrapulmonary
- *Pneumocystis jiroveci* pneumonia (PJP)

- *Salmonella* septicaemia, recurrent
- toxoplasmosis of brain
- wasting syndrome due to HIV

The Australian AIDS surveillance case definition does not refer to the CD<sub>4</sub> cell count although in the US AIDS is also defined by a CD<sub>4</sub> cell count of <200/μL, regardless of clinical condition. At levels below this, people will become increasingly vulnerable to AIDS-defining conditions.

### Clinical features

There is a multiplicity of clinical findings in HIV infection (see FIG. 27.1).

#### Fever

- Usually this is of unknown origin.

#### General

fever  
night sweats  
lethargy/malaise  
anorexia  
pharyngitis  
arthralgia  
myalgia  
lymphadenopathy

#### Neuropathic

cognitive/affective impairment  
headache  
photophobia  
meningoencephalitis  
radiculopathy  
brachial neuritis  
peripheral neuropathy  
Guillain-Barré syndrome

#### Dermatopathic

maculopapular rash  
roseola-like rash  
alopecia  
urticaria (diffuse)  
desquamation  
herpes simplex reactivation  
herpes zoster

#### Gastrointestinal

oral candidiasis  
nausea/vomiting  
diarrhoea  
mucocutaneous ulceration

#### Laboratory tests

WCC ↓  
Platelets ↓  
ESR ↑ (slight)  
s. transaminases ↑  
HIV -ve  
recovery phase:  
lymphocytosis  
atypical mononucleosis  
inversion CD<sub>4</sub> : CD<sub>8</sub> ratio  
3–12 weeks later  
HIV +ve

FIGURE 27.1 Possible clinical features of primary HIV infection

## Weight loss

- Usually severe and muscle wasting

## Respiratory

- Sinusitis
- Non-productive cough, increasing dyspnoea and fever: due to opportunistic pneumonias

More than 50% of patients present with PJP which may have an abrupt or insidious onset.<sup>6</sup> With the insidious type of onset, examination and chest X-ray are often normal early. Many other agents (e.g. CMV, cryptococcosis and TB) can be responsible. Exclusion of PJP is important as this condition carries a high mortality if untreated.<sup>6</sup>

### Practice tip

Severe PJP can have little or no chest signs, and, unless treated, patients can rapidly deteriorate and die.

## Gastrointestinal

- Chronic diarrhoea (many causes) with weight loss or dehydration

## Neurological

- Headache
- Progressive dementia (HIV encephalopathy)
- Ataxia due to myelopathy
- Seizures
- Mononeuritis
- Guillain-Barré type mononeuropathy
- Toxoplasma encephalitis
- Cryptococcal meningitis
- Peripheral neuropathy
- Progressive visual loss (CMV retinitis)
- CNS lymphoma

## Oral cavity

- Aphthous ulcers
- Angular cheilitis
- Periodontal/gingival disease
- Tonsillitis
- Oral candidiasis
- Oral hairy cell leukoplakia (frequently mistaken for candidiasis but affects lateral border of tongue)

## Genitourinary

- Cervical dysplasia
- Vaginal candidiasis
- Various STIs (e.g. HSV, HPV)

**FIGURE 27.2** Kaposi sarcoma of the skin on the face of a man with AIDS

Photo courtesy Hugh Newton-John

## Skin

- Impetigo
- Warts
- HSV
- Shingles, especially multidermatomal
- Seborrhoeic dermatitis
- Cutaneous mycoses
- Kaposi sarcoma (painless red-purple lesions on any part of the body including palms, soles, oral cavity and other parts of the GIT) (see FIG. 27.2).

**FIGURE 27.3** presents the chronology of HIV—induced disease correlated with time since infection and CD<sub>4</sub> cell levels.

## Investigations and diagnosis<sup>6</sup>

The laboratory investigation of AIDS covers three broad areas:

- 1 Tests for HIV infection:
  - antigen-antibody test or HIV rapid test
  - western blot technique (used for confirmation)
- 2 Tests of immune function:
  - CD<sub>4</sub> lymphocyte counts—the strongest predictor of possible clinical manifestations of HIV infection
  - low CD<sub>4</sub> cells (counts <500 cells/μL) = defective cell immunity<sup>2,4</sup> <200 cells/μL = severe deficiency
  - counts <200 cells/μL = severe immunodeficiency
- 3 Viral load: a measure of the serum level of RNA of the HIV virus—correlates with response to treatment and progression to AIDS and death
- 4 Tests for opportunistic infections and other problems: (e.g. other STIs, EBV, CMV, hepatitis, Mantoux test)

FIGURE 27.3 Chronology of HIV-induced disease correlated with time since infection

## Management

Patients with HIV infection require considerable psychosocial support, counselling and regular assessment from a non-judgmental, caring practitioner.

## The holistic approach

Most people with HIV infection will take ‘natural therapies’. This should be viewed as being complementary to the management suggested by the GP, and the patient should be encouraged to tell his or her doctors of the alternative medicines being taken. Anecdotal reports suggest that 75% of people with HIV regularly use ‘natural therapies’,<sup>8</sup> and in the setting of the long-term nature of the condition it is important for doctors to be supportive and create a climate of acceptance around these practices.

Positive lifestyle factors include:

- a very healthy balanced diet: high fruit and vegetable intake, pure fruit juices, high fibre, low fat, high complex carbohydrates
- toxic avoidance: processed foods, caffeine, illicit drugs, alcohol, cigarettes
- relaxation and meditation (reduction and self-monitoring of stress levels)

- appropriate sleep and exercise
- consider supplementary antioxidants
- support groups and continuing counselling

## Treatment (medication)<sup>8,9,10</sup>

Optimal antiretroviral therapy (ART) now depends on the use of combinations of drugs. Monotherapy is no longer accepted practice. The recommendations for the use of antiretroviral therapy are constantly changing. Updated guidelines can be found on the internet at <www.hivatis.org>, <www.bhiva.org>, <www.ashm.org.au> or <www.aidsinfo.nih.gov/guidelines>. Viral resistance is the limiting factor, no matter how potent an individual drug may be at reducing viral load initially. The trials of combined zidovudine and lamivudine demonstrated both a more sustained decrease in plasma viral load than either drug did alone, and a more delayed development of viral resistance. There are now many antiretroviral drugs available for use in Australia (see TABLE 27.4) and clinicians have a much wider scope of treatments available. However, many questions remain about combination therapy and further trials using viral load as a clinical endpoint should provide pointers for treatment. Currently

**Table 27.4** Currently available antiretroviral drugs<sup>9</sup>

≠ a CCR5 antagonist

the use of three drugs, referred to as highly active antiretroviral therapy (HAART), is favoured. There are many possible combinations. Side effects, which are often severe—including cardiovascular disease—and affect the quality of life, remain a problem. Resistance to HAART is now a problem. Effective (90%) results have been achieved with TRIO (etravirine, darunavir and raltegravir) therapy.<sup>11</sup> Subcutaneous injections of interleukin-2 have been shown to boost immunity.

### When to start<sup>1,12</sup>

This is a controversial issue. CD<sub>4</sub> cell count guidelines:

- < 350 µL—treat with ART
- 350–500 µL—strongly consider, offer or closely monitor

Current thinking favours early treatment. The most widely used and preferred regimen consists of 2 NTIs plus either an NNRI or a protease inhibitor<sup>9</sup> e.g. emtricitabine + tenofovir + efavirenz.

CAUTION: be aware of:

- drug interactions <www.hiv-druginteractions.org>
- contraindicated drug combinations (eTG complete, Internet. Melbourne: Therapeutic Guideline Ltd. *Antibiotics*)<sup>9</sup>
- adverse effects<sup>9</sup>
- opportunistic infections

### HAART (highly active antiretroviral therapy)

This is a combination of three (or more) agents with one or more penetrating the blood–brain barrier.

### *Pneumocystis jiroveci*<sup>9</sup>

This is an important cause of pneumonia and not usually seen until the CD<sub>4</sub><sup>+</sup> cell count is <200/µL.

It is usually treated with trimethoprim + sulfamethoxazole (cotrimoxazole) oral or IV for 21 days depending on severity, which is also given orally as prophylaxis when the cell count reaches <200. Alternative agents are IV pentamidine or oral dapsone, clindamycin and atovaquone.

### Acute HIV Infection

Treatment of seroconversion illness is not of proven clinical benefit (to date) but is optional and some clinics offer it.

### Post-exposure prophylaxis (PEP)

Undertake a risk assessment: PEP is not recommended for low-risk cases but those with significant high risk should be considered for PEP. Refer to 'Needle-stick and sharps injuries' for protocol (see CHAPTER 134).

## The HIV test: the role of the family doctor<sup>13</sup>

The astute GP will use the opportunity of a request for an HIV test to explore preventive and sexual health issues. A full sexual history and drug history must incorporate the 'three Cs' of counselling, confidentiality and consent in the pre-test interview.

Many HIV-positive patients have described how the results left them bewildered and devastated, especially with an unexpected positive result. Part of the reason given was the lack of any form of pre-test counselling. Ideally, management involves shared care with an expert consultant, with whom close liaison is essential.

## Initial consultation

- First establish why the patient is presenting 'now' for the test.
- Explore the 'hidden component' of the patient's consultation.
- Take a full sexual, medical and drug-taking history. It is recognised that this can be embarrassing for both the doctor and the patient, but those experienced in this process advise the following approach:
  - Establish a supportive, non-judgmental atmosphere. Encourage disclosure of history and patterns of partners and sexual practices in a gender-neutral situation. Make no assumptions about sexual preferences; they will be indicated by the patient as the history evolves, provided you allow this to happen; this will take time.
- Non-judgmental, matter-of-fact questions such as 'Have you injected yourself with drugs?' and (to a male patient) 'Do you have sex with men or women or both?' may permit honest disclosure.
- Stress the importance of disclosure of prior, known infections with STIs. Assess the patient's risk for an STI.
- Assess the patient's coping strategies and social network.

## Pre-test counselling

- Give information on the test (what it tells and does not tell).
- Explain about the false negative and 'window period'.
- Give appropriate information about HIV disease and other STIs.
- Dispel any myths about transmission of infection.
- Give preventive advice on safer practices (sex and IV drugs).
- Assess the possible coping mechanisms of the patient.
- Assess the patient's social support networks and interpersonal bonds.
- Reassure about confidentiality. This is a legal requirement.
- Discuss who to tell: informing sexual contacts.
- Offer tests other than STIs.

Finally:

- Discuss how the patient will cope with the test result.

- Discuss legal requirements (check with state laws).
- Advise of need for informed consent (not only for HIV test but other STIs).
- Make arrangements to discuss the test results face to face.

Consider the useful question: 'How would your behaviour change, if at all, as a result of having this test today?'

## Test result (about 2 weeks later)

This must be given in consultation (whether positive or negative): avoid the telephone.

### The negative test result

- Provide reassurance.
- Emphasise the safe sex information.
- Counter any suggestion that current risk-taking behaviour is safe.
- Retest if in high-risk category or known HIV contact or in a 'window period' of 12 weeks.
- A test in 3 months helps rule out recent acquisition.
- Maintain confidentiality.

### The positive test result

This is a very traumatic experience and good communication skills are essential. The result should be stated clearly. Good pre-test history taking, risk assessment and counselling will make the task of informing the patient of a positive test result a lot easier. Being able to inform the patient of an improved prognosis due to combination drug therapy is also of assistance in breaking the news. Be warm and open. Many patients want to be touched for reassurance. The words 'you are not dying' can be firmly stated a few times. Educate the patient about the difference between HIV infection and the acquired immunodeficiency syndrome. Discuss with the patient to whom he or she is going to tell the result and help the patient decide on the most supportive friend. Ask the patient what he or she is going to do after the consultation and make an appointment for the next day. Give the patient an HIV support line number for overnight telephone support if required. Discuss the issue of contact tracing briefly and in more depth at the next consultation, because sexual contacts should be notified. However, avoid an information overload.

Start immediate post-test counselling and education. Emphasise that an HIV-positive status does not equal AIDS and need not lead to it in the short term. Organise a consultant's appointment and provide sound patient education material.

## Interview and full clinical assessment

- Assessment of general health. Assess risk factors for cardiovascular disease and diabetes since ART can increase the overall risk at least two-fold.<sup>14</sup>
- Particular assessment of prior psychiatric history and confirm prior STIs and drugs
- Evidence of EBV (glandular fever), hepatitis B, HIV illness (acute seroconversion illness)
- Further counselling and discussion of specific problems
- Assessment of bonds and relationships with regard to support

## Examination—to set a base level

- Full examination, skin, CNS—especially fundi, chest, abdomen and genitals; urine and lung function test
- Monitor temperature and weight

## Blood tests—to set a base level and check immune status

- Repeat HIV antibody test (if any possibility of error)
- CD<sub>4</sub> cells with FBE and a differential WCC
- Viral load test
- G-6-PD screen for enzyme deficiency
- Serology for syphilis (RPR), hepatitis A, B and C (very important), toxoplasmosis, CMV
- Test for gonorrhoea and *Chlamydia*, herpes and thrush (if indicated)
- Mantoux test for tuberculosis

Encourage a holistic approach to health maintenance and enhancement. Explore the patient's feelings, anxieties, fears and confidentiality concerns. Reinforce safer practices.

## The second post-positive result consultation

- Give results of repeat HIV test and baseline tests.
- Explore patient's understanding, feelings, coping abilities and spiritual issues (if appropriate).
- Some of the common questions that patients with HIV infection ask are:
  - Am I going to get sick?
  - How long will I live for?
  - Are there any treatments available?
  - Is there a cure around the corner?
  - What is going to happen to me?
  - Should I tell my friends?
  - Should I tell my family?
  - What are the social and legal issues?

It is worth pre-empting these questions and having ready appropriate answers for that particular patient.

- Give appropriate reassurance: prognosis may be much better, in respect of long remission, than appreciated.
- Discuss support systems.
- Check personal prophylaxis (safer sex and needle-sharing habits).
- Reinforce lifestyle strategies and suggest how patients can help themselves: give case examples.
- Recommend meditation and appropriate literature.
- Provide appropriate referrals (if needed): specialist counsellors, self-help and support groups, meditation classes.
- Advise patients about their legal and ethical responsibilities not to pass on the infection to others.
- Organise contact tracing.
- Address the difficult issue of telling sexual partners.
- If the patient is unwilling to inform sexual partners or is uncertain of who they may be, then contact-tracing organisations run through state government offices are of assistance in tracing sexual partners who may be at risk.
- If a patient refuses to inform a sexual partner of the risk, then the doctor may disclose this information to the patient's partner in the following circumstances: if there is a clear risk of transmission; if the patient has been given education and counselling and this has been ignored; or if the doctor in the case has sought advice from colleagues and institutional ethics committee and before disclosure discussed it with the medical defence organisation. The doctor then should provide the patient with written advice that the patient must notify the partner, and if the patient still refuses to do so then the doctor has the right to do so.
- Discuss 'safer sex' guidelines. Condom usage is essential to prevent further viral loading and this needs to be explained, as well as the reason of protecting others.
- Advise on the importance of compliance with medication. There is rapid rebound of the virus when ART is stopped.
- Different criteria are used to guide treatment of children.

## Continuing maintenance consultations

- Provide appropriate support, encouragement and counselling.

- Frequency depends on CD<sub>4</sub> cell count (e.g. 3 to 6 monthly).
- Examination:
  - Check general condition, temperature and weight.
  - Look for unusual lung infection, diarrhoea, skin lesions, tongue and oropharynx, fevers, wasting and neurological signs.
  - Examine for signs of CMV retinitis (at risk if CD<sub>4</sub> count <100 cells/μL).
  - Monitor for depressive illness.
  - Look for early signs of AIDS-related dementia.
- Tests: CD<sub>4</sub> cell count and syphilis serology; viral load test; chest X-ray and induced sputum (if cough, shortness of breath), faeces microculture if diarrhoea persists, *Candida* mouth swabs and herpes swabs appropriately.
- Treat intercurrent illness.
- Prophylaxis—this is managed according to immune status: if CD<sub>4</sub> count <200 cells/μL use cotrimoxazole to prevent opportunistic infections, particularly PJP.

## Contact tracing

Contacts of HIV-positive patients should be traced and offered testing with counselling.<sup>5</sup> Patients with HIV infection must be advised of the risk they pose to

**Table 27.5** Red flags for HIV infection

Cell count 200–250 μL or less

seronegative sexual partners. A person who has HIV or is at risk of HIV infection must not make any blood, semen or tissue donation. Because of the probable association between genital ulcerative disease and HIV transmission, the effective management of STIs is part of the general strategy for HIV control.

## Prevention of HIV infection

### Counselling the person at risk regarding 'safer practices'

No effective vaccine has been developed. Modification of behaviour is the only valid strategy for prevention of HIV infection. Education programs to encourage sexual practices that reduce the exchange of genital secretions (safe sex) may achieve risk reduction for sexually active individuals. Condoms provide a barrier if used properly and consistently but may be too easily damaged to offer reliable protection during anal intercourse. A water-based lubricant such as K-Y gel or Lubafax should be used: oil-based lubricants such as Vaseline weaken condoms.

Discuss alternative sex practices, including touching, cuddling, body-to-body rubbing and mutual masturbation.

Emphasise the importance of being in control with drug taking, IV usage, safe sex practices and the needle-exchange program.

Of special importance is the finding that the most important biological risk factor for HIV transmission is the presence of other active STIs in either partner. This includes chlamydia, gonorrhoea, syphilis and genital herpes. Herpes is also likely to increase the risk of HIV transmission during both homosexual and heterosexual intercourse, even in the presence of condoms.<sup>13,14,15</sup>

## Health professionals

Care should be exercised whenever blood samples are taken or sharps have been used. Advise safe disposal of sharps and other disposables and appropriate sterilisation of material. Gloves should be worn for all invasive procedures. Management of needle-stick injuries and other at-risk exposures is described in CHAPTER 134. Blood donors need to be carefully screened.

## Community education

Educating the community in a non-emotional, responsible way about AIDS should be a priority.

While the personal, community and global benefits of effective AIDS education are generally acknowledged, the fear of addressing such a sensitive issue sometimes results in failure to act.<sup>14,15</sup> AIDS education in schools in particular can be an important strategy. People with HIV infection would be appropriate resource educators and the use of videos would be a most appropriate medium for education.

### When to refer<sup>16</sup>

Most patients with HIV disease need referral to a specialist or clinic that can manage the patient expertly and sympathetically.

Referral should take place at the time of:

- onset of a life-threatening opportunistic infection
- the need to initiate antiretroviral drug therapy
- administration of prophylactic pentamidine therapy
- serious psychological problems related to HIV-positive status

*It is certainly a one-sided opinion—even though generally adopted at the moment—that all infectious agents which are still unknown must be bacteria. Why should not other microorganisms just as well be able to exist as parasites in the body of animals?*

Robert Koch (1843–1910), *Zur Unter suchun g vo n Path o genen Org anismen* (1881)

Almost any infection, especially if subacute or insidious in its onset, can be baffling and can belong to the ‘fever of undetermined origin’ group of infections. Syphilis and tuberculosis were the great mimics of the past. Now malaria and Epstein–Barr mononucleosis (EBM) can be regarded as important mimics. EBM (Epstein–Barr mononucleosis, infectious mononucleosis, glandular fever) can be a perennial baffler and can be confused with HIV infection in its primary clinical phase. Any of the febrile diseases can be confusing before declaring themselves with classic symptoms such as the jaundice of hepatitis or the rash of dengue fever, or before serological tests become positive.

Viral and protozoal infections that can present as masquerades include:

- HIV infection (especially primary)
- EBV
- TORCH organisms: toxoplasmosis, rubella, CMV, HSV
- hepatitis A, B, C, D, E
- mosquito-borne infections: malaria, dengue fever, yellow fever/other haemorrhagic fevers, Japanese encephalitis, Ross River fever, West Nile fever

The TORCH organisms (TORCH being an acronym for toxoplasmosis, rubella, CMV and herpes) are well known for their adverse intra-uterine effects on the fetus. Three are viral (toxoplasmosis is a protozoan) and the first three of these fetal pathogens are acquired by passage across the placenta. Most of these organisms are noted for being opportunistic infections in immunocompromised patients, especially in later stage HIV infection.

The mosquito-borne infections causing encephalitis and haemorrhagic fevers are mainly viral, apart from the protozoan causing malaria, and are of particular significance in travellers returning from endemic areas (refer to [CHAPTER 15](#)).

The major protozoal diseases of humans are:

- blood: malaria, trypanosomiasis
- GIT: giardiasis, amoebiasis, cryptosporidium
- tissues: toxoplasmosis, leishmaniasis, babesiosis

Most of the world’s serious protozoal infections—malaria, African trypanosomiasis, leishmaniasis, amoebiasis—occur in tropical areas and are listed and explained in [CHAPTER 15](#).

## Four similar clinical presentations

Four infections—EBV, primary HIV, CMV and toxoplasmosis—produce almost identical clinical presentations and tend to be diagnosed as glandular fever or pseudoglandular fever. It is important for the first contact practitioner to consider all four possibilities, especially keeping in mind the possibility of HIV infection.

A worthwhile approach is to make a provisional diagnosis based on the clinical variations as presented in [TABLE 28.1](#).

Screening tests are:

- FBE, especially WCC
- EBV-specific antibodies
- serological test for CMV (specific antibodies)
- serological test for toxoplasmosis (specific antibodies—acute and convalescent)
- HIV antibody test (ELISA)
- NAAT (PCR) testing

## § Epstein–Barr mononucleosis

EBM is a febrile illness caused by the herpes (Epstein–Barr) virus. It can mimic diseases such as HIV primary infection, streptococcal tonsillitis, viral hepatitis and acute lymphatic leukaemia. There are three forms: the febrile, the anginose (with sore throat, see [FIG. 28.1](#)) and the glandular (with lymphadenopathy).

It may occur at any age but usually between 10 and 35 years; it is commonest in 15–25 years age group.

**Table 28.1** Clinical features differentiating HIV, EBV, CMV and toxoplasmosis infections (all can present with a similar illness)

Feature	EBV infection	HIV infection	CMV infection	Toxoplasmosis
<b>Onset</b>	Insidious	Acute	Insidious	Insidious or acute
<b>Fever</b>	A feature Intermittent	A feature	Quotidian (afternoon spikes)	Low grade
<b>Fatigue/malaise</b>	Common	Common, severe	Common	Common
<b>Tonsillar hypertrophy</b>	Common	Mild enlargement	Uncommon	Uncommon
<b>Exudative pharyngitis</b>	Common	Rare	Rare	Occurs
<b>Mucocutaneous ulcers</b>	Rare	Common	Unknown	Unknown
<b>Skin rash</b>	About 5%	Common	About 5%	About 10%
<b>Jaundice</b>	About 8%	Rare	Uncommon	Uncommon
<b>Diarrhoea</b>	Unknown	Occurs	Unknown	Unknown
<b>Cervical lymphadenopathy</b>	Common	Common	Uncommon	Common (a feature)
<b>Hepatomegaly</b>	About 8%	Rare	Common	Occasional
<b>Splenomegaly</b>	About 50%	Rare	About 50%	Up to 30%
<b>Atypical lymphocytes</b>	In 80–90%	In <50%	Common	Uncommon

**FIGURE 28.1** Tonsillitis of Epstein–Barr mononucleosis. This is often confused with bacterial tonsillitis.

### Occurrence and transmission

EBM has an annual incidence of 4–5 new cases in a population of 2500.<sup>1</sup> It usually affects people in their late teenage years or early 20s. It is endemic in most countries, affecting over 95% of the adult population worldwide. Subclinical infection is common in young children. The incubation period is at least 1 month but data are insufficient to define it accurately.

EBV is excreted in oropharyngeal secretions during the illness and for some months (sometimes years) after the clinical infection. EBM has a low infectivity and isolation is not necessary. It is apparently transmitted only by close contact, such as kissing and sharing drinking vessels.

Progress of the primary infection is checked partly by specific antibodies (which might prevent cell-to-cell spread of the virus) and partly by a cellular immune response, involving cytotoxic T-cells, which eliminates the infected cells. This response accounts for the clinical picture. The virus is never eliminated from the body.

Second attacks and fatalities do occur and there is a possible association between EBM and lymphoma.<sup>3</sup>

### Clinical features

The typical clinical features are presented in **TABLE 28.2** and **FIGURE 28.2**.

**DxT** sore throat + fever + lymphadenopathy  
→ EBM

### The rash

The rash of EBM is almost always related to antibiotics given for tonsillitis. The primary rash, most often non-specific, pinkish and maculopapular (similar to that of rubella), occurs in about 5% of cases only.

The secondary rash is most often precipitated by one of the penicillins, especially ampicillin or amoxycillin. About 90–100% of patients prescribed ampicillin or amoxycillin will be affected; up to 50% of those given penicillin will develop the rash. It can be extensive and sometimes has a purplish tinge (see **FIG. 28.3**).

**Table 28.2** Clinical features of EBM<sup>1,2</sup>**Symptoms**

Slow onset malaise 1–6 weeks  
 Fever  
 Myalgia  
 Headaches, anorexia  
 Blocked nose—mouth breathing  
 Nasal quality to voice  
 Sore throat (85%)  
 Nausea ± vomiting  
 Rash—primary 5%  
 Dyspepsia

**Clinical findings**

Exudative pharyngitis (84%)  
 Petechiae of palate (not pathognomonic) (11%)  
 Lymphadenopathy, especially posterior cervical  
 Rash—maculopapular  
 Splenomegaly (50%)  
 Jaundice ± hepatomegaly (5–10%)  
 Clinical or biochemical evidence of hepatitis

The complications of EBM are presented in **TABLE 28.3** and the differential diagnoses in **TABLE 28.4**.

**Diagnosis**

The following laboratory tests confirm the diagnosis of EBM:

- WCC shows absolute lymphocytosis.

**Typical symptoms**

- fever
- headache
- malaise
- nausea/vomiting
- nasal blockage
- sore throat
- myalgia

**FIGURE 28.2** Clinical features of Epstein-Barr mononucleosis

- Blood film shows atypical lymphocytes.
- Paul-Bunnell or Monospot test for heterophil antibody is positive (although positivity can be delayed or absent in 10% of cases).
- Diagnosis confirmed (if necessary) by EBV-specific antibodies, viral capsule antigen (VCA) antibodies—IgM, IgG and EB nuclear antigen (EBN-A).

Culture for EBV and tests for specific viral antibodies are not done routinely.

False positives for the Paul-Bunnell test are:

- hepatitis
- Hodgkin lymphoma
- acute leukaemia

**Prognosis**

EBM usually runs an uncomplicated course over 6–8 weeks. Major symptoms subside within 2–3 weeks. Patients should be advised to take about 4 weeks off work.

**Treatment**

- Supportive measures (no specific treatment)
- Rest (the best treatment) during the acute stage, preferably at home and indoors
- NSAIDs or paracetamol to relieve discomfort

**FIGURE 28.3** Typical purplish maculopapular rash of EBM precipitated by ampicillin prescribed for the acute tonsillitis of EBM

**Table 28.3** Complications of EBM<sup>1</sup>

Common
Antibiotic-induced skin rash
Prolonged debility
Hepatitis
Depression
Rare
Cardiac:
• myocarditis
• pericarditis
Haematological:
• agranulocytosis
• haemolytic anaemia
• thrombocytopenia
Respiratory tract:
• upper airway obstruction (lymphoid hypertrophy)
Miscellaneous:
• ruptured spleen
Neurological:
• cranial nerve palsies, especially facial palsy
• Guillain-Barré syndrome
• meningoencephalitis
• transverse myelitis

- Gargle soluble aspirin or 30% glucose to soothe the throat
- Advise against alcohol, fatty foods, continued activity, especially contact sports (risk of splenic rupture)
- Ensure adequate hydration
- Corticosteroids reserved for: neurological involvement, thrombocytopenia, threatened airway obstruction. Not recommended for uncomplicated cases

### Post-EBM malaise

Some young adults remain debilitated and depressed for some months. Lassitude and malaise may extend up to a year or so.

## § Cytomegalovirus infection

CMV has a worldwide distribution and causes infections that are generally asymptomatic. The virus (human herpes virus 5) may be cultured from various sites of healthy individuals. It has its most severe effects in the immunocompromised, especially those with AIDS, and also in recipients of solid organ transplants and bone marrow grafts; 90% of AIDS patients are infected with CMV and 95% have

**Table 28.4** Differential diagnoses of EBM<sup>1</sup>

Other agents that cause typical EBM syndrome
• HIV infection (acute initial illness)
• CMV
• toxoplasmosis
Exudative tonsillitis resembling EBM
• acute streptococcal pharyngitis
• adenovirus infection
• diphtheria (unlikely in Australia)
Hepatitis A, B, C, D, E
Lymphadenopathy, fever and splenomegaly
• lymphoma
• leukaemia
Complications of EBM without other manifestations
• encephalitis
Others
• drug reaction
• influenza

disseminated CMV at autopsy. CMV infection can be an important development following massive blood transfusion, including those given to infants. The incubation period of CMV ranges from 20 to 60 days and the illness generally lasts about 2 to 6 weeks.<sup>2</sup>

### Clinical features

Three important clinical manifestations are described.

- 1 *Perinatal disease*  
Intrauterine infection may cause serious abnormalities in the fetus, including CNS involvement (microcephaly, hearing defects, motor disturbances), jaundice, hepatosplenomegaly, haemolytic anaemia and thrombocytopenia. Up to 30% of CMV-affected infants have mental retardation<sup>3</sup> (see CHAPTER 109).
- 2 *Acquired CMV infection*  
In healthy adults, CMV produces an illness similar to EBM with fever, malaise, arthralgia and myalgia, generalised lymphadenopathy and hepatomegaly. However, cervical lymphadenopathy and exudative pharyngitis are rare.

The infection may be spread by blood transfusion, and CMV should be suspected on clinical grounds in a patient with a febrile illness resembling EBM following major surgery, such as open heart surgery or kidney transplantation, and where extensive transfusion has been necessary.

**FIGURE 28.4** Cytomegalovirus infection: typical quotidian intermittent fever pattern

The fever often manifests as quotidian intermittent fever spiking to a maximum in the mid-afternoon and falling to normal each day (see [FIG. 28.4](#)). There is often a relative lymphocytosis with atypical lymphocytes but the heterophil antibody test is negative. Liver function tests are often abnormal.

**Diagnosis:** Specific diagnosis can be made by demonstrating rising antibody titres from acute and convalescent (2 weeks) sera. A four-fold increase indicates recent infection. PCR testing can be used. The virus can be isolated from the urine and blood.

- 3 *CMV disease in the immunocompromised host*  
Disseminated CMV infection occurs in the immune-deficient person, notably HIV infection causing opportunistic severe pneumonia, retinitis (a feature of AIDS), encephalitis and diffuse involvement of the gastrointestinal tract.

### Treatment

In the patient with normal immunity no treatment apart from supportive measures is required, as the infection is usually self-limiting. In immunosuppressed patients various antiviral drugs, such as ganciclovir, foscarnet and fomivirsen (intraocular) have been used with some benefit.<sup>4</sup>

### § Toxoplasmosis

Toxoplasmosis, which is caused by *Toxoplasma gondii*, an obligate intracellular protozoan, is a worldwide, albeit rare, infection. The definitive host in its life cycle is the cat (or pig or sheep) and the human is an intermediate host. However, clinical toxoplasmosis is very uncommon. Infection in humans usually occurs through eating foodstuffs contaminated by infected cat faeces. Its main clinical importance is an opportunistic infection.

The five major clinical forms of toxoplasmosis are:<sup>5</sup>

- 1 asymptomatic lymphadenopathy (the commonest)
- 2 lymphadenopathy with a febrile illness, similar to EBM
- 3 acute primary infection: a febrile illness similar to acute leukaemia or EBM; a rash, myocarditis, pneumonitis, chorioretinitis and hepatosplenomegaly can occur
- 4 neurological abnormalities—includes headache and neck stiffness, sore throat and myalgia
- 5 congenital toxoplasmosis—this is a rare problem but if it occurs it typically causes CNS involvement and has a poor prognosis

In the immunocompromised, clinical forms 3 and 4 are typical features with meningoencephalitis being a serious development.

### Diagnosis

Diagnosis is by serological tests (to show a four-fold rise in antibodies), which are sensitive and reliable.

### Treatment

Patients with a mild illness or with asymptomatic infection require no treatment. Children under 5 years may be treated to avoid the possible occurrence of chorioretinitis. Symptomatic patients are treated with pyrimethamine plus sulphadiazine. Clindamycin is usually used in pregnant patients.

## Viral respiratory infections

Life-threatening viral respiratory infections include the virulent influenza viruses such as avian (bird) influenza and swine influenza and severe acute respiratory distress syndrome (SARS). These conditions are presented in [CHAPTER 49](#).

### Ross River fever

Mosquito-borne infections have devastating consequences in tropical regions (see [CHAPTER 15](#)), while others cause less morbidity and include Ross River fever.

Epidemic polyarthritides of Ross River virus, which is an alpha virus, occurs in all states of Australia. It is most prevalent in mosquito-prone areas (especially during the summer) and in tropical and temperate coastal regions and inland riverine areas.<sup>6</sup> Subclinical infection is common with variable clinical manifestations.

### Clinical features

- All age groups, especially 20–30 years
- Incubation period 3–21 days (usually 7–11)

### Symptoms (major)

- Polyarthrititis (75% of patients)—mainly fingers, wrists, feet, ankles and knees
- Maculopapular rash—widespread, often ‘subtle’, mainly trunk and limbs
- Myalgia

**DxT** polyarthrititis + fever + rash → Ross River fever

### Other symptoms

- Pyrexia (mild)
- Headache
- Nausea
- Fatigue with exercise

Signs (which may be present) include joint swelling (mainly hands and feet), tenosynovitis around the wrists and ankles (poor prognostic sign), the rash and mild lymphadenopathy.

### Outcome

In many patients the illness resolves within 2 to 6 weeks and most feel normal within 3 months, but some with a more severe arthritis can enter a chronic phase lasting 18 months or more. Depression is a common sequela.

### Diagnosis

Diagnosis is by antibody testing of serum. The differential diagnosis includes other viral infections that cause arthritis, such as hepatitis B, rubella, Barmah Forest virus (a mosquito-borne virus) and dengue, and early rheumatoid arthritis and rheumatic fever.

Barmah Forest virus, which is common in Australia, has a similar clinical presentation but is less severe.<sup>7</sup>

### Treatment

Treatment is symptomatic with bed rest and simple analgesics such as aspirin. NSAIDs are used for more severe cases. Oral corticosteroids are effective but should be avoided if possible.

### Deadly infections (worldwide)

The WHO, in its 1996 and 2011 reports,<sup>8</sup> estimated that the leading cause of approximately 50 million deaths in the world was infectious diseases, which accounted for about one-third or 17 million deaths. Other figures included diseases of the circulatory system (15 million deaths, including ischaemic heart disease—7.7 million—and stroke—6.2 million) and cancer (6 million deaths, approximately 12%).

The reports indicated that nearly 50 000 people are dying every day from infectious diseases such as cholera, hepatitis B, malaria, tuberculosis and HIV (see TABLE 28.5). At least 30 new infections have emerged in the past 20 years, and for many of them there is no treatment, cure or vaccine. These include some infections causing infant diarrhoea, *Legionella pneumophila*, *Lyme borreliosis* (Lyme disease), the Hantaan virus (which can cause a fatal haemorrhagic fever), HIV and hepatitis E and C.

The reports also said that until recently the struggle for control over infectious diseases had seemed almost over, with smallpox eradicated and six other diseases, including polio, leprosy and guinea-worm disease, singled out for eradication within a few years. A pleasing improvement occurred in measles and neonatal tetanus. However, half the world's 6 billion people were at risk of many infectious diseases, since many that seemed under control such as tuberculosis and malaria were becoming more prevalent. Some, such as yellow fever and cholera, were striking in new regions. Other infections were resistant to drugs and virtually untreatable. The previously almost forgotten infections such as *Yersinia* (the plague) had re-emerged.

The deadly haemorrhagic fevers that have broken out in isolated endemics include the zoonotic African diseases—Ebola haemorrhagic fever, Marburg haemorrhagic fever and Lassa fever. These are caused by filoviruses and for most no specific treatment is available.

**Table 28.5** The world's deadliest infectious diseases

	Infectious disease	Cause	Annual deaths
1	Acute lower respiratory infections (mostly pneumonia)	Bacterial or viral	3 400 000 (approx. 3.1 million children)
2	Diarrhoeal diseases	Bacterial or viral	1 900 000
3	HIV/AIDS*	Viral	1 800 000
4	Tuberculosis	Bacterial	1 400 000
5	Malaria	Protozoal	1 000 000
Other significant infections			
6	Hepatitis B	Viral	
7	Measles	Viral	
8	Neonatal tetanus	Bacterial	
9	Pertussis	Bacterial	
10	Intestinal worm disease		

Source: World Health Organization 1996 and 2011\* figures

Other deadly viruses include rabies (a rhabdo virus; see CHAPTER 15); the paramyxoviruses—Hanta (RNA) virus, which causes haemorrhagic and pulmonary complications; the henipavirus family, which are naturally harboured in fruit bats and include Hendra virus, Nipah virus and Cedar virus.

Another serious infection that emerged sporadically was the so-called ‘flesh eating’ *Streptococcus A* infection, which was a particularly virulent strain causing localised destruction of soft tissue.

West Nile encephalitis caused by a mosquito-transmitted virus and carried by birds has surfaced in the US and beyond, causing thousands of cases and hundreds of deaths.

The lessons to be learned include careful surveillance, attention to prevention, especially with effective immunisation programs, rational antibiotic prescribing and care with travelling to developing tropical countries.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Glandular fever
- Hepatitis B

- Hepatitis C
- Influenza
- Malaria
- Pertussis

*In its beginning the malady is easier to cure but difficult to detect, but later it becomes easy to detect but difficult to cure.*

Niccolò Machiavelli (1469–1527), *On Tuberculosis*

Bacterial infections can present diagnostic brain-teasers, and a high index of suspicion is needed to pinpoint the diagnosis. Many are rarely encountered, thus making diagnosis more difficult yet demanding vigilance and clinical flexibility.

The list includes:

- tuberculosis
- infective endocarditis
- syphilis
- septicaemia
- the zoonoses (e.g. brucellosis, Lyme disease)
- clostridial infections: tetanus, gas gangrene, puerperal infection, botulism, pseudomembranous colitis
- hidden suppuration: abscess, osteomyelitis
- mycoplasma infections: atypical pneumonia
- *Chlamydia* infections: psittacosis, non-specific arthritis, pelvic inflammatory disease, trachoma, atypical pneumonia
- legionnaire disease
- Hansen disease

*Chlamydia* and rickettsial organisms have been confirmed as being small bacterial organisms.

## Tuberculosis

Tuberculosis (TB), caused by *Mycobacterium tuberculosis*, still has a worldwide distribution with a very high prevalence in Asian countries where 60–80% of children below the age of 14 years are affected.<sup>1</sup> This has special implication in Australia, where large numbers of Asian migrants are settling. The WHO estimates that one-third of the world's population is infected by the tubercle bacillus. It remains a deadly disease with about 2 million people worldwide dying of TB every year and 8 million new cases a year.

### Clinical features

TB can be a mimic of other diseases and a high level of suspicion is necessary to consider the diagnosis, especially if there are only extrapulmonary

manifestations. There may be no symptoms or signs, even in advanced disease. Ideally patients should be referred early for specialist management.

**DxT** malaise + cough + weight loss ± fever/night sweats (± erythema nodosum) → pulmonary TB

### Primary infection

The primary infection usually involves the lungs. Transmission is by droplet infection. The focus is usually subpleural in the upper to mid zones and is almost always accompanied by lymph node involvement.

Erythema nodosum may accompany the primary infection (see FIG. 29.1). Primary TB is symptomless in most cases although there may be a vague, 'not

**FIGURE 29.1** Classic erythema nodosum involving the legs of a patient with pulmonary tuberculosis

feeling well' illness associated with a cough. In most people this pulmonary focus heals but leaves some surviving tubercle bacilli, even if it becomes calcified (the Ghon focus).

### Progressive primary tuberculosis

If the immune response is inadequate, progressive primary TB develops, with constitutional and pulmonary symptoms. Rarely, haematogenous spread can occur to the lungs ('miliary tuberculosis'), to the pleural space (tuberculosis pleural effusion) or to extrapulmonary sites such as the meninges and bone.

### Latent TB infection (LTBI)

LTBI is the presence of infection without evidence of active disease and inability to transmit the infection. However, reactivation may occur if the host's immune defences are impaired (occurs in about 10%). LTBI is very common in children in and from developing countries. The tubercular skin test is primarily intended to identify these people with a view to prophylaxis therapy. The standard preferred regimen is isoniazid (10 mg/kg up to 300 mg (o) daily for 6–9 months). This decision should be made by a consultant.

### Post-primary or adult-type pulmonary TB

Most cases of TB in adults are due to reactivation of disease some years later and not to re-infection. Symptoms include persistent cough, sputum production, haemoptysis, fever, sweating, malaise, weight loss and anorexia. The factors causing this include poor social living conditions with malnutrition, diabetes and other factors lowering natural immunity, such as immunosuppressant drugs, corticosteroids, lymphoma and HIV infection (later stage). The chest X-ray is usually abnormal—classic apical disease with infiltration and cavitation with fibrotic changes.

#### Practice tip

LTBI – Think HIV.

### Reactivated pulmonary TB

This usually presents with constitutional symptoms of poor health and night sweats, and a cough that is initially dry but may become productive and be bloodstained (see CHAPTER 42). Sometimes the infection will be asymptomatic. The natural history of TB is illustrated in FIGURE 29.2.

### Extrapulmonary TB

The main sites of extrapulmonary disease (in order of frequency in Australia) are the lymph nodes (the commonest, especially in young adults and children), genitourinary tract (kidney, epididymis, Fallopian tubes), pleura and pericardium, the skeletal system (arthritis and osteomyelitis with cold abscess formation), CNS (meningitis and tuberculomas), the eye (choroiditis, iridocyclitis), the skin (lupus vulgaris), the adrenal glands (Addison disease—see CHAPTER 23) and the GIT (ileocaecal area and peritoneum). This is increasing, especially in HIV patients.

These sites are illustrated in FIGURE 29.3.

### Miliary tuberculosis

This disorder follows diffuse dissemination of tubercle bacilli via the bloodstream especially in those with chronic disease and immunosuppression. It can occur within 3 years of the primary infection or much later because of reactivation.

The symptoms, which are insidious, include weight loss, fever and malaise. Choroidal tubercles are pathognomonic. The classic chest X-ray is multiple 1–2 mm nodules in lung fields. It is fatal without treatment. The natural history of TB infection is illustrated in FIGURE 29.2.

### TB in children

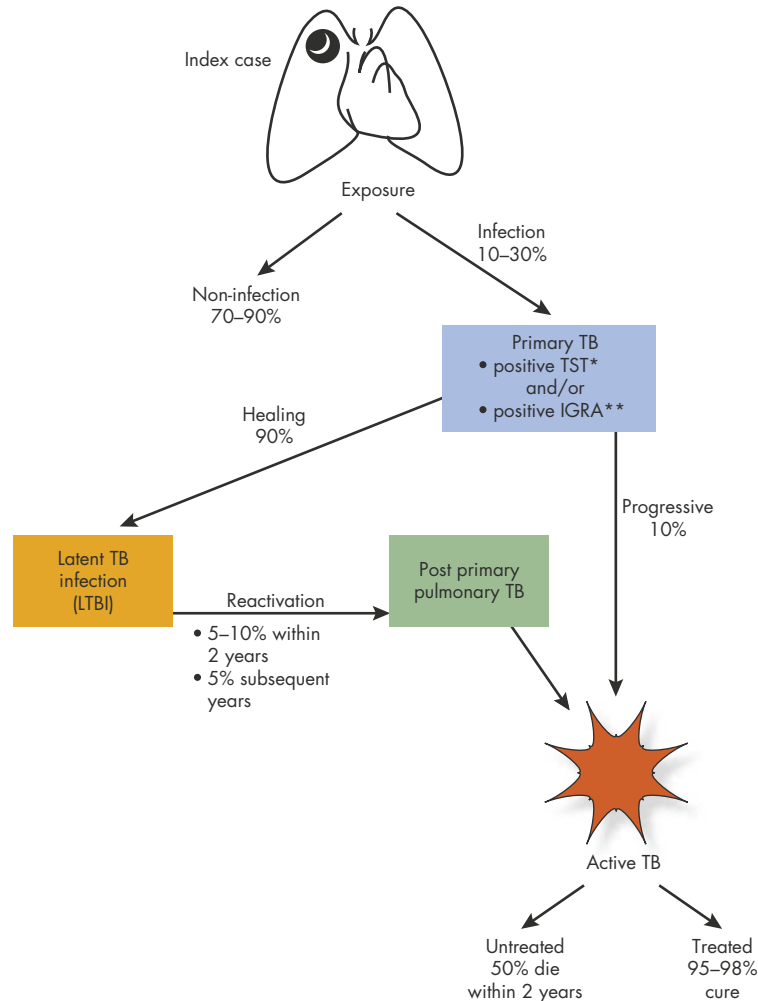

Children living in close contact with people with smear-positive pulmonary TB are highly vulnerable to acquiring the primary infection. A possible complication is miliary TB. The lifetime risk of TB disease in children with LTBI is in the order of 5–15%.<sup>2</sup> Children with LTBI should be considered for prophylaxis with a course of isoniazid.

Primary disease is the more common form in young children. Reactivation is more common in adolescents.

### Diagnosis

A high index of suspicion is critical for the diagnosis of TB. Tests include:

- Mantoux tuberculin test (TST) (a guide only)
- chest X-ray; CT scan if doubtful
- sputum or bronchial excretion or gastric aspirates for stain (acid-fast bacilli) and culture (takes about 6–8 weeks but important). Ideally requires 3 specimens over 3 days
- immunochromatographic finger-prick test (new and promising)
- interferon gamma release assay (IGRA)

**FIGURE 29.2** Natural history of TB infection

\* TST = tuberculin skin test

\*\* IGRA = interferon gamma release assay

Based on WHO algorithm and Dr Grant Jenkin (personal communication)

- NAAT/PCR test—less sensitive than culture
- biopsies on lesions/lymph nodes may be necessary
- fibre-optic bronchoscopy to obtain sputum may be necessary
- consider HIV studies

### **Tuberculin (Mantoux) testing and BCG vaccination**

A tuberculin (Mantoux) test should be performed prior to BCG vaccination in all individuals over 6 months of age. (It is read at 48–72 hours.) It is not a good test to diagnose TB.

If area of induration:

- <5 mm—negative (*note*: may be negative in presence of very active pulmonary infection)
- 5–10 mm—typical of past BCG vaccination
- >5 mm—significant in immunocompromised, close contacts and HIV infection
- >10 mm—positive = tuberculosis infection (active or inactive)
- >15 mm—highly significant for ‘normal’ people

The BCG vaccination should be given if the reaction is <5 mm induration. Do not give it for a reaction >5 mm.

**FIGURE 29.3** Pulmonary and extrapulmonary distribution of tuberculosis: the primary infection starts in the lung and then spread can occur throughout the body, especially to the lymph nodes

BCG vaccination is recommended for:

- ATSI neonates in regions of high incidence
- neonates born to patients with leprosy or family history of leprosy
- children <5 years travelling for long periods to countries of high TB prevalence

BCG vaccination should be considered for:

- neonates in household with immigrants or visitors recently arrived from countries of high prevalence (e.g. South-East Asia) (*note: tuberculin test not necessary for neonates <14 days*)
- children and adolescents <16 years with continued exposure to active TB patient and where isoniazid therapy is contraindicated

- others at increased risk (and where value of BCG vaccine uncertain), such as health care workers, travellers >5 years with significant exposure

BCG vaccination is contraindicated for:

- tuberculin reactions >5 mm
- immunocompromised or malignancies involving bone marrow lymphatics
- high-risk HIV infection
- significant fever or intercurrent illness
- generalised skin diseases, including keloid tendency
- pregnancy
- previous infection

## Areas of concern

### Resistance

This includes the increasing emergence of forms resistant to two or more front-line drugs—multidrug-resistant TB (MDR-TB). TB is much more aggressive in the immunocompromised and if not adequately treated can be fatal in 2 months, especially if they have MDR-TB. Treatment compliance is a huge issue and so the directly observed therapy (DOT) strategy for isoniazid in children is a WHO priority, as is 'DOTS plus' to control MDR-TB. TB is a more pressing problem in children requiring early treatment.

### Treatment<sup>3,4</sup>

The current antimicrobial treatment is to use four antituberculous drugs initially (rifampicin + isoniazid + pyrazinamide + ethambutol) daily for 2 months, then rifampicin + isoniazid daily for 4 months. The usual precautions with adverse reactions are required. Pyridoxine 25 mg daily is recommended for adults taking isoniazid. A 3-times-weekly regimen is also an option if DOT is employed.

Referral to experienced specialist care is appropriate.

## § Syphilis

Although syphilis is uncommon but increasing in the general population it is extremely common in certain Indigenous groups and is frequently acquired from homosexual activity or sexual contacts overseas.<sup>3</sup>

It presents either as a primary lesion or through the chance finding of positive syphilis serology. Family physicians should be alert to the various manifestations of secondary syphilis, which can cause difficulties in diagnosis. Congenital syphilis is rare where there is general serological screening of antenatal patients.

### Clinical features<sup>5,6</sup>

#### Primary syphilis

The primary lesion or chancre usually develops at the point of inoculation after an incubation period averaging 21 days. The chancre is typically firm, painless, punched out and clean (see FIG 29.4). The adjacent lymph nodes are discretely enlarged, firm and non-suppurating. Anorectal changes may occur in homosexual men.

Untreated, early clinical syphilis usually resolves spontaneously within 4 weeks, leading to latent disease, which may proceed to late destructive lesions.

#### Secondary syphilis

The interval between the appearance of the primary chancre and the onset of secondary manifestations

varies from 6 to 8 weeks. Constitutional symptoms, including fever, headache, malaise and general aches and pains, may precede or accompany the signs of secondary syphilis.

The most common feature of the secondary stage of infection is a rash, which is present in about 80% of cases. The rash is typically a symmetrical, generalised, coppery-red maculopapular eruption on the face, trunk, palms and soles and is neither itchy nor tender. It can resemble any skin disease except those characterised by vesicles.

#### Latent syphilis

Positive serology in a patient without symptoms or signs of disease is referred to as latent syphilis and is the commonest presentation of syphilis in Australia today. Possibly because of the widespread use of antibiotics, the infection often proceeds to the latent stage without a recognised primary or secondary stage.

#### Late syphilis

Tertiary manifestation of syphilis (follows >2 years' latency), which is very rare, may be 'benign' with development of gummas (granulomatous lesions) in almost any organ, or more serious with cardiovascular or CNS involvement. Benign gummatous disease is rare but cardiovascular disease and neurosyphilis occasionally occur. Careful management and follow-up of patients with early or latent disease is essential to prevent late sequelae.

Neurosyphilis includes:

- meningovascular (e.g. cranial nerve palsies)
- tabes dorsalis (e.g. sensory ataxia, lightning pains, Charcot joints)
- general paresis of the insane (e.g. dementia, psychosis)

**FIGURE 29.4** Chancre of primary syphilis in adolescent. This painless, innocuous-looking lesion was associated with a firm, enlarged lingual lymph node. Dark field examination revealed many motile treponema.

## Think of syphilis

Syphilis should not be overlooked as a cause of oral or anorectal lesions. The diagnosis of syphilis depends on a detailed history, careful clinical examination and specific examinations.

Underlying these approaches is the need to think of the possibility of syphilis with concurrent STIs.

## Syphilis and HIV infection<sup>6</sup>

HIV and syphilis are commonly associated. In patients with AIDS and syphilis, standard regimens for syphilis are not always curative. Seronegative syphilis has been reported in patients with HIV infection. Lymphadenopathy in a patient with HIV infection may be due to coexisting secondary syphilis.

## Diagnosis

### Dark field examination<sup>6</sup>

Spirochaetes can be demonstrated by microscopic examination of smears from early lesions using dark field techniques and provide an immediate diagnosis in symptomatic syphilis. The direct fluorescent antibody techniques (FTAABS) can be used on this smear.

## Serology

Serological tests provide indirect evidence of infection, and the diagnosis of asymptomatic syphilis relies heavily on these tests. The main types of tests are:

- reagin tests (VDRL and RPR)—not specific for syphilis but useful for screening
- treponemal tests (TPPA, TPI, EIA, FTA-abs)—specific tests, with the latter being sensitive and widely used
- PCR (blood or CSF)—very sensitive

## Treatment

Refer to CHAPTER 119.

## § Infective endocarditis

Infective endocarditis can be a difficult problem to diagnose but must be considered in the differential diagnosis of fever, especially in patients with a history of cardiac valvular disorders. It is caused by microbial infection of the cardiac valves or endocardium. Previously referred to as bacterial endocarditis, the term *infective endocarditis* is preferred because not all the infecting organisms are bacteria.

It may present as a fulminating or acute infection but more commonly runs an insidious course and is referred to as subacute (bacterial) endocarditis. Its incidence is increasing, probably due to the increasing

number of elderly people with degenerative valve disease, more invasive procedures, IV drug use and increased cardiac catheterisation.<sup>7</sup>

**DxT** FUO + cardiac murmur + embolism → endocarditis

## Risk factors

- Past history of endocarditis
- Rheumatically abnormal valves, especially ASTIP
- Congenitally abnormal valves
- Mitral valve prolapse
- Calcified aortic valve
- Congenital cardiac defects (e.g. VSD, PDA)
- Prosthetic valves, shunts, conduits
- IV drug use
- Central venous catheters
- Temporary pacemaker electrode catheters

*Note:* Only about 50% of patients with infective endocarditis have previously known heart disease.<sup>7</sup>

## Responsible organisms

- *Streptococcus viridans* (50% of cases) most susceptible to penicillin
- *Streptococcus bovis*
- *Enterococcus faecalis*
- *Staphylococcus aureus* (causes 50% of acute form)
- *Candida albicans/Aspergillus* (IV drug users)
- *Staphylococcus epidermidis*
- *Coxiella burnetii* (Q fever)
- HACEX group (Gram -ve bacilli) (5–10% of cases)

## Presentations

- Acute endocarditis
- Subacute endocarditis
- Prosthetic endocarditis

Infective endocarditis without cardiac murmur is frequently seen in IV drug users who develop infection on the tricuspid valve.

## Warning signs for development of endocarditis

- Change in character of heart murmur
- Development of a new murmur
- Unexplained fever and cardiac murmur = infective endocarditis (until proved otherwise)
- A febrile illness developing after instrumentation (e.g. urethral dilatation) or minor and major surgical procedures (e.g. dental extraction, tonsillectomy, abortion)

The 'classic tetrad' of clinical features:<sup>7</sup> signs of infection, signs of heart disease, signs of embolism, immunological phenomena

There is a significant high mortality and morbidity from infective endocarditis, which is often related to a delay in diagnosis.

### A golden rule

Culture the blood of every patient who has a fever and a heart murmur.

### Clinical features

The classic clinical features are summarised in **FIGURE 29.5**.

The patients are often elderly, appear pale and ill, with intermittent fever, and complain of vague aches and pains. The full clinical presentation takes time to develop. A febrile illness of 1 to 2 weeks duration is a common presentation.

### Investigation

This includes:

- FBE and ESR: ESR ↑, anaemia and leukocytosis
- urine: proteinuria and microscopic haematuria
- blood culture: positive in about 75%<sup>7</sup> (at least 3 sets of samples—aerobic and anaerobic culture)
- echocardiography—to visualise vegetations (TOE more sensitive than TTE)
- chest X-ray
- ECG

Consider kidney function tests and C-reactive protein.

### Management

The patient should be referred because optimal management requires close cooperation between physician, microbiologist and cardiac surgeon.

Any underlying infection should be treated (e.g. drainage of dental abscess). Bactericidal antibiotics are chosen on the basis of the results of the blood culture and antibiotic sensitivities. Four blood

**FIGURE 29.5** Infective endocarditis: possible clinical features

cultures should be sent to the laboratory within the first hour of admission and treatment should seldom be delayed longer than 24 hours.

### Antimicrobial treatment<sup>8,9</sup>

Consultation with an infectious diseases physician or clinical microbiologist should be sought.

### Empirical treatment<sup>8,9</sup>

Once cultures have been taken, prompt empirical antimicrobial treatment should be commenced, especially in fulminating infection suspected to be endocarditis (usually due to *Staphylococcus aureus*). Benzylpenicillin, gentamicin and flucloxacillin/dicloxacillin are recommended, for example (adults):

benzylpenicillin 1.8 g IV, 4 hourly  
plus  
flucloxacillin/dicloxacillin 2 g IV, 4 hourly  
plus  
gentamicin 4–6 mg/kg IV, daily  
Vancomycin is indicated in certain circumstances

For specific organisms isolated on culture and prosthetic valve endocarditis confer with a consultant.

### Prevention

#### Antibiotic prophylaxis<sup>8,9</sup>

The evidence for prophylaxis of endocarditis is not clear, and current international practice is not to treat low-risk cardiac abnormalities having procedures with a low incidence of bacteraemia.

It is advisable to discuss the relative risks with patients.

If in doubt, discuss the issue with the patient's cardiologist or an infectious diseases specialist.<sup>8,10</sup>

References for specific conditions: see Reference list;<sup>3,10</sup> see also <[www.circ.ahajournals.org/content](http://www.circ.ahajournals.org/content) (Paediatrics)>.

#### Low-risk patients

These include patients with murmurs not due to valve disorders, isolated secundum ASD, pacemakers, implanted defibrillators, previous rheumatic fever without valve dysfunction, previous CABGS, mitral valve prolapse without regurgitation, complete surgical or device closures of congenital heart defects.

No prophylaxis is recommended in these patients.

#### High risk of adverse outcomes<sup>11</sup>

These include past history of endocarditis, prosthetic heart valves, most congenital heart disease especially

cyanotic types and those with repaired defects, hypertrophic cardiomyopathy, cardiac transplantation recipients who develop cardiac valvulopathy, rheumatic heart disease in Indigenous patients, all acquired valvular heart disease, mitral valve prolapse with regurgitation and surgically fashioned systemic-pulmonary shunts.

### Procedures requiring prophylaxis<sup>11</sup>

- Dental: invasive dental surgery—any procedure causing bleeding from gingiva, bone or mucosa, for example, dental extractions, drainage of abscess, osteotomies, dental implants, replanting avulsed teeth, periodontal procedures including probing, endodontic surgery, intraligamentary local anaesthetic infections, root canal work
- Other procedures—examples are:
  - genitourinary procedures in the presence of infection, for example, D&C, IUCD, urethral dilatation, circumcision, prostatic surgery, vaginal delivery in presence of infection or prolonged labour
  - gastrointestinal tract in presence of infection
  - respiratory tract procedures—tonsillectomy/adenoidectomy, rigid bronchoscopy, nasal and sinus surgery
  - incision and drainage of local abscess, for example, boils, perirectal, dacryocystitis

### Recommended antibiotics

Dental procedures and URT interventions (*S. viridans* and *Streptococcus* cover):<sup>11</sup>

- amoxycillin 2 g (50 mg/kg up to adult dose) orally, 1 hour beforehand (if not on long-term penicillin)  
or
- (amoxy) ampicillin 2 g (50 mg/kg up to adult dose) IV just before procedure commences or IM 30 minutes before if having a general anaesthetic  
or
- if hypersensitive to penicillin: clindamycin or vancomycin

### Genitourinary and gastrointestinal procedures<sup>3</sup>

Enterococci prophylaxis

- amoxy/ampicillin (child: 50 mg/kg up to 2 g) IV (just before procedure)  
or
- amoxy/ampicillin 2 g (child 50 mg/kg up to 2 g) IM, 30 minutes beforehand

If hypersensitive to penicillin: vancomycin or teicoplanin plus gentamicin.

## Zoonoses

Zoonoses are those diseases and infections that are naturally transmitted between vertebrate animals and humans (see TABLE 29.1). Zoonotic diseases (which are not restricted to farming communities) can present as a mild illness but are prolonged in duration and can have debilitating sequelae.<sup>12</sup> There is a long list of diseases, which vary from country to country, and includes plague, rabies, scrub typhus, Lyme disease, tularaemia, hydatid disease, orf, anthrax, erysipeloid, listeriosis, campylobacteriosis and ornithosis (psittacosis).

### Diagnosis<sup>13</sup>

If a zoonosis is overlooked in the differential diagnosis, many will remain undiagnosed and untreated.

#### Practice tip

Think of a zoonosis in patients presenting with a flu-like illness and features of atypical pneumonia.

### Fever and sweats (flu-like illness)

Any patient with undiagnosed fever should be questioned about exposure to animals, recent travel both in and out of Australia, animal bites, cat scratches, consumption of raw milk, mosquito and tick bites, pets and occupation.

### Rash

- Consider rickettsial illness such as leptospirosis, Q fever, Lyme disease

### Cough or atypical pneumonia

- Consider Q fever, psittacosis, bovine TB

### Arthralgia/arthritis

- Consider Lyme disease, Ross River fever

### Meat workers

- Consider Q fever, leptospirosis, orf, anthrax

### Papular/pustular lesions

- Consider orf, anthrax (black)

## § Brucellosis

Brucellosis (undulant fever, Malta fever) has diminished in prevalence since the campaign to eradicate it from cattle. Entry is mainly by the mouth, or abraded or cut skin.

### Clinical features (acute brucellosis)

- Incubation period 1–3 weeks
- Insidious onset: malaise, headache, weakness
- The classic fever pattern is undulant (refer to CHAPTER 53)

Table 29.1 Major zoonoses in Australia

Zoonosis	Organism/s	Animal host	Mode of transmission	Main presenting features
<b>Q fever</b>	<i>Coxiella burnetii</i>	Various wild and domestic animals	Inhaled dust Animal contact Unpasteurised milk	Fever, rigors, myalgia, headache, dry cough
<b>Leptospirosis</b>	<i>Leptospira pomona</i>	Various domestic animals	Infected urine contaminating cuts or sores	Fever, myalgia, severe headache, macular rash
<b>Brucellosis</b>	<i>Brucella abortus</i>	Cattle	Contamination of cuts or sores by animal tissues Unpasteurised milk	Fever (undulant), sweats, myalgia, headache, lymphadenopathy
<b>Lyme disease</b>	<i>Borrelia burgdorferi</i>	Marsupials (probable)	Tick bites	Fever, myalgia, arthritis, backache, doughnut-shaped rash
<b>Psittacosis</b>	<i>Chlamydia psittaci</i>	Birds: parrots, pigeons, ducks, etc.	Inhaled dust	Fever, myalgia, headache, dry cough
<b>Bovine tuberculosis</b>	<i>Mycobacterium bovis</i>	Cattle	Unpasteurised milk	Fever, sweats, weight loss, cough (as for human pulmonary TB)
<b>Listeriosis</b>	<i>Listeria monocytogenes</i>	Various wild and domestic animals	Unpasteurised milk or cheese Contaminated vegetables Person to person	Mild febrile illness (in most) Meningoencephalitis in those susceptible (neonates, pregnancy, elderly etc.)

Possible:

- arthralgia
- lymphadenopathy
- hepatomegaly
- spinal tenderness
- splenomegaly (if severe)

Complications such as epididymo-orchitis, osteomyelitis and endocarditis can occur. Localised infections in sites such as bones, joints, lungs, CSF, testes and cardiac valves are possible but uncommon.

Symptoms of chronic brucellosis are virtually indistinguishable from chronic fatigue syndrome and can present with FUO.

**DxT** malaise + headache + undulant fever →  
brucellosis

### Diagnosis

- Blood cultures if febrile (positive in 50% during acute phase)<sup>10,13</sup>
- *Brucella* agglutination test (rising titre)—acute and convalescent (3–4 weeks) samples
- *Brucella* PCR testing—sensitive and rapid

### Treatment<sup>3</sup>

- Adults: doxycycline 100 mg (o) bd for 6 weeks + rifampicin 600 mg (o) daily for 6 weeks  
or  
gentamicin 4–6 mg/kg/day IV statim then daily for 2 weeks (monitor)
- Children: cotrimoxazole + rifampicin  
or  
gentamicin
- Relapses do occur (10%)—prolonged therapy

### Prevention and control

Involves eradication of brucellosis in cattle, care handling infected animals and pasteurisation of milk. No vaccine is currently available for use in humans.

### § Q fever

Q fever is a zoonosis due to *Coxiella burnetii*. It is the most common abattoir-associated infection in Australia and can also occur in farmers and hunters. Rash is not a major feature but can occur if the infection persists without treatment.

### Clinical features

- Incubation period 1–3 weeks
- Sudden onset fever, rigors and myalgia
- Dry cough (may be pneumonia in 20%)<sup>12</sup>

- Petechial rash (if persisting infection)
- ± Abdominal pain

Persistent infection may cause pneumonia or endocarditis so patients with valvular disease are at risk of endocarditis (culture is negative). It is a rare cause of hepatitis. The acute illness may resolve spontaneously but a chronic relapsing disease may follow. Untreated chronic infection is usually fatal.

**DxT** fever + headache + prostration →  
Q fever

### Diagnosis

- Serodiagnosis is by antibody levels in acute phase and 2–3 weeks later (4-fold increase)
- *Coxiella burnetii* PCR

### Treatment<sup>3</sup>

- Doxycycline 100 mg (o) bd for 14 days
- For endocarditis or chronic disease: prolonged course of doxycycline plus clindamycin or rifampicin
- Children: >8 same antibiotics according to weight; <8 cotrimoxazole (instead of doxycycline)

### Prevention

The disease can be prevented in abattoir workers by using Q fever vaccine.

### § Leptospirosis

Leptospirosis follows contamination of abraded or cut skin or mucous membranes with *Leptospira*-infected urine of many animals including pigs, cattle, horses, rats and dogs. In Australia it is almost exclusively an occupational infection<sup>13</sup> of farmers (especially with flooded farmland in tropics) and workers in the meat industry. There is a risk to dairy farmers splashed with urine during milking. Early diagnosis is important to prevent it passing into the immune phase.

### Clinical features

- Incubation period 3–20 days (average 10)
- Fever, chills, myalgia
- Severe headache
- Macular rash
- Light-sensitive conjunctivitis (marked suffusion)

Some may develop the immune phase (after an asymptomatic period of 1–3 days) with aseptic meningitis or jaundice and nephritis (icterohaemorrhagic fever, Weil syndrome) with a significant mortality.

**DxT** abrupt fever + headache + conjunctivitis  
→ leptospirosis

### Diagnosis

- High or rising titre of antibodies: can be cultured

### Treatment<sup>3,12</sup>

Mild cases may not require treatment.

- Doxycycline 100 mg (o) bd for 5–7 days  
or
- benzylpenicillin 1200 mg IV, 6 hourly for 5–7 days  
or
- ceftriaxone 1 g IV daily for 5–7 days

### § Lyme disease

Lyme disease (known as Lyme borreliosis) was first described in 1975 and named after the town Lyme in Connecticut (US). It is widespread in the US and is now appearing in other countries but is not endemic in Australia. Sporadic cases are seen in visitors or travellers. Very infective, it is caused by a spirochaete, *Borrelia burgdorferi*, and transmitted by *Ixodes* ticks, so that people living and working in the bush are susceptible. It has been reported in deer farmers. Lyme disease presents in three stages. If suspected refer for expert advice.

The pathognomonic sign is erythema migrans—a characteristic pathognomonic rash, usually a doughnut-shaped, well-defined rash about 6 cm in diameter at the bite site.

Stage 1: erythema migrans, flu-like illness

Stage 2: neurological problems such as limb weakness and cardiac problems

Stage 3: arthritis

### Diagnosis

- Clinical pattern especially rash of erythema migrans + serology and PCR

### Treatment

- Remove tick
- A typical regimen for adults is doxycycline 100 mg bd for 21 days or amoxycillin

### § Psittacosis ('bird fanciers disease')

Most patients are bird fanciers. Psittacosis accounts for 1–5% of hospital admissions for pneumonia. The disease may follow a low-grade course over

several months but can have a dramatically acute presentation of flu-like illness. It is indistinguishable from other atypical pneumonias except for history of contact with birds.

### Clinical features

- Incubation period 1–2 weeks
  - Fever, malaise, myalgia
  - Headache
  - Cough (usually dry)
  - Minimal chest signs
  - Splenomegaly (sometimes)
- Mortality can be as high as 20% if untreated.

### Diagnosis

- Serology—rising antibody and PCR
- Chest X-ray

### Treatment<sup>3</sup>

- Doxycycline 200 mg (o) or clarithromycin 250 mg, 12 hrly for 14 days (o)

### § Listeriosis<sup>14</sup>

Listeriosis is caused by *Listeria monocytogenes*, a bacterium widespread in nature that can contaminate food and has been found in many fresh and processed foods (e.g. dairy products, especially unpasteurised milk, soft cheese, processed meats and smoked seafood). Its significance lies in the mortality rate in high-risk groups such as pregnant women, the immunocompromised, frail aged, and very young but especially neonates and fetuses. Babies may be stillborn or aborted.

### Clinical features

It may be subclinical but possible presentations include:

- influenza-like illness (usually mild)
- food poisoning (atypical)
- meningitis, especially infants, elderly
- septicaemia (in susceptible)
- pneumonia (in susceptible)

### Diagnosis

- Microscopy or isolation of organism from infected site or blood
- Serological tests available

### Treatment

- Amoxycillin 1 g (o) 8 hourly or IV for 10–14 days<sup>3,13</sup>

## Other zoonoses

- Mosquito-transmitted infections: Murray Valley encephalitis, Ross River virus, Barmah Forest virus
- Infections from bites and scratches: cat-scratch disorder, rat bite fever
- Hydatid disease, orf, milker's nodules
- Toxoplasmosis, histoplasmosis, hookworm

## CLOSTRIDIAL INFECTIONS

### § Tetanus

This sometimes misdiagnosed bacterial infection (*Clostridium tetani*) can appear from one day to several months after the injury, which can be forgotten. A total of 10–20% of patients with tetanus have no identifiable wound of entry.<sup>15</sup> Neonatal tetanus can occur from contamination of the umbilical stump.

### Clinical features

- Prodrome: fever, malaise, headache
- Trismus (patient cannot close mouth)
- Risus sardonicus (a grin-like effect from hypertonic facial muscles)
- Opisthotonos (arched trunk with hyperextended neck)
- Spasms, precipitated by minimal stimuli

Differential diagnosis: phenothiazine toxicity, strychnine poisoning, rabies

### Management

- Give tetanus antitoxin and human tetanus immunoglobulin
- Refer immediately to expert centre
- Intubate and ventilate if necessary

### § Gangrene/Gas gangrene<sup>3</sup>

Gangrene (necrotising soft tissue infection) can involve skin and subcutaneous fat, fascia and muscle.

Gas gangrene (clostridial myonecrosis) is caused by entry of one of several clostridia organisms, for example, *Clostridium perfringens*, into devitalised tissue, such as exists following severe trauma to a leg.

### Clinical features

- Sudden onset of pain and swelling in the contaminated wound
- Brownish serous exudate
- Gas in the tissue on palpation or X-ray
- Prostration and systemic toxicity
- Circulatory failure ('shock')

## Management

- Refer immediately to surgical centre for debridement
- Start benzylpenicillin 2.4 g IV, 4 hourly + clindamycin
- Hyperbaric oxygen if available

### § Botulism<sup>3</sup>

Botulism is food poisoning caused by the neurotoxin of *Clostridium botulinum*. It can be infant botulism, of wound origin or food borne. From 12 to 36 hours after ingesting the toxin from canned, smoked or vacuum-packed food (e.g. home-canned vegetables or meat) visual problems such as diplopia suddenly appear. Suspect botulism if cranial nerve weakness with normal sensation. General muscle paralysis and prostration quickly develop. Refer immediately for antitoxin and intensive care. Avoid antibiotics.

## PNEUMONIA

Surprisingly the initial presentation of pneumonia can be misleading, especially when the patient presents with constitutional symptoms such as fever, malaise and headache rather than respiratory symptoms. A cough, although usually present, can be relatively insignificant in the total clinical picture. This problem applies particularly to atypical pneumonia but can occur with bacterial pneumonia, especially lobar pneumonia (refer to CHAPTER 42).

### § The atypical pneumonias<sup>3,10</sup>

Refer to CHAPTER 42.

### Clinical features

- Fever, malaise
- Headache
- Minimal respiratory symptoms, non-productive cough
- Signs of consolidation absent
- Chest X-ray (diffuse infiltration) incompatible with chest signs

DxT 'flu' + headache + dry cough →  
atypical pneumonia

## Serology tests and treatment

Blood tests and PCR tests are available for all the following causative organisms:

*Mycoplasma pneumoniae* (the commonest)

- Adolescents and young adults: treat with doxycycline (first line) 200 mg statim then 100 mg daily for 14 days  
or  
with roxithromycin 300 mg (o) daily for 14 days

*Legionella pneumophila* (legionnaire disease)

- Related to cooling systems in large buildings
- Incubation 2–10 days
- Diagnostic criteria include: prodromal-like illness; a dry cough, influenza, confusion or diarrhoea; lymphopenia with marked leukocytosis; hyponatraemia; PCR test and urinary antigen assay
- Patients can become very prostrate with complications—treat with azithromycin (o or IV) or erythromycin (IV or o) plus (if very severe) add ciprofloxacin or rifampicin for 14 to 21 days.

*Chlamydia psittaci* (psittacosis)

- Treat with doxycycline 100 mg bd for 14 days

*Coxiella burnetii* (see Q fever section)

*Bacterial meningitis is a medical emergency especially meningococcus meningitis which can cause rapid deterioration of the patient. Consider it if a sudden onset of the classical triad is accompanied by high fever and the signs of a very sick child. Meningococcal meningitis may be accompanied by a petechial rash and septic shock (Waterhouse–Friderichsen syndrome).*

Anisha Bahra & Katia Cikurel, *Neurology*, 1999<sup>1</sup>

Infections of the central nervous system will cover general conditions such as meningitis and encephalitis and specific organisms such as syphilis and polio. This section is highlighted because the conditions that are difficult to diagnose can have morbid outcomes, especially if the conditions are misdiagnosed. They are representative of classic 'not-to-be-missed' conditions.

Key symptoms suggestive of cerebral infection are headache, seizures and altered conscious level.

## § Meningitis

Meningitis is inflammation of the meninges (pia and arachnoid) and the cerebrospinal fluid (CSF).

The classic triad is:

- headache
- photophobia
- neck stiffness

Other symptoms include malaise, vomiting, fever and drowsiness.

## Causes (organisms)<sup>1,2</sup>

### Bacteria

- *Streptococcus pneumoniae*, *Haemophilus influenzae* (especially children), *Neisseria meningitidis* (the big three)
- *Listeria monocytogenes*, *Mycobacterium tuberculosis*, Group B *Streptococcus*, *Strep. agalactiae* (common in newborn), *Staphylococcus* spp., Gram -ve bacilli, such as *Escherichia coli*, *Borrelia burgdorferi*, *Treponema pallidum*

### Viruses

- Enteroviruses (Coxsackie, echovirus, poliovirus) mumps, herpes simplex HSV type 1, 2 or 6, varicella zoster virus, EBV, HIV (primary infection)

## Fungi

- *Cryptococcus neoformans* or *C. gattii*
- *Histoplasma capsulatum*

## Investigations

- Lumbar puncture (see TABLE 30.1)
- CT scan
- Blood culture and CSF microculture/PCR (PCR useful even if antibiotics given)

## § Bacterial meningitis<sup>2</sup>

Bacterial meningitis is basically a childhood infection. Neonates and children aged 6–12 months are at greatest risk. Meningococcal disease can take the form of either meningitis or septicaemia (meningococcaemia) or both. Most cases begin as septicaemia, usually via the nasopharynx. The onset is usually sudden (see CHAPTER 96).

## Clinical features (typical)

### Infancy

- Fever, pallor, vomiting ± altered conscious state
- Lethargy
- Increasing irritability with drowsiness
- Refusal to feed, indifference to mother
- Neck stiffness (not always present)
- Cold extremities (a reliable sign)
- May be bulging fontanelle
- Kernig sign (see FIG. 30.1): unreliable
- Opisthotonos (see FIG. 30.2): rare

### Children over 3 years, adolescents, adults

- Meningeal irritation more obvious (e.g. headache, fever, vomiting, neck stiffness)
- Later: delirium, altered conscious state

*Note:* Antibiotics may mask symptoms. Suspect meningitis if fever >3 days in reasonably well child on antibiotics.<sup>3</sup>

**Table 30.1** CSF findings in meningitis

	Bacterial (pyogenic)	Tuberculosis	Viral

**FIGURE 30.1** Kernig sign: pain in hamstrings on passive knee extension with hip flexed at 90°**FIGURE 30.2** Opisthotonos caused by advanced meningitis

### Fulminating

- Dramatic sudden-onset shock, purpura (does not blanch on pressure) ± coma
- Usually due to meningococcal septicaemia, also *H. influenzae* type B, *Streptococcus pneumoniae*

*Note:* septic shock may ensue without signs of meningitis.

### Treatment (suspected meningitis)<sup>4</sup>

First: oxygen + IV access and consult

- Take blood for culture (within 30 minutes of assessment)—ideally prior to hospitalisation
- For child give bolus of 10–20 mL/kg of N saline with added bolus up to total 60 mL/kg if signs of hypoperfusion
- Admit to hospital for lumbar puncture (preliminary CT scan to assess safety of LP in adults)
- Dexamethasone 0.15 mg/kg up to 10 mg IV (start at same time as antibiotics—shown to improve outcome)
- Ceftriaxone 4 g (child: 100 mg/kg up to 4 g) IV statim then daily for 4 days  
or  
cefotaxime 2 g (child: 50 mg/kg up to 2 g) IV 6 hourly for 3–5 days

*Note:* IV preferable but IM or interosseous better than nothing.

Antibiotics of proven effectiveness are cefotaxime, ceftriaxone, meropenem and penicillin.

### Treatment (meningococcaemia— all ages)

Treatment is extremely urgent once suspected (e.g. petechial or purpuric rash on trunk and limbs) (see FIG. 30.3). It should be given before reaching hospital. Empirical treatment is:

- benzylpenicillin 60 mg/kg IV (max. 2 g) statim (continue for 5 days)

**FIGURE 30.3** Meningococcaemia with typical early purpuric rash in a 2-year-old child

- if IV access not possible give IM  
or
- ceftriaxone 100 mg/kg IV or IM (max 4 g) statim then daily for 5 days

*Note:* Penicillin dose guide for suspected meningitis in child: <1 year 300 mg, 1–9 years 600 mg, 10+ years 1.2 g

### Prevention

- Conjugated group C and B meningococcal vaccine

### § Viral meningitis

This is basically a childhood infection. The most common causes are human herpes virus 6 (the cause of roseola infantum) and enteroviruses (Coxsackie and echovirus).

Most cases are benign and self-limiting, but the clinical presentation can mimic bacterial meningitis although there are fewer obvious signs of meningeal irritation. Lumbar puncture is important for diagnosis and also PCR for enterovirus. If positive it can allow early cessation of antibiotics if commenced empirically.<sup>2</sup> Treatment which is symptomatic includes rehydration and analgesics. Acyclovir is given for herpes meningitis. The immunocompromised require special management.

### Practice tip

Very cold hands? – Think meningitis.

### § Encephalitis<sup>1,2</sup>

Encephalitis is inflammation of the brain parenchyma. It is mainly caused by viruses although other organisms including some bacteria, *Mycoplasma*, *Rickettsia* and *Histoplasma* can cause encephalitis. Suspect it when a viral prodrome is followed by irrational behaviour, altered conscious state and possibly cranial nerve lesions.

### Clinical features

These can vary from mild to severe.

- Constitutional: fever (not inevitable), malaise, myalgia
- Meningeal features: headache, photophobia, neck stiffness
- Cerebral dysfunction: altered consciousness—confusion, drowsiness, personality changes, seizures
- Focal neurological deficit

### Causes (viral organisms)

- Herpes simplex type 1 or 2, enteroviruses, mumps, CMV, EBV, HIV, measles, influenza, arboviruses, for example, Japanese B, West Nile, Murray Valley encephalitis, Ross River
- Consider cerebral malaria in the differential diagnosis

There are three forms of mediated viral encephalitis: direct, delayed (latent) and immune mediated (postinfectious encephalomyelitis).

### *Toxoplasma gondii*

A protozoal infection seen in immunocompromised patients, especially HIV.

### Investigations

- Lumbar puncture: CSF (usually aseptic meningitis)
- CSF PCR for viral studies, esp. HSV, toxoplasma
- CT scan—often shows cerebral oedema
- Gadolinium enhanced MRI
- EEG—characteristic waves

### Treatment

Organise hospitalisation where treatment will be supportive. Suspected herpes simplex encephalitis should be treated with IV aciclovir immediately.

*Note:* Meningoencephalitis is meningitis plus some parenchymal involvement of brain substance.

## § Brain abscess<sup>4,5</sup>

A brain (cerebral) abscess is a focal area of infection in the cerebrum or cerebellum. It presents as a space-occupying intracerebral lesion. The infection can reach the brain by local spread or via the bloodstream, for example, endocarditis. There may be no clue to a focus of infection elsewhere but it can follow ear, sinus, dental, periodontal or other infection and also a skull fracture. The organisms are polymicrobial especially microaerophilic cocci and anaerobic bacteria in the non-immunosuppressed. In the immunosuppressed, *Toxoplasma*, *Nocardia* sp. and fungi.

### Clinical features

#### Raised intracranial pressure

- Headache
- Nausea and vomiting
- Altered conscious state
- Papilloedema

#### Other

- Focal neurological signs such as hemiplegia, dysphasia, ataxia
- Seizures (30%)
- Fever (may be absent)
- Signs of sepsis elsewhere: e.g. teeth, endocarditis

### Investigations

- MRI (if available) or CT scan
  - FBE, ESR/CRP, blood culture
- Note: lumbar puncture is contraindicated.
- Consider endocarditis

### Management

Management is urgent neurosurgical referral. Aspiration or biopsy is essential to guide antimicrobial treatment which may (empirically) include metronidazole IV and a cephalosporin e.g. ceftriaxone IV.

## § Spinal subdural or epidural abscess

These uncommon focal infections can be extremely difficult to diagnose so an index of suspicion is required to consider such an abscess. The usual organism is *Staphylococcus aureus*.

### Clinical features<sup>6</sup>

- Back pain (increasing) ± radiculopathy
- Percussion tenderness over spine

- Evolving neurological deficit, e.g. gradual leg weakness and sensory loss ± fever (may be absent)

### Causes

- Associated infection: furuncle, decubitus ulcer, adjacent osteomyelitis, discitis, other
- Back trauma with haematoma
- Post-subdural or epidural anaesthetic block
- One-third is spontaneous

### Investigations

- Blood culture
- MRI scan to localise abscess and spinal cord pressure

### Management

Urgent neurosurgical referral. Empirical therapy while awaiting culture results may include di/flucloxacillin IV, + gentamicin IV, or vancomycin IV.

## Prion transmitted diseases<sup>7,8</sup>

Prions are proteinaceous infected particles devoid of nucleic acid that can present with a wide spectrum of neurological presentations. The feature is transmissible spongiform encephalopathy (TSE) with Creutzfeldt–Jakob disease being the classic example. Other examples of TSE forms affecting humans are variant CJD, kuru (New Guinea) and fatal familial insomnia.

## § Creutzfeldt–Jakob disease

There are three distinct forms of CJD: sporadic (80–85%), familial (15%) and iatrogenic (1%). The annual incidence is one per million people. Usual transmission is from contaminated human tissue (e.g. corneal graft), cadaver pituitary human gonadotrophin or eating contaminated beef. There is no specific treatment for the disease.

**DxT** fatigue + psychiatric symptoms + myoclonus → CJD

### Clinical features

- Progressive dementia (starts with personality change and memory loss—eventual loss of speech)
- Myoclonus/muscle spasms
- Fatigue and somnolence
- Variable neurological features (e.g. ataxia, chorea)

## Diagnosis

- MRI: high signal intensity in thalami
- CSF: positive 14-3-3 protein immunoassay
- EEG
- Brain biopsy after death (ultimate confirmation)

## Management

- Supportive: no proven specific treatment

## § Poliomyelitis<sup>8</sup>

Polio is a highly contagious enterovirus (picornavirus) transmitted through the faeco-oral route and is a specific spinal cord anterior horn cell enterovirus. It remains endemic in the tropics. Most infections (95%) are asymptomatic. *Note:* myelitis means inflammation of the spinal cord.

## Clinical features

- Flu-like syndrome, with fever and sore throat, then
- 'Pre-paralytic' stage: nausea and vomiting, headache, stiff neck (meningeal irritation)
- Paralytic (0.1%): LMN lesion (flaccid paralysis)—may include spinal polio especially of lower limbs and/or bulbar polio ± respiratory failure. No sensory loss.

There are 2 levels of polio: minor (recovery in a few days) and major.

## Diagnosis

- Viral studies of throat and faeces—culture and PCR
- Serology
- CSF: leucocytosis, esp. lymphocytes

## Management

Symptomatic paralytic patients should be referred to hospital. Prevention is through vaccination.

## Post-polio syndrome

Many years after the primary infection (usually 20–40 years) this may present with new muscle weakness and pain as dysfunction of surviving motor neurones develops. Refer to specialist unit.

## Non-viral causes of flaccid paralysis<sup>9</sup>

- *Borrelia burgdorferi* (Lyme disease), *Mycoplasma*, diphtheria, botulism, transverse myelitis, syphilis

## § Syphilis

Neurosyphilis can present at any stage of syphilis. The main syphilitic syndromes affecting the CNS are:

- Asymptomatic syphilis: present during the interval between the secondary and tertiary stages of syphilis.
- Meningitis including acute basal meningitis and meningovascular syphilis. The latter can present with a cerebrovascular accident.
- Tabes dorsalis causing meningoradiculitis with degeneration of the parenchyma of the spinal columns of the spinal cord and involvement of the pupils. Features include lightning pains, Charcot joints, ataxia and neurotrophic ulcers, Argyll Robertson pupils.
- General paralysis of the insane with marked personality change, dementia, dysarthria and seizures.

## OTHER INFECTIONS THAT CAN INVOLVE THE CNS

### § Tuberculosis

Neurological TB may include tuberculosis meningitis, tuberculoma (presenting as a cerebral abscess), spinal arachnoiditis and spinal involvement (Pott disease). Treatment with multiple antimicrobial agents is usually complex and prolonged.

### § Human immunodeficiency virus

HIV involvement may be direct with primary infection causing encephalopathy ('AIDS' dementia), myelopathy or acute atypical meningitis in addition to secondary opportunistic infection. The latter include CNS toxoplasmosis, cytomegalovirus, herpes simplex myelitis, varicella zoster and others (see CHAPTER 27).

### § Helminthic infections

Worm infestations that can (rarely) cause intracerebral lesions through the formation of cysts or granulomas include cysticercosis (tapeworms), *Echinococcus* (hydatid) and *Schistosoma*.

Other infections may present with seizures. These include:

- Botulism (see CHAPTER 29)
- Tetanus (see CHAPTER 29)
- Rabies (see CHAPTER 15)
- Hansen disease (leprosy) (see CHAPTER 15)

*I have never yet examined the body of a patient dying with dropsy attended by albuminous urine, in whom some obvious derangement was not discovered in the kidneys.*

Richard Bright 1827

## § Chronic kidney failure

In the diagnostic model the problem of chronic kidney failure (CKF) as a masquerade has been highlighted. The reason for this is that the dysfunction associated with progressive chronic kidney disease (CKD) can be difficult to diagnose as there may be no or minimal symptoms. In fact the patient may present with a subtle terminal illness. It is important that all general practitioners are aware of the seriousness of the problem and keep it in mind when the patient presents with apparent minor problems such as fatigue or weakness. Sometimes the kidneys can develop acute failure, which may recover or progress to chronicity.

If CKD is detected early and managed appropriately then the otherwise inevitable deterioration in kidney function can be reduced by as much as 50% and may even be reversible.<sup>1</sup>

**Table 31.1** Significant causes of chronic kidney failure (approximate order of prevalence)

Diabetes mellitus
Glomerulonephritis
• IgA nephropathy (commonest)
Hypertension
Vascular
• atherosclerosis, including kidney artery stenosis
Polycystic kidneys
Obstructive nephropathy/reflux
• bilateral ureteric obstruction
• bladder outflow obstruction: prostatic enlargement, urethral stenosis
Drugs, including analgesic nephropathy
Lupus and other connective tissue disorders
Vasculitides, e.g. polyarteritis nodosa (PAN)
Gout
Amyloidosis
Hypercalcaemia

## Key facts and checkpoints

- 10% of people attending general practice<sup>1</sup> have CKD but most do not know it.
- At least 95 people per million of the population are treated for end-stage kidney disease/kidney failure (ESKF) each year.
- Two-thirds of these are under 60 years of age.
- Important causes are glomerulonephritis (25%), diabetes mellitus (35%), polycystic kidney disease (8%), reflux nephropathy (8%) and hypertension (13%) (see [TABLE 31.1](#)).<sup>2</sup>
- The commonest cause of ESKF in Australia is diabetes mellitus.
- The commonest cause of nephritis leading to kidney failure in Australia is IgA nephropathy.
- In children the incidence of chronic kidney failure is quite low (1 to 2 per million of the population).<sup>2</sup>
- Warmer climates, poorer living conditions and certain genetic predispositions are associated with a higher prevalence of kidney failure.
- Kidney failure should be considered in the diagnosis of patients with unexplained anaemia, unexplained poor health and unusually high analgesic intake.<sup>2</sup>
- Uraemic symptoms are non-specific and usually are not recognised until the creatinine clearance is less than 20% of normal.
- CKF is characterised by the accumulation of uraemic toxins and a deficiency of kidney hormones that cause dysfunction of organs other than kidneys.
- This interaction can cause phosphate retention, secondary hyperparathyroidism and bone disorders such as osteomalacia.
- Age is an issue—we lose 1% of renal function per year
- It is possible to identify stages of kidney failure (see [TABLE 31.2](#)).

**Table 31.2** Classification of chronic kidney disease stages<sup>1,3</sup>

CKD stage	GFR (mL/min)	Description	Clinical action plan
1	>90	Evidence of kidney damage (e.g. scarring on ultrasound, proteinuria/haematuria)	
2	60–89	Evidence of kidney damage Mild kidney failure	Further investigation for those at risk: <ul style="list-style-type: none"> <li>• Assess proteinuria</li> <li>• Urinalysis</li> <li>• BP</li> </ul> Cardiovascular risk reduction: <ul style="list-style-type: none"> <li>• BP, cholesterol, blood glucose, smoking, obesity</li> </ul>
3	30–59	Moderate kidney failure	As above. <ul style="list-style-type: none"> <li>• Avoid nephrotoxic drugs</li> <li>• Monitor eGFR 3 monthly</li> <li>• Prescribe antiproteinuric drugs, ACE inhibitors or ARBs if appropriate</li> <li>• Address anaemia, acidosis, hyperparathyroidism</li> <li>• Ensure drug dosages are appropriate for level of kidney function</li> </ul> Consider referral to nephrologist
4	15–29	Severe kidney failure	As above. <ul style="list-style-type: none"> <li>• Referral to nephrologist</li> <li>• Prepare for dialysis or transplantation (if appropriate)</li> </ul>
5	<15	End-stage kidney failure	As above. <ul style="list-style-type: none"> <li>• Institute dialysis or transplantation (if appropriate)</li> </ul>

## § Acute kidney failure

Acute kidney failure (AKF, a forerunner of CKF) is defined as a sudden (days to weeks) decrease in kidney function (azotaemia) with or without oliguria. It results in dysfunctional fluid and electrolyte balance and nitrogenous waste excretion with a sudden increase in blood urea and creatinine levels.

AKF is usually classified into:

- prerenal (e.g. acute circulatory failure → kidney hypoperfusion)
- postrenal (e.g. obstruction)
- kidney (intrinsic) (e.g. acute glomerulonephritis)

Early diagnosis with hospital admission is important and this is achieved by being aware of the patient at risk and the early detection of hypovolaemia, hypertension or hypotension, oliguria or urine abnormalities.

Treatment options include renal dialysis, blood filtration and fluid and electrolyte restriction.

**DxT** malaise (extreme) + a/n/v + confusion  
(± oliguria) → AKF

## § Chronic kidney disease and failure

Chronic kidney disease (CKD) is diagnosed as:<sup>1</sup>

- an estimated or measured glomerular filtration rate (GFR)<sup>1</sup> <60 mL/min/1.73m<sup>2</sup> that is present for ≥3 months with or without evidence of kidney damage
- or
- evidence of kidney damage with or without decreased GFR that is present for ≥3 months as evidenced by the following, irrespective of the underlying cause:
  - albuminuria
  - haematuria after exclusion of urological causes
  - structural abnormalities (e.g. on kidney imaging tests)
  - pathological abnormalities (e.g. renal biopsy)

Chronic kidney (or renal) failure (CKF) is defined as a severe reduction in nephron mass over an extended period of time, resulting in uraemia. It can present surreptitiously and be a real master of disguise in clinical practice. Asymptomatic CKF may be discovered

on routine health screening, as a chance finding in hospitalised or hypertensive patients, or during follow-up of patients with known kidney disease.<sup>4</sup>

### Important clinical associations<sup>5</sup>

The possibility of CKF should be monitored in patients with:

- diabetes mellitus
- hypertension
- severe gout
- a history of urinary tract abnormality (e.g. vesicoureteric reflux, bladder outflow obstruction)

The possibility of CKF should be considered and investigated in patients presenting with:

- unexplained poor health
- hypertension
- anaemia
- pruritus
- hyperparathyroidism
- pericarditis
- urinary tract symptoms or signs: proteinuria, haematuria, oedema, nocturia, loin pain, prostatic obstruction
- neurological disturbances: confusion, coma, peripheral neuropathy, seizures

Patients with CKF may present with features of acute kidney failure with the intervention of complicating factors such as:

- drug toxicity
- infection
- fluid imbalance

Urgent treatment of the following conditions, which can lead to rapid kidney failure, is essential:

- progressive nephritis
- systemic lupus erythematosus
- vasculitides (see CHAPTER 32), for example, polyarteritis nodosa, Wegener granulomatosis

### Risk factors for chronic kidney disease<sup>5</sup>

#### Non-modifiable

Age >60  
Family history  
Aboriginal or Torres Strait Islander origin

#### Modifiable

Diabetes mellitus  
Hypertension  
Smoking  
Obesity—BMI  $\geq 30$

## The clinical approach

### History

A hallmark of early-stage CKF is a non-specific history and examination, and the diagnosis is very difficult in the absence of a known past history of kidney disease. The diagnosis can be established only by kidney function tests. Symptoms from CKF are rare unless the creatinine clearance is less than 20% of normal and only become common when less than 10% of normal.

In patients with chronic kidney disease, symptomatic uraemia may be precipitated by prerenal factors, such as fluid loss from vomiting or diarrhoea, infection, antibiotic therapy especially tetracyclines, or increasing hypertension.

### Symptoms and signs

The symptoms and signs of CKF are summarised in FIGURE 31.1.

The common early presenting symptoms are generally non-specific and referable to the GIT, presumably due to the formation of ammonia in the upper GIT. However, anaemia is the main cause of symptoms.

Such symptoms include:

- malaise
- anorexia, nausea, vomiting
- tiredness/lethargy
- nocturia
- restless legs
- pruritus
- dyspnoea

If a patient presents with these symptoms and has a sallow 'lemon' tinge appearance due to a combination of anaemia and brownish pigmentation, then CKF should be highly suspected.

**DxT** fatigue + a/n/v + sallow skin → CKF

### Physical examination<sup>6</sup>

General inspection of the patient with CKF will usually reveal a sallow complexion with yellow-brown pigmentation in the skin, which is often dry and pruritic. The patient's mental state should be noted. The respiratory and pulse rates are usually rapid because of anaemia and metabolic acidosis. Other findings may include bruising, uraemic fetor, reduced mental status, pericarditis and peripheral neuropathy. The abdomen should be carefully palpated, especially

FIGURE 31.1 Clinical features of chronic kidney failure

in the kidney areas. A rectal examination is indicated to detect prostatomegaly or other rectal or pelvic pathology. Ophthalmoscopic examination may show hypertensive or diabetic retinopathy. Urinalysis should test glucose, blood and protein. This involves a dipstick testing on the first morning specimen. Proteinuria should be confirmed with a 24-hour urine protein estimation or (preferably) an albumin creatinine ratio (ACR).

### ACR guidelines

#### Normoalbuminuria

Men:	<2.5 mg/mmol
Women:	<3.5 mg/mmol

#### Microalbuminuria

Men:	2.5–25 mg/mmol
Women:	3.5–35 mg/mmol

#### Macroalbuminuria

Men:	>25 mg/mmol
Women:	>35 mg/mmol

### Investigations

- Urine dipstick (poor sensitivity and specificity)<sup>1</sup>
- 24-hour urine protein
- Albumin creatinine ratio
- Microculture of urine

- Kidney function tests (most appropriate for the GP):
  - plasma urea
  - plasma creatinine
  - creatinine clearance (more precise)
  - eGFR (the new standard)
- Plasma electrolytes:
  - sodium, potassium, chloride, bicarbonate
  - calcium and phosphate
- Consider:
  - magnesium, urate, glucose
  - lipids
  - prescribed drug level
  - cardiac studies
  - full blood count ? anaemia
  - protein electrophoresis (? myeloma)
  - ANA for lupus
  - ANCA for vasculitis
- Determination of underlying cause:
  - imaging of urinary tract—ultrasound
  - immunological tests
  - kidney biopsy

Biochemical changes—elevation of:

- potassium
- phosphate
- creatinine and urea
- urinary protein
- hydrogen ions → acidosis; anion gap

### Monitoring CKD

The traditional test in identifying and monitoring CKD is the serum creatinine level.<sup>7</sup> The normal range is about 40–120  $\mu\text{mol/L}$  (0.04–0.12  $\text{mmol/L}$ ) but the laboratory will indicate their appropriate reference level. However, serum creatinine is an unreliable and insensitive marker of CKD. To improve detection and management guidelines laboratories now report on estimated glomerular filtration rate (eGFR) using the CKP-EPI (chronic kidney disease epidemiology collaboration) formula with every request for serum creatinine concentration, which is required to calculate to GFR.<sup>8</sup>

Although common in older people, an eGFR <60 is associated with increased risks of adverse clinical outcomes, especially renal and cardiovascular.

### Guiding rule

eGFR =  $140 - \text{age}$

### Drug prescribing in CKD<sup>3,9</sup>

Drugs that can damage the kidneys include:

- classic nephrotoxic drugs e.g. gentamicin, vancomycin
- NSAIDs, COX-2 inhibitors
- ACE inhibitors and AIIIR blockers (ARBs)
- aminoglycosides
- cephalosporins (various)
- tetracyclines
- lithium
- colchicine

### Beware of the 'triple whammy'

- NSAIDs/COX-2 inhibitors
- ACE inhibitors
- diuretics

These three agents individually or in combination are implicated in over 50% of cases of iatrogenic acute kidney failure.<sup>10</sup>

Diuretics should be used with care.

### Drugs causing hyperkalaemia

- NSAIDs/COX-2
- ACE inhibitors
- ARBs
- Aldactone
- Moduretic
- Trimethoprim
- Digoxin

### Increased risk of adverse reaction

- Allopurinol:
  - vasculitis
  - liver dysfunction
- Statins:
  - liver dysfunction
  - myopathy
  - rhabdomyolysis
- Gemfibrozil: rhabdomyolysis

Do not use statins and gemfibrozil together.

- Beta lactams: interstitial nephritis
- LMW heparin: bleeding
- Aspirin/NSAID: GIT bleeding
- Omeprazole and related agents: interstitial nephritis

Dangerous drug accumulation is presented in

TABLE 31.3.

### Management

The patient should be referred to an appropriate specialist as early as possible. The underlying disease and any abnormalities causing progressive kidney damage must be corrected where possible. The

**Table 31.3** Dangerous drug accumulation in kidney impairment<sup>7</sup>

Drug	Problem
Aciclovir	Confusion, encephalopathy
Cotrimoxazole	Steven Johnson syndrome
Flagyl (long term)	Peripheral neuropathy
Penicillin (high dose IV)	Seizures
Quinalones: • ciprofloxacin • norfloxacin	Seizures
Metformin	Lactic acidosis
Sulfonylureas	Prolonged hypoglycaemia
Insulin	Hypoglycaemia
Atenolol	Bradycardia/heart block
Digoxin	Nausea, bradycardia
Sotalol	Ventricular tachycardia (Mg required before conversion)
Codeine	Confusion, acute brain syndrome
Methotrexate	Liver dysfunction Bone marrow depression
Lithium	Tremor—confusion Thyroid dysfunction

management of CKF is based on the team approach involving specialists and paramedical personnel. The patient is usually faced with years of ongoing care so that an empathic support team based around the patient's GP is very important to the patient, who will require considerable psychosocial support.

Optimum treatment includes:

- regular review
- good blood pressure control (the most effective way to slow progression)
- keeping plasma phosphate levels in normal range
- maintaining effective fluid and electrolyte balance
- prompt treatment of intercurrent illness
- judicious use of drugs
- avoiding treatment errors, especially with drugs
  - avoid potassium-sparing diuretics
  - avoid nephrotoxic medications
  - other drugs that may cause problems include digoxin, tetracyclines, gentamicin, NSAIDs, nitrofurantoin and ACE inhibitors (ACEIs)
- rapid treatment of complications, especially salt and water depletion and acute urinary tract infection

- diet: low protein, sodium and potassium
- avoid toxins: nicotine, alcohol, caffeine
- treating anaemia with human recombinant erythropoietin and iron (iron infusions)

### Targets: goals of management<sup>1,4</sup>

The following are optimal targets for patients with chronic kidney disease:

- blood pressure <130/85 mm Hg if proteinuria <1 g/day  
≤125/75 mm Hg if proteinuria >1 g/day
- cholesterol total <4.0 mmol/L  
LDL <2.5 mmol/L
- blood sugar pre-prandial 4.4–6.7 mmol/L
- HbA1c ≤7%
- haemoglobin 110–120 g/L
- serum potassium ≤6 mmol/L
- BMI 25 kg/m<sup>2</sup>
- proteinuria ≥50% reduction of baseline value
- acidosis HCO<sub>3</sub><sup>-</sup> >22 mmol/L
- phosphate PO<sub>4</sub><sup>-</sup> ≤1.75 mmol/L
- no smoking
- alcohol ≤2 standard drinks/day

The main goal is to treat blood pressure, achieve resolution of proteinuria and reduce CVD risk.

### Blood pressure control

- No added salt diet (with care)
- Drug control: none of the antihypertensive agents is specifically contraindicated but those eliminated mainly by the kidney (e.g. ACE inhibitors, atenolol, sotalol) should be given in lower dosage. ACE inhibitors should not be used in the presence of kidney artery stenosis; loop diuretics (e.g. frusemide) are effective in larger doses.<sup>2</sup> The first-line agents are ACEIs or ARBs, which should *not* be used together. They should be ceased if the creatinine levels exceed 30% above baseline or if the serum K exceeds 6 mmol/L (despite dose reduction).<sup>4</sup> The non-dihydropyridine calcium channel blockers are next choice. Beta blockers can be used. Diuretics have a vital role in the patient with diastolic heart failure (see CHAPTER 88).<sup>9</sup> Control the blood pressure to the lowest tolerable level since a lower level is associated with a slower decline in GFR.

## Anaemia

- Exclude chronic infection and iron deficiency.
- Give iron for iron deficiency and also erythropoietin especially for Hb <100 g/L initiated in a renal unit.
- Avoid transfusions where possible.

## Hyperphosphataemia control

- Balanced nutrition to reduce dietary phosphate
- Protein restriction
- Calcium carbonate tablets (to bind phosphate)

## Hyperkalaemia treatment

(A concern if >6.5 mmol/L.)

- Low potassium diet
- Cease ACEI/ARB/spironolactone (if applicable)
- Nebulised salbutamol
- IV insulin and dextrose
- IV calcium gluconate
- Oral resonium A
- Then dialysis

## Dialysis

Dialysis is indicated when all other methods fail. About two-thirds of patients receive haemodialysis and about 22% are on continuous ambulatory peritoneal dialysis and automated overnight peritoneal dialysis (nocturnal dialysis).

The preferred access is via an AV fistula usually between the radial artery and a cephalic vein.

## Transplantation

Transplantation is the treatment of choice for kidney failure except where contraindicated, such as with active malignancy or tuberculosis and perhaps the elderly. However, a critical shortage of donors remains a problem. Rejection and infection are problems, occurring especially in the first 6 months. As a rule, *never* stop the immunosuppressants. With time there is a high rate of malignancy especially of skin, lymphoma × 5–10 and solid organs × 2–3 (except breast and prostate).

## Chronic kidney failure in children

The incidence of CKF in children is about two per million of the total population per year. The commonest causes include chronic glomerulonephritis, obstructive nephropathy and reflux nephropathy. Identification of structural kidney abnormalities by obstetric ultrasound and early investigation of urinary tract infections may decrease the incidence of CKF.

Dialysis and transplantation are normally considered for children over 2 years of age with end-stage CKF. For children under 2 years there are complex ethical, psychological and technical problems.<sup>7</sup> Nevertheless the prognosis for such treatment is poor.

## When to refer<sup>4</sup>

- (Glomerular) haematuria
- eGFR <30 (stage 4 or 5 CKD)
- Rapidly declining kidney function
- Significant proteinuria >1 g/24 hours
- Glomerular haematuria with macroalbuminuria
- Kidney impairment + hypertension (poor control)
- Diabetes with kidney impairment: eGFR <60 or albuminuria/proteinuria

# Connective tissue disease and the vasculitides

32

*In its more aggravated forms diffuse scleroderma is one of the most terrible of all human ills. Like Tithonus to 'wither slowly' and like him to be 'beaten down and marred and wasted', until one is literally a mummy, encased in an ever shrinking, slow contracting skin of steel, is a fate not pictured in any tragedy.*

Sir William Osler 1898

The connective tissue diseases and the related vasculitides are groups of disorders that are difficult to classify because their causation is generally unknown. They all cause joint and soft tissue inflammation and multiple other possible manifestations that create diagnostic difficulties.

## Autoimmune diseases<sup>1</sup>

These are disorders in which the body's immune system damages its own specific organs or systems. The connective tissue diseases are a classic subgroup of autoimmune disease. Rheumatoid arthritis is the most common autoimmune disease. Organ-specific

autoimmune diseases include diabetes type 1, Hashimoto thyroiditis, pernicious anaemia, IgA glomerulonephritis, Graves disease, autoimmune hepatitis and myasthenia gravis.

It is convenient to consider a working classification of joint pain (see TABLE 32.1) that includes apparent joint pain (arthralgia), as some of the inflammatory disorders cause problems in the soft tissues around joints (e.g. giant cell arteritis and hydroxyapatite crystallopathy of the tendons around the shoulder joint).

Vasculitis is, in fact, a condition common to the connective tissue disorders and to the so-called vasculitides (see TABLE 32.2).

A major concern to all is that the diagnosis of these conditions is elusive and often delayed.

Table 32.1 A classification of rheumatological pain

Hyperacute (red hot) joints	Crystals	Urate: gout Calcium pyrophosphate Hydroxyapatite Example: staphylococcal septic arthritis
	Pus	Example: rheumatoid arthritis
Inflammation of joints	Symmetrical	Example: spondyloarthropathies
	Asymmetrical	Primary osteoarthritis (e.g. in hands)
Non-inflammatory joint disorder	Typical	Example: post-trauma, haemochromatosis
	Atypical	
Joint and soft tissue inflammation	Connective tissue disorders	SLE Scleroderma Polymyositis/dermatomyositis Polyarteritis nodosa Giant cell arteritis Polymyalgia rheumatica
	Vasculitides	Examples: fibrositis, fibromyalgia, polymyalgia
	Generalised	Examples: plantar fasciitis, epicondylitis
	Localised	
Non-articular (soft tissue) inflammation		

Source: After Dr Stephen Hall, personal communication

**Table 32.2** List of connective tissue disorders and vasculitides

#### Connective tissue disorders

Rheumatoid arthritis

SLE

Scleroderma/limited scleroderma

Polymyositis/dermatomyositis

Sjögren syndrome

Raynaud phenomenon (including Raynaud syndrome)

#### Vasculitides

##### Large vessel predominantly:

- giant cell arteritis/temporal arteritis/polymyalgia rheumatica
- Takayasu arteritis
- Behçet syndrome

##### Medium vessel:

- polyarteritis nodosa
- Kawasaki disease

##### Small vessel (mainly):

- Henoch–Schönlein purpura
- hypersensitivity vasculitis
- essential cryoglobulinaemia

##### Antineutrophil cytoplasmic antibody (ANCA) associated:

- Wegener granulomatosis
- Churg–Strauss vasculitis
- microscopic polyangiitis

## Connective tissue disease

The term 'connective tissue disease' (CTD) is a generic label applied to a group of disorders characterised by inflammation, presumed initiated by an autoimmune response to an autoantigen and perpetuated by unknown factors.<sup>2</sup> The vasculitides are a variety of CTD.

The CTDs comprise three classic conditions, namely systemic lupus erythematosus (SLE), scleroderma and polymyositis/dermatomyositis (see FIG. 32.1).<sup>1</sup>

Mixed connective tissue disorder includes features of all three disorders and is sometimes referred to as 'overlap' syndrome. Other related disorders classified as CTDs include Sjögren syndrome and Raynaud syndrome.

**FIGURE 32.1** The classic connective tissue disorders

#### Common features include:

- fatigue
- arthralgia or arthritis
- multisystem involvement
- vasculitis
- immunological abnormalities
- sicca (dry skin and mucous membranes)
- Raynaud phenomenon

## Investigations in connective tissue disease

The rapidly growing list of investigations, particularly those of autoantibodies, can be confusing. Baseline investigations to consider are FBE, ESR, C-reactive protein and rheumatoid factor. The rheumatoid factor can be positive in a great range of disorders, including rheumatoid arthritis, SLE, systemic sclerosis, Sjögren syndrome, chronic liver disease and various viral (e.g. hepatitis), bacterial (e.g. tuberculosis) and parasitic (e.g. malaria) infections. There is usually a low titre, except in rheumatoid arthritis. X-rays and HLA-B<sub>27</sub> tests are not recommended.

**TABLE 32.3** summarises the majority of autoantibodies that can be tested. The antinuclear antibody (ANA) test is a generic term for autoantibodies to several different cellular antigens. It is very sensitive for SLE, but not absolutely specific (false positives occur with viral arthritis and others e.g. Sjögren). It is especially useful in the young female presenting with fatigue, small joint arthralgia and dermatological features of SLE.

The more specific antibodies for SLE, namely to double-stranded DNA (dsDNA) and extractable nuclear antigens (ENA), should only be ordered if there is a significantly positive ANA.

**Table 32.3** Autoantibodies in connective tissue disease<sup>2</sup>

<b>Antinuclear antibody (ANA)</b>	High sensitivity >95%, low specificity for SLE
<b>Anti-dsDNA</b>	High sensitivity and specificity for SLE (60%): found in rheumatoid arthritis
<b>Antibodies to extractable nuclear antigens (ENA)</b>	
Smith (Sm)	Highly specific for SLE
U1 RNP	Common in mixed connective tissue disease, SLE
Ro (SSA)	Common in Sjögren syndrome, SLE and some other connective tissue diseases
La (SSB)	Common in Sjögren syndrome, SLE (15%)
Scl-70 (antitopoisomerase)	Common in 20–30% of patients with scleroderma
Jo1	Common in 30% of patients with polymyositis
<b>Anticentromere</b>	High sensitivity and specificity for CREST syndrome
<b>Antineutrophil cytoplasm (ANCA)</b>	High sensitivity and specificity for Wegener granulomatosis
<b>Antiphospholipids</b>	Diagnostic in antiphospholipid syndrome
Anti-cardiolipin	
Anti-β <sub>2</sub> -GP1 antibodies	
Lupus anticoagulants	Present in 5–10% of SLE
1gM × 1gG APL	

### § Antiphospholipid antibody syndrome

This syndrome may occur with SLE or in isolation and is responsible for recurrent arterial and/or venous thromboembolism, recurrent spontaneous abortions or thrombocytopenia in the presence of antiphospholipid antibodies but without features of SLE. Livedo reticularis, skin ulcers and neuropsychiatric disturbances have also been noted. If suspected,

commence aspirin 150–300 mg (o) daily and refer to a consultant.

### § Systemic lupus erythematosus

SLE (lupus), which is the commonest of the connective tissue disorders, is described as the ‘great pretender’.<sup>3</sup> It is a multisystem autoimmune disorder with a wide variety of clinical features that are due to vasculitis (see FIG. 32.2). Arthritis is the commonest feature of SLE (90% of cases). Milder manifestations outnumber more severe forms.

#### Clinical features

- Prevalence about 1 in 1000 of population
- Mainly affects women in ‘high oestrogen’ period (90% of cases)
- Peak onset between 15 and 40 years
- Fever, malaise, tiredness common
- Multiple drug allergies e.g. sulfonamides
- Problems with oral contraceptive pill and pregnancy

**DxT** polyarthritis + fatigue + skin lesions → SLE

#### Classification criteria

(SLE = four or more of these 11 criteria)

- Malar (butterfly) rash
- Discoid rash
- Photosensitivity
- Arthritis (non-erosive arthritis in ≥ 2 peripheral joints)
- Oral ulcers (usually painless)
- Serositis (pleurisy or pericarditis)
- Kidney features (proteinuria or cellular casts)
- Neurological features (intractable headache, seizures or psychosis)
- Haematological features (haemolytic anaemia, leucopenia, lymphopenia or thrombocytopenia)
- Immunological features (positive anti-DNA, antiphospholipid antibodies or anti-Sm tests and false positive syphilis serology)
- Positive antinuclear antibody (ANA) test

*Note:* Drugs that can cause a lupus-like syndrome are discussed in CHAPTER 35).

#### Diagnosis

- ESR/CRP—elevated in proportion to disease activity
- ANA test—positive in 95% (perform first) (key test)

FIGURE 32.2 Clinical features of SLE

- dsDNA antibodies—90% specific for SLE but present in only 60% (key test)
- ENA antibodies, especially Sm—highly specific
- Rheumatoid factor—positive in 50%
- LE cell test—inefficient and not used

The diagnosis cannot be made on blood tests alone. Supportive clinical evidence is necessary.

For suspected SLE, the recommended approach is to perform an ANA test. If positive then order dsDNA and ENA antibodies.

### Management<sup>4</sup>

- Appropriate explanation, support and reassurance, use of sunscreens (refer to CHAPTER 123)
- Refer to consultant rheumatologist for shared care in a multidisciplinary team

### Treatment<sup>2</sup>

Based on severity and organ involved.

- Mild: NSAIDs (for arthralgia)
- Moderate (especially skin, joint serosa involved): low-dose antimalarials (e.g. hydroxychloroquine up to 6 mg/kg once daily) (e.g. 400 mg (o) daily for 3 months, then 200 mg daily long term)

- Consider: fish body oil 0.2 mg/kg (o) daily
- Severe: corticosteroids are the mainstay (e.g. prednisolone 7.5–15 mg (o) daily): immunosuppressive drugs (e.g. azathioprine, methotrexate with folic acid, rituximab) may be used for severe arthralgia
- Avoid drugs in those in clinical remission and with normal complement levels.
- Other treatments, such as plasma exchange and immunosuppressive regimens, are available for severe disease.
- Keep in mind antiphospholipid antibody syndrome, especially with recurrent fetal loss and thrombotic episodes.

### Scleroderma (systemic sclerosis)

This can present as a polyarthritis affecting the fingers of the hand in 25% of patients, especially in the early stages. Soft tissue swelling produces a 'sausage finger' pattern. Scleroderma mainly affects the skin, presenting with Raynaud phenomenon in over 85% of patients (see FIG. 32.3).

There are three clinical variants:

- 1 limited cutaneous disease, for example, morphea
- 2 cutaneous with limited organ involvement (CREST)
- 3 diffuse systemic disease (systemic sclerosis)

### Clinical features

- Female to male ratio = 3:1
- A progressive disease of multiple organs
- Raynaud phenomenon
- Stiffness of fingers and other skin areas (see FIG. 32.4)
- 'Bird-like' facies (mouth puckered)
- Dysphagia and diarrhoea (malabsorption)
- Oesophageal dysmotility
- Respiratory symptoms: pulmonary fibrosis
- Cardiac symptoms: pericarditis, etc.
- Look for tight skin on chest (Roman breastplate)

**DxT** finger discomfort + arthralgia + GORD  
(± skin tightness) → scleroderma

### Diagnosis<sup>2,5</sup>

- ESR may be raised
- Normocytic normochromic anaemia may be present
- ANA test—up to 90% positive (relatively specific)
- Rheumatoid factor—positive in 30%
- Anticentromere antibodies—specific (positive in 90% with limited disease and 5% with diffuse)

FIGURE 32.3 Clinical features of scleroderma

**FIGURE 32.4** Scleroderma showing stiff, taut skin of fingers

- Antitopoisomerase I (anti-Scl-70) antibody is specific but only positive in 20–40%
- Skin biopsy—increase in dermal collagen

### Management

- Refer to consultant for shared care
- Empathic explanation, patient education
- Analgesics and NSAIDs for pain
- Avoid vasospasm (no smoking, beta blockers, ergotamine): calcium channel blockers such as nifedipine may help Raynaud
- Treat malabsorption if present; skin emollients
- D-penicillamine can help if there is significant systemic or cutaneous involvement<sup>6</sup>

### Localised scleroderma

- Morphea—plaques of erythema with violaceous periphery, feels hard; mainly on trunk
- Linear—may be ‘en coup de sabre’ (a sabre stroke)

### CREST syndrome

#### Clinical features

- Calcinosis
- Raynaud phenomenon
- Oesophageal dysmotility
- Sclerodactyly
- Telangiectasia
- Anticentromere antibody (invariably positive)

### Polymyositis and dermatomyositis

Polymyositis is an uncommon systemic disorder with inflammation of skin and muscle whose main feature is symmetrical muscle weakness and wasting involving the proximal muscles of the shoulder and pelvic girdles.

### Clinical features

- Any age group
- Peak incidence 40–60 years
- Female to male ratio = 2:1
- Muscle weakness and wasting proximal limb muscles
- Main complaint is weakness
- Muscle pain and tenderness in about 50%
- Arthralgia or arthritis in about 50% (resembles distribution of rheumatoid arthritis)
- Dysphagia in about 50% due to oesophageal involvement
- Raynaud phenomenon
- Consider associated malignancy: lung and ovary

**DxT** weakness + joint and muscle pain + violaceous facial rash → dermatomyositis

**FIGURE 32.5** Clinical features of polymyositis/dermatomyositis

### The rash

The distinctive rash shows features of photosensitivity. There is heliotrope violet discolouration of the eyelids (see FIG. 32.6), forehead and cheeks, and possible

**FIGURE 32.6** Heliotrope discolouration of eyelids in dermatomyositis

erythema resembling sunburn and peri-orbital oedema. There is a characteristic rash on the hands, especially the fingers and nail folds. The knees and elbows are commonly involved.

Differential diagnosis: statin-induced necrotising myositis (↑ CK levels).

### Diagnosis

- Muscle enzyme studies (serum creatine kinase and aldolase)
- Biopsies—skin and muscle
- EMG studies—show characteristic pattern

Treatment includes corticosteroids and cytotoxic drugs. Early referral is appropriate.

### § Sjögren syndrome

The under-diagnosed syndrome of dry eyes (keratoconjunctivitis sicca) in the absence of rheumatoid arthritis or any other autoimmune disease is known as primary Sjögren syndrome (SS):

- primary SS—limited or multisystem
- secondary SS—occurs in association with other CTDs including rheumatoid arthritis (accounts for 50%)

### Clinical features

- Fatigue
- Sicca (xerostomia, dry eyes, dry vagina)
- Difficulty swallowing food
- Increased dental caries; denture dysfunction
- Salivary gland enlargement
- Xerotrachea → chronic dry cough; hoarseness
- Dyspareunia
- Arthralgia ± non-erosive arthritis

Although considered benign can transform into non-Hodgkin lymphoma (44 times risk).

**DxT** dry eyes + dry mouth + arthritis → Sjögren syndrome

### Diagnosis

Autoantibody tests—positive ANA (ENA), Ro (SSA), La (SS-B)

Schirmer's tear test

### Management

- Referral to rheumatologist
- Treatment is symptomatic for dry eyes, mouth and vagina; arthralgia
- NSAIDs, hydroxychloroquine or steroids for arthritis

### § Raynaud phenomenon<sup>2</sup>

(Refer also to **CHAPTER 64**.)

It is classified as either primary (without associated disease) or secondary (when associated with any CTD).

Patients with primary Raynaud may progress to a CTD but the likelihood is low (5–15%) and the delay to diagnosis is long (average of 10 years).<sup>2</sup> The more severe the Raynaud, the more likely it is to progress to systemic disease.

Raynaud is a clinical syndrome of episodic arteriolar vasospasm usually involving the fingers and toes (one or two at a time). It may also involve the nose, ear or nipple.

## THE VASCULITIDES

The vasculitides or vasculitis syndromes are a heterogeneous group of disorders involving inflammation and necrosis of blood vessels, the clinical effects and classification depending on the size of the vessels involved. They are a variety of CTD.

Small vessel vasculitis is the common type encountered in practice. Medium vessel vasculitis includes polyarteritis nodosa and large vessel vasculitis includes giant cell arteritis.

Symptoms suggestive of vasculitis include systemic (malaise, fever, weight loss, arthralgia), skin lesions (e.g. purpura, ulcers, infarction), respiratory (wheeze, cough, dyspnoea), ENT (epistaxis, sinusitis, nasal crusting), chest pain (angina), kidney (haematuria, proteinuria, CKF) and neurological (various e.g. sensorimotor).

### Small vessel vasculitis

This is associated with many important disorders, such as rheumatoid arthritis, SLE, bacterial endocarditis, Henoch–Schönlein purpura and hepatitis B.

Skin lesions are usually associated with these disorders and the most common presentation is painless, palpable purpura, such as occurs with Henoch–Schönlein purpura.

### Rarer but deadly causes

The major vasculitides called systemic vasculitides are polyarteritis nodosa (PN), polymyalgia rheumatica (PR), giant cell arteritis (GCA), Takayasu arteritis, Behçet syndrome, Churg–Strauss vasculitis and Wegener granulomatosis (WG). Unfortunately, many patients die or become terminally ill before the diagnosis is suspected.

#### Practice tip

If a serious ANCA-associated disease is suspected, early diagnosis is life-saving because of sinister kidney damage. Perform a urine examination for haematuria and proteinuria. If positive, order an ANCA test. If positive, refer urgently.

### § Henoch–Schönlein purpura

More details are presented about this vasculitis disorder in [CHAPTER 39](#).

### § Takayasu arteritis<sup>2</sup>

Known as ‘pulseless disease’ or ‘aortic arch syndrome’, this vasculitis involves the aortic arch and other major arteries. It typically affects young Japanese female adults. Features include absence of peripheral pulses and hypertension.

### § Polyarteritis nodosa

The hallmark of PN is necrotising vasculitis of the small and medium arteries leading to skin nodules, infarctive ulcers and other serious manifestations. The cause is unknown but associations are found with drug abusers (especially adulterated drugs), B-cell lymphomas, other drugs and hepatitis B surface antigen. It should be suspected in any multisystemic disease of obscure aetiology.

#### Clinical features

- Young to middle-aged men
- Constitutional symptoms: fever, malaise, myalgia, weight loss
- Migratory arthralgia or polyarthritides
- Subcutaneous nodules along arterial lines
- Livedo reticularis and skin ulcers
- Kidney impairment and hypertension

- Cardiac disorders: arrhythmia, failure, infarction
- Diagnosis confirmed by biopsy or angiogram
- ESR raised
- Treatment with corticosteroids and immunosuppressants
- Death is usually from kidney disease

**DxT** arthralgia + weight loss + fever (± skin lesions) → polyarteritis nodosa

### § Giant cell arteritis and polymyalgia rheumatica

The basic pathology of this very important disease complex is GCA (synonyms: temporal arteritis, cranial arteritis). The clinical syndromes are polymyalgia rheumatica and temporal arteritis. The clinical manifestations of polymyalgia rheumatica invariably precede those of temporal arteritis, of which there is about a 20% association. The diagnosis is based on clinical grounds. No definite cause has been found.

#### Clinical features (polymyalgia rheumatica)

- Pain and stiffness in proximal muscles of shoulder and pelvic girdle, cervical spine (refer [FIG. 32.7](#))
- Symmetrical distribution
- Typical ages 60–70 years (rare <50)
- Both sexes: more common in women
- Early morning stiffness
- May be systemic symptoms: weight loss, malaise, anorexia
- Painful restriction of movement of shoulders and hips
- Signs may be absent later in day

Differential diagnosis: polymyalgic onset rheumatoid arthritis.

**DxT** malaise + painful shoulder girdle + morning stiffness (>50 years) → polymyalgia rheumatica

#### Clinical features (temporal arteritis)

- Headache—unilateral, throbbing ([CHAPTER 56](#))
- Temporal tenderness
- Loss of pulsation of temporal artery
- Jaw claudication
- Biopsy of artery (5 cm) is diagnostic

**DxT** fatigue + headache + jaw claudication → temporal arteritis

**FIGURE 32.7** Polymyalgia rheumatica: typical sites of areas of pain and stiffness

### Investigation

- No specific test for polymyalgia rheumatica
- ESR—extremely high, around 100
- C-reactive protein—elevated
- Mild anaemia (normochromic, normocytic)

### Treatment—for uncomplicated disease

#### Prednisolone

- Starting dose
  - temporal (giant cell) arteritis: 40–60 mg (o) daily initially for 2–4 weeks (+ aspirin 100 mg/day) then gradual reduction according to ESR/CRP
  - polymyalgia rheumatica: 15 mg (o) daily for 2–4 weeks, then taper
- Taper down gradually to the minimum effective dose (often <5 mg daily) according to the clinical response and the ESR and CRP. Aim for treatment for 2 years. Relapses are common.
- If complicated (e.g. evolving visual loss) give IV methylprednisolone for 3 days prior to oral agents.

#### Other drugs

- Azathioprine or methotrexate can be used as steroid-sparing agents.

#### Practice tip

In giant cell arteritis, a delay in diagnosis after presenting with amaurosis fugax and non-specific symptoms can have tragic consequences, in the form of ischaemic events such as blindness and strokes.

### § Behçet syndrome

Behçet syndrome is a systemic (multiorgan) vasculitis of unknown aetiology, affecting veins and arteries of all sizes. The main feature is painful oral ulceration and the hallmark is the 'pathergy' reaction whereby simple trauma such as a pinprick can cause a papule or pustule to form within a few hours at the site.

#### Clinical features

- Male to female ratio = 2:1
- Recurrent oral and/or genital ulceration
- Arthritis (usually knees)
- Ocular symptoms—pain, reduced vision, floaters (ocular inflammation)

There is no specific diagnostic test.

Associated problems/complications: repeated uveitis and retinitis → blindness, colitis, venous thrombosis, meningoencephalitis.

Treatment: high-dose steroids and specific ulcer treatment. DMARDs may be required.

#### Practice tip

Patients with Behçet eye disease should be referred promptly for an ophthalmological opinion, which may be sight-saving.<sup>2</sup>

### § Wegener granulomatosis

Now called 'granulomatosis with polyangiitis' this rare vasculitis of unknown cause has a classic triad: upper respiratory tract (URT) granuloma, fleeting pulmonary shadows (nodules) and glomerulonephritis. Without treatment it is invariably fatal and sometimes the initial diagnosis is that made at autopsy. It is difficult to diagnose, especially as the patient (usually young to middle-aged) presents with a febrile illness and respiratory symptoms, but early diagnosis is essential. It usually gets confused with benign nasal conditions.

#### Clinical features

- Adolescence to elderly, mean age 40–45 years
- Constitutional symptoms (as for PN)
- Lower respiratory tract (LRT) symptoms (e.g. cough, dyspnoea)
- Oral ulcers
- Upper respiratory symptoms: rhinorrhoea, epistaxis, sinus pain
- Eye involvement—orbital mass
- Polyarthritis

- Kidney involvement—usually not clinically apparent (about 75% get glomerulonephritis)
- Chest X-ray points to diagnosis—multiple nodes, cavitations
- Antineutrophil antibodies (c-ANCA) are a useful diagnostic marker (not specific)
- Diagnosis confirmed by biopsy, usually an open lung biopsy
- Better prognosis with early diagnosis and treatment with cyclophosphamide

32

**DxT** malaise + URTs (e.g. rhinitis, sinusitis) + LRTs (e.g. wheeze, cough) → Granulomatosis with polyangiitis

**DxT** asthma + rhinitis + vasculitis + hypereosinophilia → Churg–Strauss vasculitis

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Rheumatoid arthritis
- SLE

## References

*The disease is of long duration; to connect, therefore, the symptoms which occur in its later stages with those which mark its commencement, requires a continuance of observation of the same case, or at least a correct history of its symptoms, even for several years.*

James Parkinson (1755–1824), *An Essay on the Shaking Palsy*

In general practice there are many neurological problems that present a diagnostic dilemma, with some being true masquerades for the non-neurologist. This applies particularly to various seizure disorders, space-occupying lesions in the cerebrum and the cerebellum, demyelinating disorders, motor neurone disorders and peripheral neuropathies.

The most common pitfall that occurs with neurological disorders is misdiagnosis, and the most common reason for misdiagnosis is an inadequate history. Failure to appreciate the neurological meaning of points elicited during the history is another reason for misdiagnosis.

Some very important neurological disorders are presented in this section: Parkinson disease, which is common and can be easily misdiagnosed, especially when the classic ‘pill rolling’ tremor is absent or mild; multiple sclerosis (MS), because it is difficult to diagnose initially; and acute idiopathic demyelinating polyneuropathy (Guillain–Barré syndrome), because it can be rapidly fatal if misdiagnosed. MS can masquerade as almost anything—‘If you don’t know what it is, think of MS.’

Another brain teaser for the family doctor is to diagnose accurately the various types of epilepsy. The most commonly misdiagnosed seizure disorders are complex partial seizures or atypical generalised tonic-clonic seizures (see [CHAPTER 54](#)).<sup>1</sup> Even more difficult is the differentiation of real seizures from pseudo- or non-epileptic seizures. As a rule neurological conditions should be referred early for specialist management.

## Diplopia

The onset of diplopia (double vision) in adults is often acute, very distressing and invariably easy to diagnose. It is invariably binocular, which usually results from extraocular muscular imbalance or weakness. The type of binocular diplopia—vertical, horizontal or oblique—provides clues in identifying

the affected muscle. Monocular diplopia is double vision that occurs in one eye when the other is covered. It arises from the eye itself.

## Causes of binocular diplopia

- Ocular nerve palsies (3, 4 or 6); consider: CVA or TIA, tumour (orbital or intracerebral), aneurysm, diabetes mellitus, arteritis, head injury, ophthalmoplegic migraine (transient)
- Muscle tethering (e.g. blow-out orbital fracture)
- Multiple sclerosis (recurrent diplopia)
- Myasthenia gravis, hyperthyroidism (multiple muscle movement)

## Diagnosis

Diplopia should be differentiated from blurred vision, which is like ‘ghosting’ on a TV screen.

## Office tests

Test for double vision with each eye occluded. If diplopia persists, it is uniocular. If, however, double vision disappears when either eye is covered, there is a defect of one of the muscles moving the eyeball. Determine whether diplopia occurs in any particular direction of gaze. It is most marked when moved in the direction of action of the weak muscle. Ask patient to follow your finger, red pin or penlight with both eyes and move it in an H pattern.

- 3rd nerve—eye turned out: divergent squint
- 6th nerve—failure to abduct: convergent squint

See [FIGURE 33.1](#).

## Laboratory test

- ESR (consider arteritis)

*Note:*

- Exclude 3rd and 6th nerve palsies as they may be secondary to life-threatening conditions.
- Refer urgently if diplopia is binocular, of recent onset and persistent.

**FIGURE 33.1** Direction of movement of the right eye indicating the responsible extra-ocular muscles and cranial nerves (3 = oculomotor, 4 = trochlear, 6 = abducens)

## Motor weakness

Muscle weakness is a common feature of many disorders ranging from neurogenic and myogenic disorders to metabolic and psychiatric. It is very important clinically to be able to differentiate upper motor neurone (UMN) signs from lower motor neurone (LMN) signs (see TABLE 33.1).

**Table 33.1** Clinical differences between a lower motor neurone lesion and an upper motor neurone lesion

Manifestation	UMN	LMN
<b>Weakness</b>	Present	Present
<b>Wasting</b>	Absent or mild	Marked
<b>Power</b>	Reduced	Reduced
<b>Tone</b>	Usually increased (spastic paralysis) ± clonus	Absent or decreased (flaccid paralysis)
<b>Fasciculations</b>	Absent	May be present
<b>Reflexes</b>	Brisk tendon reflexes Abdominal absent Extensor plantar response	Absent or diminished Downgoing plantar response

## Upper motor neurone lesions

UMN signs occur when a lesion has interrupted a neural pathway at a level above the anterior horn cell.<sup>2</sup> Examples include lesions in motor pathways in the cerebral cortex, internal capsule, brain stem or spinal cord.

Clinical examples include stroke (thrombosis, embolism or haemorrhage in the brain), tumours of the various pathways, demyelinating disease (e.g. multiple sclerosis) and infection (e.g. HIV).

## Lower motor neurone lesions

LMN signs occur when a lesion interrupts peripheral neural pathways from the anterior horn cell, that is, the spinal reflex arc.

Clinical examples include peripheral neuropathy, Guillain-Barré syndrome, poliomyelitis and a thickened peripheral nerve (e.g. leprosy).

*Note:* A spinal cord lesion causes LMN signs at the level of the lesion and UMN signs below that level.

## Neurogenic and myogenic muscle weakness

It is also important to distinguish between weakness caused by neurological conditions, especially those causing LMN lesions and muscular disorders. The features are compared in TABLE 33.2. Myotonia is muscle stiffness with difficulty in relaxation after voluntary contraction e.g. dystrophia myotonica (myotonic dystrophy) (see TABLE 33.7).

**Table 33.2** Muscle weakness: main clinical differences between neurogenic and myogenic lesions

Myogenic weakness	Neurogenic weakness
Reflexes often present despite severe weakness	Reflexes often absent despite minimal weakness
Weakness out of proportion to wasting	Wasting out of proportion to weakness
Sensation normal	± Sensory changes
No fasciculation (polymyositis may cause fasciculation)	Fasciculation a feature

## Motor neurone disease (MND)

MND is a progressive neuromuscular disorder resulting in muscular limb and bulbar weakness due to death of motor neurones in the brain, brain stem and spinal cord. The sensory system is not involved, nor the cranial nerves to the eye muscles. Five to 10% of MND is inherited with an autosomal dominant pattern; the rest is sporadic. The three main patterns are:

- 1 amyotrophic lateral sclerosis (Lou Gehrig disease)—combined LMN muscle atrophy plus UMN hyper-reflexia, leading to progressive spasticity

- 2 progressive muscle atrophy—wasting beginning in the distal muscles; widespread fasciculation
- 3 progressive bulbar (LMN) palsy and pseudobulbar palsy (LMN lesions in the brainstem motor nuclei). Results in wasted fibrillating tongue, weakness of chewing and swallowing, and of facial muscles.

### Symptoms and signs

- Weakness or muscle wasting—first noticed in hands (weak grip) or feet
- Stumbling (spastic gait, foot drop)
- Difficulty with swallowing
- Difficulty with speech, for example, slurring, hoarseness
- Fasciculation (twitching) of skeletal muscles and fibrillating tongue
- Cramps
- Emotional instability, depression
- $\pm$  Muscle pain

The diagnosis is clinical. There are no diagnostic tests, but neurophysiological tests help differentiate from other conditions.

MND is incurable and progresses to death usually within 3–5 years from ventilatory failure/aspiration pneumonia.

No treatment is proven to influence outcome although riluzole, a sodium channel blocker, appears to slow progression slightly. Baclofen 10 mg bd may help symptoms of cramp. Botulinum toxin may help spasticity and propantheline or amitriptyline for drooling. Multidisciplinary care is essential.

### Tremor

Tremor is an important symptom to evaluate correctly. A list of causes is presented in **TABLE 33.3**. A common pitfall in patients presenting with tremor is for Parkinson disease (PD) to be diagnosed as benign essential tremor and for benign essential tremor to be diagnosed as PD, but the clinical distinction is not always easy and it must be remembered that as many as 20% will experience both concurrently.

### Resting tremor—Parkinsonian

The tremor of PD is present at rest. The hand tremor is most marked with the arms supported on the lap and during walking. The characteristic movement is ‘pill-rolling’ where movement of the fingers at the metacarpophalangeal joints is combined with movements of the thumb. The resting tremor decreases on finger–nose testing. The best way to evoke the tremor is to distract the patient, such as

**Table 33.3** Causes of tremor

Physiological
Benign essential (familial) tremor
Senility
Anxiety, including hyperventilation
Hyperthyroidism
Toxicity (e.g. alcohol, liver failure, uraemia)
Drugs (e.g. lithium, narcotic withdrawal)
PD
Drug-induced Parkinsonism
Cerebellar disease
Cerebral tumour (frontal lobe)
Alzheimer dementia
Wilson syndrome
Miscellaneous (e.g. red-nucleus lesion, hypoglycaemia)

focusing attention on the left hand with a view to ‘examining’ the right hand or by asking the patient to turn the head from side to side.

### Action or postural tremor

This fine tremor is noted by examining the patient with the arms outstretched and the fingers apart. The tremor may be rendered more obvious if a sheet of paper is placed over the dorsum of the hands. The tremor is present throughout movement, being accentuated by voluntary contraction.

### Causes

- Essential tremor (also called familial tremor or benign essential tremor)
- Senile tremor
- Physiological
- Anxiety/emotional
- Hyperthyroidism
- Alcohol
- Drugs, for example, drug withdrawal (e.g. heroin, cocaine, alcohol), amphetamines, lithium, sympathomimetics (bronchodilators), sodium valproate, heavy metals (e.g. mercury), caffeine, amiodarone
- Pheochromocytoma

### Intention tremor (cerebellar disease)

This coarse oscillating tremor is absent at rest but exacerbated by action and increases as the target is approached. It is tested by ‘finger–nose–finger’

touching or running the heel down the opposite shin, and past pointing of the nose is a feature. It occurs in cerebellar lobe disease and with lesions of cerebellar connections.

## Flapping (metabolic tremor)

A flapping or 'wing-beating' tremor is observed when the arms are extended with hyperextension of the wrists. It involves slow, coarse and jerky movements of flexion and extension at the wrists.

*Note:* Flapping (asterixis) is not strictly a tremor.

### Causes

- Wilson syndrome
- Hepatic encephalopathy
- Uraemia
- Respiratory failure
- Lesions of the red nucleus of the midbrain (the classic cause of a flap)

## § Essential tremor

Essential tremor, which is probably the most common movement disorder (2–5% prevalence), has been variously called benign, familial, senile or juvenile tremor.

### Clinical features

- Autosomal dominant disorder (variable penetrance)
- Often begins in early adult life, even adolescence
- Usually begins with a slight tremor in both hands
- May involve head (titubation), chin and tongue and rarely trunk and legs
- Interferes with writing (not micrographic), handling cups of tea and spoons, etc.
- Tremor most marked when arms held out (postural tremor); less evident at rest
- Tremor exacerbated by anxiety
- May affect speech if it involves bulbar musculature
- Relieved by alcohol
- Can swing arm and gait normal

### Triad of features

- Positive family history
- Tremor with little disability
- Normal gait

## Distinguishing essential tremor from Parkinson disease

This is not always easy as a postural tremor can be present in PD although the hand tremor is most

marked at rest with the arms supported on the lap. Parkinsonian tremor is slower at 4–6 Hz while essential tremor is much faster at around 8–13 Hz. Imaging is unnecessary.

A most useful way to differentiate the two causes is to observe the gait. It is normal in essential tremor but in PD there may be loss of arm swing and the step is usually shortened with stooped posture and shuffling gait.

### Management

Most patients do not need treatment and all that is required is an appropriate explanation.<sup>1</sup> If necessary, use propranolol (first choice) or primidone 62.5 mg nocte (up to 250 mg).<sup>3</sup> A typical starting dose of propranolol is 10–20 mg bd; many require 120–240 mg/day.<sup>3</sup> If the tremor is only intrusive at times of increased emotional stress, intermittent use of benzodiazepines (e.g. lorazepam 1 mg) 30 minutes before exposure to the stress may be all that is required. Modest alcohol intake (e.g. a glass of whisky) is very effective. A standard drink of alcohol often alleviates the tremor. Larger doses of alcohol have no additional effect. If drugs fail, deep brain stimulation to the thalamus can be used.

## § Parkinson disease

Parkinson disease (PD) is a disorder of the automatic processor of the brain which relies on dopamine to maintain movements at a selected size and speed. Loss of dopamine causes movements to become smaller and slower. The pathological features are loss of dopamine-producing neurones from the substantia nigra in the brain stem together with Lewy bodies in the neurones.<sup>4</sup> Genetic factors occur in 5% of individuals.

One of the most important clinical aspects of PD, which has a slow and insidious onset, is the ability to make an early diagnosis. Sometimes this can be very difficult, especially when the tremor is absent or mild, as occurs with the atherosclerotic degenerative type of Parkinsonism. The lack of any specific abnormality on special investigation leaves the responsibility for a diagnosis based on the history and examination. As a general rule of thumb the diagnosis of PD is restricted to those who respond to levodopa (L-dopa)—the rest are termed Parkinsonism or 'Parkinson plus'.

### Key facts and checkpoints

- PD is a most common and disabling chronic neurological disorder. About 90% are idiopathic.
- The prevalence in Australia is 120–150 per 100 000.<sup>5</sup> Lifetime risk is 1 in 40.

- The mean age of onset is between 58 and 62 years.<sup>5</sup>
- The incidence rises sharply over 70 years of age (peak 65 years).<sup>5</sup>

The classic tetrad of PD (see FIG. 33.2) is:<sup>6</sup>

- tremor (at rest)
- rigidity
- bradykinesia (poverty of movement)
- postural instability (loss of postural reflexes)

FIGURE 33.2 Basic clinical features of Parkinson disease

- The diagnosis is based on the history and examination.
- Always think of PD in an older person presenting with falls.
- A reduced sense of smell is one of the first symptoms.
- Non-motor automatic dysfunctions: cognition, behaviour, mood.

- Hemi-Parkinsonism can occur; all the signs are confined to one side and thus must be differentiated from hemiparesis. In fact, most cases of PD start unilaterally.
- Always consider drug-induced Parkinsonism. The usual drugs are phenothiazines, butyrophenones and reserpine. Tremor is uncommon but rigidity and bradykinesia may be severe.
- Other causes include vascular (atherosclerosis) and normal pressure hydrocephalus.

Refer to TABLE 33.4.

### Signs

- Power, reflexes and sensation are usually normal.
- The earliest abnormal physical signs to appear are loss of dexterity of rapid alternating movements and absence of arm swing, in addition to increased tone with distraction
- Positive frontal lobe signs, such as grasp and glabellar taps (only allow three blinks), are more common with Parkinsonism.

*Note:* There is no laboratory test for PD—it is a clinical diagnosis. Hypothyroidism and depression, which also cause slowness of movement, may cause confusion with diagnosis.

*Note:* The Steele–Richardson–Olszewski syndrome (also known as progressive supranuclear palsy—PSP parkinsonism, mild dementia and vertical gaze dysfunction) is worth considering.

Three major traps in missing early diagnosis:<sup>5</sup>

- Age: 10–15% are <50 years at onset
- Belief that it is a disease of men: M = F
- Absence of resting tremor (only 50% have it at onset)

### Principles of management

- Provide appropriate explanation and education.
- Explain that PD is slowly progressive and is improved but not cured by treatment. It is associated with increased mortality (RR death compared with general population ranges 1.6 to 3). The question of whether treatment reduces mortality remains controversial.<sup>7</sup>
- Refer to a specialist for shared care—from outset.
- Support systems are necessary for advanced PD.
- Walking sticks (which spread the centre of gravity) with appropriate education into their use may be necessary to help prevent falls, and constant care is required, so that admission to

**Table 33.4** Parkinson disease: symptoms and signs (a checklist)

<b>General</b>	Tiredness
	Lethargy
	Restlessness
	Trouble getting out of chair or car and turning over in bed
<b>Tremor</b>	Present at rest
	Slow rate—4 to 6 cycles per second
	Alternating, especially arms
	Pill-rolling (severe cases)
	<i>Note:</i> may be absent or unilateral
<b>Rigidity</b>	'Cogwheel'—'juddering' on passive extension of the forearm—feels like going through cogs
	Lead pipe—limbs resist passive extension through movement (constant resistance)
<b>Motor: bradykinesia/hypokinesia</b>	Slowness of initiating a movement
	Difficulty with fine finger tasks
	Micrographia (see FIG. 33.3)
	Masked facies
	Relative lack of blinking
	Impaired convergence of eyes
	Excessive salivation (late)
	Swallowing problems (can aspirate)
<b>Gait disorder</b>	Difficulty turning over in bed and rising from a chair
	Slow, soft monotonous speech/dysarthria
	No arm swing on one or both sides
	Start hesitation
	Slow, shuffling and narrow based
	Short steps ( <i>petit pas</i> )
	Slow turning circle ('turn by numbers')
	'Freezing' when approaching an obstacle
<b>Disequilibrium</b>	Festination
	Poor balance
	Impaired righting reflexes
<b>Posture</b>	Falls—may be first thing that leads to presentation
	Progressive forward flexion of trunk (stooped)
	Flexion of elbow at affected side
<b>Autonomic symptoms</b>	Constipation (common)
	Postural hypotension—may be induced by treatment
<b>Neuropsychiatric</b>	Depression (early), anxiety, sleep disorder
	Progressive dementia in 30–40% usually after 10 years <sup>6</sup>
	Hallucinations—either with Lewy body dementia or treatment

a nursing home for end-stage disease may be appropriate.

- Correct dopamine deficiency and/or block cholinergic excess in the brain.

### Management (pharmacological)<sup>8,9</sup>

Avoid postponing treatment. It should be commenced as soon as symptoms interfere with working capacity or the patient's enjoyment of life. This will be apparent only if the correct questions are asked as the patient may accept impaired enjoyment without appreciating that it is due to PD. Start low—L-dopa 100/25 (½ tab bd) and go slow. There is usually no difference between the L-dopa preparations. The dosage should be tailored so that the patient neither develops side effects nor is on an inadequate dose of medication without significant therapeutic benefit (see TABLE 33.5). The dose usually progresses to 1 tab bd, then consider add-on therapy.

The older drugs, such as anticholinergics and amantadine, still have a place in modern management but L-dopa, which basically counters bradykinesia, is the best drug and the baseline of treatment. With the onset of disability (motor disturbances) L-dopa in combination with a decarboxylase inhibitor (carbidopa or benserazide) in a 4:1 ratio should be introduced. L-dopa therapy does not significantly improve tremor but improves rigidity, dyskinesia and gait disorder. Consider benzhexol or bztropine if tremor is the feature, especially in young patients.

The new non-ergot derivative dopamine agonists can be used in treatment, especially with the L-dopa 'on-off' phenomenon (fluctuations throughout the day). They are preferred to the ergot derivatives because of a superior adverse effect profile. They appear to be most effective when used in combination. Selegiline is an effective second-line drug, especially in combination with Sinemet. If there is associated pain, depression or insomnia, the tricyclic agents (e.g. amitriptyline) can be effective.

FIGURE 33.3 Micrographia, one of the signs of Parkinson disease

Entacapone has the potential to increase 'on time' and reduce motor fluctuations in L-dopa treated

patients who are beginning to experience end-of-dose failure. The initial dose is 200 mg and best used when combined with L-dopa.

### Treatment strategy<sup>8,9</sup>

**Mild** (minimal disability):

- L-dopa preparation (low dose) e.g. L-dopa 100 mg + carbidopa 25 mg (½ tab bd—increase gradually as necessary to 1 tab (o) tds)  
*or*
- amantadine 100 mg (o) daily may help the young or the elderly for up to 12 months—if inadequate response
- selegiline up to 5 mg bd can be added to L-dopa if necessary

**Moderate** (independent but disabled, e.g. writing, movements, gait):

- L-dopa preparation
- selegiline 1 mg bd  
*and/or*
- Add if necessary—non-ergot dopamine agent
  - pramipexole start with 0.25 mg daily
  - rotigotine start with 2 mg daily

**Severe** (disabled, dependent on others):

- L-dopa (to maximum tolerated dose) + non-ergot dopamine agent
- Add entacapone 200 mg (o) with each dose of L-dopa, for example, Stalevo
- Consider antidepressants

An example of a practical treatment algorithm is presented in FIGURE 33.4.

### Long-term problems

After 3–5 years of L-dopa treatment side effects may appear in about one-half of patients:<sup>5</sup>

- involuntary movements—dyskinesia (use lower dose + pergolide or cabergoline)
- end-of-dose failure (reduced duration of effect to 2–3 hours only)—use entacapone
- 'on-off' phenomenon (sudden inability to move with recovery in 30–90 minutes)
- early morning dystonia, such as clawing of toes (due to disease—not a side effect)

### Advanced disease<sup>8</sup>

Under consultant and good home/nursing care.

- Apomorphine can be used for severe akinesia not responsive to L-dopa

**Table 33.5** Anti-Parkinson drugs<sup>8,9</sup>

Agent	Usual dose	Main adverse effects
Dopaminergic (standard and slow release)		
• L-dopa + benserazide	100/25–250/62.5 mg tds	Nausea and vomiting
• L-dopa + carbidopa	100/25–250/50 mg tds	Involuntary dyskinetic movements
		Psychiatric disturbances
		Compulsive behaviour (as below)
		On–off phenomena
		End-of-dose failure
		Constipation
Dopamine agonists		
Ergot derivatives		Nausea and vomiting
• bromocriptine	5–15 mg bd	Dizziness, fatigue
• cabergoline	0.5–3 mg daily	Compulsive behaviours (gambling, punting, hypersexuality)
• pergolide	0.05–1.0 mg tds	Pleuropulmonary changes
		Cardiac valvular disorders
Non-ergot derivatives:		
• pramipexole	0.5–1.5 mg daily	Similar to ergot agonists but less adverse effects and no cardiopulmonary effects
• rotigotine	2–4 mg daily (comes as a patch)	
• apomorphine	SC injection/infusion	Nausea, psychosis, dyskinesia
Anticholinergics		
• benzhexol	2 mg bd or tds	Dryness of mouth GIT upset
		Constipation
• benztropine	1–2 mg bd	Confusion in elderly
• biperiden	1–2 mg bd	Contraindicated in glaucoma and prostatism
COMT inhibitors		
• entacapone	200 mg with each dose L-dopa	Diarrhoea
• combination entacapone/ L-dopa-carbidopa (Stalevo)		Sleep problems
MAO-B inhibitors		
• selegiline	2.5–5 mg once daily or bd	Dry mouth
• rasagiline	1 mg daily	Neuropsychiatric disturbances
		Nausea
		Dizziness, fatigue
		Insomnia
Others		
• amantadine	100 mg bd	Nausea and vomiting
		Psychiatric disturbances
		Ankle oedema
		Livedo reticularis

- For nausea and vomiting side effects: domperidone 20 mg (o) tds 24 hours prior to apomorphine
- Better control may also be achieved with: amantadine 100 mg (o) bd
- Duodopa—levodopa into jejunum

### Contraindicated drugs

- Phenothiazines and other older antipsychotics
- Butyrophenones

### Multidisciplinary care

This important strategy includes physiotherapy, occupational therapy, physical therapy, e.g. tai chi, and psychiatry/psychology, e.g. CBT, mindfulness.

### Treatment (surgical)

This is high-frequency deep brain stimulation via electrodes into the subthalamic nucleus. The indication for surgery is erratic and disabling responses to prolonged L-dopa therapy. It is considered more appropriate for younger patients with a unilateral tremor.<sup>8</sup>

### When to refer

If the diagnosis is unclear at the time of initial presentation, it is appropriate either to review the patient at a later date or to refer the patient for more neurological assessment.

Once diagnosed or highly suspected it is best to refer to establish the diagnosis and to seek advice on

### Red flags in Parkinson disease and differential diagnosis<sup>10</sup>

Bilateral onset (PSP)  
 Poor response to L-dopa  
 Dysautonomia—bladder, orthostatic hypotension (MSA)  
 Dystonia (PSP)  
 Anterocollis (head flexed) (MSA)  
 Retrocollis (head extended) (PSP)  
 Myoclonus (CBD, CJD)  
 Early onset dementia (LBD)  
 CBD = corticobasal degeneration, CJD = Creutzfeldt–Jakob disease, LBD = Lewy body dementia, MSA = multiple system atrophy, PSP = progressive supranuclear palsy

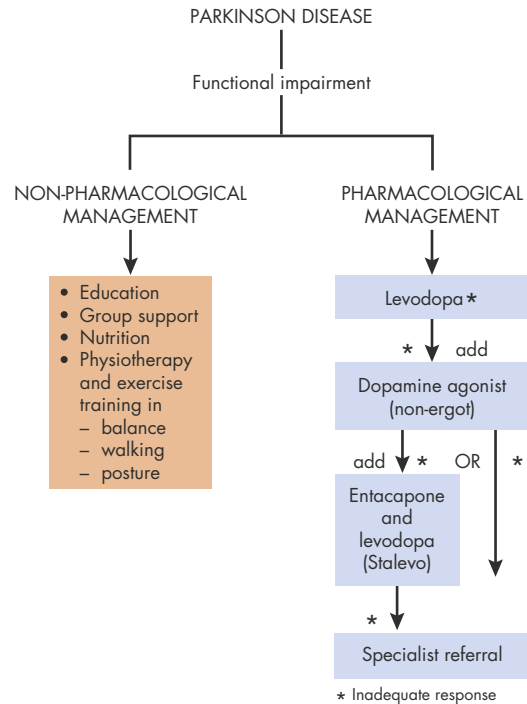

FIGURE 33.4 Management of early Parkinson disease: one possible pathway

initiation of treatment. Patients and families usually prefer this approach. In the initial years before motor fluctuations develop, management could be performed by the GP according to an overall plan developed in liaison with a neurological colleague. When fluctuations develop and end-stage diseases manifest (e.g. gait disorders), specialist supervision is appropriate.<sup>1</sup>

### Cognitive impairment with Parkinson disease<sup>4,11</sup>

This may be due to multiple factors including Parkinson associated dementia, Lewy body dementia, Alzheimer disease and medication, all of which can induce psychosis, but L-dopa is the least likely. Neuropsychiatric symptoms, which can be varied and bizarre and usually worse in the evening, can occur. Factors contributing to psychosis are illustrated in FIGURE 33.5. Management is based on monotherapy with gradual build-up of L-dopa to maximum tolerated dose, for example, 450–600 mg/day.

FIGURE 33.5 Factors contributing to psychosis

33

### Management (psychotic problems)

- Treat as an inpatient.
- Exclude and treat comorbidities, for example, UTI.
- Eliminate and wean off worst drugs.
- Increase L-dopa slowly to 150 mg tds or qid.
- Give quetiapine or olanzapine at night-time.

### Practice tips for Parkinson disease

- One of the simplest diagnostic tools for PD, as compared with Parkinsonism, is a trial of therapy with L-dopa. The response is excellent while that for Parkinsonism is poor.
- L-dopa is the gold standard for therapy.
- Ensure that a distinction is made between drug-induced involuntary movements and the tremor of PD.
- Keep the dose of L-dopa as low as possible to avoid these drug-induced involuntary movements.
- In the elderly with a fractured hip always consider PD (a manifestation of disequilibrium).
- Remember the balance of psychosis and PD in treatment.
- Keep in mind the 'sundown' effect—patients often go psychotic as the sun goes down.
- Don't fail to attend to the needs of the family, who often suffer in silence.
- If drugs are to be withdrawn they should be withdrawn slowly.

### § Multiple sclerosis

Multiple sclerosis (MS) is the most common cause of progressive neurological disability in the 20–50 year age group.<sup>10</sup> It is generally accepted that MS is

an autoimmune disorder. Genetic and environmental factors are believed to play a role.<sup>12</sup> Early diagnosis is difficult because MS is characterised by widespread neurologic lesions that cannot be explained by a single anatomical lesion, and the various symptoms and signs are subject to irregular exacerbations and remissions. The lesions are 'separated in time and space'. The most important issue in diagnosis is the need for a high index of suspicion. The use of MRI has revolutionised the diagnosis of MS.

MS is a primary demyelinating disorder with demyelination occurring in plaques throughout the white and grey matter of the brain, brain stem, spinal cord and optic nerves. The clinical features depend on their location. There is a loss of brain volume.

There is a variety of types of MS—relapsing remitting (most common), secondary progressive, progressive relapsing and primary progressive—together with 'benign' and 'malignant' forms.

### Clinical features

See FIGURE 33.6.

- More common in females
- Peak age of onset is in the fourth decade
- Transient motor and sensory disturbances
- UMN signs
- Symptoms develop over several days but can be sudden
- Monosymptomatic initially in about 80%
- Multiple symptoms initially in about 20%
- Common initial symptoms include:
  - visual disturbances of optic neuritis (blurred vision or loss of vision in one eye—sometimes both); central scotoma with pain on eye movement (looks like unilateral papilloedema)
  - diplopia (brain-stem lesion)
  - weakness in one or both legs, paraparesis or monoparesis
  - sensory impairment in the lower limbs and trunk: numbness, paraesthesia; band-like sensations; clumsiness of limb (loss of position sense); feeling as though walking on cotton wool
  - vertigo (brain-stem lesion)
- Subsequent remissions and exacerbations that vary from one individual to another
- There is a progressive form, especially in women around 50 years
- Anxiety, depression and other mood disorders are common

### Symptoms causing diagnostic confusion

- Bladder disturbances, including retention of urine and urgency
- 'Useless hand' due to loss of position sense
- Facial palsy
- Trigeminal neuralgia
- Psychiatric symptoms

In established disease, common symptoms are fatigue, impotence and bladder disturbances.

### Examination (neurological)

The findings depend on the site of the lesion or lesions and include optic atrophy, weakness, hyper-reflexia, extensor plantar responses, nystagmus (two types—cerebellar or ataxic), ataxia, incoordination and regional impairment of sensation.

### Diagnosis

The diagnosis is clinical along with the MRI and depends on the following determinants:

- Lesions are invariably UMN.
- >1 part of CNS is involved, although not necessarily at time of presentation.
- Episodes are separated in time and space.
- Practically MS can only be diagnosed after a second relapse or when the MRI shows new lesions.<sup>10</sup>
- An early diagnosis requires evidence of contrast-enhancing lesions or new T2 lesions on the MRI indicating dissemination in time.
- The diagnostic criteria is based on the internationally accepted McDonald criteria (refer [www.nice.org.uk](http://www.nice.org.uk) or Google)<sup>12,13</sup>

FIGURE 33.6 Basic clinical signs in multiple sclerosis

Other neurological disorders such as infections (e.g. encephalitis), malignancies, spinal cord compression, spinocerebellar degeneration and others must be excluded.

### Investigation

- Lumbar puncture: oligoclonal IgG detected in CSF in 90% of cases<sup>14</sup> (only if necessary)
- Visual evoked potentials: abnormal in about 90% of cases
- MRI scan: usually abnormal, demonstrating MS lesions in about 90% of cases<sup>14</sup>

### Course and prognosis

- The course is variable and difficult to predict. An early onset (<30 years) is usually 'benign' while a late onset (≥50 years) is often 'malignant'.
- MS follows a classic history of relapses and remissions in 80–85% of patients.<sup>14</sup>
- The rate of relapse is about once in 2 years.
- About 20% have a progressive course from the onset with a progressive spastic paraparesis (applies mainly to late-age onset).
- The average duration of MS is about 40 years from diagnosis to death.<sup>14</sup>
- A 'benign' course occurs in about 30% of patients with 10–20% never suffering major disability.
- The median time to needing a walking aid is 15 years.<sup>8</sup>
- The likelihood of developing MS after a single episode of optic neuritis is about 60%.

### Management principles

- All patients should be referred to a neurologist for confirmation of the diagnosis, which must be accurate.
- Explanation about the disorder and its natural history should be given.
- Acute relapses require treatment if causing significant disability.
- Depression and anxiety, which are common, require early treatment e.g. paroxetine.
- CBT or mindfulness-based interventions.

### Treatment (relapses)

#### Mild relapses

Mild symptoms, such as numbness and tingling, require only confirmation, rest and reassurance.

#### Moderate relapses

- Prednisolone—in outpatient setting

### Severe relapses or attacks<sup>8,15</sup>

These attacks include optic neuritis, paraplegia or brain-stem signs. Admit to hospital for IV therapy:

- methylprednisolone 1 g in 200 mL saline by slow IV infusion (1 hour) daily for 3 days

Observe carefully for cardiac arrhythmias.

### Drugs to prevent relapses<sup>16</sup>

Currently first-line immunomodulators are the interferons, glatiramer acetate and the monoclonal antibody natalizumab.

Interferon beta-1b (SC injection) and beta-1a (IM injection) appear to be effective (but expensive) for those with frequent and severe attacks.

Immunosuppressive agents that are used include:<sup>16</sup>

- methotrexate with folic acid
- mitozantrone (care with cardiac toxicity)
- azathioprine<sup>17</sup>

New agents being evaluated are cladribine and fingolimod.

### Treatment (symptoms)<sup>7,16</sup>

#### Spasticity

- Physiotherapy
- Baclofen 10–25 mg (o) nocte
- For continuous drug therapy: baclofen 5 mg (o) tds, increasing to 25 mg (o) tds + diazepam 2–10 mg (o) tds
- An alternative is dantrolene

#### Paroxysmal (e.g. neuralgias)

- Carbamazepine or gabapentin

#### Cannabis

The reported efficacy of the cannabis-based medicine Sativex for relaxation, pain and bladder function is still being debated. One RCT showed a positive effect on detrusor activity.<sup>18</sup>

See references 8 and 16 for treatment of other symptoms.

### Peripheral neuropathy

Peripheral neuropathy (PN) refers to all conditions causing nerve damage outside the central nervous system. It can be a mononeuropathy, such as carpal tunnel syndrome; mononeuropathy multiplex involving multiple single nerves in an asymmetric pattern (as in vasculitides); or a polyneuropathy,

which is a diffuse symmetric disorder best referred to as PN. It can be classified according to clinical progression as acute, subacute or chronic. The manifestations can be sensory, motor, autonomic or mixed (sensorimotor).

- Sensory symptoms: tingling, burning, numbness in extremities, unsteady gait (loss of position sense)
- Motor symptoms (LMN): weakness or clumsiness in hands, foot/wrist drop
- Signs: may be classic 'glove and stocking' sensory loss, sensory ataxia, LMN signs—distal muscle wasting, muscle weakness, reflexes absent or depressed, fasciculations.

### Causes

- Mostly sensory: diabetes mellitus, vitamin deficiency (folate, B1, B6, B12), alcohol, various neurotoxic drugs, leprosy, uraemia (CKF), amyloidosis, malignancy
- Mostly motor: lead poisoning, porphyria, various neurotoxic drugs, Charcot–Marie–Tooth syndrome (peroneal muscle atrophy), acquired inflammatory polyneuropathies—acute (Guillain–Barré syndrome) and chronic (chronic inflammatory demyelinating polyneuropathy)

*Note:* in many instances no cause is found despite a full history and examination.

### Management

Refer to a suitably qualified consultant for diagnosis particularly via electrophysiology.

### § Acute inflammatory polyradiculoneuropathy (Guillain–Barré syndrome)

Guillain–Barré syndrome, which is a rapidly progressive and treatable cause of PN or ascending radiculopathy, is potentially fatal. Early diagnosis of this serious disease by the family doctor is crucial as respiratory paralysis may lead to death. The underlying pathology is segmental demyelination of the peripheral nerves and nerve roots.

### Clinical features

- Weakness in the limbs (usually symmetrical)
- Paraesthesia or pain in the limbs (less common)
- Both proximal and distal muscles affected, usually starts peripherally and moves proximally
- Facial and bulbar paralysis (rare)
- Weakness of extraocular muscles (rarely)

- Reflexes depressed or absent
- Variable sensory loss but rare

Within 3–4 weeks the motor neuropathy, which is the main feature, progresses to a maximum disability, possibly with complete quadriplegia and respiratory paralysis.<sup>19</sup>

### Investigation

- CSF protein is elevated; cells are usually normal.
- Motor nerve conduction studies are abnormal.

### Management

- Admit to hospital.
- Respiratory function (vital capacity) should be measured regularly (2–4 hours at first).
- Tracheostomy and artificial ventilation may be necessary.
- Physiotherapy to prevent foot and wrist drop and other general care should be provided.
- Treatment is with plasma exchange or IV immunoglobulin (0.4 g/kg/day for 5 days), which may need to be continued monthly.<sup>8</sup>
- Corticosteroids are not generally recommended.

### Outcome

About 80% of patients recover without significant disability. Approximately 5% relapse.<sup>19</sup>

### § Chronic inflammatory demyelinating polyneuropathy<sup>8,20</sup>

This acquired immunological disorder is similar to Guillain–Barré syndrome except that it has a slower and more protracted course. Diagnosis is by nerve studies and treatment is with plasmapheresis or IV immunoglobulin.

### § Charcot–Marie–Tooth syndrome

This is an inherited autosomal dominant polyneuropathy with an insidious onset from puberty. Clinical features include weakness in the legs, variable distal sensory loss and muscle atrophy giving the 'inverted champagne bottle' appearance of the legs. The features vary according to the various subgroups. Refer for electrodiagnostic studies and specific genetic testing.

### § Familial periodic paralysis

An autosomal dominant skeletal muscle disorder. Clinical features:

- young patient (usually adolescent)

- day after vigorous exercise awakens with weakness in limbs (for 4–24 hours)
- flaccid paralysis/loss of deep tendon reflexes

Related to potassium levels—measure during symptoms. Classify as high, low or normal.

## § Myasthenia gravis

Myasthenia gravis (MG) is an acquired autoimmune disorder that usually affects muscle strength. Patients have fluctuating symptoms and variable distribution of muscle weakness. All degrees of severity, ranging from occasional mild ptosis to fulminant quadriplegia and respiratory arrest, can occur.<sup>21</sup> See TABLE 33.6. It is associated with thymic tumour and other autoimmune diseases, for example, RA, SLE, thyroid and pernicious anaemia.

### Clinical features

- Painless fatigue with exercise
- Weakness also precipitated by emotional stress, pregnancy, infection, surgery

**Table 33.6** Clinical classification of acquired myasthenia gravis

Group I	Ocular MG
Group IIA	Mild generalised MG
Group IIB	Moderate to severe MG
Group III	Acute severe (fulminating) MG with respiratory muscle weakness
Group IV	Late (chronic) severe MG

**FIGURE 33.7** Myasthenia gravis in a 40-year-old woman with a 12-month history of increasing muscular weakness including drooping of the eyelids. Ptosis, especially on the right side, is apparent.

- Variable distribution of weakness:
  - ocular: ptosis (60%) and diplopia (see FIG. 33.7); ocular myasthenia only remains in about 10%
  - bulbar: weakness of chewing, swallowing, speech (ask to count to 100), whistling and head lolling
  - limbs (proximal and distal)
  - generalised
  - respiratory: breathlessness, ventilatory failure

*Note:* The classic MG image is ‘the thinker’—the hand used to hold the mouth closed and the head up.

### Diagnosis

- Serum anti-acetylcholine receptor antibodies
- Electrophysiological tests if antibody test negative
- CT scan to detect thymoma
- Edrophonium test still useful but potentially dangerous (atropine is the antidote)

### Management principles<sup>8,21</sup>

- Refer for consultant management.
- Detect possible presence of thymoma with CT or MR scan of thorax. If present, removal is recommended.
- Thymectomy is recommended early for generalised myasthenia, especially in all younger patients with hyperplasia of the thymus, even if not confirmed preoperatively.
- Plasmapheresis is useful for acute crisis or where temporary improvement is required or patients are resistant to treatment.
- Avoid drugs that are relatively contraindicated.
- Pharmacological agents:
  - anticholinesterase drugs (e.g. pyridostigmine, neostigmine or distigmine): should be used only for mild-to-moderate symptoms
  - corticosteroids: useful for all grades of MG; should be introduced slowly

### Ptosis

It is worth remembering that the four major causes of ptosis are:

- 1 3rd cranial nerve palsy—ptosis, eye facing ‘down and out’, dilated pupil, sluggish light reflex
- 2 Horner syndrome—ptosis, miosis (constricted pupil), ipsilateral loss of sweating
- 3 Mitochondrial myopathy—progressive external ophthalmoplegia or limb weakness, induced by activity—no pupil involvement

- 4 Myasthenia gravis—ptosis and diplopia, no pupil movement

### Practice tips for myasthenia gravis

- The combination of ocular and facial weakness should alert the family doctor to the possibility of a neuromuscular disorder, especially MG or mitochondrial myopathy.<sup>20</sup> Look for weakness and fatigue.
- Beware of facioscapulohumeral dystrophy.
- Ptosis may develop only after looking upwards for a minute or longer.
- Smiling may have a characteristic snarling quality.

## § Dystonia

Dystonias are sustained or intermittent abnormal repetitive movements or postures resulting from alterations in muscle tone. The dystonic spasms may affect one (focal) or more (segmental) parts of the body or the whole body (generalised).

### Key facts and checkpoints

- Misdiagnosis is common as transient symptoms may be mistaken for an emotional or psychiatric disorder. Many cases take years to diagnose.
- Dystonias are often regarded as nervous tics.
- The cause is thought to be disorders of the basal ganglia of the brain, but mainly there is no known specific cause.
- Neuroleptic and dopamine receptor blocking agents (e.g. L-dopa, metoclopramide) can induce a severe generalised dystonia (e.g. oculogyric crisis) which is treated with benztropine 1–2 mg IM or IV.<sup>8</sup> However, L-dopa is the drug of choice in some L-dopa responsive dystonias.

### Focal dystonias

- *Blepharospasm* is a focal dystonia of the muscles around the eye resulting in uncontrolled blinking, especially in bright light. This is best treated with botulinum toxin, type A.
- *Oromandibular dystonia* affects the jaw, tongue and mouth, resulting in jaw grinding movements and grimacing. Proper speech and swallowing may be disrupted.
- *Meige syndrome* is a combination of blepharospasm and oromandibular dystonia.

*Note:* It must be differentiated from the buccal-lingual-facial movements of tardive dyskinesia.

- *Hemifacial spasm* involves involuntary, irregular muscle contractions and spasms affecting one side of the face. It usually starts with twitching around the eye and then spreads to involve all the facial muscles on one side. It is usually due to irritation of the facial nerve in its intracranial course and surgical intervention may alleviate this problem.
- *Writer's cramp, typist's cramp, pianist's cramp, golfer's cramp* are all occupational focal dystonias of the hand and/or forearm initiated by performing these skilled acts.
- *Cervical dystonia or spasmodic torticollis* is a focal dystonia of the unilateral cervical muscles. It usually begins with a pulling sensation followed by twisting or jerking of the head, leading to deviation of the head and neck to one side. In early stages patients can voluntarily overcome the dystonia.
- *Laryngeal or spastic dystonia* is a focal dystonia of the laryngeal muscles resulting in a strained, hoarse or creaking voice. It may lead to inability to speak in more than a whisper.

### Treatment

The current treatment for focal or segmental (spread to an adjacent body region) dystonias is localised injection of purified botulinum A toxin into the affected muscle groups. The dosage is highly individualised and needs to be repeated at intervals of 3 and 6 months. The injections have to be given with great caution, ideally by a registered injector.

## § Tics

Motor and vocal tics are a feature of Tourette disorder. If socially disabling treat with:

- haloperidol 0.25 mg (o) nocte, very gradually increasing to 2 g (max.) daily<sup>7</sup>  
or
- clonidine 25 mcg (o) bd for 2 weeks, then 50–75 mcg bd

## § Facial nerve (Bell) palsy<sup>15</sup>

Facial (7th nerve palsy), which is an acute unilateral lower motor neurone paresis or paralysis, is the commonest cranial neuropathy. The classic type is Bell palsy, which is usually idiopathic although attributed to an inflammatory swelling involving the facial nerve in the bony facial canal. In Ramsay–Hunt syndrome,

which is due to infection with herpes zoster causing facial nerve palsy, vesicles may be seen on the ipsilateral ear.

Associations:

- herpes simplex virus (postulated)
- diabetes mellitus
- hypertension
- thyroid disorder, for example, hyperthyroidism

### Clinical features

- Abrupt onset (can worsen over 2–5 days)
- Weakness in the face (complete or incomplete)
- Preceding pain in or behind the ear
- Impaired blinking
- Bell phenomenon—when closing the eye it turns up under the half-closed lid

Less common:

- difficulty eating
- loss of taste—anterior two-thirds of tongue
- hyperacusis

### Management

- prednisolone 1 mg/kg (o) daily in the morning for 5 days (start within 48 hours of onset)

*Note:* This is controversial, but recent randomised trials and a Cochrane review support the use of prednis(ol)one. No good evidence for antiviral drugs.

- Patient education and reassurance
- Adhesive patch or tape over eye if corneal exposure (e.g. windy or dusty conditions, during sleep)
- Artificial tears if eye is dry and at bedtime
- Massage and facial exercises during recovery

*Note:*

- At least 70–80% achieve full spontaneous recovery; higher if mild.
- Electromyography and nerve excitability or conduction studies are a prognostic guide only.
- No evidence that nucleoside analogue, for example, aciclovir, is useful but should be used for Ramsay–Hunt syndrome.
- No evidence that surgical procedures to decompress the nerve are beneficial.<sup>15</sup>

## Diagnostic triads of neurological dilemmas

All triads show a chronic onset unless indicated by an asterisk (acute onset).

If you see this combination of signs:

Charcot's triad:

- dysarthria + intention tremor + nystagmus
- visual disturbance (blurred or transient loss) + weakness in limbs ± paraesthesia in limbs

Note: There are many combinations of MS (Charcot's has historical interest).

- rigidity + bradykinesia + resting tremor
- tremor (postural or action) + head tremor + absence of Parkinsonian features
- fatiguable and weakness of eyelids and eye movements + limbs + bulbar muscles (speech and swallowing)
- ascending weakness of limbs + of face + areflexia\*
- (episodic) vertigo + tinnitus + hearing loss\*
- dementia + myoclonus + ataxia
- drowsiness + vomiting + headache (waking)
- enophthalmos + meiosis + ptosis ± anhydrosis
- blank spell + lip-smacking (or similar automation) + olfactory/gustatory hallucination
- gradual spread (Jacksonian march) of focal jerking (mouth, arm or leg) or sensory disturbance or (rarely) visual field disturbance
- ↑ intracranial pressure +/- focal signs +/- epilepsy
- dysphagia + dysphonia/dysarthria + spastic tongue
- recurrent: headache (often unilateral) + nausea (± vomiting) + visual aura\*
- recurrent: severe retro-orbital headache + rhinorrhoea + lacrimation\*
- instantaneous: headache ± vomiting ± neck stiffness
- headache + visual obscurations + papilloedema (often in obese young female)
- acute and transient: amaurosis fugax or dysphasia or hemiplegia\*
- typical facies (temporalis atrophy and frontal balding) + muscle weakness esp. hands (± myotonia) + cataracts
- ataxia + ophthalmoplegia + areflexia\*
- vertigo + provoked by movement (especially rolling in bed) + Hallpike test +ve
- UMN signs + LMN signs + fasciculations
- leg weakness + ataxic gait + clumsiness (appears about 12 years)

Consider:

- cerebellar disease (typical of MS)
- multiple sclerosis
- Parkinson disease
- essential tremor
- myasthenia gravis
- Guillain-Barré syndrome (GBS)
- Ménière syndrome
- Creutzfeldt-Jakob disease
- ↑ intracerebral pressure
- Horner syndrome
- complex partial seizure
- simple partial seizure
- cerebral tumour
- pseudobulbar palsy
- migraine with aura (formerly 'classical migraine')
- cluster headache
- subarachnoid haemorrhage until disproven
- benign intracranial hypertension
- TIA (carotid)
- dystrophia myotonica (myotonic dystrophy)
- Miller-Fisher variant of GBS
- BPPV
- motor neurone disease
- Friedreich ataxia

# Part 3

## Problem solving in general practice

---

*A great fit of the stone in my left kidney: all day I could do but three or four drops of water, but I drunk a draught of white wine and salet oyle, and after that, crabs' eyes in powder with the bone in the carp's head and then drunk two great draughts of ale with buttered cake; and I voyded with an hour much water and a stone as big as an Alexander seed. God be thanked!*

John Dee 1594

Abdominal pain represents one of the top 15 presenting symptoms in primary care<sup>1</sup> and varies from a self-limiting problem to a life-threatening

illness requiring immediate surgical intervention. Abdominal pain can be considered to be acute, subacute, chronic or recurrent. It can embrace all

**Table 34.1** Surgical causes of the acute abdomen

Process	Organ involved	Disorder
<b>Inflammation</b>	Bowel	Inflammatory bowel disease
	Appendix	Appendicitis
	Gall bladder	Cholecystitis
	Liver	Hepatitis
	Pancreas	Pancreatitis
	Fallopian tube	Salpingitis
	Colonic diverticulae	Diverticulitis
<b>Perforation</b>	Duodenum	Perforated duodenal ulcer
	Stomach	Perforated gastric ulcer
	Colon (diverticula or cancer)	Faecal peritonitis
	Gall bladder	Biliary peritonitis
	Appendix	Appendicitis
<b>Obstruction</b>	Gall bladder	Biliary colic
	Small intestine	Acute small bowel obstruction
	Large bowel	Acute large bowel obstruction
	Ureter	Ureteric colic
	Urethra	Acute urinary retention
	Mesenteric artery occlusion	Intestinal infarction
<b>Haemorrhage</b>	Fallopian tube	Ruptured ectopic pregnancy
	Spleen or liver	Ruptured spleen or liver (haemoperitoneum)
	Ovary	Ruptured ovarian cyst
	Abdominal aorta	Ruptured abdominal aortic aneurysm (AAA)
<b>Torsion (ischaemia)</b>	Sigmoid colon	Sigmoid volvulus
	Ovary	Torsion ovarian cyst
	Testes	Torsion of testes

specialties, including surgery, medicine, gynaecology, geriatrics and psychiatry. For acute abdominal conditions it is important to make a rapid diagnosis in order to reduce morbidity and mortality. Most cases require surgical referral (see TABLE 34.1). Lower abdominal pain in women adds another dimension to the problem and will be presented in a separate chapter (CHAPTER 103).

## Key facts and checkpoints

- The commonest causes of the acute abdomen in two general practice series were:  
*Series 1*—acute appendicitis (31%) and the colics (29%);<sup>2</sup>  
*Series 2*—acute appendicitis (21%), the colics (16%), mesenteric adenitis (16%).<sup>3</sup> The latter study included children.
- An international study involving referral to 26 surgical departments in 17 countries revealed non-specific abdominal pain (34%), acute appendicitis (28%) and cholecystitis (10%) as the most common conditions.<sup>1</sup>
- As a general rule, upper abdominal pain is caused by lesions of the upper GIT and lower abdominal pain by lesions of the lower GIT.
- Colicky midline umbilical abdominal pain (severe) → vomiting → distension = small bowel obstruction (SBO).
- Midline lower abdominal pain → distension → vomiting = large bowel obstruction (LBO).
- If cases of acute abdomen have a surgical cause, the pain nearly always precedes the vomiting.
- Mesenteric artery occlusion must be considered in an elderly person with arteriosclerotic disease or in patients with atrial fibrillation presenting with severe abdominal pain or following myocardial infarction.
- Up to one-third of presentations of abdominal pain are considered to be non-specific, whereby no specific cause is found.

## A diagnostic approach

A summary of the separate diagnostic models for acute abdominal pain and chronic abdominal pain are presented in TABLES 34.2 and 34.3.

## Probability diagnosis

The most common causes of acute abdomen are acute appendicitis, acute gastroenteritis, an irritable bowel syndrome, the various 'colics' and ovulation pain (mittelschmerz). Mesenteric adenitis is common in

**Table 34.2** Acute abdominal pain (adults): diagnostic strategy model (excluding trauma)

Q.	Probability diagnosis
A.	Acute gastroenteritis Acute appendicitis Mittelschmerz/dysmenorrhoea Irritable bowel syndrome Biliary colic/renal colic
Q.	Serious disorders not to be missed
A.	Cardiovascular: <ul style="list-style-type: none"> <li>myocardial infarction (usually inferior)</li> <li>ruptured AAA</li> <li>dissecting aneurysm aorta</li> <li>mesenteric artery occlusion/ischaemia</li> </ul> Neoplasia: <ul style="list-style-type: none"> <li>large or small bowel obstruction</li> </ul> Severe infections: <ul style="list-style-type: none"> <li>acute salpingitis</li> <li>peritonitis/spontaneous bacterial peritonitis</li> <li>ascending cholangitis</li> <li>intra-abdominal abscess</li> </ul> Pancreatitis Ectopic pregnancy Small bowel obstruction/strangulated hernia Sigmoid volvulus Perforated viscus
Q.	Pitfalls (often missed)
A.	Acute appendicitis Myofascial tear Pulmonary causes: <ul style="list-style-type: none"> <li>pneumonia</li> <li>pulmonary embolism</li> </ul> Faecal impaction (elderly) Herpes zoster Rarities: Porphyria Lead poisoning Haemochromatosis Haemoglobinuria Addison disease
Q.	Seven masquerades checklist
A.	Depression Diabetes (ketoacidosis) Drugs (especially narcotics) Anaemia (sickle cell) Endocrine disorder (thyroid storm, Addison) Spinal dysfunction UTI (including urosepsis)
Q.	Is the patient trying to tell me something?
A.	May be very significant. Consider Munchausen syndrome, sexual dysfunction and abnormal stress.

**Table 34.3** Chronic or recurrent abdominal pain (adult): diagnostic strategy model

Q.	Probability diagnosis
A.	Irritable bowel syndrome Diverticular disease Mittelschmerz/dysmenorrhoea Peptic ulcer/gastritis
Q.	Serious disorders not to be missed
A.	Cardiovascular: • mesenteric artery ischaemia • AAA Neoplasia: • bowel/stomach cancer • pancreatic cancer • ovarian tumours Severe infections: • hepatitis • recurrent PID
Q.	Pitfalls (often missed)
A.	Adhesions Appendicitis Food allergies Lactase deficiency Constipation/faecal impaction Chronic pancreatitis Crohn disease Endometriosis Diverticulitis Rarities: Tropical infections (e.g. hydatids, melioidosis, malaria, strongyloides) Uraemia Lead poisoning Porphyria Sickle cell anaemia Hypercalcaemia Addison disease
Q.	Seven masquerades checklist
A.	Depression Drugs Endocrine disorder (Addison disease) Spinal dysfunction UTI
Q.	Is the patient trying to tell me something?
A.	A strong possibility: consider hypochondriasis, anxiety, sexual dysfunction, Munchausen syndrome.

children. The various causes of chronic or recurrent abdominal pain are presented in **TABLE 34.3**. A study on chronic abdominal pain<sup>4</sup> showed that the commonest reasons (approximate percentages) were

no discoverable causes (50%), minor causes including muscle strains (16%), irritable bowel syndrome (12%), gynaecological causes (8%), peptic ulcers and hiatus hernia (8%).

## Serious disorders not to be missed

Most of the causes of the acute abdomen are serious and early diagnosis is mandatory to reduce mortality and morbidity.

It is vital not to misdiagnose a ruptured ectopic pregnancy, which causes lower abdominal or suprapubic pain of sudden onset, or the life-threatening vascular causes, such as a ruptured or dissecting aortic aneurysm, mesenteric artery occlusion and myocardial infarction (which can present as epigastric pain).

Perforated ulcers and strangulated bowel, such as volvulus of the sigmoid and entrapment of the small bowel in a hernial orifice or around adhesions, also demand an early diagnosis.

There are some important 'red flag' symptoms and signs<sup>1</sup> of abdominal emergencies demanding urgent attention (see box):

## Red flag pointers for acute abdominal pain

History	Signs
Collapse at toilet	Pallor and sweating
Lightheadedness	Hypotension
Ischaemic heart disease	Atrial fibrillation or tachycardia
Progressive-vomiting pain, distension	Fever
Menstrual abnormalities	Prostration
Maligancy	Rebound tenderness and guarding Decreased urine output

*Note:* collapsing at toilet (points to intra-abdominal bleeding)

## Dangers of misdiagnosis

- Ectopic pregnancy → rapid hypovolaemic shock
- Ruptured AAA → rapid hypovolaemic shock
- Gangrenous appendix → peritonitis/pelvic abscess
- Perforated ulcer → peritonitis
- Obstructed bowel → gangrene

## Pitfalls

A very common pitfall is misdiagnosing acute appendicitis, especially in the elderly, in children, in pregnancy and in those taking steroids, where the presentation may be atypical. Early appendicitis presents typically with central abdominal pain that shifts to the right iliac fossa (RIF) some 4 to 6 hours later. This causes confusion early on. It can cause diarrhoea with abdominal pain, especially if a pelvic appendix, and can be misdiagnosed as acute gastroenteritis.

Disaccharidase deficiencies, such as lactase deficiency, are associated with cramping abdominal pain, which may be severe. The pain follows some time, maybe hours, after the ingestion of milk and is accompanied by the passage of watery stool. The association with milk may be unrecognised by the patient.

Herpes zoster, especially in the elderly patient with unilateral abdominal pain in the dermatomal distribution, is a trap. Referred pain from conditions above the diaphragm, such as myocardial infarction, pulmonary embolism and pneumonia, can be misleading. The rare general medical causes, such as diabetes ketoacidosis, acute porphyria, Addison disease, lead poisoning, tabes dorsalis, sickle cell anaemia, haemochromatosis and uraemia often create a diagnostic dilemma and should be kept in mind.

## Specific pitfalls

- Misdiagnosing a ruptured ectopic pregnancy in the patient on contraception or with a history of normal menstruation or where the brownish vaginal discharge is mistaken for a normal period.
- Failing to examine hernial orifices in a patient with intestinal obstruction.
- Misleading temporary improvement (easing of pain) in perforation of gangrenous appendix or perforated peptic ulcer.
- Overlooking acute mesenteric artery obstruction in an elderly patient with colicky central abdominal pain.
- Attributing abdominal pain, frequency and dysuria to a urinary infection when the cause could be diverticulitis, pelvic appendicitis, salpingitis or a ruptured ectopic pregnancy.

## Seven masquerades checklist

Depression, diabetes, drugs, spinal dysfunction and UTI can all cause abdominal pain although the pain may be more subacute or chronic. Abdominal pain and even tenderness can accompany diabetic ketoacidosis. Drugs that can cause abdominal pain are listed in **TABLE 34.4**.

**Table 34.4** Drugs to consider as a cause of abdominal pain (other than illicit drugs)

Alcohol
Antibiotics (e.g. erythromycin)
Aspirin
Corticosteroids
Cytotoxic agents
Tricyclic antidepressants (e.g. imipramine)
Iron preparations
Nicotine
NSAIDs/COX-2 inhibitors
Sodium valproate
Phenytoin

Spinal dysfunction of the lower thoracic spine and thoracolumbar junction can cause referred pain to the abdomen. The pain is invariably unilateral, radicular in distribution, and related to activity. It can be confused with intra-abdominal problems such as biliary disease (right-sided), appendicitis and Crohn disease (right side), diverticular disorder (left-sided) and pyelonephritis.

## Psychogenic considerations

Psychogenic factors can be most relevant, especially in recurrent or chronic abdominal pain where no specific cause can be identified in most cases.<sup>5</sup> Bain and Spaulding found that 40% of cases of adult abdominal pain had non-structural causes with 28% having psychiatric diagnoses and 6% spastic colon. They noted that 'psychological disturbances are often fairly easy to identify if care is taken to obtain the personal history and to assess the patient's personality, but the diagnostic terms used to describe psychological disturbances lack precision'.

Munchausen syndrome is hospital admission by deception, often with severe abdominal pain without convincing clinical signs or abnormal investigation. Diagnosis requires a high level of suspicion.

## The clinical approach

### History

The urgency of the history will depend on the manner of presentation, whether acute or chronic. Pain has to be analysed according to its quality, quantity, site and radiation, onset, duration and offset, aggravating and relieving factors and associated symptoms and signs.

Special attention has to be paid to:

- anorexia, nausea or vomiting
- micturition
- bowel function
- menstruation/contraception
- drug intake

### Key questions

Point to where the pain is and where it travels to.

Questions to ask:

- What type of pain is it: is it constant or does it come and go?
- How severe would you rate it from 1 to 10?
- Have you ever had previous attacks of similar pain?
- What else do you notice when you have the pain?
- Do you know of anything that will bring on the pain? Or relieve it?
- What effect does milk, food or antacids have on the pain?
- Have you noticed any sweats or chills or burning of urine?
- Are your bowels behaving normally? Have you been constipated or had diarrhoea or blood in your motions?
- Have you noticed anything different about your urine?
- What medications do you take?
- How much aspirin do you take?
- Are you smoking heavily or taking heroin or cocaine?
- How much alcohol do you drink?
- How much milk do you drink?
- Have you travelled recently?
- What is happening with your periods? Is it mid-cycle or are your periods overdue?
- Does anyone in your family have bouts of abdominal pain?
- Do you have a hernia?
- What operations have you had for your abdomen?
- Have you had your appendix removed?

### Examination

A useful checklist for conducting the examination is:

- general appearance
- oral cavity
- vital parameters: temperature, pulse, BP, respiratory rate (record these in the notes)
- chest: check heart and lungs for upper abdominal pain (especially if absent abdominal signs)
- abdomen: inspection, auscultation, palpation and percussion (in that order)

The abdominal examination should be performed with the patient lying flat with one pillow under the head and the abdomen uncovered from xiphisternum to groin. Ask the patient to breathe through the mouth during the examination. Consider the following:

- inguinal region (including hernial orifices) and femoral arteries
- rectal examination: mandatory
- vaginal examination (females): for suspected problems of the fallopian tubes, uterus or ovaries
- thoracolumbar spine (if referred spinal pain suspected)
- urine analysis: white cells, red cells, glucose and ketones, porphyrins
- special clinical tests: Murphy sign (a sign of peritoneal tenderness with acute cholecystitis); iliopsoas and obturator signs
- look for hernias: Spigelian hernias occur through defects in transversus abdominal muscle lateral to the rectus sheath—usually below the level of the umbilicus

### Guidelines

- *Palpation*: palpate with gentleness—note any guarding or rebound tenderness: guarding indicates peritonitis; rebound tenderness indicates peritoneal irritation (bacterial peritonitis, blood). Feel for maximum site that corresponds to focus of the problem
- *Patient pain indicator*: the finger pointing sign indicates focal peritoneal irritation; the spread palm sign indicates visceral pain
- *Atrial fibrillation*: consider mesenteric artery obstruction
- *Tachycardia*: sepsis and volume depletion
- *Tachypnoea*: sepsis, pneumonia, acidosis
- *Pallor and 'shock'*: acute blood loss
- *Auscultation*: note bowel activity or a succussion splash (best before palpation and percussion)

Causes of a 'silent abdomen': diffuse sepsis, ileus, mechanical obstruction (advanced).

If distension, consider the six F's: fat, fluid, flatus, faeces, fetus, frightening growths.

Hypertympany indicates mechanical obstruction.

Physical signs may be reduced in the elderly, grossly obese, severely ill and patients taking corticosteroid therapy.

### Investigations

The following investigations may be selected:

- haemoglobin—anaemia with chronic blood loss (e.g. peptic ulcer, cancer, oesophagitis)

- blood film—abnormal red cells with sickle cell disease
- WCC—leucocytosis with appendicitis (75%),<sup>2</sup> acute pancreatitis, mesenteric adenitis (first day only), cholecystitis (especially with empyema), pyelonephritis
- ESR—raised with cancer, Crohn disease, abscess, but non-specific
- C-reactive protein (CRP)—use in diagnosing and monitoring infection, inflammation (e.g. pancreatic). Preferable to ESR
- liver function tests—hepatobiliary disorder
- serum amylase and/or lipase (preferable)—if raised to greater than three times normal upper level acute pancreatitis is most likely; also raised partially with most intra-abdominal disasters (e.g. ruptured ectopic pregnancy, perforated peptic ulcers, ruptured empyema of gall bladder, ruptured aortic aneurysm)
- pregnancy tests—urine and serum  $\beta$ -HCG: for suspected ectopic
- *Helicobacter pylori* testing
- urine:
  - blood: ureteric colic (stone or blood clot), urinary infection
  - white cells: urinary infection, appendicitis (bladder irritation)
  - bile pigments: gall bladder disease
  - porphobilinogen: porphyria (add Ehrlich aldehyde reagent)
  - ketones: diabetic ketoacidosis
  - air (pneumaturia): fistula (e.g. diverticulitis, other pelvic abscess, pelvic cancer)
- faecal blood—mesenteric artery occlusion, intussusception ('redcurrant jelly'), colon cancer, diverticulitis, Crohn disease and ulcerative colitis

## Radiology

The following tests can be considered according to the clinical presentation:

- plain X-ray abdomen (erect and supine): look for (see FIG. 34.1):
  - kidney/ureteric stones—70% opaque<sup>2</sup>
  - biliary stones—only 10–30% opaque
  - air in biliary tree
  - calcified aortic aneurysm
  - marked distension sigmoid  $\rightarrow$  sigmoid volvulus
  - distended bowel with fluid level  $\rightarrow$  bowel obstruction
  - enlarged caecum with large bowel obstruction
  - blurred right psoas shadow  $\rightarrow$  appendicitis

FIGURE 34.1 The acute abdomen: signs to watch for on plain abdominal X-ray

- a sentinel loop of gas in left upper quadrant (LUQ)  $\rightarrow$  acute pancreatitis
  - chest X-ray: air under diaphragm  $\rightarrow$  perforated ulcer
  - ultrasound: good for hepatobiliary system, kidneys and female pelvis: look for:
    - gallstones
    - ectopic pregnancy
    - pancreatic pseudocyst
    - aneurysm aorta/dissecting aneurysm
    - hepatic metastases and abdominal tumours
    - thickened appendix
    - paracolic collection
- Note: can be affected by gas shadows

- IVP
- contrast-enhanced X-rays (e.g. Gastrografin meal): diagnosis of bowel leakage
- barium enema
- HIDA or DIDA nuclear scan—diagnosis of acute cholecystitis (good when US unhelpful)
- CT scan: gives excellent survey of abdominal organs including masses and fluid collection:
  - pancreatitis (acute and chronic)
  - undiagnosed peritoneal inflammation (best)
  - trauma
  - diverticulitis
  - leaking aortic aneurysm
  - retroperitoneal pathology
  - appendicitis (especially with oral contrast)
- ERCP: shows bile duct obstruction and pancreatic disease
- MRI scan (especially useful with contrast)

Other tests:

- ECG
- endoscopy upper GIT
- sigmoidoscopy and colonoscopy

## Diagnostic guidelines

### General rules

- Upper abdominal pain is caused by lesions of the upper GIT.
- Lower abdominal pain is caused by lesions of the lower GIT or pelvic organs.
- Early severe vomiting indicates a high obstruction of the GIT.
- Acute appendicitis features a characteristic 'march' of symptoms: pain → anorexia, nausea → vomiting.

### Pain patterns

The pain patterns are presented in **FIGURE 34.2**. Colicky pain is a rhythmic pain with regular spasms of recurring pain building to a climax and fading. It is virtually pathognomonic of intestinal obstruction. Ureteric colic is a true colicky abdominal pain, but so-called biliary colic and kidney colic are not true colics at all.

**FIGURE 34.2** Characteristic pain patterns for various causes of 'colicky' acute abdominal pain

### Site of pain

Typical pain sites of abdominal pain (general guidelines only) are presented in **FIGURE 34.3**. Epigastric pain usually arises from disorders of the embryologic foregut, such as the oesophagus, stomach and duodenum, hepatobiliary structures, pancreas and spleen. However, as some disorders progress

the pain tends to shift from the midline to the right (gall bladder and liver) or left (spleen). Periumbilical pain usually arises from disorders of structures of the embryologic midgut, while structures from the hindgut tend to refer pain to the lower abdomen or suprapubic region.

The intra-abdominal sensory receptors can be considered as innervating visceral or parietal peritoneum. Visceral mechanoreceptors are triggered by intestinal distension or tension on mesentery or blood vessels while nociceptors are triggered by mechanical, thermal and chemical stimuli. The pain from viscera is felt as diffuse and poorly localised while stimulation of parietal peritoneal nociceptors gives a pain that is experienced directly at the site of insult.

### Abdominal pain in children

Abdominal pain is a common complaint in children, especially recurrent abdominal pain, which is one of the most common complaints in childhood. The problem causes considerable anxiety in parents and it is important to differentiate the severe problems demanding surgery from non-surgical problems. About one in 15 will have a surgical cause for pain.<sup>6</sup> A good rule is to rule out a urinary infection with urinalysis.

### Acute abdominal pain

The causes of abdominal pain can be considered in the diagnostic model category.

- 1 Common causes/probability diagnosis:
    - infant colic
    - gastroenteritis (all ages)
    - mesenteric adenitis
  - 2 Serious causes, not to be missed:
    - intussusception (peaks at 6–9 months)
    - acute appendicitis (mainly 5–15 years)
    - bowel obstruction
  - 3 Pitfalls:
    - child abuse
    - constipation/faecal impaction
    - torsion of testes
    - lactose intolerance
    - peptic ulcer
    - infections: mumps, tonsillitis, pneumonia (especially right lower lobe), EBM, UTI
    - adnexal disorders in females (e.g. ovarian)
- Rarities:
- Meckel diverticulitis
  - Henoch–Schönlein purpura
  - sickle crisis
  - lead poisoning

FIGURE 34.3 Typical sites of various causes of acute abdominal pain

#### 4 Seven masquerades checklist:

- diabetes mellitus
- drugs
- UTI

#### 5 Psychogenic consideration:

- important cause

### § Infant 'colic' (period of infant distress)

This is the occurrence in a well baby of regular, unexplained periods of inconsolable crying and fretfulness, usually in the late afternoon and evening, especially between 2 weeks and 16 weeks of age. No cause for the apparent abdominal pain can be found and it lasts for a period of at least 3 weeks. It is very common and occurs in about one-third of infants.

#### Clinical features

- Baby between 2 and 16 weeks old
- Prolonged crying—at least 3 hours
- Occurrence at least 3 days a week
- Crying worst at around 10 weeks of age
- Crying during late afternoon and early evening
- Child flexing legs and clenching fists as if severe 'stomach ache'
- Normal physical examination

#### Management

Reassure and explain to the parents. Advise the parents:

- Use gentleness (such as subdued lighting where the baby is handled, soft music, speaking softly, quiet feeding times).
- Avoid quick movements that may startle the baby.
- Make sure the baby is not hungry—underfeeding can make the baby hungry.
- If the baby is breastfed, express the watery foremilk before putting the baby to the breast.
- Provide demand feeding (in time and amount).
- Make sure the baby is burped, and give posture feeding.
- Provide comfort from a dummy or pacifier.
- Provide plenty of gentle physical contact.
- Cuddle and carry the baby around (e.g. take a walk around the block).
- A carrying device such as 'snuggly' or 'Meh Tai Sling' allows the baby to be carried around at the time of crying.
- Make sure the mother gets plenty of rest during this difficult period.
- Do not worry about leaving a crying child for 10 minutes or so after 15 minutes of trying consolation.

Refer the 5 S's, CHAPTER 91.

## Medication

Drugs are not generally recommended, but for very severe problems some preparations can be very helpful (e.g. simethicone [Infacol wind drops]).

## Intussusception

Intussusception is the diagnosis that should be foremost in one's mind with a child aged between 3 months and 2 years presenting with sudden onset of severe colicky abdominal pain, coming at intervals of about 15 minutes and lasting for 2–3 minutes. Early diagnosis, within 24 hours of the onset, is essential, for after this time there is a significant rise in morbidity and mortality. It is due to the telescoping of a segment of bowel into the adjoining distal segment (e.g. ileocaecal segment), resulting in intestinal obstruction. It is usually idiopathic but can have a pathological lead point (4–12 years) (e.g. polyp, Meckel diverticulum).

## Typical clinical features<sup>7</sup>

See FIGURE 34.4.

- Male babies > female
- Age 3 months to 2 years
- Range: birth to school age, usually 5–24 months
- Sudden-onset acute pain with shrill cry
- Vomiting
- Lethargy
- Pallor with attacks
- Intestinal bleeding: redcurrant jelly (60%)<sup>7</sup>

**DxT** pale child + severe 'colic' + vomiting → acute intussusception

**FIGURE 34.4** Typical features with pain distribution of acute intussusception

## Signs

- Pale, anxious and unwell
- Sausage-shaped mass in right upper quadrant (RUQ) anywhere between the line of colon and umbilicus, especially during attacks (difficult to feel)
- Signe de dance (i.e. emptiness in RIF to palpation)
- Alternating high-pitched active bowel sounds with absent sounds
- Rectal examination:  $\pm$  blood

## Diagnosis

- Ultrasound
- Oxygen or barium enema (with caution) also used for diagnosis and treatment

## Treatment<sup>7</sup>

- Hydrostatic reduction by air or oxygen from the 'wall' supply (preferred) or barium enema
- Surgical intervention may be necessary

## Differential diagnosis

- Acute gastroenteritis: can be difficult in those cases where there is some loose stool with intussusception and with blood and mucus without much watery stool in gastroenteritis. However, usually attacks of pain are of shorter duration, and there is loose watery stool, fever and no abdominal mass. If doubtful refer as possible intussusception.
- Impacted faeces can lead to spasms of colicky abdominal pain—usually an older child with a history of constipation.
- Other causes of intestinal obstruction (e.g. irreducible inguinal hernia, volvulus, intra-abdominal band).

## Drugs

In any child complaining of acute abdominal pain, enquiry should be made into drug ingestion. A common cause of colicky abdominal pain in children is cigarette smoking (nicotine); consider other drugs such as marijuana, cocaine and heroin.

## Acute appendicitis in children

This may occur at any age, being more common in children of school age (10–12 years) and in adolescence, and uncommon in children under 3 years of age. Special problems of early diagnosis occur with the very young (younger than 3 years) and in intellectually disabled children, many of whom present with peritonitis.

Vomiting occurs in at least 80% of children with appendicitis and diarrhoea in about 20%. The temperature is usually only slightly elevated but in about 5% of cases it exceeds 39°C.<sup>2</sup>

In children the physical examination, especially eliciting abdominal (including rebound) tenderness, and the rectal examination demand considerable tact, patience and gentleness. Jumping or hopping induces pain.

A serious point of confusion can occur between pelvic appendicitis, causing diarrhoea and vomiting, and acute gastroenteritis. A high CRP level >50 mg/L is a feature of appendicitis.<sup>6</sup> A particularly severe case of apparent gastroenteritis, especially if persistent, should be regarded as pelvic appendicitis until proved otherwise.

### § Mesenteric adenitis

This presents a difficult problem in differential diagnosis with acute appendicitis because the history can be very similar. At times the distinction may be almost impossible. In general, with mesenteric adenitis localisation of pain and tenderness is not as definite, rigidity is less of a feature, the temperature is higher, and anorexia, nausea and vomiting are also lesser features. The illness lasts about five days followed by a rapid recovery. Comparisons between the two are presented in TABLE 34.5 but if in any doubt it is advisable to consider the problem as acute appendicitis and perhaps proceed to laparoscopy/laparotomy.

Mesenteric adenitis can sometimes present an anaesthetic risk and patients are usually quite ill in the immediate postoperative period. Treatment is symptomatic and includes ample fluids and paracetamol.

## Recurrent abdominal pain

Recurrent abdominal pain (RAP)—three distinct episodes of abdominal pain over 3 or more months—occurs in 10% of school-aged children. In only 5–10% of children will an organic cause be found so that in most cases the cause remains obscure.<sup>8</sup>

### Causes (organic)

An organic cause, however, must be considered and excluded. Organic disease is more likely if:

- the pain is other than periumbilical
- the pain radiates rather than remains localised
- the pain wakes the child from sleep
- the pain is accompanied by nausea and vomiting
- the child is not completely well between attacks
- there is associated weight loss
- there is failure to thrive

**Table 34.5** Comparison of the features of acute appendicitis and mesenteric adenitis in children (guidelines only)

	Acute appendicitis	Mesenteric adenitis
<b>Typical child</b>	Older	Younger
<b>Site of onset of pain</b>	Midline Shifting to right	RIF Can be midline
<b>Preceding respiratory illness</b>	Uncommon	Invariable: URTI or tonsillitis
<b>Anorexia, nausea, vomiting</b>	++	±
<b>Colour</b>	Usually pale	Flushed: malar flush
<b>Temperature</b>	N or ↑	↑ ↑ → ↑ ↑ ↑
<b>Abdominal palpation</b>	Tender in RIF Guarding ± Rigidity	Tender in RIF Minimal guarding Usually no rigidity
<b>Rectal examination</b>	Invariably tender	Often tender but lesser degree
<b>Psoas and obturator tests</b>	Usually positive	Usually negative
<b>Full blood examination</b>	Leucocytosis	Lymphocytosis

RIF = right iliac fossa

### Possible causes

- Constipation
- Childhood migraine equivalent (pain with extreme pallor)
- Lactose intolerance (symptoms related to milk ingestion)
- Intestinal parasites (may disturb child about 60 minutes after falling asleep)

### Investigations

- Urine analysis and MSU
- FBE and ESR
- Plain X-ray (assesses faecal retention)

## Non-organic RAP

### Clinical features

Typical clinical features include:

- acute and frequent colicky abdominal pain
- pain localised to or just above umbilicus

- no radiation of pain
- pain lasts less than 60 minutes
- nausea frequent and vomiting rare
- diurnal (never wakes the child at night)
- minimal umbilical tenderness
- anxious child
- obsessive or perfectionist personality
- one or both parents intense about child's health and progress

### Psychogenic factors

Although psychogenic factors are very relevant in individual cases there is scant hard evidence to support the widely held hypothesis<sup>8</sup> that such factors account for the vast majority of RAP. Some children will have obvious psychological problems or even be school avoidant, a common factor being family disruption.

### Management<sup>8</sup>

- Give explanation, reassurance and support (ensure that the patient is involved in the discussion).
- Reassurance can only be given following a careful examination and thoughtfully chosen investigations.
- Avoid investigations, especially radiological if possible (FBE and MCU are okay).
- Acknowledge that the child has pain.
- Emphasise that the disorder is common, and usually traverses childhood without ill effects.
- Recommend simple measures (e.g. local warmth, brief rest for painful episodes).
- Advise review if episodes change in nature, pain persists for hours or there are new symptoms.
- Identify any life stresses and provide insight therapy.
- Enquire about family structures and function, and school performance.
- Discourage identification with the sick role.
- Refer for psychological assessment and counselling if necessary.

### Abdominal pain in the elderly

The elderly can suffer from a wide spectrum of disorders. Ischaemic events, emboli, cancer (in particular) and diverticulae of the colon are more common in old age; duodenal ulcer is less so. Those causes of abdominal pain that occur with more frequency include:

- vascular catastrophies: ruptured AAA, mesenteric artery occlusion
- perforated peptic ulcer

- biliary disorders: biliary pain and acute cholecystitis
- diverticulitis
- sigmoid volvulus
- strangulated hernia
- intestinal obstruction
- cancer, especially of the large bowel
- herpes zoster, causing unilateral root pain
- constipation and faecal impaction

Problems arise with management because the pain threshold is raised (colic in particular is less severe) and there is an attenuated response to infection so that fever and leucocytosis can be absent. Non-specific signs, such as confusion, anorexia and tachycardia, might be the only systemic evidence of infection.

### § Abdominal aortic aneurysm

An AAA may be asymptomatic until it ruptures or may present with abdominal discomfort and a pulsatile mass noted by the patient. There tends to be a family history and thus screening is appropriate in such families. Ultrasound screening is advisable in first-degree relatives over 50 years.

The risk of rupture is related to the diameter of the AAA and the rate of increase in diameter. The normal diameter of the abdominal aorta, which is palpated just above the umbilicus, is 10–30 mm, being 20 mm on average in the adult; an aneurysm is greater than 30 mm in diameter.<sup>9</sup> Greater than 50 mm is significantly enlarged and is chosen as the arbitrary reference point to operate because of the exponential rise in risk of rupture with an increasing diameter. Refer all cases. The patency of a Dacron graft after 5 years is approximately 95% (see FIG. 34.5).

FIGURE 34.5 Guidelines for normal and abnormal widths of the abdominal aorta in adults (to exact scale)

## Investigations

- Ultrasound (good for screening) in relatives >50 years (obesity a problem)
- CT scan (clearer imaging). Helical/spiral scan is investigation of choice.
- MRI scan (best definition)

## § Rupture of aneurysm

This is a real surgical emergency in an elderly person who presents with acute abdominal and perhaps back pain with associated circulatory collapse (see FIG. 34.6). The patient often collapses at toilet because they feel the need to defecate and the resultant Valsalva manoeuvre causes circulatory embarrassment.

FIGURE 34.6 Typical pain distribution of a ruptured abdominal aortic aneurysm

The patient should be transferred immediately to a vascular surgical unit, which should be notified in advance. Two important emergency measures for the 'shocked' patient are intravenous access for plasma expanding fluid (a central venous line is best if possible) and swift action.

**DxT** intense pain + pale and 'shocked' ± back pain → ruptured AAA

## § Mesenteric artery occlusion

Acute intestinal ischaemia arises from superior mesenteric artery occlusion from either an embolus or a thrombosis in an atherosclerotic artery. Another cause is an embolus from atrial fibrillation. Necrosis of the intestine soon follows if intervention is delayed.

FIGURE 34.7 Typical pain distribution of mesenteric arterial occlusion

## Clinical features

- Abdominal pain—gradually becomes intense (see FIG. 34.7)
- Profuse vomiting
- Watery diarrhoea—blood in one-third of patients (later) (refer CHAPTER 44)
- Patient becomes confused

**DxT** anxiety and prostration + intense central pain + profuse vomiting ± bloody diarrhoea → mesenteric arterial occlusion

## Signs

- Localised tenderness, rigidity and rebound over infarcted bowel (later finding)
- Absent bowel sounds (later)
- Shock develops later
- Tachycardia (may be atrial fibrillation and other signs of atheroma)

## Investigations

- CRP may be elevated intestinal alkaline phosphatase.
- X-ray (plain) shows 'thumb printing' due to mucosal oedema on gas-filled bowel. CT scanning gives the best definition while mesenteric arteriography is performed if embolus is suspected. However, it is commonly only diagnosed at laparotomy.

## Management

Early surgery may prevent gut necrosis but massive resection of necrosed gut may be required as a life-saving procedure. Early diagnosis (within a few hours) is essential.

*Note:*

- Mesenteric venous thrombosis can occur but usually in patients with circulatory failure.
- Inferior mesenteric artery occlusion is less severe and survival more likely.

## § Acute retention of urine

Acute retention of urine usually causes severe lower abdominal pain, which may not be apparent in a senile or demented person. Apart from the common cause of an enlarged prostate or prostatitis it can also result from bladder neck obstruction by faecal loading or other pelvic masses or anticholinergic drugs. It is often precipitated by extreme cold or an excess of alcohol. Neurogenic causes include multiple sclerosis, spinal injury and diabetes.

## Management

- Perform a rectal examination and empty rectum of any impacted faecal material.
- Catheterise with size 14 Foley catheter to relieve obstruction and drain (give antibiotic cover).
- Have the catheter in situ and seek a urological opinion. Send specimen for MCU.
- If there is any chance of recovery (e.g. if the problem is drug-induced), withdraw drug, leave catheter in for 48 hours, remove and give trial of prazosin 0.5 mg bd or terazosin.
- Check for prostate cancer and renal impairment.

## § Faecal impaction

Faecal impaction is encountered typically in the aged, bedridden, debilitated patient. It may closely resemble malignant obstruction in its clinical presentation.<sup>10</sup> Spurious diarrhoea can occur, which is known as 'faecal incontinence' (see CHAPTER 36).

## § Acute appendicitis

Acute appendicitis is mainly a condition of young adults but it affects all ages (although uncommon under 3 years). It is the commonest surgical emergency and special care has to be taken with the very young and the very old. The symptoms can vary because of the different positions of the appendix. It is basically a clinical diagnosis.

## Clinical features

See FIGURE 34.8. Typical clinical features are:

- maximum incidence 20–30 years
- initial pain is central abdominal (sometimes colicky)
- increasing severity and then continuous
- shifts and localises to RIF within 6 hours
- may be aggravated by walking (causing a limp) or coughing
- sudden anorexia
- nausea and vomiting a few hours after the pain starts
- $\pm$  diarrhoea and constipation

**DxT** localised RIF pain + a/n/v + guarding  
→ acute appendicitis

## Signs

- Patient looks unwell
- Flushed at first, then pale
- Furred tongue and halitosis
- May be febrile
- Tenderness in RIF, usually at McBurney point
- Local rigidity and rebound tenderness
- Guarding
- $\pm$  Superficial hyperaesthesia

**FIGURE 34.8** Typical pain distribution of acute appendicitis

- $\pm$  Psoas sign: pain on resisted flexion of right leg, on hip extension or on elevating right leg (due to irritation of psoas especially with retrocaecal appendix)
- $\pm$  Obturator sign: pain on flexing patient's right thigh at the hip with the knee bent and then internally rotating the hip (due to irritation of internal obturator muscle)
- Rovsing sign: tenderness in RIF while palpating in LIF
- PR: anterior tenderness to right, especially if pelvic appendix or pelvic peritonitis

### Variations and cautions

- Abscess formation  $\rightarrow$  localised mass and tenderness
- Retrocaecal appendix: pain and rigidity less and may be no rebound tenderness; loin tenderness; positive psoas test
- Pelvic appendix: no abdominal rigidity; urinary frequency; diarrhoea and tenesmus; very tender PR; obturator tests usually positive
- Elderly patients: pain often minimal and eventually manifests as peritonitis; can simulate intestinal obstruction
- Pregnancy (occurs mainly during second trimester): pain is higher and more lateral; harder to diagnose; peritonitis more common
- Perforation more likely in the very young, the aged and the diabetic

### Investigations

Few investigations including imaging are of value:

- blood cell count shows a leucocytosis (75%) with a left shift
- urea and electrolytes—to assess hydration prior to surgery
- CRP—elevated
- plain X-ray may show local distension, blurred psoas shadow and fluid level in caecum
- ultrasound shows a thickened appendix (75–90% sensitivity, 80–100% specificity);<sup>11</sup> affected by gas shadow
- CT scan also accurate and allows other causes, especially in the female pelvis, to be evaluated<sup>12</sup>
- laparoscopy
- $\beta$ -HCG

### Management

Immediate referral for surgical removal. If perforated, cover with cefotaxime and metronidazole.

## § Small bowel obstruction

The symptoms depend on the level of the obstruction (see TABLE 34.6). The more proximal the obstruction, the more severe the pain.

**Table 34.6** Small bowel obstruction: difference between a high and a low obstruction

	High	Low
<b>Frequency of spasms</b>	3–5 minutes	6–10 minutes
<b>Intensity of pain</b>	+++	+
<b>Vomiting</b>	Early, frequent Violent	Later Less severe
<b>Content:</b>	Gastric juices, then green	Faeculent (later)
<b>Dehydration and degree of illness</b>	Marked	Less prominent
<b>Distension</b>	Minimal	Marked

### Main causes

- Outside obstruction (e.g. adhesions—commonest cause, previous laparotomy), strangulation in hernia or pockets of abdominal cavity (see FIG. 34.9)—this may lead to a 'closed loop' obstruction.<sup>13</sup>
- Lumen obstructions (e.g. foreign body, trichobezoar, gallstones, intussusception, malignancy).

**FIGURE 34.9** Operative findings (corrugated drainage material) in a 65-year-old man with subacute bowel obstruction after a 21-year history of nagging abdominal pain following a cholecystectomy

### Clinical features

- Severe colicky epigastric and periumbilical (mainly) pain (see FIG. 34.10)
- Spasms last about 1 minute
- Spasms every 3–10 minutes (according to level)
- Vomiting
- Absolute constipation (nil after bowel emptied)
- No flatus
- Abdominal distension (especially if lower SBO)

**DxT** colicky central pain + vomiting + distension → SBO

FIGURE 34.10 Typical pain distribution of small bowel obstruction

### Signs and tests

- Patient weak and sitting forward in distress
  - Visible peristalsis, loud borborygmi
  - Abdomen soft (except with strangulation)
  - Tender when distended
  - Increased sharp, tinkling bowel sounds
  - Dehydration rapidly follows, especially in children and elderly
  - PR: empty rectum, may be tender
- Note:* check all hernial orifices, including umbilicus
- X-ray: plain erect film confirms diagnosis 'stepladder' fluid levels (4–5 for diagnosis) in 3–4 hours
    - Gastrografen follow-through for precise diagnosis with caution. It can cause severe diarrhoea and may be therapeutic in adhesive obstruction.
  - ± CT scan (especially if extrinsic causation)

### Management

- IV fluids and bowel decompression with nasogastric tube
- Laparotomy or hernia repair

### Large bowel obstruction

The cause is commonly colon cancer (75% of cases), especially on the left side, but it can occur in diverticulitis or in volvulus of the sigmoid colon (10% of cases) and caecum.<sup>10</sup> Sigmoid volvulus is more common in older men and has a sudden and severe onset. The pain is less severe than in SBO. Be wary of the non-surgical causes, simple constipation or acute pseudo-obstruction of the colon (Ogilvie syndrome). Consider ileus.

### Clinical features

- Sudden-onset colicky pain (even with cancer)
- Each spasm lasts less than 1 minute
- Usually hypogastric midline pain (see FIG. 34.11)
- Vomiting may be absent (or late)
- Constipation, no flatus

**DxT** colicky pain + distension ± vomiting → LBO

FIGURE 34.11 Typical pain distribution of large bowel obstruction

### Signs and tests

- Increased bowel sounds, especially during pain
- Distension early and marked
- Local tenderness and rigidity

- PR: empty rectum; may be rectosigmoid cancer or blood. Check for faecal impaction
- X-ray: distension of large bowel with separation of haustral markings, especially caecal distension
  - sigmoid volvulus shows a distended loop
  - gastrografen enema confirms diagnosis

### Management

- Drip and suction
- Surgical referral

### § Perforated peptic ulcer

Perforation of a peptic ulcer can cause acute abdominal pain both with and without a prior history of peptic ulcer. It is an acute surgical emergency requiring immediate diagnosis. Consider a history of drugs, especially NSAIDs and H<sub>2</sub>-receptor antagonists. Perforated ulcers may follow a heavy meal. There is usually no back pain. May be painless with steroids.

The maximal incidence is 45–55 years, most common in males, and a perforated duodenal ulcer is more common than a gastric ulcer.

Consider the clinical syndrome in three stages:

- 1 prostration
- 2 reaction (after 2–6 hours)—symptoms improve
- 3 peritonitis (after 6–12 hours)

### Clinical features

See **FIGURE 34.12**. Typical clinical features are:

- sudden-onset severe epigastric pain
- continuous pain but lessens for a few hours
- epigastric pain at first, and then generalised to whole abdomen

**FIGURE 34.12** Typical features of perforated peptic ulcer with typical pain radiation

- pain may radiate to one or both shoulders (uncommon) or right lower quadrant
- nausea and vomiting (delayed)
- hiccough is a common late symptom

**DxT** sudden severe pain + anxious, still, 'grey', sweaty + deceptive improvement → perforated peptic ulcer

### Signs and tests (typical of peritonitis)

- Patient lies quietly (pain aggravated by movement and coughing)
- Pale, sweating or ashen at first
- Board-like rigidity
- Guarding
- Maximum signs at point of perforation
- No abdominal distension
- Contraction of abdomen (forms a 'shelf' over lower chest)
- Bowel sounds reduced (silent abdomen)
- Shifting dullness may be present
- Pulse, temperature and BP usually normal at first
- Tachycardia (later) and shock later (3–4 hours)
- Breathing is shallow and inhibited by pain
- PR: pelvic tenderness
- X-ray: chest X-ray may show free air under diaphragm (in 75%)—need to sit upright for prior 15 minutes
  - limited Gastrografen meal can confirm diagnosis
  - CT scan is accurate

### Management

- Pain relief
- Drip and suction (immediate nasogastric tube)
- Broad-spectrum antibiotics
- Immediate laparotomy after resuscitation
- Conservative treatment may be possible (e.g. later presentation and Gastrografen swallow indicates sealing of perforation)

### § Ureteric colic

Kidney renal colic is not a true colic but a constant pain due to blood clots or a stone lodged at the pelvic-ureteric junction; ureteric colic, however, presents as severe true colicky pain due to stone movement and ureteric spasm. Fortunately, the majority of urinary calculi are small and will pass spontaneously.

Guidelines:

- loin pain—stone in kidney
- kidney/ureteric colic—ureteric stone
- strangury—stone in bladder

## Clinical features

- Maximum incidence 30–50 years (M > F)
- Intense colicky pain: in waves, each lasting 30 seconds with 1–2 minutes respite
- Begins in loin and radiates around the flank to the groin, thigh, testicle or labia (see FIG. 34.13)
- Usually lasts <8 hours
- $\pm$  Vomiting

FIGURE 34.13 Ureteric colic: typical radiation of pain in left ureteric colic

## Signs

- Patient restless: may be writhing in pain
- Pale, cold and clammy
- Tenderness at costovertebral angle
- $\pm$  Abdominal and back muscle spasm
- Smoky urine due to haematuria

## Diagnosis

- Urine: microscopy; blood testing strip (negative does not exclude calculus)
- Plain X-ray: most stones—kidney, ureter, bladder (75%)—are radio-opaque (calcium oxalate and phosphate)
- IVP: confirms opacity, level of obstruction, kidney function and any anatomical abnormalities
- Ultrasound: may locate calculus but will exclude obstruction
- Non-contrast spiral CT is the 'gold standard' (sensitivity 97%, specificity 96%) (will show easily missed radiolucent<sup>11</sup> uric acid stones)

## Management

If the diagnosis is in doubt (especially if narcotic addiction is suspected) get the patient to pass urine in the presence of an examiner and test for haematuria. While awaiting passage of urine, an indomethacin suppository may be tried for pain relief.

## Routine treatment (average size adult)

- morphine 2.5 to 5 mg IV<sup>14</sup> statim then titrate to effect  
or  
fentanyl 50–100 mcg IV then titrate to effect
- Avoid high fluid intake—provokes distension of ureter and aggravates pain.
- Most cases settle and the patient can go home when pain relief is obtained and an IVP arranged for the next day.
- Further pain can be alleviated by indomethacin suppositories but should be limited to two a day.
- An effective alternative treatment is diclofenac 75 mg IM injection then 50 mg (o) tds for 1 week. Several clinical trials have shown that NSAIDs by IM injection, including ketorolac (10–30 mg IM), are effective and at least as efficacious as opioids.<sup>14,15,16</sup>

## Outcome and follow-up

- The calculus is likely to pass spontaneously if <5 mm (90% <4 mm pass spontaneously).<sup>15</sup>
- If >5 mm intervention will usually be required by extracorporeal shock wave lithotripsy or surgery.
- If the patient passes the calculus, he or she should retrieve it and present it for analysis.
- A repeat IVP may be necessary if there is evidence of obstruction for more than 3 weeks.
- The cause of the 'stone' should be considered. Search for causes such as hyperparathyroidism, hypercalcaemia, hyperoxaluria and UTI.
- Fever with ureteric colic indicates an obstructed infected kidney.

## When to refer<sup>15</sup>

Any of the following:

- stone >5 mm in diameter
- high-grade obstruction
- gross hydronephrosis
- fever/UTI
- unremitting pain
- stone fails to progress

- type 2 diabetes
- staghorn calculus
- presence of solitary kidney

### Facts about urinary tract calculi

- The prevalence is 1 to 3 per 1000 population per year<sup>15</sup>
- The lifelong incidence is 10%
- The recurrence is up to 75% (most within 2 years)
- The typical age range is 20 to 50 years (peaks at 28 years)
- Pregnancy is a risk factor
- Male to female ratio = 3:1
- The incidence is inversely proportional to fibre intake and proportional to ingestion of animal protein and persistently low urinary volume
- Formed from urinary supersaturation with calcium (calcium oxalate, 75–80%), uric acid (7%) and cysteine (rare); also infected calculi (struvite)— $\text{Mg}^+$ ,  $\text{NH}_4^+$ ,  $\text{PO}_4^-$  (5%)

### 'Phony' colic

Some patients who present with typical colic may be feigning their pain mainly because they are opioid dependent and seeking drugs by deception. As ureteric colic can affect young people (peak age 28 years) this can be a very difficult management issue, even for the experienced.

The use of CT scanning would help in locating calculi in such patients. If in doubt an appropriate agent would be ketorolac (Toradol) 10–30 mg IM.

It is advisable to obtain a specimen of urine passed in the presence of an examiner and then tested for microscopic blood. While awaiting passage of urine an indomethacin suppository may be tried for pain relief.

### Recurrent urinary calculi

#### Investigations

- Serum electrolytes, urea, creatinine
- Serum calcium, phosphate, uric acid, magnesium
- Serum alkaline phosphatase
- Urine sample—microbiology and culture
- At least two consecutive 24-hour urine samples
- Stone analysis
- IVP

Dietary advice is given in **CHAPTER 10**.

### Biliary pain

Abdominal pain can be produced by contraction of the biliary tree upon an obstructing stone or inspissated bile. Although the stereotyped patient is female, 40, fat, fair and fertile it can occur from adolescence to old age and in both sexes.

#### Clinical features

See **FIGURE 34.14**.

Typical clinical features are:

- acute onset severe pain
- post-prandial or at night (often wakes 2–3 am)
- constant pain (not colicky)
- lasts 20 minutes to 2–6 hours
- maximal RUQ or epigastrium
- may radiate to tip of right shoulder or scapula
- painful episode builds to a crescendo for about 20 minutes; may recede or last for hours
- some relief by assuming flexed posture
- $\pm$  nausea and vomiting with considerable retching
- often a history of biliary pain (may be mild) or jaundice
- often precipitated by a fatty meal

**DxT** severe pain + vomiting + pain radiation  
→ biliary colic

**FIGURE 34.14** Typical site of pain of biliary colic and acute cholecystitis

#### Signs

- Patient anxious and restless, usually in a flexed position or rolling in agony

- Localised tenderness (Murphy sign) over fundus of gall bladder (on transpyloric plane)
- Slight rigidity

### Diagnosis

- Abdominal ultrasound/DIDA
- Helical CT
- Intravenous cholangiography if previous cholecystectomy
- LFTs may show elevated bilirubin and alkaline phosphatase

### Management

- Pain relief:<sup>17</sup>  
morphine 2.5–5 mg IV statim then titrate to effect (age-dependent)  
or  
fentanyl 50–100 mcg IV statim then titrate to effect  
or  
ketorolac 10–30 mg IM 4–6 hourly (max 90 mg daily)
- Gallstone dissolution or lithotripsy (in those unable to have surgery)
- Cholecystectomy (main procedure)

### Gallstone facts<sup>18</sup>

- Gallstones form from bile in the gall bladder and sometimes in the bile duct (especially post-cholecystectomy)
- Two main types—cholesterol and pigment (bilirubin)
- Lifetime risk in first world countries is 12–20%
- 70% of people with gall bladder stones are asymptomatic, but risk of developing symptoms is about 15% over 20 years
- Cholecystectomy almost never indicated for such stones
- Complications: acute cholecystitis (may lead to empyema, perforation, cholecystoenteric fistula), obstructive jaundice, cholangitis and acute pancreatitis (pancreatic duct obstruction)

### § Acute cholecystitis

Cholecystitis is associated with gallstones in over 90% of cases<sup>18</sup> and there is usually a past history of biliary pain. It occurs when a calculus becomes impacted in the cystic duct and inflammation develops. It is very common in the elderly. The acute attack is often precipitated by a large or fatty meal. The causative organisms are usually aerobic bowel flora (e.g. *E. coli*, *Klebsiella* species and *Enterococcus faecalis*).

### Clinical features

- Steady severe pain and tenderness
- Localised to right hypochondrium or epigastrium
- Nausea and vomiting (bile) in about 75%
- Aggravated by deep inspiration

### Signs

- Patient tends to lie still
- Localised tenderness over gall bladder (positive Murphy sign)
- Muscle guarding
- Rebound tenderness
- Palpable gall bladder (approximately 15%)
- Jaundice (approximately 15%)
- $\pm$  Fever

### Diagnosis

- Ultrasound: gallstones but not specific for cholecystitis
- HIDA scan: demonstrates obstructed cystic duct—the usual cause
- WCC and CRP: can be elevated

### Treatment

- Bed rest
- IV fluids
- Nil orally
- Analgesics
- Antibiotics
- Cholecystectomy

If evidence of sepsis, use amoxy/ampicillin 1 g IV, 6 hourly plus gentamicin 4–6 mg/kg IV daily.<sup>19</sup>

Change to amoxycillin + clavulanate 875 + 125 mg (o) 12 hourly when afebrile.

### § Acute pancreatitis

With acute pancreatitis there may be a past history of previous attacks or a past history of alcoholism (35%) or gallstone disease (40–50%). It is commonly precipitated by fatty foods and alcohol.

### Clinical features

See FIGURE 34.15.

Typical clinical features are:

- sudden onset of severe constant epigastric pain but onset can be steady
- lasts hours or a day or so
- pain may radiate to back
- pain may be relieved by sitting forwards
- nausea and vomiting
- sweating and weakness

**FIGURE 34.15** Typical pain distribution of acute pancreatitis

**DxT** severe pain + nausea and vomiting + relative lack of abdominal signs → acute pancreatitis

### Signs

- Patient is weak, pale, sweating and anxious
- Tender in epigastrium
- Lack of guarding, rigidity or rebound
- Reduced bowel sounds (may be absent if ileus)
- ± Abdominal distension
- Fever, tachycardia ± shock

### Diagnosis

- WCC—leucocytosis
- Serum lipase (preferred as more sensitive and specific) or serum amylase
- CRP—elevated
- Serum glucose ↑, calcium ↓
- Blood gases:  $P_aO_2$  (? pulmonary complications)
- LFTs: ? obstructive pattern
- Plain X-ray, may be sentinel loop
- CT scan (especially for complications)
- Ultrasound better for detecting cysts and unsuspected gallstones

### Management<sup>19</sup>

- Arrange admission to hospital.
- Basic treatment is bed rest, nil orally, nasogastric suction (if vomiting), IV fluids and analgesics (morphine).
- Use morphine 2.5–5 mg IV or fentanyl 50–100 mcg IV statim then titrate to effect.
- May require ERCP if obstructive LFTs.

## § Chronic pancreatitis

In comparison to acute pancreatitis, the pain of chronic pancreatitis is milder but more persistent. There may be epigastric pain boring through to the back. Symptoms may relapse and worsen. Investigate with CT scan and ultrasound. The patient with this problem is often labelled as ‘gastritis’, ‘ulcer’ or ‘neurotic’ because of the indeterminate nature of the pain. Malabsorption and diabetes may result from pancreatitis and weight loss and steatorrhoea become prominent features.

Pain associated with pancreatic cancer is indistinguishable from that of chronic pancreatitis but generally tends to be more severe and more prominent in the back. Use paracetamol or codeine for pain. Give pancreatic enzyme supplements (e.g. pancrelipase) for steatorrhoea.

## § Acute diverticulitis

The patient with acute diverticulitis is usually over 40 years of age, with long-standing, grumbling, left-sided abdominal pain and constipation, but can have irregular bowel habit. It occurs in less than 10% of patients with diverticular disorder.<sup>2</sup> (Refer **CHAPTER 44**.)

### Clinical features

See **FIGURE 34.16**.

Typical clinical features are:

- acute onset of pain in the left iliac fossa
- pain increased with walking and change of position
- usually associated with constipation

**FIGURE 34.16** Typical pain distribution of acute diverticulitis

**DxT** acute pain + left-sided radiation + fever  
→ acute diverticulitis

### Signs

- Tenderness, guarding and rigidity in LIF
- Fever
- May be inflammatory mass in LIF

### Investigations

- FBE: leucocytosis
- Elevated ESR
- Pus and blood in stools
- Abdominal ultrasound/CT scan (especially—can detect fistula, abscess, or perforation)
- Erect chest X-ray
- Erect and supine abdominal X-ray

### Complications

- Bleeding (can be profuse, especially in elderly)
- Perforation (high mortality)
- Abscess
- Peritonitis
- Fistula (bladder, vagina, small bowel)
- Intestinal obstruction

### Treatment<sup>19</sup>

- Hospital admission
- Rest the GIT: nil orally, dry and suction
- Analgesics
- Antibiotics:
  - mild cases: amoxycillin + clavulanate 875/125 mg (o) 12 hourly for 5 days
  - or
  - metronidazole + cephalexin
  - severe cases: (amoxy) ampicillin 1 g IV 6 hourly +
  - gentamicin 5–7 mg/kg IV/day
  - +
  - metronidazole 500 mg IV 12 hourly
  - or
  - metronidazole + ceftriaxone 1 g IV/day
- Surgery for complications
- Screening colonoscopy after acute episode

### § Peritonitis

Can be generalised due to intra-abdominal sepsis following perforation of a viscus e.g. peptic ulcer, appendix, diverticulum. Typical signs are as for

perforated peptic ulcer. Key investigations are peritoneal fluid culture and CT scan. Surgical intervention is usually required. Usual antibiotic treatment is IV cephalosporins or amoxy/ampicillin + gentamicin + metronidazole.<sup>19</sup> Spontaneous bacterial peritonitis can occur in any patient with ascites.

### § Abdominal 'stitch'

The common 'stitch in the side' is the experience of a sharp, stabbing pain in the epigastric or hypochondrium regions of the abdomen, usually during running. The sufferer should:

- stop and rest, then walk—don't run
- apply deep massage to the area with the palps (fleshy tips) of the middle three fingers
- perform slow or deep breathing

### § Chronic or recurrent abdominal pain

Advances in technology, particularly the use of ultrasound, CT scanning and endoscopy, have increased the opportunities for diagnosing chronic or recurrent abdominal pain in adults.

If the patient has 'red flag' symptoms (see below) and the above investigations are unavailable, consider the possibility of conditions such as pancreatic cancer, ovarian cancer, small bowel tumours, mesenteric ischaemia, Crohn disease, metabolic disorders such as lactase deficiency, and rarer conditions as outlined in TABLE 34.3.

Other investigations that may help:

- MRI
- laparoscopy—this may allow the identification of chronic adhesive obstruction, small bowel tumours or inflammation, or intra-abdominal malignancy

### Red flags for organic disease<sup>12</sup>

- Older patient
- Nocturnal pain or diarrhoea
- Progressive symptoms
- Rectal bleeding
- Fever
- Anaemia
- Weight loss
- Abdominal mass
- Faecal incontinence or urgency (recent onset)

## § Chronic appendicitis

It is possible to have recurrent episodes of subacute inflammation of the appendix. If suspected, laparoscopy performed during or soon after an attack is diagnostic.

## § Adhesions

There is no firm evidence that intra-abdominal adhesions are painful apart from complications such as bowel obstruction. Sometimes patients are 'cured' by laparoscopic divisions of adhesions.

## § Peptic ulcer (gastric or duodenal)

See CHAPTER 47.

### Clinical features

- Usually central epigastric pain
- Burning pain
- Relieved by antacids or food or milk
- DU: usually 2–3 hours after meals or wakes from sleep
- GU: may occur after meals but inconsistent relationship to eating

### When to refer

- All cases of acute abdominal pain where urgent surgical intervention is required
- Special urgency and early diagnosis is important with: ruptured ectopic pregnancy, ruptured AAA, mesenteric artery occlusion, ruptured viscus, perforated peptic ulcer, strangulated obstructed bowel, intussusception
- All cases where the diagnosis is not apparent
- All cases where surgery is necessary
- Medical causes, such as diabetic ketoacidosis and porphyria

### Practice tips

- Special caution is required at the extremes of age when the symptoms and signs do not often reflect the seriousness of the underlying pathology.
- If an elderly patient presents with intense acute abdominal pain, inadequately relieved by strong parenteral injections, likely causes include

mesenteric artery occlusion, acute pancreatitis and ruptured or dissecting aortic aneurysm.

- When an inflamed appendix ruptures, the abdominal pain improves for a significant period of time.
- Consider gallstones and duodenal ulcer if the patient is woken (e.g. at 2–3 am) with abdominal pain.
- Pus cells and red cells may be present in the urine with appendicitis when a pelvic appendix involves the bladder and a retrocaecal appendix involves the ureter.
- Consider diabetic ketoacidosis in a patient with abdominal pain, tenderness and rigidity and deep sighing respiration.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Appendicitis
- Diverticular disease
- Gallstones
- Infant colic
- Irritable bowel
- Kidney stones

*Rheumatic disorders are common in old age: much of rheumatology is geriatric and much of geriatrics is rheumatology.*

Dr Frank Dudley Hart<sup>1</sup> 1983

The clinical evaluation of the patient presenting with the complaint of arthralgia (painful joints) or arthritis (inflammation of the joints) can be a difficult and challenging exercise because it can be a presentation of many systemic disorders, some of which are rare. Important considerations are sex, age, the pattern of joint involvement (monoarticular or polyarticular), immediate and more remote history, family history and drug use—all of which may provide important diagnostic clues. Polyarthritis, which implies the active inflammation of five or more joints, presents a more challenging diagnostic problem.

## Key facts and checkpoints

- In a UK National Morbidity Survey, rheumatic disease composed just over 7% of all morbidity presenting to the family doctor.<sup>2</sup>
- The commonest cause was osteoarthritis (OA), which affects 5–10% of the population.
- The same study indicated an episode rate for arthritis/arthralgia of 38.6 per 1000 population.
- The population incidence of rheumatoid arthritis (RA) is 1–2%.
- There should be no systemic manifestations with OA.
- One-quarter of disability in elderly people is due to severe joint disease.
- Systemic diseases that may predispose to, or present with, an arthropathy include the connective tissue disorders, diabetes mellitus, a bleeding disorder, previous tuberculosis, the spondyloarthropathies such as psoriasis, SBE, hepatitis B, rheumatic fever, the various vasculitic or arteritic syndromes (the vasculitides) such as Wegener granulomatosis, HIV infection, lung cancer, haemochromatosis, sarcoidosis, hyperparathyroidism, Whipple disease and Paget disease.
- The pain of inflammatory disease is worse at rest (e.g. on waking in the morning) and improved by activity.
- Early diagnosis and management of RA results in considerably better outcomes.

- Causes of monoarthritis include crystal deposition disease, sepsis, osteoarthritis, trauma and spondyloarthritis.
- Gout and septic arthritis have a recognised cause and cure.
- Acute gout is almost exclusive to males: in women, it is usually seen only in those who are postmenopausal or taking thiazide diuretics.

## A diagnostic approach

A summary of the diagnostic strategy model is presented in [TABLE 35.1](#).

## Probability diagnosis

The probability diagnoses for the patient presenting with arthritis are:

- osteoarthritis (mono- or polyarthritis)
- viral arthritis (if acute and polyarthritis)

OA is very common in general practice. It may be primary, which is usually symmetrical, and can affect many joints. This clinical pattern is different from secondary OA, which follows injury and other wear-and-tear causes.

Viral polyarthritis is more common than realised. It presents usually within 10 days of the infection, and is usually mild.

## Clinical features (viral arthritis)

- Acute onset
- A polyarthritis
- Symmetric inflammation
- Mainly of hands and feet
- Rash—persists for 24 hours minimum
- Terminates rapidly—over days
- FBE: lymphopaenia, lymphocytosis,  $\pm$  atypical lymphocytes

It tends to terminate quickly and spontaneously without permanent damage to joints. It is caused by many viruses, including those causing influenza,

**Table 35.1** Arthralgia: diagnostic strategy model

Q. Probability diagnosis
A. Osteoarthritis
Viral polyarthritis (e.g. parvovirus)
Q. Serious disorders not to be missed
A. Infection:
• rheumatic fever
• endocarditis
• tuberculosis
• brucellosis
• pyogenic (septic) arthritis: e.g. gonococcus, <i>Staphylococcus</i> , <i>Kingella kingae</i>
• HIV arthropathy
• dengue fever
Cancer:
• bronchogenic carcinoma
• leukaemia/lymphoma
• secondary malignancy
Other:
• rheumatoid arthritis (RA)
• connective tissue disorders: SLE, scleroderma, polymyositis and dermatomyositis, other
Q. Pitfalls (often missed)
A. Fibromyalgia syndrome
Polymyalgia rheumatica
Crystal deposition:
• gout
• pyrophosphate (pseudogout)
Haemarthrosis
Dengue fever
Lyme disease
Ross River virus
Avascular necrosis
Rarities:
Other vasculitides (e.g. polyarteritis nodosa)
Haemochromatosis
Sarcoidosis
Whipple disease
Hyperparathyroidism
Familial Mediterranean fever
Amyloidosis
Pigmented villonodular synovitis
Q. Seven masquerades checklist
A. Depression (unlikely)
Diabetes (? arthropathy)

Drugs (especially narcotics)

Endocrine disorder (thyroid storm, Addison disease)

Spinal dysfunction (possible spondyloarthropathies)

Q. Is the patient trying to tell me something?

A. Always a consideration with pain. Psychogenic factors aggravate chronic arthritic conditions.

mumps, rubella, varicella, hepatitis B and C, infectious mononucleosis (more muscle aching), cytomegalovirus, parvovirus, Australian epidemic polyarthritis due to the alphaviruses, Ross River virus (see CHAPTER 28) and Barmah Forest virus. Adenovirus is common in children.

### Serious disorders not to be missed

These include rheumatoid arthritis (RA), which can start as a monoarthritis; pyogenic arthritis, including gonococcus, *Staphylococcus*, *Kingella* sp. and *Streptococcus* infections; tuberculosis; rheumatic fever; and bacterial endocarditis. Early diagnosis of septic arthritis is very important as it can destroy a hip in 24 hours.

It is important to be forever watchful for rheumatic fever (RF). It presents typically as a migratory polyarthritis involving large joints sequentially, one becoming hot, red, swollen and very painful as the other subsides. It rarely lasts more than 5 days in any one joint.

A flitting polyarthritis can also occur with endocarditis in addition to a systemic upset and a cardiac murmur. Gonococcal infection may present in a single joint or as flitting polyarthritis, often accompanied by a rash. Brucellosis can cause arthritis and sacroiliitis and can be confused with the spondyloarthropathies.

HIV infection is becoming a great mimicker. It can present as a chronic oligoarticular asymmetrical arthritis.<sup>3</sup> It can also present as a rash very similar to psoriasis.

With the large influx of migrants from South-East Asia the possibility of tuberculosis presenting as arthritis should be kept in mind.

Connective tissue disorders may be involved. They include SLE, progressive systemic sclerosis (scleroderma), and dermatomyositis. It is most inappropriate to settle with a general diagnosis such as 'rheumatism' or 'arthritis' and where doubtful it is important to find the specific entity causing the problem.

In respect to malignant disease, arthralgia is associated with acute leukaemia, lymphoma and neuroblastoma in children and with bronchial carcinoma, which may cause hypertrophic osteoarthropathy, especially of the wrist and ankle (not a true arthritis but simulates it). Occasionally polyarthritis may be the first feature of an occult neoplasm. Monoarticular metastatic disease may involve the knee (usually from lung or breast).

### Red flag pointers for polyarthritis

- Fever
- Weight loss
- Profuse rash
- Lymphadenopathy
- Cardiac murmur
- Severe pain and disability
- Malaise and fatigue
- Vasculitic signs
- Two or more systems involved

## Pitfalls

There are several pitfalls, most of which are rare. A common pitfall is gout. This applies particularly to older women taking diuretics, whose osteoarthritic joints, especially of the hand, can be affected. The condition is often referred to as nodular gout and does not usually present as acute arthritis.

Fibromyalgia syndrome is a real puzzle (see CHAPTER 37) as it can mimic the connective tissue disorders in its early presentation—typically a woman in the third or fourth decade.

Another ‘trap’ is haemarthrosis in a patient with a bleeding disorder.

Infective causes that may be overlooked are dengue fever, especially in travellers returning from a tropical or subtropical area, and Lyme disease, which is now surfacing in many countries, especially where ticks are found.

There are many rare causes of arthritis. Sarcoidosis causes two forms: an acute benign form, usually in the ankles and knees, and a chronic form with long-standing sarcoidosis that involves joints (large or small) adjacent to underlying bone disease.

Then there are the uncommon vasculitides, which can cause confusion in diagnosis. This group includes

polyarteritis nodosa, hypersensitive vasculitis, polymyalgia rheumatica/giant cell arteritis, Wegener granulomatosis, Henoch–Schönlein purpura and Behçet syndrome.

Haemochromatosis can present with a degenerative arthropathy that characteristically affects the second or third metacarpophalangeal joints.<sup>3</sup>

Other rare causes of arthritis are erythema nodosum, serum sickness and Sjögren syndrome.

## General pitfalls

- Not searching beyond RA when an RA pattern polyarthritis may be part of another systemic disease
- Failing to search for some cause of arthritis other than OA in a patient, especially an elderly patient (i.e. underdiagnosing); an important example of this is polymyalgia rheumatica
- Failing to consider the various drug interactions between NSAIDs, over-the-counter medications and other drugs used by the elderly
- Underdiagnosing and misdiagnosing through lack of appreciation of the many causes of arthritis, especially those presenting as part of a systemic disease

## Seven masquerades

Drug-induced arthritis usually affects the hands and is generally symmetrical. The drugs may induce autoantibodies (e.g. ANA, ANCA). Those that include a lupus syndrome include the anti-epileptics, chlorpromazine and some cardiac drugs. Various antibiotics have been associated with arthralgia, while diuretics, especially frusemide and thiazides, can precipitate gout. The problem usually resolves promptly after withdrawal of the agent.<sup>4</sup>

Intravenous drug abuse may be associated with septic arthritis, hepatitis B and C, HIV-associated arthropathy, SBE with arthritis and serum sickness reactions.

Hyperthyroidism can uncommonly cause acropathy (clubbing and swelling of the fingers) and may present as pseudogout, while hypothyroidism can present with an arthropathy or cause proximal muscle pain, stiffness and weakness. Diabetes mellitus may cause an arthropathy that can be painless or mild to moderately painful.

The spondyloarthropathies may be a causative factor. They often present with an acute monoarthritis, particularly in teenagers some time before causing sacroiliitis and spondylitis.

## Psychogenic considerations

Although 'arthralgia' is an uncommon complaint in psychoneurotic disorders, any pain syndrome can be a significant manifestation. The usual cause of arthralgia is inflammation in the joint—that is, arthritis—but a functional cause is encountered from time to time.

Furthermore, some patients who are unfortunate enough to acquire arthritis, especially the more serious disorders, certainly develop ongoing emotional and psychological problems that appear to aggravate their total problem.

So-called 'growing pains' of the lower limb are common in children, and the physical examination and investigations are normal. Parents need to be reassured that it is a benign condition, while recognising that emotional factors may be quite significant. As Apley pointed out, 'physical growth is not painful, but emotional growth can hurt like hell'.<sup>5</sup>

## The clinical approach

A priority is to determine whether or not the arthritis is caused by a primary rheumatic disorder or whether it is part of an underlying systemic disorder.

## History

Very careful enquiry about the exact onset of the arthritis is important. This includes whether it was acute or insidious, and confined to specific joints or flitting as in rheumatic fever and sometimes in infective endocarditis. Is it a true polyarthritis or monoarthritis? Symmetrical or asymmetrical? It is also important to differentiate between arthralgia (pains in or around the joints) and arthritis (inflammation of the joints). Not all arthralgia is arthritis.

A family history is important because a positive family history is associated with conditions such as RA (rarely), ankylosing spondylitis, connective tissue disorders (rarely), psoriasis, gout, pseudogout and haemophilia.

A very hot, red, swollen joint suggests either infection or crystal arthritis.

## Key questions

- Can you carefully point out exactly where you feel the pain?
- Does the pain move from joint to joint or stay in the same joint?
- Are you aware of anything that brought on the pain?
- Does the pain disturb you at night?
- Do your joints feel very sore or stiff when you wake up in the morning?
- What effect does exercise or activity have on the pain or stiffness?
- Have you had an injury in the past to your painful joint(s)?
- Do you get pain over both your shoulders and upper arms?
- Have you got a skin rash? Is it new?
- Have you had a fever, sweats or chills?
- Do you get very tired, weak or out of sorts?
- Have you noticed any change in the colour of your urine?
- Have you had a sore throat?
- Have you had sinus trouble?
- Have you had acute pain in your big toe or in other joints before?
- Do you have a history of psoriasis?
- Do you have a history of rheumatic fever?
- Do you have pain in your neck or lower back or in other joints?
- Have you had any diarrhoea?
- Have you had a discharge from your penis?
- Have you had any problems with your eyes?
- What drugs are you taking? Are you taking fluid tablets (diuretics)?
- How much alcohol would you drink a day?
- Have you been visiting the countryside or exposed to ticks or have you been to a deer farm?
- Have you travelled overseas recently?
- Have you been at risk of getting an STI?
- Have you been drinking untreated milk recently?
- Have you had cats as pets, especially as a child (associated with RA)?

## Examination

A systematic examination of the affected joint or joints should be performed, looking for signs of inflammation, deformity, swelling and limitation of movement. Tenderness and warmth indicates inflammatory activity. Erythema indicates gouty arthritis or other crystallopathy, rheumatic fever or septic arthritis.

Joint swelling:

- acute (1–4 hours) with intense pain = blood infection or crystals (e.g. gout)
- subacute (1–2 days) and soft = fluid (synovial effusion)
- chronic and bony = osteoarthritis
- chronic and soft/boggy = synovial proliferation

A coarse crepitus suggests OA. Each joint should be examined specifically. Inspection should note the presence of lumps or bumps such as Heberden nodes on the osteoarthritic DIP joints of the hands, Bouchard nodes on the osteoarthritic PIP joints of the hands, and rheumatoid nodules, which are the only pathognomonic finding of RA and gouty tophi. Signs that may be of diagnostic help are presented in **FIGURE 35.1**.

The specific inflamed joint or joints may give an indication of the disease process. Typical joints

affected by various arthropathies are illustrated in **FIGURE 35.2**.

## Investigations

**TABLE 35.2** lists the many investigations that are used to reach a diagnosis. Clinical acumen permits a judicious selection of specific tests rather than ordering an expensive battery.

It is important to keep in mind the many specific serological tests to detect infective causes of arthralgia. These include Australian epidemic

**FIGURE 35.1** Physical examination: possible findings to consider in diagnosis

FIGURE 35.2 Joints typically affected by various arthropathies

polyarthritis, Lyme disease, rubella, *Brucella*, hepatitis B, gonococcus, mycoplasma, HIV tests, parvovirus and Barmah Forest virus.

In reference to viral serology, a positive immunoglobulin M (IgM) antibody test is presumptive evidence of recent infection and is likely to be of diagnostic significance in this clinical context. However, sometimes IgM antibodies can persist for months or years.<sup>6</sup> A positive IgG antibody result indicates previous exposure to the virus but a single positive titre is of no diagnostic significance. Seroconversion or at least a fourfold rise on paired sera confirms recent infection (see FIG. 35.3).

Plain X-ray is invaluable, although in some conditions radiological changes may be apparent only when the disease is well established. Typical X-ray changes for common conditions are presented in FIGURE 35.4. Arthrography has limited value in the diagnosis of polyarthritis but is very useful for specific joints such as the shoulder and the knee. Ultrasound examination for joints such as the shoulder and the hip can be very useful.

HLA-B<sub>27</sub> should not be used for arthritis screening. It has a high sensitivity for ankylosing spondylitis, but low specificity, and should rarely be ordered.<sup>6</sup>

**Table 35.2** Investigations for arthritis

Appropriate tests can be selected from the following:

- urine analysis: blood, protein, sugar
- synovial fluid: analysis, culture
- radiology—plain X-ray
- blood and other cultures
- haemoglobin and differential WCC
- ESR
- C-reactive protein
- serum uric acid, creatinine
- 24-hour urinary uric acid
- rheumatoid factor
- anti-CCP (cyclic citrullinated peptide) antibody
- antinuclear antibody (screening test for SLE)
- dsDNA antibodies
- extractable nuclear antigen (ENA) antibodies
- HLA-B<sub>27</sub> (poor predictive value)
- various specific serological tests (e.g. Australian epidemic polyarthritis, rubella, Lyme disease, hepatitis B, Barmah Forest virus, parvovirus)
- HIV serology
- antistreptolysin O titre
- streptococcal anti-DNase B
- arthroscopy and biopsy
- bone scan

**FIGURE 35.3** Time course of IgG and IgM antibodies in viral arthritis

The various immunological tests for diagnosis of the connective tissue disorders are outlined with the description of each condition. Such screening tests include:

- rheumatoid factor and anti-CCP
- antinuclear antibodies
- dsDNA antibodies

The LE cell test has been superseded by the antinuclear, dsDNA and ENA (especially Sm) antibody

tests but the latter should only be performed if there is an elevated ANA test.<sup>6</sup>

## Arthritis in children

Arthralgia (joint pain) is a common problem in childhood and, although arthritis is rare, the complaint demands considerable respect because of the many serious problems causing it. Arthritis may be part of an infectious disease such as rheumatic fever, rubella, mumps, varicella, cytomegalovirus infection, erythema infectiosum (human parvovirus), influenza or other viral infection, and is occasionally encountered with Henoch–Schönlein purpura. Actually, viral arthritis is very common in children. An FBE is helpful as it may show lymphopaenia, lymphocytosis or atypical lymphocytes.<sup>1</sup> It is worth noting that underlying bone tumours can be present as joint pain if the tumour is adjacent to the joint. A checklist of causes is presented in **TABLE 35.3**.

*Note:* Acute-onset monoarticular arthritis associated with fever is septic until proven otherwise.

### § Juvenile idiopathic arthritis

JIA, also known as juvenile chronic arthritis and juvenile rheumatoid arthritis (US), is defined as a chronic arthritis persisting for a minimum of 6 weeks (some criteria suggest 3 months) in one or more joints in a child younger than 16 years of age.<sup>5</sup> It is rare, affecting only about 1 in 1000 children, but produces profound medical and psychosocial problems.

The commonest types of JIA are oligoarticular (pauciarticular) arthritis, affecting four or fewer joints (about 50%), and polyarticular arthritis, affecting five or more joints (about 40%). Systemic onset arthritis, previously known as Still syndrome, accounts for about 10% of cases. It is usually seen in children under the age of 5 but can occur throughout childhood. The children can present with a high remittent fever and coppery red rash, plus other features, including lymphadenopathy, splenomegaly and pericarditis. Arthritis is not an initial feature but develops ultimately, usually involving the small joints of the hands, wrists, knees, ankles and metatarsophalangeal joints.

These children should be referred once the problem is suspected or recognised. JIA is not a benign disease—50% have persistent active disease as adults.

Rheumatic fever typically occurs in children and young adults, the first attack usually occurring between 5 and 15 years of age.

**Table 35.3** Arthritis in children: causes to consider

Infections
Rheumatic fever
Septic arthritis
Meningococcaemia
Osteomyelitis
Reactive arthritis (post-infectious)
Tuberculosis
Viral infections (e.g. parvovirus, rubella, HIV)
Inflammation—chronic arthritis
Juvenile idiopathic/chronic arthritis
Subtypes:
• Oligo (pauci) articular
• Seropositive polyarticular (juvenile RA)
• Seronegative polyarticular
• Systemic onset arthritis (Still disease)
• Enthesitis related arthritis
• Psoriatic juvenile arthritis
Haematological disorders
Thalassaemia
Sickle-cell anaemia
Haemophilia
Neoplasms
Leukaemia
Lymphoma
Neuroblastoma
Orthopaedic conditions
Perthes disease
Slipped upper femoral epiphyses
Chondromalacia
Others
Henoch–Schönlein purpura
Kawasaki syndrome
Scurvy; rickets
Traumatic arthritis
Osteochondritis
Psychogenic rheumatism
Malignant tumour:
• bone
• cartilage
• synovium

## Arthritis in perspective

Five per cent of all children complain of recurrent lower limb pain, which often awakens them from their sleep. There may be emotional factors involved and parents need appropriate reassurance. A careful history and physical examination are essential, and perhaps simple basic investigations may be appropriate. As Rudge<sup>5</sup> points out, we have to be vigilant against underdiagnosis, misdiagnosis and overdiagnosis. Refer to growing pains (see CHAPTER 91) and post-activity musculoskeletal pain (see CHAPTER 66).

## Arthritis in the elderly

OA is very common with advancing age and for this reason care has to be taken not to simply attribute other causes of arthritis to OA. Other musculoskeletal conditions that become more prevalent with increasing age are:

- polymyalgia rheumatica
- Paget disease of bone
- avascular necrosis
- gout
- pseudogout (pyrophosphate arthropathy)
- malignancy (e.g. bronchial carcinoma)

## Pseudogout

This crystal deposition arthropathy (chondrocalcinosis) is noted by its occurrence in people over 60 years. It usually affects the knee joint but can involve other joints.

## Rheumatoid arthritis

Although it usually begins between the ages of 30 and 40 it can occur in elderly patients, when it occasionally begins suddenly and dramatically. This is called 'explosive' RA and fortunately tends to respond to small doses of prednisolone and has a good prognosis.<sup>7</sup> RA in the elderly can present as a polymyalgia rheumatica syndrome.

## § Rheumatic fever

RF is an inflammatory disorder that typically occurs in children and young adults following a group A *Streptococcus pyogenes* infection. It is common in developing countries and among Indigenous Australians (see CHAPTER 137) but uncommon in first world countries.<sup>8</sup>

### Clinical features

- Young person 5–15 years (can be older)
- Acute-onset fever, joint pains, malaise

- Flitting arthralgia mainly in leg (knees, ankles) and arm (elbows and wrists)
- One joint settles as the other is affected
- May follow a sore throat

However, the symptoms depend on the organs affected and arthritis may be absent.

## Diagnosis

Based on clinical criteria:

2 or more major criteria

or

1 major + 2 or more minor criteria

in the presence of supporting evidence of preceding Group A streptococcal infection.

### Major criteria

- Carditis
- Polyarthritis
- Chorea (involuntary abnormal movements)
- Subcutaneous nodules
- Erythema marginatum

### Minor criteria

- Fever ( $\geq 38^{\circ}\text{C}$ )
- Previous RF or rheumatic heart disease
- Arthralgia
- Raised ESR  $>30$  mm/hr or CRP  $>30$  mg/L
- ECG—prolonged PR interval

## Investigations

A selective combination of:

- FBC
- throat swab
- ESR
- streptococcal ASOT
- streptococcal anti-DNase B (repeat in 10–14 days)
- C-reactive protein
- plus ECG and echocardiogram (if  $\uparrow$  PR) and CXR.

## Treatment

- Rest in bed until CRP normal for 2 weeks
- Benzathine penicillin 900 mg IM (450 mg in child  $<20$  kg) statim or phenoxymethylpenicillin 500 mg (o) bd, 10 days
- Paracetamol 15 mg/kg (o) 4 hourly (max. 60 mg/kg/day); aspirin or naproxen for arthritis
- Diuretics for carditis (may be ACE inhibitor and corticosteroids)
- Prophylactic long-term penicillin

## § Septic arthritis

Acute sepsis (see FIG. 35.5) can affect any joint at any age, although it is more common in children. It evolves over hours or days and can rapidly destroy a joint structure. It is an emergency in the hip joint of children. Check for IV drug use. The commonest organisms are *S.aureus* and *N. gonorrhoea*. Diagnosis is by blood culture and synovial fluid analysis and culture. Treatment is with drainage and washout of the joint and IV followed by oral antibiotics e.g. di/flucloxacillin.

**FIGURE 35.5** Septic arthritis in a young girl who presented with a painful swollen left knee and difficulty walking. A knee aspiration revealed turbid fluid with elevated leukocytes. The joint fluid culture grew *Staphylococcus aureus*.

## § Osteoarthritis

OA is the most common type of arthritis, occurring in about 10% of the adult population and in 50% of those aged over 60.<sup>8</sup> It is a degenerative disease of cartilage and may be primary or secondary to causes such as trauma and mechanical problems, septic arthritis, crystallopathy or previous inflammatory disorders, or structural disorders such as SCFE and Perthes disorder.

### The arthritis

Primary OA is usually symmetrical and can affect many joints. Unlike other inflammatory disease the pain is worse on initiating movement and loading the joint, and eased by rest. OA is usually associated with stiffness, especially after activity, in contrast to RA.

## Joints involved

In primary OA all the synovial joints may be involved, but the main ones are:

- first carpometacarpal (CMC) joint of thumb
- first metatarsophalangeal (MTP) joint of great toe
- distal interphalangeal (DIP) joints of hands

Other joints that are affected significantly are the proximal interphalangeal joints, the knees, hips, acromioclavicular joints and joints of the spine, especially the facet joints of the cervical (C5–6, C6–7) and lumbar regions (L3–4, L4–5, L5–S1) (see FIG. 35.6).

**FIGURE 35.6** Osteoarthritis: typical joint distribution

## Clinical features

- Pain: worse by the end of the day, aggravated by use, relieved by rest, worse in cold and damp
- Variable morning stiffness
- Variable disability

## Signs

(See FIG. 35.7.)

- Hard and bony swelling
- Crepitus
- Signs of inflammation (mild)
- Restricted movements
- Joint deformity

*Note:* There should be no systemic manifestations.

Crystal arthropathy can complicate OA, especially in the fingers of people taking diuretics (e.g. nodular gout).

## Differentiation from an inflammatory arthropathy

OA does not exhibit the typical inflammatory pattern. The clinical diagnosis is based on:

- gradual onset of pain after activity (worse towards the end of the day)
- the pattern of joint involvement
- the lack of soft tissue swelling
- the transient nature of the joint stiffness or gelling
- takes <30 minutes to settle after rest while inflammatory arthritis takes at least 30 minutes

**FIGURE 35.7** Typical clinical features of osteoarthritis of the hand

## Diagnosis

The diagnosis is clinical and radiological but the degree of changes on X-ray do not always parallel levels of symptoms.<sup>8</sup>

## X-ray findings

- Joint space narrowing with sclerosis of subchondral bone
- Formation of osteophytes on the joint margins or in ligamentous attachments
- Cystic areas in the subchondral bone
- Altered shape of bone ends

## Principles of management

- Provide explanation and reassurance including patient education hand-outs.
- Correct modifiable risk factors: obesity, injury, overuse.
- Control pain and maintain function with appropriate drugs.
- Suggest judicious activity, exercise and physical therapy.
- Consider factors lowering the coping threshold (e.g. stress, depression, anxiety, overactivity).
- Refer for surgical intervention for debilitating and intractable pain or disability. Examples include OA of hip, knee, shoulder, first CMC joint of thumb, and first MTP joint, where surgery is now very successful. Osteotomies still have a limited place for a varus or valgus deformity of the knee.

## Treatment (optimal)

- *Explanation.* Provide patient education and reassurance that arthritis is not the crippling disease perceived by most patients.
- *Exercise.* A graduated exercise program is essential to maintain joint function. Aim for a good balance of relative rest with sensible exercise. It is necessary to stop or modify any exercise or activity that increases the pain. Systematic reviews have found that both exercise and education may help reduce the pain and disability in people with OA of the hip or knee.<sup>9</sup>
- *Rest.* Rest during an active bout of inflammatory activity only; prolonged bed rest contraindicated.
- *Heat.* Recommended is a hot-water bottle, warm bath or electric blanket to soothe pain and stiffness. Advise against getting too cold.
- *Diet.* If overweight it is important to reduce weight to ideal level. Obesity increases the risk of OA of the knee approximately fourfold and weight loss may slow progression;<sup>10</sup> otherwise, no specific diet has been proven to cause or

improve OA. Some people claim that their arthritis is improved by having a nutritious balanced diet consisting of fish, rice and vegetables and avoiding meat, dairy produce, alcohol, pepper and spices.

- *Correction of predisposing factors and aids.* Apart from weight reduction the following may help: walking stick, heel raise for leg length disparity, back brace, elastic or hinged joint support (e.g. knee).
- *Physiotherapy.* Referral should be made for specific purposes such as:
  - correct posture and/or leg length disparity
  - supervision of a hydrotherapy program
  - heat therapy and advice on simple home heat measures
  - teaching and supervision of isometric strengthening
  - exercises (e.g. for the neck, back, quadriceps muscle)
- *Occupational therapy.* Refer for advice on aids in the home, more efficient performance of daily living activities, protection of joints, and on the wide range of inexpensive equipment and tools.
- *Simple analgesics* (regularly for pain). Use paracetamol/acetaminophen (avoid codeine or dextropropoxyphene preparations, and aspirin if recent history of dyspepsia or peptic ulceration). Take before activity. Systematic reviews found that NSAIDs and simple analgesics reduce the pain of OA but there is no good evidence that NSAIDs are superior to simple analgesics (e.g. paracetamol) or that any one of the many NSAIDs is more effective than others.<sup>9</sup>
- *NSAIDs and aspirin.* These are the first-line drugs for more persistent pain not relieved by paracetamol or where there is evidence of inflammation, such as pain worse with resting and nocturnal pain. The risk versus benefit equation always has to be weighed carefully. As a rule, NSAIDs should be avoided if possible. Significant risks of NSAIDs are:
  - gastric erosion with bleeding
  - gastric ulceration
  - depression of kidney function (check kidney function beforehand)
  - hepatotoxicity

*Note:* Change to a suppository form will not necessarily render the upper GIT safe from irritation.

- *COX-2 specific inhibitors (CSIs).* Refer to CHAPTER 12. These new generation agents,

represented mainly by celecoxib and etoricoxib, should be considered where there is an indication for an NSAID but when the risk of NSAID-induced ulceration and bleeding is high.<sup>11</sup> Evidence shows that they have a similar efficacy to other NSAIDs and a modest absolute reduction in GIT complications.<sup>12</sup> The usual precautions need monitoring.

- *Intra-articular (IA) corticosteroids.* As a rule IA corticosteroids are not recommended but occasionally can be very effective for an inflammatory episode of distressing pain and disability on a background of tolerant pain (e.g. a flare-up in an osteoarthritic knee).
- *Viscosupplementation.* Intra-articular hylans, especially for OA of knee. Supported by level I evidence.
- *Complementary therapy.* Glucosamine, a natural amine sugar, derived from chitin in shellfish shell, has had anecdotal claims of efficacy for the treatment of OA. However, level II evidence has shown a modest benefit for the knees.<sup>13</sup> Further studies are desirable. It appears to be more effective in the postmenopausal female. The dose is 1500–2000 mg (o) daily in divided doses, with food. It is well tolerated (it is contraindicated in those with a significant seafood allergy). A 3–4 month trial is advisable.<sup>8</sup>
- *Epidemiological studies* (level III evidence) suggest that OA patients whose diet is rich in antioxidants, such as vitamin C, vitamin D and green tea, have slower progression of joint space narrowing on X-ray over long-term follow-up.<sup>14</sup>
- *Contraindicated drugs.* For OA these include the immunosuppressive and disease-modifying drugs such as oral corticosteroids, gold, anti-malarials and cytotoxic agents.
- *Surgery.* Refer for surgical intervention if debilitating and intractable pain or disability. Examples include OA of the hip, knee, shoulder, first CMC joint of thumb and first MTP joint.

## § Rheumatoid arthritis

RA, which is an autoimmune disease of unknown aetiology, is the commonest chronic inflammatory polyarthritis and affects about 1–2% of the population. The disorder can vary from a mild to a most severe debilitating expression. About 10–20% of patients have a relentless progression and require aggressive drug therapy.<sup>15</sup>

Genetic factors may represent a risk of 15–70% of developing RA.

## The arthritis

RA generally presents with the insidious onset of pain and stiffness of the small joints of the hands and feet. The pain is persistent rather than fleeting and mainly affects the fingers where symmetrical involvement of the PIP joints produces spindling while the metacarpophalangeal joints develop diffuse thickening as does the wrist (see FIG. 35.8). In 25% of cases RA presents as arthritis of a single joint such as the knee,<sup>7</sup> a situation leading to confusion with Lyme disease or a spondyloarthropathy.

**FIGURE 35.8** Chronic rheumatoid arthritis showing classic features of deformities including subluxation of joints and rheumatoid nodules

## Joints involved

- Hands: MCP and PIP joints, DIP joints (30%)
- Wrist and elbows
- Feet: MTP joints, tarsal joints (not IP joints), ankle
- Knees (common) and hip (delayed—up to 50%)
- Shoulder (glenohumeral) joints
- Temporomandibular joints
- Cervical spine (not lumbar spine)

Refer to FIGURE 35.9.

## Clinical features

- Insidious onset but can begin acutely (explosive RA)
- Any age 10–75 years: peak 30–50 years but bimodal 25–50 (peak age) and 65–75
- Female to male ratio = 3:1
- Joint pain: worse on waking, nocturnal pain, disturbed sleep; relieved with activity

**FIGURE 35.9** Rheumatoid arthritis: typical joint distribution

- Morning stiffness—can last hours
- Rest stiffness (e.g. after sitting)
- General: malaise, weakness, weight loss, fatigue
- Disability according to involvement

## Signs

- Soft swelling (effusion and synovial swelling), especially of wrist, MCP and PIP joints
- Warmth
- Tenderness on pressure or movement
- Limitation of movement
- Muscle wasting
- Later stages: deformity, subluxation, instability or ankylosing
- Look for swan necking, boutonniere and z deformities, ulnar deviation (see FIG. 35.10)
- Check for a number of everyday functions, for example:
  - power grip (lifting a jug of water)

FIGURE 35.10 Chronic rheumatoid arthritis: typical signs

- precision grip (using a key or pen), undoing buttons
- hook grip (carrying a bag)

The various possible extra-articular manifestations are summarised in FIGURE 35.11.

### Investigations

- ESR/CRP usually raised according to activity of disease
- Anaemia (normochromic and normocytic) may be present
- Rheumatoid factor
  - positive in about 70–80% (less frequent in early disease)
  - 15–25% of RA patients will remain negative<sup>15</sup>
- Anti-cyclic citrullinated peptide (anti-CCP) antibodies: more specific for RA (96% specificity)
- X-ray changes:
  - erosion of joint margin: ‘mouse-bitten’ appearance
  - loss of joint space (may be destruction)

- juxta-articular osteoporosis
- cysts
- advanced: subluxation or ankylosing
- MRI—helpful for early diagnosis

Criteria for the diagnosis of RA are presented in TABLE 35.4.

### Key points

- If the RA factor is positive, it is non-specific—order the anti-CCP antibody to confirm the diagnosis.
- RA has a strong cardiovascular risk factor.

Table 35.4 Revised criteria for the diagnosis of rheumatoid arthritis

Symptom duration of >6 weeks

Early morning stiffness of >1 hour

Arthritis in three or more regions

Bilateral compression tenderness of the metatarsophalangeal joints

Symmetry of the areas affected

Rheumatoid factor positivity

Anti-cyclic citrullinated peptide antibody positivity

Bony erosions evident on radiographs of the hands or feet, although these are uncommon in early disease

### Principles of management<sup>8,16</sup>

- Give patient education support and appropriate reassurance. The diagnosis generally has distressful implications, and so the patient and family require careful explanation and support. Some patients have little or no long-term problems but even in mild cases, continuing care and medical supervision is important.
- There has been a radical shift from palliation to early induction of disease remission, to prevent joint damage and reduce morbidity from malignancy (especially lymphoma) and cardiovascular disease.
- Since many studies show disease progression in the first 2 years, relative aggressive treatment with disease-modifying antirheumatic drugs (DMARDs) from the outset is advisable, rather than to start stepwise with analgesics and NSAIDs only.<sup>17</sup>
- Use a team approach where appropriate, including an early consultant referral for diagnosis and collaborative support.

**FIGURE 35.11** Rheumatoid arthritis: significant non-articular clinical manifestations

- Fully assess the patient's functional impairment and impact on home life, work and social activity. Involve the family in decision making.
- Make judicious use of pharmaceutical agents. For serious cases consultant collaboration is essential.
- Review the patient regularly, continually assessing progress and drug tolerance. The disease activity can be monitored with ultrasound of hands, especially if hands are thick.

### Specific advice

- *Rest and splinting.* This is necessary where practical for any acute flare-up of arthritis.
- *Exercise.* It is important to have regular exercise, especially walking and swimming. Have hydrotherapy in heated pools.
- *Smoking cessation.* This is strongly recommended.
- *Referral.* Referring to physiotherapists and occupational therapists for expertise in exercise supervision, physical therapy and advice regarding coping in the home and work is important.
- *Joint movement.* Each affected joint should be put daily through a full range of motion to keep it mobile and reduce stiffness.
- *Diet.* Although there is no special diet that seems to cause or cure RA, there is evidence that avoiding animal fats (dairy products and some meats) and using fish oils is beneficial.<sup>18</sup> A nourishing, well-balanced diet is common sense and obesity must be avoided.

Therapies used in the management of rheumatoid arthritis are presented in **TABLE 35.5**.

### Management (pharmacological)<sup>8</sup>

Best under consultant direction.

### NSAIDs

These are effective and still have a place but the adverse effects are a problem.

The use of paracetamol, fish oils and low-dose glucocorticoids may allow NSAID use to be kept to a minimum or avoided.

## Fish oil

Fish oil in doses to deliver 4 g of omega-3 long-chain polyunsaturated fatty acids daily (typically 0.2 g/kg) has been shown to reduce symptoms and the need for NSAIDs through its anti-inflammatory activity.<sup>8,18</sup>

## Glucocorticoids

Oral use should be considered in patients with severe disease as a temporary adjunct to DMARD therapy and where other treatments have failed or are contraindicated.

The dose is prednisolone 5–10 mg (o) daily. Avoid doses higher than 15 mg daily if possible.

Intra-articular injections of depot preparations are effective in larger joints.

## Disease-modifying antirheumatic drugs (DMARDs)

These agents target synovial inflammation and prevent joint damage. The choice depends on several factors, but is best left to the specialist coordinating care. In most patients with recently diagnosed RA, methotrexate is the cornerstone of management and should be commenced as early as possible.

Initial dose: methotrexate 5–10 mg (o) weekly, increasing to maximum of 25 mg weekly (o) SC or IM depending on clinical response and toxicity. Add folic acid 5 mg twice weekly.<sup>8</sup>

Biological DMARDs (bDMARDs) are the newer agents which should be considered if remission is not achieved with appropriate methotrexate monotherapy, 'triple therapy' or other combinations. All bDMARDs are more effective when combined with methotrexate.

**Warning:** All practitioners should be aware of the increased risk of infectious diseases such as the atypical pneumonias, tuberculosis and listeriosis while taking bDMARDs. All patients should report unusual or unexpected fever or symptoms. Injection site reactions are common.

## Standard initial drug therapy

Monotherapy with methotrexate (or occasionally another DMARD) is standard. Less than 20% will reach disease remission and, if not achieved, increase the dose or consider combination therapy.

## Combination therapy

Consider standard triple therapy: methotrexate + sulfasalazine + hydroxychloroquine.

Triple therapy can be used if methotrexate monotherapy has failed or initially on diagnosis, depending on the severity of the disease. Monitoring for FBE, LFTs and annual eye checks is necessary.

Several other double combinations may be used (e.g. methotrexate with cyclosporin, leflunomide or a bDMARD).

**Table 35.5** Therapies used in the management of rheumatoid arthritis<sup>19</sup>

Education (rest, literature, weight loss, joint protection advice)

NSAIDs

Simple analgesics

DMARDs:

- Immunosuppressants:
  - azathioprine
  - cyclosporin
  - leflunomide
  - methotrexate
- Cytokine inhibitors (biological DMARDs)
  - anti-TNF  $\alpha$  agents: abatacept, adalimumab, etanercept, infliximab, golimumab, rituximab
  - anti-Interleukin-1 agents: anakinra, tocilizumab

Gold salts

Quinolones:

- hydroxychloroquine
- chloroquine

Others:

- D-penicillamine
- sulfasalazine

Physical therapy (hydrotherapy, isometric exercises)

Occupational therapy (splints, aids and appliances)

Corticosteroids:

- oral prednisolone
- intra-articular
- intravenous (steroid 'pulses')

Fish body oil

Orthopaedic surgery (synovectomy, joint replacement, arthrodesis, plastic hand surgery)

Chiropody, footwear, insoles

Source: After Reilly and Littlejohn<sup>19</sup>

## CONNECTIVE TISSUE DISEASES

The connective tissue disorders have the common feature of arthritis or arthralgia. Refer to **CHAPTER 32**.

Arthritis is the commonest clinical feature of SLE (over 90%).<sup>7</sup> It is a symmetrical polyarthritis involving mainly small and medium joints, especially the proximal interphalangeal and carpal joints of the hand. It is usually non-erosive and non-deforming, although deformities of fingers and thumbs can occur due to laxity of ligaments, tendons and capsules causing joint instability.

The initial presentation is similar to RA.

Scleroderma can present as a polyarthritis affecting the fingers of the hand in 25% of patients, especially in the early stages. Soft tissue swelling produces a 'sausage finger' pattern.

Arthralgia and arthritis occur in about 50% of patients with polymyositis/dermatomyositis and may be the presenting feature before the major feature of muscle weakness and wasting of the proximal muscles of the shoulder and pelvic girdles appear. The small joints of the hand are usually affected and it may resemble RA.

## CRYSTAL ARTHRITIS

Arthritis, which can be acute, chronic or asymptomatic, is caused by a variety of crystal deposits in joints. The three main types of crystal arthritis are monosodium urate (gout), calcium pyrophosphate dihydrate (CPPD) and calcium phosphate (usually hydroxyapatite).<sup>20</sup> Refer to TABLE 35.6.

### § Gout (monosodium urate crystal disorder)

Gout is an abnormality of uric acid metabolism resulting in hyperuricaemia and urate crystal deposition. Urate crystals deposit in:

- joints—acute gouty arthritis
- soft tissue—tophi and tenosynovitis
- urinary tract—urate stones

Four typical stages of gout are recognised:

- *Stage 1*—asymptomatic hyperuricaemia
- *Stage 2*—acute gouty arthritis
- *Stage 3*—intercritical gout (intervals between attacks)
- *Stage 4*—chronic tophaceous gout and chronic gouty arthritis

Asymptomatic hyperuricaemia:

- 10 times more common than gout<sup>7</sup>
- Elevated serum uric acid (>0.42 mmol/L in men, > 0.36 mmol/L in women)

**Table 35.6** Crystal-induced disorders

Crystals	Associated disease/syndrome	Typical joints or region affected
Monosodium urate	Acute gout	Metatarsophalangeal joint of big toe
	Tophaceous gout	Also: other foot joints, ankle, knee and patellar bursa, wrist, fingers
	Asymptomatic	
	Chronic gouty arthritis	
Calcium pyrophosphate dihydrate (CPPD)	Acute pseudogout	Knee, wrist
	Destructive arthropathy (like RA)	In older people >60 years (average age 72)
	Asymptomatic (most common)	F > M (2.7:1)
Basic calcium phosphate	Acute calcific periarthritis	Shoulder (supraspinatus)
	Destructive arthropathy	
	Acute arthritis	

- Absence of clinical manifestations
- Usually does not warrant treatment

### Clinical features

Typical clinical features of gout include:<sup>8</sup>

- mainly a disorder of men (5–8% prevalence)
- onset earlier in men (40–50) than women (60+)
- acute attack: excruciating pain in great toe (see FIG. 35.11), early hours of morning
- skin over joint—red, shiny, swollen and hot
- exquisitely tender to touch
- relief with colchicine, NSAIDs, corticosteroids
- can subside spontaneously (3 to 10 days) without treatment

### Causes/precipitating factors

- Alcohol excess (e.g. binge drinking)
- Surgical operation
- Starvation
- Drugs (e.g. frusemide, thiazide diuretics)
- Chronic kidney disease
- Myeloproliferative disorders
- Lymphoproliferative disorders (e.g. leukaemia)
- Sugary soft drinks<sup>21</sup>

**FIGURE 35.12** Gout showing typical red, shiny, swollen arthritis of the first MTP joint with desquamation of the skin

- Cytotoxic agents (tumour lysis)
- Hypothyroidism
- Low-dose aspirin
- Others

### The arthritis

Monoarthritis in 90% of attacks:

- MTP joint great toe—75%
- other joints—usually lower limbs: other toes, ankles, knees

Polyarticular onset is more common in old men and may occur in DIP and PIP joints of fingers. No synovial joint is immune.

Refer to **FIGURE 35.13**.

### Other features

- Prone to recurrence
- Tophi in ears, elbows (olecranon bursa), big toes, fingers, Achilles tendon (take many years)
- Can cause patellar bursitis
- Can get cellulitis (does not respond to antibiotics)

### Nodular gout

Develops in postmenopausal women with kidney impairment taking diuretic therapy who develop pain and tophaceous deposits around osteoarthritic interphalangeal (especially DIP) joints of fingers.

### Diagnosis

- Synovial fluid aspirate → typical uric acid crystals using compensated polarised microscopy; this should be tried first (if possible) as it is the only real diagnostic feature

- Elevated serum uric acid (up to 30% can be within normal limits with a true acute attack)<sup>19</sup>
- X-ray: punched out erosions at joint margins

### Management

Management of gout includes these principles:

- good advice and patient education information
- provision of rapid pain relief
- preventing further attacks
- prevention of destructive arthritis and tophi
- dealing with precipitating factors and comorbid conditions (e.g. alcohol dependence, obesity, CKD, polycythaemia vera, diabetes, hypertension)

### The acute attack<sup>8,21</sup>

NSAIDs, in full dosage, are first-line and effective.

indomethacin 50 mg (o) tds (if tolerated) until symptoms abate (up to 3–5 days), then taper to 25 mg tds until cessation of the attack

If extreme: indomethacin 100 mg (o) statim, 75 mg 2 hours later (if tolerated), then 50 mg (o) tds for 24–48 hours, then 50–75 mg/day.

*Note:* Any other NSAID can be used. Add an antiemetic (e.g. metoclopramide 10 mg (o) tds) *or*

Colchicine:

colchicine 0.5 mg (o) statim, then 0.5 mg every 6 or 8 hours until pain relief (usually 24–28 hours) or diarrhoea develops (max. 6 mg/24 hours)

*Note:*

- Must be given early
- Avoid if kidney impairment
- Avoid use with macrolide antibiotics e.g. clarithromycin especially in CKD
- Avoid long-term use

Consider:

- corticosteroids: intra-articular following aspiration and culture (gout and sepsis can occur together); a digital anaesthetic block is advisable. An oral course can be used: start with prednisolone 40 mg/day for 4 days then decrease gradually over 10 days<sup>22</sup>
- corticotrophin (ACTH) IM in difficult cases (e.g. synthetic ACTH: tetracosactrin 1 mg IM)

*Note:*

- Avoid aspirin and urate pool lowering drugs (probenecid, allopurinol, sulphinpyrazone)
- Monitor kidney function and electrolytes

FIGURE 35.13 Gout: possible joint distribution

### Long-term therapy

When acute attack subsides preventive measures include:

- weight reduction
- a normal, well-balanced diet
- avoidance of purine-rich food, such as organ meats (liver, brain, kidneys, sweetbread), tinned fish (sardines, anchovies, herrings), shellfish and game
- reduced intake of alcohol
- reduced intake of sugary soft drinks<sup>23</sup>
- good fluid intake (e.g. water—2 litres a day)
- avoidance of drugs such as diuretics (thiazides, frusemide) and salicylates/low-dose aspirin
- wearing comfortable shoes

### Prevention (drug prophylaxis)

*Allopurinol* (a xanthine oxidase inhibitor) is the drug of choice: dose 100–300 mg daily.

Indications:

- frequent acute attacks
- tophi or chronic gouty arthritis
- kidney stones or uric acid nephropathy
- hyperuricaemia

Adverse effects:

- rash (2%)
- severe allergic reaction (rare)

Precautions:

- beware of kidney insufficiency and elderly patients—use lower doses
- beware of drug interactions:
  - azathioprine and 6 mercaptopurine—potentially lethal
  - amoxycillin—prone to rashes

### Method: treatment of intercritical and chronic gout

- Commence 6–8 weeks after last acute attack.
- Start with 50 mg daily for the first week and increase by 50 mg weekly to maximum 300 mg.
- Check uric acid level after 4 weeks: aim for level <0.38 mmol/L.
- Add colchicine 0.5 mg bd for 6 months (to avoid precipitation of gout) or indomethacin 25 mg bd or other NSAIDs.

### Probenecid (uricosuric agent)

Good for hyperexcretion of uric acid by blocking renal tubular reabsorption. Dose: 500 mg/day (up to 2 g)

Note: Aspirin antagonises effect.

### Calcium pyrophosphate crystal disorder (pseudogout)<sup>8</sup>

The finding of calcification of articular cartilage on X-ray examination is usually termed chondrocalcinosis. This is mainly a disorder of the elderly superimposed on an osteoarthritic joint. The acute attack is similar to an acute attack of gout but it affects the following joints (in order):

- knee
- 2nd and 3rd MCP joints
- wrist
- shoulder
- ankle
- elbow

It can affect tendons, especially the Achilles tendon, and cause a fever resembling septic arthritis.

The crystals in synovial fluid are readily identified by phase-contrast microscopy. X-rays are helpful in showing calcification of the articular cartilage.

Management is based on aspiration and installation of a depot glucocorticosteroid by injection into the joint (if joint infection excluded) plus analgesia. Be cautious of using NSAIDs in the elderly—paracetamol is preferred. Colchicine can be used.

Treatment includes:<sup>8</sup>

indomethacin 50 mg (o) tds (if tolerated)  
until symptoms abate  
and/or  
colchicine 0.5 mg (o) tds until attack subsides  
and  
paracetamol 500–1000 mg (o) four times  
daily, if necessary

## THE SPONDYLOARTHROPATHIES

The spondyloarthropathies are a group of related inflammatory arthropathies with common characteristics affecting the spondyles (vertebrae) of the spine. It is appropriate to regard them as synonymous with the seronegative spondyloarthropathies in contradistinction to RA, which is seropositive and affects the cervical spine only. Apart from back pain this group tends to present with oligoarthritis in younger patients. The arthritis is characteristically peripheral, asymmetrical, affects the lower limbs and can exhibit dactylitis (e.g. 'sausage' digits).

### Features<sup>24</sup>

- Sacroiliitis with or without spondylitis
- Enthesopathy, especially plantar fasciitis, Achilles tendonitis, costochondritis
- Arthritis, especially larger lower limb joints
- Extra-articular features (e.g. iritis/anterior uveitis, mucocutaneous lesions, psoriasiform skin and nail lesions, chronic GIT and GU inflammation)
- Absent rheumatoid factor
- Association with HLA-B<sub>27</sub> antigen
- Familial predisposition

### The group of disorders

- 1 Ankylosing spondylitis
- 2 Reactive arthritis
- 3 Inflammatory bowel disease (enteropathic arthritis)
- 4 Psoriatic arthritis

- 5 Juvenile onset ankylosing spondylitis
- 6 Unclassified spondyloarthritis—partial features only

## § Ankylosing spondylitis

This usually presents with an insidious onset of inflammatory back and buttock pain (sacroiliac joints and spine) and stiffness in young adults (age <40 years), and 20% present with peripheral joint involvement before the onset of back pain. It usually affects the girdle joints (hips and shoulders), knees or ankles. At some stage over 35% have joints other than the spine affected. The symptoms are responsive to NSAIDs (see CHAPTER 38).

### Key clinical criteria<sup>8</sup>

- Low back pain persisting for >3 months
- Associated morning stiffness >30 minutes
- Awoken with pain during second half of night
- Improvement with exercise and not relieved by rest
- Limitation of lumbar spine motion in sagittal and frontal planes
- Chest expansion ↓ relative to normal values
- Unilateral sacroiliitis (grade 3 to 4)
- Bilateral sacroiliitis (grade 2 to 4)

## § Reactive arthritis

Reactive arthritis is a form of arthropathy in which non-septic arthritis and often sacroiliitis develop after an acute urogenital infection (usually *Chlamydia trachomatis*) or an enteric infection (e.g. *Salmonella*, *Shigella*).

**DxT** NSU + conjunctivitis ± iritis + arthritis →  
reactive arthritis

The arthritis, which commences 1–3 weeks post infection, tends to affect the larger peripheral joints, especially the ankle (talocrural) and knees, but the fingers and toes can be affected in a patchy polyarthritic fashion. Mucocutaneous lesions, including keratoderma blennorrhagica and circinate balanitis, may occur, although the majority develop peripheral arthritis only (see FIG. 35.14).

## § Enteropathic spondyloarthropathy

Inflammatory bowel disease (ulcerative colitis, Crohn disease and Whipple disease) may rarely be associated with peripheral arthritis and sacroiliitis.

FIGURE 35.14 Possible clinical features of reactive arthritis

## § Psoriatic arthritis

Like reactive arthritis, this can develop a condition indistinguishable from ankylosing spondylitis. It is therefore important to look beyond the skin condition of psoriasis, for about 5% will develop psoriatic arthropathy. It can have several manifestations:

- 1 mainly DIP joints
- 2 identical RA pattern but RA factor negative
- 3 identical ankylosing spondylosis pattern with sacroiliitis and spondylitis
- 4 monoarthritis, especially knees
- 5 severe deformity or 'mutilans' arthritis

## Unclassified spondyloarthritis

Patients in this category seem to be the most frequently encountered in family practice. They clearly have a spondyloarthropathy but fail to meet the criteria for any one of the individual entities within the group. A typical patient is a young male

in his third decade with a painful knee or other joint, unilateral (or bilateral) back pain with one of the enthesal problems (e.g. plantar fasciitis).

## Investigations

- X-rays:
  - radiological sacroiliitis is central to the diagnosis
  - changes include narrowing of SIJs, margin irregularity, sclerosis of peri-articular bone and eventually bony fusion. Spondylitis usually follows
- ESR and CRP: most patients have an elevated ESR and CRP at some stage of their disease
- HLA-B<sub>27</sub>: this test has low specificity and has limited value except that it predicts risk to offspring if positive
- Microbiology: in patients with a history of reactive arthritis, cultures should be obtained from the urethra, faeces, urine and blood<sup>24</sup>

## Principles of management

- Identify the most active elements of the disease and treat accordingly.
- Provide patient and family education with appropriate reassurance: this is vital. Stress that, although the disease is non-curable, treatment is effective and long-term prognosis generally good.
- Provide regular assessment and support.
- Give genetic counselling—in cases of ankylosing spondylitis with positive HLA-B<sub>27</sub> the risk to offspring is significant.
- Give advice regarding work, especially with posture.
- Acute anterior uveitis requires prompt treatment and monitoring by an ophthalmologist.
- Refer for physiotherapy for exercises, stretching program, postural exercises and hydrotherapy. Appropriate physiotherapy slows deterioration in spinal function.<sup>25</sup>
- Consider referral for occupational therapy.
- Pharmacological agents:<sup>8</sup>
  - NSAIDs (e.g. indomethacin 75–200 mg (o) or 100 mg rectally nocte daily or ketoprofen 100 mg rectally nocte to control pain, stiffness and synovitis)
  - sulphasalazine (if NSAIDs ineffective)
  - intra-articular corticosteroids for severe monoarthritis and intralesional corticosteroids for enthesopathy

Refer for advice on above and especially for DMARD and bDMARD therapy.

## Cautions

- Careful monitoring is required with NSAIDs and sulphasalazine.
- Systemic corticosteroids are not indicated.
- Immunosuppressants (low dose weekly methotrexate) and bDMARDs may be needed for severe intractable problems with psoriasis and reactive arthritis.
- These conditions should be managed in collaboration with a consultant.

## When to refer

- Consider referring most severe true inflammatory disorders for diagnosis and initiation of treatment (e.g. RA, spondyloarthropathy, connective tissue disorders and suspicion of a vasculitide)
- Osteoarthritis:
  - generalised joint pain
  - associated systemic symptoms
  - deteriorating joint function
- intractable pain (especially at rest)
- if surgical procedure is contemplated<sup>8</sup>
- Rheumatoid arthritis:
  - all patients initially
  - persistent inflammation of a joint or joints
  - patient ill and corticosteroids contemplated
  - if a surgical procedure is contemplated
- Spondyloarthropathies:
  - initial referral for confirmation of diagnosis and initiation of treatment
  - disease unresponsive to conventional treatment
  - sudden deterioration in symptoms, especially pain
  - onset of uveitis or other ocular complications
  - adverse drug reactions
- Undiagnosed arthritis in presence of constitutional symptoms
- Suspicion of a suppurative or serious infective condition (e.g. septic arthritis, endocarditis, brucellosis)
- Children with evidence of juvenile idiopathic arthritis (e.g. Still syndrome)

Table 35.7 Diagnostic guidelines for arthritis

Disorder	Sex ratio	Typical age	Typical common joints involved	Associated features	Key tests
<b>OA (generalised—primary)</b>	FM 6:1	>50	DIP >PIP fingers Base thumb (1st CMC) 1st MTP joint Cervical and lumbar spines Hips and knees	Pain worse in evenings, relieved by rest	X-ray
<b>RA</b>	FM 3:1	30–50	PIP, MCP hands Wrist Base of toes (MTP joints) Symmetrical	Any joint: worse at rest, better with activity; morning stiffness Constitutional symptoms Carpal tunnel syndrome Many other general effects	RA factor Anti-CCP X-ray
<b>SLE</b>	FM 9:1	15–35	Symmetrical and variable Small joints fingers Often slight	Constitutional symptoms Fever Adverse drug reactions Any other system affected Rash (80%) Pleuritic symptoms (67%) Raynaud phenomenon	ANA dsDNA & ENA antibodies
<b>Scleroderma</b>	FM 3:1	20–50	Symmetrical Polyarthritis fingers	Raynaud (90%) Other skin changes Dysphagia	ANA Scl-70 centromere

Disorder	Sex ratio	Typical age	Typical common joints involved	Associated features	Key tests
<b>Viral arthropathies (excluding HIV)</b>	M = F	Children	Transient Usually PIP joints fingers	Rash, fever	Specific serology
<b>Ankylosing spondylitis</b>	MF 3:1	18–30	Sacroiliacs Vertebral column esp. lumbar, costovertebral Also knees, hips or ankles	Iridocyclitis Chest dysfunction Enthesopathy (e.g. plantar fasciitis)	ESR X-ray HLA-B27
<b>Psoriatic arthritis</b>	M = F	Any age	DIP joints—fingers and toes, sacroiliacs	Psoriasis rash (pre-existing) Pitted nails, 'sausage digits'	–
<b>Enteropathic arthritis</b>	M = F	Any age	Lower extremity: knees, feet, ankles Hips: sacroiliacs	Ulcerative colitis Crohn disease Whipple disease	Endoscopy
<b>Reactive arthritis:</b> Genitourinary (e.g. <i>Chlamydia</i> ) Post-dysentery (e.g. <i>Salmonella</i> )	MF 20:1 M = F	15–30	As above	Preceding dysentery or urethritis Enthesal problems Circinate balanitis Other skin lesions	ESR/CRP M and C urine Serology
<b>Gout</b>	MF 20:1	M 40–50 F >60	Big toe (MTP joint): any other possible, esp. lower limb DIP—osteoarthritis	Tophi Raised serum uric acid Urate crystals in joints Diuretics in elderly	s. urate Microsynovial fluid
<b>Pseudogout</b>	M = F	>60 especially >70	Knee	Chondrocalcinosis Pyrophosphate crystals in joint	Microsynovial fluid X-ray
<b>Polymyalgia rheumatica</b>	FM 3:1	>60	Morning stiffness and pain in girdles, esp. shoulder Joints normal or osteoarthritic	ESR ↑ ↑ ↑	ESR

Source: After Hart<sup>26</sup>

## Practice tips

- Morning stiffness and pain, improving with exercise = RA.
- Flitting polyarthritis and fever = rheumatic fever; ?endocarditis; ?SLE.
- Polyarthritis (usually PIPs) and rash = viral arthritis or drug reaction.
- If rheumatoid arthritis involves the neck, beware of atlantoaxial subluxation and spinal cord compression.
- If the patient is young—think of SLE.
- If a patient returns from overseas with arthralgia, think of drug reactions, hepatitis, Lyme disease, but if the pain is intense consider dengue fever.
- Consider the possibility of Lyme disease in people with a fever, rash and arthritis who have been exposed to tick bites in rural areas.

- If a patient presents with Raynaud phenomenon and arthritis, especially of the hands, consider foremost RA, SLE and systemic sclerosis.
- Avoid the temptation to apply on doubtful grounds a broad label such as arthritis or rheumatoid, or a precise diagnosis such as RA, and introduce drugs.<sup>27</sup> TABLE 35.7 presents the diagnostic guidelines.<sup>26</sup>

Virginia Woolf 1934, *Diary entry*

Anorectal problems are common in family practice and tend to cause anxiety in the patient that is often related to the fear of cancer. This fear may be well founded for many instances of rectal bleeding and lumps. It is important to keep in mind the association between haemorrhoids and large bowel cancer.

Anorectal problems include:

- pain
- lumps
- discharge
- bleeding
- pruritus

Common anorectal conditions are illustrated in **FIGURE 36.1**.

## ANORECTAL PAIN (PROCTALGIA)

The patient may complain that defecation is painful or almost impossible because of anorectal pain.

### Causes

Pain without swelling:

- anal fissure
- anal herpes
- ulcerative proctitis
- proctalgia fugax

**FIGURE 36.1** Common anorectal conditions

- solitary rectal ulcer
- tenesmus

Painful swelling:

- perianal haematoma
- strangulated internal haemorrhoids
- abscess: perianal, ischiorectal
- pilonidal sinus
- fistula-in-ano (intermittent)

## § Anal fissure

Anal fissures cause pain on defecation and usually develop after a period of constipation (may be a brief period) and tenesmus. Other associations are childbirth and opioid analgesics.<sup>1</sup> Sometimes the pain can be excruciating, persisting for hours and radiating down the back of both legs. Anal fissures, especially if chronic, can cause minor anorectal bleeding (bright blood) noted as spotting on the toilet paper.

### Examination

On inspection the anal fissure is usually seen in the anal margin, situated in the midline posteriorly (6 o'clock)—90% of fissures. The fissure appears as an elliptical ulcer involving the lower third of the anus from the dentate line to the anal verge (see FIG. 36.2).<sup>1</sup>

Digital examination and sigmoidoscopy are difficult because of painful anal sphincter spasm. If there are multiple fissures, Crohn disease should be suspected. These fissures look different, being indurated, oedematous and bluish in colour.

In chronic anal fissures a sentinel pile is common and in long-standing cases a subcutaneous fistula is seen at the anal margin, with fibrosis and anal stenosis.<sup>1</sup>

**FIGURE 36.2** Anal fissure with prominent skin tag situated in the mid posterior position of the anal verge: the 6 o'clock position

## Red flag pointers for anorectal pain

- Weight loss
- Change in bowel habits
- Fever >38°C
- Recurrent (consider Crohn disease)
- Exquisitely painful PR (consider abscess)

### Treatment

Management is conservative with avoidance of hard stools and warm salt (sitz) baths after bowel movements. A high residue diet and avoidance of constipation (aim for soft bulky stools) may lead to resolution and long-term prevention. A combined local anaesthetic and corticosteroid ointment applied to the fissure can provide relief and promote healing. Topical local anaesthetic applied before passing a stool may relieve pain but not promote healing. Hot baths relax the internal anal sphincter. An acute anal fissure will usually heal spontaneously or within a few weeks of a treatment of high-fibre diet, sitz baths or laxatives.<sup>2</sup> A conservative treatment is the application of diluted glyceryl trinitrate ointment (e.g. Rectogesic 2% three times daily for 6 weeks to the lower anal canal) with a gloved finger gently inserted into the anal canal. It achieves healing rates of about 50%.<sup>3,4</sup> Transient headache is the main adverse effect.

Lateral internal sphincterotomy is indicated in patients with a recurrent fissure and a chronic fissure with a degree of fibrosis and anal stenosis.<sup>5</sup> This surgical procedure is very effective. An alternative 'chemical' sphincterotomy, which is as effective as surgical treatment, is injection of botulinum toxin into the sphincter.

## § Proctalgia fugax (levator ani spasm)

### Clinical features

- Episodic fleeting rectal pain
- Varies from mild discomfort to severe spasm
- Last 3–30 minutes
- Often wakes patient from sound sleep
- Can occur any time of day
- A functional bowel disorder
- Affects adults, usually professional males

### Management<sup>6</sup>

- Explanation and reassurance
- An immediate drink (preferably hot) and local warmth

- Salbutamol inhaler (2 puffs statim) worth a trial

Alternatives include glyceryl trinitrate spray for the symptom or possibly anti-spasmodics, calcium channel blockers and clonidine.

### § Solitary rectal ulcer syndrome

These ulcers occur in young adults; they can present with pain but usually present as the sensation of a rectal lump causing obstructed defecation and bleeding with mucus. The ulcer, which is usually seen on sigmoidoscopy about 10 cm from the anal margin on the anterior rectal wall, can resemble cancer. Management is difficult and a chronic course is common. Treatment includes a high residue diet and the avoidance of constipation.

### Tenesmus

Tenesmus is an unpleasant sensation of incomplete evacuation of the rectum. It causes the patient to attempt defecation at frequent intervals. The most common cause is irritable bowel syndrome. Another common cause is an abnormal mass in the rectum or anal canal, such as cancer (e.g. prostate, anorectal), haemorrhoids or a hard faecal mass. In some cases, despite intensive investigation, no cause is found and it appears to be a functional problem.

### § Perianal haematoma

A perianal haematoma (thrombosed external haemorrhoid) is a purple tender swelling at the anal margin caused by rupture of an external haemorrhoidal vein following straining at toilet or some other effort involving a Valsalva manoeuvre. The degree of pain varies from a minor discomfort to severe pain. It has been described as the 'five day, painful, self-curing pile', which may lead to a skin tag.

### Management

Surgical intervention is recommended, especially in the presence of severe discomfort. The treatment depends on the time of presentation after the appearance of the haematoma.

- 1 *Within 24 hours of onset.* Perform simple aspiration without local anaesthetic using a 19 gauge needle while the haematoma is still fluid.
- 2 *From 24 hours to 5 days of onset.* The blood has clotted and a simple incision under local anaesthetic over the haematoma with deroofing with scissors (like taking the top off a boiled egg) to remove the thrombosis by squeezing

is recommended. Removal of the haematoma reduces the chances of the development of a skin tag, which can be a source of anal irritation.

- 3 *Day 6 onwards.* The haematoma is best left alone unless it is very painful or (rarely) infected. Resolution is evidenced by the appearance of wrinkles in the previously stretched skin.

### Follow-up

The patient should be reviewed in 4 weeks for rectal examination and proctoscopy, to examine for any underlying internal haemorrhoid that may predispose to further recurrence. Prevention includes an increased intake of dietary fibre and avoidance of straining at stool. intake of dietary fibre and avoidance of straining at stool.

### § Strangulated haemorrhoids

A marked oedematous circumferential swelling will appear if all the haemorrhoids are involved. If only one haemorrhoid is strangulated, proctoscopy will help to distinguish it from a perianal haematoma. Initial treatment is with rest and ice packs and then haemorrhoidectomy at the earliest possible time. It is best to refer for urgent surgery.

### § Perianal abscess

This is caused by infection by polymicrobial organisms of one of the anal glands that drain the anal canal.

### Clinical features

- Severe, constant, throbbing pain
- Fever and toxicity
- Hot, red, tender swelling adjacent to anal margin
- Non-fluctuant swelling

Careful examination is essential to make the diagnosis. Look for evidence of a fistula.

### Treatment

Drain via a cruciate incision, which may need to be deep (with trimming of the corners) over the point of maximal induration. A drain tube can be inserted for 7 to 10 days. Packing is not necessary.

### Antibiotics

If a perianal or perirectal abscess is recalcitrant or spreading with cellulitis, use:

- metronidazole 400 mg (o) 12 hourly for 5–7 days plus
- cephalexin 500 mg (o) 6 hourly for 5–7 days<sup>7</sup>

## § Ischiorectal abscess

An ischiorectal abscess presents as a larger, more diffuse, tender, dusky red swelling in the buttock. The presence of an abscess is usually very obvious but the precise focus is not always obvious on inspection. Antibiotics are of little help and surgical incision and drainage as soon as possible is necessary. A deep general anaesthetic is necessary.

## § Pilonidal sinus and abscess

Recurrent abscesses and discharge in the sacral region (at the upper end of the natal cleft about 6 cm from the anus) caused by a midline pilonidal sinus, which often presents as a painful abscess. Once the infection has settled it is important to excise the pits, allow free drainage of the midline cavity and lateral tracks and remove all ingrown hair. Antibiotics, which should be guided by culture (e.g. cephalexin and metronidazole), are given to complement surgical drainage only if there is severe surrounding cellulitis. Pilonidal means 'a nest of hairs' and the problem is particularly common in hirsute young men (see FIG. 36.3). Refer for excision of the sinus network if necessary.

## § Fistula-in-ano<sup>5</sup>

An anal fistula is a tract that communicates between the perianal skin (visible opening) and the anal canal, usually at the level of the dentate line. It usually arises from chronic perianal infection, especially following discharge of an abscess. It is common in patients with Crohn disease. Symptoms include recurrent abscesses, discharge of blood, pus or serous fluid, swelling and anal pain. A surgical opinion is necessary to determine the appropriate surgical

procedures, which may be complex if it traverses sphincter musculature.

## ANORECTAL LUMPS

Anorectal lumps are relatively common and patients are often concerned because of the fear of cancer. A lump arising from the anal canal or rectum, such as an internal haemorrhoid, tends to appear intermittently upon defecation, and reduce afterwards.<sup>1</sup> Common prolapsing lesions include second- and third-degree haemorrhoids, hypertrophied anal papilla, polyps and rectal prolapse. Common presenting lumps include skin tags, fourth-degree piles and perianal warts (see TABLE 36.1).

Table 36.1 Common anal lumps

Prolapsing lumps
Second- and third-degree haemorrhoids
Rectal prolapse
Rectal polyp
Hypertrophied anal papilla
Persistent lumps
Skin tag
Perianal warts (condylomata accuminata)
Anal cancer
Fourth-degree haemorrhoids
Perianal haematoma
Perianal abscess

## § Skin tags

The skin tag is usually the legacy of an untreated perianal haematoma. It may require excision for aesthetic reasons, for hygiene or because it is a source of pruritus ani or irritation. A tag may be associated with a chronic fissure.

### Treatment (method of excision)

A simple elliptical excision at the base of the skin is made under local anaesthetic. Suturing of the defect is usually not necessary.

## § Perianal warts

It is important to distinguish the common viral warts from the condylomata lata of secondary syphilis. Local therapy includes the application of podophyllin every 2 or 3 days by the practitioner or imiquimod.

## § Rectal prolapse

This is protrusion from the anus to a variable degree of the rectal mucosa (partial) or the full thickness of the rectal wall. It appears to be associated with

FIGURE 36.3 Pilonidal sinus revealing a pilonidal sinus and a lateral sinus opening after shaving. It shows the characteristic tuft of hairs protruding from the midline sinus.

constipation and chronic straining. Features can include mucus discharge, bleeding, tenesmus, a solitary rectal ulcer and faecal incontinence (75%).

Visualisation of the prolapse is an important part of the diagnosis. Surgery such as rectopexy (fixing the rectum to the sacrum) is the only effective treatment for a complete prolapse.<sup>5</sup>

Temporary shrinking of a visible prolapse in an emergency situation can be achieved by a liberal sprinkling of fine crystalline sugar.

### § Internal haemorrhoids

Haemorrhoids or piles are common and tend to develop between the ages of 20 and 50 years. About one out of two Westerners suffers from them by the time 50 is reached.<sup>3</sup> Internal haemorrhoids are a complex of dilated arteries, branches of the superior haemorrhoidal artery and veins of the internal haemorrhoidal venous plexus (see FIG. 36.4). The commonest cause is chronic constipation related to a lack of dietary fibre.

Anatomically there are three classical sites, namely 3, 7 and 11 o'clock (see FIG. 36.5).

FIGURE 36.4 Classification of haemorrhoids

FIGURE 36.5 Three sites of primary haemorrhoids, looking into the anus from below

### Clinical stages and pathology<sup>3</sup>

- *Stage 1:* First-degree internal haemorrhoids: three bulges form above the dentate line. Bright bleeding is common.
- *Stage 2:* Second-degree internal haemorrhoids: the bulges increase in size and slide downwards so that the patient is aware of lumps when straining at stool, but they disappear upon relaxing. Bleeding is a feature.
- *Stage 3:* Third-degree internal haemorrhoids: the pile continues to enlarge and slide downwards, requiring manual replacement to alleviate discomfort. Bleeding is also a feature.
- *Stage 4:* Fourth-degree internal haemorrhoids: prolapse has occurred and replacement of the prolapsed pile into the anal canal is impossible.

### Symptoms

Bleeding is the main and, in many people, the only symptom. The word 'haemorrhoid' means flow of blood. Other symptoms include prolapse, mucoid discharge, irritation/itching, incomplete bowel evacuation and pain (see FIG. 36.6).

### Treatment

Invasive treatment of haemorrhoids is based on three main procedures: rubber band ligation, cryotherapy and sphincterotomy. Injection is now not so favoured while a meta-analysis concluded that rubber band ligation was the most effective non-surgical therapy.<sup>8</sup> Surgery is generally reserved for large strangulated piles. The best treatment, however, is prevention, and softish bulky faeces that pass easily prevent haemorrhoids. People should be advised to have a diet with adequate fibre by eating plenty of fresh fruit, vegetables, whole

FIGURE 36.6 Severely prolapsed haemorrhoids requiring surgery

grain cereals or bran. They should complete their bowel action within a few minutes and avoid using laxatives.

## ANAL DISCHARGE

Anal discharge refers to the involuntary escape of fluid from or near the anus. The causes may be considered as follows.<sup>5</sup>

- 1 *Continent*
  - Anal fistula
  - Pilonidal sinus
  - STIs: anal warts, gonococcal ulcers, genital herpes
  - Solitary rectal ulcer syndrome
  - Cancer of anal margin
- 2 *Incontinent*
  - Minor incontinence—weakness of internal sphincter
  - Severe incontinence—weakness of levator ani and puborectalis
- 3 *Partially continent*
  - Faecal impaction
  - Rectal prolapse

## Anal (faecal) incontinence

Studies have revealed that up to 1 in 10 people suffer some degree of faecal incontinence, which is a common reason for institutionalisation of the elderly.<sup>9</sup> Patients may be reluctant to seek medical advice and doctors often do not ask specifically about the condition. The problem is as common in men as in women.

Apart from ageing, risk factors include perianal injury, such as childbirth injury, anal surgery, irritable bowel syndrome and neurological disorders.

If there are symptoms of anal incontinence postnatally, early referral to a physiotherapist, continence nurse adviser or colorectal surgeon is advisable.<sup>10</sup>

Among the various possible treatments there are surgical possibilities, which vary from direct sphincter repair, directed injections such as collagen and silicone into the anal sphincter, and an artificial anal sphincter (e.g. Acticon Neosphincter). A colostomy may be the last resort. It is worth keeping in mind asking patients about the possibility of this problem and knowing 'to whom to refer'.

## Rectal bleeding

Patients present with any degree of bleeding from a smear on the toilet tissue to severe haemorrhage. Various causes are presented in **FIGURE 36.7**. Common causes are polyps, colon and rectal cancer, ischaemic colitis, diverticular disease and haemorrhoids.

**FIGURE 36.7** Various causes of rectal bleeding

Local causes of bleeding include excoriated skin, anal fissure, a burst perianal haematoma and anal cancer. A characteristic pattern of bright bleeding is found with haemorrhoids. It is usually small non-prolapsing haemorrhoids that bleed.

The nature of the blood (e.g. bright red, dark red or black) and the nature of the bleeding (e.g. smear, streaked on stool, mixed with stool, massive) gives an indication of the source of the bleeding (see **TABLE 36.2**). Black tarry (melaena) stool indicates bleeding from the upper gastrointestinal tract and is rare distal to the lower ileum. Patients with melaena should be admitted to hospital.

Frequent passage of blood and mucus indicates a rectal tumour or proctitis, whereas more proximal tumours or extensive colitis present different patterns.

Substantial haemorrhage, which is rare, can be caused by diverticular disorder, angiodysplasia or more proximal lesions such as Meckel diverticulum and even duodenal ulcers. Angiodysplasias are 5 mm collections of dilated mucosal capillaries and thick-walled submucosal veins, found usually in the ascending colon of elderly patients who have no other bowel symptoms. The bleeding is persistent and recurrent. The site is identified by technetium-labelled red cell scan or colonoscopy.

**Table 36.2** Presentation and causes of rectal bleeding<sup>6</sup>

Bright red blood in toilet separate from faeces	Internal haemorrhoids
Bright red blood on toilet paper	Internal haemorrhoids Fissure Anal cancer Pruritus Anal warts and condylomata
Blood and mucus on underwear	Third-degree haemorrhoids Fourth-degree haemorrhoids Prolapsed rectum Mucosal prolapse Prolapsed mucosal polyp
Blood on underwear (no mucus)	Ulcerated perianal haematoma Anal cancer
Blood and mucus mixed with faeces	Colorectal cancer Proctitis Colitis, ulcerative colitis Large mucosal polyp Ischaemic colitis
Blood mixed with faeces (no mucus)	Small colorectal polyps Small colorectal cancer
Melaena (black tarry stools)	Gastrointestinal bleeding (usually upper) with long transit time to the anus
Torrential haemorrhage (rare)	Diverticular disorder Angiodysplasia
Large volumes of mucus in faeces (little blood)	Villous papilloma of rectum Villous papilloma of colon
Blood in faeces with menstruation (rare)	Rectal endometriosis

The history should also include an analysis of any associated symptoms such as pain, diarrhoea or constipation, presence of lumps and a sensation of urgency or unsatisfied defecation. The latter symptoms point to a rectal cause. Associated change of bowel habit suggests a diagnosis of cancer of the rectum or left colon. Bleeding from right colon cancer is often occult, presenting as anaemia.

The examination includes a general assessment, anal inspection, digital rectal examination and proctosigmoidoscopy. Even if there is an anal lesion, proximal bleeding must be excluded in all cases by

sigmoidoscopy<sup>3</sup> and by colonoscopy if there are any bowel symptoms or no obvious anal cause or a doubt about a lesion causing the symptoms.

### Red flag pointers for rectal bleeding

- Age >50 years
- Change of bowel habit
- Weight loss
- Weakness, fatigue
- Brisk bleeding
- Constipation
- Haemorrhoids (may be sinister)
- Family history of cancer

### Pruritus ani

Pruritus ani, which is itching of the anus, can be a distressing symptom that is worse at night, during hot weather and during exercise. It is seen typically in adult males with considerable inner drive, often at times of stress and in hot weather when sweating is excessive. In children, threadworm infestation should be suspected. It may be part of general itching, such as with a skin disorder, or localised whereby various anorectal disorders have to be excluded. Seborrhoeic dermatitis is a particularly common underlying factor. Consider also the more uncomfortable lichen sclerosus with its ivory white sclerotic plaques, which may also be present in the genital region.

### Signs

The skin changes can vary from minimal signs to marked pathology that can show linear ulceration, maceration or lichenification (see FIG. 36.8). Superficial skin changes can be moist and macerated or dry and scaly. Full anorectal examination is necessary.

**FIGURE 36.8** Lichen chronicus simplex. Lichenification from scratching with longstanding pruritus (see CHAPTER 122)

### Causes and aggravating factors

- Psychological factors:
  - stress and anxiety
  - fear of cancer
- Generalised systemic or skin disorders:
  - seborrhoeic dermatitis
  - eczema
  - lichen sclerosus
  - diabetes mellitus
  - candidiasis
  - psoriasis (look for fissures in natal cleft)
  - antibiotic treatment
  - worms: pinworm (threadworm)
  - diarrhoea causing excoriation
- Local anorectal conditions:
  - piles
  - fissures
  - warts
- Zealous hygiene
- Contact dermatitis:
  - dyed or perfumed toilet tissue, soap, powder
  - clothing
- Excessive sweating (e.g. tight pantyhose in summer)

### Diagnosis

- Urinalysis (? diabetes)
- Anorectal examination
- Scrapings and microscopy to detect organisms
- Stool examination for intestinal parasites

### Treatment

- Treat the cause (if known).
- Avoid local anaesthetics, antiseptics.
- Advise aqueous cream to wash anus (instead of soap).
- Most effective preparations (for short<sup>12</sup> courses):
  - methylprednisolone aceponate 0.1% in a fatty ointment base
  - or
  - hydrocortisone 1% cream/ointment
  - or
  - hydrocortisone 1% cream with clioquinol 3% or clotrimazole 1% (especially if dermatosis and *Candida* suspected)

If an isolated area and resistant, infiltrate 0.5 mL of triamcinolone intradermally. Fractionated X-ray therapy can be used if very severe.

Patient education about anal hygiene is essential.

### Practice tips for pruritus ani

- Most cases of uncomplicated pruritus ani resolve with simple measures, including explanation and reassurance.
- Avoid perfumed soaps and powders. Use bland aqueous cream or a mild soap substitute.
- Otherwise prescribe a corticosteroid, especially methylprednisolone aceponate 0.1%. Once symptoms are controlled, use hydrocortisone 1%.<sup>12</sup>
- Lifestyle stress and anxiety underlies most cases.
- In obese patients with intertrigo and excessive sweating strap the buttocks apart with adhesive tape.
- Consider perianal lichen simplex and lichen sclerosus in patients presenting with 'a sore bottom'.

*The maladies that afflict the clerks aforesaid arise from three causes; first constant sitting, secondly the incessant movement of the hand and always in the same direction, and thirdly the strain on the midline from the effort not to disfigure the books by error or cause loss to their employers.*

The physician Ramazzini 1713

Thoracic (dorsal) back pain is common in people of all ages, including children and adolescents. It accounts for 10–15% of all spinal pain. Dysfunction of the joints of the thoracic spine, with its unique costovertebral joints (which are an important source of back pain), is very commonly encountered in medical practice, especially in people whose lifestyle creates stresses and strains through poor posture and heavy lifting. Muscular and ligamentous strains may be common, but they rarely come to light in practice because they are self-limiting and not severe.

This dysfunction can cause referred pain to various parts of the chest wall and can mimic the symptoms of various visceral diseases, such as angina, biliary colic and oesophageal spasm. In similar fashion, heart and gall bladder pain can mimic spinal pain.

## Key facts and checkpoints

- The commonest site of pain in the spine is the costovertebral articulations especially the costotransverse articulation (see FIG. 37.1).
- Pain of thoracic spinal origin may be referred anywhere to the chest wall, but the commonest sites are the scapular region, the paravertebral region 2–5 cm from midline and, anteriorly, over the costochondral region.
- Thoracic (also known as dorsal) pain is more common in patients with abnormalities such as kyphosis and Scheuermann disease.
- Trauma to the chest wall (including falls on the chest such as those experienced in body contact sport) commonly lead to disorders of the thoracic spine.
- Unlike the lumbar spine the joints are quite superficial and it is relatively easy to find the affected (painful) segment.
- Intervertebral disc prolapse is very uncommon in the thoracic spine.
- The older patient presenting with chest pain should be regarded as having a cardiac cause until proved otherwise.

- If the chest pain is non-cardiac, then the possibility of referral from the thoracic spine should be considered.
- The thoracic spine is the commonest site in the vertebral column for metastatic disease.
- Scheuermann disease, which affects the lower thoracic spine in adolescents, is often associated with kyphosis and recurrent thoracic back pain. Always inspect the thoracic spine of the younger patient for kyphosis and scoliosis, ideally at 9 years of age.
- Palpation is the most important component of the physical examination.

## A diagnostic approach

A summary of the diagnostic strategy model is presented in TABLE 37.1.

## Probability diagnosis

The commonest cause of thoracic back pain is musculoskeletal, due usually to musculoligamentous

FIGURE 37.1 The functional unit of the thoracic spine

**Table 37.1** Thoracic back pain: diagnostic strategy model

Q.	Probability diagnosis
A.	Musculoligamentous strains (mainly postural) Vertebral dysfunction

Q.	Seven masquerades checklist
A.	Depression Spinal dysfunction UTI
Q.	Is this patient trying to tell me something?
A.	Yes, quite possible with many cases of back pain.

strains caused by poor posture. However, these pains are usually transitory and present rarely to the practitioner. The problems that commonly present are those caused by dysfunction of the lower cervical and thoracic spinal joints, especially those of the mid-thoracic (interscapular) area.

Arthritic conditions of the thoracic spine are not relatively common although degenerative osteoarthritis is encountered at times; the inflammatory spondyloarthropathies are uncommon.

The various systemic infectious diseases such as influenza and Epstein–Barr mononucleosis can certainly cause diffuse backache but should be assessed in context.

## Not to be missed

A special problem with the thoracic spine is its relationship with the many thoracic and upper abdominal structures that can refer pain to the back. These structures are listed in **TABLE 37.2** but, in particular, myocardial infarction and dissecting aneurysm must be considered. A complex problem described by neurosurgeons is the patient presenting with severe sudden thoracic back pain caused by an epidural haematoma related to aspirin or warfarin therapy.

## Cardiopulmonary problems

The acute onset of pain can have sinister implications in the thoracic spine where various life-threatening cardiopulmonary and vascular events have to be

**Table 37.2** Non-musculoskeletal causes of thoracic back pain

<b>Heart</b>	Myocardial infarction Angina Pericarditis
<b>Great vessels</b>	Dissecting aneurysm Pulmonary embolism (rare) Pulmonary infarction Pneumothorax Pneumonia/pleurisy
<b>Oesophagus</b>	Oesophageal rupture Oesophageal spasm Oesophagitis Oesophageal cancer
<b>Subdiaphragmatic disorders of:</b>	Gall bladder Stomach Duodenum } including ulcers Pancreas Subphrenic collection
<b>Miscellaneous infections</b>	Herpes zoster Bornholm disease Infective endocarditis
<b>Psychogenic</b>	

kept in mind. The pulmonary causes of acute pain include spontaneous pneumothorax, pleurisy and pulmonary infarction. Thoracic back pain may be associated with infective endocarditis due to embolic phenomena. The ubiquitous myocardial infarction or acute coronary occlusion may, uncommonly, cause interscapular back pain, while the very painful dissecting or ruptured aortic aneurysm may cause back pain with hypotension.

### Osteoporosis

Osteoporosis, especially in people over 60 years, including both men and women, must always be considered in such people presenting with acute pain, which can be caused by a pathological fracture. The association with pain following inappropriate physical therapy such as spinal manipulation should also be considered.

### Acute infections

Infective conditions that can involve the spine include osteomyelitis, tuberculosis, brucellosis, syphilis and *Salmonella* infections. Such conditions should be suspected in young patients (osteomyelitis), farm workers (brucellosis) and migrants from South-East Asia and third world countries (tuberculosis). The presence of poor general health and fever necessitates investigations for these infections.

### Neoplasia

Fortunately, tumours of the spine are uncommon. Nevertheless, they occur frequently enough for the full-time practitioner in back disorders to encounter some each year, especially metastatic disease.

The three common primary malignancies that metastasise to the spine are those originating in the lung, breast and the prostate (all paired structures). The less common primaries to consider are the thyroid, the kidney and adrenals and malignant melanoma.

Reticuloses such as Hodgkin lymphoma can involve the spine. Primary malignancies that develop in the vertebrae include multiple myeloma and sarcoma.

Benign tumours to consider are often neurological in origin. An interesting tumour is the osteoid osteoma, which is aggravated by consuming alcohol and relieved by aspirin.

The tumours of the spine are summarised in **TABLE 37.3**.

The symptoms and signs that should alert the clinician to malignant disease are:

- back pain occurring in an older person
- unrelenting back pain, unrelieved by rest (this includes night pain)

**Table 37.3** Significant tumours affecting the thoracic and lumbar spine

	Benign	Malignant
<b>Of bone</b>	Osteoid osteoma Haemangioma Osteoblastoma Aneurysmal bone cyst Eosinophilic granuloma	Primary: • multiple myeloma • lymphomas (e.g. Hodgkin) • sarcoma
<b>Spinal</b>	Extradural: • lipoma • neuroma • fibroma Intradural: • neuroma • ependymoma • chordoma • meningioma	Secondary: • breast • lung • prostate • adrenals/kidney • thyroid • melanoma Direct spread: • stomach • large bowel • pancreas • uterus/cervix/ovary

### Red flag pointers for thoracic back pain<sup>1</sup>

The red flag pointers are similar to those for low back pain (see **CHAPTER 38**).

#### Fracture pointer

Major trauma

Minor trauma:

- osteoporosis
- female >50 years
- male >60 years

#### Malignancy pointer

Age >50

Past history malignancy

Unexplained weight loss

Pain at rest

Constant pain

Night pain

Pain at multiple sites

Unresponsive to treatment

#### Infection pointer

Fever

Night sweats

Risk factors for infection

#### Other serious conditions

Chest pain/heaviness

Shortness of breath, cough

- rapidly increasing back pain
- constitutional symptoms (e.g. unexplained weight loss, fever, malaise)
- a history of treatment for cancer (e.g. excision of skin melanoma)

An ESR and a plain X-ray of the thoracic spine should be the initial screening test in the presence of these pointers.

A common trap for the thoracic spine is lung cancer, such as mesothelioma, which can invade parietal pleura or structures adjacent to the vertebral column.

## Pitfalls

Pitfalls include ischaemic heart disease presenting with interscapular pain, herpes zoster at the pre-eruption stage and the various gastrointestinal disorders. Two commonly misdiagnosed problems are a penetrating duodenal ulcer presenting with lower thoracic pain and oesophageal spasm, which can cause thoracic back pain.

Inflammatory rheumatological problems are not common in the thoracic spine but occasionally a spondyloarthropathy such as ankylosing spondylitis manifests here, although it follows some time after the onset of sacroiliitis.

## Seven masquerades checklist

Spinal dysfunction is the outstanding cause in this checklist, but urinary tract infection may occasionally cause lower thoracic pain. Depression always warrants consideration in any pain syndrome, especially back pain. It can certainly cause exaggeration of pre-existing pain from vertebral dysfunction or some other chronic problem.

## Psychogenic considerations

Psychogenic or non-organic causes of back pain can present a complex dilemma in diagnosis and management. The causes may be apparent from the incongruous behaviour and personality of the patient, but often the diagnosis is reached by a process of exclusion. There is obviously some functional overlay in everyone with acute or chronic pain, hence the importance of appropriate reassurance to these patients that their problem invariably subsides with time and that they do not have cancer.

## Anatomical and clinical features

The functional unit of the thoracic spine is illustrated in [FIGURE 37.1](#). Although there is scant literature and evidence about the origins of pain in the thoracic spine,<sup>3</sup>

the strongest evidence indicates that pain from the thoracic spine originates mainly from the apophyseal joints and rib articulations. Any one thoracic vertebra has 10 separate articulations, so the potential for dysfunction and the difficulty in clinically pinpointing the precise joint at a particular level are apparent.

The costovertebral joints are synovial joints unique to the thoracic spine and have two articulations—costotransverse and costocentral. Together with the apophyseal joints, they are capable of presenting with well-localised pain close to the midline or as referred pain, often quite distal to the spine, with the major symptoms not appearing to have any relationship to the thoracic spine.

Generalised referral patterns are presented in [FIGURE 24.2](#) (see [CHAPTER 24](#)), while the dermatome pattern is outlined in [FIGURE 37.2](#).

The pain pattern acts as a guide only because there is considerable dermatomal overlap within the individual and variation from one person to another. It has been demonstrated that up to five nerve roots may contribute to the innervation of any one point in the anterior segments of the trunk dermatomes, a fact emphasised by the clinical distribution of herpes zoster.

## Upper thoracic pain<sup>1</sup>

Dysfunction of the joints of the upper thoracic spine usually gives rise to localised pain and stiffness posteriorly but also can cause distal symptoms, probably via the autonomic nervous system.

A specific syndrome called the T4 syndrome<sup>4</sup> has been shown to cause vague pain and paraesthesia in the upper limbs and diffuse, vague head and posterior neck pain. Examination may reveal hypomobility of the upper thoracic segments. It has been proven to respond to spinal manipulation, which restores full mobility.

However, most of the pain, stiffness and discomfort arise from dysfunction of the upper and middle thoracic segments with patients presenting with the complaint of pain between 'my shoulder blades'.

## § Costovertebral joint dysfunction<sup>1</sup>

The unique feature of the thoracic spine is the costovertebral joint. Dysfunction of this joint commonly causes localised pain approximately 3–4 cm from the midline where the rib articulates with the transverse process and the vertebral body. In addition, it is frequently responsible for referred pain ranging from the midline, posterior to the lateral chest wall, and even anterior chest pain.

**FIGURE 37.2** Dermatomes for the thoracic nerve roots, indicating possible referral areas.

Source: Reproduced with permission from C Kenna and J Murtagh. *Back Pain and Spinal Manipulation* (2nd edn), Oxford: Butterworth-Heinemann, 1997

When the symptoms radiate laterally, the diagnosis is confirmed only when movement of the rib provokes pain at the costovertebral joint. This examination will simultaneously reproduce the referred pain.

**FIGURE 37.3** presents the pattern of referred pain from these joints and highlights the capacity of the thoracic spine to refer pain centrally to the anterior chest and upper abdomen. Confusion arises for the clinician when the patient's history focuses on the anterior chest pain and fails to mention the presence of posterior pain, should it be present. The shaded areas on **FIGURE 37.3** represent those areas where the patient experiences pain following the injection of hypertonic saline into the posterior elements of the spine.

## The clinical approach

### History

The history of a patient presenting with thoracic back pain should include a routine pain analysis, which usually provides important clues for the diagnosis. The age, sex and occupation of the patient are relevant. Pain in the thoracic area is very common in people who sit bent over for long periods, especially working at desks. Students, secretaries and stenographers are

therefore at risk, as are nursing mothers, who have to lift their babies.

People who are kyphotic or scoliotic or who have 'hunchbacks' secondary to disease such as tuberculosis and poliomyelitis also suffer from recurrent pain in this area.

Older people are more likely to present with a neoplastic problem in the thoracic spine and with osteoporosis. Senile osteoporosis is usually a trap because it is symptomless until the intervention of a compression fracture. Symptoms following such a fracture can persist for 3 months.

Pain that is present day and night indicates a sinister cause.

Features of the history that give an indication that the pain is arising from dysfunction of the thoracic spine include:

- *Aggravation and relief of pain on trunk rotation.* The patient's pain may be increased by rotating (twisting) towards the side of the pain but eased by rotating in the opposite direction.
- *Aggravation of pain by coughing, sneezing or deep inspiration.* This can produce a sharp catching pain which, if severe, tends to implicate the costovertebral joint. Care must be taken to rule out pneumonia and pleurisy.

FIGURE 37.3 Kellgren's (1939) pain referral patterns after stimulation of deep joints of the thoracic spine

- *Relief of pain by firm pressure.* Patients may state that their back pain is eased by firm pressure such as leaning against the corner of a wall.

It is very important to be able to differentiate between chest pain due to vertebral dysfunction and that caused by myocardial ischaemia.

### Key questions

- Can you recall injuring your back, such as by lifting something heavy?
- Did you have a fall onto your chest or back?
- Is the pain present during the night?
- Do you have low back pain or neck pain?
- Does the pain come on after walking or any strenuous effort?
- Does the pain come on after eating or soon after going to bed at night?
- Have you noticed a fever or sweating at any time, especially at night?
- Have you noticed a rash near where you have the pain?
- What drugs are you taking? Do you take drugs for arthritis or pain? Cortisone?
- What happens when you take a deep breath, cough or sneeze?

### Examination

The examination of the thoracic spine is straightforward with the emphasis on palpation of the spine—central and laterally. This achieves the

basic objective of reproducing the patient's symptoms and finding the level of pain. The 'LOOK, FEEL, MOVE, X-RAY' clinical approach is most appropriate for the thoracic spine.

### Inspection

Careful inspection is important since it may be possible to observe at a glance why the patient has thoracic pain. Note the symmetry, any scars, skin creases and deformities, 'flat spots' in the spine, the nature of the scapulae or evidence of muscle spasm. Look for kyphosis and scoliosis.

Kyphosis may be generalised, with the back having a smooth uniform contour, or localised where it is due to a collapsed vertebra, such as occurs in an older person with osteoporosis. Generalised kyphosis is common in the elderly, especially those with degenerative spinal disease. In the young it may reflect the important Scheuermann disease.

The younger person in particular should be screened for scoliosis (see FIG. 37.4), which becomes more prominent on forward flexion (see FIG. 37.6). Look for any asymmetry of the chest wall, inequality of the scapulae and differences in the levels of the shoulders. A useful sign of scoliosis is unequal shoulder levels and apparent 'winging' of scapula. When viewed anteriorly a difference in the levels of the nipples indicates the presence of scoliosis, or other problems causing one shoulder to drop. Inspection should therefore take place with posterior, lateral (side) and anterior views.

FIGURE 37.4 Adolescent idiopathic scoliosis: typical configuration of the trunk and thoracic spine

### Palpation

The best position is to have the patient prone on the examination table with the thoracic spine preferably in slight flexion. This is achieved by lowering the top of the table.

Test passive extension of each joint with firm pressure from the pad of the thumbs or the bony hand (either the pisiform prominence or the lateral border of the fifth metacarpal). Spring up and down with a few firm oscillations, keeping the elbows straight, but being well above the patient. Ask the patient if the pressure reproduces the pain.

Apart from asking the patient 'Is that the pain?' note:

- the distribution of pain and its change with movement
- the range of movement
- the type of resistance in the joint
- any muscle spasm

Palpation must follow a set plan in order to reproduce the patient's pain. The sequence is as follows:

- 1 central—over spinous processes
- 2 unilateral—over apophyseal joints (2–3 cm from midline)
- 3 transverse—on side of spinous processes
- 4 unilateral—costotransverse junctions (4–5 cm from midline)
- 5 unilateral—over ribs (spring over posterior rib curve with ulnar border of hand, along axis of rib)

### Movements

There are four main movements of the thoracic spine to assess, the most important of which is rotation, as this is the movement that so frequently reproduces the patient's pain where it is facet joint or costovertebral in origin.

The movements of the thoracic spine and their normal ranges are:

- |   |                         |     |
|---|-------------------------|-----|
| 1 | Extension               | 30° |
| 2 | Lateral flexion L and R | 30° |
| 3 | Flexion                 | 90° |
| 4 | Rotation L and R        | 60° |

Ask the patient to sit on the table with hands placed behind the neck and then perform the movements. Check these four active movements, noting any hypomobility, the range of movement, reproduction of symptoms and function and muscle spasm.

### Investigations

The main investigation is an X-ray, which may exclude the basic abnormalities and diseases, such as osteoporosis and malignancy. If serious diseases such as malignancy or infection are suspected, and the plain X-ray is normal, a radionuclide bone scan may detect these disorders. CT scanning has a minimal role in the evaluation of thoracic spinal pain.

Other investigations to consider are:

- FBE and ESR/CRP
- serum alkaline phosphatase
- serum electrophoresis for multiple myeloma
- Bence–Jones protein analysis
- *Brucella* agglutination test
- blood culture for pyogenic infection and bacterial endocarditis
- tuberculosis studies
- HLA-B<sub>27</sub> antigen for spondyloarthropathies
- ECG or ECG stress tests (suspected angina)
- gastroscopy or barium studies (peptic ulcer)
- MRI or CT scanning
- radionuclide bone scan if neoplastic or metabolic disease is suspected

### Thoracic back pain in children

The most common cause of thoracic back pain in children is 'postural backache', also known as 'TV backache', which is usually found in adolescent schoolgirls and is a diagnosis of exclusion.

Important, although rare, problems in children include infections (tuberculosis, discitis and osteomyelitis) and tumours such as osteoid osteoma and malignant osteogenic sarcoma.

Dysfunction of the joints of the thoracic spine in children and particularly in adolescents is very common and often related to trauma such as a heavy fall in sporting activities or falling from a height (e.g. off a horse). Fractures, of course, have to be excluded.

Inflammatory disorders to consider are juvenile ankylosing spondylitis and spinal osteochondritis (Scheuermann disease), which may affect adolescent males in the lower thoracic spine (around T9) and thoracolumbar spine. The latter condition may be asymptomatic, but can be associated with back pain, especially as the patient grows older. It is the commonest cause of kyphosis.

It is important to screen adolescent children for idiopathic scoliosis, which may be without associated backache.

### § Kyphosis<sup>5</sup>

Kyphosis is the normal curve of the thoracic spine when viewed from the side. The normal range is 20–45° (see FIG. 37.5). An excessive angle (>45–50°) occurs with a kyphotic deformity. In children a congenital cause is likely (present from infancy); in adolescents it is usually due to Scheuermann disease or is postural; in adults consider ankylosing spondylitis—and osteoporosis in the elderly. Tuberculosis of the spine can cause a gross deformity. Children with significant kyphosis should be referred for management which includes exercises, bracing or surgery.

**FIGURE 37.5** Illustration of kyphosis, which is measured by the angle between the uppermost and lowermost inclined vertebrae on the lateral X-ray

### § Scheuermann disease

This is a structural sagittal plane deformity of unknown cause affecting the T7, 8, 9 or T11, 12 areas.

#### Clinical features

- Age 11–17 years
- Males > females
- Lower thoracic spine
- Thoracic pain or asymptomatic
- Increasing thoracic kyphosis over 1–2 months
- Wedging of the vertebrae
- Pain in the wedge, especially on bending (only 20% present with pain)
- Short hamstrings
- Cannot touch toes
- Diagnosis confirmed by X-ray (lateral standing)—shows Schmorl node and anterior vertebral body wedging

#### Treatment

- Explanation and support
- Extension exercises, avoid forward flexion
- Postural correction
- Avoidance of sports involving lifting and bending
- Consider bracing or surgery if serious deformity
- If detected early hyperextension body casts followed by a Milwaukee brace can prevent deformity

### § Adolescent idiopathic scoliosis

A degree of scoliosis is detectable in 5% of the adolescent population.<sup>6</sup> The vast majority of curves, occurring equally in boys and girls, are mild and of no consequence. Eighty-five per cent of significant curves in adolescent scoliosis occur in girls.<sup>6</sup> Inheritance is a factor. The highest incidence is in first-degree female relatives (12%). The scoliotic deformity develops at 10 years of age. Such curves appear during the peripubertal period, usually coinciding with the growth spurt. The screening test (usually in 12–14 year olds but ideally as early as 9) is to note the contour of the back on forward flexion (see FIG. 37.6). The routine physical screening check of an adolescent should include this area.

#### The test

The subject stands with the feet parallel and together, and bends forward as far as possible with outstretched hands, palms facing each other, pointed between the great toes.

FIGURE 37.6 Screening for adolescent idiopathic scoliosis: testing asymmetry by forward flexion

### Investigation

A single erect PA spinal X-ray is sufficient;<sup>7</sup> the Cobb angle (see FIG. 37.7) is the usual measurement yardstick.

FIGURE 37.7 Scoliosis: the Cobb angle method of curve measurement

### Management

#### Aims

- To preserve good appearance—level shoulders and no trunk shift
- Prevent increasing curve in adult life: less than 45°
- Not to produce a straight spine on X-ray

#### Methods

- Braces:
  - Milwaukee brace (rarely used)
  - high-density polyethylene underarm orthosis
  - to be worn for 20–22 hours each day until skeletal maturity is reached.

- Surgical correction: depends on curve and skeletal maturity

### Guidelines for treatment

- Still growing:
    - <20° observe (repeat examination + X-ray)
    - 20–30° observe, brace if progressive
    - 30–45° brace
    - ≥45–50° operate
  - Growth complete:
    - <45° leave alone
    - >45° operate
- Referral to consultant: >20°

### Thoracic back pain in the elderly

Thoracic back pain due to mechanical causes is not such a feature in the elderly although vertebral dysfunction still occurs quite regularly. However, when the elderly person presents with thoracic pain, a very careful search for organic disease is necessary. Special problems to consider are:

- malignant disease (e.g. multiple myeloma, lung, prostate)
- osteoporosis
- vertebral pathological fractures
- polymyalgia rheumatica
- Paget disease (may be asymptomatic)
- herpes zoster
- visceral disorders: ischaemic heart disease, penetrating peptic ulcer, oesophageal disorders, biliary disorders

### § Dysfunction of the thoracic spine

This is the outstanding cause of pain presenting to the practitioner and is relatively easy to diagnose. It is often referred to as the thoracic hypomobility syndrome with the disorder arising in the facet joints, costovertebral joints and thoracic musculoligamentous structure, singularly or in combination. The most efficacious treatment for painful dysfunctional problems varies according to practitioners with a special interest in this area. There is a paucity of studies and evidence supporting the multiplicity of therapies, especially focal injections and physical therapy. Many claim that special mobilisation and manipulation provides effective short-term, sometimes immediate, relief.

### Typical profile:<sup>2</sup>

Age	Any age, especially between 20 and 40 years.
History of injury	Sometimes slow or sudden onset
Site and radiation	Spinal and paraspinal—interscapular, arms, lateral chest, anterior chest, substernal, iliac crest
Type of pain	Dull, aching, occasionally sharp; severity related to activity, site and posture
Aggravation	Deep inspiration, postural movement of thorax, slumping or bending, walking upstairs, activities (e.g. lifting children, making beds), beds too hard or soft, sleeping or sitting for long periods
Association	Chronic poor posture
Diagnosis confirmation	Examination of spine, therapeutic response to manipulation

### Management

#### First-line management

- Explanation with printed information
- Reassurance, including spontaneous recovery likely
- Continued activity according to pain level
- Back education program
- Analgesics (e.g. paracetamol 1 g (o) qid) first line
- Posture education
- Spinal mobilisation and manipulation (if appropriate)

#### Spinal mobilisation and manipulation

Spinal mobilisation is helpful but the more forceful manipulative therapy produces better and quicker results. There are many techniques that can be employed, the choice depending on which part of the back is affected.<sup>7</sup> The sternal thrust (Nelson hold) technique is widely used for upper thoracic segments and the crossed pisiform technique (patient prone) or posteroanterior indirect thrust (patient supine—see FIG. 37.8) is claimed to be the most—effective for the mid-thoracic spine. There is level II evidence that spinal manipulation is effective compared with placebo.<sup>8</sup>

#### § Thoracic disc protrusion

Fortunately, a disc protrusion in the thoracic spine is uncommon. This reduced incidence is related to

**FIGURE 37.8** Manipulation of the mid-thoracic spine by the posteroanterior indirect thrust technique

Source: Reproduced with permission from C Kenna and J Murtagh. *Back Pain and Spinal Manipulation* (2nd edn). Oxford: Butterworth-Heinemann, 1997

the firm splintage action of the ribcage. Most disc protrusions occur below T9, with the commonest site, as expected, being T11–12.

The common presentation is back pain and radicular pain that follows the appropriate dermatome so disc protrusion should be considered in patients with neurological signs at thoracic levels. This may include a flaccid area of the lower abdominal musculature.

However, disc lesions in the thoracic spine are prone to produce spinal cord compression, manifesting as sensory loss, bladder incontinence and signs of upper motor neurone lesion. The disc is relatively inaccessible to surgical intervention, but over the past decade there has been a significant improvement in the surgical treatment of thoracic disc protrusions, due to the transthoracic lateral approach.

#### § Syringx

A syrinx usually comes to notice as a radiological finding in the presence of thoracic back pain when it may in fact be asymptomatic. It is a rare, fluid-filled neurological cavity within the spinal cord. It is usually a congenital anomaly, but a neoplasm needs to be excluded. A syrinx usually begins at the cervical level and extends down. Treat conservatively, but refer to an expert who may consider intervention if it is symptomatic.

#### Muscle injury

Muscular injuries such as tearing are uncommon in the chest wall. The strong paravertebral muscles do not appear to be a cause of chest pain, but strains

of intercostal muscles, the serratus anterior and the musculotendinous origins of the abdominal muscles can cause pain. Injuries to these muscles can be provoked by attacks of violent sneezing or coughing or overstrain, for example, lifting a heavy suitcase down from an overhead luggage rack.

## SCAPULOTHORACIC JOINT DISORDERS<sup>9</sup>

The gliding plane between the scapula and thoracic wall permits a considerable range of scapular movement, which contributes significantly to movement of the shoulder. Several muscles including the rhomboids, serratus anterior and levator scapulae help stabilise scapular movement and may be a source of pain in the scapular region.

### § Snapping scapula

The patient complains of a loud cracking or snapping sound upon abduction of the scapula. There is often associated crepitus. Pain is felt along the medial scapular border. The patient may develop a habit ('tic') of neurotically clicking the shoulder back and forth.

On examination there is usually generalised hypermobility of the scapula, abnormal movement and tenderness to palpation along the medial edge on full abduction.

The cause (uncommon) may be an underlying bony abnormality such as a bony spur on the superior border of the scapula or an osteoma. X-rays should include a lateral view of the scapula to search for this possibility.

### Treatment

- Explanation and reassurance (if X-rays normal)—otherwise resect any bone abnormality.
- Avoid repeated scapular movement and 'trick' movements.
- Appropriate exercises under physiotherapy supervision.
- Infiltrate any very tender area in the muscle (with care) with local anaesthetic and steroid.
- Deep massage to the tender focus.

### § Scapulothoracic syndrome

This condition causes localised pain and tenderness, often severe, along the upper part of the medial scapular border, with radiation around the chest wall and shoulder girdle to the neck. Pain is usually worse with prolonged shoulder use towards the end of the day. It is commonly seen in typists, gymnasts and

other sportspeople. It is related to poor posture. The cause may include friction between the scapula and the thoracic wall, scoliosis, trauma and myofascial strain due to poor posture.

### Treatment

- Avoid the movements producing the pain.
- Posture and re-education exercises and scapula stretching.
- Deep friction massage.
- Local injections of local anaesthetic and corticosteroid into the tender area.

### § Winging of the scapula

The asymmetry may not be apparent until the patient tries to contract the serratus anterior against resistance by pushing the outstretched arm against the wall. There may be parascapular discomfort. The common cause is neurogenic paralysis of the serratus anterior muscle. Paralysis may result from injury to the long thoracic nerve (from C5, 6, 7 nerve roots) such as a neck injury or a direct blow to the suprascapular area and from injury to the brachial plexus such as excessive carrying of heavy packs, severe traction on the arm, forceful cervical manipulation. Most cases settle spontaneously, although it may take 1–2 years.

## FIBROMYALGIA, FIBROSITIS AND MYOFASCIAL TRIGGER POINTS

Fibromyalgia is relatively uncommon but when encountered presents an enormous management problem. It is not to be confused with so-called fibrositis or tender trigger points. Referral to a specialist with expertise in this condition or to a multidisciplinary pain clinic for the definitive diagnosis is recommended.

Fibrositis is not a diagnosis but a symptom, indicating a localised area of tenderness or pain in the soft tissues, especially of the upper thoracic spine. It is probably almost always secondary to upper thoracic or lower cervical spinal dysfunction.

### § Myofascial trigger points

As described by Travell and Rinzler<sup>10</sup> a trigger point is characterised by:

- circumscribed local tenderness
- localised twitching with stimulation of juxtaposed muscle
- pain referred elsewhere when subjected to pressure

Trigger spots also tend to correspond to the acupuncture points for pain relief.

### Treatment<sup>11</sup>

Local injection is relatively easy and may give excellent results. Identify the maximal point of pain and inject 5–8 mL of local anaesthetic (LA; e.g. lignocaine/lidocaine 1%) into the painful point (see FIG. 37.9). Post-injection massage or exercises should be performed.

*Don't:*

- use large volumes of LA
- use corticosteroids
- cause bleeding

*Do:*

- use a moderate amount of LA (only)

### § Fibromyalgia syndrome<sup>12</sup>

#### Clinical features

The main diagnostic features are:

- 1 a history of widespread pain (neck to low back)
- 2 pain in 11 of 18 tender points on digital palpation

FIGURE 37.9 Injection for myofascial trigger points

FIGURE 37.10 Fibromyalgia syndrome: typical tender points (the tender point map represents the 14 points recommended for use as a standard for diagnostic or therapeutic studies)

These points must be painful, not tender. Smythe and Moldofsky have recommended 14 of these points on a map as a guide for management<sup>12</sup> (see FIG. 37.10).

#### Other features

- Female to male ratio = 4:1
- Usual age onset 29–37 years; diagnosis 44–53 years
- Poor sleep pattern
- Dermatographia
- Fatigue (similar to chronic fatigue syndrome)
- Psychological disorders (e.g. anxiety, depression, tension headache, irritable digestive system)

This disorder is very difficult to treat and is usually unresponsive in the long term to passive physical therapy or injections.<sup>13</sup> Patients require considerable explanation, support and reassurance. Best evidence to date supports the value of educational programs and regular aerobic exercise.<sup>14</sup>

#### Treatment

- Explanation, reassurance and counselling
- Attention to sleep disorders, stress factors and physical factors
- Relaxation program
- Rehabilitation: graduated exercise program (e.g. walking, water exercises, swimming or cycling)
- Use paracetamol for first-line analgesia

### Medication (often disappointing)

Antidepressants (of proven short-term value);<sup>15,16</sup> start low then monthly increments as tolerated:

amitriptyline 10–75 mg (o) nocte

or

dothiepin 25–75 mg (o) nocte

or

duloxetine 30 mg (o) mane, increasing to 60 mg over 2 weeks<sup>17</sup>

*Note:* NSAIDs are of no proven benefit.

### Serious pitfalls

The following points regarding serious vertebral organic disease are worth repeating in more detail.

### Metastatic disease<sup>18</sup>

Secondary deposits in the thoracolumbar spine may be the first presenting symptoms of malignant disease. Any patient of any age presenting with progressive severe night pain of the back should be regarded as having a tumour and investigated with a technetium bone scan as part of the primary investigations.

Secondary deposits in the spine can lead to rapid onset paralysis due to spinal cord infarction. Many such metastases can be controlled in the early stages with radiotherapy.

### Multiple myeloma

Osteoporotic vertebral body collapse should be diagnosed only when multiple myeloma has been excluded. Investigations should include an ESR, Bence–Jones protein analysis, and immunoglobulin electrophoresis.

Early treatment of multiple myeloma can hold this disease in remission for many years and prevent crippling vertebral fractures (see CHAPTER 26).

### § Infective discitis, vertebral osteomyelitis and epidural/subdural abscess

Severe back pain in an unwell patient with fluctuating temperature (fever) should be considered as infective until proved otherwise. Investigations should include blood cultures, serial X-rays and nuclear bone scanning. Biphasic bone scans using technetium with either indium or gallium scanning for white cell collections usually clinch this diagnosis.

Strict bed rest with high-dose antibiotic therapy is usually curative. If left untreated, vertebral end plate and disc space collapse is common and extremely disabling. Consider tuberculosis osteomyelitis in people at risk. Suspect an epidural abscess in the presence of persistent and increased back pain. Percuss the spine for localised tenderness (see CHAPTER 30).

### When to refer

- Persistent pain or dysfunction—refer to a physical therapist.
- Evidence or suspicion of a sinister cause (e.g. neoplasia, infective discitis/osteomyelitis in a child).
- Suspicion of cardiac or gastrointestinal referred (persistent) pain.
- Significant idiopathic adolescent scoliosis or kyphosis (e.g. Scheuermann disease).

### Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Exercises for your thoracic spine
- Fibromyalgia
- Scoliosis

### Practice tips

- Feelings of anaesthesia or paraesthesia associated with thoracic spinal dysfunction are rare.
- Thoracic back pain is frequently associated with cervical lesions.
- Upper thoracic pain and stiffness is common after 'whiplash'.
- The T4 syndrome of upper to mid-thoracic pain with radiation (and associated paraesthesia) to the arms is well documented.
- Symptoms due to a fractured vertebra usually last 3 months and to a fractured rib 6 weeks.
- The pain of myocardial ischaemia, from either angina or myocardial infarction, can cause referred pain to the interscapular region of the thoracic spine.
- Beware of the old trap of herpes zoster in the thoracic spine, especially in the older person.
- Consider multiple myeloma as a cause of an osteoporotic collapsed vertebra.
- Examine movements with the patient sitting on the couch and hands clasped behind the neck.
- Spinal disease of special significance in the thoracic spine includes osteoporosis and neoplasia,

*continued*

*continued*

- while disc lesions, inflammatory diseases and degenerative diseases (spondylosis) are encountered less frequently than with the cervical and lumbar spines.
- It is imperative to differentiate between spinal and cardiac causes of chest pain: either cause is likely to mimic the other. A working rule is to consider the cause as cardiac until the examination and investigations establish the true cause.
- Always X-ray the thoracic spine following trauma, especially after motor vehicle accidents, as wedge compression fractures (typically between T4 and T8) are often overlooked.

*Last Wednesday night while carrying a bucket of water from the well, Hannah Williams slipped upon the icy path and fell heavily upon her back. We fear her spine was injured for though she suffers acute pain in her legs she cannot move them. The poor wild beautiful girl is stopped in her wildness at last.*

Francis Kilvert 1874

Low back pain accounts for at least 5% of general practice presentations. It is a massive problem worldwide. The most common cause is minor soft tissue injury, but patients with this do not usually seek medical help because the problem settles within a few days.

Most back pain in patients presenting to GPs is postulated to be due to dysfunction of elements of the mobile segment, namely the facet joint, the intervertebral joint (with its disc) and the ligamentous and muscular attachments. This problem, often referred to as mechanical back pain, will be described as vertebral dysfunction—a general term that, while covering radicular and non-radicular pain, includes dysfunction of the joints of the spine, although the specific origin in most instances cannot be determined. It is therefore appropriate to refer to this as ‘non-specific back pain’.<sup>1</sup>

## Key facts and checkpoints

- Back pain accounts for at least 5% of all presenting problems in general practice in Australia and 6.5% in Britain.<sup>2</sup>
- In the US it is the commonest cause of limitation of activity in those under the age of 45.<sup>2</sup>
- Approximately 85–90% of the population will experience back pain at some stage of their lives, while 70% of the world’s population will have at least one disabling episode of low back pain in their lives.<sup>2</sup>
- At least 50% of these people will recover within 2 weeks and 90% within 6 weeks, but recurrences are frequent and have been reported in 40–70% of patients; 2–7% develop chronic pain.<sup>3</sup>
- The most common age groups are the 30s, 40s and 50s, the average age being 45 years.<sup>4</sup>
- The most common cause of back pain is a minor strain to muscles and/or ligaments, but people suffering from this type of back pain usually do not seek medical treatment as most of these soft tissue problems resolve rapidly.

- The main cause of back pain presenting to the doctor is dysfunction of the intervertebral joints of the spine due to injury, also referred to as mechanical back pain (at least 70%).
- The second most common cause of back pain is spondylosis (synonymous with osteoarthritis and degenerative back disease). It accounts for about 10% of cases of low back pain.
- L5 and S1 nerve root lesions represent most of the cases of sciatica presenting in general practice. They tend to present separately but can occur together with a massive disc protrusion.
- An intervertebral disc prolapse has been proven in only 6–8% of cases of back pain.<sup>2</sup>

## Causes of low back pain

To develop a comprehensive diagnostic approach, the practitioner should have a clear understanding of the possible causes of low back and leg pain and of the relative frequency of their clinical presentations. The major causes of low back pain in several hundred patients presenting to the author’s general practice are summarised in **TABLE 38.1**.

**Table 38.1** Major causes of low back ± leg pain presenting in the author’s general practice

Patients	%
Vertebral dysfunction	71.8
Lumbar spondylosis	10.1
Depression	3.0
Urinary tract infection	2.2
Spondylolisthesis	2.0
Spondyloarthropathies	1.9
Musculoligamentous strains/tears	1.2
Malignant disease	0.8
Arterial occlusive disease	0.6
Other	6.4
Total	100.0

Relevant causes are illustrated in **FIGURE 38.1**.

FIGURE 38.1 Relevant causes of back pain with associated buttock and leg pain

## Anatomical and pathophysiological concepts

Recent studies have focused on the importance of disruption of the intervertebral disc in the cause of back pain. A very plausible theory has been advanced by Maigne<sup>3</sup> who proposes the existence, in the involved mobile segment, of a minor intervertebral derangement (MID). He defines it as 'isolated pain in one intervertebral segment, of a mild character, and due to minor mechanical cause'.

The MID always involves one of the two apophyseal joints in the mobile segment, thus initiating nociceptive activity in the posterior primary dermatome and myotome.

Maigne points out that the functional ability of the mobile segment depends intimately upon the condition of the intervertebral disc. Thus, if the disc is injured, other elements of the segment will be affected. Even a minimal disc lesion can produce apophyseal joint dysfunction, which is a reflex cause of protective muscle spasm and pain in the corresponding segment, with loss of function (see FIG. 38.2).

In theory, any structure with a nociceptive nerve supply may be a source of pain. Such structures include the ligaments, fascia and muscles of the lumbosacral spine, intervertebral joints, facet joints, dura mater and sacroiliac joints.<sup>5</sup>

Actually, pain can theoretically arise from any innervated structure in the region of the spine. It

**FIGURE 38.2** Reflex activity from a MID in the intervertebral motion segment. Apart from the local effect caused by the disruption of the disc (A), interference can occur in the facet joint (B) and interspinous ligament (C) leading possibly to muscle spasm (D) and skin changes (E) via the posterior rami.

Source: Reproduced with permission from C Kenna and J Murtagh. *Back Pain and Spinal Manipulation*. Sydney: Butterworths, 1989

can be neurogenic, spondylogenic, viscerogenic, vasculogenic or rarely psychogenic.

## A diagnostic approach

A summary of the diagnostic strategy model is presented in **TABLE 38.2**.

## Probability diagnosis

The commonest cause of low back pain is vertebral dysfunction or mechanical pain, which then has to be further analysed. The term can embrace musculoskeletal strain, discogenic and posterior ligament pain, and facetogenic dysfunction/pain.

Degenerative changes in the lumbar spine (lumbar spondylosis) are commonly found in the older age group. This problem, and one of its complications, spinal canal stenosis, is steadily increasing along with the ageing population.

## Serious disorders not to be missed

It is important to consider malignant disease, especially in an older person. It is also essential to consider infection such as acute osteomyelitis and tuberculosis, which is often encountered in recent immigrants, especially those from Asia and central Africa. The uncommon epidural or subdural abscess

Q.	Is this patient trying to tell me something?
A.	Quite likely. Consider lifestyle, stress, work problems, malingering, conversion reaction

Note: Associated buttock and leg pain included.

should also be kept in mind (see CHAPTER 30). These conditions are considered in more detail under infections of the central nervous system. For pain or anaesthesia of sudden onset, especially when accompanied by neurological changes in the legs, consider cauda equina compression due to a massive disc prolapse and also retroperitoneal haemorrhage. It is important to ask patients if they are taking anticoagulants. See TABLE 38.3.

**Table 38.3** 'Red flag' pointers to serious low back pain conditions<sup>6</sup>

Age >50 years or <20 years
History of cancer
Temperature >37.8°C
Constant pain—day and night especially severe night pain
Unexplained weight loss
Symptoms in other systems, e.g. cough, breast mass
Significant trauma
Features of spondyloarthropathy, e.g. peripheral arthritis (e.g. age <40 years, night-time waking)
Neurological deficit
Drug or alcohol abuse especially IV drug use
Use of anticoagulants
Use of corticosteroids
No improvement over 1 month
Possible cauda equina syndrome:
• saddle anaesthesia
• recent onset bladder dysfunction/overflow incontinence
• bilateral or progressive neurological deficit

## Pitfalls

The inflammatory disorders must be kept in mind, especially the spondyloarthropathies, which include psoriatic arthropathy, ankylosing spondylitis, reactive arthritis, inflammatory bowel disorders such as ulcerative colitis and Crohn disease, and reactive arthritis. The spondyloarthropathies are more common than appreciated and must be considered in the younger person presenting with features of inflammatory back pain (i.e. pain at rest, relieved by activity). The old trap of confusing claudication in the buttocks and legs, due to a high arterial obstruction, with sciatica must be avoided.

## General pitfalls

- Being unaware of the characteristic symptoms of inflammation and thus misdiagnosing one of the spondyloarthropathies.
- Overlooking the early development of malignant disease or osteomyelitis; if suspected, and an

X-ray is normal, a radionuclide scan should detect the problem.

- Failing to realise that mechanical dysfunction and osteoarthritis can develop simultaneously, producing a combined pattern.
- Overlooking anticoagulants as a cause of a severe bleed around the nerve roots and corticosteroids leading to osteoporosis.
- Not recognising back pain as a presenting feature of the drug addict.

## Red flag pointers for low back pain

There are several so-called 'red flag' or precautionary pointers to a serious underlying cause of back pain (see TABLE 38.3). Such symptoms and signs should alert the practitioner to a serious health problem and thus guide selection of investigations, particularly plain films of the lumbar spine.

## Seven masquerades checklist

Of these conditions, depression and urinary tract infection have to be seriously considered. For the young woman with upper lumbar pain, especially if she is pregnant, the possibility of a urinary tract infection must be considered. These patients may not have urinary symptoms, such as dysuria and frequency.

Depressive illness has to be considered in any patient with a chronic pain complaint. This common psychiatric disorder can continue to aggravate or maintain the pain even though the provoking problem has disappeared.

This is more likely to occur in people who have become anxious about their problem or who are under excessive stress. Many doctors treat such patients with a therapeutic trial of antidepressant medication, for example, amitriptyline or doxepin.

## Psychogenic considerations

The patient may be unduly stressed, not coping with life or malingering. It may be necessary to probe beneath the surface of the presenting problem.

A patient with low back pain following lifting at work poses a problem that causes considerable anguish to doctors, especially when the pain becomes chronic and complex. Chronic pain may be the last straw for patients who have been struggling to cope with personal problems; their fragile equilibrium is upset by the back pain. Many patients who have been dismissed as malingerers turn out to have a genuine problem. The importance of a caring, competent

practitioner with an insight into all facets of his or her patient's suffering, organic and functional, becomes obvious. The tests for non-organic back pain are very useful in this context.

### Yellow flag pointers

This term has been introduced to identify psychosocial and occupational factors that may increase the risk of chronicity in people presenting with acute back pain. Consider psychological issues if:

- abnormal illness behaviour
- compensation issues
- unsatisfactory restoration of activities
- failure to return to work
- unsatisfactory response to treatment
- treatment refused
- atypical physical signs

## Nature of the pain

The nature of the pain may reveal its likely origin. Establish where the pain is worst—whether it is central (proximal) or peripheral. The following are general characteristics and guides to diagnosis:

- aching throbbing pain = inflammation (e.g. sacroiliitis)
- deep aching diffuse pain = referred pain (e.g. dysmenorrhoea)
- superficial steady diffuse pain = local pain (e.g. muscular strain)
- boring deep pain = bone disease (e.g. neoplasia, Paget disease)
- intense sharp or stabbing (superimposed on a dull ache) = radicular pain (e.g. sciatica)

A comparison of the significant features of the two most common types of pain—mechanical and inflammatory—is presented in TABLE 38.4.

## The clinical approach

### History

Analysing the history invariably guides the clinician to the diagnosis. The pain patterns have to be carefully evaluated and it is helpful to map the diurnal variations of pain to facilitate the diagnosis (see FIG. 38.3).

It is especially important to note the intensity of the pain and its relation to rest and activity. In particular, ask whether the pain is present during the night, whether it wakes the patient, is present on rising or whether it is associated with stiffness.

**Table 38.4** Comparison of the patterns of pain for inflammatory and mechanical causes of low back pain<sup>8</sup>

Feature	Inflammation	Mechanical
History	Insidious onset	Precipitating injury/previous episodes
Nature	Aching, throbbing	Deep dull ache, sharp if root compression
Stiffness	Severe, prolonged Morning stiffness	Moderate, transient
Effect of rest	Exacerbates	Relieves
Effect of activity	Relieves	Exacerbates
Radiation	More localised, bilateral or alternating	Tends to be diffuse, unilateral
Intensity	Night, early morning	End of day, following activity

Continuous pain, present day and night, is suggestive of neoplasia or infection. Pain on waking also suggests inflammation or depressive illness. Pain provoked by activity and relieved by rest suggests mechanical dysfunction while pain worse at rest and relieved by moderate activity is typical of inflammation. In some patients the coexistence of mechanical and inflammatory causes complicates the pattern.

Pain aggravated by standing or walking that is relieved by sitting is suggestive of spondylolisthesis. Pain aggravated by sitting (usually) and improved with standing indicates a discogenic problem.

Pain of the calf that travels proximally with walking indicates vascular claudication; pain in the buttock that descends with walking indicates neurogenic claudication. This latter problem is encountered more frequently in older people who have a tendency to spinal canal stenosis associated with spondylosis.

### Key questions

- What is your general health like?
- Can you describe the nature of your back pain?
- Was your pain brought on by an injury?
- Is it worse when you wake in the morning or later in the day?
- How do you sleep during the night?
- What effect does rest have on the pain?
- What effect does activity have on the pain?

**FIGURE 38.3** Typical daily patterns of pain for conditions causing back pain. Note conditions that can wake patients from sleep and also the combined mechanical and inflammatory patterns.

- Is the pain worse when sitting or standing?
- What effect does coughing or sneezing or straining at the toilet have?
- What happens to the pain in your back or leg if you go for a long walk?
- Do you have a history of psoriasis, diarrhoea, penile discharge, eye trouble or severe pain in your joints?
- Do you have any urinary symptoms?
- What medication are you taking? Are you on anticoagulants?
- Are you under any extra stress at work or home?
- Do you feel tense or depressed or irritable?

## Examination

### Physical examination

The basic objectives of the physical examination are to reproduce the patient's symptoms, detect the level of the lesion and determine the cause (if possible) by provocation of the affected joints or tissues. This is done using the time-honoured method of joint examination—look, feel, move and test function. The patient should be stripped to a minimum of clothing so that careful examination of the back can be made. A neurological examination of the lower limb should be performed if symptoms extend below the buttocks. It is important to perform a rectal

examination to check for flaccidity in a patient with suspected cauda equina syndrome.

A useful screening test for a disc lesion and dural tethering is the slump test.<sup>7</sup>

The main components of the physical examination are:

- 1 inspection
- 2 active movements:
  - forward flexion (to reproduce the patient's symptoms)
  - extension (to reproduce the patient's symptoms)
  - lateral flexion (R & L) (to reproduce the patient's symptoms)
- 3 provocative tests (to reproduce the patient's symptoms)
- 4 palpation (to detect level of pain)
- 5 neurological testing of lower limbs (if appropriate)
- 6 testing of related joints (hip, sacroiliac)
- 7 assessment of pelvis and lower limbs for any deformity (e.g. leg shortening)
- 8 general medical examination, including rectal examination

### Important landmarks

The surface anatomy of the lumbar region is the basis for determining the vertebral level. Key anatomical landmarks include the iliac crest, spinous processes, the sacrum and the posterior superior iliac spines (PSISs).

- The tops of the iliac crest lie at the level of the L3–4 interspace (or the L4 spinous process).
- The PSISs lie opposite S2.

### Inspection

Inspection begins from the moment the patient is sighted in the waiting room. A patient who is noted to be standing is likely to have a significant disc lesion. Considerable information can be obtained from the manner in which the patient arises from a chair, moves to the consulting room, removes the shoes and clothes, gets onto the examination couch and moves when unaware of being watched.

The spine must be adequately exposed and inspected in good light. Patients should undress to their underpants; women may retain their brassiere and it is proper to provide them with a gown that opens down the back. Note the general contour and symmetry of the back and legs, including the buttock folds, and look for muscle wasting. Note the lumbar lordosis and any abnormalities, such as lateral

deviation. If lateral deviation (scoliosis) is present it is usually away from the painful side.

Note the presence of midline moles, tufts of hair or haemangioma that might indicate an underlying congenital anomaly, such as spina bifida occulta.

### Movements of the lumbar spine

There are three main movements of the lumbar spine. As there is minimal rotation, which mainly occurs at the thoracic spine, rotation is not so important. The movements that should be tested, and their normal ranges, are as follows:

- extension (20–30°) (see FIG. 38.4a)
- lateral flexion, left and right (30°) (see FIG. 38.4b)
- flexion (75–90°: average 80°) (see FIG. 38.4a)

Measurement of the angle of movement can be made by using a line drawn between the sacrum and large prominence of the C7 spinous process.

### Palpation

Have the patient relaxed, lying prone, with the head to one side and the arms by the sides. The levels of the spinous processes are identified by standing behind the patient and using your hands to identify the L4 and L5 spinous processes in relation to the top of the iliac crests. Mark the important reference points.

Palpation, which is performed with the tips of the thumbs opposed, can commence at the spinous process of L1 and then systematically proceed distally to L5 and then over the sacrum and coccyx. Include the interspinous spaces as well as the spinous processes. When the thumbs (or other part of the hand such as the pisiforms) are applied to the spinous processes, a firm pressure is transmitted to the vertebrae by a rocking movement for three or four 'springs'. Significant reproduction of pain is noted.

Palpation occurs at three main sites:

- centrally (spinous processes to coccyx)
- unilateral—right and left sides (1.5 cm from midline)
- transverse pressure to the sides of the spinous processes (R and L)

### Straight leg raising (SLR) test

This test is a passive test by the practitioner. The patient lies supine with both knees extended and the ankle dorsiflexed. The affected leg is raised slowly, keeping the knee extended. If sciatica with dural irritation is present, 20° to 60° of elevation causes reproduction of pain.

**FIGURE 38.4** (a) Degrees of movement of the lumbar spine: flexion and extension, (b) degree of lateral flexion of the lumbar spine

Source: Reproduced with permission from C Kenna and J Murtagh. *Back Pain and Spinal Manipulation*. Sydney: Butterworths, 1989

### Slump test

The slump test is an excellent provocation test for lumbosacral pain and is more sensitive than the SLR test. It is a screening test for a disc lesion and dural tethering. It should be performed on patients who have low back pain with pain extending into the leg, and especially for posterior thigh pain.

A positive result is reproduction of the patient's pain, and may appear at an early stage of the test (when it is ceased).

Method:

- 1 The patient sits on the couch in a relaxed manner.
- 2 The patient then slumps forward (without excessive trunk flexion), and then places the chin on the chest.
- 3 The unaffected leg is straightened.
- 4 The affected leg only is then straightened (see FIG. 38.5).
- 5 Both legs are straightened together.
- 6 The foot of the affected straightened leg is dorsiflexed.

*Note:* Take care to distinguish from hamstring pain. Deflexing the neck relieves the pain of spinal origin, not hamstring pain.

### Significance of the slump test

- It is positive if the back or leg pain is reproduced.
- If positive, it suggests disc disruption.
- If negative, it may indicate lack of serious disc pathology.
- If positive, one should approach manual therapy with caution.

FIGURE 38.5 The slump test: one of the stages

### Neurological examination<sup>7</sup>

A neurological examination is performed only when the patient's symptoms, such as pain, paraesthesia, anaesthesia and weakness, extend into the leg.

The importance of the neurological examination is to ensure that there is no compression of the spinal nerves from a prolapsed disc or from a tumour. This is normally tested by examining those functions that the respective spinal nerves serve, namely skin sensation, muscle power and reflex activity.

The examination is not daunting but can be performed quickly and efficiently in 2 to 3 minutes by

a methodical technique that improves with continued use. The neurological examination consists of:

- 1 quick tests: walking on heels (L5), walking on toes (S1)
- 2 dural stretch tests: slump test, straight leg raising
- 3 specific nerve root tests (L4, L5, S1): sensation, power, reflexes

### Main nerve roots

Refer to FIGURE 38.6 and to TABLE 66.3.

L3:

- femoral stretch test (prone, flex knee, extend hip)
- motor—extension of knee
- sensation—anterior thigh
- reflex—knee jerk (L3, L4)

L4:

- motor—resisted inversion foot
- sensation—inner border of foot to great toe
- reflex—knee jerk

L5:

- motor: walking on heels, resisted extension great toe
- sensation—middle three toes (dorsum)
- reflex—nil

S1:

- motor: walking on toes, resisted eversion foot
- sensation—little toe, most of sole
- reflex—ankle jerk (S1, S2)

### Other examination

The method of examining the sacroiliac and hip joints is outlined in CHAPTER 65.

### Investigations

Investigations for back pain can be classified into three broad groups: front-line screening tests; specific disease investigations; and procedural and preprocedural tests.

Plain X-rays of the lumbar spine are not routinely recommended in acute non-specific low back pain (pain <6 weeks) in the absence of 'red flags' as they are of limited diagnostic value and no benefits in physical function are observed.<sup>1</sup>

### Screening tests

These are most important for the patient presenting with chronic back pain when serious disease such as malignancy, osteoporosis, infection or

**FIGURE 38.6** The main motor, sensory and reflex features of the nerve roots L5 and S1

Source: Reproduced with permission of Pearson Education Inc. Upper Saddle River, New Jersey. S Hoppenfeld. *Physical Examination of the Spine and Extremities*. 1st © 1976

spondyloarthropathy must be excluded. The screening tests for chronic pain are:

- plain X-ray
- urine examination (office dipstick)
- FBE; ESR/CRP
- serum alkaline phosphatase
- PSA in males >50 years

### Specific disease investigation

Such tests include:

- peripheral arterial studies
- HLA-B<sub>27</sub> antigen test for ankylosing spondylitis and reactive arthritis
- serum electrophoresis for multiple myeloma (paraprotein)
- PSA for possible prostate cancer
- *Brucella* agglutination test
- blood culture for pyogenic infection and bacterial endocarditis
- bone scanning to demonstrate inflammatory or neoplastic disease and infections

(e.g. osteomyelitis) before changes are apparent on plain X-ray

- tuberculosis studies
- X-rays of shoulder and hip joint
- electromyographic (EMG) studies to screen leg pain and differentiate neurological diseases from nerve compression syndromes
- radioisotope scanning
- technetium pyrophosphate scan of SIJ for ankylosing spondylitis
- selective anaesthetic block of facet joint under image intensification
- selective anaesthetic block of medial branches of posterior primary rami and other nerve roots

### Procedural and preprocedural diagnostic tests

These tests should be kept in reserve for red flag pointers to chronic disorders, especially mechanical disorders, that remain undiagnosed and unabated,

and where surgical intervention is planned for a disc prolapse requiring removal.

Depending on availability and merit, such tests include:

- CT scan
- myelography or radiculography
- discography
- MRI

## Summary of diagnostic guidelines for spinal pain

- Continuous pain (day and night) = neoplasia, especially malignancy or infection.
- The big primary malignancy is multiple myeloma.
- The big three metastases are from lung, breast and prostate.
- The other three metastases are from thyroid, kidney/adrenal and melanoma.
- Pain with standing/walking (relief with sitting) = spondylolisthesis.
- Pain (and stiffness) at rest, relief with activity = inflammation.
- In a young person with inflammation think of ankylosing spondylitis.
- Stiffness at rest, pain with or after activity, relief with rest = osteoarthritis.
- Pain provoked by activity, relief with rest = mechanical dysfunction.
- Pain in bed at early morning = inflammation, depression or malignancy/infection.
- Pain in periphery of limb = discogenic → radicular or vascular → claudication or spinal canal stenosis → claudication.
- Pain in calf (ascending) with walking = vascular claudication.
- Pain in buttock (descending) with walking = neurogenic claudication.
- One disc lesion = one nerve root (exception is L5–S1 disc).
- One nerve root = one disc (usually).
- Two or more nerve roots—consider neoplasm.
- The rule of thumb for the lumbar nerve root lesions is L3 from L2–3 disc, L4 from L3–4, L5 from L4–5 and S1 from L5–S1.
- A large disc protrusion can cause bladder symptoms, either incontinence or retention.
- A retroperitoneal bleed from anticoagulation therapy can give intense nerve root symptoms and signs.

## Back pain in children

The common mechanical disorders of the intervertebral joints can cause non-specific back pain in children, which must always be taken seriously. Like abdominal pain and leg pain, it can be related to psychogenic factors, so this possibility should be considered by diplomatically evaluating problems at home, at school or with sport. It is helpful to remember that tight hamstrings are associated with non-specific back discomfort with poor forward flexion.

Especially in children under the age of 10, it is very important to exclude organic disease. Infections such as osteomyelitis and tuberculosis are rare possibilities, and 'discitis' has to be considered. This painful condition can be idiopathic, but can also be caused by the spread of infection from a vertebral body. It has characteristic radiological changes.

Tumours causing back pain include the benign osteoid osteoma and the malignant osteogenic sarcoma. Osteoid osteoma is a very small tumour with a radiolucent nucleus that is sharply demarcated from the surrounding area of sclerotic bone. Although more common in the long bones of the leg, it can occur in the spine.

In older children and adolescents (in whom back pain is common) the organic causes of back pain are more likely to be inflammatory, congenital or from developmental anomalies and trauma.

A prolapsed intervertebral disc, which can occur in adolescents, can be very unusual in its presentation. There is often marked spasm, with a stiff spine and lateral deviation, which may be out of proportion to the relatively lower degree of pain.

Other important conditions to consider are Scheuermann disease (which largely affects thoracic spine) and early onset ankylosing spondylitis.

Spondylolisthesis can occur in older children, usually due to a slip of L5 or S1, because the articular facets are congenitally absent or because of a stress fracture in the pars interarticularis. It is necessary to request standing lateral and oblique X-rays.

Consider a lumbar stress fracture in the adolescent, which can be caused by activity involving rotation and extension of the spine such as cricket fast bowling. It has an insidious onset and requires a high index of suspicion.

## Back pain in the elderly

Traumatic spinal dysfunction is still the most common cause of back pain in the elderly and may

represent a recurrence of earlier dysfunction. It is amazing how commonly disc prolapse and facet joint injury can present in the aged. However, degenerative joint disease is very common and, if advanced, can present as spinal stenosis with claudication and nerve root irritation due to narrowed intervertebral foraminae.

Special problems to consider are malignant disease, degenerative spondylolisthesis, vertebral pathological fractures and occlusive vascular disease.

## ACUTE BACK AND LEG PAIN DUE TO VERTEBRAL DYSFUNCTION

Mechanical disruption of the vertebral segment or segments is the outstanding cause to consider, while the main serious clinical syndromes are secondary to disruption with or without prolapse of the intervertebral disc, usually L4–5 or L5–S1.

TABLE 38.5 presents the general clinical features and diagnosis in acute back pain (fractures excluded) following vertebral dysfunction: the symptoms and signs can occur singly or in combination.

Fortunately, syndromes A and B are extremely rare but, if encountered, urgent referral to a surgeon is mandatory. Clinical features of the cauda equina syndrome are presented in FIGURE 38.7. Syndrome B can follow a bleed in patients taking anticoagulant therapy or be caused by a disc sequestration after inappropriate spinal manipulation.

**Table 38.5** Clinical features and diagnosis of vertebral dysfunction leading to low back and leg pain<sup>7</sup>

Clinical features	Frequency	Diagnosis
<b>Syndrome A (surgical emergency)</b>	Very rare	Spinal cord (UMN) or cauda equina (LMN) compression (FIGURE 38.7)
Saddle anaesthesia (around anus, scrotum or vagina)		
Distal anaesthesia		
Evidence of UMN or LMN lesion		
Loss of sphincter control or urinary retention		
Progressive weakness of legs peripherally and areflexia (often bilateral)		

Clinical features	Frequency	Diagnosis
<b>Syndrome B (probable surgical emergency)</b>	Uncommon	Large disc protrusion, paralysing nerve root
Anaesthesia or paraesthesia of the leg		
Foot drop		
Motor weakness		
Absence of reflexes		
<b>Syndrome C</b>	Common	Posterolateral disc protrusion on nerve root or disc disruption
Distal pain with or without paraesthesia		
Radicular pain (sciatica)		
Positive dural stretch tests		
<b>Syndrome D</b>	Very common	Disc disruption or facet dysfunction or unknown (non-specific) causation
Lumbar pain (unilateral, central or bilateral)		
± buttock and posterior thigh pain		

**FIGURE 38.7** Cauda equina syndrome due to massive prolapsed intervertebral disc

## § Vertebral dysfunction with non-radicular pain

This outstanding common cause of low back pain is considered to be due mainly to dysfunction of the pain-sensitive facet joint. The precise pathophysiology is difficult to pinpoint.

### Typical profile<sup>8</sup>

Age	Any age—late teens to old age, usually 22–55 years
History of injury	Yes, lifting or twisting
Site and radiation	Unilateral lumbar (may be central) Refers over sacrum, SIJ areas, buttocks
Type of pain	Deep aching pain, episodic
Aggravation	Activity, lifting, gardening, housework (vacuuming, making beds, etc.)
Relief	Rest, warmth
Associations	May be stiffness, usually good health
Physical examination (significant)	Localised tenderness—unilateral or central L4, L5 or S1 levels, may be restricted flexion, extension, lateral flexion
Diagnosis confirmation	Investigation, which is usually inappropriate, invariably normal

Note: diagnosis made clinically

### Management<sup>1,6,8</sup>

- Activity directed by degree of pain but normal activity encouraged from outset
- Back education program
- Analgesics—paracetamol
- Consider NSAIDs (if inflammatory pattern)
- Exercise program and swimming (as tolerated)—conflicting evidence re efficacy
- Physical therapy—mobilisation, manipulation (for persistent problems, but conflicting evidence) (see later this chapter)

Current evidence for acute low back pain can be summarised as follows:<sup>3,6,7</sup>

- beneficial—advice to stay active, NSAIDs
- likely to be beneficial—analgesics, spinal manipulation/stretching (reduces period of morbidity)
- unknown—back exercises, trigger point injections, acupuncture

For chronic low back pain (pain >12 weeks):

- beneficial—back exercises, multidisciplinary treatment program
- likely benefit—analgesics, NSAIDs, trigger point injections, spinal mobilisation/manipulation

## § Radiculopathy

Radicular pain, caused by nerve root compression from a disc protrusion (most common cause) or tumour or a narrowed intervertebral foramina, typically produces pain in the leg related to the dermatome and myotome innervated by that nerve root. Leg pain may occur alone without back pain and vary considerably in intensity.

The two nerve roots that account for most of these problems are L5 and S1 and the commonest disc lesion is L4–5, closely followed by L5–S1. A disc can be confined, extruded or sequestered. Most settle with time (6–12 weeks). The management is outlined at the end of this chapter and under 'Sciatica' (see CHAPTER 66).

## § Spondylolisthesis

About 5% of the population have spondylolisthesis but not all are symptomatic. The pain is caused by extreme stretching of the interspinous ligaments or of the nerve roots. The onset of back pain in many of these patients is due to concurrent disc degeneration rather than a mechanical problem. The pain is typically aggravated by prolonged standing, walking and exercise. The physical examination is quite diagnostic.

- Physical examination (significant): stiff waddling gait, increased lumbar lordosis, flexed knee stance, tender prominent spinous process of 'slipped' vertebrae, limited flexion, hamstring tightness or spasm
- Diagnosis confirmation: lateral X-ray (standing) (see FIG. 38.8)

### Management

This instability problem can be alleviated with relief of symptoms by getting patients to follow a strict flexion exercise program for at least 3 months. The objective is for patients to 'splint' their own spine by strengthening abdominal and spinal muscles.

Extension of the spine should be avoided, especially hyperextension. Gravity traction might help. Recourse to lumbar corsets or surgery (for spinal fusion) should be resisted although it is appropriate in a few severe intractable cases.

**FIGURE 38.8** Spondylolisthesis: illustrating a forward shift of one vertebra on another

### § Lumbar spondylosis

Lumbar spondylosis, also known as degenerative osteoarthritis or osteoarthrosis, is a common problem of wear and tear that may follow vertebral dysfunction, especially after severe disc disruption and degeneration.

Stiffness of the low back is the main feature of lumbar spondylosis. Although most people live with and cope with the problem, progressive deterioration can occur, leading to subluxation of the facet joints. Subsequent narrowing of the spinal and intervertebral foramen leads to spinal canal stenosis (see FIG. 38.9).

### Management

- Basic analgesics (depending on patient response and tolerance)
- NSAIDs (judicious use)
- Appropriate balance between light activity and rest
- Exercise program and hydrotherapy (if available)—physiotherapy supervision
- Regular mobilisation therapy may help
- Consider trials of electrotherapy, such as TENS and acupuncture
- Consider decompressive surgery for spinal canal stenosis

### THE SPONDYLOARTHROPATHIES

The seronegative spondyloarthropathies are a group of disorders characterised by involvement of the sacroiliac joints with an ascending spondylitis and extraspinal manifestations, such as oligoarthritis and enthesopathies (see FIG. 38.10; refer to CHAPTER 35).

**FIGURE 38.9** Lumbar spondylosis with degeneration of the disc and facet joint, leading to narrowing of the spinal canal and intervertebral foramen (spinal canal stenosis)

The pain and stiffness that are the characteristic findings of spinal involvement are typical of inflammatory disease: namely, worse in the morning, may occur at night and improves rather than worsens with exercise.

The main disorders in this group are ankylosing spondylitis, psoriatic arthritis, reactive spondyloarthropathies and the inflammatory bowel diseases. Hence the importance of searching for a history of psoriasis, diarrhoea, urethral discharge, eye disorders and episodes of arthritis in other joints.

### Treatment

The earlier the treatment the better the outlook for the patient; the prognosis is usually good (see earlier in chapter). Refer to consultant for shared care. The basic objectives of treatment are:

- prevention of spinal fusion in a poor position
- relief of pain and stiffness
- maintenance of optimum spinal mobility

**FIGURE 38.10** (a) Ankylosing spondylitis and psoriasis: main target areas on vertebral column and girdle joints (b) Crohn disease and ulcerative colitis: main target areas of enteropathies. Reactive arthritis targets the lumbar spine and sacral joints only.

## Malignant disease

It is important to identify malignant disease and other space-occupying lesions as early as possible because of the prognosis and the effect of a delayed diagnosis on treatment.

With respect to the neurological features, more than one nerve root may be involved and major neurological signs may be present without severe root pain. The neurological signs will be progressive.

If malignant disease is proved and myeloma is excluded, a search should be made for the six main primary malignancies that metastasise to the spine (see FIG. 38.11). If the bone is sclerotic consider prostatic secondaries, some breast secondaries or Paget disease.

## Non-organic back pain

Like headache, back pain is a symptom of an underlying functional, organic or psychological disorder. Pre-occupation with organic causation of symptoms may lead to serious errors in the assessment of patients with back pain. Any vulnerable aching area of the body is subject to aggravation by emotional factors.

Depressed patients are generally less demonstrative than patients with extreme anxiety and conversion

disorders and malingerers, and it is easier to overlook the non-organic basis for their problem.

A trial of antidepressants for a minimum of 3 weeks is recommended and quite often a positive response with relief of backache eventuates.

Failure to consider psychological factors in the assessment of low back pain may lead to serious errors in diagnosis and management. Each instance of back pain poses a stimulating exercise in differential diagnosis. A comparison of organic and non-organic features is presented in TABLE 38.6.

Assessment of the pain demands a full understanding of the patient. One must be aware of his or her type of work, recreation, successes and failures; and one must relate this information to the degree of incapacity attributed to the back pain.

Patients with psychogenic back pain, especially the very anxious, tend to overemphasise their problem. They are usually demonstrative, the hands being used to point out various painful areas almost without prompting. There is diffuse tenderness even to the slightest touch and the physical disability is out of proportion to the alleged symptoms. The pain distribution is often atypical of any dermatome and the reflexes are almost always hyperactive. It must be remembered that

**FIGURE 38.11** Important primary malignancies metastasising to the spine. Note the difference between sclerotic and osteoporotic metastases; multiple myeloma also causes osteoporotic lesions

patients with psychogenic back pain—for example, depression and conversion disorders—do certainly experience back pain and do not fall for the traps set for the malingerer.

### Tests for non-organic back pain<sup>7</sup>

Several tests are useful in differentiating between organic and non-organic back pain (e.g. that caused by depression or complained of by a known malingerer).

#### Magnuson method (the 'migratory pointing' test)

1 Request the patient to point to the painful sites.

2 Palpate these areas of tenderness on two occasions separated by an interval of several minutes, and compare the sites.

Between the two tests divert the patient's attention from his or her back by another examination.

#### Paradoxical straight leg raising test

Perform the usual SLR test. The patient might manage a limited elevation, for example, 30°. Keep the degree in mind. Ask the patient to sit up and swing the leg over the end of the couch. Distract attention with another test or some question, and then attempt to lift the straight leg to the same level achieved on

**Table 38.6** Comparison of general clinical features of organic and non-organic based low back pain<sup>8</sup>

Symptoms	Organic disorders	Non-organic disorders
Presentation	Appropriate	Often dramatic
Pain	Localised	Bilateral/diffuse Sacrococcygeal
Pain radiation	Appropriate Buttock, specific sites	Inappropriate Front of leg/whole leg
Time pattern	Pain-free times	Constant, acute or chronic
Paraesthesia/anaesthesia	Dermatomal Points with finger	May be whole leg Shows with hands
Response to treatment	Variable Delayed benefit	Patient often refuses treatment Initial improvement (often dramatic) then deterioration (usually within 24 hours)
Signs		
Observation	Appropriate Guarded	Overreactive under scrutiny Inconsistent
Tenderness	Localised to appropriate level	Often inappropriate level Withdraws from probing finger
Spatial tenderness (Magnuson)	Consistent	Inconsistent
Active movements	Specific movements affected	Often all movements affected
Axial loading test	No back pain (usually)	Back pain
SLR 'distraction' test	Consistent	Inconsistent
Sensation	Dermatomal	Non-anatomical 'sock' or 'stocking'
Motor	Appropriate myotome	Muscle groups (e.g. leg 'collapses')
Reflexes	Appropriate May be depressed	Brisk hyperactive

the first occasion. If it is possible, then the patient's response is inconsistent.

- 2 This will cause no discomfort to (most) patients with organic back pain.

### Burn's 'kneeling on a stool' test

- 1 Ask the patient to kneel on a low stool, lean over and try to touch the floor.
- 2 The person with non-organic back pain will usually refuse on the grounds that it would cause great pain or that he or she might overbalance in the attempt.

Patients with even a severely herniated disc usually manage the task to some degree.

### The axial loading test

- 1 Place your hands over the patient's head and press firmly downward (see FIG. 38.12).

## Treatment options for back pain

### General aspects of management<sup>1,6</sup>

The aim of treatment is to reduce pain, maintain function and minimise disability and work absenteeism and importantly the risk of chronicity.

*Advice to stay active.* Evidence from randomised controlled trials confirms that, in people with acute low back pain, advice to stay active speeds symptomatic recovery, reduces chronic disability and results in less time off work compared with bed rest or usual care.<sup>6</sup> Encourage the patient to stay at work or return early if possible. Keep moving despite discomfort.<sup>7</sup>

FIGURE 38.12 The axial loading test

*The caring knowledgeable therapist.* Evidence supports the positive value of education and reassurance from a confident, supportive and knowledgeable therapist.

*Relative rest.* For acutely painful debilitating back problems, 2 days of strict rest lying on a firm surface is optimal treatment.<sup>9</sup> Resting for longer than 3 days does not produce any significant healing, and patients should be encouraged to return to activities of daily living as soon as possible.

*Patient education.* Appropriate educational material leads to a clear insight into the causes and aggravation of the back disorder plus coping strategies.

*Heat.* The application of heat in some form, including heat bags, hot flannels and similar methods, can be of benefit especially in the first 2–4 weeks of acute low back pain.

*Exercises.* An early graduated exercise program as soon as the acute phase settles has been shown to promote healing and prevent relapses.<sup>10</sup> All forms of exercise (extension, flexion and isometric) appear to be equally effective (see FIG. 38.13). Swimming is an excellent activity for back disorders.

Studies support the use of exercises for chronic back pain rather than acute pain.<sup>3</sup>

## Pharmacological agents

### Basic analgesics

Analgesics such as paracetamol and codeine plus paracetamol (acetaminophen) should be used for pain

FIGURE 38.13 Examples of exercises for low back pain: (a) rotation exercise; (b) flexion exercise

relief. Paracetamol is recommended as the first-line analgesic.

### NSAIDs

These are useful where there is clinical evidence of inflammation, especially with the spondyloarthropathies, severe spondylosis and in acute radicular pain, to counter the irritation on the nerve root. NSAIDs have been shown to be more effective than placebo in acute back pain for pain relief and overall improvement. There is no evidence to distinguish different NSAIDs.<sup>3</sup>

## Injection techniques

### Trigger point injection

This may be effective for relatively isolated points using 5–8 mL of local anaesthetic. Studies indicate that it is likely to be more beneficial for chronic back pain.<sup>3</sup>

### Chymopapain

This enzyme has been advocated for the treatment of acute nuclear herniation that is still intact. The indications are similar for surgical discectomy. However, studies show that although it is more effective than placebo, it is less effective than surgical discectomy.<sup>11</sup>

## Facet joint injection

Corticosteroid injection under radio-image intensification is widely used in some clinics. The procedure is delicate and expertise is required. Best evidence to date does not support the use of these injections.

## Epidural injections

Injections of local anaesthetic with or without corticosteroids are used for chronic pain, especially for nerve root pain. The author favours the caudal (trans-sacral) epidural injection for persistent sciatica using 15 mL of half-strength local anaesthetic only (e.g. 0.25% bupivacaine) (see FIG. 38.14).

Others favour the use of steroids and the lumbar epidural approach. The evidence regarding effectiveness is conflicting.<sup>5</sup>

FIGURE 38.14 Caudal epidural injection: the needle should lie free in the space and be well clear of the dural sac

## Physical therapy

Active exercises are the best form of physical therapy (see FIGS 38.13a, b).

Passive spinal stretching at the end range is a safe, effective method (see FIG. 38.15). Spinal mobilisation is a gentle, repetitive, rhythmic movement within the range of movement of the joint. It is safe and quite effective and a variation of stretching.

Spinal manipulation is a high velocity thrust at the end range of the joint. It is generally more effective and produces a faster response but requires accurate diagnosis and greater skill. It is more effective for uncomplicated dysfunctional low back pain (without radicular pain), especially acute pain (see FIG. 38.16).<sup>3,6,12,13</sup> However, the evidence from controlled trials is conflicting. Adverse effects are uncommon, but can be serious.

## Other treatments

The following treatments have advocates for the management of back pain, although clear-cut

evidence for the efficacy of these modalities is still lacking:

- hydrotherapy
- traction
- TENS
- therapeutic ultrasound
- facet joint injection

FIGURE 38.15 Lumbosacral spinal stretching technique (for right sided pain): a traditional technique. Illustration of direction of line of force

Source: Reproduced with permission from C Kenna and J Murtagh. *Back Pain and Spinal Manipulation*. Sydney: Butterworths, 1989<sup>7</sup>

FIGURE 38.16 Lumbar spinal stretching manipulation: illustration of the specific technique for the L4–5 level with arrows indicating the direction of applied force

Source: Reproduced with permission from C Kenna and J Murtagh. *Back Pain and Spinal Manipulation*. Sydney: Butterworths, 1989<sup>7</sup>

- posterior nerve root (medial branch) blocks with or without denervation (by cryotherapy or radiofrequency)
- percutaneous vertebroplasty (injection of bone cement into fractured vertebra of osteoporosis)
- deep friction massage (in conjunction with mobilisation and manipulation)
- acupuncture (evidence for short-term benefit)
- pain clinic (if unresponsive to initial treatments)
- biofeedback
- gravitational methods (home therapy)
- lumbar supports

## MANAGEMENT GUIDELINES FOR LUMBOSACRAL DISORDERS (SUMMARY)

The management of 'mechanical' back pain depends on the cause. Since most of the problems are mechanical and there is a tendency to natural resolution, conservative management is quite appropriate. The rule is: 'if patients with uncomplicated back pain receive no treatment, one-third will get better within 1 week and by 3 weeks almost all the rest of the other two-thirds are better'.<sup>14</sup> Practitioners should have a clear-cut management plan with a firm, precise, reassuring and conservative clinical approach.

The problems can be categorised into general conditions for which the summarised treatment protocols are outlined.

- Acute pain = pain less than 6 weeks.
- Subacute pain = pain 6–12 weeks
- Chronic pain = pain greater than 12 weeks

### Management of low back pain

- Explanation and reassurance
- Back education program
- Encouragement of normal daily activities, including work, according to degree of comfort
- Regular non-opioid analgesics (e.g. paracetamol)
- Physical therapy: stretching of affected segment, muscle energy therapy, spinal mobilisation or manipulation (if no contraindication)<sup>11,13,15</sup>
- Prescribe exercises (provided no aggravation)
- Review in about 5 days (probably best time for physical therapy)
- No investigation needed initially

## § Acute low back pain<sup>6</sup>

The common problem of low back pain caused by facet joint dysfunction and/or limited disc

disruption usually responds well to the following treatment (see box). The typical patient is aged 20–55 years, is well and has no radiation of pain below the knee.<sup>15</sup>

Most of these patients can expect to be relatively pain free in 14 days and can return to work early (some may not miss work and this should be encouraged). The evidence concerning spinal manipulation is that it reduces the period of disability.

## § Sciatica with or without low back pain

Sciatica is a more complex and protracted problem to treat, but most cases will gradually settle within 12 weeks (refer to CHAPTER 66).

### Acute<sup>6</sup>

- Explanation and reassurance
- Back education program
- Resume normal activities as soon as possible
- Regular non-opioid analgesics with review as the patient mobilises
- NSAIDs for 10–14 days, then cease and review
- If severe pain unrelieved add tramadol 50–100 mg (o) or oxycodone 5–10 mg (o) 4 hourly as necessary, for short-term use<sup>6</sup>
- Walking and swimming
- Weekly or 2-weekly follow-up
- Consider: a course of corticosteroids for severe pain,<sup>6</sup> e.g. prednisolone 50 mg for 5 days, then 25 mg for 5 days, gradually tapering to 3 weeks in total.  
or  
30 mg daily mane for 3 weeks, tapering to 0 over next 2 weeks (efficacy not clearly established)

### Chronic

- Reassurance that problem will subside (assuming no severe neurological defects)
- Consider epidural anaesthesia (if slow response)
- Consider amitriptyline 10–25 mg (o) nocte increasing to maximum 75–100 mg

*Note:* An important controlled prospective study comparing surgical and conservative treatment in patients with sciatica over 10 years showed that there was significant relief of sciatica in the surgical group for 1 to 2 years but not beyond that time. At 10 years both groups had the same outcome, including neurological deficits.<sup>16</sup>

## § Sacroiliac dysfunction

See CHAPTER 66.

## § Chronic back pain

The basic management of the patient with uncomplicated chronic back pain should follow the following guidelines:

- back education program and ongoing support
- encouragement of normal activity
- exercise program
- analgesics (e.g. paracetamol)
- NSAIDs for 14–21 days (especially if inflammation, i.e. pain at rest—relieved by activity) and review
- trial of mobilisation or manipulation (at least three treatments)—if no contraindications<sup>12,13</sup>
- consider trigger point injection
- consider amitriptyline 10–25 mg (o), note increasing to maximum 75–100 mg (o)
- a multidisciplinary team approach is recommended/back schools

### General guidelines for surgical intervention for radiculopathy

#### Absolute

- Bladder/bowel control disturbance; perineal sensory change
- Progressive motor disturbance (e.g. significant foot drop, weakness in quadriceps)

#### Relative

- Severe prolonged pain or disabling pain
- Failure of conservative treatment with persistent pain (problem of permanent nerve damage)
- If all 4 of the following criteria are met:<sup>6</sup>
  - leg pain equal to or worse than back pain
  - positive straight leg raise test
  - no response to conservative therapy after 4–6 weeks
  - imaging shows a lesion corresponding to symptoms

## Prevention of further back pain

Patients should be informed that an ongoing back care program should give them an excellent outlook. Prevention includes:

- education about back care, including a good layperson's reference
- golden rules to live by: how to lift, sit, bend, play sport and so on

- an exercise program: a tailor-made program for the patient
- posture and movement training, such as the Alexander technique<sup>17</sup> or the Feldenkrais technique<sup>18</sup>

## When to refer

### Urgent referral

- Myelopathy, especially acute cauda equina compression syndrome
- Severe radiculopathy with progressive neurologic deficit
- Spinal fractures

### Other referrals

- Recalcitrant spinal canal stenosis
- Neoplasia or infection
- Undiagnosed back pain
- Paget disease
- Continuing pain of 3 months' duration without a clearly definable cause

## Practice tips

- Back pain that is related to posture, aggravated by movement and sitting, and relieved by lying down is due to vertebral dysfunction, especially a disc disruption.
- The pain from most disc lesions is generally relieved by rest.
- Plain X-rays are of limited use, especially in younger patients, and may appear normal in disc prolapse.
- Remember the possibility of depression as a cause of back pain; if suspected, consider a trial of antidepressants.
- If back pain persists, possibly worse during bed rest at night, consider malignant disease, depressive illness or other systemic diseases.
- Pain that is worse on standing and walking, but relieved by sitting, is probably caused by spondylolisthesis.
- If pain and stiffness is present on waking and lasts longer than 30 minutes upon activity, consider inflammation.
- Avoid using strong analgesics (especially opioids) in any chronic non-malignant pain state.
- Bilateral back pain is more typical of systemic diseases, while unilateral pain typifies mechanical causes.

- Back pain at rest and morning stiffness in a young person demand careful investigation: consider inflammation such as ankylosing spondylitis and reactive arthritis.
- A disc lesion of L5–S1 can involve both L5 and S1 roots. However, combined L5 and S1 root lesions should still be regarded with suspicion (e.g. consider malignancy).
- A large central disc protrusion can cause bladder symptoms, either incontinence or retention.
- Low back pain of very sudden onset with localised spasm and protective lateral deviation may indicate a facet joint syndrome.
- The T12–L1 and L1–2 discs are the groin pain discs.
- The L4–5 disc is the back pain disc.
- The L5–S1 disc is the leg pain disc.
- Severe limitation of SLR (especially to less than 30°) indicates lumbar disc prolapse.
- A preventive program for dysfunctional back pain based on back care awareness and exercises is mandatory advice.
- Remember that most back problems resolve within a few weeks, so avoid overtreatment.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Backache
- Exercises for your lower back
- Sciatica
- Spondylosis

Many patients present with the complaint that they bruise easily but only a minority turn out to have an underlying blood disorder. Purpura is bleeding into the skin or mucous membranes, appearing as multiple small haemorrhages that do not blanch on pressure. Smaller purpuric lesions that are 2 mm or less in diameter (pinhead size) are termed petechiae, while larger purpuric lesions are called ecchymoses (see FIG. 39.1).

Bruises are large areas of bleeding that are a result of subcutaneous bleeding. If bruising is abnormal and out of proportion to the offending trauma, then a disturbance of coagulation is suggested (see FIG. 39.2).

### Differential diagnosis

'Palpable purpura' due to an underlying systemic vasculitis is an important differential problem. The petechiae are raised so finger palpation is important. The cause is an underlying vasculitis affecting small vessels (e.g. polyarteritis nodosa).

The decision to investigate is difficult because decisions have to be made about which patients

**FIGURE 39.2** Severe bleeding in a diabetic patient with systemic fibrinolysis. Note the bleeding following insulin injections into the abdominal wall and an injection into the shoulder joint.

Source: Photo courtesy Hatem Salem

**FIGURE 39.1** Purpuric rash (petechiae and ecchymoses)

warrant investigation and whether the haemostatic defect is due to local or systemic pathology.<sup>1</sup> The ability to identify a bleeding disorder is important because of implications for surgery, pregnancy, medication and genetic counselling.

### Key facts and checkpoints

- Purpura = petechiae + ecchymoses.
- Abnormal bleeding is basically the result of disorders of (1) the platelet, (2) the coagulation mechanism or (3) the blood vessel.

- There is no substitute for a good history in the assessment of patients with bleeding disorders.
- An assessment of the personal and family histories is the first step in the identification of a bleeding disorder.
- When a patient complains of 'bruising easily' it is important to exclude thrombocytopenia due to bone marrow disease and clotting factor deficiencies such as haemophilia.
- The commonest cause of an acquired bleeding disorder is drug therapy (e.g. aspirin, NSAIDs, cytotoxics and oral anticoagulants).
- In general, bleeding secondary to platelet defects is spontaneous, associated with a petechial rash and occurs immediately after trauma or a cut wound.<sup>1</sup> The bleeding is usually mucosal (e.g. bleeding from gingiva, menorrhagia, epistaxis and petechiae).
- Laboratory assessment should be guided by the clinical impression.
- Bleeding caused by coagulation factor deficiency is usually traumatic and delayed (e.g. haemorrhage occurring 24 hours after a dental extraction in a haemophiliac).
- The routine screening tests for the investigation of patients with bleeding disorders can occasionally be normal despite the presence of an undeniable bleeding disorder and even a severe haemorrhagic state. Second-line investigations will need to be undertaken.

## Causes of clinical disorders

The three major mechanisms of systemic bleeding disorders are (the Virchow triad):

- 1 coagulation deficiencies (reduction or inhibition of circulatory coagulation factors)
- 2 platelet abnormalities: of platelet number or function
- 3 vascular defects: of vascular endothelium

Bleeding disorders can also be divided into impaired primary or secondary haemostasis. Primary haemostatic disorders which are the most common include von Willebrand disease (vWD), thrombocytopenia and platelet function disorders. Examples of disorders of secondary haemostasis are disorders of fibrin formation and the haemophilias.<sup>2</sup>

A list of differential diagnoses of systemic bleeding disorders is presented in **TABLE 39.1**.<sup>1</sup>

**Table 39.1** Differential diagnoses of systemic bleeding disorders

### Vascular disorders

- (a) Inherited:
- hereditary haemorrhagic telangiectasia
  - Marfan syndrome
- (b) Acquired:
- infection (e.g. meningococcus, measles, dengue)
  - purpura simplex
  - senile purpura
  - Henoch–Schönlein purpura
  - steroid purpura
  - vitamin C deficiency (scurvy)

### Coagulation factor deficiency or inhibitor

- (a) Inherited:
- haemophilia A
  - haemophilia B
  - vWD
- (b) Acquired:
- disseminated intravascular coagulation (DIC)
  - liver disease
  - vitamin K deficiency
  - oral anticoagulant therapy or overdosage

### Thrombocytopenia

- (a) Inherited:
- Fanconi syndrome
  - amegakaryocytic thrombocytopenia
- (b) Acquired:
- (Immune)
- immune thrombocytopenic purpura
  - drug-induced thrombocytopenia (e.g. heparin)
  - thrombotic thrombocytopenic purpura
  - post-transfusion purpura
- (Non-immune)
- disseminated intravascular coagulation
  - bone marrow replacement or failure
  - splenic pooling

### Functional platelet disorders

- (a) Inherited:
- Glanzmann thrombasthenia
  - Bernard–Soulier syndrome
  - storage pool deficiency
- (b) Acquired:
- drug-induced (e.g. aspirin, NSAIDs)
  - uraemia /kidney failure
  - myeloproliferative disorders
  - dysproteinaemias

## The clinical approach

Differentiation of coagulation factor deficiencies and platelet disorders as the cause of a bleeding problem can usually be determined by a careful evaluation of the history and physical examination.

## History

Factors that suggest the presence of a systemic bleeding defect include:

- spontaneous haemorrhage
- severe or recurrent haemorrhagic episodes e.g. epistaxis
- bleeding from multiple sites
- bleeding out of proportion to the degree of trauma
- cutaneous bleeding
- gastrointestinal bleeding
- postpartum haemorrhage
- bleeding from tooth extraction/oral cavity
- menorrhagia
- muscle haematomas or haemarthrosis

If a bleeding diathesis is suspected it is essential to determine whether local pathology is contributing to the blood loss (e.g. postoperative bleeding, postpartum bleeding, gastrointestinal haemorrhage).

## Diagnostic tips

- Platelet abnormalities present as early bleeding following trauma.
- Coagulation factor deficiencies present with delayed bleeding after initial haemostasis is achieved by normal platelets.
- A normal response to previous coagulation stresses (e.g. dental extraction, circumcision or pregnancy) indicates an acquired problem.
- If acquired, look for evidence of MILD: Malignancy, Infection, Liver disease, Drugs.
- A diagnostic strategy is outlined in **TABLE 39.2**.

## Family history

A positive family history can be a positive pointer to the diagnosis:

- sex-linked recessive pattern: haemophilia A or B
- autosomal dominant pattern: vWD, dysfibrinogenemias
- autosomal recessive pattern: deficiency of coagulation factors V, VII and X

Enquire whether the patient has noticed blood in the urine or stools and whether menorrhagia is present in women. A checklist for a bleeding history is

**Table 39.2** Purpura: diagnostic strategy model

Q. Probability diagnosis
A. Simple purpura (easy bruising syndrome)
Senile purpura
Corticosteroid-induced purpura
Immune thrombocytopenic purpura
Henoch–Schönlein purpura
Liver disease, especially alcoholic cirrhosis
Increased intravascular pressure, e.g. coughing, vomiting
Q. Serious disorders not to be missed
A. Malignant disease:
• leukaemia
• myeloma
Aplastic anaemia
Myelofibrosis
Severe infections:
• septicaemia
• meningococcal infection
• measles
• typhoid
• dengue/chikungunya
Disseminated intravascular coagulation
Thrombotic thrombocytopenic purpura
Fat embolism
Q. Pitfalls (often missed)
A. Haemophilia A, B vWD
Post-transfusion purpura
Trauma (e.g. domestic violence, child abuse)
Rarities:
• hereditary telangiectasia (Osler–Weber–Rendu syndrome)
• Ehlers–Danlos syndrome
• scurvy
• Fanconi syndrome
Q. The masquerades
A. Drugs: examples (see 'Medication Record')
• sodium valproate
• various antibiotics
• quinine/quinidine
• thiazide diuretics
• NSAIDs/salicylates
• cytotoxics
• oral anticoagulants/heparin
Anaemia:
• aplastic anaemia
Q. Psychogenic factors
A. Factitious purpura

**Table 39.3** Checklist for a bleeding history

Skin bruising	Tonsillectomy
Epistaxis	Other operations
Injury	Childbirth
Domestic violence	Haematuria
Menorrhagia	Rectal bleeding
Haemarthrosis	Drugs
Tooth extraction	Family history
Unusual haematomas	Comorbidities (e.g. liver disease, kidney disease)

presented in **TABLE 39.3**. The actual size and frequency of the bruises should be recorded where possible and if none are present at the time of the consultation the patient should return if any bruises reappear.

### Key questions

- How long has the problem been apparent to you?
- Do you remember any bumps or falls that might have caused the bruising?
- What sort of injuries cause you to bruise easily?
- Have you noticed bleeding from other areas such as your nose or gums?
- Has anyone in your family had a history of bruising or bleeding?
- What is your general health like?
- Do you have any tiredness, weight loss, fever or night sweats?
- Did you notice a viral illness or sore throat beforehand?
- How much alcohol do you drink?
- What happened in the past when you had a tooth extracted?
- Have you ever had painful swelling in your joints?

### Medication record

It is mandatory to obtain a complete drug history. Examples of drugs and their responses are:

- vascular purpura:
  - prednisolone/other steroids
- thrombocytopenia:
  - cytotoxic drugs
  - carbamazepine
  - gold
  - sodium valproate
  - heparin
  - ranitidine
  - sulphonamides

- quinine, quinidine
- thiazide diuretics
- penicillins, vancomycin
- chloramphenicol
- functional platelet abnormalities:
  - aspirin
  - NSAIDs
- coagulation factor deficiency:
  - warfarin

### Examination

Careful examination of the skin is important. Note the nature of the bleeding and the distribution of any rash, which is characteristic in Henoch–Schönlein purpura. Senile purpura in the elderly is usually seen over the dorsum of the hands, extensor surface of the forearms and the shins. Purpura on the legs indicates platelet disorders, meningococcal septicaemia and paraproteinaemias; on the fingers and toes indicates vasculitis.

Note the lips and oral mucosa for evidence of hereditary telangiectasia. Gum hypertrophy occurs in monocytic leukaemia. Search for evidence of malignancy, such as sternal tenderness, lymphadenopathy and splenomegaly. Examine the ocular fundi for evidence of retinal haemorrhages. Urinalysis, searching for blood (microscopic or macroscopic), is important.

### Investigations

The initial choice of investigations depends upon the bleeding pattern.

If coagulation defect suspected:

- prothrombin time (PT), i.e. INR
- activated partial thromboplastin time (APTT)
- fibrinogen level
- thrombin time (TT)

If platelet pathology suspected:

- platelet count
- skin bleeding time (of doubtful value)
- platelet function analyser (PFA-100)

If inherited disorders suspected:

- factor VIII
- vW factor activity
- vW factor antigen

The full blood examination and blood film is useful in pinpointing the aetiology. Platelet morphology gives a diagnostic guide to inherited platelet disorders. The skin-bleeding time as a screening test of haemostasis has been shown recently to be severely limited by its lack of specificity and sensitivity and

its routine use cannot be recommended. It is not a useful predictor of surgical risk of haemorrhage.<sup>1,3</sup> Other sophisticated tests, such as von Willebrand's screen and platelet aggregation (e.g. PFA-100), can be advised by the consulting haematologist. One of considerable value is the bone marrow examination, which is useful to exclude the secondary causes of thrombocytopenia, such as leukaemia, other marrow infiltrations and aplastic anaemia.

Other tests to consider: ESR/CRP, autoimmune screening, LFTs, plasma electrophoresis, skin biopsy. Be cautious of pseudo-thrombocytopenia due to laboratory error—exclude on a blood film and consider a repeat collection.

A summary of appropriate tests is presented in TABLE 39.4 and of blood changes for some coagulation factor deficiencies in TABLE 39.5.

## Abnormal bleeding in children

Abnormal bleeding in children is not uncommon and once again the clinical history, particularly the past and family history, provides the most valuable information. It is important to keep non-accidental injury, such as child abuse, in mind in the child presenting with 'easy bruising'. However, it is appropriate to exclude a bleeding disorder, especially a platelet disorder. Vigorous coughing or vomiting in a child can cause petechiae on or around the eyelids.

Coagulation disorders, including haemophilia and vWD, are usually suspected on clinical grounds because of widespread bruising or because of prolonged bleeding following procedures such as circumcision and tonsillectomy.

**Table 39.4** Laboratory investigation checklist for the easy bruiser

Full blood count  
Platelet count  
Prothrombin time (INR)  
Thrombin time (TT)  
Activated partial thromboplastin time

**Table 39.5** Blood changes for specific coagulation factor disorders

	Haemophilia A	vWD	Vitamin K deficiency
PT	Normal	Normal	↑
APTT	↑	↑	↑
TT	Normal	Normal	Normal

A common condition is haemorrhagic disease of the newborn, which is a self-limiting disease usually presenting on the second or third day of life because of a deficiency of coagulation factors dependent on vitamin K. The routine use of prophylactic vitamin K in the newborn infant has virtually eliminated this problem.

Idiopathic (immune) thrombocytopenic purpura (ITP) is the commonest of the primary platelet disorders in children. Both acute and chronic forms have an immunological basis. The diagnosis is based on the peripheral blood film and platelet count. The platelet count is commonly below 50 000/mm<sup>3</sup> (50 × 10<sup>9</sup>/L). Spontaneous remission within 4 to 6 weeks occurs with acute ITP in childhood.<sup>3</sup>

The commonest vascular defects in childhood are:

- anaphylactoid (Henoch–Schönlein) purpura
- infective states
- nutritional deficiency (usually inadequate dietary vitamin C)

## § Henoch–Schönlein purpura

HSP is the commonest vasculitis of children. It affects small vessels, producing a leucocytoclastic vasculitis with a classic triad of non-thrombocytopenic purpura, large joint arthritis and abdominal pain. It is diagnosed clinically by the characteristic distribution of the rash (which is a palpable purpura) over the lower limbs, extending onto the buttocks (see FIG. 39.3), but it can also involve the upper limbs, trunk and even the face.

The onset of HSP typically follows an upper respiratory tract infection including a group A streptococcal tonsillopharyngitis.

The bleeding time, coagulation time and platelet counts are normal. The prognosis is good; most recover fully in a few months.

**FIGURE 39.3** Henoch–Schönlein purpura in a 5-year-old boy showing the typical distribution of the rash on the lower limbs

FIGURE 39.4 Henoch-Schönlein purpura: typical distribution

### Clinical features

- All ages, mainly in children
- Rash, mainly on buttocks and legs (see FIG. 39.4)<sup>4</sup>
- Rash can occur on hands, arms and trunk
- Arthritis: mainly ankles and knees
- Abdominal pain—colicky (vasculitis of GIT)
- Haematuria (reflects nephritis)

### Associations

- Kidney involvement—deposition of IgA immune complex (a serious complication)
- Melaena
- Intussusception
- Scrotal involvement

### Investigations

- FBE
- Urine: protein and blood; spun specimen, micro for casts

### Management

- Largely symptomatic—analgesics
- No specific therapy
- Short course of steroids for abdominal pain (if intussusception excluded)
- If haematuria: follow-up urine microscopy and kidney function especially if no resolution

**DxT** arthralgia + purpuric rash ± abdominal pain → Henoch-Schönlein purpura

### Practice tip

Beware of CKF.

## § Infective states

The purpura associated with severe infections, such as meningococcaemia and other septicaemias, is due primarily to a severe angitis. Disseminated intravascular coagulation usually follows.<sup>3</sup>

## Abnormal bleeding in the elderly

The outstanding causes are senile purpura and purpura due to steroids.<sup>5</sup> The cause in both instances is atrophy of the vascular supporting tissue.

## VASCULAR DISORDERS

The features are:

- easy bruising and bleeding into skin
- $\pm$  mucous membrane bleeding
- investigations normal

## § Simple purpura (easy bruising syndrome)

This is a benign disorder occurring in otherwise healthy women usually in their 20s or 30s. The feature is bruising on the arms, leg and trunk with minor trauma. The patient may complain of heavy periods. Major challenges to the haemostatic mechanism, such as dental extraction, childbirth and surgery, have not been complicated by excessive blood loss.

## § Factitial purpura

Unexplained bruising or bleeding may represent self-inflicted abuse or abuse by others. In self-inflicted abuse the bruising is commonly on the legs or areas within easy reach of the patient.

## PLATELET DISORDERS

The features are:

- petechiae  $\pm$  ecchymoses
- bleeding from mucous membranes
- platelet counts  $<50\,000/\text{mm}^3$  ( $50 \times 10^9/\text{L}$ )

## § Immune (idiopathic) thrombocytopenic purpura

### Clinical features

- Acute onset in children
- Easy bruising
- Epistaxis and menorrhagia common
- No systemic illness
- Splenomegaly rare

- Isolated thrombocytopenia
- Other blood cells normal
- Otherwise normal physical examination
- Normal bone marrow with normal or increased megakaryocytes (acute leukaemia should be excluded)

**DxT** bruising + oral bleeding + epistaxis → ITP

The two distinct types caused by immune destruction of the platelets are:

- acute thrombocytopenia of childhood—usually in children, usually post-viral
- chronic ITP—autoimmune disorder, usually in adult women; all cases should be referred to a specialist unit

## § Acute thrombocytopenia of childhood

This is caused by a reaction to a virus infection resulting in the production of cross-reacting antibodies against platelets.

There is an early risk of spontaneous haemorrhage, so refer/admit to hospital especially if the platelet count is  $<30 \times 10^9/\text{L}$  or there is active bleeding.

The prognosis is good, invariably self-limiting—90% resolve in 6 months. It may recur with further viral infections. The rest pass into chronic ITP.

Bleeding is treated with immunoglobulin or steroids.

## § Chronic idiopathic (immune) thrombocytopenic purpura

Chronic ITP is a relapsing illness that rarely undergoes spontaneous remission and may require treatment with prednisolone or biological agents e.g. rituximab. Enquire about drug history. Some require splenectomy but this operation is avoided where possible, especially in young children, because of the subsequent risk of severe infection, particularly with *Streptococcus pneumoniae*.<sup>5</sup> (Refer later in this chapter.)

## § Thrombotic thrombocytopenic purpura

This is an uncommon life-threatening syndrome of haemolytic anaemia, thrombocytopenia and extremely high LDH. Clinical features include fever

(non-infectious), neurologic and kidney abnormalities. The defect is in the absence of a specific protease in the plasma.

## COAGULATION DISORDERS

The features are:

- ecchymoses
- haemarthrosis and muscle haematomas
- usually traumatic and delayed

The inherited disorders such as haemophilia A and B are uncommon and involve deficiency of one factor only. The acquired disorders, such as disseminated intravascular coagulation (DIC), occur more commonly and invariably affect several anticoagulation factors (see TABLE 39.6).

## Inherited coagulation disorders

A list of the inherited bleeding disorders is included in TABLE 39.1. The better known disorders are vWD, haemophilia A and haemophilia B (Christmas disease).

### § von Willebrand disease

This is the most common disorder of haemostasis (incidence 1% of population) and is usually a mild problem with an excellent prognosis.<sup>6</sup> There are about 22 types.

**Table 39.6** International nomenclature of clotting factors

Factor	Common synonyms
I	Fibrinogen*
II	Prothrombin*
III	No longer used
IV	No longer used
V	Proaccelerin
VI	No longer used
VII	Proconvertin (tissue factor)
VIII	Antihæmophilic factor A Antihæmophilic globulin
IX	Antihæmophilic factor B (Christmas factor)
X	Stuart–Prower factor
XI	Plasma thromboplastin antecedent
XII	Hageman factor, contact factor
XIII	Fibrin stabilising factor

## Clinical features

- Autosomal dominant inheritance (common types)
- Equal sex incidence
- Prolonged bleeding time
- Bleeding tendency exacerbated by aspirin
- Platelets normal
- Defective platelet adhesion at site of trauma combined with factor VIII deficiency<sup>5</sup>
- APTT prolonged
- Positive vW factor antigen
- Menorrhagia and epistaxis common
- Haemarthroses rare

**DxT** menorrhagia + bruising + increased bleeding—1. incisions 2. dental 3. mucosal → vWD

## Treatment

- No specific treatment
- Avoid aspirin (including Alka-Seltzer), NSAIDs, IM injections
- Be cautious of surgical and dental procedures
- Preparations that help include desmopressin acetate (DDAVP), factor VIII concentrates and tranexamic acid

### § Haemophilia A

## Clinical features

- Spontaneous haemarthroses, especially knees, ankles and elbows, are almost pathognomic
- X-linked recessive pattern of inheritance
- Invariably only males affected (1 in 5000)
- Females theoretically affected if haemophilic father and carrier mother
- The human factor gene has long been identified
- Severity levels:
  - severe—bleed spontaneously
  - moderate—bleed with mild trauma or surgery
  - mild—bleed after major trauma or surgery
- Deficiency of factor VIII
- APTT prolonged
- Normal prothrombin time and fibrinogen
- Many seropositive for HIV, hepatitis B or C (factor VIII concentrate transmission)
- Low platelet count should suspect HIV-associated ITP<sup>6</sup>

**DxT** spontaneous haemarthrosis + muscle bleeds + delayed bleeding → haemophilia A

### Treatment

- Infusion of recombinant factor VIII concentrates<sup>6</sup>
- Avoid aspirin

### § Haemophilia B (Christmas disease)

- Identical clinical features to haemophilia A
- Also an X-linked recessive hereditary disorder
- Incidence of 1 in 30 000
- Deficiency of coagulation factor IX
- Same laboratory findings as haemophilia A apart from specific factor assays
- Treatment is with recombinant factor IX concentrates

### Splenectomy

Main indications:

- immune thrombocytopenic purpura
- haemolytic anaemias especially hereditary spherocytosis
- hypersplenism
- trauma
- Hodgkin/non-Hodgkin lymphoma

### Post-splenectomy management<sup>7</sup>

Immediate problem is thrombocytosis ( $\uparrow$  platelets to  $600\text{--}1000 \times 10^9/\text{L}$ ) for 2–3 weeks with risk of thromboembolism.

Long-term risk is overwhelming infection (pneumococcus [especially] *Haemophilus influenzae* and meningococcus), especially in young children in the first 2 years post-splenectomy. For elective surgery give immunisation at least 2 weeks before surgery.

### Prophylaxis

- Education about risks and early recognition of infection (special care with malaria)
- Pneumococcal immunisation—give 2–3 weeks preoperative, repeat 5-yearly; avoid in pregnancy
- *Haemophilus* type B vaccine—once only if not immunised
- Meningococcus vaccine—every 5 years
- Influenza vaccine—annual
- Long-term penicillin: amoxycillin daily or phenoxymethylpenicillin bd
- Urgent hospital admission if infection develops

### Management principles<sup>1</sup>

- Make the correct diagnosis.
- Stop or avoid drugs affecting the haemostatic system.
- Control bleeding episodes with appropriate drugs, blood products and local measures, such as simple compression or topical haemostatic agents.
- Infuse appropriate blood components for the treatment of coagulation factor deficiencies and some platelet disorders (e.g. factor VIII for haemophilia A, fresh frozen plasma for multiple factor deficiency).
- Refer patients with identified defects to a consultant haematologist or haemophilia centre.
- Supervise advanced planning in patients intending pregnancy, surgery or dental extraction.

### When to refer<sup>1</sup>

- Management of haemorrhage is not amenable to simple measures such as local therapy with simple compression and other measures.
- Elective surgery or pregnancy is being planned.
- Platelet count  $<30 \times 10^9/\text{L}$ .

### Practice tips

- A careful history and physical examination will usually pinpoint the cause of the bleeding disorder.
- Drug therapy can lead to unmasking of pre-existing haemostatic disorders (e.g. platelet dysfunction induced by aspirin may cause spontaneous bleeding in patients with underlying vWD).
- Think of disseminated intravascular coagulation (DIC) in any acutely ill patient with abnormal bleeding from sites such as the mouth or nose, venepuncture or with widespread ecchymoses. The clinical situations are numerous, such as septicaemia, obstetric emergencies, disseminated malignant disease, falciparum malaria and snake bites.
- Be cautious of non-prescription therapies affecting oral anticoagulants or causing platelet dysfunction (e.g. ginkgo biloba).

*There is a disorder of the breast marked with strong and peculiar symptoms, considerable for the kind of danger belonging to it. The seat of it, and sense of strangling, and anxiety with which it is attended, may make it not improperly be called angina pectoris.*

William Heberden (1710–1801)

The presenting problem of chest pain is common yet very threatening to both patient and doctor because the underlying cause in many instances is potentially lethal, especially with chest pain of sudden onset. The causes of acute chest pain are summarised and presented in **FIGURE 40.1**.

### Key facts and checkpoints

- Chest pain represents an acute coronary event until proved otherwise.
- Immediate life-threatening causes of spontaneous chest pain are:
  - myocardial infarction (MI) and unstable angina (acute coronary syndromes: ACS)

- pulmonary embolism
- aortic dissection
- tension pneumothorax
- The main differential diagnoses of ACS include aortic dissection, pericarditis, oesophageal reflux and spasm, biliary colic and hyperventilation with anxiety.
- The history remains the most important clinical factor in the diagnosis of ischaemic heart disease. With angina a vital clue is the reproducibility of the symptom.
- Consider unstable angina = pre-myocardial infarction.
- Unrecognised MI may be atypical (50%) or silent (50%). More common with diabetes, hypertension, elderly and females.

**FIGURE 40.1** Causes of acute chest pain

## A diagnostic approach

The diagnostic strategy model (see TABLE 40.1) can be used to analyse chest pain according to the five self-posed questions.

### Probability diagnosis

The commonest causes encountered in general practice are musculoskeletal or chest wall pain and psychogenic disorders. The former is a very important yet often overlooked cause and sometimes inappropriately referred to as fibrositis or neuralgia. Causes include costochondritis, muscular strains, dysfunction of the sternocostal joints and dysfunction of the lower cervical spine or upper thoracic spine, which can cause referred pain to various areas of the chest wall. Angina is common and must always be considered. If angina-like pain lasts longer than 15 minutes myocardial infarction must be excluded.

### Red flag pointers for acute chest pain

- Dizziness/syncope
- Pain in arms L>R, jaw
- Thoracic back pain
- Sweating
- Palpitations
- Dyspnoea
- Pain on inspiration
- Pallor
- Past history: ischaemia, diabetes, hypertension

### Serious disorders not to be missed

The usual triad of malignancy, myocardial ischaemia and severe infections (see TABLE 40.1) must be considered. In addition, other cardiovascular catastrophes, such as a dissecting aortic aneurysm and pulmonary embolus, must be excluded, although uncommon, especially in those at risk. Spontaneous pneumothorax should also be considered, especially in a young male of slight build. Malignancies of the lung are relatively common and may present as pain when the previously asymptomatic tumour invades nerves or the spine.

The severe infections that cause chest pain include pneumonia/pleurisy, pericarditis and mediastinitis.

### Pitfalls

Unfortunately, myocardial infarction and angina are often missed. Referred pain from spinal dysfunction, especially if referred anteriorly, is commonly

Table 40.1 Chest pain: diagnostic strategy model

Q. Probability diagnosis
A. Musculoskeletal (chest wall)
Psychogenic
Angina
Q. Serious disorders not to be missed
A. Cardiovascular:
• myocardial infarction/unstable angina
• aortic dissection
• pulmonary embolism/infarction
Neoplasia:
• lung cancer
• tumours of spinal cord and meninges
Severe infections:
• pneumonia/pleuritis (pleurisy)
• mediastinitis
• pericarditis
Pneumothorax
Q. Pitfalls (often missed)
A. Mitral valve prolapse
Oesophageal spasm
Gastro-oesophageal reflux
Biliary colic
Herpes zoster
Fractured rib (e.g. cough fracture)
Spinal dysfunction
Rarities:
• Pancreatitis
• Bornholm disease (pleurodynia)
• cocaine inhalation (can ↑ ischaemia)
• hypertrophic cardiomyopathy
Q. Seven masquerades checklist
A. Depression (possible)
Anaemia (indirect)
Spinal dysfunction
Q. Is the patient trying to tell me something?
A. Consider functional causes, especially anxiety with hyperventilation, opioid dependency.

Note: Chest pain is myocardial ischaemia until proved otherwise.

overlooked. Other pitfalls include a cough fracture of a rib, herpes zoster (prior to the eruption) and gastrointestinal disorders, including oesophageal spasm, reflux and cholecystitis. Oesophageal problems may be clinically indistinguishable from angina. Mitral valve prolapse can cause chest pain although the mechanism is unclear: think of it in an unwell female prone to palpitations and chest pain. The pain tends to be sharp, fleeting, non-exertional and located near the cardiac apex.

## General pitfalls

General pitfalls include:

- not being 'coronary aware' in patients presenting with chest pain
- referred pain from spinal disorders, especially of the lower cervical spine—one of the great pitfalls in medical practice
- labelling chest pain as psychological in an anxious patient presenting with acute chest pain
- assuming that pain radiating down the inside of the left arm is always cardiac in origin
- being unaware that up to 20% of myocardial infarctions are silent, especially in elderly patients, and that pulmonary embolism is often painless

## Seven masquerades checklist

Of this group spinal dysfunction is possible. Disc lesions from the lower cervical spine are unlikely to cause chest wall pain, but dysfunction of the facet joints of this area of the spine and the upper thoracic spine is a common cause of referred pain to the chest wall. Nerve root pain from spinal problems is rarely found in the chest wall. Pathological fractures secondary to osteoporosis or malignancy in the vertebrae cause posterior wall pain.

## Psychogenic considerations

With psychogenic causes the pain can occur anywhere in the chest, and tends to be continuous and sharp or stabbing rather than constricting. Associated symptoms include palpitations, deep breathing, fatigue, tremor, agitation and anxiety. Abnormal stress, tension, anxiety or depression may precipitate the pain, which often lasts hours or days.

## The clinical approach

### History

A meticulous history of the behaviour of the pain is the key to diagnosis. The pain should be analysed into its usual characteristics: site and radiation, quality, intensity, duration, onset and offset, precipitating and relieving factors, and associated symptoms. Association with serious medical problems such as diabetes, Marfan syndrome, anaemia and connective tissue disorders (e.g. SLE, RA) should be kept in mind. The ability to take a detailed history will obviously be limited with severe acute pain.

### Associated symptoms

- *Syncope*. Consider myocardial infarction, pulmonary embolus and dissecting aneurysm.

- *Pain on inspiration*. Consider pleuritis, pericarditis, pneumothorax and musculoskeletal (chest wall pain).
- *Thoracic back pain*. Consider spinal dysfunction, acute coronary syndromes, angina, aortic dissection, pericarditis and gastrointestinal disorders such as a peptic ulcer, biliary colic/cholecystitis and oesophageal spasm.

## Key questions

- Where exactly do you get the pain?
- Does the pain travel anywhere?
- Can you give me a careful description of the pain?
- How long did the pain last and could you do anything to relieve it?
- Is the pain brought on by exertion and relieved by rest?
- Do cold conditions bring it on?
- Do you have any other symptoms, such as breathlessness, faintness, sweating or back pain?
- Is the pain made worse by breathing or coughing, or by movement or pressing on that area?
- Is there any blood in any sputum you bring up?
- Is your pain associated with what you eat and drink? Or with a bitter taste in your mouth?
- Do you get the pain on stooping over and after lying in bed at night?
- Do antacids relieve your pain?
- Have you noticed a rash where you get the pain?
- Have you had a blow to your chest or an injury to your back?

## Examination

The examination should focus on the following areas:

- general appearance—evidence of atherosclerosis (senile arcus, thickened vessels), pale and sweating (myocardial infarction, dissecting aneurysm or pulmonary embolus), hemiparesis (? aortic dissection)
- pulses—both radial and femoral—check for nature of pulse and absence of femoral pulses
- blood pressure
- temperature
- palpation of chest wall, lower cervical spine and thoracic spine—look for evidence of localised tenderness, pathological fracture, spinal dysfunction, herpes zoster
- palpation of legs—check for evidence of deep venous thrombosis
- examination of chest—check for evidence of pneumothorax

- auscultation of chest:
  - reduced breath sounds, hyper-resonant percussion note and vocal fremitus → pneumothorax
  - friction rub → pericarditis or pleurisy
  - basal crackles → cardiac failure
  - apical systole murmur → mitral valve prolapse
  - aortic diastolic murmur → proximal dissection (aortic regurgitation)

*Note:* In the presence of a myocardial infarction, the examination may be normal but the patient, apart from being cold, clammy or shocked, may have muffled heart sounds, a gallop rhythm, a systolic

murmur. With an aortic dissection the patient may also appear cold, clammy and shocked, but may show absent femoral pulses, hemiparesis and a diastolic murmur of aortic regurgitation.

- upper abdominal palpation—check for tenderness suggestive of gall bladder disease or peptic ulceration

Possible findings on examination of a patient with chest pain are presented in **FIGURE 40.2**.<sup>1</sup>

## Investigations<sup>1</sup>

The following investigations to aid diagnosis are available, although the majority are sophisticated and confined to hospitals with high-technology imaging

**FIGURE 40.2** Possible examination findings in a patient with chest pain

departments. The fundamental tests that are readily available to the GP—ECG, chest X-ray and cardiac enzymes—should help confirm the diagnosis in most instances.

### Electrocardiogram (ECG)

This may be diagnostic for ischaemia and myocardial infarction, although it is important to bear in mind that it may be normal with both, including the early minutes to hours of an acute infarction.

It can be helpful to differentiate between myocardial infarction, pulmonary embolism and pericarditis. The ECG in pulmonary embolism may be normal but if massive may show right axis deviation, right BBB and right ventricular strain. Pericarditis is characterised by low voltages and saddle-shaped ST segment elevation.

### Exercise stress test

This is the key test for defining chest pain as cardiac in origin. Physical stress, such as the motor-driven treadmill or a bicycle ergometer, is used to elicit changes in the ECG to diagnose myocardial ischaemia.

### Exercise thallium scan

This radionuclide myocardial perfusion scan using thallium can complement the exercise ECG.

### Ambulatory Holter monitor

This monitor is especially useful for silent ischaemia, variant angina and arrhythmias.

### Chest X-ray

The routine CXR is taken in full inspiration. Ask for an expiration film if pneumothorax is suspected.

### Blood glucose

Tests association with diabetes.

### Haemoglobin and blood film

Anaemia is a possible associated factor.

### Serum enzymes

Damaged necrosed myocardial tissue releases cellular enzymes, which are markers of this damage:

- troponin I and troponin T (the key marker)
- creatinine kinase (CK) and creatinine kinase–myocardial bound fraction (CK–MB)
- myoglobin

### Echocardiography

This can be used in the early stages of myocardial infarction to detect abnormalities in heart wall motion,

when ECGs and enzymes are not diagnostic. Stress echocardiography is a new technique that is useful where standard exercise testing has been unhelpful.

### Isotope scanning

- 1 Technetium-99m pyrophosphate studies:
  - myocardium—to diagnose posterolateral myocardial infarction in the presence of bundle branch block
  - pulmonary—to diagnose pulmonary embolism
- 2 Gated blood pool nuclear scan (radionuclide ventriculography)—this scan tests left ventricular function at rest and exercise in patients with myocardial ischaemia.

### Angiography (arteriography)

Angiography should be selective:

- 1 coronary—to evaluate coronary arteries
- 2 pulmonary—to diagnose pulmonary thromboembolism

### Transoesophageal echocardiography (TOE)

This investigation is for dissecting aneurysm (immediate diagnosis).

### Oesophageal studies

- Endoscopy
- Barium swallow
- Oesophageal manometry
- Radionuclide transit studies

### Spine—X-ray

- Cervical spine
- Thoracic spine

## Site, radiation and features of chest pain syndromes

### § Myocardial ischaemia<sup>1</sup>

Coronary artery disease includes the acute coronary syndromes (unstable angina and myocardial infarction) and other variants of angina.

The typical retrosternal distribution of myocardial ischaemia is shown in **FIGURE 40.3**. Retrosternal pain or pain situated across the chest anteriorly should be regarded as cardiac until proved otherwise.

The wide variation of sites of pain, umbilicus to jaw, including neck, inside of arms, epigastrium and interscapular, should always be kept in mind (see **FIG. 40.4**). Pain is referred into the left arm 20 times more commonly than into the right arm.

FIGURE 40.3 Pain of myocardial ischaemia: typical site

FIGURE 40.4 Pain of myocardial ischaemia: other sites

The quality of the pain is usually described as pressure, heaviness or tightness. The patient often uses the clenched fist sign to illustrate a sense of constriction.

The radiation of pain will assist in differentiating ischaemic pain from that caused by pericarditis. Enquiry about precipitating and relieving factors will enable a differentiation to be made between ischaemic pain and the almost identical pain caused by reference from the spine. Associated symptoms include dyspnoea, dizziness, nausea and vomiting and sweating (diaphoresis).

If a retrosternal pain almost identical with that of myocardial ischaemia is precipitated not by exertion but by bending, lifting, straining or lying down, oesophageal reflux and spasm is a possible diagnosis. This is frequently confused with ischaemic heart disease and can cause radiation into the left arm.

**Stable angina.** The pain of angina tends to last a few minutes only (average 3–5 minutes) and is relieved by rest and glyceryl trinitrate (nitroglycerine). The pain may be precipitated by an arrhythmia.

The types of acute coronary syndromes are summarised in TABLE 40.2.<sup>2</sup>

Table 40.2 Types of acute coronary syndromes

	Serum markers		ECG at evaluation
	Creatinine kinase	Troponin	
Unstable angina			
Low risk	Normal	Non-detectable	Normal
High risk	Normal	Detectable	ST depression
Myocardial infarction			
Non-ST elevation (NSTEMI)	Elevated	Detectable	ST depression, no Q wave
ST elevation (STEMI)	Elevated	Detectable	± Q wave or new LBBB

STEMI = ST elevation myocardial infarction

- 1 **Myocardial infarction.** Ischaemic pain lasting longer than 15 to 20 minutes is usually infarction. The pain is typically heavy and crushing, and can vary from mild to intense. Occasionally the attack is painless, typically in diabetics. Pallor, sweating and vomiting may accompany the attack.
- 2 **Unstable angina.** This term includes rest angina, new onset effort angina, post infarct angina and post coronary procedure angina. Severe ischaemic chest pain can last 15–20 minutes or more. It is classified as low risk or high risk ‘minor myocardial damage’.

For management purposes it is best to classify the clinical presentation of acute ischaemic chest pain as an ST elevation myocardial infarction (STEMI) or a non-ST elevation acute coronary syndrome (NSTEMI), which includes NSTEMI and unstable angina.

## § Aortic dissection

The pain, which is usually sudden, severe and midline, has a tearing sensation and is usually situated retrosternally and between the scapulae (see FIG. 40.5). It radiates to the abdomen, flank and legs. An important diagnostic feature is the inequality in the pulses (e.g. carotid, radial and femoral). There may also be occlusion of the coronary or kidney arteries with appropriate symptoms and signs. Hemiplegia, aortic incompetence or cardiac tamponade can occur.

FIGURE 40.5 Pain of aortic dissection

### § Pulmonary embolism<sup>3</sup>

This has a dramatic onset following occlusion of the pulmonary artery or a major branch, especially if more than 50% of the cross-sectional area of the pulmonary trunk is occluded.

The diagnosis can present clinical difficulties, especially when dyspnoea is present without pain. Embolism usually presents with retrosternal chest pain (see FIG. 40.6) and may be associated with syncope and breathlessness. In addition, hypotension, acute right heart failure or cardiac arrest occurs with a massive embolus. The physical examination can be deceptively normal. Pulmonary infarction is generally less dramatic than embolism and it is usually accompanied by pleuritic chest pain and haemoptysis. It complicates embolism in about 10% of patients. The diagnosis is usually confirmed by a CT pulmonary angiogram (best) and/or V/Q scan (see later in chapter) and ECG (look for T wave inversion V1–V4).

FIGURE 40.6 Pain of pulmonary embolism

### § Pleuritis<sup>3</sup>

Inflammation of the pleura is due to underlying pneumonia (viral or bacterial), pulmonary infarction, tumour infiltration or connective tissue disease (e.g. SLE).

#### Clinical features

- Often sudden onset
- Pain usually localised without radiation
- Sharp knife-like pain
- Continuous pain with sharp exacerbations
- Aggravated by inspiration, sneezing and coughing
- May be associated dyspnoea, cough, haemoptysis

### § Epidemic pleurodynia (Bornholm disease)

Unilateral knife-like chest pain (and upper abdominal pain) following an URTI. It is caused by a Coxsackie B virus. CXR is normal; diagnosis is by exclusion. It settles within a week with simple analgesics.

### § Acute pericarditis

Pericarditis causes three distinct types of pain:

- 1 pleuritic (the commonest), aggravated by cough and deep inspiration, sometimes brought on by swallowing; worse with lying flat, relieved by sitting up
- 2 steady, crushing, retrosternal pain that mimics myocardial infarction
- 3 pain synchronous with the heartbeat and felt over the praecordium and left shoulder

Occasionally, two and rarely all three types of pain may be present simultaneously (see Fig. 40.7).

The cardinal sign is a pericardial friction rub.

FIGURE 40.7 Pain of pericarditis

FIGURE 40.8 Pain of pneumothorax (right side)

### § Spontaneous pneumothorax

The acute onset of pleuritic pain and dyspnoea in a patient with a history of asthma or emphysema is the hallmark of a pneumothorax. It is due to a rupture of a subpleural 'bleb' or a small air-containing cyst. It often occurs in young, slender males without a history of lung disorders. The pain varies from mild to severe and can be felt anywhere in the chest, sometimes being retrosternal. Typical pain distribution is shown in FIGURE 40.8. The diagnosis is made on expiration film.

If a tension pneumothorax becomes painful and dyspnoea becomes rapidly more intense, urgent decompression of air is essential (see later in chapter). A comparison of the serious causes of acute chest pain is summarised in TABLE 40.3.

### Oesophageal pain

Gastro-oesophageal reflux can cause oesophagitis characterised by a burning epigastric or retrosternal pain that may radiate to the jaw. The pain is aggravated or precipitated by lying flat or bending over, especially after meals, and is more frequent at night. The pain is worse if oesophageal spasm is present. Oesophageal motor disorders, including spasm, may occur in isolation. The pain may radiate uncommonly to the back (see FIG. 40.9). It may be precipitated by eating, especially hot or cold food and drink, and may be relieved by eating or by glyceryl trinitrate (nitroglycerine) and other nitrates. Features differentiating angina-like oesophageal pain and cardiac pain are presented in TABLE 40.4. Gastrointestinal causes of chest pain are summarised in TABLE 40.5.<sup>1</sup>

### Spinal pain

The commonest cause of pain of spinal origin is vertebral dysfunction of the lower cervical or upper dorsal region (see CHAPTER 37). The spinal problem

FIGURE 40.9 Oesophageal pain

may be a disc prolapse (relatively common in the lower cervical spine, but rare in the upper thoracic spine) or dysfunction of the facet joints or costovertebral joints causing referred pain. This referred pain can be present anywhere in the chest wall, including anterior chest, which causes confusion with cardiac pain (see FIG. 40.10). The pain is dull and aching. It may be aggravated by exertion, certain body movements or deep inspiration. The old trap for unilateral nerve root pain is herpes zoster.

FIGURE 40.10 Possible pain sites for thoracic spinal dysfunction (left side)

### § Costochondritis<sup>3</sup>

This causes mild to moderate anterior chest wall pain that may radiate to the chest, back or abdomen. It is usually unilateral, sharp in nature and exaggerated by breathing, physical activity or a specific position. It may be preceded by exercise or a URTI and can persist for several months. It is diagnosed by eliciting tenderness at the costochondral junction of the affected ribs and needs to be differentiated from Tietze syndrome, where there is a tender, fusiform swelling at the costochondral junction (refer to CHAPTER 100).

**Table 40.3** A comparison of the serious causes of acute chest pain

	Myocardial infarction	Angina	Pulmonary embolus	Aortic dissection	Pericarditis	Pneumothorax

GU = gastric ulcer; DU = duodenal ulcer

## Psychogenic pain

Psychogenic chest pain can occur anywhere in the chest, but often it is located in the left submammary region, usually without radiation (see FIG. 40.11). It tends to be continuous and sharp or stabbing. It may mimic angina but tends to last for hours or days. It is

usually aggravated by tiredness or emotional tension and may be associated with shortness of breath, fatigue and palpitations.

Da Costa syndrome (effort syndrome) is recurrent attacks of stabbing left-sided submammary pain, usually associated with anxiety  $\pm$  depression.

**FIGURE 40.11** Typical sites of psychogenic pain

## Chest pain in children

Chest pain in children is rarely the result of serious pathology but is an important complaint, especially in adolescents. A US study has shown that the mean age for childhood chest pain is 11.9 years.<sup>4</sup> Most cases are of unknown aetiology (probably psychogenic), while common causes include musculoskeletal disorders, cough-induced pain, costochondritis, psychogenic disturbance (includes hyperventilation) and asthma. See TABLE 40.6.

Chest pain in children younger than 12 years old is more likely to have a cardiorespiratory cause, such as cough, asthma, pneumonia or heart disease,

**Table 40.6** Common causes of chest pain in children

Cause	%
Idiopathic	21
Musculoskeletal	16
Cough	10
Costochondritis	9
Psychogenic	9
Asthma	7
Trauma	5
Pneumonia	4
GIT problems	4
Cardiovascular	4

Source: Adapted from Selbst<sup>4</sup>

while chest pain in adolescents is more likely to be associated with a psychogenic disturbance.

Causes of musculoskeletal pain include strains to pectoral, shoulder or back muscles after excessive exercise, and minor trauma from sports such as football or wrestling.

Breast problems can present as chest pain.

### Cardiac causes

Myocardial ischaemia is very rare in children but should be considered in any child with exercise-induced chest pain, adolescents with long-standing diabetes and children with sickle-cell anaemia.

### § Precordial catch (Texidor twinge or stitch in the side)<sup>5</sup>

This complaint, which is common in children and adolescents, presents as a unilateral low chest pain that lasts usually 30 seconds to 3 minutes, typically with exercise, such as long-distance running. The pain is relieved by straightening up and taking very slow deep breaths followed by shallow breaths.

### Chest pain in the elderly

Chest pain is a very important symptom in the elderly as the life-threatening cardiovascular conditions—myocardial infarction and angina, dissecting aneurysm and ruptured aorta—are an increasing manifestation with age. In a community survey in Glasgow, 20% of men and 12% of women over 65 years were found to have ischaemic heart disease.<sup>6</sup> The elderly patient presenting with chest pain is most likely to have angina or myocardial infarction. Other important disorders to consider are herpes

zoster, cough fracture of the rib, malignancy, pleurisy, pulmonary embolus and gastro-oesophageal reflux.

### § Angina pectoris

#### Main features

- There is a 2–3% incidence between 25 and 64 years.<sup>7</sup>
- The history is the basis of diagnosis.
- Angina is an oppressive discomfort rather than a pain.
- It is mainly retrosternal: radiates to arms, jaw, throat, back.
- It may be associated with shortness of breath, nausea, faintness and sweating.
- It occurs during exercise, emotion, after meals or in cold.
- It is relieved within a few minutes with rest.
- Physical examination is usually not helpful, except during an attack.
- Mitral valve prolapse, oesophageal spasm and dissecting aneurysm are important differential diagnoses.
- The causes of angina are summarised in TABLE 40.7.

*Note:* Ensure that the patient is not anaemic or thyrotoxic. Fever and tachycardia also have to be excluded.

**Table 40.7** Causes of angina

Coronary artery atheroma  
Valvular lesions (e.g. aortic stenosis)  
Rapid arrhythmias  
Anaemia

#### Rarities:

- vasculitis
- trauma
- collagen disease

#### Variants<sup>1,7</sup>

- *Stable angina.* Pain occurs with exertion and is usually predictable.
- *Unstable angina* (also referred to as crescendo angina, pre-infarct angina and acute coronary insufficiency). It is increasing angina (severity and duration) over a short period of time, precipitated by less effort and may come on at rest, especially at night. It may eventually lead to complete infarction, often with relief of symptoms. It is due to unstable plaque.
  - *Nocturnal angina.* Pain occurs during the night. It is related to unstable angina.

- *Decubitus angina*. The pain occurs when lying flat and is relieved by sitting up.
- *Variant angina or Prinzmetal angina or spasm angina*.<sup>7</sup> The pain occurs at rest and without apparent cause. It is associated with typical transient ECG changes of ST elevation (as compared with the classic changes of ST depression during effort angina). It can lead to infarction and cause arrhythmias. It is caused by coronary artery spasm.

## Aids to diagnosis

### ECG

This may be normal or show ischaemia or evidence of earlier infarction. During an attack it may be normal or show well-marked depression of the ST segment, symmetrical T-wave inversion (see FIG. 40.12) or tall upright T waves.

### Exercise ECG

This is positive in about 75% of patients with severe coronary artery disease and should be performed if the diagnosis is in doubt, for prognostic reasons or to aid in the timing of additional investigations (e.g. coronary angiography). A normal stress test does not rule out coronary artery disease.

### Exercise thallium-201 scan

This test is helpful in some difficult circumstances such as in the presence of left branch bundle block (LBBB), old infarction and Wolff–Parkinson–White (WPW) syndrome (when exercise test is of little use) and with mitral valve prolapse, which gives high false positive tests. It helps determine the presence and extent of reversible myocardial ischaemia since thallium is only taken up by perfused tissue.

### Ambulatory Holter monitoring

This may be useful in some patients.

**FIGURE 40.12** Typical ECG pattern for angina pectoris: this tracing is usually observed during an attack

*Note:* there is no specific ECG of angina; the most that can be said is that an ECG is consistent with angina

## Gated blood pool nuclear scan

This test assesses the ejection fraction, which is a reliable index of ventricular function and thus aids assessment of patients for coronary artery bypass surgery.

## Echocardiography

This assesses global and regional wall motion abnormalities and assesses valvular dysfunction and pericardium status.

## Coronary angiography

This test accurately outlines the extent and severity of coronary artery disease. It is usually used to determine the precise coronary artery anatomy prior to surgery.

The relationship between the degree of angina and coronary artery disease is not clear-cut. Some people with severe angina have normal coronary arteries.

Indications for coronary angiography are presented in TABLE 40.8.

'Ultrafast CT' may replace angiography.

**Table 40.8** Indications for coronary angiography

Strong positive exercise stress test
Suspected left main coronary artery disease
Angina resistant to medical treatment
Suspected but not otherwise proven angina
Acute coronary syndromes
Angina after myocardial infarction
Patients over 30 years with aortic and mitral valve disease being considered for valve surgery

## Management of stable angina

### Preventions

This is especially important for those with a positive family history and an unsatisfactory lifestyle. Modification of risk factors:

- no smoking
- weight reduction
- optimal low-fat diet
- control of hypertension
- control of diabetes
- control of blood lipids

### General advice for the stable angina patient

- Reassure patient that angina has a reasonably good prognosis: 30% survive more than 10 years;<sup>8</sup> spontaneous remission can occur.
- Attend to any risk factors.
- If inactive, take on an activity such as walking for 20 minutes a day.

- Take regular exercise to the threshold of angina.
- If tense and stressed, cultivate a more relaxed attitude to life—consider a stress management/relaxation course.
- Avoid precipitating factors.
- Don't excessively restrict lifestyle.

### Medical treatment<sup>9</sup>

#### The acute attack

- Nitrates:  
glyceryl trinitrate (nitroglycerine) 600 mcg tab  
*or*  
300 mcg (½ tab) sublingually (SL)  
*or*  
glyceryl trinitrate SL 400 mcg metered dose spray: 1–2 sprays; repeat after 5 minutes if pain persists (maximum two doses)  
*or*  
isosorbide dinitrate 5 mg sublingually; repeat every 5 minutes if pain persists (maximum 3 tablets)  
*or*  
nifedipine 5 mg capsule (suck or chew) if intolerant of nitrates
- Aspirin 150 mg (o)  
Tips about glyceryl trinitrate tablets:
  - warn patient about headache and other side effects
  - sit down to take the tablet
  - take ½ (initially) or 1 tablet every 5 minutes
  - take a maximum of 3 tablets in 15 minutes
  - tablets must be fresh
  - discard the bottle after being opened for 3 months or after 2 days if carried on the person
  - keep tablets out of light and heat
  - if pain relieved quickly, spit out residual tablet
  - advise patient to get medical advice if no relief after 3 tablets

*Note:* avoid nitrates if patient has taken sildenafil or vardenafil in the previous 24 hours or tadalafil in the previous 5 days.

#### Mild stable angina

Angina that is predictable, precipitated by more stressful activities and relieved rapidly:

- aspirin 150 mg (o) daily  
*or*  
(if intolerant of aspirin) clopidogrel 75 mg (o) daily  
glyceryl trinitrate (SL or spray) prn
- Consider a beta blocker or long-acting nitrate or nicorandil

#### Moderate stable angina

Regular predictable attacks precipitated by moderate exertion:

*add* (if not contraindicated)  
beta blocker e.g. atenolol 25–100 mg (o) once daily  
*or*  
metoprolol 25–100 mg (o) twice daily  
plus nitrates  
glyceryl trinitrate (transdermal: ointment or patches) daily (use for 12–16 hours only)  
*or*  
isosorbide mononitrate 60 mg (o) SR tablet mane

*Note:* Aim for a daily nitrate-free interval.

#### Persistent angina

Not prevented by beta blocker:

*add*  
a dihydropyridine calcium-channel blocker (CCB)  
(must have beta blocker cover)  
nifedipine CR 30–60 mg (o) once daily  
*or*  
amlodipine 2.5–10 mg (o) once daily  
plus nitrates

If beta blocker contraindicated (use a non-dihydropyridine calcium-channel blocker):

diltiazem 30–90 mg (o) tds or CR 180–360 mg (o) daily  
*or*  
verapamil (according to directions)  
*and/or*  
nicorandil 5 mg (o) bd, increasing after a week to 10–20 mg bd  
plus nitrates

#### Refractory stable angina

Replace CCB with perhexiline.

#### Unstable angina

Includes onset of angina at rest, abrupt worsening of angina and angina following acute myocardial infarction.

- Should be hospitalised for stabilisation and further evaluation. May need IV nitrate therapy.
- The objectives are to optimise therapy and consider coronary angiography with a view to a corrective procedure.

#### Rules of practice

- For variant angina (spasm) use nitrates and calcium antagonist (avoid beta blockers).

- As a rule, avoid the combination of verapamil and a beta blocker (risk of tachycardia and heart block).
- Tolerance to nitrate use is a problem, so 24-hour coverage with long-acting preparations is not recommended.
- Consider using the potassium channel opening vasodilator nicorandil 5 mg (o) bd to 10–20 mg (o) bd (after 1 week). Can use as alternative to long-acting nitrates
- Nitrates can be used prophylactically prior to any exertion that is likely to provoke angina (e.g. glyceryl trinitrate spray or tablet or isosorbide dinitrate 5 mg tablet)
- Avoid nitrates if the patient has used a 5 phosphodiesterase inhibitor in the past 1–5 days.

### Non-medical treatment<sup>9</sup>

#### Percutaneous intervention (PCI) and coronary angioplasty (the gold standard)

One current technique is dilating coronary atheromatous obstructions by inflating a balloon against the obstruction—percutaneous transluminal coronary angioplasty (PTCA) (see FIG. 40.13) and maintaining patency with intracoronary stent devices.

Two complications of the balloon inflation angioplasty are acute coronary occlusion (2–4%) and restenosis, which occurs in 30% in the first 6 months after angioplasty.<sup>8</sup>

FIGURE 40.13 Percutaneous transluminal angioplasty (PTCA) with an inflatable balloon

#### Intra-coronary stents

PTCA followed by stenting is now the most favoured procedure to maintain patency of the obstructed coronary vessel (see FIG. 40.14). Modern drug eluting stents, which include drugs such as primolimus, sirolimus or paclitaxel, can be used as well as the bare metal stent. Stent patients require long-term antiplatelet agents (e.g. aspirin plus clopidogrel) (specialist advice is required).

#### Coronary artery surgery

The main surgical techniques in current use are coronary artery bypass grafting (CABG) using either a vein (usually the saphenous) (see FIG. 40.15)

FIGURE 40.14 Illustration of stenting a coronary artery

or internal mammary arterial implantation (see FIG. 40.16) or both and endarterectomy.

Symptomatic patients with significant left main coronary obstruction should undergo bypass surgery, and those with two or three vessel obstruction and good ventricular function are often considered for angioplasty or surgery. A significant improvement in the quantity and quality of life can be expected.

### § Myocardial infarction

#### Clinical guidelines<sup>10</sup>

- Variable pain; may be mistaken for indigestion
- Similar to angina but more oppressive
- So severe, patient may fear imminent death—*angor animi*

FIGURE 40.15 Coronary artery bypass grafting to relieve coronary obstruction

**FIGURE 40.16** Internal mammary arterial transplantation to relieve obstruction

- About 20% have no pain. These have a high mortality rate
- 'Silent infarcts' in diabetics, hypertensives, females and elderly; one report (*European Heart Journal*, 14 February 2006, online) reported that 40% of infarcts were silent and undetected in older patients
- 60% of those who die do so before reaching hospital, within 2 hours of the onset of symptoms
- Hospital mortality is 8–10%<sup>10</sup>
- Like CVA, seems to peak at 6–10 am

Diagnosis is based on 2 out of 3 criteria: history of prolonged ischaemic pain, typical ECG appearance, and rise and fall of cardiac enzymes.

### Aetiology

- Thrombosis with occlusion
- Haemorrhage under a plaque
- Rupture of a plaque
- Coronary artery spasm

### Signs

These may be:

- no abnormal signs
- pale/grey, clammy, dyspnoeic
- restless and apprehensive
- variable BP with pain ↓ heart pump failure
- variable pulse: watch for bradyarrhythmias
- mild cardiac failure: third or fourth heart sound, basal crackles

**FIGURE 40.17** Typical ECG features of myocardial infarction, illustrating a Q wave, ST elevation and T-wave inversion

### Investigations

- 1 **ECG.** The ECG is valuable with characteristic changes in a full thickness infarction. The typical features (see FIG. 40.17) are:
  - the Q wave: broad (>1 mm) and deep >25% length R wave
    - occurs normally in leads AVR and V1; III (sometimes)
    - abnormal if in other leads
    - occurs also with LBBB, WPW and ventricular tachycardia (VT)
    - usually permanent feature after full thickness AMI
  - T wave and ST segment:
    - transient changes (inversion and elevation respectively)

The typical progression is shown in FIGURE 40.18.

*Note:*

- Q waves do not develop in subendocardial infarction.
  - The strategies for management of AMI are based on the distinction between Q wave (transmural) or non-Q wave (subendocardial) infarction.
  - Q wave infarction has been proved to benefit from thrombolytic therapy but non-Q wave infarction has not.
  - A normal ECG, especially early, does not exclude AMI. Q waves may take days to develop.
- 2 **Cardiac enzymes.** The typical enzyme patterns are presented in FIGURE 40.19. As a rule, large infarcts tend to produce high serum enzyme levels. The elevated enzymes can help time the infarct:
    - Troponin I or T:
      - starts rising at 3–6 hours, peaks at 10 hours and persists for about 5–14 days
      - now the preferred test
      - positive in unstable angina

**FIGURE 40.18** Typical evolution of ECG changes with myocardial infarction

- may have to wait until 10 hours before recording a negative result
- not useful for repeat MI
- both proteins, I and T, provide same information
- reference interval  $<0.1 \mu\text{g/L}$
- creatinine kinase (CK):
  - after delay of 6–8 hours from the onset of pain it peaks at 20–24 hours and usually returns to normal by 48 hours
  - CK-MB: myocardial necrosis is present if  $>15\%$  of total CK; unlike CK, it is not affected by intramuscular injections

### 3 Technetium pyrophosphate scanning

- It is performed from 24 hours to 14 days after onset.
- It scans for 'hot spots', especially when a posterolateral AMI is suspected and ECG is unhelpful because of pre-existing LBBB.

**FIGURE 40.19** Typical cardiac enzyme patterns following myocardial infarction

4 *Echocardiography*. This is used to assist diagnosis when other tests are not diagnostic.

*Note:* The clinical diagnosis may be the most reliable, as the ECG and enzymes may be negative.

## Management of acute coronary syndromes

### General principles<sup>10,11</sup>

- Aim for immediate attendance if suspected.
- Pre-hospital: make diagnosis, assess risk, ensure stability.
- Call a mobile coronary care unit.
- Achieve coronary perfusion and minimise infarct size.
- Prevent and treat cardiac arrest; have a defibrillator available to treat ventricular fibrillation.
- Optimal treatment is in a modern coronary care unit (if possible) with continuous ECG monitoring (first 48 hours), a peripheral IV line and intranasal oxygen.
- Pay careful attention to relief of pain and apprehension.
- Establish a caring empathy with the patient.
- Give aspirin as early as possible (if no contraindications).
- Prescribe a beta blocker and an ACE inhibitor early (if no contraindications).

*Note:* For a STEMI it is important to re-establish flow as soon as possible, usually by either thrombolytic therapy or primary angioplasty (preferably with stenting). Rescue angioplasty is usually used when large infarcts have not perfused at 60–90 minutes.<sup>9</sup>

### Hospital management<sup>9,11</sup>

- As for first-line management.
- Confirm ECG diagnosis: STEMI or NSTEMACS.

- Take blood for cardiac enzymes particularly troponin levels, urea and electrolytes.
- Organise an urgent cardiology consultation for risk stratification and a decision whether to proceed to coronary angiography and coronary reperfusion with PCI (or CABG) or with thrombolysis.

### Management of STEMI<sup>11</sup>

The optimal first-line treatment for the patient with a STEMI is urgent referral to a coronary catheter laboratory ideally within 60 minutes (the golden hour) of the onset of pain for assessment after coronary angiography for percutaneous transluminal coronary angioplasty (PTCA). If available and performed by an interventional cardiologist it has the best outcomes (level I evidence).

The principle is to achieve rapid reperfusion via primary angioplasty with a stent (optimal stent status currently under evaluation).

Adjunct therapy will include aspirin/clopidogrel and heparin and possibly a glycoprotein IIb/IIIa platelet inhibitor such as prasugrel, ticagrelor or abciximab.

#### First-line management (e.g. outside hospital)

- Perform an ECG and classify ACS into STEMI or NSTEMI, and notify the medical facility that will receive the patient (discuss over the telephone). The ECG is the sole test required to select patients for emergency perfusion
- Oxygen 4–6 L/min (aim to keep  $P_{aO_2} > 90\%$ )
- Secure an IV line (withdraw blood for tests especially troponin levels)
- Glyceryl trinitrate (nitroglycerine) 300 mcg ( $\frac{1}{2}$  tab) SL or spray (every 5 minutes as necessary to maximum of three doses). Beware of sildenafil (Viagra) and related drugs use and bradycardia—correct with atropine
- Aspirin 300 mg
- Morphine 2–5 mg IV statim bolus: 1 mg/min until pain relief (up to 15 mg) (If feasible it is preferable to give IV morphine 1 mg/min until relief of pain; this titration is easier in hospital.)

Acceptable time delay guidelines to PCI (from first medical contact to balloon inflation):<sup>11</sup>

Symptom time:	<1 hour	1–3 hours	3–12 hours	>12 hours
Acceptable delay:	60 minutes	90 minutes	120 minutes	Not recommended

### Management of NSTEMI

All patients with NSTEMI should have their risk stratified to direct management decisions.

#### Fibrinolytic therapy

If angioplasty is unachievable either through timing or the unavailability of the service (such as in rural locations) thrombolysis is an indication for STEMI and the sooner the better, but preferably within 12 hours of the commencement of chest pain.<sup>11</sup> The decision should be made by an experienced consultant, especially as PCI is not usually possible once fibrinolytic therapy has been given.

Second-generation fibrin-specific agents (reteplase, alteplase or tenecteplase) are the agents of choice. Streptokinase can be used but it is inappropriate for use in Indigenous people and those who have received it on a previous occasion. There are several other contraindications for the use of fibrinolytic agents.

Further management strategies include:

- Full heparinisation for 24–36 hours (after rt-PA—not after streptokinase), especially for large anterior transmural infarction with risk of embolisation, supplemented by warfarin.
- Use LMW heparin (e.g. enoxaparin 1 mg/kg SC bd or unfractionated heparin 5000–7500 units SC 12 hourly).
- Beta blocker (if no thrombolytic therapy or contraindications) as soon as possible: atenolol 25–100 mg (o) daily  
or  
metoprolol 25–100 mg (o) twice daily
- Consider glyceryl trinitrate IV infusion if pain recurs.
- Start early introduction of ACE inhibitors (within 24–48 hours) in those with significant left ventricular (LV) dysfunction (and other indications).
- Statin therapy to lower cholesterol.
- Treat hypokalaemia.
- Consider magnesium sulphate (after thrombolysis).
- Consider frusemide.

#### Post-AMI drug management

Proven:<sup>1,12,13</sup>

- beta blockers—within 12 hours
- ACE inhibitors—within 24 hours
- aspirin 75–150 mg + clopidogrel 75 mg (o) daily (alternatives to clopidogrel: ticagrelor or prasugrel)
- lipid-lowering drugs (e.g. statins)
- warfarin

Targets:

- BP <130/80; TC <4 mol/L; LDLC <2 mmol/L; TG <2 mmol/L

### Ongoing management

- Education and counselling
- Bed rest 24–48 hours
- Check serum potassium and magnesium
- Early mobilisation to full activity over 7–12 days
- Light diet
- Sedation
- Beta blocker (o): atenolol or metoprolol
- Warfarin where indicated (certainly if evidence of thrombus with echocardiography)
- ACE inhibitors for left ventricular failure and to prevent remodelling
- monitor psychological issues (e.g. anxiety)

### On discharge

- Rehabilitation program
- Continued education and counselling
- No smoking
- Reduce weight
- Encourage consumption of omega-3 fatty acids
- Regular exercise, especially walking
- Exercise test (to be considered)
- Continue beta blockers for 2 years
- Continue ACE inhibitors
- Aspirin 100–300 mg daily or clopidogrel 75 mg daily
- Warfarin where indicated (at least 3 months)

## Special management issues

### Indications for coronary angiography

- Development of angina
- Strongly positive exercise test
- Consider after use of streptokinase

### Management of the extensive infarction

- ACE inhibitors (even if no CCF)
- Radionuclide studies (to assess left ventricular function)
- Beta blockers (proven value in severe infarction) if no contraindications or LV dysfunction
- Anticoagulation

## Treating and recognising complications of STEMI

### Acute left ventricular failure

- Signs: basal crackles, extra (third or fourth) heart sounds, X-ray changes

- Treatment (according to severity) (refer to **CHAPTER 88**):
  - oxygen
  - diuretic (e.g. frusemide)
  - morphine IV
  - glyceryl trinitrate: IV, SL, (o) or topical
  - ACE inhibitors

### Cardiogenic shock (a major hospital management procedure)

Requires early specialist intervention which may include:

- treat hypotension with inotropes
- intra-aortic balloon pump
- urgent angiography ± angioplasty/surgery

### Pericarditis

This occurs in first few days after AMI (usually anterior AMI), with onset of sharp pain.

- Signs: pericardial friction rub
- Treatment:<sup>9</sup> anti-inflammatory medication (e.g. aspirin, indomethacin or ibuprofen for pain) with caution

*Note:* Avoid anticoagulants.

### Post-AMI syndrome (Dressler syndrome)

This occurs weeks or months later, usually around 6 weeks.

- Features: pericarditis, fever, pericardial effusion (an autoimmune response)
- Treatment: as for pericarditis

### Left ventricular aneurysm

This is a late complication.

- Clinical: cardiac failure
- Features: arrhythmias, embolisation
- Signs: double ventricular impulse, fourth heart sound, visible bulge on X-ray
- Diagnosis: 2D electrocardiography
- Treatment:
  - antiarrhythmic drugs
  - anticoagulants
  - medication for cardiac failure
  - possible aneurysmectomy

### Ventricular septal rupture and mitral valve papillary rupture

This presents with severe cardiac failure and a loud pansystolic murmur. Both have a poor prognosis and early surgical intervention may be appropriate.

## Cardiac arrhythmias

All types are common with STEMI and require treatment according to guidelines in **CHAPTER 70**. Methods may include defibrillation, cardioversion and pacemaking. Past infarct prophylaxis with IV lignocaine is not indicated.<sup>9</sup>

## Anxiety and depression

Patients require anticipatory guidance and support including education, reassurance and counselling. If necessary anxiolytic agents and antidepressants may help recovery.

## Management of other serious spontaneous causes of chest pain

### § Aortic dissection

- Early definitive diagnosis is necessary: best achieved by transoesophageal echocardiography.
- 50% of patients are hypertensive; so need pharmacological control of hypertension with IV nitroprusside and beta blockers.
- Emergency surgery needed for many, especially for type A (ascending aorta involved).

*Note:* There is an increased incidence during pregnancy.

### § Pulmonary embolus

Investigations to diagnose suspected pulmonary embolus (choose from):<sup>3,14,15</sup>

- chest X-ray and ECG
- CT pulmonary angiography (first-line study)
- radionuclide imaging—the ventilation/perfusion (V/Q) study
- digital subtraction angiography
- D-dimer assay
- Doppler sonography of lower limbs
- arterial blood gases

## Management (specialist care)

Needs supportive medical care and anti-coagulation:

heparin IV: 5000 U as immediate bolus,  
continuous infusion 30 000 U over 24 hours  
*or*  
heparin 12 500 U (sc) bd

*Note:* The dose of heparin should then be adjusted daily to maintain the APTT between 1.5 and 2 times control.

- Continue heparin 5–10 days.
- Warfarin (o) after 3 to 4 days or immediate; then continue heparin for 3 days after international normalised ratio (INR) at desired level.

*Note:* Thrombolytic therapy either IV or into the pulmonary artery can be used for major embolism. Surgical embolectomy is rarely necessary but needed if very extensive.

### § Pneumothorax

- Most episodes resolve spontaneously without drainage (at least 20% lung collapse).
- Drainage of the pleural space indicated for a large pneumothorax >25% pleural area, with persistent dyspnoea.
- Guidelines:
  - <25% collapse, no symptoms: observe
  - <25% collapse + persisting symptoms: drain
  - >25% collapse: usually drain
- For recurrent attacks, excision of cysts or pleurodesis may be necessary.
- Statistics indicate a 30–50% recurrence rate of spontaneous pneumothorax (most within 12 months), 35% on the same side, 10–15% on the opposite side. Recurrence should not recur after a pleurodesis where the lung surface has been rendered adherent to the chest wall.

## Acute tension pneumothorax

For urgent cases insert a 12–16 gauge needle into the pleural space through the second intercostal space on the affected side. Replace with a formal intercostal catheter connected to underwater seal drainage.

## Treatment of oesophageal disorders

### Gastro-oesophageal reflux

- Achieve normal weight if overweight.
- Avoid coffee, alcohol and spicy foods.
- Avoid large meals and overeating (keep to small meals).
- Use antacids or alginate compounds (e.g. Gaviscon, Mylanta Plus).
- If persistent: acid suppression—H<sub>2</sub>-receptor blockers (e.g. cimetidine, ranitidine)  
*or*  
proton-pump inhibitors (e.g. omeprazole)

## Oesophageal spasm<sup>16</sup>

Long-acting nitrates (e.g. isosorbide dinitrate 10 mg tds)

or

Calcium-channel blockers (e.g. nifedipine CR 20–30 mg once daily)

*Note:* Attend to lifestyle and dietary factors, as for reflux.

## Musculoskeletal causes of chest wall pain

There are many musculoskeletal causes, most of which can be eliminated by the history and physical examination. Some of the causes listed in [TABLE 40.9](#) are very uncommon and often part of a general disorder, such as ankylosing spondylitis. Muscular tears or strains of the chest wall are quite common. A differential diagnosis is a fractured rib including a cough fracture.

Musculoskeletal chest pain is typically aggravated or provoked by movements such as stretching, deep inspiration, sneezing and coughing. The pain tends to be sharp and stabbing in quality but can have a constant aching quality.

Costochondritis is a common cause of anterior pain, which is generally well localised to the costochondral junction and may also be a component of an inflammatory disorder, such as one of the spondyloarthropathies.

Management is generally conservative with analgesics, gentle massage with analgesic creams and NSAIDs if there is an inflammatory component. Other measures that can help for very painful

**Table 40.9** Musculoskeletal causes/origins of chest wall pain (front and back)

Injury to thoracic spine → dysfunction

Vertebral fracture:

- trauma
- pathological:
  - osteoporosis
  - metastatic disease
  - multiple myeloma

Intercostal muscle strains/tears

Rib disorders:

- fractures
- slipping rib

Costochondritis

Tietze syndrome

Fibromyalgia

chest wall problems are localised injections of local anaesthetic with or without corticosteroids (with care not to penetrate the parietal pleura) and a modified support (especially for rib injuries) in the form of a special elasticised rib belt (called a universal rib belt) that gives excellent support and symptom relief while permitting adequate lung expansion.

## Posterior chest (thoracic back) pain

Disorders of the musculoskeletal system represent the most common cause of thoracic (dorsal) back pain, especially dysfunction of the joints of the thoracic spine. Refer to [CHAPTER 37](#) for more detail. Probably the commonest cause is costovertebral dysfunction caused by overstress of rib articulations with vertebrae (the costovertebral joints). This fact is clearly demonstrated with the midline thoracic back pain following cardiac surgery when these joints are compressed during sternotomy and splaying of the chest walls.

The back pain may be associated with simultaneous referred anterior chest pain or abdominal pain (see [FIG. 37.3](#) in [CHAPTER 37](#)).

## Acute thoracic back pain

Although posterior pain is invariably caused by vertebral dysfunction, there are several other important causes, including serious bone disease (leading to compression fractures) and life-threatening visceral and vascular causes. Refer to red flag pointers and [TABLE 37.3](#) and management guidelines in [CHAPTER 37](#).

*Note:*

- Intervertebral disc protrusions are rare in the thoracic spine.
- Rarely, a penetrating peptic ulcer can present with mid to lower thoracic back pain.

## When to refer

- Obvious or suspected myocardial infarction, especially with extensive infarction
- Transfer to major centre with complications of AMI:
  - rupture of septum or papillary muscle
  - aneurysm
  - refractory arrhythmias
  - cardiogenic shock
- Patients with persistent post-infarction angina
- Angina:
  - patient with angina not responding to drug treatment
  - patient with unstable angina

- angina lasting for longer than 15 minutes (unresponsive to sublingual nitrate) needs urgent hospital admission
- Suspected or proven pulmonary embolus or dissecting aneurysm or other serious life-threatening problem (after initial first-line measures, e.g. decompression of tension pneumothorax)
- Suspected oesophageal or other gastrointestinal disorder (e.g. duodenal ulcer), for endoscopy or appropriate gastroenterological evaluation

### Practice tips

- All sudden acute chest pain is cardiac (and potentially fatal) until proven otherwise.
- A careful history is the basis of the diagnosis.
- Mitral valve prolapse is often an undiagnosed cause of chest pain: keep it in mind, especially if pain is recurrent and intermittent (proved by echocardiography).
- Calcium antagonists can cause peripheral oedema, so be careful not to attribute this to heart failure.
- The pain of oesophageal spasm can be very severe and mimic myocardial infarction.
- Oesophageal spasm responds to glyceryl trinitrate: do not confuse with angina.
- Intervertebral disc protrusions are a very rare cause of severe sudden thoracic pain (T2–9).
- Infective endocarditis can cause pleuritic posterior chest pain.
- Family doctors need to monitor carefully patients who are taking anticoagulants. The INR ratio, which needs to be kept between 2 and 3, should be tested at least monthly.
- The sudden onset of dyspnoea without chest pain can occur frequently with (painless) myocardial infarction and pulmonary embolism.
- If a patient recovering from an AMI suddenly develops shortness of breath, consider ventricular septal rupture, mitral valve papillary rupture (with mitral regurgitation), pulmonary embolus and other serious complications.
- Treat (indefinitely) all post-MI patients with ACE inhibitors, and all post-MI and acute ischaemic syndrome patients with beta blockers.<sup>12,13</sup>

- Use antiplatelet agents indefinitely—100–300 mg aspirin daily or, if contraindicated, clopidogrel 75 mg daily or warfarin. Some studies favour combining aspirin and clopidogrel.

Henry Shaw (1818–85), *Josh Billin* gs

Constipation is the difficult passage of small hard stools. The Rome III criteria (refer [www.romecriteria.org](http://www.romecriteria.org)) define it as having two or more of the following, for at least 12 weeks:

- infrequent passage of stools <3/week
- passage of lumpy or hard stools at least 25% of time
- straining >25% of time
- sensation of incomplete evacuation >25% of time
- use of manual manoeuvres >25% of time
- sensation of anorectal obstruction/blockage >25% of time

Accordingly it affects more than 1 in 5 in the population.<sup>1</sup>

However, the emphasis should be on the consistency of the stool rather than on the frequency of defecation; for example, a person passing a hard stool with difficulty once or twice a day is regarded as constipated, but the person who passes a soft

- Intractable constipation (obstipation) is a challenge at both ends of the age spectrum but improved agents have helped with management.

stool comfortably every two or three days is not constipated. Various causes of chronic constipation are summarised in [FIGURE 41.1](#).

## A diagnostic approach

Using the diagnostic strategy model (see [TABLE 41.1](#)), the five self-posed questions can be answered as follows.

## Probability diagnosis

The commonest is 'idiopathic' constipation where there is no structural or systemic disease. This is also referred to as 'functional' constipation.

Probably the most frequent single factor causing constipation in Western society is deficiency in dietary fibre, including fruit, green leafy vegetables and wholemeal products. The amount of fibre in our diet is directly related to stool weight and to colonic transit time. The average colonic transit time in the large bowel for Westerners is 60 hours; for a rural African on a very high-fibre diet it is 30 hours. Constipation is also a common problem in pregnancy.

## Serious disorders not to be missed

### Neoplasia

It is obvious that colonic or anorectal neoplasms must not be missed in a patient, especially middle-aged or elderly, presenting with constipation or other change in bowel habit. Most cases present with either complete or incomplete bowel obstruction.

Extrinsic malignancy, such as lymphoma or ovarian cancer, compressing or invading the rectum, also has to be considered. Cancer of the large bowel is most prevalent in our society and appropriate screening examinations, including rectal examination, sigmoidoscopy and colonoscopy, must be considered where appropriate.

## Key facts and checkpoints

- The survey showed 10% of adults and 6% of children reported constipation in the preceding 2 weeks.
- Up to 20% of British adults take regular laxatives.<sup>2</sup>
- Constipation from infancy may be due to Hirschsprung disorder.
- Diet is the single most important factor in preventing constipation.
- Beware of the recent onset of constipation in the middle-aged and the elderly.
- Bleeding suggests cancer, haemorrhoids, diverticular disorder and inflammatory bowel disease.
- Unusually shaped stools (small pellets or ribbon-like) suggest irritable bowel syndrome.
- Always examine the abdomen and rectum.
- Plain abdominal X-rays are generally not useful in the diagnosis of chronic constipation.
- The flexible sigmoidoscope is far superior to the rigid sigmoidoscope in investigation of the lower bowel.

FIGURE 41.1 Causes of chronic constipation

## Megacolon

In children it is important to detect the presence of megacolon, for example megacolon secondary to Hirschsprung disorder. Symptoms dating from birth suggest Hirschsprung disorder, which occasionally may present for the first time in adult life.

## Neurological disorders

Constipation, often with faecal impaction, is a common accompaniment to paraplegia, multiple sclerosis, cerebral palsy and autonomic neuropathy.

## Alarm symptoms

- Recent constipation in >40 years of age
- Rectal bleeding
- Family history of cancer

## Pitfalls

The pitfalls can be summarised as follows:

- impacted faeces
- depressive illness

- purgative abuse
- local anal lesions
- drugs

Although patients with impacted faeces usually present with spurious diarrhoea, it is a form of idiopathic constipation and is very commonly encountered in general practice, especially in bedridden elderly people.

Anal pain or stenosis, such as fissure-in-ano, thrombosed haemorrhoids, perianal haematoma or ischio-rectal abscess, leads to constipation when the patient is hesitant to defecate.

## General pitfalls and tips

- Ensure the patient is truly constipated, and not having unreal expectations of regularity.
- Ensure that the anthraquinone group of laxatives, including 'Ford pills', is never used long term because they cause melanosis coli and associated megacolon.
- Be very wary of alternating constipation and diarrhoea (e.g. colon cancer).

- In a busy practice be careful not to let 'familiarity breed contempt' (e.g. onset of hyperparathyroidism, cancer).
- Avoid relying solely on the rectal examination to exclude cancer.

## Seven masquerades checklist

Three of the primary masquerades (see TABLE 41.1) are important causes of constipation, namely drugs, depression and hypothyroidism. Many drugs (see TABLE 41.2) may be associated with constipation, especially codeine and its derivatives, antidepressants, aluminium and calcium antacids. A careful drug history is thus mandatory. Fortunately the constipation is usually relieved once the drug

**Table 41.1** Chronic constipation: diagnostic strategy model

Q. Probability diagnosis
A. Functional constipation <sup>3</sup> <ul style="list-style-type: none"> <li>• primary—slow transit, dyssynergic defecation</li> <li>• lifestyle—diet, low fluids, bad habits</li> </ul>
Q. Serious disorders not to be missed
A. Intrinsic neoplasia: colon, rectum or anus, especially colon cancer
Extrinsic malignancy (e.g. lymphoma, ovary)
Hirschsprung (children)
Q. Pitfalls (often missed)
A. Impacted faeces
Local anal lesions e.g. fissure, haemorrhoids
Drug/purgative abuse
Hypokalaemia
Depressive illness
Acquired megacolon
Diverticular disease
Rarities:
• lead poisoning
• hypercalcaemia
• hyperparathyroidism
• dolichocolon (large colon)/megarectum
• Chagas disease
• systemic sclerosis
Q. Seven masquerades checklist
A. Depression
Diabetes (autonomic neuropathy)
Drugs
Thyroid disorder (hypo)
Spinal dysfunction (severe only)
Q. Is the patient trying to tell me something?
A. May be functional (e.g. depression, anorexia nervosa).

is withdrawn. Constipation can be a significant symptom in all types of depressive illness and may be aggravated by treatment with antidepressants.

**Table 41.2** Drugs associated with constipation

Analgesics (inhibitors of prostaglandin synthesis)
Antacids (containing calcium carbonate or aluminium hydroxide)
Anticholinergic agents, antispasmodics
Antidiarrhoeal agents
Antiepileptics
Antihistamines (H <sub>1</sub> -receptor blockers)*
Antiparkinson drugs*
Antipsychotic drugs*
Barbiturates
Barium sulphate
Benzodiazepines
Calcium-channel blockers (verapamil)
Calcium supplements
Cholestyramine
Clonidine
Cough mixtures
Cytotoxic drugs
Diuretics that cause hypokalaemia
Gabapentin
Ganglionic blocking agents
Heavy metal (especially lead)
Iron supplements
Laxatives (chronic use)
Monoamine oxidase inhibitors
Muscle relaxants
Opioid analgesics (e.g. codeine)
SSRIs
Tricyclic antidepressants*

\* Denotes anticholinergic effect.

The metabolic causes of constipation include hypothyroidism, hypercalcaemia and porphyria. We occasionally encounter the patient with hypercalcaemia, for example, hyperparathyroidism, but thyroid dysfunction is relatively common in general practice.

Diabetes rarely can be associated with constipation when an autonomic neuropathy can lead to alternating bouts of constipation and diarrhoea.

## Psychogenic considerations

Constipation may be a manifestation of an underlying functional problem and psychiatric disorder, such as depression, anorexia nervosa, schizophrenia or drug abuse. Drug abuse must always be considered, keeping in mind that narcotics and laxatives present with rebound constipation. More commonly, it may reflect the inactive lifestyle of the patient and provide a good opportunity for appropriate counselling.

## The clinical approach

### History

It is important to ask patients to define exactly what they mean by constipation. Some people believe that just as the earth rotates on its axis once a day, so should their bowels open daily to ensure good health. As always, a careful history is appropriate, including stool consistency, frequency, ease of evacuation, pain on defecation and the presence of blood or mucus. A dietary history is very relevant in the context of constipation.

### Key questions

- How often do you go to the toilet?
- What are your bowel motions like?
- Are they bulky, hard, like rabbit pellets or soft?
- Is there pain on opening your bowels?
- Have you noticed any blood?
- Have you noticed any lumps?
- Do you have any soiling on your underwear?
- How do you feel in yourself?
- What medications are you taking?

### Diary

Ask the patient to keep a 10-day diary recording frequency and nature of stools, and whether any difficulty was experienced when passing stool.

### Examination

The important aspects are abdominal palpation and rectal examination. Palpation may reveal the craggy mass of a neoplasm, faecal retention (especially in the thin patient) or a tender spastic colon. The perianal region should be examined for localised disease. The patient should be asked to bear down to demonstrate perianal descent, haemorrhoids or mucosal prolapse. Perianal sensation and the anal reflex should be

tested. Digital rectal examination is mandatory, and may reveal a rectal tumour and faecal impaction, as well as testing for rectal size and tone. If there is a history from infancy, a normal or narrow rectum suggests congenital megacolon (Hirschsprung disorder) but, if dilated, acquired megacolon.

General signs that may be significant in the diagnosis of constipation are summarised in **FIGURE 41.2**.

**FIGURE 41.2** Possible significant abdominal signs in the patient with constipation

### Rectal examination

The most important first step is to *do* the examination.

### Method

- Explain to the patient what will happen.
- After inspection with the patient in the left lateral position and with knees drawn up, a lubricated gloved index finger is placed over the anus.
- Part the buttocks.
- Ask the patient to concentrate on slow deep breathing.

- With gentle backwards pressure the finger is then inserted slowly into the anal canal and then into the rectum (it helps patient comfort if they push down or squeeze to accommodate the finger).
- Rotate the finger anteriorly to feel the prostate in males and the cervix in females.
- The finger will reach to about 7–8 cm with gentle thrusting into the perineum.
- Gently withdraw the finger and examine the whole circumference of the rectum by sweeping the finger from posterior on both sides.

### Points to note

- Any pain: fissure, proctitis, excoriation from diarrhoea (a rectal examination will not be possible in the presence of a fissure)
- Induration from a chronic fissure or fistula in the anal canal
- The sphincter tone
- The nature of the faeces (? impaction)
- The rectal wall: cancer is usually indurated, elevated and ulcerated; a villous adenoma has a soft velvety feel
- Posteriorly: the sacrum and coccyx
- Laterally: the side walls of the pelvis
- Anteriorly: cervix and pouch of Douglas in the female; prostate and rectovesical pouch in the male

### Prostate examination

- It feels larger if the patient has a full bladder.
- The normal prostate is a firm smooth rubbery bilobed structure (with a central sulcus) about 3 cm in diameter.
- A craggy hard mass suggests cancer.
- An enlarged smooth mass suggests benign hypertrophy.
- A tender, nodular or boggy mass suggests prostatitis.

### Practice tip on treatment

A suitable method of doing a rectal examination on a home visit (in the absence of gloves in the doctor's bag) is to apply moist soap around the finger and caked under the nail (in case of breakage), then plastic wrap and finally petroleum jelly (e.g. Vaseline).

Before resorting to a good old-fashioned '3H' enema (hot water, high and a hell of a lot), use a sorbitol compound (e.g. Microlax 5 mL enema). It can be carried in the doctor's bag, is very easy to insert and is most effective.

### A common pitfall

In the female the cervix or a vaginal tampon can be mistaken for a mobile extrarectal tumour.

### Endoscopy

Sigmoidoscopy—in particular, flexible sigmoidoscopy with examination of the rectosigmoid—is important in excluding local disease; search for abnormalities such as blood, mucus or neoplasia. The insufflation of air sometimes reproduces the pain of the irritable bowel syndrome.

It is worth noting that 60% of polyps and cancers will occur in the first 60 cm of the bowel<sup>4</sup> and diverticular disorder should be evident with the flexible sigmoidoscope.

The presence of melanosis coli is an important sign—it may give a pointer to the duration of the constipation and the consequent chronic intake (perhaps denied) of anthraquinone laxatives.

### Investigations

These can be summarised as follows:

- Haematological:
  - haemoglobin
  - ESR
- Stools for occult blood
- Biochemistry (where suspected):
  - thyroid function tests
  - serum calcium
  - serum potassium
  - carcinoembryonic antigen (a tumour marker)
- Radiological:
  - CT colonography (virtual colonography)
  - double contrast barium enema (especially for primary colonic disease, e.g. megacolon)
  - bowel transit studies, using radio-opaque shapes taken orally and checking progress by abdominal X-ray or stool collection
- Physiological tests:
  - anal manometry—test anal tone
  - rectal sensation and compliance, using an inflatable rectal balloon
  - dynamic proctography, to determine disorders of defecation
  - Rectal biopsy, to determine aganglionia

### Constipation in children

Constipation is quite common in children but no cause has been discovered in 90–95%. The most common factor is diet. Constipation often begins after weaning or with the introduction of cow's milk. It is rare with

breastfeeding. Low fibre intake and a family history of constipation may be associated factors.<sup>5</sup> Most children develop normal bowel control by 4 years of age (excluding any physical abnormality). It is normal to have a bowel movement every 2–3 days, providing it is of normal consistency and is not painful.

It is important to differentiate between encopresis and constipation:

- *encopresis* or faecal incontinence is the inappropriate passage of normal stool
- *constipation* is difficulty or delay in passing the stool with incomplete emptying of the rectum: this can present as *soiling*, due to faecal retention with overflow of liquid faeces (paradoxical diarrhoea)

## Other important conditions

Hirschsprung disorder:

- consider if delay in passing first meconium stool and subsequent constipation

Anal fissure in infants:

- consider if stool hard and associated with pain or bleeding
- the mainstay of treatment is dietary manipulation

## Principles of treatment of functional constipation

- Encourage relaxed child–parent interaction with toilet training, such as appropriate encouragement, ‘after breakfast habit’ training.
- Introduce psychotherapy or behaviour modification program, especially where ‘fear of the toilet’ exists.
- Establish an empty bowel: remove any severely impacted faeces with microenemas (e.g. Microlax), and even disimpaction under anaesthesia if necessary. A good guide if faecal ‘rocks’ are visible on X-ray.
- Advice for parents of children over 18 months:
  - Drink ample non-milk fluids each day—several glasses of water, unsweetened fruit juice or milk.
  - Use prune juice, which contains sorbitol.
  - Get regular exercise—walking, running, outside games or sport.
  - Provide high-fibre foods—high-fibre cereals, wholegrain bread, brown rice, wholemeal pasta, fresh fruit with skins left on where possible, dried fruits such as sultanas, apricots or prunes, fresh vegetables.

- Use a pharmaceutical preparation as a last resort to achieve regularity.

*First line:*<sup>6</sup>

- paraffin oil (e.g. Parachoc): RCT evidence indicates suitable and better than stimulant laxative

osmotic laxative (e.g. lactulose):

- 1–5 years: 5 mL bd
- 6–12 years: 10 mL bd
- >12 years: 15 mL bd

or

macrogol 3350 with electrolytes:

- 2–12 years: 1 sachet Movicol half in 60 mL water once daily
- >12 years: 1 sachet Movicol (or 2 Movicol half) daily

Severe constipation/faecal impaction:

- consider admission to hospital
- abdominal X-ray
- macrogol 3350 with electrolytes (double above doses and water)
- Microlax enema

If unsuccessful, add ColonLYTLEY via nasogastric tube or sodium phosphate enema (Fleet Enema) (not <2 years).

## Constipation in the elderly

Constipation is a common problem in the elderly with a tendency for idiopathic constipation to increase with age. In addition the chances of organic disease increase with age, especially colorectal cancer, so this problem requires attention in the older patient. Faecal impaction is a special problem in the aged confined largely to bed. Constipation is often associated with Parkinson disease. In the elderly an osmotic laxative such as sorbitol or lactulose may be required for long-standing refractory constipation but stimulant and other non-osmotic laxatives should be avoided.

## Manual disimpaction

If manual disimpaction should be necessary, the unpleasant procedure can be rendered virtually odourless if the products are ‘milked’ or scooped directly into a container of water. A large plastic cover helps restrict the permeation of the smell.

Discomfort and embarrassment are reduced by this method and by adequate premedication (e.g. IV midazolam and IV fentanyl) if large faecaliths are present.

## § Idiopathic constipation

It is best to classify idiopathic constipation into three subgroups:

- 1 simple constipation
- 2 slow transit constipation
- 3 normal transit constipation (irritable bowel syndrome)

Of these, the commonest is simple constipation, which is essentially related to a faulty diet and bad habit. Avery Jones,<sup>7</sup> who defined the disorder, describes it as being due to one or more of the following causes:

- faulty diet
- neglect of the call to stool
- unfavourable living and working conditions
- lack of exercise
- travel

*Dyschezia*, or lazy bowel, is the term used to describe a rectum that has become unresponsive to faecal content, and this usually follows repeated ignoring of calls to defecate.

Slow transit constipation occurs primarily in women with an apparently normal colon, despite a high-fibre intake and lack of the other causes described by Avery Jones. Many are young, with a history dating from early childhood or, more commonly, adolescence. Constipation may follow childbirth, uncomplicated abdominal surgery or a period of severe dieting. However, in the majority no precipitating cause is evident.

A *defecatory disorder* is where there is a paradoxical contraction rather than normal relaxation of the anal sphincter and associated muscles responsible for evacuation.

## Management

Most patients have simple constipation and require reassurance and education once an organic cause has been excluded.

## Advice to patients

- Adequate exercise, especially walking, is important.
- Develop good habit: answer the call to defecate as soon as possible. Develop the 'after breakfast habit'. Allow time for a good relaxed breakfast and then sit on the toilet. Don't miss meals—food stimulates motility.
- Avoid laxatives and codeine compounds (tablets or mixture).

- Take plenty of fluids, especially water and fruit juices (e.g. prune juice).
- Eat an optimal bulk diet. Eat foods that provide bulk and roughage, such as vegetables and salads, cereals (especially wheat fibre), fresh and dried fruits, and wholemeal bread. Enough fibre should be taken to convert stools that sink to stools that float.

Examples of food with good bulk properties are presented in **TABLE 41.3**.<sup>8</sup> Fruit has good fibre, especially in the skin, and some have natural laxatives (e.g. prunes, figs, rhubarb, apricots).

**Table 41.3** Foods with bulk-forming properties (from least to most)

Potato
Banana
Cauliflower
Peas
Cabbage
Lettuce
Apple
Carrot
Bran

## Treatment (pharmaceutical preparations)

Some patients may not tolerate unprocessed bran but tolerate pharmaceutical preparations better (see **TABLE 41.4**). An appropriate choice would be one of the hydrophilic bulk-forming agents such as ispaghula or psyllium. Avoid stimulant laxatives except for short sharp treatments.

## First-line therapy<sup>6</sup>

Use a general bulking agent e.g. psyllium or ispaghula granules 1–2 teaspoonsful (o) once or twice daily.

## Second-line therapy

Use an osmotic laxative or a fibre-based stimulant preparation e.g. macrogol 3350 + 1 to 2 sachets, each dissolved in 125 mL water once daily  
 or  
 lactulose syrup, 15–30 mL (o) daily until response, then 10–20 mL daily  
 or  
 dried fruits with senna leaf (Nu-Lax) 10 g nocte

**Table 41.4** Therapeutic agents (laxatives) to treat constipation (with examples)

Hydrophilic bulk-forming agents
Psyllium mucilloid (Agiofibe, Metamucil)
Sterculia (Granocol, Normacol)
Ispaghula (Agiolax, Fybogel)
Methylcellulose
Wheat bran/dextrin (Benefiber)
Crude fibre (Fibyrax Extra)
Stimulant (irritant) laxatives
Sodium picosulfate
Anthraquinones: senna (Senokot/Sennetabs), senna with dried fruits (Nu-Lax), sennosides A and B; cascara
Frangula bark (in Normacol Plus)
Castor oil
Triphenylmethanes: bisacodyl (e.g. Dulcolax); picosulfate
Osmotic laxatives
Macrogol 3350 with electrolytes (e.g. Movicol)
Magnesium sulphate (Epsom salts/Colocap Balance)
Magnesium hydroxide (milk of magnesia)
Lactulose (several agents)
Mannitol
Sodium phosphate mixture
Sorbitol (Sorbilax)
Saline laxatives
Stool-softening/lubricating agents
Liquid paraffin (Agarol)
Docusate—poor evidence of efficacy
Poloxamer
Glycerin suppositories
Sorbital/sodium compounds (Microlax)
Laxatives in suppository form
Glycerin/glycerol suppository
Sorbitol sodium compounds (e.g. Fleet Enema)
Sodium phosphate enema (e.g. Fleet)
Stimulant microenema or suppository (e.g. Bisa-lax)
Stool-softener microenema (e.g. Enamax)

*Note:* ColonLYTELY used for colonoscopy preparation contains macrogol, sodium sulphate and other mineral salts

### Third-line therapy

(Recheck cause.)

Magnesium sulphate 1–2 teaspoons (15 g) in water once or twice daily (if normal kidney function)

or

as capsules (Colocap Balance) 15 caps over 15 minutes

or

combined bulking/stimulating agent (e.g. frangula/sterculia [Normacol plus])

or

glycerin suppository (retain for 15–20 minutes)

or

sodium citrate or phosphate enema (e.g. Fleet Enema)

or

Microlax enema

## § Faecal impaction

This is a difficult problem, especially in the older person who may not be aware of the problem especially if they have spurious diarrhoea. Symptoms include malaise, anorexia and nausea, confusion, headache, abdominal discomfort  $\pm$  colic and bloating, a sense of inadequate defecation and frequent amounts of small stool. Complications include spurious diarrhoea, faecal incontinence, bowel obstruction, urinary incontinence or retention. It often follows opioid medication. Confirm with rectal examination  $\pm$  plain X-ray of abdomen. Treat with oral or osmotic laxatives (e.g. 8 sachets of macrogol 3350 for 3 days with or without rectal suppositories) or enema e.g. Fleet Enema, Microlax.

## § Colorectal cancer

### General features

- Commonest GIT malignancy
- Second most common cause of death from cancer in Western society
- Generally men over 50 years (90% of all cases)
- Mortality rate about 60%
- Good prognosis if diagnosed early
- Two-thirds in descending colon and rectum

Refer to section on genetics of colorectal cancer (see CHAPTER 18).

### Predisposing factors

- Ulcerative colitis (long-standing)
- Familial: familial adenomatous polyposis (FAP), hereditary non-polyposis colorectal cancer
- Colonic adenomata
- Decreased dietary fibre

### Lifetime risk

This is determined by the family history (see TABLE 41.5).

Consider referral to a familial cancer clinic for assessment.

### Symptoms

- Blood in the stools
- Mucus discharge

**Table 41.5** Family history and lifetime risk of colorectal cancer<sup>9</sup>

Family history	Lifetime risk
None: population risk	1:50
One first-degree relative >45 years	1:17
One first-degree relative and one second-degree relative	1:12
One first-degree relative <45 years	1:10
Two first-degree relatives (any age)	1:6
Hereditary non-polyposis colon cancer	1:2
Familial adenomatous polyposis	1:1

- Recent change in bowel habits (constipation more common than diarrhoea)
- Alternating constipation with spurious diarrhoea
- Bowel leakage when flatus passed
- Unsatisfactory defecation (the mass is interpreted as faeces)
- Abdominal pain (colicky) or discomfort (if obstructing)
- Rectal discomfort
- Symptoms of anaemia
- Rectal examination—this is appropriate because many cancers are found in the lowest 12 cm and most can be reached by the examining finger

### Obstruction (distension with ↑ pain)

If obstructing, there is a risk of rupture of the caecum.

Surgery is needed to circumvent the closed loop obstruction.

### Spread

- Lymphatics → epigastric and para-aortic nodes
- Direct → peritoneum
- Blood → portal circulation

Various forms of presentation of large bowel cancers are shown in **FIGURE 41.3**.

### Investigations

- FOBT: immunochemical tests (e.g. Inform and InSure) do not require dietary or medication restriction
- CT colonography (investigation of choice)
- Serum CEA level is not useful for diagnosis but is useful for monitoring response to treatment
- Sigmoidoscopy, especially flexible sigmoidoscopy
- Double contrast, barium enema may miss tumours and is being superseded by other imaging
- Ultrasonography and CT scanning not useful in primary diagnosis; valuable in detecting spread especially hepatic metastases
- PET scanning (if available) is useful for follow-up

If FOBT is positive—investigate by colonoscopy or by flexible sigmoidoscopy.

**FIGURE 41.3** Various forms of presentation of large bowel cancer

## Screening<sup>10</sup>

An FOBT every 2 years is now recommended for all people from 50 years (see guidelines in **CHAPTER 9**).

Colonoscopy is recommended as follows:

- Moderate risk: every five years from 50 years or 10 years younger than when a family member presented
- High risk: guided by clinical genetics team but as a rule yearly or 2 yearly commencing at 25 years, and every 12 months from 12–15 years of age if a strong family history of FAP.<sup>11</sup>

In addition, flexible sigmoidoscopy and rectal biopsy for those with ulcerative colitis. Refer to a bowel cancer specialist to plan appropriate surveillance.

## Management

Early surgical excision is the treatment, with the method depending on the site and extent of the cancer. Dukes' classification gives a guide to prognosis (see **TABLE 41.6**). The survival rates for Dukes C cancer have improved with more effective chemotherapy.

**Table 41.6** Modified Dukes' classification of colorectal cancer

Stage	Pathologic description	Approx. 5-year survival %*
A	Cancer limited to mucosa and submucosa	88
B	Cancer extends into muscularis or serosa	70
C	Cancer involves regional lymph nodes	43
D	Distant metastases (e.g. liver)	7

\* percentage ranges cover several studies

Source: Cancer Council Australia, 2008

Overall survival just over 50%<sup>11</sup>

Follow-up includes:

- CEA antigen
- colonoscopy
- abdominal imaging: ultrasound or CT scan of liver

## § Congenital megacolon Hirschsprung disorder (aganglionosis)

### Clinical features

- Congenital
- Constipation from infancy

- Abdominal distension from infancy
- Possible anorexia and vomiting
- Male to female ratio = 8:1
- Rectal examination—narrow or normal rectum
- Abdominal X-ray/barium enema—distended colon full of faeces to narrow rectum
- Diagnosis, confirmed by full thickness biopsy, shows absence of ganglion cells
- Absent rectoanal reflex on anal manometry

### Treatment

Resect narrow segment after preliminary colostomy.

## § Acquired megacolon

### Clinical features

- In older children and adults
- Mainly due to bad habit
- Can be caused by:
  - chronic laxative abuse
  - milder form of Hirschsprung disorder
  - Chagas disease (Latin America)<sup>2</sup>
  - hypothyroidism (cretinism)
  - systemic sclerosis
- Marked abdominal distension
- Rectal examination—dilate loaded rectum, lax sphincter
- Abdominal X-ray/barium enema—distended colon full of faeces but no narrowed segment

### Treatment

Re-education of bowel habit is required.

## When to refer<sup>4</sup>

Patients with constipation or change in bowel habit of recent onset without obvious cause need further investigation.

- Patients with chronic symptoms who do not respond to simple measures should be referred.

## Practice tips

- The objectives of treatment should be to exclude organic disease and then reassure and re-educate the patient about normal bowel function.
- Discourage long-term use of laxatives, suppositories and microenemas.
- The laxatives to discourage should include anthraquinone derivatives, bisacodyl, phenolphthalein, magnesium salts, castor oil and mineral oils.

- First-line treatment of functional constipation (unresponsive to simple measures) is a bulking agent. An osmotic laxative is good second-line therapy.
- Bleeding with constipation indicates associated organic illness—exclude bowel cancer. Bright red blood usually means haemorrhoids.
- Beware of hypokalaemia causing constipation in the elderly patient on diuretic treatment.
- If cancer can be felt on rectal examination an abdominal perineal procedure with colostomy usually follows; if not, an anterior resection is generally the rule.

*I bounded into bed. The bound made me cough—I spat—it tasted strange—it was bright red blood—I don't want to find this is real consumption—I shan't have my work written. That's what matters. How unbearable it would be to die—nothing real finished.*

Katherine Mansfield (1888–1923), Diary entry 1918

Cough is one of the five most common symptoms presenting in family practice. There is a wide range of causes (see TABLE 42.1) with the great majority being minor and self-limiting, although the possibility of serious causes such as bronchial carcinoma should always be kept in mind.

It is a feature of smokers, who often have a morning cough with little sputum. Coughing can also be initiated by pleural irritation. It is a reflex that provides an essential protective service. It serves to remove substances that may have been accidentally inhaled and removes excess secretions or exudates that may accumulate in the airway.

**Table 42.1** Significant causes of cough

Non-productive (dry cough)

Upper respiratory tract infection

Lower respiratory tract infection:

- viral
- mycoplasma

Inhaled irritants:

- smoke
- dust
- fumes

Drugs

Inhaled foreign body

Bronchial neoplasm

Pleurisy

Interstitial lung disorders:

- fibrosing alveolitis
- extrinsic allergic alveolitis
- pneumoconiosis
- sarcoidosis

Tuberculosis

Left ventricular failure (esp. nocturnal cough)

Whooping cough (pertussis)

Gastro-oesophageal reflux and hiatus hernia

Postnasal drip

Productive cough

Chronic bronchitis

Bronchiectasis

Pneumonia

Asthma

Foreign body (later response)

Bronchial carcinoma (dry or loose)

Lung abscess

Tuberculosis (when cavitating)

## Key facts and checkpoints

- Cough is the commonest manifestation of lower respiratory tract infection.
- Cough is the cardinal feature of chronic bronchitis.
- Cough is a feature of asthma with sputum production, especially at night.
- Cough can have a psychogenic basis.
- Cough may persist for many weeks following an acute upper respiratory tract infection (URTI) as a result of persisting bronchial inflammation and increased airway responsiveness.<sup>1</sup>
- Postnasal drip is the commonest cause of a persistent or chronic cough, especially causing nocturnal cough due to secretions (mainly from chronic sinusitis) tracking down the larynx and trachea during sleep.
- The commonest causes of haemoptysis are URTI (24%), acute or chronic bronchitis (17%), bronchiectasis (13%), TB (10%). Unknown causes totalled 22% and cancer 4% (figures from a UK study).<sup>2</sup>

## A diagnostic approach

A summary of the diagnostic strategy model is presented in TABLE 42.2.

## Probability diagnosis

The most common cause of cough is an acute respiratory infection, whether a URTI or acute bronchitis.<sup>3</sup> Persistent coughing with a URTI is

**Table 42.2** Cough: diagnostic strategy model

Q.	Probability diagnosis
A.	Upper respiratory infection Postnasal drip/rhinitis/sinusitis Smoking Acute bronchitis Chronic bronchitis/COPD
Q.	Serious disorders not to be missed
A.	Cardiovascular: • left ventricular failure Neoplasia: • lung cancer Severe infections: • tuberculosis • pneumonia • influenza • lung abscess • HIV infection • SARS (coronavirus) Asthma Cystic fibrosis Inhaled foreign body Pneumothorax
Q.	Pitfalls (often missed)
A.	Atypical pneumonias Gastro-oesophageal reflux (nocturnal) Smoking (children/adolescents) Bronchiectasis Whooping cough (pertussis) Interstitial lung disorders Sarcoidosis
Q.	Seven masquerades checklist
A.	Drugs (several)
Q.	Is the patient trying to tell me something?
A.	Anxiety and habit.

usually due to the development of sinusitis with a postnasal drip.

Chronic bronchitis is also a common cause of cough.

### Serious disorders not to be missed

Bronchial carcinoma must not be overlooked. A worsening cough is the commonest presenting problem. A bovine cough is suggestive of cancer: the explosive nature of a normal cough is lost when laryngeal paralysis is present, usually resulting from bronchial carcinoma infiltrating the left recurrent laryngeal nerve.

Chronic cough may be the first presentation of *Pneumocystis jiroveci* pneumonia in an HIV-infected

patient. Careful but tactful questioning of the patient in relation to IV drug use, sexual practice and previous blood transfusions is important. Important causes of a chronic cough are summarised in **TABLE 42.3**.

The possibility of a foreign body should always be kept in mind, especially in children, and severe

### Red flag pointers for cough

- Age >50 years
- Smoking history
- Asbestos history exposure
- Persistent cough
- Overseas travel
- TB exposure
- Haemoptysis
- Unexplained weight loss
- Dyspnoea

**Table 42.3** Some causes of chronic cough<sup>2,4,5</sup>

Normal chest X-ray (includes most causes)
Chronic postnasal drip
Asthma
Asthma + postnasal drip
Postinfective bronchial hyper-responsiveness
Gastro-oesophageal reflux:
• symptomatic
• asymptomatic
Chronic bronchitis
Chronic heart failure
Drugs (e.g. ACE inhibitors, inhaled steroids)
Snoring and obstructive sleep apnoea
Irritants: occupational and household
Smoker's cough
Whooping cough (pertussis)
Habit
Functional
Idiopathic
Abnormal chest X-ray
Bronchiectasis
Cancer: bronchial, larynx
Cardiac failure
COPD
Cystic fibrosis
Inhaled foreign body
Interstitial lung disorders (e.g. sarcoidosis)
Tuberculosis

infections such as TB and pulmonary abscess must not be misdiagnosed.

It is also important not to overlook asthma in which a nocturnal cough, without wheezing, is a feature in children.

## Pitfalls

Causes that tend to be overlooked, especially in the presence of a normal X-ray, are gastro-oesophageal reflux, postnasal drip and asthma. Gastro-oesophageal reflux is more common as a cause of reflex coughing, especially at night, than appreciated. Whooping cough, especially immunisation-modified, can be difficult to diagnose, particularly if the characteristic whoop is absent.

## General pitfalls

- Attributing cough due to bronchial carcinoma in a smoker to 'smoker's cough'
- Overlooking TB, especially in the elderly, by equating symptoms to old age, bronchitis or even smoking
- Overlooking the fact that bronchial carcinoma can develop in a patient with other pulmonary conditions, such as chronic bronchitis
- Being slow to order a chest X-ray
- Failing to recognise that pertussis presents in adults

## Seven masquerades checklist

The applicable masquerade is drugs, many of which can produce a wide variety of disorders of the respiratory tract that cause a cough. Pulmonary infiltration with fibrosis may result from some cytotoxic drugs, especially bleomycin. Over 20 different drugs are known to produce an SLE-like syndrome, sometimes complicated by pulmonary infiltrates and fibrosis. Cough can be a feature of some of the ACE inhibitors and beta blockers, inhaled steroids and sulfasalazine.

## Psychogenic considerations

A cough can occur for psychosocial reasons. Coughing is under cerebral control and a slight cough before commencing a speech is normal and presumably assists in clearing mucus from around the vocal cords.<sup>6</sup> This can readily become a nervous habit or mannerism. A typical 'psychogenic' cough is barking in quality—the 'Cape Barren goose' cough. It does not occur during sleep.

## The clinical approach

### History

The nature of the cough may provide important diagnostic clues but it is the associated symptoms, such

as the nature of the sputum, breathlessness, wheezing and constitutional symptoms, that provide the most helpful diagnostic value. A history of smoking habits, past and present, is essential and an occupational and hobby history requires investigation. Significant occupations (past or present) include mining (pneumoconiosis), aircraft manufacturing (asbestosis and mesothelioma), farming ('farmer's lung'—allergic pneumonitis from mouldy hay) and bird handling ('bird fancier's lung'—allergic alveolitis or psittacosis from pigeons or budgerigars). A past history of recurrent lung infections from childhood is suggestive of cystic fibrosis and bronchiectasis, a history of hay fever and eczema suggests asthma, while a family history involves asthma, cystic fibrosis, emphysema ( $\alpha_1$ -antitrypsin deficiency) and tuberculosis.

## Key questions<sup>7</sup>

- How would you describe the cough?
- How long has the cough been present?
- Do you cough up sputum?
- Describe the sputum, especially its colour.
- Is there any blood in the sputum?
- How much sputum do you produce—a teaspoonful, an eggcupful or more?
- Is there a burning sensation in your throat or chest when you cough?
- Have you noticed any other symptoms?
- What about chest pain or fever, shivers or sweats?
- Do you have a wheeze?
- Have you had previous attacks of wheezing or hay fever?
- Is there a history of asthma in your family?
- Have you lost weight?
- Has anyone in the family had TB or a persistent cough?
- How much do you smoke?
- Are you exposed to any smoke or fumes?
- What kind of work do you do?
- Where have you worked in the past?
- Is there a chance you have been exposed to asbestos?
- Do you keep birds at home?
- Do you have any birds nesting outside your bedroom?
- Is there a possibility of a foreign body such as a peanut 'having gone down the wrong way'?
- Have you had an operation recently or been confined to bed?
- Have you noticed any swelling of your legs?
- Have you been exposed to birds such as pigeons?

## Examination

Physical examination includes a general examination with a search for features such as enlarged cervical or axillary glands, which may indicate bronchial carcinoma, as would Horner syndrome (constricted pupil, ptosis). A careful examination of the lungs and cardiovascular system is also appropriate. Fine crackles on auscultation indicate pulmonary oedema of heart failure, interstitial pulmonary fibrosis and early lobar pneumonia, while coarse crackles indicate resolving pneumonia, bronchiectasis and TB. Careful inspection of the sputum forms an important part of the physical examination of the lungs. This should include its colour and consistency, presence of particulate matter and a 24-hour sputum watch.

## Investigations

This applies particularly to patients with haemoptysis. Investigations include:<sup>8</sup>

- haemoglobin, blood film and white cell count
- sputum cytology and culture
- ESR (elevated with bacterial infection, bronchiectasis, TB, lung abscess and bronchial carcinoma)
- pulmonary function tests/spirometry
- radiology:
  - plain chest X-ray (shows many problems)
  - tomography: helps more precise localisation of lesion, may show cavitation
  - bronchography: shows bronchiectasis (a very unpleasant procedure)
  - CT scanning (more sensitive than plain X-ray)
  - CT pulmonary angiogram
  - ventilation/perfusion isotope scan: for pulmonary infarction
  - echocardiogram (pulmonary hypertension)
- skin tests
- lung biopsy
- bronchoscopy (best at time of haemoptysis)

However, all that is needed initially is a plain chest X-ray.

## Diagnostic characteristics

There are important characteristics of cough that may point to the causation. **TABLE 42.1** compares typical causes of dry and productive cough.

## Character of the cough

- Brassy → tracheitis and bronchitis (major bronchi); extrinsic pressure on trachea
- Barking → laryngeal disorders (e.g. laryngitis)

- Croupy (with stridor) → laryngeal disorders (e.g. laryngitis, croup)
- Bovine (no power) → vocal cord paralysis (left-recurrent laryngeal nerve)
- Weak cough → indicates bronchial carcinoma
- Paroxysmal with whoops → whooping cough
- Painful → tracheitis; left ventricular failure

## Timing

- Nocturnal cough →
  - asthma
  - left ventricular failure
  - postnasal drip
  - chronic bronchitis
  - whooping cough
- Waking cough →
  - bronchiectasis
  - chronic bronchitis
  - GORD

## Associations

- Changing posture →
  - bronchiectasis
  - lung abscess
- Meals →
  - hiatus hernia (possible)
  - oesophageal diverticulum
  - tracheo-oesophageal fistula
- Wheezing →
  - asthma
- Breathlessness →
  - asthma
  - left ventricular failure
  - COPD

## Sputum

A healthy, non-smoking individual produces approximately 100–150 mL of mucus a day. This normal bronchial secretion is swept up the airways towards the trachea by the mucociliary clearance mechanism and is usually swallowed. The removal from the trachea is assisted also by occasional coughing although this is carried out almost subconsciously.<sup>6</sup>

Excess mucus is expectorated as sputum. The commonest cause of excess mucus production is cigarette smoking. Muroid sputum is clear and white.

## Character of sputum

- Clear white (muroid) → normal or uninfected bronchitis
- Yellow or green (purulent) → due to cellular material (neutrophils or eosinophil granulocytes)

- $\pm$  infection (not necessarily bacterial infection)
- asthma due to eosinophils
- bronchiectasis (copious quantities)
- Rusty  $\rightarrow$  lobar pneumonia (*S. pneumoniae*): due to blood
- Thick and sticky  $\rightarrow$  asthma
- Profuse, watery  $\rightarrow$  alveolar cell carcinoma
- Thin, clear mucoid  $\rightarrow$  viral infection
- Redcurrant jelly  $\rightarrow$  bronchial carcinoma
- Profuse and offensive  $\rightarrow$  bronchiectasis; lung abscess
- Thick plugs (cast-like)  $\rightarrow$  allergic bronchopulmonary *Aspergillus*; bronchial carcinoma
- Pink frothy sputum  $\rightarrow$  pulmonary oedema

**Table 42.4** Causes of haemoptysis (blood-stained sputum)

Acute infection

- URTI
- acute bronchitis

} commonest causes<sup>1</sup>

Chronic bronchitis

Bronchiectasis

Lobar pneumonia (rusty sputum)

Tuberculosis

Neoplastic:

- bronchial carcinoma
- metastatic carcinoma
- tumour of larynx or trachea

Pulmonary infarction/embolism

Foreign body

Cardiac:

- left ventricular failure
- mitral stenosis

Anticoagulant therapy

Unknown

Rarer causes:

Idiopathic pulmonary haemosiderosis

Goodpasture syndrome

Blood disorders including anticoagulants

Trauma

Iatrogenic (e.g. endotracheal tubes)

*Note:* Haemoptysis must be distinguished from blood-stained saliva caused by nasopharyngeal bleeding or sinusitis, also haematemesis.<sup>6</sup> Copious haemoptysis is due to bronchiectasis or TB.

## § Haemoptysis

Blood-stained sputum (haemoptysis), which varies from small flecks of blood to massive bleeding, requires thorough investigation. Always consider malignancy or TB. Often the diagnosis can be made by chest X-ray. Causes are presented in **TABLE 42.4**. Haemoptysis must be distinguished from blood-stained saliva caused by nasopharyngeal bleeding or sinusitis and also from haematemesis.<sup>6</sup> Acute bronchitis produces streaky haemoptysis.

## § Productive cough

- Chronic bronchitis: mucoid or purulent; rarely exceeds 250 mL per day<sup>6</sup>
- Bronchiectasis: purulent sputum; up to 500 mL/day
- Asthma: mucoid or purulent; tenacious sputum
- Lung abscess: purulent and foul-smelling
- Foreign body: can follow impaction

## Cough in children<sup>3</sup>

Cough in children is a very common symptom, but troublesome persistent cough is a great cause of anxiety among parents and probably the commonest symptom for which the family doctor is consulted. Age-related causes of chronic cough (present at least 4 weeks) are presented in **TABLE 42.5**. Most children with chronic cough do NOT have asthma. A chest X-ray is advisable for a persistent cough.

Common causes are:

- asthma
- recurrent viral bronchitis
- acute URTIs
- allergic rhinitis
- croup

Disorders not to be missed are:

- asthma
- cystic fibrosis
- inhaled foreign body
- tracheo-oesophageal fistula
- pneumonia
- whooping cough

Several clinicians describe the catarrhal child syndrome as the commonest cause of cough.<sup>3</sup> This refers to children who develop a postnasal drip following acute respiratory infection and allergic rhinitis. Recurrent cough in children can usually be explained by recurrent viral respiratory infections which commonly occur when first exposed to other

**Table 42.5** Chronic cough in children: age-related causes to consider

Early months of life
Milk inhalation/reflux
Asthma
Toddler/preschool child
Asthma
Bronchitis
Whooping cough
Cystic fibrosis
Croup
Foreign body inhalation
Tuberculosis
Bronchiectasis
Early school years
Asthma

Mycoplasma pneumonia
Adolescence
Asthma
Psychogenic
Smoking

Source: After Selecki and Helman<sup>9</sup>

children. Their airways tend to be overactive. There is a slight predisposition to asthma.

If asthma is suspected, a therapeutic trial of salbutamol 200 mcg 4 hourly via a spacer may be worthwhile.

### Psychogenic causes

Habit cough can occur in children, especially those with a history of school phobia. The cough does not occur during sleep and remains unchanged with exertion or infection.

### § Croup (laryngotracheobronchitis)

#### Clinical features

- Characteristic barking cough with stridor
- Sounds like a dog barking or a seal
- Children 9 months to 3 years
- Usually 11 pm to 2 am
- Auscultation confirms inspiratory stridor
- Occurs in small local epidemics

Management—refer to **CHAPTER 96**.

### Cough in the elderly

Important causes of cough to consider in the elderly include chronic bronchitis, lung cancer, bronchiectasis and left ventricular failure, in addition to the acute upper and lower respiratory infections to which they are prone. It is important to be surveillant for bronchial carcinoma in an older person presenting with cough, bearing in mind that the incidence rises with age. One study found the causes of chronic cough in the elderly to be postnasal drip syndrome 48%, gastro-oesophageal reflux 20% and asthma 17%.<sup>10</sup>

### COMMON RESPIRATORY INFECTIONS

Respiratory infections, especially those of the upper respiratory tract, are usually regarded as trivial, but they account for an estimated one-fifth of all time lost from work and three-fifths of time lost from school, and are thus of great importance to the community.<sup>11</sup> The majority of respiratory infections are viral in origin and antibiotics are therefore not indicated.

URTIs are those involving the nasal airways to the larynx, while lower respiratory tract infections (LRTIs) affect the trachea downwards.

Combined URTI and LRTI include influenza, measles, whooping cough and laryngotracheobronchitis.

### § The common cold (acute coryza)

This highly infectious URTI, which is often mistakenly referred to as 'the flu', produces a mild systemic upset and prominent nasal symptoms (see **FIG. 42.1**).

#### Clinical features

- Malaise and tiredness
  - Sore, runny nose
  - Sneezing
  - Sore throat
  - Slight fever
- Other possible symptoms:
- headache
  - hoarseness
  - cough

The watery nasal discharge becomes thick and purulent in about 24 hours and persists for up to a week. Secondary bacterial infection is uncommon.

#### Management

Advice to the patient includes:

- rest—adequate sleep and rest
- drink copious fluids

FIGURE 42.1 The main symptoms and complications of the common cold

- analgesics—paracetamol (acetaminophen) or aspirin (max. 8 tablets a day in adults)
- steam inhalations for a blocked nose
- cough mixture for a dry cough
- gargling aspirin in water or lemon juice for a sore throat
- vitamin C powder or tablets (e.g. 2 g daily) may aid recovery, however clinical trials are inconclusive
- clinical trials of zinc lozenges and echinacea give contradictory results to date<sup>11</sup>

## § Influenza

Influenza causes a relatively debilitating illness and should not be confused with the common cold. The differences are presented in TABLE 42.6. The incubation period is usually 1–3 days and the illness commences abruptly with a fever, headache, shivering and generalised muscle aching (see FIG. 42.2).

### Clinical criteria<sup>12</sup>

During an influenza epidemic:

- fever  $>38^{\circ}\text{C}$  plus at least one respiratory symptom and one systemic symptom
- cough (dry)
- sore throat
- coryza
- prostration or weakness
- myalgia
- headache
- rigors or chills

Table 42.6 Comparison of common cold and influenza

	Common cold	Influenza
<b>Incubation period</b>	12 hours to 5 days	1–3 days
<b>Fever</b>	±	++
<b>Cough</b>	(later)	+
<b>Sore throat</b>	++	±
<b>Rhinitis sneezing rhinorrhoea</b>	+	–
<b>Muscle aches</b>	–	+
<b>Toxaemia</b>	–	±
<b>Causes</b>	Rhinoviruses Parainfluenza Influenza B, C Coronavirus RSV	Influenza A Influenza B Novel strains influenza A e.g. H5N1

Diagnosis: Nasal/throat swabs for viral PCR (rapid and best); viral antigen detection or culture.

### Complications

- Secondary bacterial infection
- Pneumonia due to *Staphylococcus aureus* (mortality up to 20%)<sup>1</sup>

FIGURE 42.2 The main features of influenza

- Encephalomyelitis (rare)
- Depression (a common sequela)

## Management

Advice to the patient includes:

- rest in bed until the fever subsides
- analgesics: paracetamol and aspirin is effective or codeine and aspirin (or paracetamol), especially if a dry cough
- fluids: maintain high fluid intake

## Antiviral agents<sup>12</sup>

- Neuraminidase inhibitors (cover influenza A and B):  
zanamivir (Relenza) 10 mg by inhalation bd  
oseltamivir (Tamiflu) 75 mg (o) bd

Both should be commenced within 36 hours of onset and given for 5 days.

*Note:* All the above agents have been shown in RCTs to be beneficial, with a reduction in symptoms by at least 24 hours compared with placebo.<sup>12,13</sup>

## Prevention

Influenza vaccination offers some protection for up to 70% of the population for about 12 months.<sup>1</sup> (See CHAPTER 9.)

## § Swine origin flu

(The swine variety of H1N1 influenza A)

This strain presents with typical influenza symptoms commonly accompanied by gastrointestinal symptoms (especially diarrhoea). Like avian flu it tends to occur in a pandemic and affects the young in particular.

The treatment is the same as for influenza in general with neuraminidase inhibitors. A vaccine is now available.

Avian (bird) flu due to H5N1 strain: refer to CHAPTER 28.

## BRONCHITIS

### § Acute bronchitis

This is acute inflammation of the tracheobronchial tree that usually follows an upper respiratory infection. Although generally mild and self-limiting, it may be serious in debilitated patients.

### Clinical features

Features of acute infectious bronchitis are:

- cough and sputum (main symptoms)
- wheeze and dyspnoea

- usually viral infection
- can complicate chronic bronchitis—often due to *Haemophilus influenzae* and *Streptococcus pneumoniae*
- scattered wheeze on auscultation
- fever or haemoptysis (uncommon)

## Outcome

- It improves spontaneously in 4–8 days in healthy patients.

## Treatment<sup>12,14,15</sup>

- Symptomatic treatment
- Inhaled bronchodilators for airflow limitation
- Antibiotics usually not needed in previously healthy adult or child
- Use antibiotics only if evidence of acute bacterial infection with fever, increased sputum volume and sputum purulence:  
amoxycillin 500 mg (o) 8 hourly for 5 days  
or  
doxycycline 200 mg (o) statim, 100 mg, especially if mycoplasma suspected daily for 5 days.

## § Chronic bronchitis

This is a chronic productive cough for at least 3 successive months in 2 successive years:

- wheeze, progressive dyspnoea
- recurrent exacerbations with acute bronchitis
- occurs mainly in smokers

Refer to COPD (in CHAPTER 83).

## PNEUMONIA<sup>16</sup>

This is inflammation of lung tissue. It usually presents as an acute illness with cough, fever and purulent sputum plus physical signs and X-ray changes of consolidation.

However, the initial presentation of pneumonia can be misleading, especially when the patient presents with constitutional symptoms (fever, malaise and headache) rather than respiratory symptoms. A cough, although usually present, can be relatively insignificant in the total clinical picture. This diagnostic problem applies particularly to atypical pneumonia but can occur with bacterial pneumonia, especially lobar pneumonia.

## § Community-acquired pneumonia<sup>12,14</sup>

CAP occurs in people who are not or have not been in hospital recently, and who are not institutionalised

or immunocompromised. The choice of antibiotic is initially empirical. CAP is usually caused by a single organism, especially *Streptococcus pneumoniae*, which is now becoming resistant to antibiotics.<sup>15</sup> Treatment is usually for 5–10 days for most bacterial causes, 2 weeks for *Mycoplasma* or *Chlamydia* infection and 2–3 weeks for *Legionella*.

### Typical pneumonia

The commonest community-acquired infection is with *Streptococcus pneumoniae* (majority), now becoming resistant to antibiotics, or *Haemophilus influenzae*.<sup>15</sup>

### Clinical features

- Often history of viral respiratory infection
- Rapidly ill with high temperature, dry cough, pleuritic pain, rigors or night sweats
- 1–2 days later may be rusty-coloured sputum
- Rapid and shallow breathing follows
- X-ray and examination: focal chest signs, consolidation

## § The atypical pneumonias

Refer to CHAPTER 29.

### Clinical features

- Fever, malaise
- Headache
- Minimal respiratory symptoms, non-productive cough
- Signs of consolidation absent
- Chest X-ray (diffuse infiltration) incompatible with chest signs

### Causes

- *Mycoplasma pneumoniae*—the commonest:
  - adolescents and young adults
  - treat with:
    - roxithromycin 300 mg (o) daily
    - or
    - doxycycline 100 mg bd for 14 days
- *Legionella pneumophila* (legionnaire disease):
  - related to cooling systems in large buildings
  - incubation 2–10 days

Diagnostic criteria include:

- prodromal influenza-like illness
- a dry cough, confusion or diarrhoea
- very high fever (may be relative bradycardia)
- lymphopaenia with moderate leucocytosis
- hyponatraemia

Patients can become prostrate with complications. Treat with:

azithromycin IV (first-line) or erythromycin (IV or oral)  
plus (if very severe)  
ciprofloxacin or rifampicin

- *Chlamydia pneumoniae*:
  - similar to *Mycoplasma*
- *Chlamydia psittaci* (psittacosis):
  - treat with roxithromycin or erythromycin or doxycycline
- *Coxiella burnetii* (Q fever):
  - treat with doxycycline 200 mg (o) statim then 100 mg daily for 14 days

## Antibiotic treatment according to severity<sup>11,12</sup>

### Mild pneumonia

This does not require hospitalisation.

amoxycillin/clavulanate 875/125 mg (o)  
12 hourly for 7 days especially if *S. pneumoniae*  
isolated or suspected  
plus (especially if atypical pneumonia suspected)  
roxithromycin 300 mg (o) daily for 7 days

### Moderately severe pneumonia

This requires hospitalisation—see box Guidelines for severe pneumonia and hospital admission.

- Neonates
- Age over 65 years
- Coexisting illness
- High temperature:  $>38^{\circ}\text{C}$
- Clinical features of severe pneumonia
- Involvement of more than one lobe
- Inability to tolerate oral therapy
  - Benzylpenicillin 1.2 g IV 4–6 hourly for 7 days
  - or
  - Procaine penicillin 1.5 g IM daily (drugs of choice for *S. pneumoniae*)
  - or
  - Ceftriaxone 1 g IV daily for 7 days (in penicillin-allergic patient)
- If not so severe and oral medication tolerated can use amoxycillin/clavulanate or cefaclor or doxycycline
- If atypical pneumonia use doxycycline, erythromycin or roxithromycin

### Severe pneumonia

The criteria for severity (with increased risk of death) are presented in the box Guidelines for severe pneumonia and hospital admission.<sup>14,15,16</sup>

## Guidelines for severe pneumonia and hospital admission

- Altered mental state/acute onset confusion
- Rapidly deteriorating course
- Respiratory rate >30 per minute
- Pulse rate >125 per minute
- BP <90/60 mmHg
- Hypoxia  $P_aO_2$  <60 mm Hg or  $O_2$  saturation <92%
- Leucocytes <4 × 10<sup>8</sup>/L or >20 × 10<sup>9</sup>/L

azithromycin 500 mg IV daily (covers *Mycoplasma*, *Chlamydia* and *Legionella*)  
plus  
cefotaxime 1 g IV 8 hourly  
or  
ceftriaxone 1 g IV daily

## Pneumonia in children

### Clinical features

- Tachypnoea, expiratory grunt
- Possible focal chest signs
- Diagnosis often only made by chest X-ray

### Pathogens

- Viruses are the most common cause in infants.
- *Mycoplasma* are common in children over 5 years.
- *S. pneumoniae* is a cause in all age groups.
- Pathogens are difficult to isolate—may need blood culture.

### Treatment

Almost all those under 48 months should be admitted to hospital. Indicators for hospital admission are shown in the box.

- Minimal handling
- Careful observations including pulse oximetry
- Attend to hydration
- Antibiotics indicated in all cases. Refer to guidelines<sup>12</sup>

Mild (general guidelines only):<sup>16</sup>

amoxycillin (o) or roxithromycin (o)

Moderate:

benzylpenicillin IV + roxithromycin (o)

Severe:<sup>15</sup>

flucloxacillin IV + gentamicin IV ± azithromycin (o)

## Pneumonia in children: guidelines for hospitalisation<sup>14</sup>

Infants:

- RR > 70
- Intermittent apnoea
- Not feeding

Older children:

- RR > 50
- Grunting
- Signs of dehydration

Both groups:

- $S_aO_2 \leq 92\%$
- Cyanosis
- Difficulty breathing
- Family/social issues

## CHRONIC PERSISTENT COUGH

A cough associated with a viral respiratory infection should last no more than 2 weeks. If it does, it is termed *persistent*. A cough lasting 2 months or more is defined as a chronic cough. A cough that lasts longer than 3 to 4 weeks requires scrutiny. TABLE 42.3 includes some causes of chronic cough.

A chronic cough can be divided into productive and non-productive. If productive, the presence of pus is significant, as purulent sputum usually means bacterial infection in the bronchi and/or sinuses.<sup>4</sup> The main organisms are *Haemophilus influenzae* (the most common), *S. pneumoniae* and *Moraxella*. Such infections are most susceptible to amoxycillin or amoxycillin/clavulanate or parenteral cephalosporins.

## Non-productive cough

Some of the many causes of a non-productive cough are included in TABLE 42.1 and more than one may be operative in a patient simultaneously; for example, an allergic snorer with oesophageal reflux taking an ACE inhibitor for hypertension may have a viral respiratory infection.<sup>4</sup> It has been shown that a non-productive or irritating cough is usually caused by persistent stimulation of irritant receptors in the trachea and major bronchi, and may result in the production of small amounts of mucoid sputum.

Investigations to be considered in intractable chronic cough include a chest X-ray, spirometry, CT scan of the thorax (searching in particular for a tumour) and ambulatory oesophageal pH monitoring.

If bronchial hyper-responsiveness is proven, a trial of inhaled or oral corticosteroids can be used in these patients.<sup>5</sup>

## Gastro-oesophageal reflux

This common condition is the most likely cause of a persistent, non-productive cough in an apparently

well patient with a history of reflux. Recent studies utilising 24-hour ambulatory oesophageal pH monitoring have demonstrated that in patients with persistent unexplained cough the predominant cause is asymptomatic gastro-oesophageal reflux.<sup>4,5</sup> In the absence of evidence of aspiration the cough is considered to be due to stimulation of a distal oesophageal-tracheobronchial reflex. Other studies have established a relationship between bronchial asthma and reflux or swallowing disorders whereby microaspiration can initiate an inflammatory response in the airways.

Indications for 24-hour ambulatory oesophageal pH monitoring in chronic cough include:

- unexplained chronic cough after clinical assessment
- symptomatic gastro-oesophageal reflux
- chronic cough with known aetiology unresponsive to therapy

If reflux is proven or suspected, treat with routine conservative anti-reflux measures and at least a 4-week trial of histamine H<sub>2</sub>-receptor antagonists. If cough persists, refer for further evaluation.<sup>5</sup>

If all investigations and treatment trials (including anti-reflux and corticosteroids) prove unrewarding, a trial of ipratropium bromide both nebulised (500 mcg, qid) and to a lesser degree metered dose inhaler (4 × 20 µg puffs qid) has been found to be effective.<sup>5,17</sup>

However, for patients with idiopathic chronic cough it is important to provide ongoing interest and support, and not eventually to dismiss them as 'just a cough'.

## § Bronchial carcinoma

Lung cancer accounts for 25% of cancer deaths in men and 24% of cancer deaths in women (rapidly rising), with cigarette smoking being the most common cause of lung cancer in both sexes.<sup>11</sup> It is also the most common lethal cancer in both sexes in Australia. Bronchial carcinoma accounts for over 95% of primary lung malignancies. The prognosis is poor—the 5-year overall survival is 12–14%.<sup>18</sup> The mesothelioma incidence continues to rise.

### Clinical features

- Most present between 50 and 70 years (mean 67 years)
- Only 10–25% asymptomatic at time of diagnosis<sup>9</sup>
- If symptomatic—usually advanced and not resectable

### Local symptoms

- Cough (42%)
- Chest pain (22%)
- Wheezing (15%)
- Haemoptysis (7%)
- Dyspnoea (5%)

### General

- Anorexia, malaise
- Weight loss—unexplained

### Others

- Unresolved chest infection
- Hoarseness
- Symptoms from metastases

The possible physical findings are summarised in **FIGURE 42.3**.

### Investigations

- Chest X-ray
- CT scanning
- Fibre-optic bronchoscopy
- PET scanning
- Fluorescence bronchoscopy (helps early detection)
- Tissue diagnosis where possible

*Note:* Based on a 2003 Cochrane review, no proven effect of any screening for asymptomatic patients.

Causes of a solitary pulmonary nodule on X-ray are presented in **TABLE 42.7**.

**Table 42.7** Causes of a solitary pulmonary nodule (on X-ray)<sup>19</sup>

Common
Bronchial carcinoma
Solitary metastasis
Granuloma (e.g. TB)
Hamartoma
Less common
Bronchial adenoma
AVM
Hydatid
Others (e.g. haematoma, cyst)

### Management

Refer to a respiratory physician to determine the type of cancer. They are usually classified as small cell lung (oat cell) poorly differentiated cancer (15–20% incidence) (SCLC) and non-small cell lung cancer (NSCLC), which includes squamous cell carcinoma, adenocarcinoma and large cell carcinoma (approximately 20–30% of each).

**Local complications**

- Horner syndrome
- small pupil
- ptosis
- loss of sweating (ipsilateral)
- enophthalmos

rib pain

hoarseness

bovine cough

severe inner arm pain  
(brachial plexus)

dysphagia

pleural effusion

**Metastatic complications**

- brain
- headache
- personality change
- seizures
- limb weakness/sensory loss
- vomiting

bone

- back pain (vertebrae)
- rib pain

liver

- jaundice (late)

**Also**

- anaemia
- paraneoplastic syndromes
- paralysis diaphragm

**FIGURE 42.3** Possible physical findings of bronchial carcinoma

The main aim of management is a curative resection of NSCLC in those who can benefit from it. Surgery is not an option for SCLC since it metastasises so rapidly (80% have metastasised at the time of diagnosis).<sup>14</sup> Chemotherapy is suitable for the deadly SCLC but currently only extends life expectancy from 3 to 20 months (at best). It also has an important place in treating NSCLC. The main role of radiotherapy is palliative.

### § Mesothelioma

Mesothelioma is a malignant tumour of mesothelial cells usually at the pleura. It is associated with prior asbestos exposure, possibly decades earlier (90% report exposure).

Clinical features include chest pain, dyspnoea, weight loss and recurrent pleural effusions. Diagnosis is based on imaging and on histology after pleural biopsy. Prognosis is poor and treatment is palliative support.

### § Bronchiectasis

Bronchiectasis is dilatation of the bronchi when their walls become inflamed, thickened and irreversibly damaged, usually following obstruction followed by infection. Predisposing causes include whooping cough, measles, TB, inhaled foreign body (e.g. peanuts in children), bronchial carcinoma, cystic fibrosis and congenital ciliary dysfunction (Kartagener

syndrome). The left lower lobe and lingula are the commonest sites for localised disease.

### Clinical features

- Chronic cough—worse on waking
- Mild cases: yellow or green sputum only after infection
- Advanced:
  - profuse purulent offensive sputum
  - persistent halitosis
  - recurrent febrile episodes
  - malaise, weight loss
- Episodes of pneumonia
- Sputum production related to posture
- Haemoptysis (blood-stained sputum or massive) possible

### Examination

- Clubbing
- Coarse crackles over infected areas (usually lung base)
- Other respiratory signs are given in TABLE 49.6 (see CHAPTER 49)

### Investigations

- Chest X-ray (normal or bronchial changes)
- Sputum examination: for resistant pathogens and to exclude TB
- Cytology: to rule out neoplasia
- Main pathogens: *Streptococcus pneumoniae*, *Pseudomonas aeruginosa*, *Haemophilus influenzae* (commonest)
- CT scan: can show bronchial wall thickening—high resolution CT scan is the new gold standard for diagnosis
- Spirometry
- Bronchograms: very unpleasant and used only if diagnosis in doubt or possible localised disease amenable to surgery (rare)

### Management<sup>20</sup>

- Explanation and preventive advice.
- Postural drainage (e.g. lie over side of bed with head and thorax down for 10–20 minutes 3 times a day).
- Antibiotics according to organism—it is important to eradicate infection to halt the progress of the disease. Amoxycillin 500 mg (o) tds for 2–3 weeks or roxithromycin is recommended for first presentation.<sup>20</sup>
- Bronchodilators, if evidence of bronchospasm.<sup>21</sup>

## Tuberculosis

Although cough is a feature pulmonary TB may be symptomless and detected by X-ray screenings.<sup>8</sup> (Refer to CHAPTER 29.)

## Symptomatic treatment of cough

Symptomatic treatment of cough should be reserved for patients who have acute self-limiting causes of cough, especially an acute viral infection. There are many cough mixtures available and the major constituents of these mixtures are shown in TABLE 42.8.<sup>8</sup> The recommended mixture should be tailored to the patient's individual requirements. These mixtures should be used only in the short term.<sup>20</sup> Cough medicines are generally not recommended in children but for a very dry irritating cough in children 5–12 years use pholcodine 5–10 mg (o) tds or qid.<sup>21</sup>

Table 42.8 Cough mixtures: major constituents

Cough suppressants

*Opioid:*

Codeine

Dihydrocodeine

Hydrocodone

Pholcodine

Ethylmorphine

Normethadone

*Others:*

Carbetapentane

Dextromethorphan

Oxolamine

Expectorants/mucolytics:

Senega

Ammonia

Guaiphenesin

Bromhexine

Analgesics/antipyretics:

Paracetamol (acetaminophen)

Salicylates (e.g. aspirin)

Decongestants

*Sympathomimetic:*

Ephedrine

Pseudoephedrine

Phenylephrine

Phenylpropanolamine

Methoxyphenamine

*Antihistamine:*

Promethazine

Pheniramine

Chlorpheniramine

Diphenhydramine

Dexchlorpheniramine  
Brompheniramine  
Triprolidine  
Anticholinergic:  
Atropine  
Isopropamide

Source: After Williams and Bowes<sup>8</sup>

Strategies recommended to manage chronic cough in adults include:<sup>21</sup>

- sedating antihistamine at night
- PPIs because recurrent coughing causes acid reflex and vice versa
- low-dose inhaled corticosteroid

Short term: codeine phosphate 25–30 mg (o) every 3–6 hours.

If intractable: 2 mL lignocaine 2% via nebuliser, for 5–10 minutes up to 4 times daily for up to 7 days.

## When to refer

- Patients in whom bronchoscopy is necessary to exclude bronchial carcinoma
- Persistent hoarseness in a patient who requires expert laryngeal examination
- Evidence of pulmonary TB

## Practice tips

- Unexplained cough over the age of 50 is bronchial carcinoma until proved otherwise (especially if there is a history of smoking).
- Consider TB in the presence of an unusual cough  $\pm$  wheezing.
- Bronchoscopy is essential to exclude adequately a suspicion of bronchial carcinoma when the chest X-ray is normal.
- Bright red haemoptysis in a young person may be the initial symptom of pulmonary TB.
- Avoid settling for a diagnosis of bronchitis as an explanation of haemoptysis until bronchial carcinoma has been excluded.
- Coughing may be so severe that it terminates in vomiting or loss of consciousness (post-tussive syncope).
- Large haemoptyses are usually due to bronchiectasis or TB.
- The presence of white cells in the sputum renders it yellow or green (purulent) but does not necessarily imply infection.

*There are two kinds of deafness. One is due to wax and is curable; the other is not due to wax and is not curable.*

Sir William Wilde (1815–76)

Deafness is defined as impairment of hearing, regardless of its severity.<sup>1</sup> It is a major community health problem requiring a high index of suspicion for diagnosis, especially in children. Deafness may be conductive, sensorineural or a combination of both (mixed).

### Key facts and checkpoints

- Deafness occurs at all ages but is more common in the elderly (see FIG. 43.1). Fifty per cent of people over 80 years have deafness severe enough to be helped by a hearing aid.
- The threshold of normal hearing is from 0 to 20 decibels (dB), about the loudness of a soft whisper.
- One in seven of the adult population suffers from some degree of significant hearing impairment (over 20 dB in the better hearing ear).<sup>2</sup>
- One child in every 1000 is born with a significant hearing loss. The earlier it is detected and treated the better.
- Degrees of hearing impairment with vocal equivalent:<sup>2,3</sup>
  - mild = loss of 20–40 dB (soft-spoken voice)
  - moderate = loss of 40–60 dB (normal-spoken voice)
  - severe = loss of 70–90 dB (loud spoken voice)
  - profound = loss of over 90 dB (shout)
- More women than men have a hearing loss.
- People who have worked in high-noise levels (>85 dB) are more than twice as likely to be deaf.
- There is a related incidence of tinnitus with deafness.

### A diagnostic approach

It is useful to consider the causes of deafness in terms of pathophysiology (conductive or sensorineural hearing loss) and anatomical sites (see FIG. 43.2).

Conductive hearing loss is caused by an abnormality in the pathway conducting sound waves

FIGURE 43.1 Prevalence of hearing problems with increasing age

from the outer ear to the inner ear,<sup>1</sup> as far as the footplate of the stapes.

Sensorineural hearing loss (SNHL) is a defect central to the oval window involving the cochlea (sensor), cochlear nerve (neural) or, more rarely, central neural pathways.<sup>1</sup>

Congenital deafness is an important consideration in children, while presbycusis is very common in the aged. The commonest acquired causes of deafness are impacted cerumen (wax), serous otitis media and otitis externa. Noise-induced deafness is also a common problem.

It is important not to misdiagnose an acoustic neuroma, which can present as acute deafness, although slow progressive loss is more typical. A summary of the diagnostic strategy model, which includes several important causes of deafness, is presented in TABLE 43.1 and a checklist of ototoxic drugs in TABLE 43.2.

### Symptoms

The symptoms vary so that some barely notice a problem while others are severely disabled.

Common symptoms include inability to:

- hear speech and other sounds loudly enough
- hear speech and music clearly, even when loud enough
- understand speech even when loud enough—a problem of language reception

FIGURE 43.2 Causes of deafness according to anatomical site

People with mild hearing loss notice only subtle differences and may have trouble hearing certain high-frequency sounds, such as 's', 'f' or 'th'. They may also have trouble hearing in certain situations, such as at a party or in a crowd where there is a lot of background noise. Those with moderate hearing loss have trouble hearing in many situations.

## The clinical approach

### History

The history should include an account of the onset and progression of any deafness, noise exposure, drug history, a history of swimming or diving, air travel and head injury and family history. A recent or past episode of a generalised infection would be relevant and the presence of associated aural symptoms, such as ear pain, discharge, tinnitus and vertigo. Vertigo may be a symptom of Ménière syndrome, multiple sclerosis, acoustic neuroma or syphilis.

Several important clues can be obtained from the history. The often sudden onset of hearing loss in an ear following swimming or showering is suggestive of wax, which swells to block the ear canal completely.

Patients with conductive loss may hear better in noisy conditions (paracusis) because we raise our voices when there is background noise. Conversely, people with sensorineural deafness (SND) usually have more difficulty hearing in noise as voices become unintelligible.

### Examination

Inspect the facial structures, skull and ears. The ears are inspected with an otoscope to visualise the external meatus and the tympanic membrane (TM) and the presence of obstructions such as wax, inflammation or osteomata.

The examination requires a clean external auditory canal. Gentle suction is useful for cleaning pus debris. Syringing is reserved for wax in people with an intact TM and a known healthy middle ear.

It is an advantage to have a pneumatic attachment to test drum mobility. Reduction of TM mobility is an important sign in secretory otitis media.

There are several simple hearing tests. The distance at which a ticking watch can be heard can be used but the advent of the digital watch has affected this traditional method.

**Table 43.1** Deafness and hearing loss: diagnostic strategy model

Q. Probability diagnosis
A. Impacted cerumen
Serous otitis media
Otitis externa
Congenital (children)
Presbycusis
Q. Serious disorders not to be missed
A. Neoplasia:
• acoustic neuroma
• temporal lobe tumours (bilateral)
• otic tumours
• nasopharyngeal carcinoma
Severe infections:
• generalised infections (e.g. mumps, measles)
• meningitis
• syphilis
Perforated tympanic membrane
Cholesteatoma
Perilymphatic fistula (post-stapedectomy)
Ménière syndrome
Q. Pitfalls (often missed)
A. Foreign body
Temporal bone fracture
Otosclerosis
Barotrauma
Noise-induced deafness
Rarities:
• Paget disease of bone
• multiple sclerosis
• osteogenesis imperfecta
Q. Seven masquerades checklist
A. Diabetes
Drugs
Thyroid disorder (hypo)
Q. Is this patient trying to tell me something?
A. Unlikely.

### Whisper test

Occlude far ear. Have the patient cover near eye with one hand to prevent lip reading. Place your mouth at the near side. Strongly whisper '68' then '100' from a distance of 60 cm. Ask the patient to repeat the words. Then repeat using a normal speaking voice.

**Table 43.2** Known ototoxic drugs

Alcohol

Aminoglycosides:

- amikacin
- gentamicin
- kanamycin
- neomycin
- streptomycin
- tobramycin

Diuretics:

- ethacrynic acid
- frusemide

Chemotherapeutic agents

Quinine and related drugs

Salicylates/aspirin excess

### Hair-rubbing method

In children and in adults with a reasonable amount of hair grab several hairs close to the external auditory canal between the thumb and index finger. Rub the hairs lightly together to produce a relatively high-pitched 'crackling' sound (see FIG. 43.3). If this sound cannot be heard, a moderate hearing loss is likely (usually about 40 dB or greater). Like the whisper test, this test is a rough guide only.

### Tuning fork tests

If deafness is present, its type (conduction or sensorineural) should be determined by tuning fork testing. The most suitable tuning fork for preliminary testing is the C<sub>2</sub> (512 cps) fork. The fork is best activated by striking it firmly on the bent elbow.

**FIGURE 43.3** Simple hair-rubbing method of testing possible deafness

Weber test

The vibrating tuning fork is applied firmly to the midpoint of the skull or to the central forehead or to the teeth.

This test is of value only if the deafness is unilateral or bilateral and unequal (see FIG. 43.4). Normally the sound is heard equally in both ears in the centre of the forehead. With sensorineural deafness the sound is transmitted to the normal ear, while with conduction deafness it is heard better in the abnormal ear.

Lateralisation of the sound to one ear indicates a conductive loss on that side, or a sensorineural loss on the other side.

FIGURE 43.4 Weber test

Rinne test

The tuning fork is held:

- outside the ear (tests air conduction) and
- firmly against the mastoid bone (tests bone conduction)

It therefore compares air and bone conduction in the same ear (see FIG. 43.5). A variation of the test includes placing the tuning fork on the mastoid process and the patient indicates when it can no longer be heard. The fork is then placed at the external auditory meatus and the patient indicates whether the sound is now audible. Normally air conduction is better than bone conduction and the sound will again be heard.

A comparison of the interpretation of these tests is summarised in TABLE 43.3.

Table 43.3	A comparison of the Rinne and Weber tests	
State of the hearing	Rinne test	Weber test
Normal	Positive: AC > BC	Equal in both ears
Conduction deafness	Negative: BC > AC	Louder in the deaf ear
Very severe conduction deafness	Negative: BC > AC May hear BC only	Louder in the deaf ear
Sensorineural deafness	Positive: AC > BC	Louder in the better ear
Very severe sensorineural deafness	'False' negative (without masking)	Louder in the better ear

AC = air conduction; BC = bone conduction

Audiometric assessment

Audiometric assessment includes the following:

- pure tone audiometry
- impedance tympanometry
- electric response audiometry
- oto-acoustic emission testing

FIGURE 43.5 Rinne test comparing air conduction (a) with bone conduction (b)

### Pure tone audiometry<sup>4,5</sup>

Pure tone audiometry is a graph of frequency expressed in hertz versus loudness expressed in decibels. The tone is presented either through the ear canal (a test of the conduction and the cochlear function of the ear) or through the bone (a test of cochlear function).

FIGURES 43.6 and 43.7 are typical examples of pure tone audiograms.

FIGURE 43.6 Pure tone audiogram for severe conductive deafness in left ear

Source: After Black<sup>4</sup>

FIGURE 43.7 Pure tone audiogram for unilateral (left) sensorineural deafness. Suspect a viral or congenital origin in children; check adults for acoustic neuroma.

The difference between the two is a measure of conductance. If the two ears have different thresholds, a white noise masking sound is applied to the better ear to prevent it hearing sound presented to the test ear. The normal speech range occurs between 0 and 20 dB in soundproof conditions across the frequency spectrum.

### Tympanometry

Tympanometry measures the mobility of the tympanic membrane, the dynamics of the ossicular chain and the middle-ear air cushion. The test consists of a sound applied at the external auditory meatus, otherwise sealed by the soft probe tip.

### Deafness in children

Deafness in childhood is relatively common and often goes unrecognised. One to two of every 1000 newborn infants suffer from SND.<sup>1</sup> Congenital deafness may be due to inherited defects, to prenatal factors such as maternal intrauterine infection or drug ingestion during pregnancy, or to perinatal factors such as birth trauma, and haemolytic disease of the newborn.

Deafness may be associated with Down syndrome and Waardenburg syndrome. Waardenburg syndrome, which is dominantly inherited, is diagnosed in a patient with a white forelock of hair and different coloured eyes.

Acquired deafness accounts for approximately half of all childhood cases. Purulent otitis media and secretory otitis media are common causes of temporary conductive deafness. However, one in 10 children will have persistent middle-ear effusions and mild to moderate hearing loss in the 15–40 dB range.<sup>6</sup>

Permanent deafness in the first few years of life may be due to virus infections, such as mumps or meningitis, ototoxic antibiotics and several other causes.

### Screening<sup>1</sup>

The aim of screening should be to recognise every deaf child by the age of 8 months to 1 year—before the vital time for learning speech is wasted. High-risk groups should be identified and screened, for example, a family history of deafness, maternal problems of pregnancy, perinatal problems, survivors of intensive care, very low birthweight and gestation <33 weeks, cerebral palsy and those with delayed or faulty speech. The guidelines for early signs of normal hearing are presented in TABLE 43.4.

Optimal screening times:

- 8 to 9 months (or earlier)
- school entry

There has been a proposition from the National Universal Hearing Screening Committee to introduce testing of newborn hearing following results<sup>7</sup> supporting this strategy after the finding of a higher incidence than appreciated. The average age at which these deaf children were diagnosed was 26 months.

**Table 43.4** Early signs of normal hearing

Age	Typical response
1 month	Should notice sudden constant sounds (e.g. car motor, vacuum cleaner) by pausing and listening.
3 months	Should respond to loud noise (e.g. will stop crying when hands are clapped).
4 months	Should turn head to look for source of sound, such as mother speaking behind the child.
7 months	Should turn instantly to voices or even to quiet noises made across the room.
10 months	Should listen out for familiar everyday sounds.
12 months	Should show some response to familiar words and commands, including his or her name.

## Early signs of hearing loss

A high index of suspicion is essential in detecting hearing loss in children and any parental concern should be taken seriously. The presentation of hearing loss will depend on whether it is bilateral or unilateral, its severity and age of onset.

Typical presentations include:

- malformation of skull, ears or face
- failure to respond in an expected way to sounds, especially one's voice
- preference for, or response only to, loud sounds
- no response to normal conversation or to television
- speech abnormality or delay
- absence of 'babbling' by 12 months
- no single words or comprehension of simple words by 18 months
- learning problems at school
- disobedience
- other behavioural problems
- inability to detect sound direction (unilateral loss)
- inability to follow simple commands or less than 20 spoken words by 2 years

## Screening methods

Hearing can be tested at any age. No child is too young to be tested and this includes the newborn. Informal office assessments, such as whispering in the child's ear or rattling car keys, are totally inadequate for

excluding deafness and may be potentially harmful if they lead to false reassurance.

Pneumatic otoscopy is essential to exclude middle-ear effusions.

Pure tone audiometry is unreliable in children under 4 years of age, so special techniques such as tympanometry are required. Tympanometry assesses TM compliance, and is highly sensitive and specific for detecting middle-ear pathology in children beyond early infancy.

Auditory brain stem response testing is used to evaluate children (particularly young infants) for whom information on behavioural hearing tests is either unobtainable or unreliable.<sup>6</sup>

## Management

Children with middle-ear pathology and hearing loss should be referred to a specialist. All children with SNHL (even those with profound deafness), as well as children with conductive losses not correctable by surgery, benefit from amplification. All children need referral to a specialist centre skilled in educational and language remediation.

## Deafness in the elderly<sup>8</sup>

The prevalence of hearing loss increases exponentially with age. The commonest reason for bilateral progressive SND is presbycusis, which is the high-frequency hearing loss of advancing age (see FIG. 43.8). There appears to be a genetic predisposition to presbycusis.<sup>8</sup>

**FIGURE 43.8** Presbycusis: bilateral high-frequency sensorineural deafness

Some features include:

- loss of high-frequency sounds
- usually associated with tinnitus

- intolerance to very loud sounds
- difficulty picking up high-frequency consonants, e.g. 'f', 's'—these sounds are often distorted or unheard, and there is confusion with words such as 'fit' and 'sit', 'fun' and 'sun'

Deafness is associated with various types of mental illness in the aged, including anxiety, depression, paranoid delusions, agitation and confusion because of sensory deprivation. The possibility of deafness should be kept in mind when assessing these problems.

## Signs indicating referral for hearing test

Possible indications for referring the older person:

- speaking too loudly
- difficulty understanding speech
- social withdrawal
- lack of interest in attending parties and other functions
- complaints about people mumbling
- requests to have speech repeated
- complaints of tinnitus
- setting television and radio on high volume

## Sudden deafness

Sudden deafness refers to sudden SNHL of greater than 30–35 dB with an onset period of between 12 hours and 3 days.<sup>9</sup> It specially excludes gradual progressive causes of SND, such as cumulative noise trauma or presbycusis, and also excludes causes of sudden deafness that may be related to pathology in the external auditory canal, TM or middle ear.

The main causes are given in **TABLE 43.5**.

**Table 43.5** Causes of sudden deafness

### Trauma:

- head injury
- diving
- flying
- acoustic blast

### Postoperative:

- previous stapedectomy

Viral infections (e.g. mumps, measles, herpes zoster)

Ototoxic drugs (e.g. aminoglycosides)

Cerebellopontine angle tumours (e.g. acoustic neuroma)

### Vascular disease:

- polycythaemia
- diabetes

Ménière syndrome

Cochlear otosclerosis

In several instances, despite a careful clinical examination and investigation, an explanation for sudden SND cannot be found. The cause of deafness in these cases is thought to be either vascular obstruction of the end artery system or viral cochleitis.<sup>7,8</sup> Fortunately, spontaneous recovery usually results.

Patients with sudden SND require immediate referral. It is a difficult problem both in diagnosis and management. Early diagnosis and a high index of suspicion are fundamental.<sup>8</sup> Two important conditions that deserve special reference are perilymphatic fistula, which occurs after stapedectomy, and an acoustic neuroma presumably causing compression of the internal auditory artery by the tumour in the internal auditory meatus.

## § Otosclerosis

Otosclerosis is a disease of the bone surrounding the inner ear and is the most common cause of conductive hearing loss in the adult with a normal tympanic membrane. The normal middle ear bone is replaced by vascular, spongy bone that becomes sclerotic.

## Clinical features<sup>3</sup>

Usually:

- a progressive disease
- develops in the 20s and 30s
- family history (autosomal dominant)
- bilateral or unilateral
- female preponderance
- affects the footplate of the stapes
- may progress rapidly during pregnancy
- conductive hearing loss
- begins in lower frequencies, then progresses
- SND may be present
- impedance audiometry shows characteristic features of conductive loss with a mild sensorineural loss
- may be associated with Ménière syndrome

## Management

- Referral to an ENT consultant
- Stapedectomy (approximately 90% effective)
- Hearing aid (less effective alternative)

## § Cholesteatoma<sup>7</sup>

A cholesteatoma is a sac of keratinising squamous epithelium that arises from a perforation involving the periphery of the TM. In other words, it is a 'big sac of skin' (refer to **CHAPTER 50**). It is dangerous to the ear because it tends to expand and destroy adjacent

structures, including the TM, ossicular chain and cochlear. Destruction of the first two may result in conductive hearing loss of up to 60 dB. Irreversible SND caused by otic capsule erosion may also occur. Surgical correction is mandatory.

### § Wax impaction<sup>10</sup>

Ear wax impaction occurs in about 5% of the normal population but is more prevalent in older people especially with the use of hearing aids. It is also common in those who use cotton buds (which should be avoided), where cerumen is packed onto the TM leading to a conductive hearing loss. The average wax production is 2.81 mg/week. Most ear wax clears spontaneously without treatment.

Methods of removal include:

- gentle syringing with warm (body temperature) water or normal saline solution—by trained practitioner (avoid syringing if infection or perforated TM)
- consider cerumenolytic drops for several days before syringing
  - carbamide peroxide (Ear Clear)
  - docusate sodium (Waxsol)
  - hydrogen peroxide
  - sodium bicarbonate
  - oil based (e.g. olive oil, almond oil)

Keratitis obturans is an accumulation of keratin to form a pearly-white plug that requires removal.

### § Noise-induced hearing loss

#### Clinical features

- Onset of tinnitus after work in excessive noise
- Speech seems muffled soon after work
- Temporary loss initially but becomes permanent if noise exposure continues
- High-frequency loss on audiogram

Sounds exceeding 85 dB are potentially injurious to the cochlea, especially with prolonged exposures. Common sources of injurious noise are industrial machinery, weapons and loud music.

### § Tinnitus

Tinnitus is defined as a sound perceived by the ear that arises from an internal source. When pathology in the inner ear is the cause, the tinnitus is non-pulsating, continuous and may have variable frequencies and intensity.

A thorough history and examination should be conducted so that tinnitus can be classified as

objective (e.g. heard with stethoscope) or non-objective and pulsatile, or non-pulsatile.

Precautions:

- exclude wax, drugs including marijuana, NSAIDs, salicylates, quinine and aminoglycosides,<sup>9</sup> vascular disease, depression, aneurysm, vascular tumours (e.g. glomus tumour), venous hum (jugular vein), acoustic neuroma (progressive and unilateral), Ménière syndrome and infections (e.g. viral cochleitis)
- beware of lonely elderly people living alone (suicide risk)

*Note:* Otosclerosis in young adults causes deafness and tinnitus.

#### Investigations

- Audiological examination by audiologist
- Tympanometry and speech discrimination
- MRI (if serious cause suspected)

#### Management

- Treat any underlying cause and aggravating factors. Otherwise, minimise symptoms.
- Educate and reassure the patient (tinnitus is nearly always amenable to treatment).

#### Holistic approach (options)

Mainly based on acoustic desensitisation:

- Relaxation techniques
- Tinnitus retraining therapy (clinical psychologist)
- Cognitive behaviour therapy
- Background 'noise' (e.g. music played during night for masking)
- Tinnitus maskers
- Hearing aids (based on audiologist assessment)
- Consider hypnotherapy

#### Medical (trials of options)

- Clonazepam 0.5 mg nocte
- Minerals (e.g. zinc and magnesium)
- Betahistine (Serc) 8–16 mg daily (max. 32 mg)
- Carbamazepine or sodium valproate
- Antidepressants

#### Acute severe tinnitus

- Lignocaine 1% IV slowly (up to 5 mL)

### Hearing aids

Hearing aids are most useful in conductive deafness. This is due to the relative lack of distortion, making amplification simple. In SND the dual problem

of recruitment and the hearing loss for higher frequencies may make hearing aids less satisfactory. Modern aids selectively amplify higher frequencies and 'cut out' excessive volume peaks that would cause discomfort. A trial of such aids should be made by a reliable hearing-aid consultant following full medical assessment.

### Cochlear implants<sup>8,11</sup>

The cochlear implant or 'bionic ear' is used in adults and children with severe hearing loss unresponsive to powerful hearing aids. The implant consists of an array of 22 electrodes inserted into the cochlea following mastoidectomy, attached to a receiver implanted in the skull next to the ear. External sounds are detected by an external processor worn behind the ear and connected to the implanted receiver with an external induction coil. Near normal speech and hearing may be achieved in children with congenital or acquired deafness with early implantation. The device is most suitable for children over 2 years and adults with severe deafness.

### Advice for families

Relatives and close friends need considerable advice about coping with deaf family members. They should be told that the deaf person may hear in a quiet room but not in a crowd, and advised of the range of aids and services available and the importance of proper maintenance of any hearing aids (especially with aged people).

#### Do

- Face the light when speaking to them.
- Speak directly to them.
- Speak clearly and naturally.
- Speak at a uniform pitch: avoid lowering your voice during or at the end of a sentence.
- Speak within 2 metres.
- Be tolerant and relaxed.
- Be patient with mistakes.
- Write key words on a paper pad when necessary.

#### Don't

- Speak with your back to them.
- Mumble your words.
- Use exaggerated lip movements.
- Shout.
- Put your hand or fingers over your mouth when talking.
- Repeat one word over and over.

### Red flags for priority referral<sup>8</sup>

- Asymmetrical sensorineural hearing loss
- Cranial nerve defects
- Ear canal or middle-ear mass
- Deep ear pain
- Discharging ear

### When to refer

- See 'Red flags' above.
- Sudden deafness.
- Any child with suspected deafness, including poor speech and learning problems, should be referred to an audiology centre.
- Any child with middle-ear pathology and hearing loss should be referred to a specialist.
- Unexplained deafness.

### Practice tips

- A mother who believes her child may be deaf is rarely wrong in this suspicion.
- Suspect deafness in an infant with delayed development and in children with speech defects or behavioural problems.
- Audiological assessment should be performed on children born to mothers with evidence of intrauterine infection by any of the TORCH organisms (toxoplasmosis, rubella, cytomegalovirus and herpes virus).
- No child is too young for audiological assessment. Informal office tests are inadequate for excluding hearing loss.
- Sounds tend to be softer in a conductive hearing loss and distorted with sensorineural loss.
- People with conductive deafness tend to speak softly, hear better in a noisy environment, hear well on the telephone and have good speech discrimination.
- People with SND tend to speak loudly, hear poorly in a noisy environment, have poor speech discrimination and hear poorly on the telephone.

Tung-su Pai (time under tain)

Diarrhoea is defined as an intestinal disorder characterised by abnormal frequency and liquidity of faecal evacuations.

Acute self-limiting diarrhoea, which is very common and frequently not seen by the medical practitioner, is usually infective and mild, and resolves within days. In Australia most infective cases are viral. The causes of diarrhoea are numerous, thus making a detailed history and examination very important in leading to the diagnosis. 'Chronic' diarrhoea is that lasting at least 4–6 weeks. Important causes are presented in **FIGURE 44.1**.

The terminology for acute infective diarrhoea can be confusing. A simple classification is:

- vomiting and diarrhoea = gastroenteritis
- diarrhoea (only) = enteritis

### Key facts and checkpoints

- The characteristics of the stool provide a useful guide to the site of the bowel disorder.
- Disorders of the upper GIT tend to produce diarrhoea stools that are copious, watery or fatty, pale yellow or green.

- Colonic disorder tends to produce stools that are small, of variable consistency, brown and may contain blood or mucus.
- Acute gastroenteritis should be regarded as a diagnosis of exclusion.
- Chronic diarrhoea is more likely to be due to protozoal infection (e.g. amoebiasis, giardiasis or *Cryptosporidium*) than bacillary dysentery.
- A history of travel, especially to countries at risk of endemic bowel infections, is essential.
- Certain antibiotics can cause an overgrowth of *Clostridium difficile*, which produces pseudomembranous colitis.
- Coeliac disease, although a cause of failure to thrive in children, can present at any age.
- In disorders of the colon the patient experiences frequency and urgency but passes only small amounts of faeces.
- Diarrhoea can be classified broadly into 4 types:
  - acute watery diarrhoea
  - bloody diarrhoea (acute or chronic)
  - chronic watery diarrhoea
  - steatorrhea

#### General

- diet
- antibiotics
- laxatives
- irritable bowel syndrome
- lactose intolerance
- steatorrhea (e.g. coeliac disease)
- poisons
- endocrine

#### Organic disease of bowel

chronic infections (e.g. *Giardia lamblia*)

carcinoma of bowel

- diverticular disorder  
inflammatory bowel disease:
- ulcerative colitis
  - Crohn disease
  - pseudomembranous colitis

impacted faeces with spurious diarrhoea

**FIGURE 44.1** Important causes of chronic diarrhoea

## A diagnostic approach

A summary of the diagnostic strategy model is presented in **TABLE 44.1**.

**Table 44.1** Diarrhoea: diagnostic strategy model

Q. Probability diagnosis
A. Acute: <ul style="list-style-type: none"> <li>• Gastroenteritis/infective enteritis</li> <li>• Dietary indiscretion</li> <li>• Antibiotic reaction</li> </ul> Chronic: <ul style="list-style-type: none"> <li>• Irritable bowel syndrome</li> <li>• Drug reactions (e.g. laxatives)</li> <li>• Chronic infections</li> </ul>
Q. Serious disorders not to be missed
A. Neoplasia: <ul style="list-style-type: none"> <li>• colorectal cancer</li> <li>• ovarian cancer</li> <li>• peritoneal cancer</li> </ul> HIV infection (AIDS) <ul style="list-style-type: none"> <li>• Infections:           <ul style="list-style-type: none"> <li>• cholera</li> <li>• typhoid/paratyphoid</li> <li>• amoebiasis</li> <li>• malaria</li> <li>• enterohaemorrhagic <i>E. coli</i> enteritis</li> </ul> </li> </ul> Inflammatory bowel disease: <ul style="list-style-type: none"> <li>• Crohn/ulcerative colitis</li> <li>• pseudomembranous colitis</li> </ul> Non-microbial food poisoning e.g. death cap mushroom <ul style="list-style-type: none"> <li>• Intussusception</li> <li>• Pelvic appendicitis/pelvic abscess</li> </ul>
Q. Pitfalls
A. - short bowel syndrome
- amyloidosis
- toxic shock
- Zollinger–Ellison syndrome

Q. Seven masquerades checklist

A. Diabetes  
Drugs (e.g. metformin)  
Thyroid disorder (hyper)

Q. Is the patient trying to tell me something?

A. Yes, diarrhoea may be a manifestation of anxiety state or irritable bowel syndrome.

## Probability diagnosis

### Acute diarrhoea

Common causes are:

- gastroenteritis/enteritis:
  - bacterial: *Salmonella* sp., *Campylobacter jejuni*, *Shigella* sp., enteropathic *Escherichia coli*, *Staphylococcus aureus* (food poisoning)
  - viral: rotavirus (50% of children hospital admissions<sup>1</sup>), norovirus, astrovirus, adenovirus
- dietary indiscretions (e.g. binge eating)
- antibiotic reactions

### Red flag pointers for diarrhoea

- Unexpected weight loss
- Persistent/unresolved
- Fever
- Overseas travel
- Severe abdominal pain
- Family history: bowel cancer, Crohn disease

### Chronic diarrhoea

Irritable bowel syndrome was the commonest cause of chronic diarrhoea in a UK study.<sup>2</sup>

Drug reactions are also important. These include ingestion of laxatives, osmotic agents such as lactose and sorbitol in chewing gum, alcohol, antibiotics, thyroxine and others.

Acute gastroenteritis that persists into a chronic phase is relatively common, especially in travellers returning from overseas. Important considerations are *Giardia lamblia*, *C. difficile*, *Yersinia*, *Entamoeba histolytica*, *Cryptosporidium* and HIV infection.

### Serious disorders not to be missed

Colorectal carcinoma must be considered with persistent diarrhoea, especially if of insidious onset.

AIDS due to symptomatic HIV infection needs consideration, especially in those at risk. The serious infectious disorders that can affect international travellers, such as cholera, typhoid, paratyphoid and amoebiasis, should also be kept in mind.

In children, coeliac disease and fibrocystic disease can present as chronic diarrhoea while intussusception, although not causing true diarrhoea, can present as loose, redcurrant jelly-like stools and should not be misdiagnosed (as gastroenteritis). Appendicitis must also be considered in the onset of acute diarrhoea and vomiting.

Infection with enterohaemorrhagic strains of *E. coli* (e.g. O157:H7, O111:H8) may lead to the haemolytic uraemic syndrome or thrombotic thrombocytopenic purpura, particularly in children. What appears to be simple enteritis can eventuate to be fatal.

**Clue:** Think of it with atypical gastroenteritis and bloody diarrhoea. Avoid antibiotics.

Death cap mushroom (the world's most lethal)—*Amanita phalloides* (FIGURE 44.2)—causes severe gastroenteritis followed by delayed hepatic failure and AKF.

FIGURE 44.2 *Amanita phalloides* (death cap mushroom)

Source: Shutterstock.com

## Pitfalls

There are many traps in evaluating the patient with diarrhoea, including drug ingestion, especially vitamin C (sodium ascorbate powder), which causes diarrhoea. Faecal impaction with spurious diarrhoea is an age-old pitfall, as is lactase deficiency, which may go undiagnosed for many years. In recent times infection with *G. lamblia* may smoulder on for months with watery, offensive stools before diagnosis.

## General pitfalls

- Not considering acute appendicitis in acute diarrhoea—can be retrocaecal or pelvic appendicitis
- Missing faecal impaction with spurious diarrhoea
- Failing to perform a rectal examination
- Failing to consider acute ischaemic colitis in an elderly patient with the acute onset of bloody diarrhoea stools (following sudden abdominal pain in preceding 24 hours)

## Seven masquerades checklist

The significant masquerades include diabetes, when an autonomic neuropathy may cause alternating bouts of constipation and diarrhoea, thyrotoxicosis and drugs. Drugs that can cause diarrhoea are summarised in TABLE 44.2.

Table 44.2 Drugs that can cause diarrhoea

Alcohol, esp. chronic abuse (often overlooked!)
Antibiotics, esp. penicillin derivatives
Antihypertensives, selected (e.g. methyldopa)
Acarbose
Cardiac agents (e.g. digoxin, quinidine)
Chenodeoxycholic acid
Cisapride
Colchicine
Cytotoxic agents (e.g. methotrexate)
Food and drug additives: sorbitol, mannitol, fructose, lactose
Heavy metals
H <sub>2</sub> -receptor antagonists
Iron-containing compounds
Laxatives
Magnesium-containing antacids/magnesium supplements
Metformin
Misoprostol
NSAIDs
Orlistat
Prostaglandins
Quinidine
Salicylates
Sildenafil
Statins
Theophylline
Thyroxine

## Pseudomembranous colitis (antibiotic-associated diarrhoea)

This colitis can be caused by the use of any antibiotic, especially clindamycin, lincomycin, ampicillin and the cephalosporins (an exception is vancomycin). It

is usually due to an overgrowth of *C. difficile*, which produces a toxin that causes specific inflammatory lesions, sometimes with a pseudomembrane. It may occur, uncommonly, without antibiotic usage.

### Clinical features

- Profuse, watery diarrhoea
- Abdominal cramping and tenesmus  $\pm$  fever
- Within 2 days of taking antibiotic (can start up to 4 to 6 weeks after usage)
- Persists 2 weeks (up to 6) after ceasing antibiotic

Diagnosed by characteristic lesions on sigmoidoscopy and a tissue culture assay for *C. difficile* toxin.

### Treatment<sup>3</sup>

- Cease antibiotic  
Mild to moderate: metronidazole 400 mg (o) tds for 10 days  
Severe: vancomycin 125 mg (o) qid for 10 days (in consultation with specialist)

### Psychogenic considerations

Anxiety and stress can cause looseness of the bowel. The irritable bowel syndrome, which is a very common condition, may reflect underlying psychological factors and most patients find that the symptoms are exacerbated by stress. Look for evidence of depression.

In children chronic diarrhoea can occur with the so-called 'maternal deprivation syndrome', characterised by growth and developmental retardation due to adverse psychosocial factors.

## The clinical approach

### History

As always, the history is the key to the diagnosis. First establish what the patient means by the term 'diarrhoea', his or her normal pattern and how the presenting problem varies from normal.

It is important to analyse the nature of the stools, the frequency of diarrhoea, associated symptoms, including abdominal pain, and constitutional symptoms, such as fever. Food intake in the past 72 hours and recent travel abroad may give a clue to acute gastroenteritis or food poisoning (an acute, self-limiting illness of diarrhoea and vomiting). The difference between food poisoning and infective gastroenteritis is presented in TABLE 44.3. However, there can be an overlap of features from a specific

organism and the exercise may be semantic, but it may provide a clue to food-borne causation. A summary of non-microbial food poisoning is presented in TABLE 44.4.

A drug history is relevant, as is a family history of diarrhoea, which may be significant for coeliac disease, Crohn disease and cystic fibrosis.

**Table 44.3** Comparison of acute diarrhoea due to bacterial food poisoning and infective gastroenteritis

	Food poisoning	Infective gastroenteritis
<b>Responsible organisms</b>	Toxins from: <i>Staphylococcus aureus</i> <i>Salmonella</i> sp. <i>Clostridium perfringens</i> <i>Clostridium difficile</i> <i>Vibrio parahaemolyticus</i> <i>Aeromonas hydrophilia</i> <i>Bacillus cereus</i>	Viral Bacterial e.g. <i>Campylobacter jejuni</i> <i>Escherichia coli</i> <i>Shigella</i> sp. <i>Salmonella</i> sp.
<b>Incubation period (onset from contact)</b>	Short—within 24 hours Average—12 hours <i>S. aureus</i> —2–4 hours	3–5 days
<b>Diarrhoea</b>	Watery	Diarrhoea $\pm$ blood
<b>Other features</b>	Abdominal cramps (milder) Dehydration Headache Vomiting	Abdominal cramps
<b>Typical foods</b>	Chicken Meat Seafood Rice Custards and cream ( <i>S. aureus</i> )	Milk Water Chicken

**Table 44.4** Non-microbial food poisoning<sup>4</sup>

Food (specific types)	Toxin	Onset	Features (symptoms)
Mushrooms	Muscarine	Minutes to hours	N, V, D, P: CNS symptoms
Toadstools	Amatoxin	Hours	N, V, D, P: hepatic failure
Immature or sprouting potatoes	Solanine	Within hours	N, V, D, P Throat constriction
Fish	Ichthysarcotoxin Various (e.g. ciguatera, scombrototoxin)	10–60 minutes (occasionally longer)	N, V, D, P Circumoral tingling CNS symptoms Collapse
Mussels	Mytilotoxin	5–30 minutes	N, V, P CNS: paralysis
Grain, esp. rye	Ergot fungus	Minutes to 24 hours	N, V, P Circulatory and CNS
Fava beans (favism)	Enzyme deficiency	Rapid	V, D Acute haemolysis

N = nausea; V = vomiting; D = diarrhoea; P = abdominal pain

Enquire sensitively about sexual activity. Patients at risk from HIV infection should be discreetly evaluated.

## Key questions

### Acute diarrhoea

- Where did you eat in the 24 hours before the diarrhoea started?
- What food did you eat during this time?
- Did you have chicken or seafood recently? (Chicken may be contaminated with *Salmonella* or *Campylobacter* and seafood with *Vibrio parahaemolyticus*.)
- Did any other people get the same problem?
- Have you travelled overseas recently? Where?
- Have you noticed any blood or mucus in your motions?
- Have you had any previous attacks?
- Have you noticed fever, weakness or other symptoms?

### Chronic diarrhoea

- Have you noticed any blood or mucus in the motion?
- Have you travelled overseas recently? Where?
- Do you have pain and is it relieved by opening your bowels or passing wind?
- Does anyone else in your family have diarrhoea?

- Have you had any operations on your abdomen recently?
- What medications are you taking?
- Are you taking antibiotics?
- Do you take vitamin C for your health?
- Do you take laxatives?
- How much alcohol do you drink? Fruit juice?
- How much milk do you drink?
- What about thick shakes, ice-cream and yoghurt?
- Do you get clammy or shaky, or have you lost weight?
- Have you had trouble with pain in your joints, back pain, eye trouble or mouth ulceration?
- Do you have trouble flushing your motions down the toilet?
- Do you get diarrhoea during the night?
- Are you under a lot of stress?

## Significance of symptoms

### Abdominal pain

Central colicky abdominal pain indicates involvement of the small bowel, while lower abdominal pain points to the large bowel.

### Nature of stools

If small volume, consider inflammation or carcinoma of colon; if large volume, consider laxative abuse and malabsorption.

If there is profuse bright red bleeding, consider diverticulitis or carcinoma of colon, and if small amounts with mucus or mucopus consider inflammatory bowel disorder. The presence of blood in the stools excludes functional bowel disorder. Diarrhoea at night suggests organic disease. In steatorrhoea the stools are distinctively pale, greasy, offensive, floating and difficult to flush. It is exacerbated by fatty foods.

'Rice water' stool is characteristic of cholera and 'pea soup' stool of typhoid fever.

## Examination

The extent of the examination depends on the nature of the presenting problem. If it is acute, profuse and associated with vomiting, especially in a child, the examination needs to be general to assess the effects of fluid, electrolyte and nutritional loss. An infant's life is in danger from severe gastroenteritis and this assessment is a priority. The general nutritional and electrolyte assessment is also relevant in chronic diarrhoea with malabsorption, and this includes looking for evidence of muscle weakness (e.g. hypokalaemia, hypomagnesaemia, tetany [hypocalcaemia], bruising [vitamin K loss]).

The examination should also focus on the abdomen (systematic palpation), the rectum and the skin. Possible helpful signs are included in **FIGURE 44.3**.

## The stool

Ideally the stool should be examined. The consistency of the stool as an aid to diagnosis<sup>2,4</sup> is summarised in **TABLE 44.5**, the features of the stool in **TABLE 44.6**, and the characteristics that distinguish between small and large bowel diarrhoea<sup>1</sup> are presented in **TABLE 44.7**. Note the presence of blood or mucus or steatorrhoea.

**Table 44.5** Stool consistency as an aid to diagnosis

Consistency	Probable cause
Liquid and uniform	Small bowel disorder (e.g. gastroenteritis)
Loose with bits of faeces	Colonic disorder
Watery, offensive, bubbly	<i>Giardia lamblia</i> infection
Liquid or semiformed, mucus $\pm$ blood	<i>Entamoeba histolytica</i>
Bulky, pale, offensive	Malabsorption
Pellets or ribbons	Irritable bowel syndrome

**Table 44.6** Stool features as an aid to diagnosis

Stool appearance	Cause to consider
China clay	Obstructive jaundice
Black stool	Melaena (blood) in faeces
Pea soup	Typhoid fever
Rabbit pellets	Irritable bowel syndrome
Redcurrant jelly	Intussusception
Rice water	Cholera
Silver stool	Carcinoma of ampulla of Vater
Toothpaste	Hirschsprung disease

**Table 44.7** Distinction between small and large bowel diarrhoea

	Small bowel	Large bowel
<b>Volume</b>	Large	Small
<b>Pain</b>	Central	Lower/LIF
<b>Borborygmi</b>	++	—
<b>Undigested food</b>	+	—
<b>Steatorrhoea</b>	+/-	—
<b>Blood</b>	—	+
<b>Mucus</b>	—	+
<b>Urgency</b>	—	+
<b>Tenesmus</b>	—	+

## Investigations<sup>4</sup>

The following list includes a range of tests that may be required. Appropriate tests should be judiciously selected and in some instances, such as acute self-limiting diarrhoea, no investigations are necessary.

- Stool tests:
  - microscopy for parasites and red and white cells (warm specimen for amoebiasis)
  - cultures: may need special requests for *Campylobacter* sp., *C. difficile* and toxin, *Yersinia* sp., *Cryptosporidium* sp., *Aeromonas* sp. (stools must be collected fresh on three occasions)
- Blood tests: haemoglobin; MCV, WCC, ESR, iron, ferritin, folate, vitamin B12, calcium, electrolytes, thyroid function, HIV tests
- Antibody tests, total IgA (e.g. IgA anti-endomysial, IgA transglutaminase for coeliac disease); PCR tests (where applicable)

FIGURE 44.3 Possible significant signs in the patient with diarrhoea

- Haemagglutination tests for amoebiasis
- *C. difficile* tissue culture assay
- Malabsorption studies
- Endoscopy:
  - proctosigmoidoscopy
  - flexible sigmoidoscopy/colonoscopy (with biopsy)
  - small bowel biopsy (coeliac disease)
- Radiology:
  - plain X-ray abdomen—of limited value
  - small bowel enema
  - barium enema, especially double contrast

*Note:* HIV patients should be investigated in specialist centres.

### Principles of treatment<sup>4</sup>

When an underlying cause of diarrhoea can be identified, apart from some common infections, management should be directed at that cause. There are a few situations in which the causative bacterial or parasitic pathogen requires specific treatment, for example, giardiasis. The management is determined by the nature of the pathogen and the severity of the illness.

However, in Australia most infective cases are viral. The basic principle therefore is to achieve and maintain adequate hydration until the illness resolves. In adults and children oral rehydration is indicated unless there is evidence of impending circulatory

'shock' demanding intravenous therapy. Oral rehydration solution containing sodium, potassium and glucose should be considered for patients with mild to moderate dehydration. Adults should drink 2 to 3 L of the solution in 24 hours.

In general, treatment should not be directed specifically at altering the frequency and consistency of the stools. The antimotility drugs (loperamide, diphenoxylate and codeine) have a role restricted to short-term control of symptoms in adults during periods of significant social inconvenience, such as travel. It must be emphasised that antimotility drugs are never indicated for management of acute diarrhoea in infants and children.<sup>5</sup>

The traditional absorbent agents, such as kaolin/pectin mixtures, activated charcoal and other mineral clays, have not been shown to be of value and may interfere with absorption of other drugs. They should not be used.

Specific antibiotics are reserved for the treatment of giardiasis, amoebiasis, antibiotic-associated diarrhoea, cholera and typhoid. Although antibiotics are usually unnecessary, in most cases they may be indicated for severe cases of *Campylobacter* enteritis, *Salmonella* enteritis, shigellosis and traveller's diarrhoea.

## MALABSORPTION

It is important to distinguish the steatorrhoea of various malabsorption syndromes from diarrhoea. Important causes are presented in TABLE 44.8.

The common causes are coeliac disease, chronic pancreatitis and postgastrectomy.

### Clinical features

- Bulky, pale, offensive, frothy, greasy stools
- Stools difficult to flush down toilet
- Weight loss
- Prominent abdomen
- Failure to thrive (in infants)
- Increased faecal fat
- Signs of multiple vitamin deficiencies (e.g. A, D, E, K)
- Sore tongue (glossitis)
- Hypochromic or megaloblastic anaemia (possible)

Refer for specific investigations (e.g. FBE, barium studies, small bowel biopsy, faecal fat [ $>21$  g/3 days]).

### § Coeliac disease<sup>3</sup>

Synonyms: coeliac sprue, gluten-sensitive enteropathy.

*Note:* It can appear at any age; refer to coeliac disease in children (see later in chapter).

**Table 44.8** Important causes of malabsorption

Primary mucosal disorders
Gluten-sensitive enteropathy (coeliac disease)
Tropical sprue
Lactose intolerance (lactase deficiency)
Crohn disease (regional enteritis)
Whipple disease
Parasite infections (e.g. <i>Giardia lamblia</i> )
Lymphoma
Maldigestion states
Luminal abnormalities:
• postsurgery (e.g. gastrectomy, ileal resection)
• systemic sclerosis
Pancreatic disorders
Chronic pancreatitis
Cystic fibrosis
Pancreatic tumours (e.g. Zollinger–Ellison)

It is widely underdiagnosed because most patients present with non-GIT symptoms, such as tiredness.

There is a genetic factor in this autoimmune disorder with a 1 in 10 chance if a first-degree relative is affected. Consider screening under 2 years if there is such an association.

### Clinical features

- Classic tetrad: diarrhoea, weight loss, iron/folate deficiency, abdominal bloating
- Malaise, lethargy
- Flatulence
- Mouth ulceration
- Diarrhoea with constipation (alternating)
- Pale and thin patient
- No subcutaneous fat

### Diagnosis

- Elevated faecal fat
- Characteristic duodenal biopsy: villous atrophy (key test)
- Total IgA level
- IgA anti-glutadin antibodies (screening—limited)
- IgA anti-endomysial antibodies ( $>90\%$  sensitivity and specificity)

- IgA transglutaminase antibodies (>90% sensitivity and specificity)

### Associations

- Iron-deficiency anaemia
- Type 1 diabetes
- Pernicious anaemia
- Primary biliary cirrhosis
- Subfertility
- Malignancy, especially lymphoma
- Dermatitis herpetiformis
- IgA deficiency
- Autoimmune thyroid disease
- Osteoporosis
- Neurological (e.g. seizures, ataxia, peripheral neuropathy)
- Down syndrome

### Management

- Diet control: high complex carbohydrate and protein, low fat, gluten-free (no wheat, barley, rye and oats)
- Treat specific vitamin and mineral deficiencies
- Give pneumococcal vaccination (increased risk of pneumococcus sepsis)

### Gluten-free diet

Avoid foods containing gluten either as an obvious component (e.g. flour, bread, oatmeal), or as a hidden ingredient (e.g. dessert mix, stock cube).

Forbidden foods include:

- standard bread, pasta, crispbreads, flour
- standard biscuits and cakes
- breakfast cereals made with wheat or oats
- oatmeal, wheat bran, barley/barley water
- 'battered' or bread-crumbed fish, etc.
- meat and fruit pies
- most stock cubes and gravy mixes

### § Whipple disease

This is a rare malabsorption disorder usually affecting white males. It is caused by the bacillus *Tropheryma whipplei*. It may involve the heart, lungs and CNS.

### Clinical features

- Males >40 years
- Chronic diarrhoea (steatorrhoea)
- Arthralgia (migratory seronegative arthropathy mainly of peripheral joints)
- Weight loss

- Lymphadenopathy
- $\pm$  Fever

### Diagnosis

- PCR for *T. whipplei*
- Jejunal biopsy—stunted villi

### Treatment

IV ceftriaxone for 2 weeks then cotrimoxazole or tetracycline for up to 12 months

This produces a dramatic improvement.

## Diarrhoea in the elderly

The older the patient, the more likely a late onset of symptoms that reflect serious underlying organic disease, especially malignancy. Colorectal cancer needs special consideration. The older the patient, especially the bedridden elderly patient, the more likely the presentation of faecal impaction with spurious diarrhoea. The possibility of drug interactions, including digoxin, should also be considered. Ischaemic colitis must be considered in an elderly patient.

### § Ischaemic colitis

This is due to atheromatous occlusion of mesenteric vessels (low blood flow) (see CHAPTER 34).

### Clinical features

Clinical features include:

- sharp abdominal pain in an elderly patient with bloody diarrhoea (low blood flow)  
*or*
- periumbilical pain and diarrhoea about 15–30 minutes after eating
- maybe loud bruits over central abdomen
- other evidence of generalised atherosclerosis
- barium enema shows 'thumb printing' sign due to submucosal oedema
- the definitive test is aortography and selective angiography of mesenteric vessels
- most episodes resolve—may be followed by a stricture

## Diarrhoea in children

The commonest cause of diarrhoea in children is acute infective gastroenteritis, but there are certain conditions that develop in childhood and infancy

and require special attention. The presentation of small amounts of redcurrant jelly-like stool with intussusception should also be kept in mind. Of the many causes only a few are commonly seen. The two commonest causes are infective gastroenteritis and antibiotic-induced diarrhoea.

Important causes of diarrhoea in children are:

- infective gastroenteritis
- antibiotics
- overfeeding (loose stools in newborn)
- dietary indiscretions
- toddler's diarrhoea
- sugar (carbohydrate) intolerance
- food allergies (e.g. milk, soya bean, wheat, eggs)
- maternal deprivation
- malabsorption states: cystic fibrosis, coeliac disease

*Note:* Exclude surgical emergencies (e.g. acute appendicitis), infections (e.g. pneumonia), septicaemia, otitis media <5 years.

## § Acute gastroenteritis

*Note:* Dehydration from gastroenteritis is an important cause of death, particularly in obese infants (especially if vomiting accompanies the diarrhoea).

### Definition

It is an illness of acute onset, of less than 10 days' duration associated with fever, diarrhoea and/or vomiting, where there is no other evident cause for the symptoms.<sup>5</sup>

### Causes

- Mainly rotavirus (developed countries) and adenovirus: viruses account for about 80%
- Bacterial: *C. jejuni* and *Salmonella* sp. (two commonest), *E. coli* and *Shigella* sp.
- Protozoal: *G. lamblia*, *E. histolytica*, *Cryptosporidium*
- Food poisoning—staphylococcal toxin

*Differential diagnoses.* These include septicaemia, urinary tract infection, intussusception, appendicitis, pelvic abscess, partial bowel obstruction, diabetes mellitus and antibiotic reaction<sup>4</sup> (see TABLE 44.9).

*Note:* Exclude acute appendicitis and intussusception in the very young.

### Symptoms

- Anorexia, nausea, poor feeding, vomiting, fever, diarrhoea (fever and vomiting may be absent)
- Fluid stools (often watery) 10–20 per day

**Table 44.9** Differential diagnosis of acute diarrhoea and vomiting in children

#### Bowel infection

- viruses
- bacteria
- protozoal
- food poisoning—staphylococcal toxin

#### Systemic infection

#### Abdominal disorders

- appendicitis
- pelvic abscess
- intussusception
- malrotation

#### Urinary tract infection

#### Antibiotic reaction

#### Diabetes mellitus

- Crying—due to pain, hunger, thirst or nausea
- Bleeding—uncommon (usually bacterial)
- Anal soreness

*Viral indication:* large volume, watery, typically lasts 2–3 days, systemic symptoms uncommon.

*Bacterial indication:* small motions, blood, mucus, abdominal pain and tenesmus.

*Dehydration:* must be assessed (see TABLE 44.10).

*Complications:*

- febrile convulsions
- sugar (lactose) intolerance (common)
- septicaemia, especially *Salmonella*

### Management

Management is based on the assessment and correction of fluid and electrolyte loss.<sup>5,6</sup> Since dehydration is usually isotonic with equivalent loss of fluid and electrolytes, serum electrolytes will be normal.

*Note:* The most accurate way to monitor dehydration is to weigh the child, preferably without clothes, on the same scale each time. However, the easiest is clinical assessment (e.g. vomiting, no urine, lethargy and thirst).

### Avoid

- Drugs: anti-diarrhoeals, anti-emetics and antibiotics
- Lemonade or similar sugary soft drink: osmotic load too high, can use if diluted 1 part to 4 parts water but sugar may be poorly tolerated

Table 44.10 Assessment of hydration

	Mild	Moderate	Severe
<b>Body weight loss</b>	4–5%	6–9%	≥10%
<b>Symptoms/general observations</b>	Thirsty Alert Restless	Thirsty Restless Lethargic Irritable	Infants: drowsy, limp, cold, sweaty, cyanotic limbs, comatose Older: apprehensive, cold and sweaty, cyanotic limbs
<b>Signs</b>	Normal	Dry mucous membranes, absent tears	Rapid feeble pulse Hypotensive Sunken eyes and fontanelles Very dry mucous membranes
<b>Pinched skin test</b>	Normal	Retracts slowly (1–2 seconds)	Retracts very slowly (>2 seconds)
<b>Urine output</b>	Normal	Decreased	Nil
<b>Treatment</b>	Oral rehydration: • small amounts of fluids often • continue breast-feeding • solids after 24 hours • provide maintenance fluid and loss	Oral rehydration: • consider nasogastric tube for steady fluid infusion or • IV infusion	Admit to hospital Urgent IV infusion: isotonic fluid

### To treat or not to treat at home

- Treat at home—if family can cope, vomiting is not a problem and no dehydration.
- Admit to hospital—if dehydration or persisting vomiting or family cannot cope; also infants <6 months and high-risk patients.

### Advice to parents (for mild-to-moderate diarrhoea)

If applicable, remove child from day care or school and keep away from food preparation areas. Advise about hygiene, including handwashing and napkin disposal. If children are not dehydrated, encourage eating and drinking as tolerated.

### General rules

- Give small amounts of fluids often
- Start solids after 24 hours
- Continue breastfeeding (should be increased in frequency e.g. hourly)  
or
- Continue formula feeding if tolerated or resume it after 24 hours.
- Consider stool culture and test for rotavirus for symptoms that persist and worsen

### Day 1

Give fluids, a little at a time and often (e.g. 5 mL every 1–2 minutes by spoon or syringe or 50 mL every 15 minutes if vomiting a lot). A good method is to give 200 mL (about 1 cup) of fluid every time a watery stool is passed or a big vomit occurs.

The ideal fluid is Gastrolyte or New Repalyte. Other suitable oral rehydration preparations are WHO-recommended solutions Electrolade and Glucolyte.

A new product is Hydralyte paediatric rehydration, which is a solution as an 'ice-block' formulation:

- children 1–2 years—one 'ice-block' per hour
- older children—as often as desired.

**Warning:** Do *not* use straight lemonade or mix up Gastrolyte with lemonade or fluids other than water.

#### Alternatives are:

• lemonade (not low-calorie)	1 part to 6 parts water
• sucrose (table sugar)	1 teaspoon to 120 mL water
• glucose	1 teaspoon to 120 mL water
• cordials (not low-calorie)	1 part to 16 parts water
• fruit juice	1 part to 4 parts water

*Method of assessing fluid requirements<sup>3</sup>*

- Fluid loss (mL) = % dehydration × body weight (kg) × 10
- Maintenance (mL/kg/24 h): 1–3 mo: 120 mL; 4–12 mo: 100 mL; >12 mo: 80 mL
- Allow for continuing loss.  
Example: 8 month 10 kg child with 5% dehydration:  
Fluid loss =  $5 \times 10 \times 10 = 500$  mL  
Maintenance =  $100 \times 10 = 1000$  mL  
Total 24-hour requirement (min.) = 1500 mL  
Approximate average hourly requirement = 60 mL
- Aim to give more (replace fluid loss) in the first 6 hours.
- Rule of thumb: give 100 mL/kg (infants) and 50 mL/kg (older children) in first 6 hours.

**Days 2 and 3**

Reintroduce your baby's milk or formula diluted to half strength (i.e. mix equal quantities of milk or formula and water). Their normal food can be continued but do not worry that your child is not eating food. Solids can be commenced after 24 hours. Best to start with bread, plain biscuits, jelly, stewed apple, rice, porridge or non-fat potato chips. Avoid fatty foods, fried foods, raw vegetables and fruit, and wholegrain bread.

**Day 4**

Increase milk to normal strength and gradually continue reintroduction to usual diet.

**Breastfeeding.** If your baby is not vomiting, continue breastfeeding but offer extra fluids (preferably Gastrolyte) between feeds. If vomiting is a problem, express breast milk for the time being while you follow the oral fluid program.

**Note:** Watch for lactose intolerance as a sequela—explosive diarrhoea after introducing formula. Replace with a lactose-free formula.

If acute invasive or persistent *Salmonella* are present, give antibiotics (ciprofloxacin or azithromycin).

**CHRONIC DIARRHOEA IN CHILDREN****§ Sugar intolerance**

**Synonyms:** carbohydrate intolerance, lactose intolerance.

The commonest offending sugar is lactose.

Diarrhoea often follows acute gastroenteritis when milk is reintroduced into the diet (some recommend

waiting for 2 weeks). Stools may be watery, frothy, smell like vinegar and tend to excoriate the buttocks. They contain sugar. Exclude giardiasis.

A simple test follows.

- Line the napkin with thin plastic and collect fluid stool.
- Mix 5 drops of liquid stool with 10 drops of water and add a Clinitest tablet (detects lactose and glucose but not sucrose).
- A positive result indicates sugar intolerance.

Diagnosis: lactose breath hydrogen test

**Treatment**

- Remove the offending sugar from the diet.
- Use milk preparations in which the lactose has been split to glucose and galactose by enzymes, or use soya protein.

**Note:** Most milk allergies improve with age.

**§ Toddler's diarrhoea**

A clinical syndrome of loose, bulky, non-offensive stools with fragments of undigested food in a well, thriving child. The onset is usually between 8 and 20 months. Associated with high fructose intake (fruit juice diarrhoea).

Diagnosis by exclusion; treatment by dietary adjustment.

**§ Cow's milk protein intolerance<sup>7</sup>**

This is not as common as lactose intolerance. Diarrhoea is related to taking a cow's milk formula and relieved when it is withdrawn.

Allergic responses to cow's milk protein may result in a rapid or delayed onset of symptoms. Delayed onset may be more difficult to diagnose, presenting with diarrhoea, malabsorption or failure to thrive.

It is diagnosed by unequivocal reproducible reactions to elimination and challenge. If diagnosed, remove cow's milk from the diet and replace with either soy milk, a hydrolysed or an elemental formula (see CHAPTER 80).

**§ Inflammatory bowel disorders**

These disorders, which include Crohn disease and ulcerative colitis, can occur in childhood. A high index of suspicion is necessary to make an early diagnosis. Approximately 5% of cases of chronic ulcerative colitis have their onset in childhood.<sup>5</sup>

## § Chronic enteric infection

Responsible organisms include *Salmonella* sp., *Campylobacter*, *Yersinia*, *G. lamblia* and *E. histolytica*. With persistent diarrhoea it is important to obtain microscopy of faeces and aerobic and anaerobic stool cultures. *G. lamblia* infestation is not an uncommon finding and may be associated with malabsorption, especially of carbohydrate and fat. Giardiasis can mimic coeliac disease.

## § Coeliac disease

(See earlier in chapter.)

Clinical features in childhood:

- usually presents at 9–18 months, but any age
- previously thriving infant
- anorexia, lethargy, irritability
- failure to thrive
- malabsorption—abdominal distension
- offensive frequent stools

Diagnosis: duodenal biopsy (definitive)

Treatment: remove gluten from diet

## § Cystic fibrosis

Cystic fibrosis which presents in infancy is the commonest of all inherited disorders (1 per 2500 live births). Refer to [CHAPTER 18](#).

## ACUTE GASTROENTERITIS IN ADULTS

### Features

- Invariably a self-limiting problem (1–3 days)
- Abdominal cramps
- Possible constitutional symptoms (e.g. fever, malaise, nausea, vomiting)
- Other meal sharers affected → food poisoning
- Consider dehydration, especially in the elderly
- Consider possibility of enteric fever

## § Traveller's diarrhoea

The symptoms are usually as above but very severe diarrhoea, especially if associated with blood or mucus, may be a feature of a more serious bowel infection such as amoebiasis. Possible causes of diarrhoeal illness are presented in [TABLE 14.1](#), in [CHAPTER 14](#). Most traveller's diarrhoea is caused by *E. coli*, which produces a watery diarrhoea within 14 days of arrival in a foreign country. (For specific treatment refer to the section on Traveller's diarrhoea in [CHAPTER 14](#).)

## Persistent traveller's diarrhoea

Any traveller with persistent diarrhoea after visiting less developed countries, especially India and China, may have a protozoal infection such as amoebiasis or giardiasis.

If there is a fever and blood or mucus in the stools, suspect amoebiasis. Giardiasis is characterised by abdominal cramps, flatulence and bubbly, foul-smelling diarrhoea.

## Principles of treatment of diarrhoea

### Acute diarrhoea

- Maintenance of hydration:

Antiemetic injection (for severe vomiting)  
prochlorperazine IM, statim

or

metoclopramide IV, statim

- Antidiarrhoeal preparations:

(avoid if possible: loperamide preferred)

loperamide (Imodium) 2 caps statim then 1 after each unformed stool (max: 8 caps/day)

or

diphenoxylate with atropine (Lomotil) 2 tabs  
statim then 1–2 (o) 8 hourly

### General advice to patient

#### Rest

Your bowel needs a rest and so do you. It is best to reduce your normal activities until the diarrhoea has stopped.

#### Diet

Eat as normally as possible but drink small amounts of clear fluids such as water, tea, lemonade and yeast extract (e.g. Marmite). Then eat low-fat foods such as stewed apples, rice (boiled in water), soups, poultry, boiled potatoes, mashed vegetables, dry toast or bread, biscuits, most canned fruits, jam, honey, jelly, dried skim milk or condensed milk (reconstituted with water).

At first, avoid alcohol, coffee, strong tea, fatty foods, fried foods, spicy foods, raw vegetables, raw fruit (especially with hard skins), Chinese food, wholegrain cereals and cigarette smoking.

On the third day introduce dairy produce, such as a small amount of milk in tea or coffee and a little butter or margarine on toast. Add also lean meat and fish (either grilled or steamed).

### Treatment (antimicrobial drugs)<sup>3</sup>

Bacterial diarrhoea in adults and older children is usually self-limiting and does not require antibiotic treatment (they may be used to shorten the course of a persistent infection). *Campylobacter*, *Salmonella*, *Shigella* and *E. coli* are the most common causes. As a rule, use oral rehydrate solution 2–3 L orally over 24 hours if mild to moderate dehydration. If severe, intravenous rehydration with N saline is recommended.

It is advisable not to use antimicrobials except where the following specific organisms are identified. The drugs should be selected initially from the list below or modified according to the results of culture and sensitivity tests.<sup>3</sup> Only treat if symptoms have persisted for more than 48 hours. Adult doses are shown for the following enteric infections.

#### *Shigella* dysentery (moderate to severe)

Cotrimoxazole (double strength) 1 tab (o) 12 hourly for 5 days: use in children (children's doses)  
or  
norfloxacin 400 mg (o) 12 hourly for 5 days (preferred for adults)  
or  
ciprofloxacin 500 mg (o) bd for 5 days

#### Giardiasis

This protozoal infestation is often misdiagnosed. It should be considered for a persistent profuse, watery, bubbly, offensive diarrhoea (see CHAPTER 15).

Tinidazole 2 g (o), single dose (may need repeat)  
or  
metronidazole 400 mg (o) tds for 7 days (in children: 30 mg/kg/day [to max. 1.2 g/day] as single daily dose for 3 days)

#### *Salmonella* enteritis

Antibiotics are not generally advisable but if severe or prolonged use:

ciprofloxacin 500 mg (o) bd for 5–7 days  
or  
azithromycin 1 g (o) day, then 500 mg for 6 days  
or  
ceftriaxone IV or ciprofloxacin IV if oral therapy not tolerated

*Note:* *Salmonella* is a notifiable disease; infants under 15 months are at risk of invasive *Salmonella* infection.

#### *Campylobacter*

A zoonosis that is usually self-limiting.

Antibiotic therapy indicated in severe or prolonged cases:

azithromycin 500 mg (o) 12 hourly for 3 days  
or  
ciprofloxacin 500 mg (o) 12 hourly for 3 days  
or  
norfloxacin 400 mg (o) 12 hourly for 5 days

#### *Cryptosporidium* species

Usually self-limiting, may need fluid and electrolytes and anti-motility agents.

If severe, nitazoxamide (shared care).

#### Amoebiasis (intestinal)

See CHAPTER 15.

metronidazole 600–800 mg (o) tds for 6–10 days  
plus  
diloxanide furoate 500 mg (o) tds for 10 days

#### *Blastocystis hominis* (a parasitic infection)

Pathogenicity is disputed: give therapy only if severe. Associated with poor hygiene (travel, pets, dam/tank water, oysters).

metronidazole for 7 days  
Specialist advice should be sought.

### Treatment for special enteric infections

#### Typhoid/paratyphoid fever

See CHAPTER 15.

azithromycin 1 g (o) daily for 7 days  
or  
(if not acquired in the Indian subcontinent or SE Asia)  
ciprofloxacin 500 mg (o) 12 hourly for 7–10 days (use IV if oral therapy not tolerated)

If ciprofloxacin is contraindicated (e.g. in children) or not tolerated, then use:

ceftriaxone 3 g IV daily until culture and sensitivities available, then choose oral regimens

*If severe:* administer same drug and dosage IV for first 4–5 days.

#### Cholera

Antibiotic therapy reduces the volume and duration of diarrhoea. Rehydration is the key.

azithromycin 1 g (child 20 mg/kg up to 1 g)(o) as a single dose

or

ciprofloxacin 1 g (o) as a single dose

For pregnant women and children:

amoxycillin (child: 10 mg/kg up to) 250 mg (o)  
6 hourly for 4 days

### INFLAMMATORY BOWEL DISEASE<sup>3</sup>

Inflammatory bowel disease (IBD) should be considered when a young person presents with:

- bloody diarrhoea and mucus
- colonic pain and fever
- constitutional symptoms including weight loss and malaise
- extra-abdominal manifestations such as arthralgia, low back pain (spondyloarthropathy), eye problems (iridocyclitis), liver disease and skin lesions (pyoderma gangrenosum, erythema nodosum)

Investigations include FBE, vitamin B12 and folate, LFTs (abnormal enzymes), HLA B<sub>27</sub>, faecal calprotectin (if normal, no intestinal inflammation; if abnormal, needs colonoscopy) and lactoferrin.

Two important disorders are ulcerative colitis (UC) and Crohn disease, which have equal sex incidence and can occur at any age, but onset peaks between 20 and 40 years.

### § Ulcerative colitis

#### Clinical features

- Mainly a disease of Western societies
- Mainly in young adults (15–40 years)
- High-risk factors—family history, previous attacks, low-fibre diet
- Recurrent attacks of loose stools
- Blood, or blood and pus, or mucus in stools
- Abdominal pain slight or absent
- Fever, malaise and weight loss uncommon
- Begins in rectum (continues proximally)—affects only the colon: it usually does not spread beyond the ileocaecal valve
- An increased risk of carcinoma after 7–10 years

#### Main symptom

- Bloody diarrhoea

#### Diagnosis

- Faecal calprotectin: a sensitive test

- Proctosigmoidoscopy: a granular red proctitis with contact bleeding
- Barium enema: characteristic changes

#### Prognosis

- 5% mortality in an acute attack
- Recurrent attacks common

### § Crohn disease

*Synonyms:* regional enteritis, granulomatous colitis.  
The cause is unknown but there is a genetic link.

#### Clinical features

- Recurrent diarrhoea in a young person (15–40 years)
- Blood and mucus in stools (less than UC)
- Colicky abdominal pain (small bowel colic)
- Right iliac fossa pain (confused with appendicitis)
- Constitutional symptoms (e.g. fever, weight loss, malaise, anorexia, nausea)
- Signs include perianal disorders (e.g. anal fissure, fistula, ischiorectal abscess), mouth ulcers
- Skip areas in bowel: ½ ileocolic, ¼ confined to small bowel, ¼ confined to colon, 4% in upper GIT

#### Main symptom

- Colicky abdominal pain

#### Diagnosis

- Sigmoidoscopy: 'cobblestone' appearance (patchy mucosal oedema)
- Colonoscopy: useful to differentiate from UC
- Biopsy with endoscopy

#### Prognosis

Less favourable than UC with both medical and surgical treatment.

#### Management principles of both

- Education and support including support groups
- Treat under consultant supervision
- Treatment of acute attacks depends on severity of the attack and the extent of the disorder:
  - mild attacks: manage out of hospital
  - severe attacks: hospital, to attend to fluid and electrolyte balance
- Role of diet controversial: consider a high-fibre diet but maintain adequate nutrition
- Pharmaceutical agents (the following can be considered):
  - 5-aminosalicylic acid derivatives (mainly UC): sulfasalazine (mainstay), olsalazine, mesalazine

- corticosteroids (mainly for acute flares): oral, parenteral, topical (rectal foam, suppositories or enemas)
- for severe disease, immunomodifying drugs (e.g. azathioprine, cyclosporin, methotrexate) and biological agents (e.g. infliximab)
- Surgical treatment: reserve for complications; avoid surgery if possible

## ALTERNATING DIARRHOEA AND CONSTIPATION

Alternating diarrhoea and constipation are well-known symptoms of incomplete bowel obstruction (cancer of colon and diverticular disease) and irritable bowel syndrome.

### § Irritable bowel syndrome (IBS)<sup>3,8</sup>

#### Clinical features

- Typically in younger women (21–40 years)
- Any age or sex can be affected
- May follow attack of gastroenteritis/traveller's diarrhoea
- Cramping abdominal pain (central or iliac fossa)—FIGURE 44.4
- Pain usually relieved by passing flatus or by defecation
- Variable bowel habit (constipation more common)
- Diarrhoea usually worse in morning—several loose, explosive bowel actions with urgency
- The Bristol stool chart was devised to assist with the subclassification of stool types and bowel habits <[www.continence.org.au/pages/bristol-stool-chart.html](http://www.continence.org.au/pages/bristol-stool-chart.html)>
- Often precipitated by eating
- Faeces sometimes like small, hard pellets or ribbon-like
- Anorexia and nausea (sometimes)
- Bloating, abdominal distension, borborygmi
- Tiredness common

The Rome III diagnostic criteria for IBS are presented in TABLE 44.11.

IBS is a diagnosis of exclusion. A thorough physical examination, investigations (FBE, ESR and stool microscopy or culture) and colonoscopy are necessary. Insufflation of air at colonoscopy may reproduce the abdominal pain of IBS.

#### Possible related causes

Bowel infection, food irritation (e.g. spicy foods), lactose (milk) intolerance, low-fibre diet, high

FIGURE 44.4 Classic symptoms of irritable bowel syndrome

Table 44.11 Rome III diagnostic criteria for irritable bowel syndrome<sup>\*9,10</sup>

In the preceding 3 months, the patient has had abdominal discomfort for at least 3 days per month with two of the following three features:

- relieved by defecation
- onset associated with a change in stool frequency
- onset associated with a change in form (appearance) of stool (loose, watery or pellet-like)

Symptoms that cumulatively support the diagnosis of irritable bowel syndrome:

- abnormal stool frequency (for research purposes may be defined as more than three bowel movements per day and less than three bowel movements per week)
- abnormal stool form (lumpy/hard or watery/mushy)
- abnormal stool passage (straining, urgency or feeling of incomplete evacuation)
- passage of mucus
- bloating or feeling of abdominal distension

Note: Red flags must be excluded

\* in absence of structural or metabolic abnormalities to explain symptoms

fatty foods, laxative overuse, use of antibiotics and codeine-containing analgesics, psychological factors.

#### Management

The patient must be reassured and educated with advice that the problem will not cause malignancy or inflammatory bowel disease and will not shorten life

### Red flag pointers for non-IBS disease<sup>9</sup>

- Age of onset >50 years
- Fever
- Unexplained weight loss
- Rectal bleeding
- Pain waking at night
- Persistent daily diarrhoea/steatorrhoea
- Recurrent vomiting
- Major change in symptoms
- Mouth ulcers
- ↑ CRP, ESR
- Anaemia
- Family history bowel cancer or IBD

expectancy. The basis of initial treatment is simple dietary modification (FODMAPs), exercise, fluids (2–3 L water daily) and non-fermentable fibre.

### Self-help advice to the patient

Anyone with IBS should try to work on the things that make the symptoms worse. If you recognise stresses and strains in your life, try to develop a more relaxed lifestyle. You may have to be less of a perfectionist in your approach to life.

Try to avoid any foods that you can identify as causing the problem. You may have to cut out smoking and alcohol and avoid laxatives and codeine (in painkillers). A high-fibre (non-fermentable) and low-carbohydrate diet and 2–3 L of water a day may be the answer to your problem.

A low FODMAP diet can produce good benefits.<sup>11</sup> FODMAP refers to fermentable oligosaccharides, disaccharides, monosaccharides and polyols, which are poorly absorbed. All of these carbohydrates need to be eliminated (under a dietitian's guidance) then reintroduced one at a time.

See <[www.med.monash.edu/cecs/gastro/fodmap](http://www.med.monash.edu/cecs/gastro/fodmap)>, available as an app—the Monash University low FODMAP Diet.

### § Diverticular disorder

Diverticular disorder is a problem of the colon (90% in descending colon) and is related to lack of fibre in the diet. It is usually symptomless.

### Clinical features

- Typical in middle aged or elderly—over 40 years
- Increases with age
- Present in one in three people over 60 years (Western world)
- Diverticulosis—symptomless

- Diverticulitis—infected diverticula and symptomatic (refer CHAPTER 34)
- Constipation or alternating constipation/diarrhoea
- Intermittent cramping lower abdominal pain in LIF
- Tenderness in LIF
- Rectal bleeding—may be profuse (± faeces)
- May present as acute abdomen or subacute obstruction
- Usually settles in 2–3 days

### Complications (of diverticulitis)

- Abscess
- Perforation
- Peritonitis
- Obstruction (refer CHAPTER 34)
- Fistula—bladder, vagina

### Investigations

- WBC and ESR—to determine inflammation
- Sigmoidoscopy
- Barium enema

### Management

- It usually responds to a high-fibre diet.
- Avoidance of constipation.

### Advice to the patient

The gradual introduction of fibre with plenty of fluids (especially water) will improve any symptoms you may have and reduce the risk of complications. Your diet should include:

- 1 cereals, such as bran, shredded wheat, muesli or porridge
- 2 wholemeal and multigrain breads
- 3 fresh or stewed fruits and vegetables

Bran can be added to your cereal or stewed fruit, starting with 1 tablespoon and gradually increasing to 3 tablespoons a day. Fibre can make you feel uncomfortable for the first few weeks, but the bowel soon settles to your improved diet.

### When to refer

#### Children with diarrhoea

- Infant under 3 months
- Moderate to severe dehydration
- Diagnosis of diarrhoea and vomiting in doubt (e.g. blood in vomitus or stool, bile-stained vomiting, high fever or toxemia, abdominal signs suggestive of appendicitis or obstruction)
- Failure to improve or deterioration
- A pre-existing chronic illness

## Adults

- Patient with chronic or bloody diarrhoea
- Any problem requiring colonoscopic investigation
- Patients with anaemia
- Patients with weight loss, abdominal mass or suspicion of neoplasia
- Patients with anal fistulae
- Patients not responding to treatment for giardiasis
- Infection with *E. histolytica*
- Long-term asymptomatic carrier of typhoid or paratyphoid fever
- Patient with persistent undiagnosed nocturnal diarrhoea
- Patients with IBS with a significant change in symptoms
- Patients with inflammatory bowel diseases with severe exacerbations, possibly requiring immunosuppressive therapy and with complications
- Patients with ulcerative colitis of more than 7 years' duration (screening by colonoscopy for carcinoma)

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education* 6th edition:

- Coeliac disease in adults
- Coeliac disease in children
- Diarrhoea—acute diarrhoea in adults
- Gastroenteritis in children

## Practice tips

- Oral antidiarrhoeal drugs are contraindicated in children; besides being ineffective they may prolong intestinal recovery.
- Anti-emetics can readily provoke dystonic reactions in children, especially if young and dehydrated.

- Acute diarrhoea is invariably self-limiting (lasts 2–5 days). If it lasts longer than 7 days, investigate with culture and microscopy of the stools.
- If diarrhoea is associated with episodes of facial flushing or wheezing, consider carcinoid syndrome.
- Recurrent pain in the right hypochondrium is usually a feature of IBS (not gall bladder disease).
- Recurrent pain in the right iliac fossa is more likely to be IBS than appendicitis.
- Beware of false correlations or premature conclusions (e.g. attributing the finding of diverticular disorder on barium meal to the cause of the symptoms).
- Undercooked chicken is a common source of enteropathic bacterial infection.
- Consider alcohol abuse if a patient's diarrhoea resolves spontaneously on hospital admission.

*There is not a sight in nature so mortifying as that of a Distracted Person, when his imagination is troubled, and his whole soul is disordered and confused.*

Joseph Addison (1672–1719)

The disturbed and confused patient is a complex management problem in general practice. The cause may be a single one or a combination of several abnormal mental states (see **TABLE 45.1**).<sup>1</sup> The cause may be an organic mental disorder, which may be a long-term insidious problem such as dementia, or an acute disorder (delirium), often dramatic in onset. On the other hand, the cause of the disturbance may be a psychiatric disorder such as panic disorder, mania, major depression or schizophrenia.

The manifestations of the disturbance are many and include perceptual changes and hallucinations,

**Table 45.1** A general classification of psychiatric disorders<sup>1</sup>

#### Organic mental disorders

- acute organic brain syndrome (delirium)
- chronic organic brain syndrome (dementia)

#### Psychoactive and substance use disorders

- toxic states
- drug dependency
- withdrawal states

#### Schizophrenic disorders

#### Mood disorders:

- major depression
- bipolar (manic depressive) disorder
- adjustment disorders with depressed mood
- dysthymia

#### Anxiety disorders

- generalised anxiety disorder
- panic disorder
- obsessive–compulsive disorder
- phobic disorders
- post-traumatic stress disorder

#### Disorders specific to children

#### Other disorders:

- postpartum psychiatric illness
- eating disorders
- personality disorders
- body dysmorphic disorder

## Key facts and checkpoints

- Depression affects 15% of people over 65 and can mimic or complicate any other illness, including delirium and dementia.<sup>1</sup>
- Elderly patients with depression are at a high risk of suicide.
- Always search vigorously for the cause or causes of delirium.
- Seeing patients in their home is the best way to evaluate their problem and support systems. It allows opportunities for a history from close contacts and for checking medication, alcohol intake and other factors.
- The diagnosis of dementia can be overlooked: a Scottish study showed that 80% of demented patients were not diagnosed by their GP.<sup>2</sup>
- Patients with a chronic brain syndrome (dementia) are at special risk of an acute brain syndrome (delirium) in the presence of infections and many prescribed drugs.<sup>1</sup>
- Consider prescribed and illicit substances, including the severe anticholinergic delirium syndrome.
- The key feature of dementia is impaired memory.
- The two key features of delirium are disorganised thought and attention.
- Hallucination guidelines:
  - Auditory: psychoses e.g. schizophrenia
  - Visual: almost always organic disorder
  - Olfactory: temporal lobe epilepsy
  - Tactile: cocaine abuse, alcohol withdrawal

disorientation, changes in consciousness, changes in mood from abnormally elevated to gross depression, agitation and disturbed thinking, including delusions.

## A diagnostic approach

A summary of the diagnostic strategy model for the disturbed or confused patient is presented in **TABLE 45.2**.

## Glossary of terms

**Alzheimer disease** A term used for both senile and presenile dementia, which has characteristic pathological degenerative changes in the brain.

**Cognition** The mental functions of perception, thinking and memory. It is the process of 'knowing'.

**Compulsions** Repeated, stereotyped and seemingly purposeful actions that the person feels compelled to carry out but resists, realising they are irrational (most are associated with obsessions).

**Confusion** Disorientation in time, place and person. It may be accompanied by a disturbed conscious state (TABLE 75.1, CHAPTER 75).

**Conversion** The process by which thoughts or experiences unacceptable to the mind are repressed and converted into physical symptoms.

**Delirium** (also termed 'toxic confusional state') A relatively acute disorder in which impaired consciousness is associated with abnormalities of perception or mood.

**Delusions** Abnormal, illogical or false beliefs that are held with absolute conviction despite evidence to the contrary.

**Dementia** An acquired, chronic and gradually progressive deterioration of memory, intellect and personality. Presenile dementia or early onset dementia is dementia under 65 years of age. Senile dementia refers to older patients (usually over 80 years).

**Dissociation** A psychological disorder in which unpleasant memories or emotions are split off from consciousness and the personality and buried into the unconsciousness.

**Depersonalisation** An alteration in the awareness of the self—the person feels unreal.

**Hallucinations** Disorders of perception quite divorced from reality. Features:

- mostly auditory or visual
- a false perception—not a distortion
- perceived as normal perceptions
- independent of the person's will

**Illusions** False interpretations of sensory stimuli such as mistaking people or familiar things.

**Obsessions** Recurrent or persistent thoughts, images or impulses that enter the mind despite efforts to exclude them.

**Somatisation** The conversion of mental experiences or states into bodily symptoms, with no physical causation.

**Table 45.2** The disturbed mind: diagnostic strategy model

Q. Probability diagnosis

- A. The 4 Ds:
- dementia
  - delirium (look for cause)
  - depression
  - drugs: toxicity, withdrawal

Q. Serious disorders not to be missed

- A. Cardiovascular:
- CVAs
  - cardiac failure
  - arrhythmia
  - acute coronary syndromes
- Neoplasia:
- cerebral
  - cancer (e.g. lung)
- Severe infections:
- septicaemia
  - HIV infection
  - infective endocarditis
- Hypoglycaemia
- Bipolar disorder/mania
- Schizophrenia states
- Anxiety/panic
- Subdural haematoma

Q. Pitfalls (often missed)

- A. Illicit drug withdrawal
- Fluid and electrolyte disturbances
- Faecal impaction (elderly)
- Urinary retention (elderly)
- Hypoxia
- Pain syndromes (elderly)
- Rarities:
- hypocalcaemia
  - kidney failure
  - hepatic failure
  - prion diseases (e.g. Creutzfeldt-Jakob disease)

Q. Seven masquerades checklist (all possible)

- A. Depression
- Diabetes
- Drugs
- Anaemia
- Thyroid disorder
- Spinal dysfunction (severe pain in elderly)
- UTI

Q. Is the patient trying to tell me something?

- A. Consider anxiety, depression, emotional deprivation or upset, change in environment, serious personal loss.

## Probability diagnosis

The diagnosis depends on the age and presentation of the patient. In a teenager the probable causes of acute confusion or irrational behaviour include drug toxicity or withdrawal, schizophrenia, severe depression or a behavioural disorder.

It is the elderly who commonly present with confusion. The questions that must be asked are:

- Is the problem one of the 4 Ds—dementia, delirium, depression, drugs or something else?
- If delirium is the problem, what is the cause?

Depression affects 15% of people over 65 and can mimic other causes of confusion and behavioural disturbance.

Significant prescribed drugs include hypnotics, sedatives, oral hypoglycaemics, antihypertensives, digoxin, antihistamines, anticholinergic drugs and antipsychotics.

## Serious disorders not to be missed

There are many serious underlying disorders that must be considered, especially with delirium (see **TABLE 45.3**). Cerebral organic lesions, including space-occupying lesions (e.g. cerebral tumour, subdural haematoma), severe infection (systemic or intracerebral) and cancer at any site, especially lung, breast, bowel, or lymphoma, must be ruled out.

The sudden onset of delirium may suggest angina, myocardial infarction or a cerebrovascular accident. Twenty per cent of patients with delirium also have underlying heart failure.<sup>3</sup>

## Pitfalls

There are many pitfalls, especially with drug toxicity or withdrawal from the so-called illicit drugs. In the elderly in particular, fluid and electrolyte disturbances, such as dehydration, hypokalaemia, hyponatraemia and hypocalcaemia, can cause delirium. Bowel disturbances such as faecal impaction or constipation can cause delirium and incontinence of both faeces and urine.

## Seven masquerades checklist

All the following disorders can cause disturbed or confused behaviour, particularly in the elderly:

- depression: a very important cause of 'pseudodementia'
- drugs: toxicity or withdrawal (see **TABLE 45.4**)

**Table 45.3** Important causes of delirium (typical examples of each group)

Drug intoxication and drug sensitivity	
Anticholinergics	
Antidepressants	
Sedatives	
Alcohol, opioids, etc.	
Withdrawal from substances of abuse and prescribed drugs	
Alcohol	
Opioids	
Amphetamines	
Cannabis	
Sedatives and anxiolytics	
Infections	
Specific:	Urinary tract
	Lower respiratory (e.g. pneumonia)
	Otitis media
	Cellulitis
Intracranial:	Meningitis
	Encephalitis
Systemic:	Infective endocarditis
	Septicaemia
	HIV virus
	Other viral infections
	Malaria
Metabolic disturbances	
Uraemia, hepatic failure	
Electrolyte disturbances	
Dehydration	
Endocrine disturbances	
Diabetic ketoacidosis, hypoglycaemia	
Hypothyroidism/hyperthyroidism	
Nutritional and vitamin deficits	
Vitamin B complex deficiency (esp. B6, B12)	
Wernicke encephalopathy	
Hypoxia	
Respiratory failure, cardiac failure, anaemia	
Vascular	
CVA	
Acute coronary syndromes	
Head injury and other intracranial problems	
Seizures	
Complex partial seizures	
'Subtle' causes	
Pain (e.g. herpes zoster)	
Emotional upset	
Environmental change	
Peri-operative	
Faecal impaction	
Urinary retention	

**Table 45.4** Prescribed drugs that can cause delirium

Anticholinergic:

- antiparkinsonian (e.g. benztropine)
- tricyclic antidepressants

Tranquillisers and hypnotics:

- major tranquilisers (e.g. chlorpromazine)
- minor tranquilisers (e.g. diazepam)
- hypnotics
- lithium

Anti-epileptics

Antihistamines 1 and 2

Antihypertensives

Corticosteroids

Cardiac drugs:

- digoxin
- diuretics
- beta blockers

Opioids

Sympathomimetics

- diabetes: especially hypoglycaemia, which can occur with type 2
- anaemia: often from self-neglect or chronic blood loss
- thyroid disorders: both hyperthyroidism and hypothyroidism can present with disturbed behaviour; 'myxoedemic madness' may be precipitated by atropine compounds
- urinary tract infection: causes or contributes to 20% of cases of hallucinations or illusions<sup>2</sup>
- spinal dysfunction: with its many severe pain syndromes, such as sciatica, can be a significant factor

## Psychogenic factors

Apart from the primary psychiatric disorders of anxiety, depression, mania and schizophrenia, relatively simple and subtle social problems, such as loneliness, boredom, a domestic upset, financial problem or similar issue, can trigger a confusional state.

## The clinical approach

### History

Developing rapport with the disturbed or confused patient is essential and can be helped by a warm handshake or a reassuring pat on the shoulder. The basis of the history is a careful account from relatives or witnesses about the patient's behaviour.

When communicating with the patient, speak slowly and simply (avoid shouting), face the patient and maintain eye contact. Important features are the past history and recent psychosocial history, including recent bereavement, family upsets and changes in environment. Search for evidence of depression and note any organic symptoms such as cough, constipation and so on.

### Mental status examination

The most practical bedside screening test of mental function is the Mental Status Questionnaire of Kahn and colleagues,<sup>4</sup> which includes 10 simple questions.

- 1 What is the name of this place?
- 2 What city are you in now?
- 3 What year is it?
- 4 What month is it?
- 5 What is the date today?
- 6 What year were you born?
- 7 When is your birthday?
- 8 How old are you?
- 9 Who is the prime minister/president?
- 10 Who was the prime minister/president before him?

(Interpretation: normal 9–10; mildly impaired 8–9; confused/demented 7 or less.)

Other MMSEs are presented in [CHAPTER 8](#).

### Examination

The patient's general demeanour, dress and physical characteristics should be noted at all times. Assess the patient's ability to hear, see, speak, reason, obey commands, stand and walk. Any problems related to the special senses can cause confusion.

Look for features of alcohol abuse, Parkinson disease and hypothyroidism.

Examine the neurological system and keep in mind the possibility of a subdural haematoma, which may have followed a forgotten fall.

Don't omit the rectal examination to exclude faecal impaction, melaena, cancer and prostatomegaly (in males), and also check the bladder for evidence of chronic retention.

### Investigations

Investigations to consider for delirious or demented patients (unknown cause):

- urinalysis and microscopy
- cultures of blood and urine
- total and differential blood count; ESR
- blood glucose
- urea and creatinine and electrolytes

- calcium and phosphate
- vitamin D
- thyroid function tests
- liver function tests
- serum vitamin B12 and folate levels
- ECG/troponin (? acute coronary syndrome)
- chest X-ray
- cerebral CT scan, especially non-contrast CT
- syphilis serology
- HIV
- arterial blood gases

## Behavioural emergencies: management of the acutely disturbed patient<sup>5</sup>

Delirious or psychotic patients can be paranoid and respond defensively to the world around them. This behaviour can include aggressive and violent behaviour resulting in danger to themselves, their friends and family and to their medical attendants.

Dangerousness should be assessed from features such as the patient's past history (especially previous dangerous behaviour), age and sex, recent stress, victim behaviour, muscle bulk, presence of weapons, degree of overactivity and the manner of handling of the present distress by others. The patient may be in a state of acute panic and trying to flee a situation or in an agitated psychotic state prepared to confront the situation. It should be emphasised that most violent individuals are not mentally ill.

Most cases require an injection (the ideal intravenous administration can be extremely difficult and hazardous), which is often interpreted as a physical attack. It may not be possible to diagnose the cause of the problem before giving the injection.

## Approach to management

- Assess the environment and don't move into the patient's space until in a position of control.
- React calmly. Communicate calmly and simply.
- State your task firmly and simply.
- Try to control the disturbed patient gently.
- Ensure the safety of all staff and make certain that heroics are not attempted in dangerous circumstances.
- An adequate number of staff to accompany the doctor is essential—six is ideal (one for immobilisation of each limb, one for the head and one to assist with drugs).<sup>1</sup>
- Patients should be placed on the floor in the prone position.

## Principles of sedative administration<sup>1</sup>

- Use the safest possible route of administration whenever possible (i.e. oral in preference to parenteral but often impractical). Intravenous administration has the lowest margin of safety.
- Parenteral administration should be restricted to severely disturbed patients.
- Closely monitor vital signs during and after sedative administration.
- Avoid intramuscular diazepam because of poor absorption.
- Be cautious of intravenous midazolam (Hypnovel) in such patients because of the risk of respiratory depression.
- Avoid benzodiazepines in patients with respiratory insufficiency. Haloperidol is an alternative.
- Patients have died from cardiopulmonary arrest after repeated sedative administration (especially benzodiazepines), so intensive monitoring is essential.

Monitor the following adverse effects:

- respiratory depression
- hypotension
- dystonic reactions, including choking
- neuroleptic malignant syndrome

## Treatment options<sup>1,5</sup>

The treatment in acute medical and psychiatric settings depends on the appropriate mode of administration. Benzodiazepines are generally the drugs of first choice over antipsychotics in tranquillisation.<sup>5</sup> However, the IV route allows titration to the desired degree of sedation and has a more immediate effect.

### Oral medication

diazepam 5–20 mg (o), repeated every 2–6 hours (max: 120 mg/24 hours)

or

lorazepam 1–2 mg (o), repeated every 2–6 hours (max: 10 mg/24 hours)

If sedation is not achieved, add an antipsychotic medication e.g. olanzapine 5–10 mg initially or risperidone 0.5–1 mg initially

### Intravenous medication

diazepam or midazolam  
2.5–5 mg increments IV, repeated every

3–4 minutes until required level of sedation (rousable drowsiness) is reached—up to a maximum of 20–30 mg, when specialist advice is needed especially if further boluses are necessary *and/or* droperidol 5–10 mg IV

### Intramuscular medication

If this route considered appropriate:

midazolam 5–10 mg IM  
*or* (if history of benzodiazepine tolerance)  
 droperidol 5–10 mg IM  
*or*  
 olanzapine 5–10 mg repeated every 2–4 hours  
*or*  
 combination midazolam/droperidol

(These first two injections can be repeated in 20 minutes if required. Droperidol is similar to haloperidol but more sedating. Keep in mind the rare but potentially fatal laryngeal dystonia with high doses—cover with benztrapine 2 mg IM.)

### Postdisturbance evaluation

Determine the likely cause, such as:

- acute organic brain syndrome: toxic causes, infection
- alcohol or drugs (illicit or prescribed): intoxication, withdrawal
- manic illness
- severe depression
- schizophrenic syndrome
- severe panic

### § Acute organic brain syndrome (delirium)

The many labels of acute organic brain syndrome include:

- delirium
- acute confusional state
- toxic confusional state
- confusional episode
- acute brain syndrome

### Main clinical features

- Clouding of conscious state
- Disorientation
- Impaired attention
- Impaired memory
- Global cognitive defect—onset over days/hours

Refer to the box.

### DSM-5 criteria for delirium<sup>6</sup>

Diagnosis of delirium requires evidence of:

- A Disturbance of consciousness, attention and awareness
- B Clinical features appearing over a short period
- C A change in cognition:
  - perceptual disturbance
  - incoherent speech
  - disorientation
  - memory impairment/deficit
- D A & C not better explained by another disorder
- E Evidence of a cause

### Other clinical features<sup>1</sup>

- The patients are usually elderly.
- Anxiety and agitation can be severe but in hypoactive deliria (usually due to metabolic disturbance) the conscious state can vary from drowsiness to coma.
- Odd behaviour with mood swings can occur.
- Psychotic symptoms can occur.
- Delusions are usually fleeting.
- The disturbance is usually worse at night and may be aggravated by sedation.
- Visual hallucinations are a feature of alcohol withdrawal.
- Attacks on bystanders may result (uncommon).

Always seek a cause.<sup>1</sup> A list of causes is presented in TABLE 45.3. The most important causes are:

- infections (usually in urinary tract, lungs or ear, or systemic in young or elderly)
- prescribed drugs

### Anticholinergic delirium

Consider this cause (from drugs with anticholinergic properties or illicit substances). Features include hyperactivity, marked thought disorder, vivid visual hallucinations and very disturbed behaviour.

### Differential diagnosis of delirium

In the earlier stages it may mimic the various psychiatric disorders, including anxiety, depression, various hallucinatory states, particularly agitated schizophrenia (rarely), extreme manic states, complex partial seizures, dementia. Consider deafness. Delirium is common in the hospital setting.

## Investigations

Investigations are those listed under 'The clinical approach' earlier in the chapter.

## Treatment

Principles:

- Acute delirium is a medical emergency.
- Establish normal hydration, electrolyte balance and nutrition.
- Consider alcohol withdrawal and give a trial of thiamine when the cause of delirium is unknown.
- Attend to helpful environmental factors (e.g. calm atmosphere, a night-light, orientation clues, presence of friends and relatives).
- Give oxygen if hypoxic e.g. respiratory distress

## Medication

Medication<sup>1</sup> may not be needed but will be if there are symptoms of anxiety, aggression or psychosis.

For psychotic behaviour:

haloperidol 0.5 mg (o) as a single dose  
or  
olanzapine 2.5–10 mg (o) daily in 1 or 2 doses

If oral administration is not possible or when parenteral medication is required (cover with benztropine 2 mg (o) or IM):

haloperidol 0.5 mg IM as single dose  
or  
olanzapine 2.5 mg IM as single dose

For anticholinergic delirium:

tacrine hydrochloride 15–30 mg with caution by slow IV injection (an antidote)

Note:

- Avoid benzodiazepines, especially in children and in patients with respiratory insufficiency.
- Consider necessity for pain relief.
- Use lower doses of parenteral medications in the very old and frail.

## § Dementia (chronic organic brain syndrome)

Dementia or neurocognitive disorder is an important diagnosis to consider in the elderly patient. The DSM criteria for dementia are presented in **CHAPTER 8**.

The main feature of dementia is impairment of memory, especially recent memory, when the person

cannot remember what has happened a few hours (or even moments) earlier but may clearly remember the events of the past.

The more serious behavioural changes encountered with dementia tend to occur in the advanced stages. However, these disturbances may be precipitated by illness such as infections, emotional upset and drugs. These serious disturbances include:

- uninhibited behaviour
- hallucinations (generally uncommon)
- paranoid delusions

If a stable patient becomes acutely disturbed, delirium should be suspected.

## Presenile dementia — Alzheimer type

The main features are:

- onset in late 50s and early 60s
- insidious onset
- early loss of short-term memory
- progressive decline in intellect
- death in 5–10 years
- more common in Down syndrome

## Differential diagnosis of dementia

There are two approaches to the differential diagnosis, including consideration of the classic causes of disturbed behaviour as summarised in the mnemonic in **TABLE 45.5**.<sup>7</sup>

However, the foremost differential diagnosis should be 'pseudodementia' caused by severe depression.

A simple comparison between schizophrenia and dementia is shown in **TABLE 45.6**.

A vigorous search for a possible cause of dementia is warranted since there are a significant number of reversible causes. In particular, it is important to exclude the psychiatric conditions that may mimic dementia.

## Treatment

- To control psychotic symptoms or disturbed behaviour:  
risperidone 0.5–2 mg (o) daily  
or  
olanzapine 2.5–10 mg (o) daily in 1 or 2 doses
- To control symptoms of anxiety and agitation:  
oxazepam 15 mg (o) 1 to 4 times daily. Avoid benzodiazepines for more than 2 weeks.

**Table 45.5** Differential diagnosis of dementias

<b>D</b> = Delirium drugs (see toxic)
<b>E</b> = Emotional disorder = depression endocrine = thyroid
<b>M</b> = Memory = benign forgetfulness
<b>E</b> = Elective = anxiety disorders/neuroses
<b>N</b> = Neurological: • CVA • head trauma
<b>T</b> = Toxic: • drugs/medication • metabolic disease
<b>I</b> = Intellect—low or retarded
<b>A</b> = Amnesic disorders—Korsakov syndrome
<b>S</b> = Schizophrenia (chronic)

**Table 45.6** Comparison of schizophrenia and dementia

	Dementia	Schizophrenia
<b>Onset</b>	Middle-aged or elderly	Young
<b>Memory</b>	Always impaired	Usually unaffected
<b>Delusions</b>	Rare	Frequent
<b>Hallucinations</b>	Uncommon	Frequent
<b>Thought broadcasting</b>	Never	Frequent

## The acute psychotic patient

Acute psychosis is the presence of the mental state where appreciation of reality is impaired as evidenced by the presence of typical psychotic symptoms such as delusions, hallucinations, mood disturbance and bizarre behaviour.<sup>8</sup>

The differential diagnoses of patients presenting with psychoses is presented in **TABLE 45.7**.

## Early diagnosis

Early recognition of a psychosis, particularly schizophrenia, is extremely important, as early

**Table 45.7** Causes of psychoses<sup>8</sup>

Functional psychoses:

- schizophrenia
- schizoaffective disorder (core symptoms of schizophrenia + mood symptoms)
- bipolar mood disease (depressed or manic phase)

Drug-induced psychoses

Organic based psychoses

Other:

- delusional disorder (paranoid psychoses)
- brief psychotic disorder
- folie à deux (psychosis occurring simultaneously in two close associates)

intervention leads to improved outcomes. Early or prodromal symptoms include the following:

- social withdrawal
- reduced attention and concentration
- reduced drive and motivation
- depressed mood
- anxiety
- irritability/agitation
- suspiciousness
- sleep disturbance
- deterioration in role functioning

It is appropriate to ask the correct questions in order to elicit psychotic symptoms. These are presented in **TABLE 45.8**.

**Table 45.8** Questions for eliciting psychotic symptoms

Anxiety	Have you been feeling especially nervous or fearful? Have you felt tense and shaky, or experienced palpitations?
Depressed mood	Have you been feeling sad or 'down in the dumps' recently, not enjoying activities as much as before?
Elevated mood	Have you been feeling especially good in yourself, more cheerful than usual and full of life?

*continued*

Table 45.8 continued

Auditory hallucinations	Do you hear voices of people talking to you even when there is no-one nearby?
Thought insertion	Have you felt that thoughts are being put into your mind? Do you experience telepathy?
Thought withdrawal	Have you experienced thoughts being taken out of your mind?
Thought broadcasting	Have you felt that other people are aware of your thoughts?
Thought echo	Have you experienced voices or people echoing your thoughts?
Delusion of control	Have you felt under the control or influence of an outside force?
Delusions of reference	Do programs on the television or radio hold special meaning for you?
Delusions of persecution	Do you feel that you are being singled out for special treatment? Is there a conspiracy against you?
Delusions of grandeur	Do you feel special, with unusual abilities or power?
Delusions of guilt	Do you believe that you have sinned or have done something deserving punishment?

### DSM-5 key diagnostic criteria<sup>6</sup>—schizophrenia

- A Two or more of following, each present for a significant portion of time during a one-month period
- |   |                         |
|---|-------------------------|
| 1 delusions                                   | } at least one of these |
| 2 hallucinations                              |                         |
| 3 disorganised speech                         |                         |
| 4 grossly disorganised or catatonic behaviour |                         |
| 5 negative symptoms e.g. flat affect          |                         |
- B Social, learning or occupational dysfunction  
 C Continuous signs of disturbance for at least 6 months  
 D No evidence of other psychoses e.g. bipolar  
 E Not attributable to effects of substance abuse or other medical condition

## § Schizophrenia and associated disorders

The term 'schizophrenia' (Bleuler 1911) refers to a group of severe psychiatric illnesses characterised by severe disturbances of emotion, language, perception, thought processes, volition and motor activity. The causes of schizophrenia disorders are unknown, but genetic factors and drug abuse are implicated.

### Signs and symptoms of schizophrenia

- Positive
  - delusions
  - hallucinations
  - thought disorder
  - disorganised speech and behaviour
- Negative
  - flat affect
  - poverty of thought
  - lack of motivation
  - social withdrawal
  - reduced speech output
- Cognitive
  - distractibility
  - impaired working memory
  - impaired executive function (e.g. planning)
  - impaired insight
- Mood
  - mania (elevation)
  - depression

Other features include:

- bizarre behaviour
- subject to tension, anxiety or depression
- deterioration in work and study performance
- peak incidence 15–25 years<sup>9</sup>—smaller peak at 40 years
- lifetime prevalence 1 in 100
- equal sex incidence
- high risk of suicide

### Differential diagnosis

Organic factors need to be excluded, especially drugs:

- amphetamines
- hallucinogens (e.g. LSD)
- marijuana

A comparison of delirium, dementia and functional psychosis is presented in TABLE 45.9.

### Management

Drug treatment is only a part of total management. Explanation and appropriate reassurance to the

**Table 45.9** Comparison of the clinical features of delirium, dementia and acute functional psychoses<sup>9</sup>

Feature	Delirium	Dementia	Acute psychosis
Onset	Rapid	Slow—insidious	Rapid
Duration	Hours to weeks	Months to years	Depends on response to treatment
Course over 24 hours	Fluctuates—worse at night	Minimal variation	Minimal variation
Consciousness	Reduced	Alert	Alert
Perception	Misperceptions common, especially visual	Misperceptions rare	May be misperceptions
Hallucinations	Common, visual (usually) or auditory	Uncommon	Common, mainly auditory
Attention	Distractable	Normal to impaired	Variable—may be impaired
Speech	Variable, may be incoherent	Difficulty finding correct words	Variable: normal, rapid or slow
Organic illness or drug toxicity	One or both present	Often absent	Usually absent

family with patient and family supportive care is obviously essential. Supportive psychotherapy is important in all phases. A team approach is necessary to cope with the disorder, which usually has a devastating effect on the family. Referral for specialist care is appropriate.

### Acute phase

- Hospitalisation usually necessary
- Drug treatment for the psychosis<sup>1</sup>

Drug treatment may include the first-generation (typical or conventional) antipsychotics such as haloperidol and chlorpromazine, which are effective for managing the 'positive' symptoms, or the second generation (atypical) antipsychotics such as risperidone, olanzapine, quetiapine, clozapine, amisulpride and aripiprazole, which in addition are more effective at treating the 'negative' and other symptoms of schizophrenia.<sup>10</sup>

The usual practice rule is to start with a second-generation antipsychotic at a low dose and titrate upwards at a rate and to a level that is optimal for the patient. Patients with a first psychotic episode may respond to lower than usual doses.<sup>6</sup>

- 1 When oral medication is possible, first-line treatment is one of (with starting doses):<sup>5,6,11</sup>

amisulpride 100 mg nocte  
 asenapine 5 mg sublingual bd  
 aripiprazole 10 mg once daily  
 olanzapine 5 mg nocte  
 paliperidone 3 mg once daily  
 quetiapine 50 mg bd → 200 mg bd (by day 5)

risperidone 0.5–1 mg nocte → 2 mg nocte  
 sertindole 4 mg (o) once daily  
 ziprasidone 40 mg bd → 80 mg bd

If response is inadequate in 3 weeks increase the dose according to prescribing guidelines.

If no response after 4–6 weeks consider a change to:

- an alternative second-generation agent (above)  
*or*
- a first-generation antipsychotic such as:

chlorpromazine 200 mg once daily → 500 mg  
 haloperidol 1.5 mg once daily → 7.5 mg  
 trifluoperazine 2 mg bd

- 2 Parenteral medication should be avoided if possible in acute care but if required:

haloperidol 2.5–10 mg IM, initially, up to 20 mg in 24 hours, depending on the response

*or*

olanzapine 5–10 mg IM initially (do not use with benzodiazepines concurrently)

*add*

benztropine 1–2 mg (o) bd (to avoid dystonic reaction)

*or*

zuclopenthixol acetate 50–150 mg IM as a single dose

If dystonic reaction:

benztropine 1–2 mg IV or IM

If very agitated use:

diazepam 5–10 mg (o) up to 40 mg/day or 5–10 mg IV

## Chronic phase

Long-term antipsychotic medication is recommended to prevent relapse.<sup>1</sup>

- Examples of oral medication regimens:<sup>11</sup>  
 olanzapine 10–20 mg (o) nocte  
*or*  
 risperidone 1–2 mg (o) bd  
*or*  
 quetiapine 150 mg (o) bd
- Aim for lowest possible dose to maintain control.
- Chlorpromazine is not recommended for long-term use because of photosensitivity reactions.
- Use depot preparations if compliance is a problem:<sup>5,11</sup>  
 fluphenazine decanoate 12.5 mg IM, statim then 12.5–50 mg every 2–4 weeks  
*or*  
 haloperidol decanoate 50 mg IM, statim then 50–200 mg every 4 weeks  
*or*  
 flupenthixol decanoate 10 mg IM, statim then 20–40 mg every 2–4 weeks  
*or*  
 risperidone 25–50 mg IM every 2 weeks, titrated to clinical response  
*or*  
 zuclopenthixol 100 mg IM, statim then titrated to 200–400 mg every 2–4 weeks

Tips with depot preparations:

- Start with IM test doses and then titrate to recommended controlling levels (half or full starting dose).
- May take 2–4 months to produce a stable response, so oral supplements may be necessary.
- Not as effective as oral therapy.
- Give as deep IM injection with 21 gauge needle in buttock.
- Use lowest possible dose to avoid tardive dyskinesia.
- Reassess at least every 3 months.
- Closely monitor patient for movement disorders.

## Drug-resistant schizophrenia

Consider other causes (e.g. substances abuse). ECT may help the agitated patient, especially if catatonic. Consider a trial of clozapine (300–600 mg daily) with strict monitoring for blood dyscrasias or olanzapine (5–20 mg daily).

## Movement disorders from antipsychotic medication<sup>1</sup>

### Acute dystonias

- Usually bizarre muscle spasms affect face, neck, tongue and trunk
- Oculogyric crises, opisthotonos and laryngeal spasm

Treatment:

benztropine 1–2 mg IV or IM

### Akathisia

- Subjective motor restlessness of feet and legs
- Generally later onset in course of treatment

Treatment:

- reduce dosage until akathisia less troublesome or substitute thioridazine
- can use oral propranolol, diazepam or benztropine as a short-term measure

### Parkinsonian

- Seen relatively early in treatment
- The akinesia can be confused with drug-induced depression

Treatment:

- use lower dose or substitute a phenothiazine in low dosage
- alternatively, use benztropine or benzhexol

### Tardive dyskinesia

Tardive dyskinesia is a syndrome of abnormal involuntary movements of the face, mouth, tongue, trunk and limbs. This is a major problem with the use of long-term antipsychotic drugs and may occur months or years (usually) after starting treatment and with drug withdrawal. Avoid prolonged use of metoclopramide.

Differential diagnosis:

- spontaneous orofacial dyskinesia
- senile dyskinesia
- ill-fitting dentures
- neurological disorders causing tremor and chorea

If drug withdrawal is ineffective, use tetrabenazine 12.5 mg (o) daily, increasing as necessary.<sup>12</sup> The risks and benefits of continuing therapy have to be weighed.

*Note:* Because of the difficulty with managing tardive dyskinesia, prevention in the form of using the lowest possible dosage of antipsychotic

medication is essential. This involves regular review and adjustment if necessary.

### Neuroleptic (antipsychotic) malignant syndrome

This is a potentially fatal adverse effect that can develop at any time. It develops in hours to days.

Syndrome: high temperature, muscle rigidity, altered consciousness. Milder variants can occur (refer to **CHAPTER 53**).

Treatment:

- discontinue medication
- ensure adequate hydration with IV fluids
- if life-threatening:  
bromocriptine 2.5 mg (o) bd, gradually increasing to 5 mg (o) tds  
and  
dantrolene 50 mg IV every 12 hours for up to 7 doses
- consultant referral

### Cardiac dysfunction

Various psychotropic agents, particularly the phenothiazines, are prone to cause the adverse effect of prolongation of the QT interval with potential severe outcomes.

### § Bipolar disorder

The mood disorders are divided into depressive disorders and bipolar disorders. Bipolar is a broad term to describe a recurrent illness with episodes of either mania or depression with return to normal function in between. The swing in moods in bipolar

**FIGURE 45.1** Bipolar disorder (manic depression): possible mood swings

### DSM-5 criteria for a manic episode

- A Distinct period for at least 1 week of abnormal and persistent elevated, expansive or irritable mood
  - B Three or more of these unusual features:
    - 1 inflated self-esteem or grandiosity
    - 2 decreased need for sleep
    - 3 talkative/accelerated speech
    - 4 racing thoughts or flights of ideas
    - 5 distractibility as reported or observed
    - 6 increased goal-directed activity or psychomotor agitation
    - 7 excessive activity with 'painful' consequences
  - C Marked impaired social or occupational functioning or need for hospitalisation or psychotic features
  - D Episode not due to substance abuse or other medical condition
- A–D = a manic episode: at least one in a lifetime for diagnosis

disorders (manic depressive disorders) is illustrated in **FIGURE 45.1**. It affects 1%–2% of the population.

Bipolar I disorder has one fully fledged manic or mixed episode and usually depressive episodes.

Bipolar II disorder is defined as a major depressive episode with at least one hypomanic episode but no classic manic episodes.

The symptoms of mania may appear abruptly.

Typical inherent features include:

- reckless behaviour, overspending
- hasty decisions (e.g. job resignation, hasty marriages)
- impaired judgment
- increased sexual drive and activity
- poor insight into the problem
- variable psychotic symptoms—paranoia, delusions, auditory hallucinations

*Note:* The peak onset is in early adult life. There is a strong hereditary basis. Episodes may be precipitated by stress.

'Hypomania' is the term used to describe the symptoms of mania that are similar to but less severe (without criterion C) and of shorter duration.

The subsequent major depressive phase is associated with a high risk of suicide.

Good questions to ask the patient with suspected 'bipolar' disorder:

- How have you been feeling in yourself?
- Have you felt especially good about yourself?

- Do you feel that you are special or have special powers?
- Have you been spending more than usual?
- Have you been needing less sleep than usual?

### Management of acute mania

This is a medical emergency requiring hospitalisation for protection of both family and patient. Involuntary admission is usually necessary. It may be a first episode or a relapse due to poor treatment compliance or substance abuse. A recent meta-analysis indicates that antipsychotics are the most efficacious drugs.

### Treatment

First line:

olanzapine 5 mg (o) nocte initially  
or  
risperidone 0.5–1 mg (o) nocte initially

Second line:

haloperidol or other first-generation antipsychotic  
or  
lithium carbonate 750–1000 mg (o) daily in 2 or 3 divided doses increasing according to serum levels  
or  
sodium valproate 200–400 mg (o) bd initially  
or  
carbamazepine 100–200 mg (o) bd initially

Failure to respond to treatment:

- ensure maximum concentration of first drug
- switch to a different drug e.g. olanzapine to lithium
- combine drugs e.g. second-degree antipsychotic + lithium
- ECT is of proven benefit for recalcitrant patients

Remember to provide supportive psychotherapy with appropriate psychosocial interventions.

### Prophylaxis for recurrent bipolar disorder

(Over 90% will have a recurrence at some time: consider medication if two or more episodes of either mania or depression in the previous 4 years.)

### Recommended prophylactic agents<sup>5</sup>

lithium 125–500 mg (o) bd then adjusted  
or  
second-generation antipsychotic agent  
or (if depression prominent)  
lamotrigine or carbamazepine or sodium valproate

Use long-term lithium (e.g. 3–5 years). Target plasma level for maintenance is usually 0.6–0.8 mmol/L. A US study recommended lithium as the prime mood stabiliser.<sup>14</sup>

- If poor response, use another agent.
- Unwanted side effects of lithium include:
  - a fine tremor
  - muscle weakness
  - weight gain
  - gastrointestinal symptoms
- With anti-epileptics adjust dosage according to clinical response and toxicity.

### Management of bipolar depression<sup>11,15</sup>

This is a difficult component to treat and antidepressants should not be used alone.<sup>11</sup> Many mood-stabilising agents appear to have a bimodal (antidepressant and antimania) effect and can be useful in the absence of classical antidepressants.<sup>15</sup>

A recommended regimen is:

lithium, valproate, carbamazepine, quetiapine,  
lamotrigine or olanzapine  
plus  
an antidepressant (e.g. SSRI, SNRI or MAOI)

Antidepressants are usually withdrawn within 1–2 months because of a propensity to precipitate mania.

ECT is an effective treatment for bipolar depression while psychological therapies such as CBT and psychoeducation have proven efficacy.

Bipolar I patients usually recover but proceed to have further episodes of depression or mania.<sup>11</sup>

### § Body dysmorphic disorder<sup>5</sup>

Body dysmorphic disorder is characterised by a preoccupation with the belief that some aspect of physical appearance is abnormal, unattractive or diseased. The person's concern and distress is out of proportion to any imagined or actual defect and usually not amenable to reassurance. This preoccupation causes significant functional impairment. The condition rarely presents directly and may be over-represented in the area of dermatology or plastic surgery. It begins in late childhood or early adolescence. The person's focus is on the face, head or secondary sexual characteristics.

Patients may be helped by counselling and psychotherapy including CBT. There is clinical evidence that SSRIs help if the symptoms suggest an obsessive-compulsive disorder. An antipsychotic agent may help where beliefs are delusional or in the context of a psychotic disorder.

## § Depression

Depression is very common and presents in a great range of severity. In the context of 'the disturbed patient' depression can be confused with dementia or a psychosis, particularly if the following are present:

- psychomotor agitation
- psychomotor retardation
- delusions
- hallucinations

### Assessment<sup>1</sup>

The following questions need to be addressed:

- Is the depression primary (i.e. not secondary to another psychiatric condition such as schizophrenia or anxiety disorder)?
- Is it part of a bipolar disorder? Has there been a previous manic or hypomanic episode? If so, a different approach to treatment is required.
- Is the depression caused by another illness or physical factor (e.g. hypothyroidism, cerebrovascular disease or medication)?
- Is the patient psychotic?
- Is the patient a suicide risk?

The treatment of depression is presented in **CHAPTER 19**.

## PSYCHOACTIVE SUBSTANCE USE DISORDERS

It is important for the GP to be aware of the effects of self-administration of psychoactive substances, especially their toxic or withdrawal effects. They form significant consideration for the differential diagnosis of disturbed patient behaviour. The following substances can cause these effects.

### Alcohol

Toxic and withdrawal effects, including delirium tremens, are outlined in **CHAPTER 21**. Abrupt withdrawal can cause symptoms ranging from tremors, agitation and dysphoria (feeling thoroughly miserable) to fully developed delirium tremens. Epileptic seizures may also occur.

### Barbiturate dependence

Tolerance and symptoms on withdrawal are the main features. Barbiturate withdrawal is a very serious, life-threatening problem and may be encountered in elderly people undergoing longstanding hypnotic withdrawal. Symptoms include anxiety, tremor, extreme irritability, twitching, seizures and delirium.

### Management<sup>1</sup>

Undertake withdrawal with medical supervision as an inpatient.

Transfer the patient to phenobarbitone or diazepam.

phenobarbitone 120 mg (o) hourly until sedation  
or

phenobarbitone 30 mg for each 100 mg of shorter-acting barbiturate

reduce the dose gradually over 10 to 14 days

or

diazepam 20–40 mg orally, daily

reduce the dose gradually over 10 to 14 days

### Benzodiazepine dependence

Withdrawal symptoms in the dependent patient include anxiety, restlessness, irritability, palpitation and muscle aches and pains, but delirium and seizures are uncommon except with very high doses. The shorter the half-life, the greater the dependence.

Withdrawal is best achieved by supervising a gradual reduction in dosage aided by relaxation techniques and behavioural strategies to help patients cope with insomnia and anxiety.

Refer to **CHAPTER 21** for the effects of opioid dependence, stimulant substance abuse, hallucinogen abuse and cannabis use and dependence.

## PSYCHIATRIC DISORDERS OF CHILDHOOD AND ADOLESCENCE<sup>1</sup>

The following disturbance problems do occur and must be taken seriously, especially the potential for suicide in the second decade. Many of these disorders are presented in more detail in **CHAPTER 94**.

### Attention deficit hyperactivity disorder

Clinical features:

- short attention span
- distractibility
- overactivity
- impulsiveness
- antisocial behaviour

### Depression

Major depression follows the same criteria as for adults. Suicidal ideation has to be considered and taken very seriously if present. Imipramine is probably the drug of choice.

## Bipolar disorders

Mania is seldom diagnosed before puberty. Adolescents may present (uncommonly) with symptoms of mania or hypomania.

## Schizophrenia and related disorders

Schizophrenia is rare before puberty. The criteria for diagnosis are similar to adults:

- delusion
- thought disorder
- hallucinations
- 6 months or more of deterioration in functioning

## Autism

Aggression and irritability can be a feature, especially during adolescence.

## Tourette syndrome

Behavioural problems can be part of this syndrome, which requires the attention of an experienced consultant.

## Obsessive–compulsive disorders

In about one-third of cases the onset is between 5 and 15 years of age.

## VIOLENCE AND DANGEROUSNESS

Dangerousness has been defined as a 'propensity to cause serious physical injury or lasting psychological harm to others' and, in the context of the mentally abnormal, 'the relative probability of their committing a violent crime'.<sup>16</sup>

Dangerousness is not related only to mental illness and, interestingly, most offenders have no psychiatric diagnosis. It is not an inherited, immutable characteristic of an individual but tends to surface on impulse in a particular context given a whole range of situational factors. Prediction of the risk of violence is not straightforward.

Various groups have been identified as contributing risk factors for violent conduct.<sup>16</sup>

- Schizophrenic psychoses, including: older male paranoid schizophrenics; younger males prone to act violently and impulsively, presumably due to hallucinatory commands
- Morbid jealousy: associated with delusions of infidelity
- Antisocial personality disorder
- Mood disorder: violence, usually associated with depression (rarely mania); married women with severe depression (violence against young children); history of suicide attempts in depression

- Episodic discontrol syndrome (similar to intermittent explosive disorder)
- Intellectual disability combined with personality disorder and behavioural disturbances
- Alcohol abuse or dependency
- Amphetamine or benzodiazepine abuse or dependency

From a management viewpoint, homicidal threats must be taken very seriously.

## SUICIDE AND PARASUICIDE

The haunting issue of suicide and parasuicide is presented in **CHAPTER 19**. The disturbed patient is always a suicide risk rather than a homicide risk. The importance of recognising depression with an associated suicide risk in the elderly patient has been emphasised heavily in this chapter.

## Facts and figures<sup>17</sup>

- More than 90% of suicides occur without underlying chronic conditions but most people are significantly depressed at the time.
- In Australia suicide is the second most common cause of death between the ages of 11 and 25 years. Children as young as 5 years of age have committed suicide.
- Those who talk about suicide may attempt it later.
- About half those committing suicide have seen a doctor within their last month of life.
- Around 80–90% of suicides have given clear or subtle warnings to family, friends or doctors.
- There is no evidence that asking patients about suicidal ideation provokes suicidal acts.
- Doctors in Australia and other Western countries have a high suicide rate.

## Suicide risk

Blumenthal's<sup>18</sup> overlapping model lists five groups of risk factors (see **FIG. 45.2**):

- 1 Psychiatric disorders:
  - affective disorder and alcohol abuse in adults
  - schizophrenia
  - depression and conduct disorder in young people
- 2 Personality traits:
  - impulsiveness and aggression
- 3 Environmental and psychosocial factors:
  - poor social supports
  - chronic medical illness (e.g. AIDS)
  - significant loss

**FIGURE 45.2** Overlap model for understanding suicidal behaviour.

Source: After Blumenthal SJ, Kupfer DJ, Generalised treatable strategies for suicidal behaviour, *Annals New York Academy of Science*, 1986; 487: 327–40.

- 4 Family history and genetics (both nature and nurture):
  - emulation of relatives
  - specific ethnic groups in custody
- 5 Biological factors:
  - possible serotonin deficiency

## Parasuicide

Parasuicide is attempted suicide; in many cases patients are drawing attention to themselves as a 'plea for help'. It is important for the GP to take an active role in the support of the patient and family after discharge from hospital, but preferably in conjunction with a psychiatric or counselling service. Arrange frequent consultations at first and ensure adequate follow-up, especially for missed appointments.

## PERSONALITY DISORDERS

People with personality disorders may become very distressed and acutely disturbed under stress or provocation, and this may involve dramatic scenes, including public suicide threats. It is important to recognise personality disorders because they usually

cause considerable distress to the patients, their family, society and GPs. The prevalence is estimated as 11–12%.<sup>5</sup>

In practice the personality disorders of most concern are those that present with hostility, either verbal or physical, particularly if a suicide or homicide threat is involved. It is a mistake to assume that those patients who manifest violent or psychopathic behaviour have a personality disorder or, conversely, the meek and mild are free from personality disorder.

The diagnosis of personality disorder can be difficult. As practitioners we tend to have a 'gut feeling' about the diagnosis but often find it difficult to classify the personality of the patient and then to manage it appropriately.

The main characteristics of a personality disorder are:<sup>5</sup>

- lack of confidence and low self-esteem
- long history from childhood
- difficulties with interpersonal relationships and society
- recurrent maladaptive behaviour
- relatively fixed, inflexible and stylised reaction to stress

**Table 45.10** Summary of main personality disorders

Main cluster group	Subtypes	Main features of disorder
<b>A</b> <b>Withdrawn</b>  <i>Synonyms:</i> <ul style="list-style-type: none"> <li>• odd</li> <li>• eccentric</li> </ul>	Paranoid	Suspicious, oversensitive, argumentative, defensive, hyperalert, cold and humourless
	Schizoid	Shy, emotionally cold, introverted, detached, avoids close relationships
	Schizotypal	Odd and eccentric, sensitive, suspicious and superstitious, socially isolated, odd speech, thinking and behaviour. Falls short of criteria for schizophrenia
<b>B</b> <b>Antisocial</b>  <i>Synonyms:</i> <ul style="list-style-type: none"> <li>• dramatic</li> <li>• emotional</li> <li>• sociopathic</li> <li>• flamboyant</li> <li>• erratic</li> </ul>	Antisocial (sociopathic, psychopathic)	Impulsive, insensitive, selfish, callous, superficial charm, lack of guilt, low frustration level, doesn't learn from experience, relationship problems (e.g. promiscuous), reckless disregard for safety of self and others
	Histrionic (hysterical)	Self-dramatic, egocentric, immature, vain, dependent, manipulative, easily bored, emotional scenes, inconsiderate, seductive, craves attention and excitement
	Narcissistic ('prima donna')	Morbid self-admiration, exhibitionist, insensitive, craves and demands attention, exploits others, preoccupied with power, lacks interest in and empathy with others, bullying, insightful
	Borderline ('hell-raiser')	Confused self-image/identity, impulsive, reckless, emptiness, 'all or nothing' relationships—unstable and intense, damaging reckless behaviour, full of anger and guilt, lacks self-control, uncontrolled gambling, spending etc.
		<i>Note:</i> High incidence suicide and parasuicide; drug abuse
<b>C</b> <b>Dependent</b>  <i>Synonyms:</i> <ul style="list-style-type: none"> <li>• anxious</li> <li>• fearful</li> <li>• inhibited</li> </ul>	Avoidant (anxious)	Anxious, self-conscious, fears rejection, timid and cautious, low self-esteem, overreacts to rejection and failure
	Dependent	Passive, weak willed, lacks vigour, lacks self-reliance and confidence, overaccepting, avoids responsibility, seeks support
	Obsessional (obsessive-compulsive)	Rigid, perfectionist, pedantic, indecisive, egocentric, preoccupied with orderliness and control
<b>Other (unofficial categories)</b>	Passive-aggressive	Procrastinates, childishly stubborn, dawdles, sulks, argumentative, clings, deliberately inefficient and hypercritical of authority figures
	Hypochondrial	Health-conscious, disease fearing, symptom preoccupation
	Depressive (dysthymic, cyclothymic)	Pessimistic, anergic, low self-esteem, gloomy, chronic mild depression

- minimal insight
  - perception of difficulties as external to themselves
- The medical/psychiatric significance:
- maladaptive relationships with GPs and society
  - problem of sexually dysfunctional lives
  - risk of substance abuse and self-destructive behaviour
  - prone to depression and anxiety (usually low grade)
  - susceptible to 'breakdown' under stress

Personality is the result of a genetic template and the continuing interaction of the person with outside influences (peer pressures, family interactions, influential events) and personal drives in seeking an identity. The outcome is a unique behaviour pattern manifest as a personality trait or character reflective of the individual's self-image and fundamental to his or her sense of personal identity.<sup>19</sup>

Although personality is unique, it is possible to make a hypothesis that one is normal or abnormal. If abnormal, it is possible to stereotype it according to the predominant symptoms or behaviours.

Using the International Classification of Disease (ICD-10) and the DSM-5 classification, various subtypes are readily identifiable (see TABLE 45.10),<sup>6</sup> which can be considered in three main groups. There is a considerable overlap between the subtypes within a group<sup>20</sup> and it is more important to understand the specific features of a person's personality rather than categorise them.<sup>21</sup>

The antisocial personality disorders (ASPD) group (1–2% of population) tend to come to the attention of GPs more frequently, with some individuals representing 'heart-sink' patients because of demanding, angry or aggressive behaviour. They are more common among people in prison. The withdrawn group are typically withdrawn, suspicious and socially isolated but fall short of a true psychotic syndrome. GPs have problems communicating with them because they are often suspicious, which can make proper physical examination and management difficult.

In the dependent and inhibited groups, which may overlap with an anxiety state, the main features are nervousness, timidity, emotional dependence and fear of criticism and rejection. They are frequent attenders (the 'fat file' syndrome) and are often accompanied by friends and relatives because of their insecurity.

## Management

The best treatment is a supportive, 'therapeutic' community and an understanding and supportive GP. Psychotherapies are the key to long-term treatment. It is vital to understand that people with personality disorders perceive the world from a fundamentally different perspective. Problematic patients, if agreeable, may respond well to psychological intervention and behavioural techniques, especially operant conditioning (reinforcing acceptable behaviour) and aversive conditioning (correcting inappropriate behaviour).<sup>5,19</sup> CBT has the most to offer.

The borderline and narcissistic disorders in particular respond well to specific types of psychotherapeutic intervention. Patients' self-esteem needs careful support while maladaptive modes of behaviour are confronted. Hospitalisation is rarely required except for those at risk of suicide (e.g. antisocial patients).

Medication has limitations but may be useful to treat those individuals who temporarily decompensate into a psychosis, an anxiety state or depression. One study has shown that antipsychotic medication in low dosage (e.g. haloperidol 5 mg daily) is effective in treating the problematic behaviours in paranoid and some antisocial personality disorders.<sup>22</sup>

There are dangers to the therapist and it is important not to 'buy into' a particular psychopathy, especially with seductive, manipulative or paranoid patients.<sup>18</sup>

## When to refer<sup>17</sup>

Indications for referral to a psychiatrist:

- severe depression
- high suicide risk
- actual suicide attempt: recent or in the past
- suspected psychiatric disorders in the elderly: ?depression or schizophrenia; ?depression or dementia
- failure to improve with treatment
- poor family and social supports

## Patient education resources

*I got my giddiness in 1690 (at the age of 23) by eating 100 golden pippins at a time at Richmond. Four years later at a place 20 miles further on in Surrey I got my deafness; and these two 'friends' have visited me one or other year since, and being old acquaintances have often sought fit to come together.*

Jona than Swift (1667–1745), describing his Ménière syndrome

When patients complain of 'dizziness', they can be using this term to describe many different phenomena, and hence a careful history is required to unravel the problem. Other patients may use different terms to explain the same sensation, for example, 'giddiness', 'swimming in the head', 'my brain spinning', 'whirling' and 'swinging'.

'Dizzy' comes from an old English word, *dysig*, meaning foolish or stupid. Strictly speaking, it means unsteadiness or lightheadedness—without movement or motion or spatial disorientation.

'Vertigo', on the other hand, comes from the Latin *vertere* (to turn) and *-igo* for a condition. It should describe a hallucination of rotation of self or the surroundings in a horizontal or vertical direction.<sup>1</sup>

The term 'dizziness', however, is generally used collectively to describe all types of equilibrium disorders and, for convenience, can be classified as shown in FIGURE 46.1.

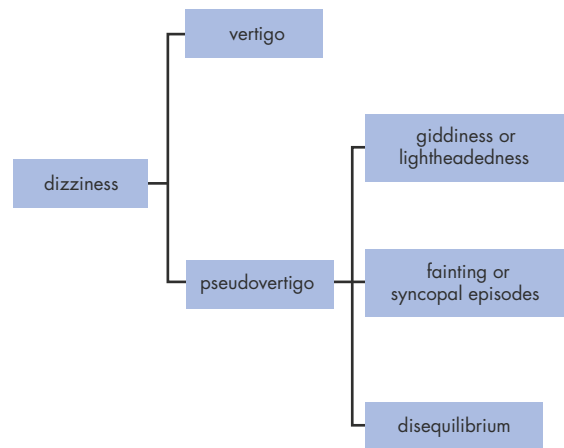

FIGURE 46.1 Classification of dizziness

## Key facts and checkpoints

- Approximately one-third of the population will have suffered from significant dizziness by age 65 and about a half by age 80.<sup>2</sup>
- The commonest causes in family practice are postural hypotension and hyperventilation.
- The ability to examine and interpret the sign of nystagmus accurately is important in the diagnostic process.
- A drug history is very important, including prescribed drugs and others such as alcohol, cocaine, marijuana and illicit drugs.
- Ménière syndrome is overdiagnosed. It has the classic triad: vertigo–tinnitus–deafness (sensorineural).
- Vertebrobasilar insufficiency is also overdiagnosed as a cause of vertigo. It is a rare cause but may result in dizziness and sometimes vertigo but rarely in isolation.

## Defined terminology

### Vertigo

Vertigo is defined as an episodic sudden sensation of circular motion of the body or of its surroundings or an illusion of motion, usually a rotatory sensation. Other terms used by the patient to describe this symptom include 'everything spins', 'my head spins', 'the room spins', 'whirling', 'reeling', 'swaying', 'pitching' and 'rocking'. It is frequently accompanied by autonomic symptoms such as nausea, retching, vomiting, pallor and sweating.

Vertigo is characteristically precipitated by standing or turning the head or by movement. Patients have to walk carefully and may become nervous about descending stairs or crossing the road and usually seek support. Therefore the vertiginous patient is usually very frightened and tends to remain immobile during an attack.

Patients may feel as though they are being impelled by some outside force that tends to pull them to one side, especially while walking.

True vertigo is a symptom of disturbed function involving the vestibular system or its central connections. It invariably has an organic cause. Important causes are presented in **TABLE 46.1**, while **FIGURE 46.2** illustrates central neurological centres that can cause vertigo.

Nystagmus is often seen with vertigo and, since 80–85% of causes are due to an ear problem, tinnitus and hearing disorders are also associated. In acute cases there is usually a reflex autonomic discharge producing sweating, pallor, nausea and vomiting.

## Giddiness

Giddiness is a sensation of uncertainty or ill-defined lightheadedness. Other terms used by patients include 'a swimming sensation', 'walking on air' and 'ground going beneath me'. It usually contains no elements of rotation, impulsion, tinnitus, deafness, nausea or vomiting.

The patient with giddiness, although fearful of falling or swooning, can nonetheless walk without difficulty if forced to do so.

Giddiness is a typical psychoneurotic symptom.

## Syncopal episodes

Syncope may present as a variety of dizziness or lightheadedness in which there is a sensation of

**Table 46.1** Causes of vertigo

### Peripheral disorders

#### Labyrinth:

- labyrinthitis: viral or suppurative
- Ménière syndrome
- benign paroxysmal positional vertigo (BPPV)
- drugs
- trauma
- chronic suppurative otitis media

#### Eight nerve:

- vestibular neuronitis
- acoustic neuroma
- drugs

### Cervical vertigo

#### Central disorders

##### Brain stem (TIA or stroke):

- vertebrobasilar insufficiency
- infarction

##### Cerebellum:

- degeneration
- tumours

##### Migraine

##### Multiple sclerosis

**FIGURE 46.2** Diagrammatic illustration of central centres that can cause vertigo

impending fainting or loss of consciousness. Common causes are cardiogenic disorders and postural hypotension, which are usually drug-induced.

## Disequilibrium

Disequilibrium implies a condition in which there is a loss of balance or instability while walking, without any associated sensations of spinning. Other terms used to describe this include 'unsteadiness on feet', 'the staggers', 'swaying feeling' and 'dizzy in the feet'.

Disequilibrium is usually of neurogenic origin.

## A diagnostic approach

A summary of the diagnostic strategy model is presented in **TABLE 46.2**.

## Probability diagnosis

In medical school we gain the wrong impression that the common causes of dizziness or vertigo are the relatively uncommon causes, such as Ménière syndrome, aortic stenosis, Stokes–Adams attacks, cerebellar disorders, vertebrobasilar disease and hypertension. In the real world of medicine, one is impressed by how often dizziness is caused by relatively common benign conditions, such as hyperventilation associated with anxiety, simple syncope, postural hypotension due to drugs and old age, inner ear infections, wax in the ears, post head injury, motion sickness and alcohol intoxication. In most instances making the correct diagnosis (which, as ever, is based on a careful history) is straightforward, but finding the underlying cause of true vertigo can be very difficult.

The common causes of vertigo seen in general practice are benign paroxysmal positional vertigo (BPPV, so often related to cervical vertebral dysfunction), accounting for about 25% of cases, acute vestibulopathy (vestibular neuronitis) and vestibular migraine.

Viral labyrinthitis is basically the same as vestibular neuronitis, except that the whole of the inner ear is involved so that deafness and tinnitus arise simultaneously with severe vertigo. The most common causes of recurrent spontaneous vertigo are Ménière syndrome and vestibular migraine.

## Serious disorders not to be missed

### Neoplasia

The important serious disorders to keep in mind are space-occupying tumours, such as acoustic neuroma, medulloblastoma and other tumours (especially posterior fossa tumours) capable of

**Table 46.2** Dizziness/vertigo: diagnostic strategy model

Q.	Probability diagnosis
A.	Anxiety-hyperventilation (G) Postural hypotension (G/S) Simple faint—vasovagal (S) Acute vestibulopathy (V) Benign paroxysmal positional vertigo (V) Motion sickness (V) Vestibular migraine (V) Cervical dysfunction/spondylosis
Q.	Serious disorders not to be missed
A.	Neoplasia: <ul style="list-style-type: none"> <li>• acoustic neuroma</li> <li>• posterior fossa tumour</li> <li>• other brain tumours, primary or secondary</li> </ul> Intracerebral infection (e.g. abscess) Cardiovascular: <ul style="list-style-type: none"> <li>• arrhythmias</li> <li>• myocardial infarction</li> <li>• aortic stenosis</li> </ul> Cerebrovascular: <ul style="list-style-type: none"> <li>• vertebrobasilar insufficiency</li> <li>• brain stem infarct (e.g. PICA thrombosis)</li> </ul> Multiple sclerosis Carbon monoxide poisoning
Q.	Pitfalls (often missed)
A.	Ear wax—otosclerosis Arrhythmias Hyperventilation Alcohol and other drugs Cough or micturition syncope Vestibular migraine/migrainous vertigo Parkinson disease Ménière syndrome (overdiagnosed) Rarities: <ul style="list-style-type: none"> <li>• Addison disease (<b>CHAPTER 23</b>)</li> <li>• neurosyphilis</li> <li>• autonomic neuropathy</li> <li>• hypertension</li> <li>• subclavian steal</li> <li>• perilymphatic fistula</li> <li>• Shy–Drager syndrome</li> </ul>
Q.	Seven masquerades checklist
A.	Depression Diabetes (possible: hypo/hyper) Drugs Anaemia Thyroid disorder (possible) Spinal dysfunction UTI (possible)
Q.	Is the patient trying to tell me something?
A.	Very likely. Consider anxiety and/or depression.

G = giddiness; S = syncope; V = vertigo

causing vertigo, intracerebral infections and cardiovascular abnormalities.

It is important to bear in mind that the commonest brain tumour is a metastatic deposit from lung cancer.<sup>3</sup>

### Red flags for dizziness/vertigo

- neurological signs
- ataxia out of proportion to vertigo
- nystagmus out of proportion to vertigo
- central nystagmus
- central eye movement abnormalities

46

### Acoustic neuroma

This uncommon tumour should be suspected in the patient presenting with the symptoms shown in the diagnostic triad below. Headache may occasionally be present.

**DxT** (unilateral) tinnitus + hearing loss + unsteady gait → acoustic neuroma

Diagnosis is best clinched by high-resolution MRI. Audiometry and auditory evoked responses are also relevant investigations.

### Cardiac disorders

Cardiac disorders that must be excluded for giddiness or syncope are the various arrhythmias, such as Stokes–Adams attacks caused by complete heart block, aortic stenosis and myocardial infarction.

### Cerebrovascular causes

The outstanding cerebrovascular causes of severe vertigo are vertebrobasilar insufficiency and brain stem infarction. Vertigo is the commonest symptom of transient cerebral ischaemic attacks in the vertebrobasilar distribution.<sup>1</sup>

Severe vertigo, often in association with hiccoughs and dysphagia, is a feature of the variety of brain stem infarctions known as the lateral medullary syndrome due to posterior inferior cerebellar artery (PICA) thrombosis. There is a dramatic onset of vertigo with cerebellar signs, including ataxia and vomiting. There are ipsilateral cranial nerve (brain stem) signs with contralateral spinothalamic sensory loss of the face and body. Diagnosis is by CT or MRI scanning.

### Neurological causes

Important neurological causes of dizziness are multiple sclerosis and complex partial seizures.

The lesions of multiple sclerosis may occur in the brain stem or cerebellum. Young patients who present with a sudden onset of vertigo with ‘jiggly’ vision but without auditory symptoms should be considered as having multiple sclerosis. Five per cent of cases of multiple sclerosis present with vertigo.

### Pitfalls

A list of conditions causing dizziness that may be misdiagnosed is presented in TABLE 46.2. Wax in the ear certainly causes dizziness, though its mechanism of action is controversial. Cough and micturition syncope do occur, although they are uncommon.

Ménière syndrome is a pitfall in the sense that it tends to be overdiagnosed.

### Seven masquerades checklist

Of these conditions, drugs and vertebral dysfunction (of the cervical spine) stand out as important causes. Depression demands attention because of the possible association of anxiety and hyperventilation.

Diabetes mellitus has an association through the possible mechanisms of hypoglycaemia from therapy or from an autonomic neuropathy.

### Drugs

Drugs usually affect the vestibular nerve rather than the labyrinth. Drugs commonly associated with dizziness are presented in TABLE 46.3.

**Table 46.3** Drugs that can cause dizziness

Alcohol
Antibiotics: streptomycin, gentamicin, kanamycin, tetracyclines
Antidepressants
Anti-epileptics: phenytoin
Antihistamines
Antihypertensives
Aspirin and salicylates
Cocaine
Diuretics in large doses: intravenous frusemide, ethacrynic acid
Glyceryl trinitrate
Quinine-quinidine
Tranquillisers: phenothiazines, phenobarbitone, benzodiazepines

## Cervical spine dysfunction

It is not uncommon to observe vertigo in patients with cervical spondylosis or post cervical spinal injury. It has been postulated<sup>4</sup> that this may be caused by the generation of abnormal impulses from proprioceptors in the upper cervical spine, or by osteophytes compressing the vertebral arteries in the vertebral canal. Some instances of BPPV are associated with disorders of the cervical spine.

## Psychogenic considerations

This may be an important aspect to consider in the patient presenting with dizziness, especially if the complaint is giddiness or lightheadedness. An underlying anxiety, particularly agoraphobia and panic disorder, may be the commonest cause of this symptom in family practice and clinical investigation of hyperventilation may confirm the diagnosis. The possibility of depression must also be kept in mind.<sup>5</sup> Many of these patients harbour the fear that they may be suffering from a serious disorder, such as a brain tumour or multiple sclerosis, or face an impending stroke or insanity. Appropriate reassurance to the contrary is often positively therapeutic for that patient.

## The clinical approach

The essentials of the diagnostic approach include careful attention to the history and physical examination, and judicious selection of specific office tests and special investigations.

## History

It is important to get patients to explain the precise nature of the symptoms, even asking their opinion as to the cause of their dizziness.

## Key questions

The following questions should be addressed:

- Is it vertigo or pseudovertigo?
- Symptom pattern:
  - paroxysmal or continuous?
  - effect of position and change of posture?
- Any aural symptoms? Tinnitus? Deafness?
- Any visual symptoms?
- Any neurological symptoms?
- Any nausea or vomiting?
- Any symptoms of psychoneurosis?
- Any recent colds?
- Any recent head injury (even trivial)?
- Any drugs being taken?
  - alcohol?
  - marijuana?
  - hypotensives?
  - psychotropics?
  - other drugs?

## Examination

A full general examination is appropriate with particular attention being paid to the cardiovascular and central nervous systems and the auditory and vestibular mechanisms.

## Guidelines

Examination guidelines are:

- 1 ear disease:
  - auroscopic examination: ? wax ? drum
  - hearing tests
  - Weber and Rinne tests
- 2 the eyes:
  - visual acuity
  - test movements for nystagmus
- 3 cardiovascular system:
  - evidence of atherosclerosis
  - blood pressure: supine, standing, sitting
  - cardiac arrhythmias
- 4 cranial nerves:
  - 2nd, 3rd, 4th, 6th and 7th
  - corneal response for 5th
  - 8th—auditory nerve
- 5 the cerebellum or its connections:
  - gait
  - coordination
  - reflexes
  - Romberg test
  - finger nose test: ? past pointing
- 6 the neck, including cervical spine
- 7 general search for evidence of:
  - anaemia
  - polycythaemia
  - alcohol dependence

## Office tests for dizziness

- Ask the patient to perform any manoeuvre that may provoke the symptom.
- Carry out head positional testing to induce vertigo and/or nystagmus (e.g. Hallpike manoeuvre) (see FIG. 46.3). Avoid if prominent spontaneous vertigo and nystagmus.
- Take blood pressure measurements in three positions.

- Perform forced hyperventilation (20 to 25 breaths per minute) for 2 minutes.
- Carry out palpation of carotid arteries and carotid sinus (with care).

## Investigations

Appropriate laboratory tests should be selected from **TABLE 46.4**.

**Table 46.4** Investigations

Haemoglobin
Blood glucose
ECG: ? Holter monitor
Audiometry
Brain-stem evoked audiometry
Caloric test
Visual evoked potentials (MS)
Electrocochleography
Electro-oculography (electronystagmography)
Rotational tests
Radiology:
• chest X-ray (? bronchial carcinoma)
• cervical spine X-ray
• CT scan
• MRI (the choice to locate acoustic neuroma or other tumour—may detect MS and vascular infarction)

## Diagnostic guidelines

- A sudden attack of vertigo in a young person following a recent URTI is suggestive of vestibular neuronitis.
- Dizziness is a common symptom in menopausal women and is often associated with other features of vasomotor instability.
- Phenytoin therapy can cause cerebellar dysfunction.
- Postural and exercise hypotension are relatively common in the older atherosclerotic patient.
- Acute otitis media does not cause vertigo but chronic otitis media can, particularly if the patient develops a cholesteatoma, which then erodes into the internal ear causing a perilymphatic fistula.

## Dizziness in children

Dizziness is not a common symptom in children. Vertigo can have sinister causes and requires referral

because of the possibility of tumours, such as a medulloblastoma. A study by Eviatar and Eviatar<sup>6</sup> of vertigo in children found that the commonest cause was a seizure focus particularly affecting the temporal lobe. Other causes included psychosomatic vertigo, vestibular migraine and vestibular neuritis.

Apart from the above causes it is important to consider:

- infection (e.g. meningitis, meningoencephalitis, cerebral abscess)
- trauma, especially to the temporal area
- middle-ear infection
- labyrinthitis (e.g. mumps, measles, influenza)
- BPPV (short-lived attacks of vertigo in young children between 1 and 4 years of age: tends to precede adulthood migraine)<sup>7</sup>
- hyperventilation
- drugs—prescribed
- illicit drugs (e.g. cocaine, marijuana)
- cardiac arrhythmias
- alcohol toxicity

A common trap is the acute effect of alcohol in curious children who can present with the sudden onset of dizziness.

## Dizzy turns in girls in late teens

- These are commonly due to blood pressure fluctuations.
- Give advice related to reducing stress, lack of sleep and excessive exercise.
- Reassure that it settles with age (rare after 25 years).

## Dizziness in the elderly

Dizziness is a relatively common complaint of the elderly. Common causes include postural hypotension related mainly to drugs prescribed for hypertension or other cardiovascular problems. Cerebrovascular disease, especially in the areas of the brain stem, is also relevant in this age group. True vertigo can be produced simply by an accumulation of wax in the external auditory meatus, being more frequent than generally appreciated.

Middle-ear disorder is also sometimes the cause of vertigo in an older person but disorder of the auditory nerve, inner ear, cerebellum, brain stem and cervical spine are common underlying factors.

Malignancy, primary and secondary, is a possibility in the elderly. The possibility of cardiac arrhythmias as a cause of syncopal symptoms increases with age.

## Dizzy turns in elderly women

If no cause such as hypertension is found, advise them to get up slowly from sitting or lying, and to wear firm elastic stockings.

## § Acute vestibulopathy (vestibular failure)

Causes:

- vestibular neuritis
- stroke—AICA or PICA

Vestibular neuritis covers both vestibular neuronitis and labyrinthitis, which are considered to be a viral infection of the vestibular nerve and labyrinth respectively, causing a prolonged attack of vertigo that can last for several days and be severe enough to require admission to hospital.<sup>8</sup>

It is analogous to a viral infection of the 7th nerve causing Bell palsy. The attack is similar to Ménière syndrome except that there is no hearing disturbance.

**DxT** acute vertigo + nausea + vomiting  
→ vestibular neuritis

**DxT** same symptoms + hearing loss ± tinnitus  
→ acute labyrinthitis

## Characteristic features

- single attack of vertigo without tinnitus or deafness
- usually preceding 'flu-like' illness
- mainly in young adults and middle age
- abrupt onset with vertigo, ataxia, nausea and vomiting
- generally lasts days to weeks
- examination shows lateral or unidirectional nystagmus—rapid component away from side of lesion (no hearing loss)
- caloric stimulation confirms impaired vestibular function

It is basically a diagnosis of exclusion.

## Treatment

- Rest in bed, lying very still
- Gaze in the direction that eases symptoms

The following drugs can be used (see TABLE 46.5):

prochlorperazine (Stemetil) 12.5 mg IM (if severe vomiting) but may slow recovery or 5–10 mg (o) tds

or promethazine 10–25 mg IM or slow IV then 10–25 mg (o) for 48 hrs  
or (recommended as best)  
diazepam (which decreases brain-stem response to vestibular stimuli)<sup>2</sup> 5–10 mg IM for the acute attack, then 5 mg (o) tds for 2–3 days

A short course of corticosteroids often promotes recovery (e.g. prednisolone 1 mg/kg (up to 100 mg) (o) daily in morning for 5 days, then taper over 15 days and cease).<sup>1, 10</sup>

**Table 46.5** Symptomatic relief of acute vertigo<sup>o</sup>: pharmaceutical options

Anti-emetics:

- prochlorperazine
- metoclopramide

Antihistamines:

- promethazine
- betahistine

Benzodiazepines (short period use for vertigo):

- diazepam
- lorazepam

## Outcome

Both are self-limiting disorders and usually settle over 5–7 days or several weeks. Labyrinthitis usually lasts longer and during recovery rapid head movements may bring on transient vertigo.

## § Benign paroxysmal positional vertigo

BPPV is a common type of acute vertigo that is induced by changing head position—particularly tilting the head backwards, changing from a recumbent to a sitting position or turning to the affected side.

## Features

- Affects all ages, especially the elderly
- The female to male ratio is 2:1
- Recurs periodically for several days
- Each attack is brief, usually lasts 10–60 seconds, and subsides rapidly
- Severe vertigo on getting out of bed
- Can occur on head extension and turning head in bed

- Attacks are not accompanied by vomiting, tinnitus or deafness (nausea may occur)
- In one large series 17% were associated with trauma, 15% with viral labyrinthitis, while about 50% had no clear predisposing factor other than age. One accepted theory of causation is that fine pieces of floating crystalline calcium carbonate deposits (otoconia) that are loose in the labyrinth settle in the posterior semicircular canal and generate endolymphatic movement.<sup>11</sup> It may also be a variation of cervical dysfunction.
- Diagnosis is confirmed by head position testing. From a sitting position the patient's head is rapidly taken to a head-hanging position 30° below the level of the couch—do three times, with the head (1) straight, (2) rotated to the right, (3) rotated to the left. Hold on for 30 seconds and observe the patient carefully for vertigo and nystagmus. There is a latent period of few seconds before the onset of the symptoms—see **FIGURE 46.3**.
- Tests of hearing and vestibular function are normal
- There is usually spontaneous recovery in weeks (most return to regular activity after 1 week)
- Recurrences are common: attacks occur in clusters

**FIGURE 46.3** Hallpike manoeuvre: positional testing for benign paroxysmal positional vertigo (head rotated to 45° then taken rapidly from a sitting position to a hanging position). Repeat with head turned to the opposite side. A positive response is the onset of symptoms  $\pm$  nystagmus with the affected ear lowermost.

## Management

- Give appropriate explanation and reassurance
- Avoidance measures: encourage the patient to move in ways that avoid the attack
- Drugs are not recommended
- Special exercises
- Cervical traction may help

## Particle repositioning manoeuvres

*Patient-performed exercises.* Most patients appear to benefit from exercise, such as the Brandt and Daroff procedure<sup>12</sup> or the Cawthorne–Cooksey exercises<sup>9</sup> that consist essentially of repeatedly inducing the symptoms of vertigo. Rather than resorting to avoidance measures, the patient is instructed to perform positional exercises to induce vertigo, hold this position until it subsides, and repeat this many times until the manoeuvre does not precipitate vertigo. The attacks then usually subside in a few days.

*Therapist-performed exercises.* Physical manoeuvres performed as an office procedure include the Epley and Semont manoeuvres (refer <[www.neurology.org](http://www.neurology.org)>).

## Surgical treatment

Rarely surgical treatment is required; it involves occlusion of the posterior semicircular canal rather than selective neurectomy.

## § Ménière syndrome

This is caused by a build-up of endolymph.

- It is commonest in the 30–50 years age group.
- It is characterised by paroxysmal attacks of vertigo, tinnitus, nausea and vomiting, sweating and pallor, deafness (progressive).
- Onset is abrupt—patient may fall and then be bedridden for 1–2 hours. Patient doesn't like moving head.
- Attacks last 30 minutes to several hours.
- There is a variable interval between attacks (twice a month to twice a year).
- Nystagmus is observed only during an attack (often to side opposite affected inner ear).
- Examination:
  - sensorineural deafness (low tones)
  - caloric test: impaired vestibular function
  - audiometry: sensorineural deafness, loudness recruitment
  - special tests
- There are characteristic changes in electrocochleography.

**DxT** vertigo + vomiting + tinnitus +  
sensorineural deafness → Ménière syndrome

## Treatment

The aim is to reduce endolymphatic pressure by reducing the sodium and water content of the endolymph.

## Acute attack<sup>13</sup>

Anticipation of attack (fullness, tinnitus):

prochlorperazine 25 mg suppository  
or  
30 g urea crystals in orange juice (preferably  
30 minutes before in prodromal phase)

Treatment:

diazepam 5 mg IV ± prochlorperazine 12.5 mg  
IM. Consider betahistine 8 mg (o) tds if  
persistent or episodic

## Long term

- Reassurance with a careful explanation of this condition to the patient, who often associates it with malignant disease
- Excess intake of salt, tobacco and coffee to be avoided
- A low-salt diet is the mainstay of treatment (<3 g per day)
- Alleviate abnormal anxiety by using stress management, meditation or possibly long-term sedation (fluid builds up with stress)
- Referral for neurological assessment
- Diuretic (e.g. hydrochlorothiazide/amiloride daily)—check electrolytes regularly

Surgery may be an option for intractable cases.

## § Vestibular migraine (migrainous vertigo)

Migraine is a relatively common cause of vertigo and often unrecognised because of its many guises. It should be strongly suspected if there is a past and/or family history of migraine and also where there is a history of recurrent bouts of spontaneous vertigo or ataxia that persist for hours or days in the absence of aural symptoms.<sup>14</sup> Vertigo, which is usually not violent, may take the place of the aura that precedes the headache or may be a migraine equivalent whereby the vertigo replaces the symptoms of headache, which may be an inconspicuous feature

in some cases. Nausea and vomiting may be present. Pizotifen or propranolol are recommended for prophylaxis.

## When to refer

- Vertigo of uncertain diagnosis, especially in children
- Possibility of tumour, or bacterial infection
- Vertigo in presence of suppurative otitis media despite antibiotic therapy
- Presumed viral labyrinthitis not abating after 3 months
- Vertigo following trauma
- Presumed Ménière syndrome, not responding to conservative medical management
- Evidence of vertebrobasilar insufficiency
- BPPV persisting for more than 12 months despite treatment with particle repositioning exercises

## Practice tips

- A careful drug history often pinpoints the diagnosis.
- Always consider cardiac arrhythmias as a cause of acute dizziness.
- Consider phenytoin therapy as a cause of dizziness in an epileptic patient.
- If an intracerebral metastatic lesion is suspected, consider the possibility of carcinoma of the lung as the primary source.
- Three important office investigations to perform in the evaluation are blood pressure measurement (lying, sitting and standing), hyperventilation and head positional testing.
- Cervical vertigo is very common and appropriate cervical mobilisation methods with care should be considered.
- BPPV is also common and prescribing a set of exercises to desensitise the labyrinth is recommended. Use either the Brandt–Daroff procedure or the Cawthorne–Cooksey program.<sup>11</sup>
- Think of migraine particularly in a younger patient presently with unexplained recurrent vertigo.

## Patient education resources

Hand-out sheets from *Murtagh's Patient Education*  
6th edition:

- Labyrinthitis
- Ménière syndrome
- Vertigo: benign positional vertigo
- Vertigo: exercises for benign positional vertigo

*Half the patients who get you up in the middle of the night and think they are dying are suffering from wind!*

Francis Young (1884–1954), Advice to a younger doctor

Dyspepsia or indigestion is a difficult, sometimes vague, symptom to define or evaluate and requires very careful questioning to clarify the exact nature of the complaint.

Dyspepsia embraces the following:

- nausea
- heartburn/regurgitation
- upper abdominal discomfort
- lower chest discomfort
- acidity
- epigastric fullness or unease
- abdominal distension

The discomfort can sometimes amount to pain.

Diagnoses to consider in dyspeptic patients are summarised in [TABLE 47.1](#).<sup>1</sup>

## Glossary of terms

**Dyspepsia** Pain or discomfort centred at the upper abdomen that is chronic or recurrent in nature.

**Flatulence** Excessive wind. It includes belching, abdominal bloating or passing excessive flatus.

**Heartburn** A central retrosternal or epigastric burning sensation that spreads upwards to the throat.

## Flatulence

### Excessive belching

- Usually functional
- Organic disease uncommon
- Due to air swallowing (aerophagy)
- Common in anxious people who gulp food and drink
- Associated hypersalivation

### Management tips

- Make patient aware of excessive swallowing
- Avoid fizzy (carbonated) soft drinks
- Avoid chewing gum
- Don't drink with meals
- Don't mix proteins and starches

### Table 47.1 Diagnoses to consider in dyspeptic patients

#### Gastrointestinal disorders

Gastro-oesophageal reflux, including hiatus hernia

Functional (non-ulcer) dyspepsia

Oesophageal motility disorders (dysmotility)

Peptic ulcer

Upper GIT malignancies (e.g. oesophagus, stomach, pancreas)

Hepatobiliary disease (e.g. hepatitis, biliary dyskinesia, cholelithiasis)

Pancreatitis

Upper GIT inflammation:

- oesophagitis
- gastritis
- duodenitis

Irritable bowel syndrome

#### Non-gastrointestinal disorders

Myocardial ischaemia

Drug reaction

Alcohol effect

Somatisation

Anxiety/stress

Depression

- Eat slowly and chew food thoroughly before swallowing
- Eat and chew with the mouth closed

If persistent: simethicone preparation (e.g. Mylanta II, Phazyme).

If desperate: place one small cork between the back teeth after meals for 30 minutes.

## Excessive flatus

Flatus arises from two main sources:

- swallowed air

- bacterial fermentation of undigested carbohydrate  
Exclude:
- malabsorption
- irritable bowel syndrome
- anxiety → aerophagy
- drugs, especially lipid-lowering agents
- lactose intolerance

### Management

- Assess diet (e.g. high fibre, beans and legumes, cabbage, onions, grapes and raisins)
- Avoid drinking with eating, especially with leafy vegetables
- Cook vegetables thoroughly
- Trial a lactose-free diet
- Consider simethicone preparations (e.g. No Gas)

### Key facts and checkpoints

- Dyspepsia or indigestion is a common complaint; 80% of the population<sup>1</sup> will have experienced it at some time.
- Consider heartburn as ischaemic heart disease until proved otherwise.
- The presence of oesophagitis is suggested by pain on swallowing hot or cold liquids (odynophagia).
- All reflux is not due to hiatus hernia.
- Many patients with hiatus hernia do not experience heartburn.
- All patients with dysphagia must be investigated to rule out malignancy.
- Ten per cent of people in the community develop peptic ulcer (PU) disease.
- The major feature of PU disease is epigastric pain.
- The pain of duodenal ulcer (DU) classically occurs at night.
- At any time 10–20% of chronic NSAIDs users have peptic ulceration (greater than non-users).<sup>2</sup>
- NSAIDs mainly cause gastric ulcers (GU, gastric antrum and prepyloric region) with the duodenum affected to a lesser extent.
- Dyspeptic symptoms correlate poorly with NSAID-associated ulcer.

### A diagnostic approach

A summary of the diagnostic strategy model is presented in **TABLE 47.2**.

It is best to consider dyspepsia as:

- ulcer-like—localised pain

**Table 47.2** Dyspepsia: diagnostic strategy model

Q. Probability diagnosis
A. Irritable upper GIT (functional dyspepsia)
Gastro-oesophageal reflux
Drugs
Oesophageal motility disorder (e.g. gastroparesis)
Q. Serious disorders not to be missed
A. Neoplasia:
• cancer: stomach, pancreas, oesophagus
Cardiovascular
• ischaemic heart disease
• congestive cardiac failure
Pancreatitis
Peptic ulcer (PU)
Q. Pitfalls (often missed)
A. Myocardial ischaemia
Food allergy (e.g. lactose intolerance)
Pregnancy (early)
Hepatobiliary disease
Other gall bladder disease
Post vagotomy
Duodenitis
Autoimmune gastritis
Rarities:
• hyperparathyroidism
• mesenteric ischaemia
• Zollinger–Ellison syndrome
• kidney failure
• scleroderma
Q. Seven masquerades checklist
A. Depression
Diabetes (rarely)
Drugs
Q. Is this patient trying to tell me something?
Anxiety and stress are common associations of which patients are often unaware. Consider irritable bowel syndrome; somatisation.

- dysmotility-like—diffuse discomfort, feeling full after meals (early satiety), nausea, bloating
- acid-reflux-like—indigestion or heartburn with acid reflux or regurgitation

The ulcer-like category may be due to an ulcer and if not is termed functional (non-ulcer) dyspepsia.

### Pitfalls

Perhaps the commonest mistake is to attribute the discomfort of myocardial ischaemia to a disorder of the GIT. A sense of fullness or pressure in the epigastrium can certainly accompany ischaemia.

## General pitfalls

- Reflux oesophagitis and PU can mimic ischaemic heart disease.
- Overlooking gastric cancer as a cause of dyspepsia.
- Failing to stress that weight reduction to ideal level will generally alleviate gastro-oesophageal reflux.
- Overlooking drugs as a cause (see TABLE 47.3).

**Table 47.3** Drugs that may cause dyspepsia

Alcohol
Anticholinergics
Aspirin
Bisphosphonates, esp. alendronate
Calcium-channel blockers
Corticosteroids
Digitalis
Lipid-lowering agents
Narcotics
Nicotine
NSAIDs
Potassium supplements (slow release)
Tetracycline
Theophylline
Tricyclic antidepressants

## The clinical approach

### History

It is worthwhile spending some time clarifying the exact nature of the presenting complaint: what the patient means by 'indigestion' or 'heartburn'.<sup>1</sup> The relationship of the symptom to eating is very important, and whether it occurs after each meal or after specific meals.

In particular, care should be taken to consider and perhaps exclude ischaemic heart disease.

### Key questions

- How would you describe the discomfort?
- Can you show me exactly where it is and where it radiates?
- What makes your discomfort worse?
- What relieves your discomfort?
- What effect do food, milk and antacids have?
- What effect do coffee, onions or garlic have?
- What effect does a big meal have?
- What about drinking alcohol? Wine?
- What effect does exercise have?
- Do fried or fatty foods make it worse?
- Do hot spicy foods affect it?
- Does the problem come on at night soon after you go to bed?
- Does it wake you up at night?
- Does bending over (e.g. gardening) make it worse?
- Do you have periods of freedom from the problem?
- Are you under a lot of stress or have a lot of worry?
- Do you go flat out all day?
- Do you rush your meals?
- Do you chew your food properly?
- What drugs or medicines do you take?
- How much alcohol do you have? Do you smoke?
- Have you noticed anything else when you have the problem?
- Do you get constipated or have diarrhoea?
- Have you lost weight recently?
- Do you feel the discomfort between your shoulder blades, or in your shoulders or throat?

## Symptoms analysis

### Site and radiation

The site and radiation of pain or discomfort can provide a lead to the diagnosis. Refer to FIGURE 40.9 in CHAPTER 40. If it is felt in the interscapular area, consider oesophageal spasm, gall bladder disease or a DU. Retrosternal discomfort indicates oesophageal disorders or angina, while epigastric discomfort suggests disorders of the biliary system, stomach and duodenum.

### Character of the pain

There tends to be considerable overlap in the character of the pain from the various disorders but some general characteristics apply:

- burning pain → gastro-oesophageal reflux (GORD)
- constricting pain → ischaemic heart disease or oesophageal spasm
- deep gnawing pain → PU
- heavy ache or 'killing' pain → psychogenic pain

### Aggravating and relieving factors

Examples of these factors include:

- eating food may aggravate a GU but relieve a DU

- eating fried or fatty foods will aggravate biliary disease, functional dyspepsia and oesophageal disorders
- bending will aggravate GORD
- alcohol may aggravate GORD, oesophagitis, gastritis, PU, pancreatitis

### Associated symptoms

Relevant examples:

- difficulty in swallowing → oesophageal disorders
- lump or constriction in throat → psychogenic
- acid regurgitation → GORD, oesophagitis
- anorexia, weight loss → stomach cancer
- water brash → GORD, hiatus hernia, PU
- symptoms of anaemia → chronic oesophagitis or gastritis, PU, cancer (stomach, colon)
- flatulence, belching, abnormal bowel habits → irritable bowel syndrome
- diarrhoea 30 minutes after meal → mesenteric ischaemia

### Examination

The physical examination does not often provide the key to the diagnosis but it is important to perform very careful palpation and inspection. Look for evidence of clinical anaemia and jaundice. Diffuse mild abdominal tenderness and a pulsatile abdominal aorta are common findings but do not necessarily discriminate between organic and functional problems. Specific epigastric tenderness suggests peptic ulceration while tenderness over the gall bladder area (Murphy sign) indicates gall bladder disease. An epigastric mass indicates stomach cancer.

### Investigations

Do not overinvestigate. Investigations tend to be unrewarding in most instances of dyspepsia and could be postponed if the history is suggestive of a functional cause and the symptoms are not severe.<sup>1</sup> A trial of treatment such as changing adverse lifestyle factors, dietary modification and antacids could be the initial approach. Age is important in determining the extent of investigations, which are more relevant in those over 40 years.

The investigation of choice is endoscopy, which is superior to barium studies in investigation of the upper GIT. Gastroscopy is indicated for the *alarm* symptoms:

- abnormal symptoms of reflux/dyspepsia
- change of symptoms

- dysphagia
- unexplained weight loss
- GIT bleeding
- pain radiating to back
- pain waking at night
- abnormal signs on examination

### *Helicobacter pylori* tests<sup>3</sup>

*Helicobacter pylori* has been proved to cause ulcers. Most DUs and about two-thirds of GUs have been attributed to *H. pylori* infection.

Non-invasive tests:

- serological—IgC antibodies (sensitivity 85–90%, specificity 90–99%); excellent for diagnosis, not for follow-up
- urea breath test (high sensitivity 97% and specificity 96%), good for follow-up
- stool antigen test (sensitivity 96%, specificity 97%)

Invasive tests:

- gastric mucosal biopsy during endoscopy can detect *H. pylori* through histology or rapid urease testing or *H. pylori* culture

### Dyspepsia in the elderly

An organic disorder is more likely in the older patient, in whom it is important to consider stomach cancer. Symptoms such as anorexia, vomiting and weight loss point to such a problem.

Other conditions causing dyspepsia that are more prevalent in this age group are:

- constipation
- mesenteric artery ischaemia
- congestive cardiac failure

### Dyspepsia in children

Dyspepsia is an uncommon problem in children but can be caused by drugs, oesophageal disorders and gastro-oesophageal reflux in particular.<sup>4</sup> Reflux can be considered to be physiological or pathological.

### § Gastro-oesophageal reflux

Regurgitation of feeds because of gastro-oesophageal reflux is a common physiological event in newborn infants. A mild degree of reflux is normal in babies, especially after they burp; this condition is called *possetting*.

### Symptoms

Milk will flow freely from the mouth soon after feeding, even after the baby has been put down for

a sleep. Sometimes the flow will be forceful and may even be out of the nose.

Despite this vomiting or regurgitation, the babies are usually comfortable and thrive. Some infants will cry, presumably because of heartburn.<sup>4</sup>

In a small number the reflux may be severe enough (pathological) to cause serious problems such as oesophagitis with haematemesis or anaemia, stricture formation, failure to thrive, apnoea and aspiration.

### Prognosis

Reflux gradually improves with time and usually ceases soon after solids are introduced into the diet. Most cases clear up completely by the age of 9 or 10 months, when the baby is sitting. Severe cases tend to persist until 18 months of age.

### Investigations

These are not necessary in most cases but in those with persistent problems or complications referral to a paediatrician is recommended. The specialist investigations include barium meal with cine scanning, oesophageal pH monitoring or endoscopy and biopsy.

### Management

Appropriate reassurance with parental education is important. It should be pointed out that changes in feeding practice and positioning will control most reflux.

The infant should be placed on the left side for sleeping with the head of the cot elevated about 20–30 degrees. The old bucket method, in which the child is placed in a bucket, is not necessary.

Smaller, more frequent feeds and thickening agents are appropriate.

### Thickening of feeds

Giving the baby thicker feeds usually helps those with more severe reflux. The old-fashioned remedy of using cornflour blended in bottles is still useful.

Bottle-fed babies (powdered milk formula):

*Carobel*: Add slightly less than 1 full scoop per bottle.

*Gaviscon*: Mix slightly less than ½ teaspoon of Infant Gaviscon Powder with 120 mL of formula in the bottle.

*Cornflour (maize based)*: Mix 1 teaspoon with each 120 mL of formula. Check with your doctor or nurse for the proper method.

*Prethickened formulas include Karicare and S26 AR*: Very simple to use but more expensive.

Breastfed babies:

*Carobel*: Add slightly less than 1 full scoop to 20 mL cool boiled water or 20 mL expressed breast milk and give just before the feed.

*Gaviscon*: Mix slightly less than ½ teaspoon of Infant Gaviscon Powder with 20 mL cool boiled water or expressed breast milk and give just after the feed.

For persistent or complicated reflux, including painful oesophagitis, specialist-monitored treatment will include the use of antacids and proton-pump inhibitors (e.g. omeprazole) or H<sub>2</sub>-receptor blocking agents (e.g. ranitidine).<sup>5</sup>

## § Gastro-oesophageal reflux disease (GORD)<sup>6,7</sup> in adults

### Clinical features

- Nausea
- Bloating and belching
- Heartburn
- Acid regurgitation, especially lying down at night
- Water brash (mouth fills with saliva)
- Nocturnal cough with possible asthma-like symptoms
- Diagnosis usually made on history
- Investigation usually not needed (reserve for alarm features as described in the red flag box and non-responsive treatment)

### Red flag pointers for upper GIT endoscopy

- Anaemia (new onset)
- Dysphagia
- Odynophagia (painful swallowing)
- Haematemesis or melaena
- Unexplained weight loss > 10%
- Vomiting
- Older age > 50 years
- Chronic NSAID use
- Severe frequent symptoms
- Family history of upper GIT or colorectal cancer
- Short history of symptoms

### Complications

- Oesophagitis ± oesophageal ulcer
- Iron-deficiency anaemia
- Oesophageal stricture

- Respiratory: chronic cough, asthma, hoarseness
- Barrett oesophagus (from prolonged reflux)

## Barrett oesophagus

- Usually a metaplastic response to prolonged reflux
- A premalignant condition (adenocarcinoma)
- Lower oesophagus lined with gastric mucosa (at least 3 cm)
- Prone to ulceration
- Needs careful management
- Consider 2 yearly endoscopies with biopsies

## Investigations<sup>6</sup>

- Endoscopy (see Red flag pointers)—perform prior to empirical therapy. Limited role—about one third negative
- Barium swallow and meal
- 24-hour ambulatory oesophageal pH monitoring

## Management of GORD<sup>6,7,8,9</sup>

### Stage 1

- Patient education/appropriate reassurance
- Consider acid suppression or neutralisation
- Attend to lifestyle:
  - reduce weight if overweight (this alone may abolish symptoms)
  - reduce or cease smoking
  - reduce or cease alcohol (especially with dinner)
  - avoid fatty foods (e.g. pastries, french fries)
  - reduce or cease coffee, tea and chocolate
  - avoid coffee and alcohol late at night
  - avoid gaseous drinks
  - leave at least 3 hours between the evening meal and retiring
  - increase fibre intake (e.g. high fibre cereals, fruit and vegetables)
  - small regular meals and snacks
  - eat slowly and chew food well
  - sleep on the left side
  - main meal at midday; light evening meal
  - avoid spicy foods and tomato products
- Drugs to avoid: anticholinergics, theophylline, calcium-channel blockers, doxycycline. Pill-induced oesophagitis occurs, especially with tetracyclines, slow-release potassium, iron sulphate, corticosteroids, NSAIDs—avoid taking dry; use ample fluids
- Elevation of head of bed or wedge pillow: if GORD occurs in bed, sleep with head of bed elevated 10–20 cm on wooden blocks or use a wedge pillow (preferable)

- Antacids (see TABLES 47.4 and 47.5): best is liquid alginate/antacid mixture e.g. Gaviscon/Mylanta plus 20 mL on demand or 1–2 hours before meals and bedtime

Table 47.4 Antacids in common use

#### Antacids

Water soluble: Calcium carbonate

Sodium:

- bicarbonate
- citrotartrate

Note: Excess is prone to cause alkalosis—apathy, mental changes, stupor, kidney dysfunction, tetany

Water insoluble:

Aluminium:

- hydroxide
- glycinate
- phosphate

Magnesium:

- alginate
- carbonate
- hydroxide
- trisilicate

#### Combination antacids

Antacid + alginic acid

Antacid + oxethazaine

Antacid + simethicone

Table 47.5 Side effects of common antacids

Aluminium hydroxide:	Constipation
Magnesium trisilicate:	Diarrhoea
Sodium bicarbonate:	Alkalosis
	Milk alkali syndrome
	Aggravation of hypertension
Calcium carbonate:	Alkalosis
	Constipation
	Milk alkali syndrome
	Hypercalcaemia

Antacids are appropriate for rapid relief of mild intermittent or occasional breakthrough symptoms but are ineffective for long-term management.

## Stage 2<sup>6</sup>

If no relief after several weeks, the following approaches are recommended by the Gastroenterological Society of Australia (GESA).<sup>6</sup>

Reduce acid secretion. Select from:

- Proton-pump inhibitor (PPI) for 4 weeks (preferred agent) 30–60 minutes before food  
lansoprazole 30 mg mane  
or  
omeprazole 20 mg mane  
or  
pantoprazole 40 mg mane  
or  
esomeprazole 20 mg mane  
or  
rabeprazole 20 mg mane
- H<sub>2</sub>-receptor antagonists (oral use for 8 weeks)  
famotidine 20 mg bd  
or  
nizatidine 150 mg bd or 300 mg nocte  
or  
ranitidine 150 mg bd pc or 300 mg nocte

Although the more traditional step-up approach of 1. Antacids → 2. H<sub>2</sub>-receptor antagonists → 3. PPI can be used, there has been a change to favour a high level (more potent) initial therapy with PPIs at standard dose (a step-down approach; see FIG. 47.1). This is based on the grounds of outcomes, speed of response and total cost.

Surgery is usually for young patients with severe reflux. The gold standard is a short loose 360-degree fundoplication.

FIGURE 47.1 The stepwise approach to the management of dyspeptic symptoms<sup>7</sup>

## § Functional (non-ulcer) dyspepsia<sup>7,10</sup>

This term applies to the 60% of patients presenting with dyspepsia in which there is discomfort on eating in the absence of demonstrable organic disease. This

can be considered in two categories (although there is overlap):

- ulcer-like dyspepsia  
or
- dysmotility-like dyspepsia

## Ulcer-like dyspepsia

Treat as for GORD. A practical approach is to commence with a 4-week trial of a PPI or an H<sub>2</sub>-receptor antagonist and cease if symptoms resolve.<sup>7</sup>

## Dysmotility-like dyspepsia

### Clinical features

- Discomfort with early sense of fullness on eating
- Nausea
- Overweight
- Emotional stress
- Poor diet (e.g. fatty foods)
- Similar lifestyle guidelines to GORD

### Management

- Treat as for GORD (stage 1).
  - Include antacids.
  - If not responsive:
    - Step 1: H<sub>2</sub>-receptor antagonists
    - Step 2: prokinetic agents
- domperidone 10 mg tds  
or  
metoclopramide 10 mg tds

## § Peptic ulcer disease<sup>10,11</sup>

### Features (general)

- Common: 10–20% incidence over a lifetime
- Point prevalence of ulcer disease: 3–5%
- DU:GU = 4:1
- DUs common in men 3:1
- Cumulative mortality of 10%
- Risk factors:
  - male sex
  - family history
  - smoking (cause and delayed healing)
  - stress
  - common in blood group O
  - NSAIDs 2–4 times increase in GU and ulcer complications
  - *H. pylori*: if absent and no NSAIDs, no ulcer
- Unproven risk factors:
  - corticosteroids
  - alcohol (except for gastric erosion)
  - diet (does reduce recurrence of PU)

- Types of ulcers:
  - lower oesophageal
  - gastric
  - stomal (postgastric surgery)
  - duodenal

### Clinical features

- Episodic burning epigastric pain related to meals (1–2 hours after)
- Relieved by food or antacids (generally)
- Dyspepsia common
- May be 'silent' in elderly on NSAIDs
- Physical examination often unhelpful

### Investigations

- Endoscopy (investigation of choice):<sup>12</sup> 92% predictive value
- Barium studies: 54% predictive value
- Serum gastrin (consider if multiple ulcers)
- *H. pylori* test: serology or urea breath test; diagnosis usually based on urease test performed at endoscopy

### Complications

- Perforation
- Bleeding → haematemesis and melaena
- Obstruction—pyloric stenosis
- Anaemia (blood loss)
- Cancer (in GU)
- Oesophageal stenosis

### Bleeding peptic ulcer

This can be treated with endoscopic haemostasis with heater probe or injection of adrenaline or both. Also IV omeprazole 80 mg bolus, then 8 mg/hr IV infusion for 3 days. Surgery is an option.

### Management of peptic ulcer disease

Aims of treatment:

- relieve symptoms
- accelerate ulcer healing
- prevent complications
- minimise risk of relapse

The treatment of a GU is similar to that for a DU except that GUs take about 2 weeks longer to heal and the increased risk of malignancy has to be considered.

### Stage 1<sup>7</sup>

General measures: (lifestyle and symptom relief)

- same principles as for GORD
- stop smoking

- avoid irritant drugs: NSAIDs, aspirin
- normal diet but avoid foods that upset
- antacids

If *H. pylori* positive—eradicate with combined therapy. Confirm eradication with a urea breath test (DU) or repeat gastroscopy (GU) and repeat if still present.<sup>8</sup>

If *H. pylori* negative—treat with full-dose PPI.

Proton-pump inhibitors (PPIs) provide more potent acid suppression and heal GUs and DUs more rapidly than H<sub>2</sub>-receptor antagonists.

- 4–8-week oral course

Use with caution in:

- the elderly
- those on drugs, especially warfarin, anticonvulsants, beta blockers
- liver disease

### Therapy to eradicate *Helicobacter pylori*<sup>13</sup>

This organism has a proven link with PU disease (both DU and benign non-drug induced GU), gastric cancer and maltoma (a gastric lymphoma) because of mucosal infection. This hypothesis is supported by a very low relapse of DU in subjects eradicated of *H. pylori*. Most infected people are asymptomatic but infection leads to a lifetime risk of peptic ulcer disease in 15–20% and of gastric cancer in up to 2%.<sup>10</sup> Twenty per cent of people have a variety of symptoms including those from gastritis and duodenitis. Treatment is based on combination triple or quadruple therapy, which can achieve a successful eradication rate of 85–90%.

### Drug treatment regimens (examples)<sup>7</sup>

First-line therapy:

PPI (e.g. omeprazole or esomeprazole 20 mg)

*plus*

clarithromycin 500 mg

*plus*

amoxicillin 1 g

All orally twice daily for 7 days and is the preferred regimen. Available as a combination pack.

*or*

PPI + clarithromycin + metronidazole 400 mg (twice daily for 7 days)—if hypersensitive to penicillin

*or*

other combinations: quadruple therapy e.g. bismuth + PPI + tetracycline + metronidazole (for failed triple combination)

*Note:* Resistance to metronidazole is common (>50%) and to clarithromycin is increasing (about 5% plus) but uncommon with tetracycline and amoxycillin.<sup>6</sup>

Maintenance anti-secretory therapy is usually unnecessary for *H. pylori* ulcers after successful eradication.<sup>7</sup>

### Surgical treatment

Indications (now uncommon) include:

- failed medical treatment after 1 year
- complications:
  - uncontrollable bleeding
  - perforation
  - pyloric stenosis
- suspicion of malignancy in GU
- recurrent ulcer after previous surgery

### NSAIDs and peptic ulcers<sup>7,14</sup>

- 1 *Ulcer identified in NSAID user:*
  - stop NSAID (if possible)
  - check smoking and alcohol use
  - try alternative anti-inflammatory analgesic:
    - paracetamol
    - COX-2 selective drug
    - enteric-coated, slow-release aspirin
    - corticosteroids intra-articular or oral
  - PPI for 4 weeks (gives best results)

*Note:* Healing time is doubled if NSAID continued.<sup>2</sup> About 90% heal within 12 weeks. Check healing by endoscopy at 12 weeks. Do *H. pylori* test.

- 2 *Prevention of ulcers in NSAID user:*<sup>14</sup> Primary prophylaxis is usually reserved for those at significantly increased risk, for example older persons (>75 years) and past history PU.

Use one of the following PPIs:

esomeprazole 20 mg daily

or

omeprazole 20 mg daily

or

pantoprazole 40 mg daily

Increased dietary fibre assists DU healing and prevention.

*Note:* Do *H. pylori* test and if present, it should be eradicated with combination therapy.

### § Autoimmune gastritis<sup>7</sup>

This is an inflammatory condition with antibodies to parietal cells and intrinsic factor. It is asymptomatic

and may lead to pernicious anaemia. Diagnosis is confirmed by histology or endoscopy. *H. pylori* is absent.

Treat with iron and vitamin B12.

### § Stomach cancer

#### Clinical features

- Male to female ratio = 3:1
- Usually asymptomatic early
- Consider if upper GIT symptoms in patients over 40 years, especially weight loss
- Recent-onset dyspepsia in middle age
- Dyspepsia unresponsive to treatment
- Vague fullness or epigastric distension
- Anorexia, nausea,  $\pm$  vomiting
- Dysphagia—a late sign
- Onset of anaemia
- Changing dyspepsia in GU
- Changing symptoms in pernicious anaemia
- *H. pylori* now implicated as a cause

Risk factors:  $\uparrow$  age, blood group A, smoking, atrophic gastritis

#### Limited physical findings

- Palpable abdominal mass (20%)
- Signs (see FIG. 47.2) in advanced cases

**DxT** malaise + anorexia + dyspepsia + weight loss  $\rightarrow$  stomach cancer

**DxT** triple loss of appetite + weight + colour  $\rightarrow$  stomach cancer

#### Investigations

- Endoscopy and biopsy is optimal test
- Barium meal—false negatives

#### Treatment

- Surgical excision: may be curative if diagnosed early but overall survival is poor

### When to refer

- Infants with persistent gastro-oesophageal reflux not responding to simple measures
- Failure to respond to stage 1 therapy for heartburn, when endoscopy is required
- Patients with persistent or recurrent ulcers
- Any patient with a PU complication, such as haemorrhage, obstruction or perforation

FIGURE 47.2 Late signs of stomach cancer

### Practice tips

- Scleroderma is a rare but important cause of oesophagitis.
- Advise patients never to 'dry swallow' medications.
- Dysphagia always warrants investigation, not observation.
- Beware of attributing anaemia to oesophagitis.
- Epigastric pain aggravated by any food, relieved by antacids = chronic GU.
- Epigastric pain before meals, relieved by food = chronic DU.

- Keep in mind the malignant potential of a GU.
- A change in the nature of symptoms with a GU suggests the possibility of malignant change.
- Avoid the long-term use of water-soluble antacids.
- Investigate the alarm symptoms—dysphagia, bleeding, anaemia, weight loss, waking at night, pain radiating to the back.

*We swallow approximately 1200 times daily, largely subconsciously. While we take the fundamental function for granted, disordered swallowing can be a devastating condition, with substantial morbidity for those affected.*

Ian Cook 1996

Dysphagia is difficulty in swallowing. It is a common problem affecting up to 22% of patients in the general practice setting.<sup>1</sup> It is usually associated with a sensation of hold-up of the swallowed bolus and is sometimes accompanied by pain.

Its origin is considered as either oropharyngeal or oesophageal. Oropharyngeal dysphagia is usually related to neuromuscular dysfunction and is commonly caused by stroke. Oesophageal dysphagia is usually due to motor disorders, such as achalasia or diffuse oesophageal spasm, and to peptic oesophageal strictures often secondary to reflux. In this type of dysphagia there is a sensation of a hold-up, which may be experienced in either the cervical or retrosternal region.<sup>1</sup> Causes are usually classified as functional, mechanical and neurological (see TABLE 48.1).

Table 48.1 Causes of dysphagia	
Functional	Examples: muscle tension, 'express swallowing'
Neurological	Examples: stroke, myasthenia, MND
Mechanical	
• luminal	Example: foreign body
• mural	Example: stricture, tumour
• extramural	Example: extrinsic compression (i.e. goitre)

Dysphagia must not be confused with globus sensation, which is the sensation of the constant 'lump in the throat' although there is no actual difficulty swallowing food. If dysphagia is progressive or prolonged then urgent attention is necessary.

There are only a few common causes of dysphagia and these are usually readily diagnosed on the history and two or three investigations. A careful history is very important, including a drug history and psychosocial factors.

## Diagnostic guidelines

- Any disease or abnormality affecting the tongue, pharynx or oesophagus can cause dysphagia.
- Patients experience a sensation of obstruction at a definite level with swallowing food or water; hence, it is convenient to subdivide dysphagia into oropharyngeal and oesophageal.
- Pain from the oropharynx is localised to the neck.
- Pain from the oesophagus is usually felt over the T2–6 area of the chest.
- Oropharyngeal causes: difficulty initiating swallowing; food sticks at the suprasternal notch level; regurgitation; aspiration.
- Oesophageal causes: food sticks to mid to lower sternal level; pain on swallowing solid foods, especially meat, potatoes and bread, and then eventually liquids.
- A pharyngeal pouch usually causes regurgitation of undigested food and gurgling may be audible over the side of the neck.
- Neurological disorders typically result in difficulty swallowing or coughing or choking due to food spillover, especially with liquids.
- Dysphagia for solids only indicates a structural lesion, such as a stricture or tumour.
- Dysphagia for liquids and solids is typical of an oesophageal motility disorder, namely achalasia.<sup>2</sup>
- GORD tends to exclude achalasia.

## Red flag pointers for dysphagia

- Age >50 years
- Recent or sudden onset
- Unexplained weight loss
- Painful swallowing
- Progressive dysphagia
- Dysphagia for solids
- Hiccoughs
- Hoarseness
- Neurological symptoms/signs

- Gastroenterologists claim that the big three common causes referred to them are benign peptic stricture, cancer and achalasia.<sup>3</sup>
- Intermittent dysphagia for both liquids and solids is characteristic of a motility disorder such as oesophageal achalasia.
- Malignant oesophageal obstruction is usually evident when there is a short history of rapidly progressive dysphagia and significant weight loss.<sup>4</sup>

A summary of the diagnostic strategy model is presented in **TABLE 48.2**.

## Examination

It is worthwhile focusing on the following features:

- general examination including hands and skin ? scleroderma
- assess nutritional status including BMI
- mouth, pharynx, larynx (look for paralysis) ? dentition
- neck, especially for lymph nodes and thyroid
- neurological, especially cranial nerve function and muscle weakness disorders or evidence of stroke
- special oesophageal obstruction test:
  - hand the patient a glass of water and place a stethoscope over the left upper quadrant of abdomen
  - measure time between swallowing and murmur produced by bolus passing the cardia (normal: 7–10 seconds)
- assess aspiration risk e.g. through having a sip of water<sup>1</sup>

## Investigations

- Full blood examination: ? anaemia
- Neurological cause: oesophageal motility study (manometry)
- Mechanical:
  - extrinsic compression (e.g. barium swallow, CT scan, chest X-ray)
  - intrinsic (e.g. endoscopy ± barium swallow)
  - PET scan: good for identifying oesophageal cancer and gastro-oesophageal function

The primary investigation in suspected pharyngeal dysphagia is a video barium swallow<sup>5</sup> while endoscopy is generally the first investigation in cases of suspected oesophageal dysphagia. Barium swallow should precede endoscopy in the latter when there is a suspected oesophageal 'ring' and suspected

**Table 48.2** Dysphagia: diagnostic strategy model (excluding oropharyngeal infections and strokes)

Q.	Probability diagnosis
A.	Functional (e.g. 'express' swallowing, psychogenic) Tablet-induced irritation Pharyngotonsillitis Reflux oesophagitis
Q.	Serious disorders not to be missed
A.	Neoplasia: <ul style="list-style-type: none"> <li>• cancer of the pharynx, oesophagus, stomach</li> <li>• extrinsic tumour</li> </ul> AIDS (opportunistic oesophageal infection) Stricture, usually benign peptic stricture Scleroderma Neurological causes: <ul style="list-style-type: none"> <li>• pseudobulbar palsy</li> <li>• multiple sclerosis/myasthenia gravis</li> <li>• motor neurone disease (amyotrophic sclerosis)</li> <li>• Parkinson disease</li> </ul>
Q.	Pitfalls (often missed)
A.	Foreign body Drugs (e.g. phenothiazines, bisphosphonates) Subacute thyroiditis Extrinsic lesions (e.g. lymph nodes, goitre) Upper oesophageal web (e.g. Plummer–Vinson syndrome) Eosinophilic oesophagitis Oesophageal candidiasis Radiotherapy Achalasia Upper oesophageal spasm (mimics angina) <i>Rarities (some):</i> <ul style="list-style-type: none"> <li>• Sjögren syndrome</li> <li>• aortic aneurysm</li> <li>• aberrant right subclavian artery</li> <li>• lead poisoning</li> <li>• cervical osteoarthritis (large osteophytes)</li> <li>• other neurological causes</li> <li>• other mechanical causes</li> </ul>
Q.	Seven masquerades checklist
A.	Depression Drugs Thyroid disorder
Q.	Is this patient trying to tell me something?
A.	Yes. Could be functional ? globus sensation.

oesophageal dysmotility. If endoscopy and radiology are negative, consider oesophageal motility studies to look specifically for achalasia or other less common motility disorders.

## SPECIFIC CONDITIONS

### § Benign peptic stricture

- Fibrous stricture of lower third oesophagus (can be higher)
- Follows years of reflux oesophagitis
- Usually older patients
- Dysphagia with solid food
- Diagnosis confirmed by endoscopy and barium swallow

#### Treatment

- Dilate the stricture
- Treat reflux vigorously

### § Oesophageal cancer

- Dysphagia at beginning of meal
- Dysphagia for solid food steadily progressive over weeks
- Can remain silent and tends to be invasive when diagnosed
- Hiccoughs may be an early sign
- Hoarseness and cough (upper third)
- Discomfort or pain—throat, retrosternal, interscapular
- Weight loss can be striking
- Associations: GORD, tobacco, Barrett oesophagus
- Diagnosis confirmed by barium swallow and endoscopy
- Both SCC (commonest) and adenocarcinoma
- Adenocarcinoma associated with Barrett mucosa
- Treatment is usually palliative surgery

**DxT** fatigue + progressive dysphagia + weight loss → oesophageal cancer

### § Achalasia

- A disorder of oesophageal motility
- Widely dilated oesophagus
- Empties poorly through a smoothly tapered lower end
- Gradual onset of dysphagia for both liquids and solids
- Fluctuating symptoms
- Diagnosis confirmed by barium swallow or manometry
- Manometry is the only way to diagnose with certainty<sup>1</sup>

#### Treatment

- Conservative in the elderly (e.g. nifedipine/or endoscopic botulinum toxin injection into the sphincter)<sup>6</sup>
- Pneumatic dilatation of lower oesophageal sphincter or surgical myotomy

*Note:* Prokinetic drugs have no place in treatment.

### § Drug-induced oesophageal ulceration<sup>3</sup>

- Tetracycline, especially doxycycline, can cause painful ulceration in all age groups.
- Delayed passage of some drugs (due to pre-existing disorders) can cause local ulceration, even perforation (especially in elderly) (e.g. iron tablets, slow-release potassium, aspirin, NSAIDs, bisphosphonates, zidovudine, antibiotics).
- The elderly are prone to the problem if they ingest drugs upon retiring to bed with insufficient liquid washdown.

### § Globus sensation (cricopharyngeal spasm)

Also referred to as 'globus hystericus' or 'lump in the throat', it is the subjective sensation of a lump in the throat. It appears to be associated with psychological stress (e.g. unresolved hurt, grief, non-achievement). Suppression of sadness is most often implicated.<sup>6</sup> No specific aetiology or physiological mechanism has been established. The symptom can be associated with GORD, from frequent swallowing or emotionally based dry throat.

#### Clinical features

- Sensation of being 'choked up' or 'something stuck' or lump—a very real sensation
- Not affected by swallowing
- Eating and drinking may provide relief
- Normal investigations

#### Approach to patient

- Careful history and examination
- Exclude organic cause (refer TABLE 48.2)
- May require investigations if doubtful diagnosis

#### Management

- Usually settles with education, reassuring support and time (up to several months)
- Avoid swallowing very hot drinks
- No drug of proven value
- Treat any underlying psychological disorder

## § Odynophagia

Pain on swallowing is basically caused by irritation of an inflamed or ulcerated (in particular) mucosa by the swallowed food bolus.

Important causes include:

- GORD (the commonest cause) with associated oesophagitis
- oesophageal spasm
- oesophageal candidiasis, especially in the immunosuppressed
- herpes simplex oesophagitis, also in the immunosuppressed
- cytomegalovirus oesophagitis, in the immunosuppressed
- pill-induced oesophagitis/ulceration
- oesophageal cancer
- achalasia

## § Eosinophilic oesophagitis<sup>7,8</sup>

Eosinophilic oesophagitis is increasingly being recognised as a cause of dysphagia, gastro-oesophageal reflux and acute food bolus obstruction in both children (particularly) and adults. It may present as infant colic.<sup>8</sup> It should be considered in those who regularly experience food getting stuck in their throat. It is associated with allergic disorders such as hay fever, cow's milk allergy and asthma. The IgE is elevated. Refer to gastroscopy, which may show eosinophilic infiltrates in the oesophagus on mucosal biopsies. However, symptoms usually resolve within 72 hours of eliminating the offending food. A six-food elimination diet (cow's milk protein, wheat, soy, eggs, seafood and peanuts) has been shown to reduce symptoms in up to 90%.<sup>1</sup> Treatment of the acute attack includes IM buscopan and a swallowed topical corticosteroid aerosol e.g. fluticasone twice daily for 8 weeks.<sup>9</sup>

### Practice tips

- Although dysphagia is a common psychogenic symptom it must always be taken seriously and investigated.
- Mechanical dysphagia represents cancer until proved otherwise.

- Progressive dysphagia and weight loss in an elderly patient is oesophageal cancer until proved otherwise.
- Oesophageal cancer usually causes pain, wasting and regurgitation.
- Globus sensation or hystericus, an anxiety disorder, should not be confused with dysphagia. It is the subjective sensation of a lump or mass in the throat. Usually seen in young women.
- Cancer-induced achalasia occurs with tumours at the gastro-oesophageal junction usually due to adenocarcinoma of the stomach.
- Severe oesophageal reflux predisposes to adenocarcinoma.
- Oesophageal strictures can be benign, usually secondary to chronic reflux oesophagitis, or due to malignancy.
- Be careful of a change of symptoms in the presence of long-standing reflux. Consider stricture or cancer.
- A prominent hard lymph node in the left supraclavicular fossa (Troisier sign) is suggestive of cancer of the stomach.
- Dysphagia can be caused by a tight fundoplication and can be diagnosed by manometry or barium swallow.<sup>1</sup>

Dyspnoea is the subjective sensation of breathlessness that is excessive for any given level of physical activity. It is a cardinal symptom affecting the cardiopulmonary system and can be very difficult to evaluate. Appropriate breathlessness following activities such as running to catch a bus or climbing several flights of stairs is not abnormal but may be excessive due to obesity or lack of fitness.

The New York Heart Association functional and therapeutic classification applied to dyspnoea is:

- Grade 1 No breathlessness
- Grade 2 Breathlessness on severe exertion
- Grade 3 Breathlessness on mild exertion
- Grade 4 Breathlessness at rest

## Key facts and checkpoints

- Determination of the underlying cause of dyspnoea in a given patient is absolutely essential for effective management.
- The main causes of dyspnoea are lung disease, heart disease, obesity and functional hyperventilation.<sup>1</sup>
- The most common cause of dyspnoea encountered in family practice is airflow obstruction, which is the basic abnormality seen in chronic asthma and chronic obstructive pulmonary disease (COPD).<sup>2</sup>
- Wheezing, which is a continuous musical or whistling noise, is an indication of airflow obstruction.
- Some patients with asthma do not wheeze and some patients who wheeze do not have asthma.
- Other important pulmonary causes include restrictive disease, such as fibrosis, collapse and pleural effusion.
- Dyspnoea is not inevitable in lung cancer but occurs in about 60% of cases.<sup>3</sup>
- Normal respiratory rate is 12–16 breaths/minute.

## Terminology

It is important to emphasise that dyspnoea or breathlessness is a subjective sensation of the desire for increased respiratory effort and must be considered in relation to the patient's lifestyle and individual tolerance of discomfort. It also depends on the age, physical fitness and physical expectations of the person. Patients may complain of tightness in the chest and this must be differentiated from angina.

## Glossary of terms

- Hyperpnoea** An increased level of ventilation (e.g. during exertion).
- Hyperventilation** Overbreathing.
- Orthopnoea** Breathlessness lying down flat.
- Paroxysmal nocturnal dyspnoea** Inappropriate breathlessness causing waking from sleep.
- Tachypnoea** An increased rate of breathing.

## Difference between heart and lung causes

The distinguishing features between dyspnoea due to heart disease and to lung disease are presented in TABLE 49.1.

The history is a good indication and a useful guideline is that dyspnoea at rest is typical of lung disease, especially asthma, while it tends to be present on effort with heart disease as well as with COPD.

## Wheezing

Wheezing is any continuous musical expiratory noise heard with the stethoscope or otherwise. Wheeze includes stridor, which is an inspiratory wheeze.

## Common causes of wheezing

Localised:

- partial bronchial obstruction:
  - impacted foreign body
  - impacted mucus plugs
  - extrinsic compression

**Table 49.1** Comparison of distinguishing features between dyspnoea due to heart disease and lung disease

Lung disease	Heart disease
History of respiratory disease	History of hypertension, cardiac ischaemia or valvular heart disease
Slow development	Rapid development
Present at rest	Mainly on exertion
Productive cough common	Cough uncommon and then 'dry'
Aggravated by respiratory infection	Usually unaffected by respiratory infection

Source: After Sandler<sup>1</sup>

Generalised:

- asthma
- obstructive bronchitis
- bronchiolitis

## 'Cardiac asthma' and bronchial asthma

The term 'cardiac asthma' is used to describe a wheezing sensation such as that experienced with paroxysmal nocturnal dyspnoea. Differentiating features are presented in **TABLE 49.2**.

## Is it asthma or COPD?

This question is often asked, especially in the middle-aged or elderly person with dyspnoea. Differentiating features are presented in **TABLE 49.3**.

**Table 49.2** Comparison of distinguishing features between 'cardiac asthma' and bronchial asthma

	Cardiac	Bronchial
<b>Dyspnoea</b>	Mainly inspiratory	Mainly expiratory
<b>Cough</b>	Follows dyspnoea	Precedes dyspnoea
<b>Sputum</b>	Pink and frothy	Thick and gelatinous
<b>Relief</b>	Standing up (by an open window) Intravenous diuretic/CPAP, morphine	Coughing up sputum Bronchodilator
<b>Lung signs</b>	Mainly crackles	Mainly wheezes

Source: After Sandler<sup>1</sup>

**Table 49.3** Comparison of asthma and COPD

	Asthma	COPD
<b>Symptoms &lt;35 years</b>	Common	Unusual
<b>Smoking history</b>	Possible	Invariable
<b>Chronic cough</b>	Uncommon	Common
<b>Dyspnoea</b>	Diurnal and variable	Constant and progressive
<b>Response to inhaled bronchodilator</b>	Good	Poor
<b>Nocturnal waking with symptoms</b>	Common	Uncommon
<b>Airflow obstruction</b>	Reversible	Non-reversible

## A diagnostic approach

A summary of the diagnostic strategy model is presented in **TABLE 49.4**.

**Table 49.4** Dyspnoea: diagnostic strategy model

- Q. Probability diagnosis
- A. Bronchial asthma  
Bronchiolitis (children)  
COPD  
Ageing; lack of fitness  
Left heart failure  
Obesity
- Q. Serious disorders not to be missed
- A. Cardiovascular:
- acute heart failure (e.g. AMI)
  - arrhythmia
  - pulmonary embolism
  - fat embolism
  - pulmonary hypertension
  - dissecting aneurysm
  - cardiomyopathy
  - pericardial tamponade
  - anaphylaxis
- Neoplasia:
- bronchial carcinoma, other malignancy
- Severe infections:
- SARS
  - avian influenza
  - pneumonia
  - acute epiglottitis (children)

Respiratory disorders:

- inhaled foreign body
- upper airways obstruction
- pneumothorax
- atelectasis
- pleural effusion
- tuberculosis
- Acute respiratory distress syndrome

Neuromuscular disease:

- infective polyneuritis
- poliomyelitis

---

Q. Pitfalls (often missed)

A. Interstitial lung disease

- idiopathic pulmonary fibrosis
- extrinsic allergic alveolitis
- sarcoidosis

Chemical pneumonitis

Metabolic acidosis

Radiotherapy

Kidney failure (uraemia)

Multiple small pulmonary emboli

---

Q. Seven masquerades checklist

A. Depression

Diabetes

Drugs

Anaemia

Thyroid disorder (thyrotoxicosis)

Spinal dysfunction (ankylosing spondylitis)

---

Q. Is the patient trying to tell me something?

A. Consider functional hyperventilation (anxiety and panic attacks).

---

## Probability diagnosis

The common causes of dyspnoea are lung disease, heart disease, obesity, anaemia (tissue hypoxia) and functional hyperventilation. More specifically, bronchial asthma, COPD, acute pulmonary infections and left heart failure (often insidious) are common individual causes.

## Serious disorders not to be missed

Severe cardiovascular events such as acute heart failure, which may be precipitated by myocardial infarction (may be silent, especially in diabetics), a life-threatening arrhythmia, pulmonary embolism, dissecting aneurysm or a cardiomyopathy (such as viral myocarditis) require early diagnosis and corrective action. Recurrent pulmonary embolism may present a diagnostic problem. There may be a history of deep venous thrombosis, pregnancy, malignancy or taking the contraceptive pill.<sup>4</sup>

Severe infections such as lobar pneumonia, tuberculosis and myocarditis must be considered. In children acute epiglottitis, croup, bronchiolitis, pneumonia and bronchitis are serious infections responsible for respiratory distress.

Primary carcinoma is an important consideration, especially in dyspnoea of gradual onset. Other malignant conditions to consider are metastases, lymphangitis carcinomatosa, lymphomas and pleural mesothelioma. Pleural effusion may be the mode of presentation of some of these serious disorders.

## Pitfalls

Interstitial pulmonary disease can be a diagnostic dilemma because the physical signs and X-ray appearances can be minimal in the early stages despite the presence of significant dyspnoea. Allergic alveolitis, such as that caused by birds (e.g. hypersensitivity to their droppings) can be a pitfall. The diagnosis is easier if a known disease associated with pulmonary infiltration, such as sarcoidosis, is present. Measuring the diffusing capacity will help with diagnosis.

Pericardial tamponade may cause difficulty in diagnosis either with an acute onset, such as malignancy involving pericardium or insidiously. The patient usually has a weak pulse with pulsus paradoxus, hypotension and a raised jugular venous pressure.

It is important to be careful not to attribute dyspnoea simply to obesity or lack of fitness when it could have a true organic disorder such as heart failure.

## Seven masquerades checklist

Most of the masquerades have to be considered as underlying causes. Depression can be associated with dyspnoea, anaemia is an important cause of dyspnoea, thyrotoxicosis can rarely present with dyspnoea, and diabetic ketoacidosis can cause rapid deep breathing.

Drugs must also be considered, especially as a cause of interstitial pulmonary fibrosis that presents with dyspnoea, cough and fever. Drugs that cause this disorder include several cytotoxic agents (especially bleomycin, cyclophosphamide, methotrexate), amiodarone, sulphasalazine, penicillamine, nitrofurantoin, gold salts and adrenergic nasal sprays.<sup>3</sup> Poisons that may cause hyperventilation are salicylate, methyl alcohol, theophylline overdose and ethylene glycol. Anaemia must be considered especially in those at risk. Dyspnoea is unlikely to be caused solely by chronic anaemia unless the haemoglobin level is less than 8 g/dL.<sup>4</sup> It is more likely to occur if another predisposing cause, such as ischaemic heart disease, is present.

## Red flag pointers for dyspnoea

History	Examination
Sudden onset	Pallor/cyanosis
Ischaemic heart disease	Dyspnoea at rest
Migrant: Africa, Asia	Fever
Recent travel	Hypotension
Asthma/allergy	Tachycardia
Unexplained weight loss	Tachypnoea
Significant trauma	Chest wall signs
HIV	Altered conscious state
Drugs: social, biologicals	Elevated JVP
	Wheezing

## Psychogenic considerations

Functional dyspnoea or hyperventilation is common. However, it is important to exclude organic causation such as asthma, drugs and thyrotoxicosis before settling with the psychogenic label and to reassure the patient strongly if there is no organic cause. Any uncomfortable sensation in the chest may be interpreted as dyspnoea by anxious patients. Depression, anxiety and panic attacks may be underlying the problem. Characteristic associated features of hyperventilation with anxiety include dizziness, faintness, palpitations, yawning, paraesthesia of the hands and legs, inability to take a deep breath or a sensation of smothering. These patients may exhibit sighing and irregular breathing on examination. In true psychogenic dyspnoea, chest X-rays and pulmonary function tests are normal but symptoms are often reproduced after 15–30 seconds of voluntary hyperventilation. It is important to remember that it may be present in a patient who has organic disease of a mild degree such as asthma.

## The clinical approach

### History

Special attention should be paid to evaluating exactly what the patient means by breathlessness or restriction of breathing. The analysis should then include provoking factors and associated symptoms with a view to differentiating between pulmonary causes such as asthma and COPD. Wheeze is often (but not always) present in asthma and chronic airflow obstruction. Most respiratory causes of dyspnoea also produce cough. The rate of

development of dyspnoea gives an indication of the possible cause (see TABLE 49.5).<sup>5</sup> The sudden onset of dyspnoea at rest is suggestive of pulmonary embolism or pneumothorax. Severe dyspnoea developing over 1 or 2 hours is most likely due to left heart failure or bronchial asthma. Bronchial asthma is usually easily distinguished from left heart failure by the history

**Table 49.5** Typical causes of dyspnoea related to time of onset

Sudden
Lung collapse
Inhaled foreign body/other choking
Spontaneous pneumothorax
Arrhythmia
Anaphylaxis
Myocardial infarction
Pulmonary embolism
Rapid (over a few hours)
Asthma
Hyperventilation (can be sudden)
Acute exacerbations of COPD
Pneumonia
Diabetic ketoacidosis
Extrinsic allergic alveolitis
High altitude
Left heart failure (acute pulmonary oedema)
Pericardial tamponade
Poisons
Over days or weeks
Congestive heart failure
Pleural effusion
Carcinoma of the bronchus/trachea
Over months or years
COPD
Tuberculosis
Fibrosing alveolitis
Pneumoconiosis
Non-respiratory causes
Anaemia
Hyperthyroidism
Obesity

of previous attacks, by the absence of chest pain and the absence of cardiac murmurs. 'My breathing feels tight' indicates asthma. A complaint of 'suffocation or feeling smothered' or 'just not getting enough air' may be a pointer to functional dyspnoea.

The dyspnoea of asthma tends to occur at rest and at night, while that with chronic airflow obstruction occurs with exertion.

## Examination

The routine findings from inspection, percussion and auscultation will determine whether the underlying lung disease is localised or generalised. The generalised findings for various disorders of the lungs are summarised in **TABLE 49.6**.

Careful inspection is mandatory. The patient should be stripped to the waist and observed for

factors such as cyanosis, clubbing, mental alertness, dyspnoea at rest, use of accessory muscles, rib retraction and any other abnormalities of the chest wall. A coarse tremor or flap of the outstretched hands indicates carbon dioxide intoxication.<sup>6</sup> To obtain maximum value from auscultation, request the patient to open his or her mouth and take deep breaths. Adventitious sounds that are not audible during tidal breathing may then be heard. Wheezes are high-pitched continuous sounds heard either in expiration or inspiration, being more pronounced in expiration.

Crackles are short interrupted sounds heard mainly at the end of inspiration, resembling the crackling sound of hair being rubbed between the fingers near the ear. Fine crackles, previously referred to as crepitations, occur typically in lobar pneumonia

**Table 49.6** Comparison of examination findings for various lung disorders

	Trachea	Chest wall movement	Percussion note	Breath sounds	Vocal fremitus	Adventitious sounds
<b>Normal</b>	Midline	Equal expansion	Resonant	Vesicular	Normal	Nil: $\pm$ few transient inspiratory basal crackles
<b>Asthma</b>	Midline	Decreased (bilateral)	Resonant	Vesicular—prolonged expiration	Normal or decreased	Expiratory wheezes
<b>Emphysema</b>	Midline	Decreased (bilateral)	Resonant to hyper-resonant	Vesicular—decreased	Decreased	Nil or the crackles and wheezes of chronic bronchitis
<b>Consolidation (e.g. lobar pneumonia)</b>	Midline	Decreased on affected side	Dull	Bronchial	Increased	Fine late inspiratory crackles
<b>Collapse: major bronchus</b>	Towards affected side	Decreased (unilateral)	Dull	Absent or decreased	Absent or decreased	Nil
<b>Collapse: peripheral bronchus</b>	Towards affected side	Decreased (unilateral)	Dull	Bronchial	Increased	Coarse crackles
<b>Pleural effusion (&gt;500 mL)</b>	Towards opposite side (if massive)	Decreased (unilateral)	Stony dull	Absent or decreased	Absent or decreased	None
<b>Pneumothorax (large)</b>	Towards opposite side (if tension)	Decreased (unilateral)	Hyper-resonant	Absent or decreased	Absent or decreased	None
<b>Fibrosis (generalised)</b>	Midline	Decreased (bilateral)	Normal	Vesicular	Increased	Fine crackles
<b>Bronchiectasis</b>	Midline	Slight decrease	Resonant to dull	Bronchial	Normal or decreased	Coarse crackles $\pm$ localised wheeze

and diffuse interstitial fibrosis, and are not cleared by coughing. Medium crackles are typical of congestive cardiac failure, and coarse crackles indicate airway mucus and usually clear on coughing.

### Causes of pulmonary crackles

- Left ventricular failure
- Idiopathic pulmonary fibrosis
- Extrinsic allergic alveolitis
- Pneumonia
- Bronchiectasis
- Chronic bronchitis
- Asbestosis
- Pulmonary fibrosis

### Investigations

The two most important initial investigations for respiratory disease are chest X-ray and pulmonary function tests.

### Pulmonary function tests (PFTs)

These relatively simple tests provide considerable information.

#### Peak expiratory flow rate

The most practical instrument for office use to detect chronic airway obstruction due to asthma or chronic bronchitis is the mini peak flow meter, which measures peak expiratory flow rate (PEFR).

The interpretation of the tests, which vary according to sex, age and height, requires charts of predicted normal values. A chart for PEFR in normal adult subjects is presented in Appendix V. The value for a particular patient should be the best of three results.

### Spirometry

Spirometry is the gold standard test. The measurement of the forced vital capacity (FVC) and the forced expiratory volume in one second ( $FEV_1$ ) provide a very useful guide to the type of ventilatory deficit. Both the FVC and the  $FEV_1$  are related to sex, age and height.

The  $FEV_1$  expressed as a percentage of the FVC is an excellent measure of airflow limitation. In normal subjects it is approximately 70%. A normal spirometry pattern is shown in **FIGURE 49.1** and abnormal patterns in **FIGURE 49.2**. **FIGURE 49.3** summarises the relative values for these conditions.

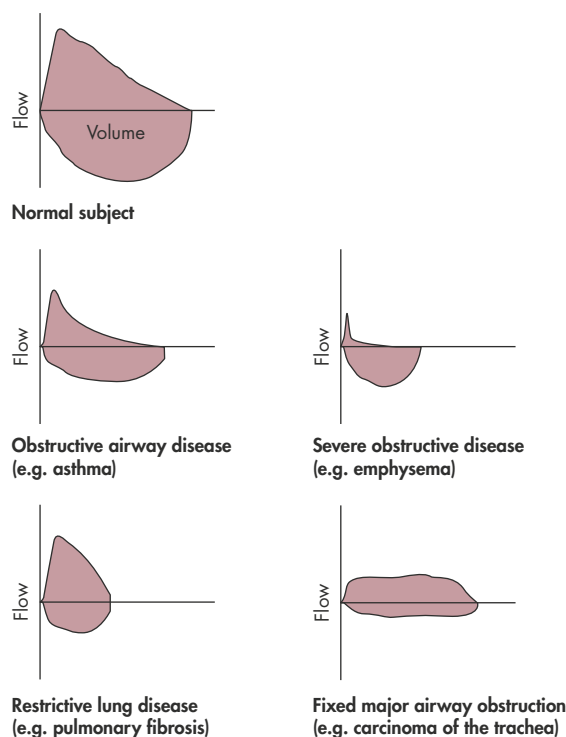

#### Lung volume

Tidal volume (TV) and vital capacity (VC) can be measured by a simple spirometer but the total lung

**FIGURE 49.1** Spirometry patterns showing normal flow volume loop.

Source: Reprinted with permission

**FIGURE 49.2** Maximum expiratory and inspiratory flow volume curves with examples of relative changes of patterns.

FIGURE 49.3 Spirograms

capacity and the residual volume are measured by the helium dilution method in a respiratory laboratory.

### Diffusing capacity (gas transfer factor)

This test measures the carbon monoxide uptake by a single breath analysis for whole lungs. In normal lungs the transfer factor is a true measure of the diffusing capacity of the lungs for oxygen and depends on the thickness of the alveolar-capillary membrane.<sup>5</sup> Gas transfer is usually reduced in patients with severe degrees of emphysema and fibrosis, anaemia and congestive cardiac failure.

### Pulse oximetry

The outstanding monitoring aid, transcutaneous pulse oximetry, estimates oxygen saturation ( $\text{SpO}_2$ ) of capillary blood. The estimates are generally very accurate and correlate to within 5% of measured arterial  $\text{O}_2$  saturation ( $\text{SaO}_2$ ).<sup>7</sup> The ideal level is 97–100%; median levels—neonates 97%, children 98%, adults 98%.

### Histamine challenge test

This test indicates the presence of airway or bronchial hyper-reactivity, which is a fundamental feature with asthma. The test should not be performed on those with poor lung function and only performed by a respiratory technician under medical supervision. The test is potentially dangerous.

### Other investigations (to select from)

- Haemoglobin, red cell indices and PCV
- White blood cell count (e.g. eosinophilia of asthma)

- ESR/CRP
- Arterial blood gas analysis
- Cardiological investigations:
  - ECG, including exercise
  - echocardiography (technically difficult in emphysema)
  - nuclear gated blood pool scan to assess heart function
  - cardiac enzymes
- Other medical imaging:
  - high-resolution CT
  - MRI
  - ventilation and perfusion radionuclide scan (pulmonary embolism)
- Bronchoscopy, especially fibre-optic bronchoscopy
- Thoracentesis and pleural biopsy
- Open lung biopsy
- Alpha<sub>1</sub>-antitrypsin measurement (normal range 1.1–2.2 g/L)

## Pleural effusion

### Key points

- Normal pleural space has 10–20 mL fluid
- Can be detected on X-ray if >300 mL fluid in pleural space
- Can be detected clinically if >500 mL fluid
- Can be subpulmonary—simulates a raised diaphragm
- May be asymptomatic
- Dyspnoea common with large effusion
- Chest pain in setting of pleuritis, infection or trauma
- Signs: refer TABLE 49.6
- The fluid may be transudate or exudate (diagnosed by aspirate)
- If blood stained—malignancy, pulmonary infarction, TB

### Transudate

Protein content <30 g/L; lactic dehydrogenase <200 IU/L.

### Causes

- Heart failure (90% of cases)
- Hypoproteinaemia, e.g. nephrotic syndrome
- Liver failure with ascites
- Constrictive pericarditis
- Hypothyroidism
- Ovarian tumour—right-sided effusion (Meigs syndrome)

## Exudate

Protein content >30 g/L; lactic dehydrogenase >200 IU/L

## Causes

- Infection—bacterial pneumonia, pleurisy, empyema, TB, viral
- Malignancy—bronchial carcinoma, mesothelioma, metastatic
- Pulmonary infarction
- Connective tissue diseases (e.g. SLE, RA)
- Acute pancreatitis
- Lymphoma
- Sarcoidosis
- HIV with parasitic pneumonia

## Management

Aspiration if symptomatic: may require repeats and pleurodesis. Treat the underlying cause.

## Dyspnoea in children

There are numerous causes of dyspnoea in children but the common causes are asthma, bronchiolitis and pulmonary infections. The important infections that can be fatal—croup, epiglottitis and myocarditis—must be kept in mind and intensively managed.

Bronchiolitis is an important cause of respiratory distress in infants under 6–12 months. It should not be confused with asthma (refer to [CHAPTER 96](#)).

Sudden breathlessness or stridor may be due to an inhaled foreign body. Signs of lobar collapse may be present but physical examination may be of little help and a chest X-ray is essential.

Cardiovascular disorders, including congenital heart disease, can cause dyspnoea. Extra respiratory causes include anaemia, acidosis, aspiration, poisoning and hyperventilation.

## Dyspnoea in the elderly

Dyspnoea in the elderly is common and is caused usually by heart failure and COPD. The other associations with ageing, such as lung cancer, pulmonary fibrosis and drugs, are relevant. The classic problem of the aged is acute heart failure that develops typically in the early morning hours. The acute brain syndrome is a common presentation of all these disorders.

## Respiratory disease in the elderly

The respiratory system, like most other bodily systems, matures until about the age of 25 years and subsequently slowly loses efficiency due to a variety

of factors such as disease, smoking, pollution and ageing. There is a decline in lung function and gas exchange and decreased ventilatory responses to hypoxia and hypercapnia.

## § Heart failure

Heart failure occurs when the heart is unable to maintain sufficient cardiac output to meet the demands of the body. Dyspnoea is a common early symptom as pulmonary congestion causes hypoxia (increased ventilation) and decreased compliance (increased work). The incidence of congestive cardiac failure (CCF) has been increasing steeply, partly due to the ageing population.

## Symptoms

- Increasing dyspnoea progressing to (in order):
  - fatigue, especially exertional fatigue
  - paroxysmal nocturnal dyspnoea
  - weight change: gain or loss

It is convenient to divide heart failure into left and right heart failure but they rarely occur in isolation and often occur simultaneously. Right failure is invariably secondary to left failure. Furthermore, some cardiologists stress the importance of differentiating between systolic and diastolic dysfunction. Both present in the same way clinically and hence referral for cardiac studies to obtain measurement of the left ventricular function is required. This permits an accurate diagnosis and guide to treatment and an accurate prognosis.

Refer to Chronic heart failure ([CHAPTER 88](#)).

## § Chronic obstructive pulmonary disease

Chronic bronchitis and emphysema should be considered together as both these conditions usually coexist to some degree in each patient. An alternative, and preferable, term—chronic obstructive pulmonary disease (COPD)—is used to cover chronic bronchitis and emphysema with chronic airflow limitation.<sup>6</sup>

For more detail on the management of COPD refer to [CHAPTER 83](#).

## INTERSTITIAL LUNG DISEASES

Interstitial lung diseases comprise a group of disorders that have the common features of inflammation (pneumonitis) and fibrosis of the interalveolar septum, representing a non-specific reaction of the lung to injury of various causes.<sup>8</sup>

In many there is a hypersensitivity reaction to various unusual antigens. The fibrosis may be localised as following unresolved pneumonia, bilateral as with tuberculosis or widespread.

Consider possibility of fibrosis of lungs in chronic dyspnoea and a dry cough with normal resonance.

Causes of widespread interstitial pulmonary fibrosis include:

- sarcoidosis
- idiopathic pulmonary fibrosis
- extrinsic allergic alveolitis (hypersensitivity pneumonitis)
- drug-induced
- lymphangitis carcinomatosa
- various occupational lung disorders
- rheumatoid arthritis
- acute pulmonary oedema
- immunological (e.g. connective tissue disorders, vasculitis)

Common clinical features:

- dyspnoea and dry cough (insidious onset)
- fine inspiratory crackles at lung base with faint breath sounds
- cyanosis and finger clubbing may be present
- PFTs:
  - restrictive ventilatory deficit
  - decrease in gas transfer factor
- characteristic X-ray changes

High-resolution CT scanning has been a major advance in diagnosis. May show 'honeycomb lung'.

## Sarcoidosis

Sarcoidosis is a multisystemic disorder of unknown aetiology which is characterised by non-caseating granulomatous inflammation that involves the lung in about 90% of affected patients. A characteristic feature is bilateral hilar lymphadenopathy, which is often symptomless and detected on routine chest X-ray (CXR). Radiological lung involvement can

be associated with or occur independently of hilar lymphadenopathy.

## Clinical features<sup>8,9</sup>

- May be asymptomatic (one-third)
- Onset usually third or fourth decade (but any age)
- Bilateral hilar lymphadenopathy (on CXR)
- Cough
- Fever, malaise, arthralgia
- Erythema nodosum
- Ocular lesions (e.g. anterior uveitis)
- Other multiple organ lesions (uncommon)
- Overall mortality 2–5%

Erythema nodosum with an acute swinging fever, malaise and arthralgia in a young adult female is diagnostic of sarcoidosis.

## Diagnosis

Histological evidence from biopsy specimen, usually transbronchial biopsy (essential if an alternative diagnosis, e.g. lymphoma, cannot be excluded) or skin biopsy in cases of erythema nodosum. A better modern diagnostic method is biopsy via video-assisted thoracoscopy.

Supporting evidence:

- elevated serum ACE (non-specific)
- PFTs: restrictive pattern; impaired gas transfer in advanced cases
- $\pm$ ve Kveim test (not recommended these days)
- serum calcium

## Treatment

Sarcoidosis may resolve spontaneously (hilar lymphadenopathy without lung involvement does not require treatment).

Indications for treatment with corticosteroids:

- no spontaneous improvement or worsening after 3–6 months
- symptomatic pulmonary lesions
- eye, CNS and other systems involvement

## Glossary of terms

**Chronic airflow limitation** A physiological process measured as impairment of forced expiratory flow which is the major cause of dyspnoea in these patients.

**Chronic bronchitis** A clinical condition characterised by a productive cough on most days for at least 3 months of the year for at least 2 consecutive years in the absence of any other respiratory disease that could be responsible for such excessive sputum production (such as tuberculosis or bronchiectasis).

**COPD** A chronic, slowly progressive disorder characterised by the presence of airway obstruction which may (or may not) be partially reversible by bronchodilator therapy.<sup>8</sup>

**Emphysema** This is defined in pathological rather than clinical terms, as permanent dilatation and destruction of lung tissue distal to the terminal bronchioles.

- hypercalcaemia, hypercalciuria
- erythema nodosum with arthralgia
- persistent cough

### Corticosteroid treatment<sup>9</sup>

- Prednisolone 20–40 mg (o) daily for 6–8 weeks, then reduce to lowest dose that maintains improvement.<sup>9</sup> If there is no response, taper the dose to zero. If there is a response, taper the dose to 10–15 mg (o) daily as a maintenance dose for 6–12 months.<sup>9</sup>
- Prednisolone 20–30 mg for 2 weeks for erythema nodosum of sarcoidosis.

### § Idiopathic pulmonary fibrosis

Idiopathic pulmonary fibrosis, also known as idiopathic fibrosing interstitial pneumonia and cryptogenic fibrosing alveolitis, is the most common diagnosis among patients presenting with interstitial lung disease.

Patients usually present in the fifth to seventh decade with the clinical features as outlined under interstitial lung diseases such as slowly progressive dyspnoea over months to years. Chest X-ray abnormalities are variable but include bilateral diffuse nodular or reticulonodular shadowing favouring the lung bases. High-resolution CT scans are effective for diagnosis. Open lung biopsy may be needed for diagnosis and staging. The usual prognosis is poor with death occurring about 2–5 years after diagnosis. The usual treatment is high doses of oral corticosteroids with azathioprine and no smoking.<sup>9</sup>

### § Extrinsic allergic alveolitis

Extrinsic allergic alveolitis (hypersensitivity pneumonitis) is characterised by a widespread diffuse inflammatory reaction in both the small airways of the lung and the alveoli, due to the inhalation of allergens, which are usually spores of micro-organisms such as thermophilic actinomycetes in 'farmer's lung' or (more commonly) avian protein from droppings or feathers in 'bird fancier's lung'. Occupational causes of extrinsic alveolitis have been described by Molina<sup>10</sup> (see TABLE 49.7).

Illness may present as acute or subacute episodes of pyrexia, chills and malaise with dyspnoea and a peripheral neutrophil several hours after exposure.<sup>10</sup> Management is based on prevention, namely avoiding exposure to allergens or wearing protective, fine-mesh masks. Prednisolone can be used (with caution) to control acute symptoms. It should be pointed out that this allergic disorder is different from the infection psittacosis.

**Table 49.7** Various causes of extrinsic allergic alveolitis

Occupation/disease	Source of antigen
Farmer's lung	Mouldy hay, grain and straw
Bagassosis	Mouldy sugar cane fibre (bagasse)
Bird fancier's lung	Avian proteins: dropping dust (e.g. from pigeons); 'bloom' on budgerigar feathers
Mushroom workers	Mushroom compost
Cheese washer's lung	Moulds or mites on cheese
Wheat weevil lung	Infested wheat flour (insect)
Ventilator pneumonitis	Humidified hot air system Air-conditioning system
Wood pulp worker's disorder	Contaminated wood dust
Detergent worker's disorder	Proteolytic enzymes
Suberosis	Mouldy cork bark
Rat handler's lung	Rat urine and serum
Malt worker's lung	Mouldy barley
Coffee worker's lung	Coffee dust
Sisal worker's lung	Sisal dust
Sericultural workers	Silkworms
Furrier's lung	Fur dust
Sausage workers	Dust
Prawn workers	Prawn fumes

### § Drug-induced interstitial lung disease<sup>9</sup>

Drugs are an important cause of this disorder and have three main effects:

- 1 *Alveolitis with or without pulmonary fibrosis.* This is mainly due to cytotoxic drugs, nitrofurantoin and amiodarone. The drug should be removed and consideration given to prescribing prednisolone 50 mg (o) daily for several weeks, depending on response.
- 2 *Eosinophilic reactions.* This is presumably an immunological reaction, which may present as wheezing, dyspnoea, a maculopapular rash and pyrexia. The many implicated drugs include various antibiotics, NSAIDs, cytotoxic agents, major tranquillisers and antidepressants, and anti-epileptics. Treatment is drug removal and a

short course of prednisolone 20–40 mg (o) daily for 2 weeks.

- 3 *Non-cardiogenic acute pulmonary oedema.* This is rare and has been reported to occur with opioids, aspirin, hydrochlorothiazide,  $\beta_2$ -adrenoceptor agonists (given IV to suppress premature labour), cytotoxics, interleukin-2, heroin.

## OCCUPATIONAL PULMONARY DISEASE

Various types of acute and chronic pulmonary diseases are related to exposure to noxious substances such as dusts, gases and vapours in the workplace. Common chemical causes include formaldehyde used in processed woods, e.g. chipboard and medium-density fibre. GPs have a crucial role in the identification of the possible work-relatedness of lung disease.

Disorders due to chemical agents include:

- obstructive airways disorders, such as occupational asthma, acute bronchitis, (chronic) industrial bronchitis, byssinosis (asthma-like condition due to cotton dust)
- extrinsic allergic alveolitis
- pulmonary fibrosis (pneumoconiosis) due to mineral dust
- lung cancer due to industrial agents such as asbestos, various hydrocarbons
- pleural disorders, usually associated with asbestosis

### § Pneumoconiosis

The term 'pneumoconiosis' refers to the accumulation of dust in the lungs and the reaction of tissue to its presence, namely chronic fibrosis. The main cause worldwide is inhalation of coal dust, a specific severe variety being progressive massive fibrosis (complicated coal worker's pneumoconiosis) in which the patient suffers severe dyspnoea of effort and cough often productive of black sputum. **TABLE 49.8** summarises the important causes.

Of particular concern are diseases caused by inhalation of fibres of asbestos, which is a mixture of silicates of iron, magnesium, cadmium, nickel and aluminium. The diseases include asbestosis, diffuse pleural thickening, pleural plaques, mesothelioma and increased bronchial carcinoma in smokers. Pulmonary asbestosis has classic X-ray changes but high-resolution CT scans may be required to confirm the presence of calcified pleural plaques. It usually takes 10–20 years from exposure for asbestosis to develop and 20–40 years for mesothelioma to develop,<sup>8</sup> while bronchial carcinoma is caused by the synergistic effects of asbestosis and cigarette smoking.

**Table 49.8** Selected pneumoconioses

Fibrotic lung disease	Agent	Typical occupations
Coal dust		
Coal worker's pneumoconiosis	Coal dust	Coal mining
Metal dust		
Siderosis	Metallic iron or iron oxide	Mining Welding Foundry work
Inorganic dusts		
Silicosis	Silica (silicon dioxide)	Quarrying Rock mining Stone cutting Sandblasting
Silicate dusts		
Asbestosis	Asbestos	Mining Shipbuilding Insulation Power stations Wharf labouring

### § Acute respiratory distress syndrome (ARDS)

ARDS, also known as acute lung injury and formerly called 'adult respiratory distress syndrome', refers to acute hypoxaemic respiratory failure following a pulmonary or systemic insult with no apparent cardiogenic cause of pulmonary oedema. This occurs about 12–48 hours after the event.<sup>11</sup> The most common cause is sepsis which accounts for about one-third of ARDS patients. The mortality rate is 30–40% increasing if accompanied by sepsis. Management is based on early diagnosis, early referral, identification and treatment of the underlying condition and then optimal intensive care.<sup>12</sup>

#### Clinical features

- Sudden onset of respiratory distress
- Stiff lungs—reduced lung compliance
- Bilateral pulmonary infiltrates on X-ray
- No apparent evidence of heart failure

- Absence of elevated left atrial pressure
- Specific gas exchange abnormalities
- Signs: tachypnoea, laboured breathing, rib retraction, central cyanosis, fine crackles on auscultation

The differential diagnoses are pneumonia and acute heart failure. Common risk factors/associations for ARDS include (indirectly—systemic)—sepsis, shock, trauma, burns, drug overdose (e.g. heroin), multiple transfusions, obstetric complications (e.g. eclampsia, amniotic fluid embolism), and many direct causes such as pulmonary aspiration, toxic gas inhalation, blast injury and pneumonia (e.g. SARS).

### § Severe acute respiratory syndrome (SARS)

SARS is a respiratory illness of varying severity (mild to severe) with a known mortality rate of about 10% of clinically established cases. All cases to date exhibit a high fever of  $>38^{\circ}\text{C}$ . It is considered to be an atypical pneumonia caused by a quite unique coronavirus. Cases have acquired SARS following exposure to endemic areas of South-East Asia. Severe cases (up to 10% mortality) can progress to ARDS.

Suspected case = fever  $>38^{\circ}\text{C}$  + cough, breathing difficulty or dyspnoea + contact with SARS person/area. Plain X-rays may show pulmonary infiltrates while high-resolution CT scans may show typical patterns.

#### Key features

- Symptoms of atypical pneumonia: fever, cough, dyspnoea
- Associated may be myalgia, diarrhoea, headache, sore throat, rhinorrhoea, confusion, malaise, rash
- Virulent virus—droplet spread
- Incubation period 2–7 days
- Crackles and wheezes may be present on auscultation but no hallmark sign
- Non-specific X-ray signs
- Prime CT scans may show typical changes
- Diagnosis confirmed by PCR studies or isolation of the virus on culture
- Complications appear to be confined to the lung

Optimal treatment for SARS by drugs is still being evaluated. Preventive measures, including wearing of face masks (NIOSH standard mask best) and appropriate infection control procedures, are important. Wear a mask, gloves, goggles and gown for clinical assessment of suspected cases and switch off air-conditioning (refer to [CHAPTER 28](#)).

### Practice tips

- Remember to order a chest X-ray and pulmonary function tests in all doubtful cases of dyspnoea.
- All heart diseases have dyspnoea as a common early symptom.
- Increasing dyspnoea on exertion may be the earliest symptom of incipient heart failure.
- Several drugs can produce a wide variety of respiratory disorders, particularly pulmonary fibrosis and pulmonary eosinophilia. Amiodarone and cytotoxic drugs, especially bleomycin, are the main causes.
- Dyspnoea in the presence of lung cancer may be caused by many factors, such as pleural effusion, lobar collapse, upper airway obstruction and lymphangitis carcinomatosa.
- The abrupt onset of severe dyspnoea suggests pneumothorax or pulmonary embolism.
- If a patient develops a relapse of dyspnoea while on digoxin therapy, consider the real possibility of digoxin toxicity and/or electrolyte abnormalities leading to left heart failure.
- Recurrent attacks of sudden dyspnoea, especially waking the patient at night, are suggestive of asthma or left heart failure.
- Causes of hyperventilation include drugs, asthma, thyrotoxicosis and panic attacks/anxiety.

### Bronchial carcinoma

Dyspnoea is associated with about 60% of cases of lung cancer<sup>3</sup> (see [CHAPTER 42](#)). It is not a common early symptom unless bronchial occlusion causes extrinsic collapse. In advanced cancer, whether primary or secondary, direct spread or metastases may cause dyspnoea. Other factors include pleural effusion, lobar collapse, metastatic infiltration, upper airway obstruction due to superior vena cava (SVC) obstruction and lymphangitis carcinomatosa. A special problem arises with coexisting chronic bronchitis and emphysema.

### When to refer

- Patients with acute onset of severe dyspnoea
- All patients with heart failure resistant to initial therapy or where the diagnosis is in doubt
- Patients with pulmonary disease of uncertain aetiology, especially those requiring respiratory function tests
- Those in whom lung cancer is suspected

*The ears should be kept perfectly clean; but it must never be done in company. It should never be done with a pin, and still less with the fingers, but always with an ear picker.*

St Jean Baptiste de la Salle (1651–1719)

Pain in the ear (otalgia) is a common symptom in general practice. It affects all ages, but is most prevalent in children, where otitis media is the commonest cause. Ear pain may be caused by disorders of the ear or may arise from other structures, and in many instances the precise diagnosis is difficult to make. Important causes of ear pain are summarised in **TABLE 50.1**.<sup>1</sup>

A patient with a painful ear often requests urgent attention, and calls in the middle of the night from anxious parents of a screaming child are commonplace. Infants may present with nothing except malaise, vomiting or screaming attacks.

### Key facts and checkpoints

- Of patients presenting with earache, 77% can be expected to have acute otitis media and 12% otitis externa.<sup>2</sup>
- Approximately one of every 25 patients in general practice will present with an earache.
- Two-thirds of children will sustain at least one episode of otitis media by their second birthday; one in seven children will have had more than six episodes by this age.<sup>3</sup>
- Otitis media is unlikely to be present if the tympanic membrane (TM) is mobile. Pneumatic otoscopy greatly assists diagnosis since the most valuable sign of otitis media is absent or diminished motility of the TM.
- Bullous myringitis, which causes haemorrhagic blistering of the eardrum or external ear canal, is an uncommon cause of severe pain. It is caused by a virus, probably influenza.<sup>4</sup>
- The antibiotic of first choice for acute otitis media (children and adults) is amoxycillin.
- Otitis externa can be distinguished from otitis media by pain on movement of the pinna.

### A diagnostic approach

The five self-posed questions can be answered using the diagnostic strategy model (see **TABLE 50.2**).

**Table 50.1** Causes of ear pain

1 Ear
External ear:
• Perichondritis
• Otitis externa:
— <i>Candida albicans</i>
— <i>Aspergillus nigr</i> a
— <i>Pseudomonas</i> spp.
— <i>Staphylococcus aureus</i>
• Furunculosis
• Trauma
• Neoplasia
• Herpes zoster (Ramsay–Hunt syndrome)
• Viral myringitis
• Wax-impacted
Middle ear:
• Eustachian insufficiency
• Eustachian tube dysfunction
• Barotrauma
• Acute otitis media
• Chronic otitis media and cholesteatoma
• Acute mastoiditis
2 Periotic cause
Dental disorders
Upper cervical spinal dysfunction
TMJ arthralgia
Parotitis
Temporal arteritis
Lymph node inflammation
Other referred causes
Pharyngeal disorders
Tonsillitis
Glossopharyngeal neuralgia

### Probability diagnosis

The commonest cause of ear pain is acute otitis media. Chronic otitis media and otitis externa are also common. In the tropics, ‘tropical ear’ due to acute bacterial otitis is a particular problem.

**Table 50.2** The painful ear: diagnostic strategy model

Q.	Probability diagnosis
A.	Otitis media (viral or bacterial) Otitis externa (fungal, viral or bacterial) TMJ arthralgia Eustachian tube dysfunction
Q.	Serious disorders not to be missed
A.	Neoplasia of external ear Cancer of other sites (e.g. tongue, nasopharynx) Herpes zoster (Ramsay–Hunt syndrome) Acute mastoiditis Cholesteatoma Necrotising otitis externa
Q.	Pitfalls (often missed)
A.	Foreign bodies in ear Hard ear wax Barotrauma Dental causes (e.g. abscess) Referred pain: neck, throat Unerupted wisdom tooth and other dental causes TMJ arthralgia Facial neuralgias, esp. glossopharyngeal Chondromalacia nodularis helices Furuncles of canal or pinna Post tonsillectomy: <ul style="list-style-type: none"> <li>• from the wound</li> <li>• from TMJ due to mouth gag</li> </ul>
Q.	Seven masquerades checklist
A.	Depression Spinal dysfunction (cervical)
Q.	Is the patient trying to tell me something?
A.	Unlikely, but always possible with pain. More likely in children. Consider factitious pain.

Temporomandibular joint (TMJ) arthralgia, which may be acute or chronic, is also common and must be considered, especially when otitis media and otitis externa are excluded.

## Serious disorders not to be missed

As always, it is important not to overlook malignant diseases, especially the obscure ones, such as cancer of the tongue, palate or tonsils, which cause referred pain.

Locally destructive cholesteatoma associated with chronic otitis media must be searched for. It signifies the ‘unsafe’ ear (see FIG. 50.1) that must be distinguished from the so-called ‘safe’ ear (see FIG. 50.2).

Herpes zoster should be considered, especially if it does not erupt on the pinna and is confined to the ear canal (usually the posterior wall), and especially in the older person.

**FIGURE 50.1** Infected ear: unsafe perforation

**FIGURE 50.2** Infected ear: safe perforation

## Pitfalls

The medical aphorism ‘more things are missed by not looking than by not knowing’ applies particularly to the painful ear—good illumination and focusing the auroscope are mandatory. Particular attention should be paid to the external canal—look for hard wax, otitis externa, furuncles and foreign objects such as insects.

It may not be possible to visualise the TMs so it is important to clean the canal to permit this (if possible, on the first visit). Otitis media may coexist with otitis externa. Barotrauma should be considered, especially if pain follows air travel or diving.

## General pitfalls

- Failing to visualise the TM before diagnosis and treatment
- Not checking out possible referral sites such as the oropharynx and teeth
- Overlooking common musculoskeletal causes such as TMJ arthralgia and cervical spondylosis
- Failing to recognise the unsafe ear

## Red flag pointers for painful ear

- Offensive discharge >9 days
- Downward displacement of pinna
- Swelling behind ear
- Neurological symptoms (e.g. headaches, drowsiness)
- Older person: unexplained, intractable ear pain
- Persistent fever

## Seven masquerades checklist

Of the conditions in the checklist, depression and dysfunction of the upper cervical spine have to be considered. Depressive illnesses should be considered in any patient complaining of chronic pain.

Disorders of the upper cervical spine are a commonly overlooked cause of periotic pain. Pain from the C2 and C3 levels is referred to the posterior region of the ear.

## Psychogenic considerations

Such factors are unlikely, unless the pain causes discomfort in the periotic region, which is likely to be magnified by a depressive state.

## The clinical approach

### History

In assessing the painful ear the relevant features are:

- site of pain and radiation
- details of the onset of pain
- nature of the pain
- aggravating or relieving factors, especially swimming
- associated features such as deafness, discharge, vertigo, tinnitus and irritation of the external ear, sore throat

Agonising pain may be caused by perichondritis or furunculosis of the external ear and by the rare problem of herpes zoster (Ramsay–Hunt syndrome).<sup>5</sup> Movement of the pinna markedly increases the

pain of acute otitis externa and perichondritis, and movement of the jaw usually causes an exacerbation of TMJ arthralgia or severe otitis externa.

## Key questions (especially children)

- Where is the pain?
- Is it in the ear, behind or below it?
- Is it in one ear or both ears?
- Have you noticed any other symptoms such as sore throat, fever or vomiting?
- Has anyone hit you over the ear?
- Has there been a discharge from the ear?
- Have you noticed any deafness?
- Are you allergic to penicillin?
- Have you been swimming in a spa, and where?
- Have you been in an aeroplane?

## Examination

The patient's general state and behaviour is observed during the history taking. Sudden, jabbing pain may indicate neuralgia, particularly glossopharyngeal neuralgia or a severe infection. The external ear is carefully inspected and the pinna manipulated to determine any tenderness.

Palpate the face and neck and include the parotid glands, regional lymph nodes and the skin. Inspect the TMJs—tenderness from dysfunction typically lies immediately in front of the external auditory meatus. Palpate the TMJ over the lateral aspect at the joint disc. Ask the patient to open the mouth fully when tenderness is maximal. The TMJ can be palpated posteriorly by inserting the little finger into the external canal.

Inspect both ear canals and TMs with the auroscope, using the largest earpiece that comfortably fits into the canal. Better visualisation of the TM can be achieved by pulling the pinna back in young children and up and back in older children—see **FIGURE 50.3** for normal appearance. Impacted wax may not explain the otalgia. If herpes zoster involves the facial nerve, vesicles may be noted in and around the external auditory meatus (notably the posterior wall).

If the diagnosis is still doubtful look for causes of referred pain; inspect the cervical spine, the nose and postnasal space and the mouth, including the teeth, pharynx and larynx.

Pharyngeal and mandibular causes of periotic pain are summarised in **FIGURES 50.4** and **50.5**.

Inspect sites supplied by the nerves V2, IX, X, XI, C1, C2 and C3 to exclude other causes of referred pain.

FIGURE 50.3 Normal right tympanic membrane

FIGURE 50.4 Pharyngeal causes of otalgia

Source: Courtesy of Bruce Black

## Investigations

Investigations are seldom necessary. Hearing tests are essential, especially for children. Simple tests such as speech discrimination, hair rubbing and tuning fork tests can be used. Otherwise audiometry can be used. Audiometry combined with tympanometry and physical measurement of the volume of the ear canal can be performed in children, irrespective of age.

FIGURE 50.5 Mandibular causes of otalgia

Source: Courtesy of Bruce Black

Swabs from discharge, especially to determine bacterial causes, such as *Staphylococcus aureus* or *Pseudomonas* spp. infection, may be necessary. However, swabs are of no value if the TM is intact.

Radiology and CT/MRI scanning may be indicated for special conditions such as a suspected extraotic malignancy.

## Ear pain in children

Important causes of primary otalgia in children include otitis media, otitis externa, external canal furuncle or abscess, chronic eczema with fissuring of the auricle, impacted wax, foreign body, barotrauma, perichondritis, mastoiditis and bullous myringitis. Secondary otalgia includes pharyngeal lesions, dental problems, gingivostomatitis, mumps and postauricular lymphadenopathy. Peritonsillar abscess (quinsy) may cause ear pain.

## Foreign bodies

Foreign bodies (FBs) are frequently inserted into the ear canal (see FIG. 50.6). They can usually be syringed out or lifted with thin forceps. Various improvised methods can be used to remove FBs in cooperative children. These include a probe to roll out the FB or a rubber catheter used as a form of suction or otherwise a fine sucker.<sup>6</sup>

## Probe method

This requires good vision using a head mirror or head light and a thin probe. The probe is inserted under and just beyond the FB. Lever it in such a way that the tip of the probe 'rolls' the foreign body out of the obstructed passage.

**FIGURE 50.6** Foreign body (bead) in ear canal of a 3-year-old child, showing reactive tissue in ear canal

### Rubber catheter suction method

The only equipment required for this relatively simple and painless method is a straight rubber catheter (large type) and perhaps a suction pump. The end of the catheter is cut at right angles, a thin smear of petroleum jelly is applied to the rim and this end is applied to the FB. Suction is applied either orally or by a pump. Gentle pump suction is preferred but it is advisable to pinch closed the suction catheter until close to the FB as the hissing noise may frighten the child.

### Insects in the ear

Live insects should be immobilised by first instilling Aquaear drops or olive oil, and then syringing the ear with warm water.

Dead flies that have originally been attracted to pus are best removed by suction.

*Note:* If simple methods such as syringing fail to dislodge the FB it is important to refer for examination and removal under microscopic vision. Syringing should not be performed if there is a possibility of the FB perforating the TM.

## § Otitis media in children

Otitis media is very common in children and is the most common reason a child is brought in for medical attention. Persistent middle ear effusions may follow and affect the language and cognitive development of young children.

### Clinical features

- Two peaks of incidence: 6–12 months of age and school entry
- Seasonal incidence coincides with URTIs
- Bacteria cause two-thirds of cases<sup>7</sup>

- The commonest organisms are *Streptococcus pneumoniae*, *Haemophilus influenzae* and *Moraxella catarrhalis*
- Fever, irritability, otalgia and otorrhoea may be present
- The main symptoms in older children are increasing earache and hearing loss
- Pulling at the ears is a common sign in infants
- Removal of wax is necessary in about 30% to visualise the TM

### Visualisation of the tympanic membrane

Use the largest ear speculum that will comfortably fit in the child's ear. A good technique to enable the examination of the ears (also nose and throat) in a reluctant child is where the child is held against the parent's chest while the parent's arm embraces the child's arm and trunk.

Note the following features of the TM: translucency, colour, position and motility.

### Treatment

Many children with viral URTIs have mild reddening or dullness of the eardrum and antibiotics are not warranted particularly in the absence of systemic features (fever and vomiting).<sup>7</sup> Best practice at this stage is symptomatic relief with analgesics and either watchful waiting or antibiotics.<sup>8</sup> In contrast, where the eardrum is red or yellow and bulging, with loss of anatomical landmarks, antibiotic therapy is indicated.

The debate about the role of antibiotics in acute otitis media is controversial. An Australian study revealed that antibiotics provided only modest benefit: up to 20 children must be treated to prevent one child from experiencing pain by 2–7 days after presentation.<sup>8,9</sup> A North American survey concluded: 'treat children who are very ill (approximately 15%) with antibiotics immediately. Treat all others for pain and pain only and follow up according to age. Treat with antibiotics if more serious symptoms develop, or the fever, pain and other symptoms do not resolve within the time frame'.<sup>10</sup>

### Possible clinical indications for antibiotics in children with painful otitis media<sup>8</sup>

- <2 years with bilateral otitis media
- Sick child with fever
- Vomiting
- Red–yellow bulging TM
- Loss of TM landmarks or perforation
- Persistent fever and pain after 48 hours conservative approach
- Risk of complications in those at risk

The antibiotic of choice is:<sup>7</sup>

amoxycillin 15 mg/kg 8 hourly up to 500 mg (o)  
for 5 days

or

amoxycillin 30 mg/kg 12 hourly (o) for 5 days

Amoxycillin is also the preferred choice in the US and UK.<sup>11</sup>

If  $\beta$ -lactamase-producing bacteria are suspected or documented, or initial treatment fails, use:

cefaclor 10 mg/kg/day (max. 750 mg/day) orally  
in three divided doses for 5–7 days (cefaclor is  
second choice irrespective of cause)

or

(if resistance to amoxycillin is suspected or  
proven) amoxycillin/potassium clavulanate

With appropriate treatment most children with acute otitis media are significantly improved within 48 hours. Parents should be encouraged to contact their doctor if no improvement occurs within 72 hours. This problem is usually due to a resistant organism or suppuration. The patient should be re-evaluated at 10 days.

It is of interest that some practitioners refer to the 'Pollyanna' phenomenon when treating otitis media; that is, all antibiotics seem to work!

### Antibiotic drops

A randomised trial has found that antibiotic eardrops are superior to oral antibiotics for the treatment of acute otorrhoea in children with grommets.<sup>12</sup> This method has advocates among specialists who recommend ciprofloxacin drops following aural toilet.

### Symptomatic treatment

Rest the patient in a warm room with adequate humidity. Use analgesics such as paracetamol (acetaminophen) in high dosage. Although the use of antihistamines and decongestants has not been verified scientifically, the author has found nasal decongestants (as oxymetazoline nasal drops or sprays) effective in distressed children with an associated URTI. Otherwise, avoid antihistamines and decongestants.

Follow-up: adequate follow-up with hearing assessment is mandatory.

### Complications<sup>8</sup>

- *Middle ear effusion.* 70% of children will have an effusion present 2 weeks from the time of diagnosis, 40% at 4 weeks, with 10% having persistent effusions for 3 months or more. If the

effusion is still present at 6–8 weeks, a second course of antibiotics should be prescribed.<sup>2</sup> If the effusion persists beyond 3 months refer for an ENT opinion.

- *Acute mastoiditis.* This is a major complication that presents with pain, swelling and tenderness developing behind the ear associated with a general deterioration in the condition of the child (see FIG 50.7). Such a complication requires immediate referral.
- *Chronic suppurative otitis media.* Discharge through a perforation of the TM >6 weeks.

**FIGURE 50.7** Mastoiditis in a child with recurrent otitis media showing erythema and swelling behind the ear. Surgical drainage was performed

- *Rare complications.* These include labyrinthitis, petrositis, facial palsy and intracranial abscess.
- *Serous otitis media (glue ear).* This represents incomplete resolution of suppurative otitis media. Signs include loss of drum mobility, hearing loss and abnormal impedance confirmed by pneumatic otoscopy or tympanometry. Most resolve spontaneously but any necessary treatment includes medications such as bromhexine elixir and Demazin syrup, auto-inflations and 'Otovent' assisted nasal inflation.

If an effusion lasts for >3 months, arrange for a hearing assessment and consider referral to an ENT surgeon for possible tympanostomy tubes (grommets).<sup>13</sup>

*Note:* a proposed *S. pneumoniae* and *H. influenzae* conjugate vaccine may be an effective preventive measure for childhood otitis media.

### Recurrent acute otitis media

Antibiotic prevention of acute otitis media is indicated (arguably) if it occurs more often than every other month or for three or more episodes in 6 months or >4 in 12 months:<sup>14</sup>

chemoprophylaxis (for about 4 months)  
amoxycillin twice daily (first choice)  
or  
cefaclor twice daily

Consider *Pneumococcus* vaccine in children over 18 months of age (if not already given) in combination with the antibiotic. Avoid smoke exposure (cigarettes and wood fires) and group child care.

Consider review by ENT consultant.

### Viral infections

Most children with viral URTIs have mild reddening or dullness of the eardrum and antibiotics are not warranted. If painful bullous otitis media is present, either prick the bulla with a sterile needle for pain relief, or instil dehydrating eardrops such as anhydrous glycerol.

### Ear pain in the elderly

Causes of otalgia that mainly afflict the elderly include herpes zoster (Ramsay–Hunt syndrome), TMJ arthralgia, temporal arteritis and neoplasia. It is especially important to search for evidence of malignancy.

### § Acute otitis media

Acute otitis media causes deep-seated ear pain, deafness and often systemic illness (see FIG. 50.8). The sequence of symptoms is a blocked ear feeling, pain

**FIGURE 50.8** Acute otitis media causing true otalgia. The ear drum bulges laterally due to pus in the middle ear. Perforation and otorrhoea imminent.

and fever. Discharge may follow if the TM perforates, with relief of pain and fever.

The commonest organisms are viruses (adenovirus and enterovirus), and the bacteria *H. influenzae*, *S. pneumoniae*, *Moraxella* (previously *Neisseria catarrhalis*) and  $\beta$ -haemolytic streptococci.

The two cardinal features of diagnosis are inflammation and middle ear effusion.

### Appearance of the tympanic membrane (all ages)

*Translucency.* If the middle ear structures are clearly visible through the drum, otitis media is unlikely.

*Colour.* The normal TM is a shiny pale-grey to brown: a yellow colour is suggestive of an effusion.

### Diagnosis

The main diagnostic feature is the redness of the TM. The inflammatory process usually begins in the upper posterior quadrant and spreads peripherally and down the handle of the malleus (see FIG. 50.9). The TM will be seen to be reddened and inflamed with engorgement of the vessels, particularly along the handle of the malleus. The loss of light reflex follows and anatomical features then become difficult to recognise as the TM becomes oedematous. Bulging of the drum is a late sign. Blisters are often seen on the TM and this is thought to be due to a viral infection in the epidermal layers of the drum.

- erythema of prominent blood vessels progressing down handle of malleus
- normal drum

- progressive erythema
- loss of light reflex

- bulging pars flaccida
- red pars tensa
- anatomical structures unidentifiable

**FIGURE 50.9** The appearances of the left tympanic membrane in the progressive development of acute otitis media

### Treatment of acute otitis media (adults)

- Analgesics to relieve pain
- Adequate rest in a warm room
- Nasal decongestants for nasal congestion
- Antibiotics until resolution of all signs of infection
- Treat associated conditions (e.g. adenoid hypertrophy)
- Follow-up: review and test hearing audiometrically

### Antibiotic treatment<sup>7</sup>

First choice:

amoxycillin 750 mg (o) bd for 5 days<sup>7</sup>

or

500 mg (o) tds for 5 days

A longer course (up to 10 days) may be required depending on severity and response to 5-day course.

Alternatives:

doxycycline 100 mg (o) bd for 5–7 days (daily for milder infections)

or

cefaclor 250 mg (o) tds for 5–7 days

or

(if resistance to amoxycillin is suspected or proven)  
amoxycillin/potassium clavulanate 500/125 mg (o) tds for 5 days (the most effective antibiotic)

Consider surgical intervention for failed therapy.

### CHRONIC OTITIS MEDIA

There are two types of chronic suppurative otitis media and they both present with deafness and discharge without pain. The discharge occurs through a perforation in the TM: one is safe (see FIG. 50.10a), the other unsafe (see FIG. 50.10b).

#### § Chronic discharging otitis media (safe)<sup>7</sup>

If aural discharge persists for >6 weeks after course of antibiotics, treatment can be with topical steroid and antibiotic combination drops, following ear toilet. The toileting can be done at home by dry mopping with rolled tissue spear. If persistent, referral to exclude cholesteatoma or chronic osteitis is advisable.

#### Recognising the unsafe ear

Examination of an infected ear should include inspection of the attic region, the small area of drum between the lateral process of the malleus, and the roof of the external auditory canal immediately above it. A perforation here renders the ear 'unsafe' (see FIG. 50.1); other perforations, not involving the drum margin (see FIG. 50.2), are regarded as 'safe'.<sup>13</sup>

**FIGURE 50.10** (a) Chronic otitis media with loss of the tympanic membrane; this is 'safe ear' (b) Unsafe ear: chronic otitis media with attic cholesteatoma.

### Cholesteatoma<sup>13</sup>

Refer **CHAPTER 43**.

The status of a perforation depends on the presence of accumulated squamous epithelium (termed cholesteatoma) in the middle ear, because this erodes bone. An attic perforation contains such material; safe perforations do not.

Red flags for cholesteatoma include meningitis-type features, cranial nerve deficits, sensorineural hearing loss and persistent deep ear pain.

Cholesteatoma is visible through the hole as white flakes, unless it is obscured by discharge or a persistent overlying scab. Either type of perforation can lead to chronic infective discharge, the nature of which varies with its origin. Mucus admixture is recognised by its stretch and recoil when this discharge is being cleaned from the external auditory canal. The types of discharge are compared in **TABLE 50.3**.

**Table 50.3** Comparison of types of discharge

	Unsafe	Safe
<b>Source</b>	Cholesteatoma	Mucosa
<b>Odour</b>	Foul	Inoffensive
<b>Amount</b>	Usually scant, never profuse	Can be profuse
<b>Nature</b>	Purulent	Mucopurulent

### Management

If an attic perforation is recognised or suspected, specialist referral is essential. Cholesteatoma cannot be eradicated by medical means: surgical removal is necessary to prevent a serious infratemporal or intracranial complication.

### § Otitis externa

Otitis externa (see **FIG. 50.11**), also known as 'swimmer's ear', 'surfer's ear' and 'tropical ear', is common in a country whose climate and coastal living leads to extensive water sports. It is more prevalent in hot humid conditions and therefore in the tropics.

Predisposing factors are allergic skin conditions, ear canal trauma, water penetration (swimming, humidity, showering), water and debris retention (wax, dermatitis, exostoses), foreign bodies, contamination from swimming water including spas, and use of Q tips and hearing aids.

### Common responsible organisms

- Bacteria:
  - *Pseudomonas* sp.
  - *Escherichia coli*
  - *S. aureus*
  - *Proteus* sp.
  - *Klebsiella* sp.
- Fungi:
  - *Candida albicans*
  - *Aspergillus* sp.

FIGURE 50.11 Otitis externa

### Clinical features

- Itching at first
- Otalgia/pain (mild to intense) in 70%
- Fullness in ear canal
- Scant discharge
- Hearing loss

### Signs

- Oedema (mild to extensive)
- Tenderness on moving auricle or jaw
- Erythema
- Discharge (offensive if coliform)
- Pale cream 'wet blotting paper' debris—*C. albicans*
- Black spores of *Aspergillus nigr*a
- TM granular or dull red

Obtain culture, especially if resistant *Pseudomonas* sp. suspected, by using small ear swab.

Note: 'Malignant' otitis externa occurs in diabetics due to *Pseudomonas* infection at base of skull.

### Management

#### Aural toilet

Meticulous aural toilet by gentle suction and dry mopping with a wisp of cotton wool on a fine broach under good lighting is the keystone of management. This enables topical medication to be applied directly to the skin.

#### Syringing

This is appropriate in some cases but the canal must be dried meticulously afterwards. For most cases it is not recommended.

### Dressings

Dressings are essential in all but the mildest forms. After cleaning and drying, insert 10–20 cm of 4 mm Nufold gauze impregnated with a steroid and antibiotic cream.

For severe otitis externa, a wick is important and will reduce the oedema and pain in 12 to 24 hours (see FIG. 50.12). The wick can be soaked in an astringent (e.g. aluminium acetate 4% solution or glycerin and 10% ichthammol). The wick needs replacement daily until the swelling has subsided.

FIGURE 50.12 Insertion of a wick; it is packed gradually by short back-and-forth movements of the forceps.

Source: Courtesy of Bruce Black

### Topical antimicrobials<sup>7</sup>

The most effective, especially when the canal is open, is an antibacterial, antifungal and corticosteroid preparation such as Kenacomb or Sofradex drops (2–3 drops tds), Locacorten-Vioform drops (2–3 drops bd) or Ciproxin HC (3 drops bd). Be cautious of ear drops with neomycin (hypersensitivity). The tragus should be pumped for 30 seconds after instillation by pressing on it repeatedly, within the limitation of any pain.

### Other measures

- Strong analgesics are essential
- Antibiotics have a minimal place in treatment unless a spreading cellulitis has developed (refer if in doubt)
- Prevent scratching and entry of water
- Use a wick soaked in combination steroid and antibiotic ointment for more severe cases

### Practice tip for severe 'tropical ear'

Prednisolone (o) 15 mg statim then 10 mg 8 hourly for 6 doses followed by:

- Merocel ear wick
- topical Kenacomb or Sofradex drops

### Prevention

- Keep the ear dry, especially those involved in water sports
- Protect the ear with various water-proofing methods:
  - cotton wool coated with petroleum jelly
  - use an antiseptic drying agent (eg. ethanol) after swimming and showering
  - tailor-made ear plugs (eg. EAR foam plugs)
  - silicone putty or Blu-Tack
  - a bathing cap pulled well forward allows these plugs to stay *in situ*
- Avoid poking objects such as hairpins and cotton buds in the ear to clean the canal
- If water enters, shake it out or use Aquaeear drops (spirit drops help dry the canal)

### Necrotising otitis externa

This severe complication usually due to *Pseudomonas aeruginosa* can occur in the immunocompromised, diabetic or elderly patient. It involves cartilage and bone and should be considered with treatment failure, severe persistent pain, fever and visible granulation tissue. Urgent referral is advisable.

### § Ear exostoses ('surfer's ear')

These periosteal bony overgrowths are usually caused by water retention in the ear. They are often multiple. They tend to trap keratin, wax and water, leading to infection.

### Prevention

- Use plugs or Blu-Tack to waterproof ear.
- Dry thoroughly with hair dryer after swimming.

They may require surgical removal.

### § Furunculosis

Furunculosis is a staphylococcal infection of the hair follicle in the outer cartilaginous part of the ear canal. It is usually intensely painful. Fever occurs only when the infection spreads in front of the ear as cellulitis. The pinna is tender on movement—a sign that is not a feature of acute otitis media. The furuncle (boil) may be seen in the external auditory meatus (see FIG. 50.13).

### Management

- If pointing, it can be incised after a local anaesthetic or freezing spray
- Warmth (eg. use hot face washer, hot water bottle)
- If fever with cellulitis—dicloxacillin

FIGURE 50.13 Furuncle (boil) in hair-bearing area at opening of the ear canal

### § Perichondritis

Perichondritis is infection of the cartilage of the ear characterised by severe pain of the pinna, which is red, swollen and exquisitely tender. It is rare and follows trauma or surgery to the ear. As the organism is frequently *P. pyocaneus* the appropriate antibiotics must be carefully chosen (eg. ciprofloxacin).

### § Infected ear lobe

The cause is most likely a contact allergy to nickel in an earring, complicated by a *S. aureus* infection.

### Management

- Discard the earrings
- Clean the site to eliminate residual traces of nickel
- Swab the site and then commence antibiotics (eg. flucloxacillin or erythromycin)
- Instruct the patient to clean the site daily, and then apply the appropriate ointment
- Use a 'noble metal' stud to keep the tract patent
- Advise the use of only gold, silver or platinum studs in future

### § Eustachian tube dysfunction

This is a common cause of discomfort.<sup>15</sup> Symptoms include fullness in the ear, pain of various levels and impairment of hearing. The most common causes of dysfunction are disorders causing oedema of the tubal

lining, such as viral URTI and allergy when the tube is only partially blocked; swallowing and yawning may elicit a crackling or popping sound. Examination reveals retraction of the TM and decreased mobility on pneumatic otoscopy. The problem is usually transient after a viral URTI.

### Treatment

- Systemic and intranasal decongestants (e.g. pseudoephedrine or corticosteroids in allergic patients)
- Autoinflation by forced exhalation against closed nostrils (avoid in active intranasal infection)
- Avoid air travel, rapid altitude change and underwater diving

### § Otic barotrauma

Barotrauma is damage caused by undergoing rapid changes in atmospheric pressure in the presence of an occluded Eustachian tube (see FIG. 50.14). It affects scuba divers and aircraft travellers.

**FIGURE 50.14** Mechanism of barotrauma, with blocking of the Eustachian tube due to increased pressure at the sites indicated.

Source: Courtesy of Bruce Black

The symptoms include temporary or persisting pain, deafness, vertigo, tinnitus and perhaps discharge.

Inspection of the TM may reveal (in order of seriousness): retraction; erythema; haemorrhage (due to extravasation of blood into the layers of the TM); fluid or blood in the middle ear; perforation. Perform conductive hearing loss tests with tuning fork.

### Treatment

Most cases are mild and resolve spontaneously in a few days, so treat with analgesics and reassurance. Menthol inhalations are soothing and effective. Refer

if any persistent problems for consideration of the Politzer bag inflation or myringotomy.

### Prevention

*Flying.* Perform repeated Valsalva manoeuvres during descent. Use decongestant drops or sprays before boarding the aircraft, and then 2 hours before descent.

*Diving.* Those with nasal problems, otitis media or chronic tubal dysfunction should not dive.

### § Penetrating injury to tympanic membrane

A penetrating injury to the TM can occur in children and adults from various causes such as pencils and slivers of wood or glass. Bleeding invariably follows and infection is the danger.

### Management

- Remove blood clot by suction toilet or gentle dry mopping
- Ensure no FB is present
- Check hearing
- Prescribe a course of broad spectrum antibiotics (e.g. cotrimoxazole)
- Prescribe analgesics
- Instruct patient not to let water enter ear
- Review in 2 days and then regularly
- At review in 1 month the drum should be virtually healed
- Check hearing 2 months after injury

Complete healing can be expected within 8 weeks in 90–95% of such cases.<sup>16</sup>

### Temporomandibular joint arthralgia

If rheumatoid arthritis is excluded, a set of special exercises, which may include 'chewing' a piece of soft wood over the molars, invariably solves this problem (see CHAPTER 52). If an obvious dental malocclusion is present, referral is necessary.

### When to refer

#### Otitis media

- Incomplete resolution of acute otitis media
- Persistent middle ear effusion for 3 months after an attack of acute otitis media
- Persistent apparent or proved deafness
- Evidence or suspicion of acute mastoiditis or other severe complications
- Frequent recurrences (e.g. four attacks a year)
- Presence of craniofacial abnormalities

## Other ear problems

- Attic perforation/cholesteatoma
- FBs in ear not removed by simple measures such as syringing
- No response to treatment after 2 weeks for otitis externa
- Suspicion of carcinoma of the ear canal
- Acute TM perforation that has not healed in 6 weeks
- Chronic TM perforation (involving lower two-thirds of TM)

### Practice tips

- The pain of acute otitis media may be masked by fever in babies and young children.
- A red TM is not always caused by otitis media. The blood vessels of the drum head may be engorged from crying, sneezing or nose blowing. In crying babies, the TM as well as the face may be red.
- In otitis externa, most cases will resolve rapidly if the ear canal is expanded and then cleaned meticulously.
- If an adult presents with ear pain but normal auroscopy, examine possible referral sites, namely TMJ, mouth, throat, teeth and cervical spine.
- Consider mastoiditis if foul-smelling discharge is present over 7 + days.
- Antibiotics have no place in the treatment of otic barotrauma.
- It is good medicine to make relief of distressing ear pain a priority. Adequate analgesics must be given. There is a tendency to give too low a dose of paracetamol in children. The installation of nasal drops in infants with a snuffy nose and acute otitis media can indirectly provide amazing relief of pain.
- Spirit ear drops APF are a cheap and simple agent to use for recurrent otitis externa where wetness of the ear canal is a persistent problem.

Q. Seven masquerades checklist	
A. Drugs (hypersensitivity)	
Thyroid disorder (hyperthyroidism)	
Q. Is the patient trying to tell me something?	
A. Unlikely.	

## Key facts and checkpoints

- Acute conjunctivitis accounts for over 25% of all eye complaints seen in general practice.<sup>2</sup>
- A purulent discharge indicates bacterial conjunctivitis.<sup>3</sup>
- A clear or mucous discharge indicates viral or allergic conjunctivitis.
- Viral conjunctivitis can be slow to resolve and may last for weeks.
- Pain and visual loss suggest a serious condition such as glaucoma, uveitis (including acute iritis) or corneal ulceration.
- Beware of the unilateral red eye—think beyond bacterial or allergic conjunctivitis. It is rarely conjunctivitis and may be a corneal ulcer, keratitis, foreign body, trauma, uveitis or acute glaucoma.<sup>4</sup>
- Keratitis (inflammation of the cornea) is one of the most common causes of an uncomfortable red eye. Apart from the well-known viral causes (herpes simplex, herpes zoster, adenovirus and measles), it can be caused by fungal infection (usually on a damaged cornea), bacterial infection or inflammatory disorder such as ankylosing spondylitis.<sup>5</sup>
- Herpes simplex keratitis (dendritic ulcer) often presents painlessly as the neurotrophic effect grossly diminishes sensation.

## The clinical approach

The five essentials of the history are:

- history of trauma, especially as indicator of intra-ocular foreign body (IOFB)
- vision
- the degree and type of discomfort
- presence of discharge
- presence of photophobia

The social and occupational history is also very important. This includes a history of exposure to a 'red eye' at school, work or home; incidents at work such as injury, welding, foreign bodies or chemicals; and genitourinary symptoms.

When examining the unilateral red eye keep the following diagnoses in mind:

- trauma
- foreign body, including IOFB
- corneal ulcer
- iritis (uveitis)
- viral conjunctivitis (commonest type)
- acute glaucoma

The manner of onset of the irritation often gives an indication of the cause. Conjunctivitis or uveitis generally has a gradual onset of redness, while a small foreign body will produce a very rapid hyperaemia. Photophobia occurs usually with uveitis and keratitis. It is vital to elicit careful information about visual acuity. The wearing of contact lenses is very important as these are prone to cause infection or the 'overwear syndrome', which resembles an acute ultraviolet (UV) burn.

## The key eye symptoms

The key eye symptoms are:

- itch
- irritation
- pain (with pus or watering)
- loss of vision (red or white eye)
  - red = front of eye
  - white = back of eye

## Key questions

- Have you noticed blurring of your vision?
- Have you been in close contact with others with the same condition?
- Have you had a cold or running nose recently?
- Do you wear contact lenses?
- Can you recall scratching or injuring your eye?
- What were you doing at the time you noticed trouble?
- Have you been putting any drops, ointments or cosmetics in or around your eye?
- Do you suffer from hay fever?
- Do you have any problems with your eyelids?
- Had your eyes been watering for some time beforehand?
- Have you had any other problems?
- Have you been exposed to arc welding?

## Red eye red flags (urgent ophthalmic referral)<sup>3,6</sup>

- Severe ocular pain
- Severe orbital pain
- Reduction of vision
- Loss of vision
- Diplopia
- Dilated pupil
- Abnormal corneal signs
- Globe displacement
- Endophthalmitis
- Microbial keratitis ± contact lens use

## Loss of vision in the red eye

Consider:

- iritis (uveitis)
- scleritis
- acute glaucoma (pain; nausea and vomiting)
- chemical burns

## The painful red eye

Causes to consider:

- keratitis
- uveitis (iritis)
- episcleritis
- scleritis
- acute glaucoma
- hypopyon (pus in the anterior chamber)
- endophthalmitis (inflammation of internal structures—may follow surgery)
- corneal abrasion/ulceration

Pain with discharge:

- keratitis

Pain with photophobia:

- uveitis
- episcleritis

## Examination

The basic equipment:

- eye testing charts at 45 cm (18 in) and 300 cm (10 ft)
- multiple pinholes
- torch (e.g. Cobalt blue)
- magnifying aid (e.g. binocular loupe)
- glass rod or cotton bud to aid eyelid eversion
- fluorescein sterile paper strips
- anaesthetic drops
- Schiotz tonometer
- ophthalmoscope
- Ishihara colour vision test

The four essentials of the examination are:

- testing and recording vision
- meticulous inspection under magnification
- testing the pupils
- testing ocular tension<sup>4</sup>

Also:

- local anaesthetic test
- fluorescein staining
- subtarsal examination

## Inspection

A thorough inspection is essential, noting the nature of the inflammatory injection, whether it is localised (episcleritis) or diffuse, viewing the iris for any irregularity, observing the cornea, and searching for foreign bodies, especially under the eyelids, and for any evidence of penetrating injury. No ocular examination is complete until the eyelid is everted and closely inspected. Both eyes must be examined since many patients presenting with conjunctivitis in one eye will have early signs of conjunctivitis in the other. Use fluorescein to help identify corneal ulceration. Local anaesthetic drops instilled prior to the examination of a painful lesion are recommended. The local anaesthetic test is a sensitive measure of a surface problem—if the pain is unrelieved a deeper problem must be suspected.

Palpate for enlarged pre-auricular lymph nodes, which are characteristic of viral conjunctivitis.

The nature of the injection is important. In conjunctivitis the vessels are clearly delineated and branch from the corners of the eye towards the cornea, since it involves mainly the tarsal plate. Episcleral and scleral vessels are larger than conjunctival vessels and are concentrated towards the cornea (see FIG. 51.1).

Ciliary injection appears as a red ring around the limbus of the cornea (the ciliary flush), and the individual vessels, which form a parallel arrangement, are not clearly visible. Ciliary injection may indicate a more serious deep-seated inflammatory condition such as anterior uveitis or a deep corneal infection. The presence of fine follicles on the tarsal conjunctivae indicates viral infection while a cobblestone appearance indicates allergic conjunctivitis.

*Note:* Slit lamp examination is ideal for the examination of the eye.

## Investigations

These include:

- swab of discharge for micro and culture or for viral studies

FIGURE 51.1 Physical signs to search for in a patient with a red eye (eyelids everted)

- ESR/CRP
- HLA B27 antigen
- imaging

## Red eye in children

Children can suffer from the various types of conjunctivitis (commonly), uveitis and trauma. Of particular concern is orbital cellulitis, which may present as a unilateral swollen lid and can rapidly lead to blindness if untreated. Bacterial, viral and allergic conjunctivitis are common in all children. Conjunctivitis in infants is a serious disorder because of the immaturity of tissues and defence mechanisms. Serious corneal damage and blindness can result.

### Neonatal conjunctivitis (ophthalmia neonatorum)

This is conjunctivitis in an infant less than 1 month old and is a notifiable disease. Chlamydial and gonococcal infections are uncommon but must be considered if a purulent discharge is found in the first few days of life.<sup>7</sup> In both conditions the parents must be investigated for associated venereal infection and treated accordingly (this includes contact tracing) (see CHAPTER 137).

*Chlamydia trachomatis* accounts for 50% or more of cases. Its presentation in neonates is acute, usually 1–2 weeks after delivery, with moderate mucopurulent discharge. It is a systemic disease and may be associated with pneumonia. The diagnosis is confirmed by PCR tests on the conjunctival secretions.

Treatment is with oral erythromycin for 21 days and local sulfacetamide eye drops.

*Neisseria gonorrhoeae* conjunctivitis, which usually occurs within 1–2 days of delivery, requires vigorous treatment with intravenous cephalosporins or penicillin and local sulfacetamide drops. The discharge is highly infectious and the organism has the potential for severe corneal infection or septicæmia.<sup>7</sup>

Other common bacterial organisms can cause neonatal conjunctivitis, and herpes simplex virus type II can cause conjunctivitis and/or eyelid vesicles or keratitis.<sup>2</sup>

## § Trachoma

More than 6 million people worldwide have trachoma-caused blindness.

Trachoma is a chlamydial conjunctivitis that is prevalent in outback areas and in the Indigenous population. *C. trachomatis* is usually transmitted by human contact between children and mothers and also by flies, especially where hygiene is inadequate. It is the most common cause of blindness in the world. Recurrent and untreated disease leads to lid scarring and intumed lashes (entropion) with corneal ulceration and visual loss. It is important to commence control of the infection in childhood.

### Treatment

- Prevention/community education
- Antibiotics—azithromycin
- Surgical correction (where relevant)

## § Blocked nasolacrimal duct

Delayed development of the nasolacrimal duct occurs in about 6% of infants,<sup>7</sup> resulting in blocked lacrimal drainage; the lacrimal sac becomes infected, causing a persistent discharge from one or both eyes. In the majority of infants, spontaneous resolution of the problem occurs by the age of 6 months.

### Management

- Local antibiotics for infective episodes
- Bathing with normal saline
- Frequent massage over the lacrimal sac
- Referral for probing of the lacrimal passage before 6 months if the discharge is profuse and irritating or between 6 and 12 months if the problem has not self-corrected (refer CHAPTER 91)

## Red eye in the elderly

In an elderly patient there is an increased possibility of acute glaucoma, uveitis and herpes zoster. Acute angle closure glaucoma should be considered in any

patient over the age of 50 presenting with an acutely painful red eye.

Eyelid conditions such as blepharitis, trichiasis, entropion and ectropion are more common in the elderly.

## ACUTE CONJUNCTIVITIS

Acute conjunctivitis is defined as an episode of conjunctival inflammation lasting less than 3 weeks.<sup>2</sup> The two major causes are infection (either bacterial or viral) and acute allergic or toxic reactions of the conjunctiva (see TABLE 51.2).

### Clinical features

- Diffuse hyperaemia of tarsal or bulbar conjunctivæ
- Absence of ocular pain, good vision, clear cornea
- Infectious conjunctivitis is bilateral (usually) or unilateral (depending on the cause), with a discharge, and a gritty or sandy sensation

## § Bacterial conjunctivitis

Bacterial infection may be primary, secondary to a viral infection or secondary to blepharitis.

### History

Purulent discharge with sticking together of eyelashes in the morning is typical. It usually starts in one eye and spreads to the other. There may be a history of contact with a person with similar symptoms. The organisms are usually picked up from contaminated fingers, face cloths or towels.

### Clinical features

- Gritty red eye
- Purulent discharge
- Clear cornea

### Examination

There is usually a bilateral mucopurulent discharge with uniform engorgement of all the conjunctival blood vessels and a non-specific papillary response (see FIG. 51.2). Fluorescein staining is negative.

### Causative organisms

These include:

- *Streptococcus pneumoniae*
- *Haemophilus influenzae*
- *Staphylococcus aureus*
- *Streptococcus pyogenes*
- *N. gonorrhoeae* (a hyperacute onset)
- *Pseudomonas aeruginosa*

Table 51.2 Major causes of a red eye

	Site of inflammation	Pain	Discharge	Vision	Photophobia	Pupil	Cornea	Ocular tension
<b>Bacterial conjunctivitis</b>	Conjunctiva, including lining of lids (usually bilateral)	Irritation—gritty	Purulent, lids stuck in the morning	Normal	No	Normal	Normal	Normal
<b>Viral conjunctivitis</b>	Conjunctiva, lining of lids often follicular (uni or bilateral)	Gritty	Watery	Normal	No	Normal	Normal	Normal
<b>Allergic (vernal) conjunctivitis</b>	Conjunctiva, papillary swellings on lid linings (bilateral)	Gritty—itching	Watery	Normal	No	Normal	Normal	Normal
<b>Contact hypersensitivity (dermato-conjunctivitis)</b>	Conjunctiva and eyelids Oedema	Itching	Watery	Normal—may be blurred	No	Normal	Normal	Normal
<b>Subconjunctival haemorrhage</b>	Beefy red area fading at edge (unilateral)	No	No	Normal	No	Normal	Normal	Normal
<b>Herpes simplex keratitis</b>	Unilateral—circumcorneal Dendritic ulcer	Yes—gritty	No, reflex lacrimation	Blurred, but variable, depends on site	Yes	Normal	Abnormal	Normal
<b>Corneal ulcer</b>	Unilateral—circumcorneal (exclude foreign body)	Yes	No, reflex lacrimation	Blurred, but variable, depends on site	Yes	Normal	Abnormal	Normal
<b>Scleritis/episcleritis</b>	Localised deep redness Tender area	Yes	No	Normal	No	Normal	Normal	Normal
<b>Acute uveitis/iritis</b>	Maximum around cornea	Yes—radiates to brow, temple, nose	No, reflex lacrimation	Blurred	Yes	Constricted, may be irregular	Normal	Normal or low
<b>Acute glaucoma</b>	Diffuse but maximum circumcorneal	Yes, severe with nausea and vomiting	No, reflex lacrimation	Haloed around lights	Yes	Dilated Absent light reflex	Hazy	Hard, elevated

**FIGURE 51.2** Acute bacterial conjunctivitis with mucopurulent discharge, no corneal stain

Diagnosis is usually clinical but a swab should be taken for smear and culture with:<sup>2</sup>

- hyperacute or severe purulent conjunctivitis
- prolonged infection
- neonates

### Management

Limit the spread by avoiding close contact with others, use of separate towels and good ocular hygiene.

#### Mild cases

Mild cases may resolve with saline irrigation of the eyelids and conjunctiva but may last up to 14 days if untreated.<sup>8</sup> An antiseptic eye drop such as propamidine isethionate 0.1% (Brolene) 1–2 drops, 6–8 hourly for 5–7 days can be used.

#### More severe cases

Chloramphenicol 0.5% eye drops, 1–2 hourly for 2 days,<sup>1</sup> decrease to 4 times a day for another 7 days (max. 10 days—cases of aplastic anaemia have been reported with long-term use).

Use also chloramphenicol 1% eye ointment each night or framycetin 0.5% eye drops 1–2 drops, every 1 to 2 hours for first 24 hours, decreasing to 8 hourly until discharge resolves for up to 7 days.

### Practice tip

Brick red eye—think of chlamydia.

### Specific organisms

- *Pseudomonas* and other coliforms: use topical gentamicin and tobramycin.
- *N. gonorrhoeae*: use appropriate systemic antibiotics.

- *Chlamydia trachomatis*—may be sexually transmitted. Shows a brick red follicular conjunctivitis with a stringy mucus discharge.

### § Viral conjunctivitis

The most common cause of this very contagious condition is adenovirus.

#### History

It is commonly associated with URIs and is the type of conjunctivitis that occurs in epidemics (pink eye).<sup>1</sup> The conjunctivitis usually has a 2–3 week course; it is initially one-sided but with cross-infection occurring days later in the other eye. It can be a severe problem with a very irritable, watering eye.

#### Examination

The examination should be conducted with gloves. It is usually bilateral with diffuse conjunctival infection and productive of a scant watery discharge. Viral infections typically but not always produce a follicular response in the conjunctivae (tiny, pale lymphoid follicles) and an associated pre-auricular lymph node (see FIG. 51.3). Subconjunctival haemorrhages may occur with adenovirus infection. High magnification, ideally a slit lamp, may be necessary to visualise some of the changes, such as small corneal opacities, follicles and keratitis.

**FIGURE 51.3** Viral conjunctivitis: watery eye, lid swelling, typical eyelid follicles, associated local lymphadenopathy

Diagnosis is based on clinical grounds and a history of infected contacts. Viral culture and serology can be performed to identify epidemics.

#### Treatment

- Limit cross-infection by appropriate rules of hygiene and patient education.

- Treatment is symptomatic—cool compress and topical lubricants (artificial tear preparations), naphazoline (e.g. Albalon), vasoconstrictors (e.g. phenylephrine) or saline bathing.
- Do not pad; avoid bright light.
- Watch for secondary bacterial infection. Avoid corticosteroids, which reduce viral shedding and prolong the problem.

### § Primary herpes simplex infection

This viral infection produces a follicular conjunctivitis. About 50% of patients have associated lid or corneal ulcers/vesicles which are diagnostic.<sup>2</sup> Only a minority (less than 15%) develop corneal involvement with the primary infection.

Dendritic ulceration highlighted by fluorescein staining is diagnostic (see FIG. 51.4). Antigen detection or culture may allow confirmation.

#### Treatment (herpes simplex keratitis)

- Attend to eye hygiene
- Aciclovir 3% ointment, 5 times a day for 14 days or for at least 3 days after healing<sup>8</sup>
- Atropine 1% 1 drop, 12 hourly, for the duration of treatment will prevent reflex spasm of the pupil (specialist supervision)
- Debridement by a consultant

FIGURE 51.4 Herpes simplex keratitis—gritty, watery eye with typical dendritic ulcer, stained with fluorescein

### § Chlamydial conjunctivitis

Chlamydial conjunctivitis is encountered in three common situations:

- neonatal infection (first 1–2 weeks)
- young patient with associated venereal infection
- isolated Aboriginal people with trachoma

Take swabs for culture and PCR testing.  
Systemic antibiotic treatment:<sup>8</sup>

neonates: erythromycin for 3 weeks  
children over 6 kg and adults: azithromycin 1 g (o) as single dose

*Note:* Partner must be treated in cases of STI.

## ALLERGIC CONJUNCTIVITIS

Allergic conjunctivitis results from a local response to an allergen. It includes:

- vernal (hay fever) conjunctivitis, and
- contact hypersensitivity reactions, e.g. reaction to preservatives in drops

### § Vernal (hay fever) conjunctivitis

This is usually seasonal and related to pollen exposure. There is usually associated rhinitis (see CHAPTER 80).

#### Treatment

Tailor treatment to the degree of symptoms. Antihistamines may be required but symptomatic measures usually suffice.

Treatment options:

- 1 Topical antihistamines/vasoconstrictors
- 2 Mast cell stabilisers, e.g. sodium cromoglycate 2% drops, 1–2 drops per eye 4 times daily or ketotifen
- 3 Combination of 1 and 2
- 4 Topical steroids (severe cases)

Artificial tear preparations may give adequate symptomatic relief.

### § Contact hypersensitivity

Common topical allergens and toxins include topical ophthalmic medications, especially antibiotics, contact lens solutions (often the contained preservative) and a wide range of cosmetics, soaps, detergents and chemicals. Clinical features include burning, itching and watering with hyperaemia and oedema of the conjunctiva and eyelids. A skin reaction of the lids usually occurs.

#### Treatment

- Withdraw the causative agent.
- Apply normal saline compresses.
- Treat with naphazoline or phenylephrine.
- If not responding, refer for possible corticosteroid therapy.

## § Subconjunctival haemorrhage

Subconjunctival haemorrhage, which appears spontaneously, is a beefy red localised haemorrhage with a definite posterior margin (see Fig. 51.5). If it follows trauma and extends backwards it may indicate an orbital fracture. It is usually caused by a sudden increase in intrathoracic pressure such as coughing and sneezing. It is not related to hypertension but it is worthwhile measuring the blood pressure to help reassure the patient.

**FIGURE 51.5** Subconjunctival haemorrhage: this is usually localised haemorrhage that appears spontaneously. It is pain free. If traumatic and extends posteriorly it may indicate an orbital fracture.

51

## Management

No local therapy is necessary. The haemorrhage absorbs over 2 weeks. Patient explanation and reassurance is necessary. If haemorrhages are recurrent a bleeding tendency should be excluded.

## § Episcleritis and scleritis

Episcleritis and scleritis present as a localised area of inflammation (see FIGS 51.1 and 51.6). The episclera is a vascular layer that lies just beneath the conjunctiva and adjacent to the sclera. Both may become inflamed but episcleritis (which is more localised) is essentially self-limiting while scleritis (which is rare) is more serious as the eye may perforate.<sup>3</sup> Both conditions may be confused with inflammation associated with a foreign body, pterygium or pinguecula. There are no significant associations with episcleritis, which is usually idiopathic, but scleritis may be associated with connective tissue disease, especially rheumatoid arthritis and herpes zoster and rarely sarcoidosis and tuberculosis.

## Clinical features

Episcleritis:

- no discharge
- no watering
- vision normal (usually)
- often sectorial
- usually self-limiting

Treat with topical or oral steroids.

Scleritis:

- painful loss of vision
- urgent referral

## History

A red and sore eye is the presenting complaint. There is usually no discharge but there may be reflex lacrimation. Scleritis is much more painful than episcleritis<sup>3</sup> and the eye becomes intensely red.

## Examination

With scleritis there is a localised area of inflammation that is tender to touch (FIG. 51.6), and more extensive than with episcleritis, being uniform across the eye. The inflamed vessels are larger than the conjunctival vessels.

**FIGURE 51.6** Episcleritis showing inflammation of the conjunctival and episcleral tissue only. Note the absence of violaceous colour that is seen in scleritis.

## Management

An underlying cause such as an autoimmune condition should be identified. Refer the patient, especially for scleritis. Corticosteroids or NSAIDs may be prescribed.

## § Uveitis (iritis)

The iris, ciliary body and the choroid form the uveal tract, which is the vascular coat of the eyeball.<sup>7</sup>

Anterior uveitis (acute iritis or iridocyclitis) is inflammation of the iris and ciliary body and this is usually referred to as acute iritis (see FIG. 51.7). The iris is sticky and sticks to the lens. The pupil may become small because of adhesions, and the vision is blurred.

FIGURE 51.7 Diagrammatic representation of eye structures involved in inflammatory disorders

Causes include autoimmune-related diseases such as the seronegative arthropathies (e.g. ankylosing spondylitis), SLE, IBD, sarcoidosis and some infections (e.g. toxoplasmosis and syphilis).

### Clinical features

- Eye redness, esp. around edge of iris
- Eye discomfort or pain
- Increased tearing
- Blurred vision
- Sensitivity to light
- Floaters in the field of vision
- Small pupil

The examination findings are summarised in TABLE 51.2. The affected eye is red with the injection being particularly pronounced over the area covering the inflamed ciliary body (ciliary flush). However, the whole bulbar conjunctivae can be injected. The patient should be referred to a consultant. Slit lamp examination aids diagnosis.

Management involves finding the underlying cause. Treatment includes pupil dilatation with atropine drops and topical steroids to suppress inflammation. Systemic corticosteroids may be necessary. The prognosis of anterior uveitis is good if treatment and follow-up are maintained, but recurrence is likely.

Posterior uveitis (choroiditis) may involve the retina and vitreous. Blurred vision and floating opacities in the visual field may be the only symptoms. Pain is not a feature. Referral to detect the causation and for treatment is essential.

## § Acute glaucoma

Acute glaucoma should always be considered in a patient over 50 years presenting with an acutely painful red eye. Permanent damage will result from misdiagnosis. The attack characteristically strikes in the evening when the pupil becomes semidilated.<sup>3</sup>

### Clinical features

- Patient >50 years
- Pain in one eye
- ± Nausea and vomiting
- Impaired vision
- Haloes around lights
- Hazy cornea
- Fixed semidilated pupil
- Eye feels hard

### Management

Urgent ophthalmic referral is essential since emergency treatment is necessary to preserve eyesight. If immediate specialist attention is unavailable, treatment can be initiated with acetazolamide (Diamox) 500 mg IV and pilocarpine 4% drops to constrict the pupil or pressure-lowering drops.

## § Keratoconjunctivitis sicca

Dry eyes are a common problem, especially in elderly women. Lack of lacrimal secretion can be functional (e.g. ageing), or due to systemic disease (e.g. rheumatoid arthritis, SLE, Sjögren syndrome), drugs (e.g.  $\beta$ -blockers) or other factors, including the menopause. Up to 50% of patients with severe dry eye have Sjögren syndrome.

### Clinical features

- A variety of symptoms
- Dryness, grittiness, stinging and redness

- Sensation of foreign body (e.g. sand)
- Photophobia if severe
- Slit light examination diagnostic with special stains

### Treatment

- Treat the cause.
- Bathe eyes with clean water.
- Use artificial tears: hypromellose (e.g. Tears Naturale), polyvinyl alcohol (e.g. Tears Plus).
- Be cautious of adverse topical reactions.
- Refer severe cases.

## EYELID AND LACRIMAL DISORDERS

There are several inflammatory disorders of the eyelid and lacrimal system that present as a 'red and tender' eye without involving the conjunctiva. Any suspicious lesion should be referred.

### § Styte (external hordeolum)

A styte is an acute abscess of a lash follicle or associated glands of the anterior lid margin, caused usually by *S. aureus*. The patient complains of a red tender swelling of the lid margin, usually on the medial side (see FIG. 51.8). A styte may be confused with a chalazion, orbital cellulitis or dacryocystitis.

FIGURE 51.8 Hordeolum—a styte. This is a focal staphylococcal infection of the root of an eyelash.

### Management

- Use heat to help it discharge by using direct steam from a thermos (see FIG. 51.9) onto the enclosed eye or by hot compresses.
- Perform lash epilation to allow drainage of pus (incise with a size 11 blade if epilation does not work).
- Use chloramphenicol ointment if the infection is spreading locally.<sup>3</sup>

FIGURE 51.9 Steaming the painful eye: allow steam to rise from a thermos onto the closed eye for 10–15 minutes

### § Chalazion (meibomian cyst)

Also known as internal hordeolum, this granuloma of the meibomian gland in the eyelid may become inflamed and present as a tender irritating lump in the lid. Look for evidence of blepharitis. Differential diagnoses include sebaceous gland carcinoma and basal cell carcinoma.

### Management

Conservative treatment may result in resolution. This involves heat either as steam from a thermos or by applying a hot compress (a hand towel soaked in hot water) followed by light massage and the application of chloramphenicol ointment for 5 days. If the chalazion is very large, persistent or uncomfortable, or is affecting vision, it can be incised and curetted under local anaesthesia. This is best performed through the inner conjunctival surface using a chalazion clamp (blepharostat) (see FIG. 51.10).

Meibomianitis is usually a staphylococcal micro-abscess of the gland and oral antistaphylococcal antibiotics (not topical) are recommended (e.g. dicloxacillin 500 mg (o) 6 hourly (adult)). Surgical incision and curettage may also be necessary.

### § Blepharitis

This common chronic condition is characterised by inflammation of the lid margins and is commonly associated with secondary ocular effects such as styes, chalazia and conjunctival or corneal ulceration (see FIG. 51.11). Blepharitis is frequently associated with seborrhoeic dermatitis (especially) and atopic

**FIGURE 51.10** Excision of a meibomian cyst, using a chalazion clamp and curette

**FIGURE 51.11** Blepharitis: common complicating features

dermatitis, and less so with rosacea.<sup>9</sup> There is a tendency to colonisation of the lid margin with *S. aureus*, which causes an ulcerative infection.

The three main types are:

- seborrhoeic blepharitis
- staphylococcal blepharitis
- blepharitis associated with rosacea

### Clinical features<sup>9</sup>

- Persistent sore eyes or eyelids
- Irritation, grittiness, burning, dryness and 'something in the eye' sensation
- Lid or conjunctival swelling and redness
- Crusts or scales around the base of the eyelids
- Discharge or stickiness, especially in morning
- Inflammation and crusting of the lid margins

### Management

- Eyelid hygiene is the mainstay of therapy. The crusts and other debris should be gently cleaned with a cotton wool bud dipped in a 1:10 dilution of baby shampoo or a solution of sodium bicarbonate, once or twice daily. Application of a warm water or saline soak with gauze for 20 minutes is also effective.
- For chronic blepharitis short-term use of a corticosteroid ointment (e.g. hydrocortisone 0.5%) can be very effective.
- Ocular lubricants such as artificial tear preparations may greatly relieve symptoms of keratoconjunctivitis sicca (dry eyes).
- Control scalp seborrhoea with regular medicated shampoos.
- Treat infection with an antibiotic ointment smeared on the lid margin (this may be necessary for several months) (e.g. tetracycline hydrochloride 1% or framycetin 0.5% or chloramphenicol 1% ointment to lid margins 3–6 hourly).<sup>8</sup>
- Systemic antibiotics such as flucloxacillin may be required for lid abscess.
- Avoid wearing make-up and contact lenses if inflammation is present.

### § Dacryocystitis

Acute dacryocystitis is infection of the lacrimal sac secondary to obstruction of the nasolacrimal duct at the junction of the lacrimal sac (see FIG. 51.12). Inflammation is localised over the medial canthus. There is usually a history of a watery eye for months beforehand. The problem may vary from being mild (as in infants) to severe with abscess formation.

### Management

- Use local heat: steam or a hot moist compress.
- Use analgesics.
- In mild cases, massage the sac and duct, and instil astringent drops (e.g. zinc sulfate + phenylephrine).
- For acute cases systemic antibiotics are best guided by results of Gram's stain and culture but initially use di/flucloxacillin or cephalexin.
- Measures to establish drainage are required eventually. Recurrent attacks or symptomatic watering of the eye are indications for surgery such as dacryocystorhinostomy.

**FIGURE 51.12** Acute dacryocystitis with abscess formation. Associated obstruction of the nasolacrimal duct at the junction of the lacrimal sac, which has become infected.

## Dacroadenitis

Dacroadenitis is infection of the lacrimal gland presenting as a tender swelling on the outer upper margin of the eyelid. It may be acute or chronic and has many causes. It is usually caused by a viral infection (e.g. mumps), which is treated conservatively with warm compresses. Bacterial infection is treated with appropriate antibiotics.

## § Orbital cellulitis

Orbital cellulitis includes two basic types—peri-orbital (or preseptal) and orbital (or postseptal) cellulitis. The latter is a potentially blinding and life-threatening condition. It is especially important in children in whom blindness may develop in hours. The patient, often a child, presents with unilateral swollen eyelids that may be red. Ask about a history of sinusitis, peri-ocular trauma, surgery, bites and immunocompromise.

Features to look for in orbital cellulitis include:<sup>3</sup>

- a systemically unwell patient
- proptosis
- peri-ocular swelling and erythema
- tenderness over the sinuses
- ocular nerve compromise (reduced vision, impaired colour vision or abnormal pupils)
- restricted and painful eye movements (see FIG. 51.13)

In peri-orbital cellulitis, which usually follows an abrasion, there is no pain or restriction of eye movement (see FIG. 51.14).

Immediate referral to hospital for specialist treatment is essential for both types. Treatment is

**FIGURE 51.13** Important signs in the patient presenting with orbital cellulitis

**FIGURE 51.14** Peri-orbital cellulitis following an abrasion to the eye. Treat this as an urgent condition.

with IV cefotaxime until afebrile, then amoxycillin/clavulanate for 7–10 days for peri-orbital cellulitis and for orbital cellulitis, IV cefotaxime + di(fl)u cloxacillin together followed by amoxycillin/clavulanate (o) 10 days.<sup>8</sup>

## § Herpes zoster ophthalmicus

Herpes zoster ophthalmicus (shingles) affects the skin supplied by the ophthalmic division of the trigeminal nerve. The eye may be affected if the nasociliary branch is involved. Ocular problems include conjunctivitis, uveitis, keratitis and glaucoma.

Immediate referral is necessary if the eye is red, vision is blurred or the cornea cannot be examined. Apart from general eye hygiene, treatment usually

includes one of the oral anti-herpes virus agents such as oral aciclovir 800 mg, 5 times daily for 10 days or (if sight is threatened) aciclovir 10 mg/kg IV slowly 8 hourly for 10 days (provided this is commenced within 3 days of the rash appearing)<sup>5,8</sup> and topical aciclovir ointment 4 hourly (see CHAPTER 124).

### § Pinguecula and pterygium<sup>10</sup>

Pinguecula is a yellowish elevated nodular growth on either side of the cornea in the area of the palpebral fissure. It is common in people over 35 years. The growth tends to remain static but can become inflamed—pingueculitis. Usually no treatment is necessary unless they are large, craggy and uncomfortable, when excision is indicated. If irritating, topical astringent drops such as naphazoline compound drops (e.g. Albalon) can give relief.

Pterygium is a fleshy overgrowth of the conjunctiva onto the nasal side of the cornea and usually occurs in adults living in dry, dusty, windy areas. Excision of a pterygium by a specialist is indicated if it is likely to interfere with vision by encroaching on the visual axis, or if it becomes red and uncomfortable or disfiguring.

## CORNEAL DISORDERS<sup>11</sup>

Patients with corneal conditions typically suffer from ocular pain or discomfort and reduced vision. The common condition of dry eye may involve the cornea while contact lens disorders, abrasions/ulcers and infection are common serious problems that threaten eyesight. Inflammation of the cornea—keratitis—is caused by factors such as UV light, e.g. ‘arc eye’, herpes simplex, herpes zoster ophthalmicus and the dangerous microbial keratitis. Bacterial keratitis is an ophthalmological emergency which should be considered in the contact lens wearer presenting with pain and reduced vision.

Topical corticosteroids should be avoided in the undiagnosed red eye.

### § Corneal abrasion and ulceration

There are many causes of abrasions, particularly trauma from a foreign body embedded on the corneal surface or ‘cul-de-sac’ FB, contact lenses, fingernails including ‘french nails’, and UV burns. The abrasion may be associated with an ulcer, which is a defect in the epithelial cell layer of the cornea. Common causes of a corneal ulcer are listed in TABLE 51.3.

**Table 51.3** Corneal ulceration: common causes

Trauma
Contact lens wear/injury
Infection—microbial keratitis:
• bacterial (e.g. <i>Pseudomonas</i> [contact lens])
• viral (e.g. herpes simplex [dendritic ulcer], herpes zoster ophthalmicus)
• fungal
• protozoal (e.g. <i>Acanthamoeba</i> )
Neurotrophic (e.g. trigeminal nerve defect)
Immune related (e.g. rheumatoid arthritis)
Spontaneous corneal erosion
Chronic blepharitis
Overexposure (e.g. eyelid defects)

### Symptoms

- Ocular pain
- Foreign body sensation
- Watering of the eye (epiphoria)
- Blepharospasm
- Blurred vision

Diagnosis is best performed with a slit lamp using a cobalt blue filter and fluorescein staining.

### Management (corneal ulcer)

- Stain with fluorescein.
- Check for a foreign body.
- Treat with chloramphenicol 1% ointment ± homatropine 2% (if pain due to ciliary spasm).
- Double eye pad (if not infected).
- Review in 24 hours.
- A 6 mm defect heals in 48 hours.
- Consider specialist referral.

### § Superficial punctate keratitis

Punctate keratopathy presents as scattered small lesions on the cornea which stain with fluorescein if they are deep enough. It is a non-specific finding and may be associated with blepharitis, viral conjunctivitis, trachoma, keratitis sicca (dry eyes),

### Practice tips

- Think corneal abrasion if the eye is ‘watering’ and painful (e.g. caused by a large insect like a grasshopper or other foreign body)
- If a slit lamp is unavailable, the direct ophthalmoscope can be used to provide illumination as well as blue light for corneal examination. Magnifying loupes can then be used for viewing the illuminated cornea.

UV light exposure (e.g. welding lamps, sunlamps), contact lenses and topical ocular agents. Management involves treating the cause and careful follow-up.

### § Microbial keratitis

This is responsible for at least 1.5 million new cases of blindness every year in the developing world and for significant morbidity in developed countries.

#### Risk factors

- Contact lens wear
- Corneal trauma, especially agriculture trauma
- Corneal surgery
- Post-herpetic corneal lesion
- Dry eye
- Corneal anaesthetic
- Corneal exposure (e.g. VII nerve lesion)
- Ocular surface disease including ulceration

*Pseudomonas aeruginosa* is the most common causative organism in contact lens wearers.

*Acanthamoeba* is associated with bathing or washing in contaminated water.

Urgent referral to an ophthalmologist or eye clinic is needed to avoid rapid corneal destruction with perforation especially with bacterial keratitis. An appropriate 'covering' topical antibiotic is ciprofloxacin 0.3% ointment.

### § Problems with contact lenses

Because a contact lens is a foreign body, various complications can develop and a history of the use of contact lenses is important in the management of the red eye.

#### Infection

Infection is more likely to occur with soft rather than hard lenses. They should not be worn for sleeping since this increases the risk of infection 10-fold.<sup>12</sup> One cause is *Acanthamoeba* keratitis acquired from contaminated water that may be used for cleaning the lenses.

#### Hard lens trauma

This may cause corneal abrasions with irreversible endothelial changes or ptosis, especially with the older polymethyl-methacrylate-based lenses. Patients should change to modern gas permeable hard lenses.

#### Lost lenses

Patients should be reassured that lenses cannot go behind the eye. The edge of the lens can usually be seen by everting the upper lid.

### Preventive measures<sup>13</sup>

- Wash hands before handling lenses.
- Do not use tap water or saline.
- Clean lenses with disinfecting solution.
- Store overnight in a clean airtight case with fresh disinfectant.
- Change the lens container solution daily.
- Discard disposable lenses after 2 weeks.
- Do not wear lenses while sleeping.
- Do not wear lenses while swimming in lakes, rivers or swimming pools.

Refer to an ophthalmologist if a painful red eye develops, especially if a discharge is present.

### § Flash burns

A common problem, usually presenting at night, is bilateral painful eyes caused by UV 'flash burns' to both corneas some 5–10 hours previously. The mechanism of injury is UV rays from a welding machine causing superficial punctate keratitis. Other sources of UV light such as sunlamps and snow reflection can cause a reaction.

#### Management

- Local anaesthetic (long-acting) drops: once-only application (do not allow the patient to take home more drops).
- Instil homatropine 2% drops statim or other short-acting ocular dilating agent (be careful of glaucoma).
- Use analgesics (e.g. codeine plus paracetamol) for 24 hours.
- Use broad spectrum antibiotic eye ointment in lower fornix (to prevent infection).
- Use firm eye padding for 24 hours, when eyes reviewed (avoid light).

The eye usually heals completely in 48 hours. If not, check for a foreign body.

*Note:* Contact lens 'overwear syndrome' gives the same symptoms.

### § Cavernous sinus arteriovenous fistula

Such a fistula produces conjunctival hyperaemia but no inflammation or discharge. The lesion causes raised orbital venous pressure. The fistula may be secondary to head injuries or may arise spontaneously, particularly in postmenopausal women. They need radiological investigation.

The classic symptom is a 'whooshing' sound synchronous with the pulse behind the eye, and the sign is a bruit audible with the stethoscope placed over the orbit.

## § Penetrating eye injuries

These require urgent referral to an ophthalmologist.

Consider:

- X-ray
- tetanus prophylaxis
- transport by land
- injection of anti-emetic (e.g. metoclopramide)

Use no ointment or eye drops, including local anaesthetic.

If significant delay is involved give one dose (in adults) of:<sup>8</sup>

gentamicin 1.5 mg/kg IV plus  
cefotaxime 1 g or ceftriaxone 1 g IV (can give  
ceftriaxone IM but with lignocaine 1%)  
or  
vancomycin IV + oral ciprofloxacin

## § Endophthalmitis

This is an intra-ocular bacterial infection which may complicate any penetrating injury including intra-ocular surgery. It should be considered in patients with such a history presenting with a red painful eye. Pus may be seen in the anterior chamber (hypopyon).

Urgent referral is mandatory. If significant delay, use ciprofloxacin (o) + vancomycin IV.<sup>8</sup>

## When to refer

- Uncertainty about the diagnosis
- Patients with uveitis, acute glaucoma, episcleritis/scleritis or corneal ulceration
- Deep central corneal and intra-ocular foreign bodies
- Prolonged infections, with a poor or absent response to treatment or where therapy may be complicating management
- Infections or severe allergies with possible ocular complications
- Sudden swelling of an eyelid in a child with evidence of infection suggestive of orbital cellulitis—this is an emergency

- Emergency referral is also necessary for hyphaema, hypopyon, penetrating eye injury, acute glaucoma, severe chemical burn
- Herpes zoster ophthalmicus: if the external nose is involved then the internal eye may be involved
- Summary for urgent referral:
  - trauma (significant)/penetrating injury
  - hyphaema >3 mm
  - corneal ulcer
  - severe conjunctivitis
  - uveitis/acute iritis
  - Behçet syndrome
  - acute glaucoma
  - giant cell arteritis
  - orbital cellulitis (pre- and post-)
  - acute dacryocystitis
  - keratitis
  - episcleritis/scleritis
  - endophthalmitis
  - herpes zoster ophthalmicus

*Note:* As a general rule never use corticosteroids or atropine in the eye before referral to an ophthalmologist.

## Practice tips

- Avoid long-term use of any medication, especially antibiotics (e.g. chloramphenicol: course for a maximum of 10 days).<sup>2</sup>  
*Note:* Beware of allergy or toxicity to topical medications, especially antibiotics, as a cause of persistent symptoms.
- As a general rule avoid using topical corticosteroids or combined corticosteroid/antibiotic preparations.
- Never use corticosteroids in the presence of a dendritic ulcer.
- To achieve effective results from eye ointment or drops, remove debris such as mucopurulent exudate with bacterial conjunctivitis or blepharitis by using a warm solution of saline (dissolve a teaspoon of kitchen salt in 500 mL of boiled water) to bathe away any discharge from conjunctiva, eyelashes and lids.
- A gritty sensation is common in conjunctivitis but the presence of a foreign body must be excluded.<sup>3</sup>
- Beware of the contact lens 'overwear syndrome', which is treated in a similar way to flash burns.

### Red eye golden rules

- Always test and record vision
- Beware of the unilateral red eye
- Conjunctivitis is almost always bilateral
- Irritated eyes are often dry
- Never use steroids if herpes simplex is suspected
- A penetrating eye injury is an emergency
- Consider an intra-ocular foreign body
- Beware of herpes zoster ophthalmicus if the nose is involved
- Irregular pupils: think iritis, injury and surgery
- Never pad a discharging eye
- Refer patients with eyelid ulcers
- If there is a corneal abrasion look for a foreign body

Patient (Anonymous), describing 'tic douloureux'

When a patient complains of pain in the face rather than the head, the physician has to consider foremost the possibilities of dental disorders, sinus disease, especially of the maxillary sinuses, temporomandibular Joint (TMJ) dysfunction, eye disorders, lesions of the oropharynx or posterior third of the tongue, trigeminal neuralgia and chronic paroxysmal hemicrania.

The key to the diagnosis is the clinical examination because even the most sophisticated investigation may provide no additional information.

A basic list of causes of facial pain is presented in **TABLE 52.1**.<sup>1</sup> The causes can vary from the simple, such as aphthous ulcers, herpes simplex and dental caries, to serious causes, such as carcinoma of the tongue, sinuses and nasopharynx or osteomyelitis of the mandible or maxilla.

## Key facts and checkpoints

- Dental disorders are the commonest cause of facial pain, accounting for up to 90% of pain in and about the face.<sup>2</sup>
- The most common dental disorders are dental caries and periodontal diseases.
- The mean age of onset of trigeminal neuralgia is 50–52 years.
- There is a similarity in the 'occult' causes of pain in the ear and in the face (refer to **FIGS 50.4** and **50.5**).
- Sinusitis occurs mainly as part of a generalised upper respiratory infection. Swimming is another common predisposing factor.
- Dental root infection must be sought in all cases of maxillary sinusitis.

## A diagnostic approach

A summary of the diagnostic strategy model is presented in **TABLE 52.2**.

## Probability diagnosis

The commonest cause of facial pain is dental disorders, especially dental caries. Another common cause is sinusitis, particularly maxillary sinusitis.

**Table 52.1** Diagnoses to consider in orofacial pain

Positive physical signs
Cervical spinal dysfunction
Dental pathology
Erysipelas
Eye disorders
Herpes zoster
Nasopharyngeal cancer
Oropharyngeal disorders: <ul style="list-style-type: none"> <li>• ulceration (aphthous, infective, traumatic, others)</li> <li>• cancer</li> <li>• gingivitis/stomatitis</li> <li>• tonsillitis</li> <li>• erosive lichen planus</li> </ul>
Paranasal sinus disorders
Parotid gland: <ul style="list-style-type: none"> <li>• mumps</li> <li>• sialectasis</li> <li>• cancer</li> <li>• pleomorphic adenoma</li> </ul>
TMJ dysfunction
Temporal arteritis
Absent physical signs
Atypical facial pain
Chronic paroxysmal hemicrania
Depression-associated facial pain
Facial migraine (lower half headache)
Glossopharyngeal neuralgia
Migrainous neuralgia (cluster headache)
Trigeminal neuralgia (tic douloureux)

TMJ dysfunction causing TMJ arthralgia is a very common problem encountered in general practice and it is important to have some simple basic strategies to give the patient.

**Table 52.2** Pain in the face: diagnostic strategy model

Q. Probability diagnosis
A. Dental pain: <ul style="list-style-type: none"> <li>• caries</li> <li>• periapical abscess</li> <li>• fractured tooth</li> </ul> Maxillary/frontal sinusitis TMJ dysfunction
Q. Serious disorders not to be missed
A. Cardiovascular: <ul style="list-style-type: none"> <li>• myocardial ischaemia</li> <li>• aneurysm of cavernous sinus</li> <li>• internal carotid aneurysm</li> <li>• ischaemia of posterior inferior cerebellar artery</li> </ul> Neoplasia: <ul style="list-style-type: none"> <li>• cancer: mouth, sinuses, nasopharynx, tonsils, tongue, larynx</li> <li>• metastases: orbital, base of brain, bone</li> </ul> Severe infections: <ul style="list-style-type: none"> <li>• herpes zoster</li> <li>• erysipelas</li> <li>• periapical abscess → osteomyelitis</li> <li>• acute sinusitis → spreading infection</li> </ul> Temporal arteritis
Q. Pitfalls (often missed)
A. TMJ dysfunction Migraine variants: <ul style="list-style-type: none"> <li>• facial migraine</li> <li>• chronic paroxysmal hemicrania</li> </ul> Eye disorders: <ul style="list-style-type: none"> <li>• glaucoma</li> <li>• iritis</li> <li>• optic neuritis</li> </ul> Chronic dental neuralgia Salivary gland: <ul style="list-style-type: none"> <li>infection, calculus, obstruction, cancer</li> </ul> Acute glaucoma (upper face) Cranial nerve neuralgias: <ul style="list-style-type: none"> <li>• trigeminal neuralgia</li> <li>• glossopharyngeal neuralgia</li> </ul>
Q. Seven masquerades checklist
A. Depression Spinal dysfunction (cervical spondylosis)
Q. Is the patient trying to tell me something?
A. Quite probably. Atypical facial pain has underlying psychogenic elements.

### Red flag pointers for pain in the face

- Persistent pain: no obvious cause
- Unexplained weight loss
- Trigeminal neuralgia: possible serious cause
- Herpes zoster involving nose
- Person >60 years: consider temporal arteritis, malignancy

### Serious disorders not to be missed

It is important not to overlook cancer of various structures, such as the mouth, sinuses, nasopharynx, tonsils, tongue, larynx and parotid gland, which can present with atypical chronic facial pain.

It is important therefore to inspect these areas, especially in the elderly, but lesions in the relatively inaccessible nasopharynx can be easily missed. Nasopharynx cancer spreads upwards to the base of the skull early and patients can present with multiple cranial nerve palsies before either pain or bloody nasal discharge.<sup>1</sup>

Tumours may arise in the bones of the orbit, for example, lymphoma or secondary cancer, and may cause facial pain and proptosis. Similarly, any space-occupying lesion or malignancy arising from the region of the orbit or base of the brain can cause facial pain by involvement (often destruction) of trigeminal sensory fibres. This will lead to a depressed ipsilateral corneal reflex.

Also, aneurysms developing in the cavernous sinus<sup>1</sup> can cause pain via pressure on any of the divisions of the trigeminal nerve, while aneurysms from the internal carotid arising from the origin of the posterior communicating artery can cause pressure on the oculomotor nerve.

Temporal arteritis typically causes pain over the temporal area but can cause ischaemic pain in the jaws when chewing.

### Pitfalls

Commonly overlooked causes of facial pain include TMJ arthralgia and dental disorders, especially of the teeth, which are tender to percussion, and oral ulceration. Diagnosing the uncommon migraine variants, particularly facial migraine and chronic paroxysmal hemicrania, often presents difficulties, including differentiating between the neuralgias. Glossopharyngeal neuralgia, which is rare, causes pain in the back of the throat, around the tonsils and adjacent fauces. The lightning quality of the pain of neuralgia gives the clue to diagnosis.

### Common pitfalls

- Failing to refer unusual or undiagnosed causes of facial pain
- Overlooking infective dental causes, which can cause complications
- Failing to consider the possibility of malignant disease of 'hidden' structures in the older patient

### Seven masquerades checklist

Of these, depression and cervical spinal dysfunction must be considered. The upper cervical spine can cause facial pain from lesions of C2 or C3 via the lesser occipital or greater auricular (see FIG. 52.1) nerves, which may give pain around the ear. It is important to remember that the C2 and C3 nerves share a common pathway with the trigeminal nerve (see CHAPTER 62).

FIGURE 52.1 Dermatomes of C2 and C3, with the overlap area indicated

Depressive illness can present with a variety of painful syndromes and facial pain is no exception. The features of depression may be apparent and thus antidepressants should be prescribed. Usually the facial pain and the depression subside concomitantly.

### Psychogenic considerations

Psychogenic factors have to be considered in every painful condition. They are considered to be high in patients with atypical facial pain.

## The clinical approach

### History

Diagnosis of nearly all types of facial pain must be based almost entirely on the history. It is often difficult to delineate the exact nature and distribution of the pain. The history should include the typical analysis of pain, especially noting the site and radiation of the pain.

### Examination

The patient's general state and behaviour should be noted. Any sudden jabbing pain in the face causing the characteristic 'tic' may indicate neuralgia.

Palpate the face and neck to include the parotid glands, eyes, regional lymph nodes and the skin. Inspect the TMJs and cervical spine. Carefully inspect the nose, mouth, pharynx and postnasal space. In particular inspect the teeth, percussing each tooth if dental disorder is suspected. Bimanual palpation of the floor of the mouth is performed to detect induration or submandibular and submental lymph node enlargement.

The sinuses, especially the maxillary sinuses, should be inspected and a torch light should be placed inside the mouth to test transillumination of the maxillary sinuses. It works best when one symptomatic side can be compared with an asymptomatic side.

Perform a neurological examination on the cranial nerves with special emphasis on the trigeminal, oculomotor and glossopharyngeal nerves.

### Investigations

If investigations are being contemplated referral may be appropriate. The association of multiple sclerosis and tumours with neuralgias may have to be investigated. Radiological investigations include plain X-rays of the paranasal sinuses, CT scans, MRI and orthopantomograms.

### Facial pain in children

Apart from trauma, facial pain in children is almost invariably due to dental problems, rarely migraine variants and occasionally childhood infections such as mumps and gingivostomatitis. A serious problem sometimes seen in children is orbital cellulitis secondary to ethmoiditis.

Sinusitis occurs in children, especially older children, and it should be suspected with persistent bilateral mucopurulent rhinorrhoea (beyond 10 days).

## Facial pain in the elderly

Many of the causes of facial pain have an increased incidence with age, in particular trigeminal neuralgia, herpes zoster, cancer, glaucoma, TMJ dysfunction and cervical spondylosis. Glossopharyngeal neuralgia does not seem to have a particular predilection for the elderly. Xerostomia due to decreased secretions of salivary glands may cause abrasion with minor trauma. It may aggravate the pain of glossitis, which is common in the elderly.

## DENTAL DISORDERS

### Dental caries

Dental caries, impacted teeth, infected tooth sockets and dental roots can cause pain in the maxillary and mandibular regions. Caries with periapical and apical abscess formation produce pain from infection extending around the apex of the tooth into the alveolar bone. Retention of a fractured root may cause unilateral paroxysmal pain. Impacted third molars (wisdom teeth) may be associated with surrounding soft tissue inflammation (pericoronitis), causing pain that may be localised to the mandible or radiate via the auriculotemporal nerve to the ear. *Candida albicans*, which is an oral commensal, may colonise dentures causing hyperaemia and painful superficial ulceration of the denture-bearing mucosa.

### Features of dental caries

- Pain is usually confined to the affected tooth but it may be diffuse.
- Pain is almost always aggravated by thermal changes in the mouth:
  - cold—if dental pulp vital
  - hot—if dental pulp is necrotic
- Pain may be felt in more than one tooth.
- Dental pain will not cross the midline.

### Treatment of dental pain

- Arrange urgent dental consultation
  - Pain relief:<sup>3</sup>
    - aspirin 600 mg (o), 4–6 hourly
    - or
    - paracetamol 0.5–1 g (o), 4–6 hourly
- If pain is severe add:
- codeine 30 mg (o), 4–6 hourly

## Tooth abscess, inflamed wisdom tooth or root canal infection<sup>4</sup>

Dental treatment will usually alleviate the problem; however, if severe:

amoxycillin 500 mg (o) tds for 5 days

If unresponsive:

amoxycillin/clavulanate 875/125 mg (o) bd  
(adjust to children's dose)

add metronidazole 400 mg (o) 12 hourly for 5 days

For patients hypersensitive to penicillin:

clindamycin 300–450 mg (o) 8 hourly for 5 days

## Gingivitis and periodontitis

Refer to CHAPTER 72.

## Alveolar osteitis (dry socket)

Refer for specialised toileting. This usually heals naturally in 14 days. Antibiotics are of no proven use (see FIG. 52.2).<sup>4</sup>

**FIGURE 52.2** Dry tooth socket: this is a very painful condition mainly in the lower molars unrelieved by analgesics following a tooth extraction 1–3 days earlier. The socket has few or no blood clots and sensitive bone surfaces covered by a greyish layer of necrotic tissue.

## § Ludwig angina

This is a rapidly swelling cellulitis occurring in both the sublingual and submaxillary spaces without abscess formation, often arising from a root canal infection. It resembles an abscess and should be treated as one. It is potentially life-threatening as it can compromise the airway.

### Management

- Culture and sensitivity testing
- Specialist consultation
- Empirical treatment:  
amoxycillin 2 g IV, 6 hourly  
plus  
metronidazole 500 mg IV, 12 hourly

### Pain from paranasal sinuses

Infection of the paranasal sinuses may cause localised pain. Localised tenderness and pain may be apparent with frontal or maxillary sinusitis. Sphenoidal or ethmoidal sinusitis causes a constant pain behind the eye or behind the nose, often accompanied by nasal blockage. Chronic infection of the sinuses may be extremely difficult to detect. The commonest organisms are *Streptococcus pneumoniae*, *Haemophilus influenzae* and *Moraxella catarrhalis*.

Expanding lesions of the sinuses, such as mucocoeles and tumours, cause local swelling and displace the contents of the orbit—upwards for maxillary, laterally for the ethmoids and downwards for the frontal.

### § Maxillary sinusitis

The maxillary sinus is the one most commonly infected.<sup>5</sup> It is important to determine whether the sinusitis is caused by stasis following a URTI or acute rhinitis, or due to dental root infection. Most episodes are of viral origin.

### Clinical features (acute sinusitis)

- Facial pain and tenderness (over sinuses)
- Toothache
- Headache
- Purulent postnasal drip
- Nasal discharge
- Nasal obstruction
- Rhinorrhoea
- Cough (worse at night)
- Prolonged fever
- Epistaxis

Suspect bacterial cause if high fever and purulent nasal discharge.

### Clinical features (chronic sinusitis)

- Vague facial pain
- Offensive postnasal drip
- Nasal obstruction
- Toothache

- Malaise
- Halitosis

### Some simple office tests

#### Diagnosing sinus tenderness<sup>6</sup>

To differentiate sinus tenderness from non-sinus bone tenderness palpation is useful. This is best done by palpating a non-sinus area first and last (see FIG. 52.3), systematically exerting pressure over the temporal bones (T), then the frontal (F), ethmoid (E) and maxillary (M) sinuses, and finally zygomas (Z), or vice versa.

FIGURE 52.3 Diagnosing sinus tenderness: T (temporal) and Z (zygoma) represent no sinus bony tenderness, for purposes of comparison

Differential tenderness both identifies and localises the main sites of infection (see FIG. 52.3).

#### Diagnosing unilateral sinusitis

A simple way to assess the presence or absence of fluid in the frontal sinus, and in the maxillary sinus (in particular), is the use of transillumination. It works best when one symptomatic side can be compared with an asymptomatic side.

It is necessary to have the patient in a darkened room and to use a small, narrow-beam torch. For the maxillary sinuses remove dentures (if any). Shine the light inside the mouth (with lips sealed), on either

side of the hard palate, pointed at the base of the orbit. A dull glow seen below the orbit indicates that the antrum is air-filled. Diminished illumination on the symptomatic side indicates sinusitis.

A CT scan may show mucosal thickening without fluid levels. Plain films are not indicated.

## Management (acute bacterial sinusitis)

### Principles

- Exclude dental root infection.
- Control predisposing factors.
- Use appropriate antibiotic therapy.
- Establish drainage by stimulation of mucociliary flow and relief of obstruction.

### Guidelines for antibiotic therapy

Consider therapy for severe cases displaying at least three of the following:

- persistent mucopurulent nasal discharge (>7–10 days)
- facial pain
- poor response to decongestants
- tenderness over the sinuses especially maxillary
- tenderness on percussion of maxillary molar and premolar teeth that cannot be attributed to by a single tooth

### Measures

- Analgesics
- Antibiotics:<sup>4</sup>  
amoxycillin 500 mg (o) tds for 7 days  
or (if sensitive to penicillin)  
doxycycline 100 mg (o) bd for 7 days  
or  
cefaclor 500 mg (o) tds for 7 days  
or  
amoxycillin + clavulanate 875/125 mg (o) tds for 7–14 days if poor response to above (indicates resistant *H. influenzae*)
- In complicated or severe disease, use intravenous cephalosporins or flucloxacillin
- Nasal decongestants (oxymetazoline-containing nasal drops or sprays)<sup>5</sup> for 5–10 days only if congestion
- Inhalations (a very important adjunct)
- Nasal saline irrigation

Antihistamines and mucolytics are of no proven value.

### Invasive methods

Surgical drainage may be necessary by atrial lavage or frontal sinus trephine.

## Inhalations for sinusitis

The old method of towel over the head and inhalation bowl can be used, but it is better to direct the vapour at the nose. Equipment needed is a container, which can be an old disposable bowl, a wide-mouthed bottle or tin, or a plastic container.

For the inhalant, several household over-the-counter preparations are suitable such as Friar's Balsam (5 mL), Vicks VapoRub (1 teaspoon), or menthol (5 mL).

The cover can be made from a paper bag (with its base cut out), a cone of paper or a small cardboard carton (with the corner cut away).

### Method

- 1 Add 5 mL or 1 teaspoon of the inhalant to 0.5 L (or 1 pint) of boiled water in the container.
- 2 Place the paper or carton over the container.
- 3 Get the patient to apply nose and mouth to the opening and breathe in the vapour deeply and slowly through the nose, and then out slowly through the mouth.
- 4 This should be performed for 5–10 minutes, three times a day, especially before retiring.

After inhalation, upper airway congestion can be relieved by autoinsufflation.

## § Chronic sinusitis

Chronic sinusitis or recurrent sinusitis may arise from chronic infection or allergy. It may be associated with nasal polyps and vasomotor rhinitis, but is frequently associated with a structural abnormality of the upper airways. Refer to **CHAPTER 59**.

It does not usually cause pain unless an acute infection intervenes. The acute or chronic attack is treated as for the acute attack but with 14 days of antibiotics. Those with an allergic mucous membrane may respond to intranasal corticosteroids. Surgical intervention will benefit chronic recurrence with mechanical blockage.

## § TMJ dysfunction

This condition is due to abnormal movement of the mandible, especially during chewing. The basic cause is dental malocclusion. The pain is felt over the joint and tends to be localised to the region of the ear and mandibular condyle but may radiate forwards to the cheek and even the neck.

### Examination

- Check for pain and limitation of mandibular movements, especially on opening the mouth.

- Palpate about the joint bilaterally for tenderness, which typically lies immediately in front of the external auditory meatus; palpate the temporalis and masseter muscles.
- Palpate the TMJ over the lateral aspect of the joint disc.
- Ask the patient to open the mouth fully when tenderness is maximal. The TMJ can be palpated posteriorly by inserting the little finger into the external canal.
- Check for crepitus in mandibular movement.

### Treatment

If organic disease such as rheumatoid arthritis and obvious dental malocclusion is excluded, a special set of instructions or exercises can alleviate the annoying problem of TMJ arthralgia in about 3 weeks.

#### Method 1: 'Chewing' the piece of soft wood

- Obtain a rod of soft wood approximately 15 cm long and 1.5 cm wide. An ideal object is a large carpenter's pencil.
- Instruct the patient to position this at the back of the mouth so that the molars grasp the object with the mandible thrust forward.
- The patient then rhythmically bites on the object with a grinding movement for 2–3 minutes at least 3 times a day.

#### Method 2: The 'six by six' program

This is a specific program recommended by some dental surgeons. The six exercises should be carried out six times on each occasion, six times a day, taking about 1–2 minutes.

Instruct the patient as follows:

- 1 Hold the front one-third of your tongue to the roof of your mouth and take six deep breaths.
- 2 Hold the tongue to the roof of your mouth and open your mouth six times. Your jaw should not click.
- 3 Hold your chin with both hands keeping the chin still. Without letting your chin move, push up, down and to each side. Remember, do not let your chin move.
- 4 Hold both hands behind your neck and pull chin in.
- 5 Push on upper lip so as to push head straight back.
- 6 Pull shoulders back as if to touch shoulder blades together.

These exercises should be pain-free. If they hurt, do not push them to the limit until pain eases.

## Treatments

### Injection into the TMJ<sup>7</sup>

- Indications: painful rheumatoid arthritis, osteoarthritis or TMJ dysfunction not responding to conservative measures. Inject a 1 mL solution of local anaesthetic and corticosteroid in equal parts.
- Dental management that may be required for malfunction of the bite includes dental occlusal splinting.
- NSAIDs: A trial of NSAIDs, e.g. ibuprofen 400 mg (o) tds for 10 days, for TMJ inflammation may need consideration. Cease if no response after 10 days.

## Inflammatory or ulcerative oropharyngeal lesions

A variety of ulcerative conditions and infections of structures such as gingivae, tongue, tonsils, larynx and pharynx can cause facial pain (refer to [CHAPTER 72](#)). Gingivostomatitis, herpes labialis (cold sores) and aphthous ulceration are common examples. Lesions of the posterior third of the tongue, the oropharynx, tonsils and larynx may radiate to the region of the ear via the tympanic branch of the ninth nerve or the auricular branch of the tenth nerve.

### § Trigeminal neuralgia

Trigeminal neuralgia (tic douloureux) is a condition of often unknown cause that typically occurs in patients over the age of 50, affecting the second and third divisions of the trigeminal nerve and on the same side of the face. Brief paroxysms of pain, often with associated trigger points, are a feature.

### Clinical features

- Site: sensory branches of the trigeminal nerve (see [FIG. 52.4](#)) almost always unilateral (often right side)
- Radiation: tends to commence in the mandibular division and spreads to the maxillary division and (rarely) to the ophthalmic division
- Quality: excruciating, searing jabs of pain like a burning knife or electric shock
- Frequency: variable and no regular pattern
- Duration: seconds to 1–2 minutes (up to 15 minutes)
- Onset: spontaneous or trigger point stimulus
- Offset: spontaneous
- Precipitating factors: talking, chewing, touching trigger areas on face (e.g. washing, shaving, eating), cold weather or wind, turning onto pillow

**FIGURE 52.4** Typical cutaneous sensory distribution of the trigeminal nerve and its branches

- Aggravating factors: trigger points usually in the upper and lower lip, nasolabial fold or lower eyelid (see FIG. 52.5)
- Relieving factors: nil
- Associated features: rarely occurs at night; spontaneous remissions for months or years
- Signs: there are no signs, normal corneal reflex

### Causes

- Unknown
- Local pressure on the nerve root entry zone by tortuous pulsatile dilated small vessels (probably up to 75%)
- Multiple sclerosis
- Neurosyphilis
- Tumours of the posterior fossa

*Note:* Precise diagnosis is essential. MRI may be helpful.

### Treatment

- Patient education, reassurance and empathic support is very important in these patients.

### Medical therapy

carbamazepine (from onset of the attack to resolution)<sup>8</sup> 50 mg (elderly patient) or 100 mg (o) bd initially; gradually increase the dose to avoid drowsiness every 7 days to 200 mg bd (maintenance); higher dosage to maximum 600 mg bd may be necessary

**FIGURE 52.5** Trigeminal neuralgia: typical trigger points

Alternative drugs if carbamazepine not tolerated or ineffective (but question the diagnosis if lack of response):

gabapentin 300 mg daily initially, then increase  
lamotrigine 400 mg (o) daily  
phenytoin 300–500 mg daily  
clonazepam  
baclofen  
sodium valproate

### Surgery

- Refer to a neurosurgeon if medication ineffective
- Possible procedures include:
  - decompression of the trigeminal nerve root (e.g. gel foam packing between the nerve and blood vessels)
  - if severe, refer for neuroablative treatment, e.g. thermocoagulation/radiofrequency neurolysis
  - surgical division of peripheral branches

### § Glossopharyngeal neuralgia<sup>8,9</sup>

This is an uncommon condition of the ninth cranial nerve and branches of the vagus nerve with similar clinical features of severe, lancinating pains, particularly felt in one ear, the base of the tongue or beneath the angle of the jaw. The pain usually lasts 30–60 seconds.

- Sites: back of throat around tonsillar fossa and adjacent fauces deep in ear

- Radiation: ear canal, neck
- Triggers: swallowing, coughing, talking, yawning, laughing
- Treatment: as for trigeminal neuralgia

## Migrainous neuralgia (cluster headache)

As described in [CHAPTER 56](#), the pain is unilateral and centred around the eye with associated lacrimation and stuffiness of the nose.

## § Facial migraine (lower half headache)<sup>8</sup>

Migraine may rarely affect the face below the level of the eyes, causing pain in the area of the cheek and upper jaw. It may spread over the nostril and lower jaw. The pain is dull and throbbing, and nausea and vomiting are commonly present. The treatment is as for other varieties of migraine with simple analgesics or ergotamine for infrequent attacks.

## § Chronic paroxysmal hemicrania

In the rare condition of chronic or episodic paroxysmal hemicrania there is a unilateral facial pain that can resemble chronic cluster headache but the duration is briefer, about 15 minutes, and it may recur many times a day even for years. It responds dramatically to indomethacin.<sup>10</sup>

## Herpes zoster and postherpetic neuralgia

Refer to [CHAPTER 123](#). Herpes zoster may present as hyperaesthesia or a burning sensation in any division of the fifth nerve, especially the ophthalmic division.

## § Atypical facial pain

This is mainly a diagnosis of exclusion whereby patients, usually middle-aged to elderly women, complain of diffuse pain in the cheek (unilateral or bilateral) without demonstrable organic disease. The pain does not usually conform to a specific nerve distribution (although in the maxillary area), varies in intensity and duration and is not lancinating as in trigeminal neuralgia. It is usually described as deep-seated and 'boring', severe, continuous and throbbing in nature. It is a very confusing and difficult problem to treat. These patients tend to show psychoneurotic tendencies but caution is needed in labelling them as functional.

## Treatment

Trial of an antidepressant<sup>8</sup>, e.g.:

amitriptyline 10–75 mg nocte  
or  
dothiepin 25–150 mg nocte  
or  
carbamazepine

## Temporal arteritis

This may produce mild or severe unilateral or bilateral headache. There may be ischaemic pain in the jaws when chewing. There may be marked scalp tenderness over the affected arteries. See [CHAPTER 32](#) for management.

## § Erysipelas

Classical erysipelas is a superficial form of cellulitis involving the face. It usually presents with the sudden onset of butterfly erythema with a well-defined edge (see [FIG. 52.6](#)). It often starts around the nose and there may be underlying sinus or dental infection which should be investigated. There is an associated 'flu like' illness and fever. It is invariably caused by *Streptococcus pyogenes*. Treatment is by phenoxymethylpenicillin or di/flucloxacillin for 7–10 days.

**FIGURE 52.6** Erysipelas: typical spreading distribution of the infection

## When to refer

- Severe trigeminal neuralgia
- Unusual facial pain, especially with a suspicion of malignancy
- Positive neurological signs, such as impaired corneal reflex, impaired sensation in a trigeminal dermatome, slight facial weakness, hearing loss on the side of the neuralgia

- Possible need for surgical drainage of sinusitis—indications for surgery include failure of appropriate medical treatment, anatomical deformity, polyps, uncontrolled sinus pain<sup>5</sup>
- Dental root infection causing maxillary sinusitis
- Other dental disorders

### Practice tips

- Malignancy must be excluded in the elderly with facial pain.
- Problems from the molar teeth, especially the third (wisdom), commonly present with periauricular pain without aural disease and pain in the posterior cheek.
- Facial pain never crosses the midline; bilateral pain means bilateral lesions.
- If no obvious cause of persistent pain, refer to exclude sinister cause: don't overdiagnose sinusitis.

*Why! the fever itself is nature's instrument.*

Thomas Sydenham (1624–89), *Medical Observation s*

Although fever is a sign of disease and usually occurs in response to infection (mainly viral), its presence is recognised as playing an important role in the individual's defence against infection. The infecting pathogen triggers hypothalamic receptors, causing the thermostatic mechanisms to be reset to maintain core temperature at a higher level. The elevation in temperature results from increased heat production (e.g. shivering) or decreased loss (e.g. peripheral vasoconstriction). The elevation in body temperature activates T-cell production, increases the effectiveness of interferons and limits the replication of some common viruses.<sup>1</sup>

## Key facts and checkpoints

- Fever plays an important physiological role in the defence against infection.
- Normal body temperature (measured orally mid-morning) is 36–37.2°C (average 36.8°C).
- Fever can be defined as an early morning oral temperature >37.2°C or a temperature >37.8°C at other times of day.<sup>2</sup>
- Oral temperature is about 0.4°C lower than core body temperature.
- Axillary temperature is 0.5°C lower than oral temperature.
- Rectal, vaginal and ear drum temperatures are 0.5°C higher than oral and reflect core body temperature.
- There can be a normal diurnal variation of 0.5–1°C (lowest in early morning and highest in late afternoon).
- Fevers due to infections have an upper limit of 40.5–41.1°C (105–106°F).
- Hyperthermia (temperature above 41.1°C) and hyperpyrexia appear to have no upper limit.
- Infection remains the most important cause of acute fever.<sup>3</sup>
- Symptoms associated with fever include sweats, chills, rigors and headache.
- General causes of fever include infections, malignant disease, mechanical trauma (e.g. crush

injury), vascular accidents (e.g. infarction, cerebral haemorrhage), immunogenic disorders (e.g. drug reactions, SLE), acute metabolic disorders (e.g. gout), and haemopoietic disorders (e.g. acute haemolytic anaemia).<sup>3</sup>

- Drugs can cause fever, presumably because of hypersensitivity.<sup>3</sup> Important examples are allopurinol, antihistamines, barbiturates, cephalosporins, cimetidine, methyldopa, penicillins, isoniazid, quinidine, phenolphthalein (including laxatives), phenytoin, procainamide, salicylates and sulphonamides.
- Drug fever should abate by 48 hours after discontinuation of the drug.<sup>4</sup>
- Infectious diseases at the extremes of age (very young and aged)<sup>3</sup> often present with atypical symptoms and signs. Their condition may deteriorate rapidly.
- Overseas travellers or visitors may have special, even exotic infections and require special evaluation (refer to **CHAPTER 15**).
- Immunologically compromised patients (e.g. AIDS patients) pose a special risk for infections, including opportunistic infections.
- A febrile illness is characteristic of the acute infection of HIV: at least 50% have an illness like glandular fever. Think of it!

## § Chills/rigors<sup>2</sup>

The abrupt onset of fever with a chill or rigor is a feature of some diseases. Examples include:

- bacteraemia/septicaemia
- pneumococcal pneumonia
- pyogenic infection with bacteraemia
- lymphoma
- pyelonephritis
- visceral abscesses (e.g. perinephric, lung)
- malaria
- biliary sepsis (Charcot triad—jaundice, right hypochondrial pain, fever/rigors)

Features of a true chill are teeth chattering and bed shaking, which is quite different from the chilly

sensations that occur in almost all fevers, particularly those in viral infections. The event lasts 10–20 minutes.

Other features:

- shaking cannot be stopped voluntarily
- absence of sweating
- cold extremities and pallor (peripheral vascular shutdown)
- dry mouth and pilo-erection: lasts 10–20 minutes

## Hyperthermia

Hyperthermia or hyperpyrexia is a temperature greater than 41.1°C (106°F). A more accurate definition is a state when the body's metabolic heat production or environmental heat load exceeds normal heat loss capacity. Hyperthermia may be observed particularly in the tropics, in malaria and heatstroke. It can occur with CNS tumours, infections or haemorrhages because of its effect on the hypothalamus.

### § Heatstroke (sunstroke, thermic fever)<sup>5</sup>

This is the sudden onset of hot, dry, flushed skin with a rapid pulse, temperature above 40°C, and confusion or altered conscious state in a person exposed to a very hot environment. The BP is usually not affected initially but circulatory collapse may precede death. It is a life-threatening emergency. The diagnosis is clinical. Differential diagnoses include severe acute infection, toxic shock, food, chemical and drug poisoning. The elderly and debilitated are susceptible as are children left in cars.

#### Treatment

- Immediate effective cooling water applied to skin
- Icepacks at critical points (e.g. axillae, neck, head)
- Ice water bath if possible
- Aim to bring down temperature by 1°C every 10 minutes

### § Malignant hyperthermia

This is a rare hereditary disorder characterised by rapidly developing hyperpyrexia, muscular rigidity and acidosis in patients undergoing major surgery.

## Sweats

Sweating is a heat loss mechanism, and diffuse sweating that may soak clothing and bedclothing permits rapid release of heat by evaporation. In

febrile patients the skin is usually hot and dry—sweating occurs in most when the temperature falls. It is characteristic of only some fevers (e.g. septic infections and rheumatic fever).

### § Factitious fever

Factitious fever is usually encountered in hospitalised patients attempting to malingering. The situation is usually suspected when:

- a series of high temperatures is recorded to form an atypical pattern of fluctuation
- there is excessively high temperature (41.1°C) and above
- a recorded high temperature is unaccompanied by warm skin, tachycardia and other signs of fever such as a flushed face and sweating
- there is an absence of diurnal variation

The patient may have surreptitiously dipped the thermometer in warm water, placed it in contact with a heat source or heated the bulb by friction with bedclothes or even mucous membranes of the mouth.

### § Neuroleptic malignant syndrome

This is often confused with 'malignant' hyperthermia and heat stroke. The syndrome includes high temperature, muscle rigidity, autonomic dysfunction and altered consciousness. It is a rare and potentially lethal reaction in patients taking antipsychotic drugs, particularly occurring with haloperidol alone or with other drugs especially lithium carbonate. Refer to CHAPTER 45.

## Measurement of temperature

Temperature can be measured by several methods, including the mercury thermometer, the liquid crystal thermometer and the electronic probe thermometer. The mercury thermometer, however, is probably still the most widely used and effective temperature-measuring instrument.

### Basic rules of usage

- 1 Before use, shake down to 35–36°C.
- 2 After use:
  - shake down and store in antiseptic
  - do not run under hot water
  - wipe rectal thermometer with alcohol and store separately
- 3 Recording time is 3 minutes orally and 1–2 minutes rectally.

### Oral use

- 1 Place under the tongue at the junction of the base of the tongue and the floor of the mouth to one side of the frenulum—the ‘heat’ pocket.
- 2 Ensure that the mouth is kept shut.
- 3 Remove dentures.

*Note:* This is unsuitable for children 4 years and under, especially if irritable.

### Rectal use

This is an appropriate route for babies and young children under the age of 4 years but should be used with care. The rule is ‘3 cm in for 3 minutes’ and some authorities claim that this method is the gold standard, especially in infants.

### Method

- 1 Lubricate the stub with petroleum or KY jelly.
- 2 Insert for 3 cm past anal verge.
- 3 Keep the thermometer between the flexed fingers with the hand resting on the buttocks (see FIG. 53.1).

FIGURE 53.1 Rectal temperature measurement in infants

Don't:

- dig thermometer in too hard
- hold it too rigidly
- allow the child to move around

### Axillary use

This is unreliable with poor sensitivity and generally should be avoided but may be practical in young children.<sup>6,7</sup>

If used, place high in the axilla for 3 minutes. Fever is present if the temperature is above 37.2°C.

### Groin use

This route is not ideal but is more reliable than the axilla. It closely approximates oral temperature. In infants, the thigh should be flexed against the abdomen.

### Vaginal use

This is mainly used as an adjunct to the assessment of ovulation during the menstrual cycle. It should be placed deeply in the vagina for 5 minutes before leaving bed in the morning.

### Infrared eardrum use

Otic thermography is now accepted standard practice. The tympanic membrane (TM) accurately reflects hypothalamic temperature, which in turn reflects core body temperature. The TM is also immune from the effects of eating, drinking and smoking. A systematic review in the Cochrane study describes the tympanic temperature as being inaccurate and unreliable.<sup>8</sup> However, some Australian authorities believe that in general practice the benefits of convenience outweigh lack of accuracy.<sup>9</sup> The normal range is the same as for rectal temperature.

### Skin use

Plastic strip thermometers placed on the forehead are very inaccurate and should not be used.

### Accidental breakage in the mouth

If children bite off the end of a mercury thermometer there is no need for alarm, as the small amount of mercury is non-toxic and the piece of glass will usually pass in the stool.

### The clinical approach

The initial approach is to evaluate the severity of the problem and the nature of the illness. Some infections, particularly bacterial infections, are life-threatening and this requires urgent diagnosis and hospital admission.

According to Yung and Stanley<sup>3</sup> it is helpful to consider fever in three categories: less than 3 days duration; between 4 and 14 days duration; and protracted fever (more than 14 days).

### Fever of less than 3 days duration

This is very commonly encountered in family practice, often due to a self-limiting viral infection of the respiratory tract. It is important, however, to be vigilant for other infections, so evidence of an infectious disease, urinary tract infection, pneumonia

or other infection should be sought. A routine urine examination, especially in females, is an important screening investigation. The majority of patients can be managed conservatively.

## Fever present for 4 to 14 days

If fever persists beyond 4–5 days a less common infection should be suspected since most common viral infections will have resolved by about 4 days.<sup>3</sup> A checklist of causes is presented in TABLE 53.1. The careful history is mandatory, as outlined later in the chapter for fever of unknown origin (FUO). The basic examination and investigations are along similar lines.

**Table 53.1** Common causes of fever of 4–14 days duration

Influenza
Sinusitis
Epstein–Barr mononucleosis (EBM)
Enteroviral infection
Infective endocarditis
Dental infections
Hepatobiliary infections: hepatitis, cholecystitis, empyema of gall bladder
Abscess
Pelvic inflammatory disease
Cytomegalovirus infection
Lyme disease
Travel-acquired infection: typhoid, dengue, hepatitis, malaria, amoebiasis
Zoonosis: brucellosis, Q fever, leptospirosis, psittacosis
Drug fever

## Temperature chart

Charting the patterns of fever may be a diagnostic help because some febrile conditions follow a predictable temperature pattern.<sup>10</sup> Examples are presented in FIGURE 53.2.

### Intermittent fever

This is a fever in which the temperature rises for a few hours each day and then returns to normal (see FIG. 53.2a). Examples include various pyogenic infections, cytomegalovirus and lymphoma.

### Relapsing fever

The fever returns to normal for days before rising again. Malaria is the classic example of periodic

relapsing fever: in quartan fever, caused by *Plasmodium malariae* (see FIG. 53.2a), the attacks occur every 72 hours (the term *quartan* means every 4th day by inclusive counting). This compares with tertian fever from *Plasmodium vivax* in which paroxysms of malaria occur every 48 hours.

### Remittent fever

This is a fever in which the temperature returns towards normal for a variable period but is always elevated (see FIG. 53.2d). Common examples are collections of pus (e.g. pelvic abscess, wound infection, empyema and carcinoma). It is a common feature of empyema.

### Undulant fever

Undulant fever is characterised by bouts of continuous or remittent fever for several days, followed by afebrile remissions lasting a variable number of days. It is commonly a feature of brucellosis infection but is also seen in the lymphomas, especially Hodgkin lymphoma (see FIG. 53.2b). The latter is referred to as Pel–Ebstein fever with fevers lasting 3 to 10 days followed by afebrile periods of 3 to 10 days.

### Continuous fever pattern

This is common with viral infections such as influenza (see FIG. 53.2c).

### Quotidian fever

In this pattern the fever recurs daily (see FIG. 53.2d). Daily fever spikes in the morning are characteristic of *Pseudomonas* infection (e.g. pulmonary superinfection); afternoon spikes are indicative of cytomegalovirus infection; and evening spikes suggest localised collection of pus (e.g. empyema of the gall bladder).

Double quotidian fever (two fever spikes in a day) is caused by adult Still syndrome, gonococcal endocarditis and visceral leishmaniasis.

If risk factors are present, especially if taking antibiotics, consider the investigations outlined in TABLE 96.1, in CHAPTER 96.

### Postoperative fever

This is fever occurring within 24 hours after surgery—common with abdominal surgery.

Causes to consider:

- pulmonary atelectasis (common)
- wound haematoma
- deep venous thrombosis
- myocardial infarction
- allergic drug reaction

FIGURE 53.2 Examples of fever patterns from temperature charts

Septic problems related to the operation usually develop after several days.

## Fever in children

In children, most authorities would consider a fever of 38.5°C and above to be significant and warrant close scrutiny.<sup>11</sup>

The fever is usually a response to a viral infection. Fever itself is not harmful until it reaches a level of 41.5°C.<sup>1</sup> Hyperthermia is uncommon in children. Temperatures above 41°C are usually due to CNS infection or the result of human error, for example:

- shutting a child in a car on a hot day
- overwrapping a febrile child

Complications include dehydration (usually mild) and febrile convulsions, which occur in 5% of febrile children between 6 months and 5 years. Febrile convulsions are triggered by a rapid rise in temperature rather than its absolute level.

*Note:* Teething does *not* cause fever.

## § Approach to the febrile infant

It is important to decide whether the child looks well or seriously ill. Identification of the very ill child is presented in [CHAPTER 96](#).

If the child is well and has no risk factors (e.g. unreliable caregiver, poor access to treatment, medical risk factors, taking antibiotics) treat expectantly. The only test required is urine microscopy and culture. Educate the caregiver about review if serious signs develop. Treat the fever as outlined in [TABLE 96.1](#), in [CHAPTER 96](#).

## Management

- Treatment of low-grade fevers should be discouraged.
- Treatment of high-grade fevers includes:
  - treatment of the causes of the fever (if appropriate)
  - adequate fluid intake/increased fluids
  - paracetamol (acetaminophen) is the preferred antipyretic since aspirin is potentially dangerous in young children (use if temperature >38.5°C). The usual dose of 10–15 mg/kg every 4–6 hours may represent undertreatment. Use 20 mg/kg as a loading dose and then 15 mg/kg maintenance
  - evidence favours tepid sponging for first 30 minutes combined with paracetamol<sup>12</sup>
  - ibuprofen 5–10 mg/kg every 6 hours is a suitable antipyretic

## Advice to parents

- Dress the child in light clothing (stripping off is unnecessary).
- Do not overheat with too many clothes, rugs or blankets.
- Give frequent small drinks of light fluids, especially water.
- Sponging with cool water and using fans is not effective.

## Febrile convulsions

Refer to [CHAPTER 96](#).

## Fever in the elderly

The elderly tend to have a problem with impaired thermoregulation and so they may not develop a fever in response to suppurative infection compared with younger people. This can be misleading in the diagnostic process.

## Important facts

- Any fever in the elderly is significant.
- Viral infection is a less common cause of fever in the elderly.
- Fever in the elderly is sepsis until proven otherwise (common sites are the lungs and urinary tract).

The elderly are more vulnerable to hyperthermia and hypothermia. Heatstroke classically occurs in epidemic form during a heatwave. The syndrome consists of hyperpyrexia, decreased sweating, delirium and coma. The core temperature is usually over 41°C.

## 'Alarm bell' signs

In many patients the existence of a life-threatening infective illness is obvious and prompt action is essential. In others the diagnosis is not clear-cut but there are certain warning signs (see Red flags box).

These 'red flag' symptoms and signs are obviously super 'sensitive'. Patients with some of these features may have potentially life-threatening diseases, but this list would include many with viral infections.

## Fever of undetermined origin

Fever of undetermined origin (FUO), also referred to as pyrexia of unknown origin (PUO), has the following criteria:<sup>13</sup>

- illness for at least 3 weeks
- fevers >38.3°C (100.9°F)
- undiagnosed after 1 week of intensive study

### Red flag pointers for fever

- High fever
- Repeated rigors
- Drenching night sweats
- Severe myalgia (? sepsis)
- Severe pain anywhere (? sepsis)
- Severe sore throat or dysphagia (? *Haemophilus influenzae* epiglottitis)
- Altered mental state
- Incessant vomiting
- Unexplained rash
- Jaundice
- Marked pallor
- Tachycardia
- Tachypnoea

Most cases represent unusual manifestations of common diseases and not rare or exotic diseases. Examples are tuberculosis, bacterial endocarditis, hepatobiliary disease and lung cancer.<sup>14</sup>

Keep in mind that the longer the duration of fever, the less likely the diagnosis is to be infectious—fevers that last greater than 6 months are rarely infectious (only 6%). One study showed that 9% are factitious.<sup>15</sup>

Patients with FUO in definite need of further investigation are:

- babies <3 months of age
- children with fever >40°C
- adults >50 years
- diabetics
- the immunocompromised
- travellers

### A diagnostic approach

A knowledge of the more common causes of FUO is helpful in planning a diagnostic approach (refer to TABLE 53.2).

#### History

The history should include consideration of past history, occupation, travel history, sexual history, IV drug use (leads to endocarditis and abscesses), animal contact, medication and other relevant factors. Symptoms such as pruritus, a skin rash and fever patterns may provide clues for the diagnosis. The average patient with a difficult FUO needs to have a careful history taken on at least three separate occasions.<sup>16</sup>

#### Examination

A common mistake is the tendency to examine the patient only once and not re-examine. The patient

**Table 53.2** Common causes of FUO

Common examples of each group selected

Infection (up to 40%)

Bacteria:

- pyogenic abscess (e.g. liver, pelvic)
- urinary infection
- biliary infection (e.g. cholangitis)
- chronic septicaemia
- infective endocarditis
- Lyme disease
- tuberculosis
- brucellosis
- osteomyelitis
- typhoid/paratyphoid fever

Viral, rickettsial, *Chlamydia*:

- Epstein–Barr mononucleosis
- cytomegalovirus
- HIV virus infection (primary HIV, AIDS, ARC)
- Q fever
- psittacosis

Parasitic:

- malaria
- toxoplasmosis
- amoebiasis

Malignancy (up to 30%)

Reticuloendothelial:

- leukaemia
- lymphomas

Solid (localised) tumours:

- kidney
- liver
- pancreas
- stomach
- lung
- sarcoma

Disseminated

Immunogenic (up to 20%)

Drug fever

Connective tissue diseases/vasculitides:

- rheumatic fever
- rheumatoid arthritis
- SLE
- polyarteritis nodosa/Wegener granulomatosis
- giant cell arteritis/polymyalgia rheumatica

Sarcoidosis

Inflammatory bowel disease (e.g. Crohn)

Factitious (1–5%)

Hyperthyroidism (0.5–1%)

Remain unknown (5–25%)

Source: After Kumar and Clark<sup>16,17</sup>

should be examined regularly (as for history taking) as physical signs can develop eventually. HIV infection must be excluded. Special attention should be paid to the following (see FIG. 53.3):

- skin—look for rashes, vesicles and nodules
- the eyes and ocular fundi
- temporal arteries
- sinuses
- teeth and oral cavity—? dental abscess, other signs
- heart—murmurs, pericardial rubs
- lungs—abnormalities including consolidation, pleuritic rub
- abdomen—enlarged/tender liver, spleen or kidney

- rectal and pelvic examination (note genitalia)
- lymph nodes, especially cervical (supraclavicular)
- blood vessels, especially of the legs—? thrombosis
- urine (analysis)

### Investigations

Basic investigations include:

- haemoglobin, red cell indices and blood film
- white cell count
- ESR/C-reactive protein
- chest X-ray and sinus films
- urine examination (analysis and culture)
- routine blood chemistry
- blood cultures

FIGURE 53.3 Sites to consider in FUO (malignancy is indicated by a star)

Further possible investigations:

- stool microscopy and culture
- culture of sputum (if any)
- specific tests for malaria, typhoid, EBM, Q fever, brucellosis, psittacosis, cytomegalovirus, toxoplasmosis, syphilis, various tropical diseases and others
- NAAT (e.g. PCR) tests
- HIV screening
- tests for rheumatic fever
- tuberculin test
- tests for connective tissue disorders (e.g. DNA antibodies, C-reactive protein)
- upper GIT series with small bowel follow-through
- CT and ultrasound scanning for primary and secondary neoplasia:
  - gall bladder functioning
  - occult abscesses
- MRI—best for detecting lesions of the nervous system
- echocardiography—for suspected endocarditis
- isotope scanning for specific causes
- aspiration or needle biopsy
- laparoscopy for suspected pelvic infection
- tissue biopsies (e.g. lymph nodes, skin, liver, bone marrow) as indicated

### § FUO in children

Fever in children is usually a transient phenomenon and subsides within 4–5 days. At least 70% of all infections are viral. Occasionally a child will present with FUO which may be masked from antibiotic administration. Common causes of prolonged fever in children differ from those in adults. Most cases are not due to unusual or esoteric disorders,<sup>18</sup> the majority representing atypical manifestation of common diseases.

A summary of the common causes (with the most common ranked first) is as follows.<sup>18</sup>

#### Infectious causes (40%)

- Viral syndrome
- Urinary tract infection
- Pneumonia
- Pharyngitis
- Sinusitis
- Meningitis

#### Collagen-vascular disorders (15%)

- Rheumatic arthritis
- Systemic lupus erythematosus

- Rheumatic fever
- Henoch–Schönlein syndrome

#### Neoplastic disorders (7%)

- Leukaemia
- Reticulum cell sarcoma
- Lymphoma

#### Inflammatory diseases of the bowel (4%)

### § Septicaemia

The diagnosis of septicaemia can be easily missed, especially in small children, the elderly and the immunocompromised, and in the absence of classic signs, which are:

- fever
- rash (suggestive of meningococcus)
- tachycardia
- tachypnoea
- cool extremities

Patients with septicaemia require urgent referral as it has a very high mortality rate. Investigations should include two sets of blood cultures and other appropriate cultures (e.g. urine, wound, sputum). Empirical initial treatment (after blood cultures) is di/flucloxacillin 2 g IV 1 gentamicin 4–6 mg/kg IV (statim).<sup>19</sup>

### Glossary of terms

**Bacteraemia** The transient presence of bacteria in the blood (usually asymptomatic) caused by local infection or trauma.

**Septicaemia (sepsis)** The multiplication of bacteria or fungi in the blood, usually causing a systemic inflammatory response (SIRS). SIRS is defined as 2 or more of (in adults):

- temperature  $>38^{\circ}\text{C}$  or  $<36^{\circ}\text{C}$
- respiratory rate  $>20/\text{min}$
- heart rate  $>90/\text{min}$
- WCC  $>12 \times 10^9/\text{L}$  or  $<4 \times 10^9/\text{L}$

**Severe sepsis** Sepsis associated with organ dysfunction, hypoperfusion or hypotension with 2 or more of: fever, tachycardia, tachypnoea, and elevated WCC.

**Septic shock** Sepsis with critical tissue perfusion causing acute circulatory failure including hypotension and peripheral shutdown—cool extremities, mottled skin, cyanosis.

**Pyemia** A serious manifestation of septicaemia whereby organisms and neutrophils undergo

*continued*

continued

embolisation to many sites, causing abscesses, especially in the lungs, liver and brain.

**Primary septicaemia** Septicaemia where the focus of infection is not apparent, while in secondary septicaemia a primary focus can be identified.

Examples of secondary septicaemia in adults are:

- urinary tract (e.g. *Escherichia coli*)
- respiratory tract (e.g. *Streptococcus pneumoniae*)
- pelvic organs (e.g. *Neisseria gonorrhoea*)
- skin (e.g. *Staphylococcus aureus*)
- gall bladder (e.g. *E. coli*, *Streptococcus faecalis*)

Patients with septicaemia require urgent referral.

When patients present with the complaint of a ‘funny turn’ it is usually possible to determine that they have one of the more recognisable presenting problems, such as fainting, ‘blackouts’, lightheadedness, weakness, palpitations, vertigo or migraine. However, there are patients who do present with confusing problems that warrant the label of ‘funny turn’. The most common problem with funny turns is that of misdiagnosis, so a proper and adequate history-taking is of great importance.

It is important to remember that seemingly ‘funny turns’ may be the subjective interpretation of cultural and linguistic communication barriers, especially in an emotional and frustrated patient.<sup>1</sup> Various causes of faints, fits and funny turns are presented in [TABLE 54.1](#). A useful simple classification is to consider them as:

- syncope
- seizures
- sleep disorders—sleep apnoea/narcolepsy/cataplexy
- labyrinthine

## Key facts and checkpoints

- The commonest cause of ‘funny turns’ presenting in general practice is lightheadedness, often related to psychogenic factors such as anxiety, panic and hyperventilation.<sup>2</sup> Patients usually call this ‘dizziness’.
- Absence attacks occur with minor forms of epilepsy and with partial seizures such as complex partial seizures.
- The psychomotor attack of complex partial seizure presents as a diagnostic difficulty. The most commonly misdiagnosed seizure disorder is that of complex partial seizures or variants of generalised tonic–clonic seizures (tonic or clonic or atonic).
- The diagnosis of epilepsy is made on the history (or video electroencephalogram [EEG]), rather than on the standard EEG, although a sleep-deprived EEG is more effective.
- The triad—angina + dyspnoea + blackout or lightheadedness—indicates aortic stenosis.

- Severe cervical spondylosis can cause vertebrobasilar ischaemia by causing pressure on the vertebral arteries that pass through the intervertebral foramina, especially with head turning or looking up.

## A diagnostic approach

A summary of the diagnostic strategy model is presented in [TABLE 54.2](#).

### Red flag pointers for faints, fits and funny turns

- Onset in older person
- Neurological symptoms and signs
- Headache
- Tachycardia
- Irregular pulse
- Fever
- Drugs: social or prescribed
- Cognitive impairment
- Confusion: gradual onset

## The clinical approach

### History

The clinical history is of paramount importance in unravelling the problem. A reliable eye-witness account of the ‘turn’ is invaluable, as is the setting or circumstances in which the ‘episode’ occurred.

It is essential at first to determine exactly what the patient means by ‘funny turn’. In the process of questioning it is appropriate to evaluate the mental state and personal and social factors of the patient. It may be appropriate to confront the patient about feelings of depression, anxiety or detachment from reality.

It is important to break up the history into three components. First is the lead-up to the episode; second is an adequate description of what took place during the episode; third is the events that took place after the episode.

**Table 54.1** Faints, fits and funny turns: checklist of causes (excluding tonic-clonic seizure and stroke)

Psychogenic/communication problems

Breath-holding attack

Conversion reactions (hysteria)

Culture/language conflicts

Fugue states

Hyperventilation

Malingering

Personality disorders

Phobia/anxiety states

Psychoses/severe depression

Other conditions

Transient ischaemic attacks

Complex partial seizure (temporal lobe epilepsy)

Tonic, clonic or atonic seizures

Primary absence seizure

Migraine variants or equivalents e.g. acute confusional migraine

Cardiovascular disorders:

- arrhythmias
- postural hypotension
- long QT syndrome
- aortic stenosis

Vertigo

Drug reaction

Alcohol and other substance abuse

Hypoglycaemia

Anaemia

Amnesic episodes

Metabolic/electrolyte disturbances

Vasovagal/syncope

Carotid sinus sensitivity

Cervical spondylosis

Sleep disorders:

- sleep apnoea
- narcolepsy/cataplexy

Autonomic failure

**Table 54.2** Faints, fits and funny turns: diagnostic strategy model

Q. Probability diagnosis

- A. Anxiety related/hyperventilation  
Vasovagal syncope  
Postural hypotension  
Breath-holding attacks (children)

Q. Serious disorders not to be missed

A. Cardiovascular:

- arrhythmias
- aortic stenosis
- postural orthostatic tachycardia syndrome (POTS)

Cerebrovascular:

- TIAs

Neoplasia:

- space-occupying lesions

Severe infections:

- infective endocarditis

Hypoglycaemia

Q. Pitfalls (often missed)

A. Atypical migraine

Cardiac arrhythmias/long QT syndrome

Simple partial seizures

Complex partial seizures

Atypical tonic-clonic seizures

Acute confusional state/delirium

Drugs/alcohol/marijuana

Electrolyte disturbances (e.g. hypokalaemia)

Sleep disorders

Transient global amnesia

Rarities:

- atrial myxoma

Q. Seven masquerades checklist

A. Depression

Diabetes (hypoglycaemia)

Drugs

Anaemia

Spinal dysfunction (cervical spondylosis)

Q. Is this patient trying to tell me something?

- A. Highly likely. Pseudo-seizures, psychogenic and 'communication' disorders quite significant.

Apart from the events, note the patient's feelings, symptoms, circumstances and provocative factors. Search for possible secondary gain.

### Onset

A sudden onset may be due to cardiovascular causes, especially arrhythmias, which may include the more common supraventricular tachycardias in addition to the less common but more dramatic arrhythmias that may cause unconsciousness. Other causes of a sudden onset include the various epilepsies, vasovagal attacks and TIAs.

### Precipitating factors<sup>2</sup>

Enquire about precipitating factors such as emotion, stress, pain, heat, fright, exertion, suddenly standing up, coughing, head movement or hypersomnolence:

- emotion and stress suggest hyperventilation
- fright, pain → vasovagal attack

- standing up → postural hypotension
- exertion → aortic stenosis
- head movement → cervical spondylosis with vertebrobasilar insufficiency
- hypersomnolence → narcolepsy

### Associated symptoms<sup>2</sup>

Certain associated symptoms give an indication of the underlying disorder:

- breathing problems and hyperventilation suggest an anxiety state
- tingling in extremities or tightening of the hand → anxiety/hyperventilation
- visual problems → migraine or TIA
- fear or panic → anxiety or complex partial seizure
- hallucinations (taste/smell/visual) → complex partial seizure
- speech problems → TIA or anxiety
- sweating, hunger feelings → hypoglycaemia
- related to food → migraine
- first thing in morning → consider 'hangover'

### Drug history

This requires careful analysis and includes alcohol intake and illicit drugs such as marijuana, cocaine and amphetamines. Prescribed drugs that can cause lightheadedness or unconsciousness are listed in **TABLE 54.3** and those causing seizures in **TABLE 54.4**.

**Table 54.3** Typical drugs that may cause lightheadedness or blackouts

Alcohol  
Antiepileptics  
Antihypertensives  
Barbiturates  
Benzodiazepines  
OTC anticholinergic compounds  
Peripheral vasodilators:  
• ACE/ARB inhibitors  
• glyceryl trinitrate  
• hydralazine  
• prazosin  
Phenoxybenzamine  
SSRI antidepressants  
Tricyclic antidepressants

Sudden cessation of certain drugs such as phenothiazines can also be responsible for 'funny turns'.

### Past history

The past history may give an indication of the cause of the 'turn'. Such conditions include hypertension,

**Table 54.4** Important causes of convulsive seizures

Epilepsy:

- first presentation
- known patient with recurrence

Cerebral hypoxia

Hypoglycaemia

Poor cerebral perfusion:

- oedema of eclampsia

Neurotrauma

Cerebrovascular accident

CNS infections:

- meningitis
- encephalitis
- septicaemia
- septic emboli
- cerebral abscess

Toxins

Alcohol excess

Hyperthermia

Metabolic disorders

Drugs:

- antidepressants
- theophylline
- amphetamine
- antibiotics e.g. norfloxacin, ciprofloxacin
- cocaine
- local anaesthetics

Anaphylaxis

Expanding brain lesion:

- neoplasm
- haematoma

migraine, epilepsy, rheumatic heart disease, atherosclerosis (e.g. angina, vascular claudication), alcohol or other substance abuse and psychiatric disorders.

### Diary of events

If the diagnosis is elusive it may help to get the patient to keep a diary of circumstances in which events take place, keeping in mind the importance of the time period prior, during and post episode.

### Examination

Important focal points of the physical examination include:

- evaluation of the mental state, especially for anxiety
- looking for evidence of anaemia, alcohol abuse and infection
- cerebrovascular examination: carotid arteries, ocular fundi, bruits

- cardiovascular examination: pulses, BP, heart (the BP should be taken lying, sitting and standing)
- the cervical spine

### Various manoeuvres

Subject the patient to a number of manoeuvres to try to induce various sensations in order to identify the one that affects them. These should include sudden assumption of the erect posture from a squat, spinning the patient and then a sudden stop, head positioning with either ear down (see FIG. 46.3, CHAPTER 46), Valsalva manoeuvre, and hyperventilation for 60 seconds. Children can spin a showbag 'windmill' while hyperventilating (blowing). Ask 'Which one mimics your complaint?'

### Investigations

Depending on the clinical findings, investigations can be selected from the following tests:

- full blood count: ? anaemia ? polycythaemia
- blood sugar: ? diabetes ? hypoglycaemia
- urea and electrolytes
- ECG: ? ischaemia ? arrhythmia
- 24-hour ambulatory cardiac (Holter) monitor: ? arrhythmia
- radiology/imaging:
  - cervical X-ray
  - chest X-ray
  - carotid duplex Doppler scan: ? carotid artery stenosis
  - CT scan
  - MRI scan
- EEG or video EEG; include those recorded with sleep deprivation, hyperventilation or photic stimulation
- positron emission tomography (PET) or single photon emission computerised tomography (SPECT) may show localised brain dysfunction when others are negative

### In neonates and children

The various forms of seizures are also encountered in childhood when most patients with epilepsy are diagnosed. There is a concern, supported by evidence, that children are being misdiagnosed. It is appropriate to take a visual recording of the attack.<sup>3</sup>

Neonatal seizures are dangerous and require specialised care to identify the cause and quickly stop the seizure. Pyridoxine may be used.

### EPILEPSY SYNDROMES

The following are special age-related epilepsy syndromes seen in children.<sup>4,5</sup> (See CHAPTER 84.)

### § Febrile seizures

Tonic-clonic seizures occur in 2–5% of children usually aged 3 months to 5 years who have a high fever generally caused by a viral infection. The long-term prognosis is good. For seizures lasting more than 5 minutes use midazolam or diazepam.

### § Infantile spasms (hypsarrhythmia)

Also known as West syndrome, these are generalised tonic seizures with sudden flexion of the arms, forward flexion of the trunk and extension of the legs, lasting only a few seconds, with usual age onset between 3 and 8 months. They are usually restricted to the first 3 years of life and are replaced by other forms of attacks. Prognosis for cognitive development is also unfavourable. The most effective therapy is corticotrophin (ACTH) IM injection. Otherwise, oral prednisolone, vigabatrin, benzodiazepines or sodium valproate can be used.

### § Lennox–Gastaut syndrome (myoclonic epilepsy of infancy)

This uncommon syndrome refers to a triad of severe difficult-to-control seizures (usually tonic with drop attack), mental retardation and characteristic EEG. The seizures usually begin between ages 1 and 6 years with a peak onset at 3 to 5 years. Prognosis is also poor. Sodium valproate is the therapy of choice.

### § Benign childhood epilepsy with centrotemporal spikes

This disorder usually begins in children aged 2 to 13 years with a peak age of 5 to 8 years. It is the most common form of childhood focal epilepsy. There is a strong family history of epilepsy. The feature is a simple partial motor or somatosensory seizure involving the face and mouth during sleep, producing a typical 'glugging' sound. The child usually wakes from sleep, goes to the parents and is unable to speak and has hemifacial contortions. It may progress to a tonic-clonic seizure. There is a characteristic EEG pattern. The prognosis is excellent as remission usually occurs around puberty. Carbamazepine is the therapy of choice.

### § Childhood and juvenile absence epilepsy

These children present with frequent absence seizures (formerly 'petit mal'), often over a hundred daily. Peak age of onset is 4 to 8 years. The absence

seizures can be very subtle. Signs include alteration of awareness (usually in the classroom), sudden onset, facial and other automatisms. Juvenile absence epilepsy presents later (10–15 years). First-line treatment is ethosuximide (best tolerated) or sodium valproate.

### § Juvenile myoclonic epilepsy (myoclonic epilepsy of Janz)

This is a triad of seizures: myoclonic jerks, tonic-clonic seizures and absences. Onset is around puberty but may occur earlier. The myoclonic jerks and tonic-clonic seizures usually occur in the early morning after waking. Mental development is usually normal but the disorder is usually lifelong and is well controlled with sodium valproate.

### § Medial temporal lobe epilepsy

This syndrome of complex partial seizures, which usually last 1 to 3 minutes, is seen in childhood. Transient postictal confusion and speech dysfunction is common. Those with medically intractable seizures respond well to surgery.

### § Dravet syndrome

Known as severe myoclonic epilepsy of infancy, it is a catastrophic form with a very poor prognosis. Early diagnosis and treatment are essential.

## NON-EPILEPTIC EVENTS RESEMBLING EPILEPTIC SEIZURES<sup>4</sup>

Many normal and abnormal behaviours seen in children resemble seizures but are unrelated to epilepsy. A careful history is very important. The following are examples:

- *Postures of spasticity and movement disorders.* These occur in neurologically handicapped children such as those with cerebral palsy.
- *Syncope.* The child may describe a 'sinking feeling', or 'everything getting louder' prior to the loss of consciousness.
- *Breath-holding.* This often occurs after a crying spell and clonic movements may be seen at the end of the event.
- *Masturbation.* This behaviour leads to a tonic-like posture of the legs and preoccupation, especially in young girls.<sup>6</sup>
- *Munchausen-by-proxy.*<sup>7</sup> This syndrome of fictitious epilepsy described by a parent is becoming more recognised.

- *Psychogenic seizures (pseudo seizures).* A diagnostic dilemma exists when these coexist with genuine seizures. These should be suspected when they occur in particular circumstances and the description of the 'seizure' is bizarre.
- *Shuddering.* Shuddering or shivering spells can resemble myoclonic jerks.
- *Night terrors.*<sup>8</sup> These episodes, which usually affect children aged 2–4 and 6–9, generally develop within 2 hours of sleep onset and last 1 to 2 minutes (sometimes longer). They are alarming and the child usually cannot be reassured or settled. A 6-week trial of phenytoin or imipramine can be used for severe problems.
- *Tics.* Motor tics can be quite complex but are usually brief involuntary movements involving the face and upper limbs.

## Blackouts

The important causes of blackout include the various syncopes that are listed in [TABLE 75.4](#) (see [CHAPTER 75](#)) and the various forms of epilepsy. The classic tonic-clonic seizure is described in [CHAPTER 74](#), while descriptions of other seizures producing blackouts or funny turns now follow.

Important causes of convulsions (tonic-clonic seizures) are listed in [TABLE 54.4](#). Refer to [CHAPTER 84](#).

### § Complex partial seizures

In complex partial seizures (known also as temporal lobe epilepsy) the symptomatology varies considerably from patient to patient and is often a diagnostic problem. It is the commonest type of focal epilepsy and the attacks vary in time from momentary to several minutes (usually 1 to 3 minutes).

### Possible manifestations<sup>2</sup>

- Commonest: slight disturbance of perception and consciousness
- Hallucinations: visual, taste, smell, sounds
- Absence attacks or vertigo
- Illusions—objects/people shrink or expand
- Affective feelings—fear, anxiety, anger
- Dyscognitive effects: *déjà vu* (familiarity), *jamais vu* (unreality), waves emanating from epigastrium
- Objective signs: lip-smacking, swallowing/chewing/sucking, unresponsive to commands or questions, pacing around a room

Unreal or detached feelings are common in complex partial seizures. There can be permanent

short-term memory loss. The sensation of strange smells or tastes is more common than auditory or visual hallucinations.<sup>1</sup> They can progress to tonic-clonic seizures.

### Diagnosis

- EEG is diagnostic in 50–60% of cases; a repeat EEG will increase rate to 60–80%
- EEG/video telemetry helpful with frequent attacks
- CT or MRI scan—to exclude tumour when diagnosis confirmed

### Medication

carbamazepine (first choice):<sup>5,9</sup> children and adults

or

sodium valproate (second choice): not <2 years or (others)

vigabatrin, phenytoin, phenobarbitone, tiagabine

### § Tonic-clonic seizures

Variants of tonic-clonic seizures are more common than realised. Some patients may simply stiffen or drop to the ground while others may have one or two jerks or shakes only:

- stiffen and fall = tonic
- floppy and fall = atonic
- shaking only = clonic

Refer to CHAPTER 75 and CHAPTER 84.

### Simple partial seizures

In simple partial seizures (Jacksonian epilepsy) there is no loss of consciousness. These include focal seizures, which may proceed to a generalised tonic-clonic seizure or to motor seizures.

### § Jacksonian (motor seizure)

Typically, jerking movements begin at the angle of the mouth or in the thumb and index finger and 'march' to involve the rest of the body (e.g. thumb → hand → limb → face ± leg on one side and then on to the contralateral side). A tonic-clonic or complex partial seizure may follow.

### Medication
